
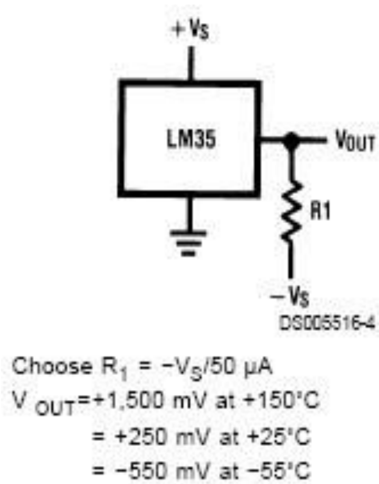
Fig: 3.6 Bottom View

Applications:

The LM35 can be applied easily in the same way as other integrated-circuit temperature sensors. It can be glued or cemented to a surface and its temperature will be within about 0.01°C of the surface temperature. This presumes that the ambient air temperature is almost the same as the surface temperature; if the air temperature were much higher or lower than the surface temperature, the actual temperature of the LM35 die would be at an intermediate temperature between the surface temperature and the air temperature. This is especially true for the TO-92 plastic package, where the copper leads are the principal thermal path to carry heat into the device, so its temperature might be closer to the air temperature than to the surface temperature. To minimize this problem, be sure that the wiring to the LM35, as it leaves the device, is held at the same temperature as the surface of interest. The easiest way to do this is to cover up these wires with a bead of epoxy which will insure that the leads and wires are all at the same temperature as the surface, and that the LM35 die’s temperature will not be affected by the air temperature. The TO-46 metal package can also be soldered to a metal surface or pipe without damage. Of course, in that case the V− terminal of the circuit will be grounded to that metal. Alternatively, the LM35 can be mounted inside a sealed-end metal tube, and can then be dipped into a bath or screwed into a threaded hole in a tank. As with any IC, the LM35 and accompanying wiring and circuits must be kept insulated and dry, to avoid leakage and corrosion.



Features:

Calibrated directly in ° Celsius (Centigrade)

Linear + 10.0 mV/°C scale factor

0.5°C accuracy guaranteeable (at +25°C)

Rated for full −55° to +150°C range

Suitable for remote applications

Low cost due to wafer-level trimming

Operates from 4 to 30 volts

Less than 60 µA current drain

Low self-heating, 0.08°C in still air

Nonlinearity only ±1/4°C typical

Low impedance output, 0.1 W for 1 mA load

Testing of Temperature sensor LM35 using OP-AMP Circuit:

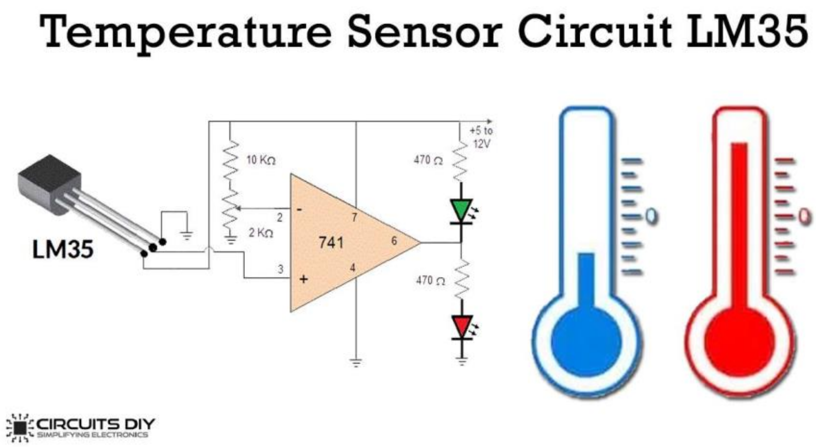


Fig: - 3.7 LM35 testing circuit

Gain calculation:

Gain A = 1+ R_f / R_1

If R_f =4k & R_1=1k Then Gain A=5

Output of LM35:

		Before Amplification,	After amplification With gain of 5
0^0 C	→	0V,	0V
1^0C	→	10mV,	50mV
25^0C	→	250mV,	1.25V
100^0C	→	1000mV,	5V

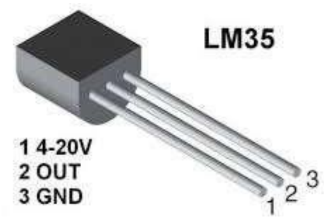

Fig: 3.8 LM35

3.3.4 Pulse Sensor

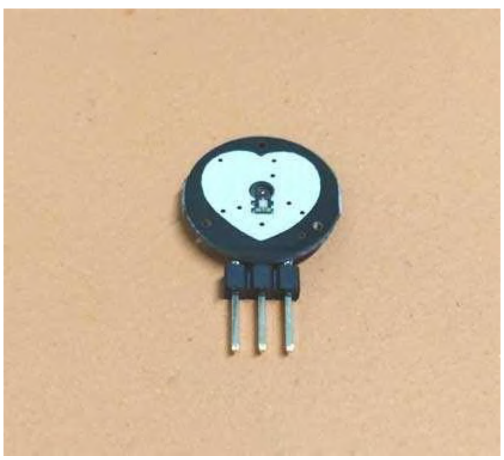

Fig: 3.9 Pulse sensor

Features

- Biometric Pulse Rate or Heart Rate detecting sensor
- Plug and Play type sensor
- Operating Voltage: +5V or +3.3V
- Current Consumption: 4mA
- Inbuilt Amplification and Noise cancellation circuit.
- Diameter: 0.625”
- Thickness: 0.125” Thick

Warning: This sensor is not medical or FDA approved. It is purely intended for hobby projects/demos and should not be use for health critical applications.

Pin Configuration

Pin Number	Pin Name	Wire Colour	Description
1	Ground	Black	Connected to the ground of the system
2	Vcc	Red	Connect to +5V or +3.3V supply voltage
3	Signal	Purple	Pulsating output signal.

How Pulse sensor works

The working of the **Pulse/Heart beat sensor** is very simple. The sensor has two sides, on one side the LED is placed along with an ambient light sensor and on the other side we have some circuitry. This circuitry is responsible for the amplification and noise cancellation work. The LED on the front side of the sensor is placed over a vein in our human body. This can either be your Finger tip or you ear tips, but it should be placed directly on top of a vein.

Now the LED emits light which will fall on the vein directly. The veins will have blood flow inside them only when the heart is pumping, so if we monitor the flow of blood we can monitor the heart beats as well. If the flow of blood is detected then the ambient light sensor will pick up more light since they will be reflect ted by the blood, this minor change in received light is analysed over time to determine our heart beats.

How to use Pulse sensor

Using the pulse sensor is straight forward, but positioning it in the right way matters. Since all the electronics on the sensor are directly exposed it is also recommended to cover the sensor with hot glue, vinyl tape or other non conductive materials. Also it is not recommended to handle these sensors with wet hands. The flat side of the sensor should be placed on top of the vein and a slight presser should be applied on top of it, normally clips or Velcro tapes are used to attain this pressure.

To use the sensor simply power it using the Vcc and ground pins, the sensor can operate both at +5V or 3.3V system. Once powered connect the Signal pin to the ADC pin of the microcontroller to monitor the change in output voltage. If you are using a development board like Arduino then you can use the readily available code which will make things a lot easier. Refer the datasheet at the bottom of the page for more information on how to interface the sensor with Arduino and how to mount it.

Applications

- Sleep Tracking
- Anxiety monitoring
- Remote patient monitoring/alarm system

- Health bands
- Advanced gaming consoles

3.3.5 WIFI Module:

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IoT devices. We've featured several projects using this module, such as How To Make Smart Home Electronics: A Smart Mailbox and How To Read Your Arduino's Mind: Building A Childproof Lock. This tutorial will walk you through setting up ESP8266 Wi-fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

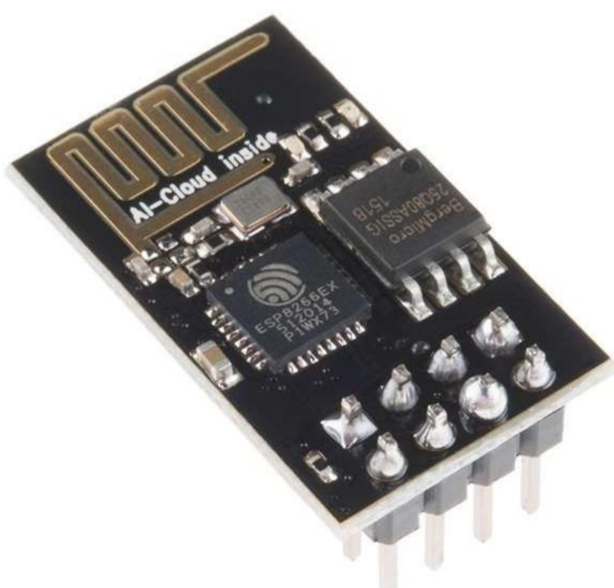

Figure 3.10 ESP8266 ESP-01 module

ESP-01 Features – Sparkfun**:**

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266's pins are according to the following diagram:

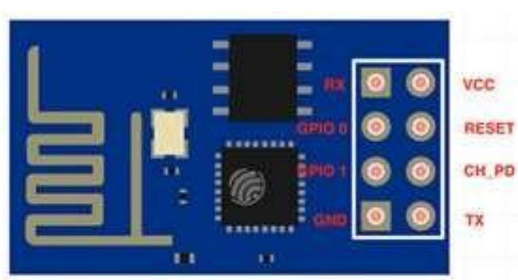

Figure 3.11 ESP8266 Pinout

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wifi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

Use the following diagram to connect the ESP8266 module to the Arduino:

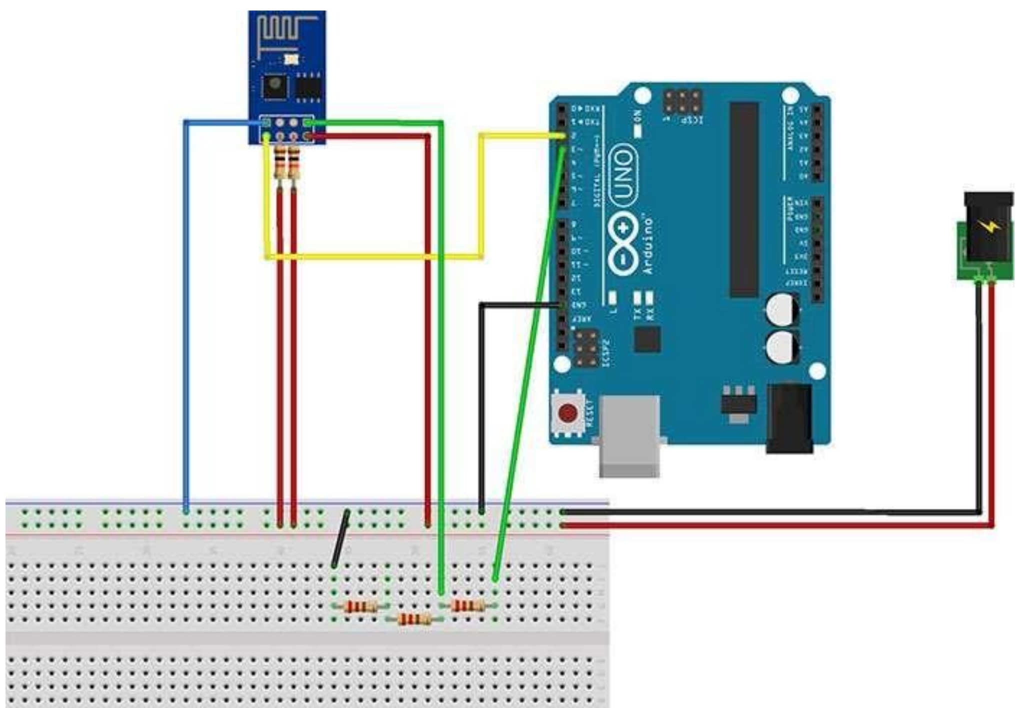

Figure 3.12 Connection between ESP8266 and Arduino Uno

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
  - You can use something like this: https://www.sparkfun.com/products/114
- Breadboard and jumper wires

3.3.6 Switches

Introduction

A switch is an electrical component that can break an electrical circuit, interrupting the current or diverting it from one conductor to another. The most familiar form of switch is a manually operated electromechanical device with one or more sets of electrical contacts. Each set of contacts can be in one of two states: either 'closed' meaning the contacts are touching and electricity can flow between them, or 'open', meaning the contacts are separated and non-conducting.

Figure: 3.13 switches in a row

Construction

Keys are placed for giving instructions to the particular part. For example if need to operate a robot .keys are placed and each key is giving an instruction through which the robot moves. If we need to operate the

Electronics specification and abbreviation	Expansion of abbreviation	British mains wiring name	American electrical wiring name	Description	Symbol	IEC60617
SPST	Single pole, single throw	One-way	Two-way	A simple on-off switch: The two terminals are either connected together or disconnected		

				from each other. An example is a light switch.		
SPDT	Single pole, double throw	Two-way	Three-way	A simple changeover switch: C (COM, Common) is connected to L1 or to L2.		
SPCO SPTT, c.o.	Single pole changeover *or* Single pole, centre off *or* Single Pole, Triple Throw			Similar to *SPDT*. Some suppliers use *SPCO/SPTT* for switches with a stable off position in the centre and *SPDT* for those without.[citation needed]		
DPST	Double pole, single throw	Double pole	Double pole	Equivalent to two *SPST* switches controlled by a single mechanism		
DPDT	Double pole, double throw			Equivalent to two *SPDT* switches controlled by a single mechanism: A is connected to B and D to E, or A is connected to C and D to F.		
DPCO	Double pole changeover *or* Double pole, centre off			Equivalent to *DPDT*. Some suppliers use *DPCO* for switches with a stable off position in the centre and *DPDT*for		

		those without.		
Intermediate switch	Four-way switch	*DPDT* switch internally wired for polarity-reversal applications: only four rather than six wires are brought outside the switch housing; with the above, B is connected to F and C to E; hence A is connected to B and D to C, or A is connected to C and D to B.		
Switches with larger numbers of poles or throws can be described by replacing the "S" or "D" with a number or in some cases the letter "T" (for "triple"). In the rest of this article the terms SPST, SPDT and intermediate will be used to avoid the ambiguity in the use of the word "way".

Working

A pair of contacts is said to be "closed" when current can flow from one to the other. When the contacts are separated by an insulating air gap, an air space, they are said to be "open", and no current can flow at typical voltages.

Switches are classified according to the arrangement of their contacts in electronics. Electricians installing building wiring use different nomenclature, such as "one-way", "two-way", "three-way" and "four-way" switches

In a push-button type switch, in which the contacts remain in one state unless actuated, the contacts can either be normally open (abbreviated "n.o." or "no") until closed by operation of the switch, or normally closed ("n.c. or "nc") and opened by the switch action. A switch with both types of contact is called a changeover switch. These may be "make-before-break" which momentarily connect both circuits, or may be "break-before-make" which interrupts one circuit before closing the other

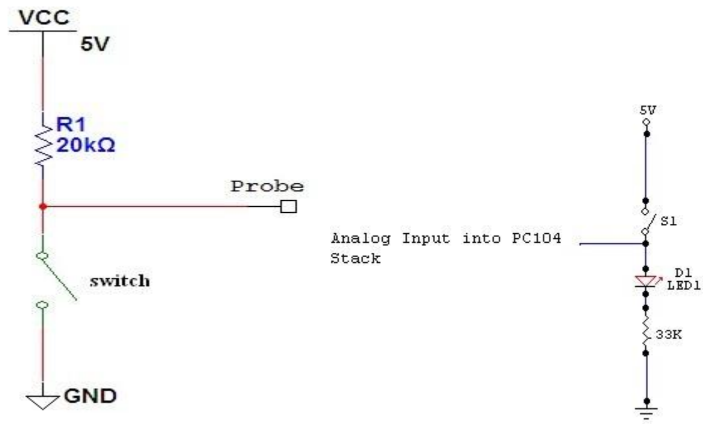

Figure 3.14: circuits of the switch

3.3 SOFTWARE COMPONENTS

- Proteus simulation
- Arduino software
- Programming language

3.3.1 Arduino Software

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs.

3.3.1.2 Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

1) Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

2) Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to windows.

3) Simple, clear programming environment - The Arduino Software (IDE) is easy- to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

4) Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

5) Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the

breadboard version of the module in order to understand how it works and save money

6) Getting Started with Arduino and Genuino products:- Install the Arduino Software (IDE) on Windows PCs This document explains how to install the Arduino Software (IDE) on Windows machines.

7) Download the Arduino Software(IDE).

➢ How to Download the Arduino Software (IDE)

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

3.3.1.3 INSTALLATION

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.15 cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.3.16 Mini-B Cable

Step 2 − Download Arduino IDE Software

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

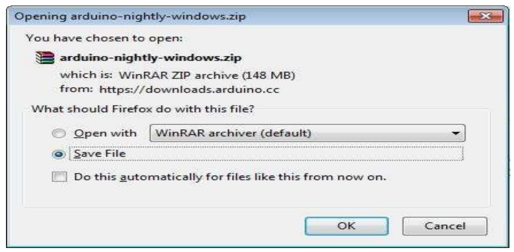

Fig.3.17 Arduino IDE Software

Step 3 − Power Up Your Board

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port. Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE

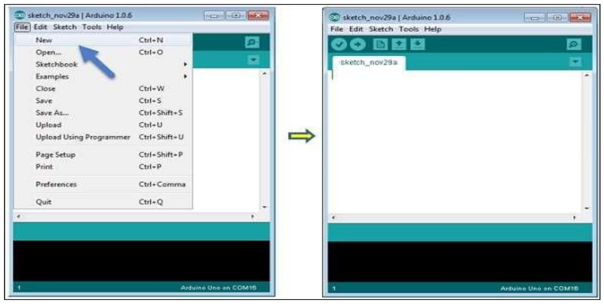
After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

Step 5 − Open Your First Project

Once the software starts, you have two options −

Create a new project.

Open an existing project example.



.

Fig.3.18 Creating New File

Step 6 − Select Your Arduino Board

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

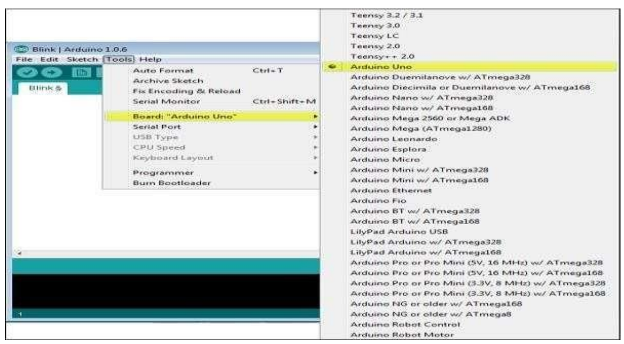


Fig.3.19 Tools Board

Step 7 − Select Your Serial Port

Select the serial device of the Arduino board. Go to Tools → Serial Port menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

Step 8 − Upload The Program To Your Board

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

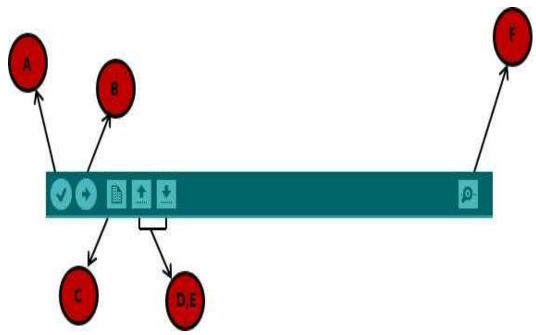

Fig.3.20 Uploading Program

A − Used to check if there is any compilation error. **B** − Used to upload a program to the Arduino board. **C** − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

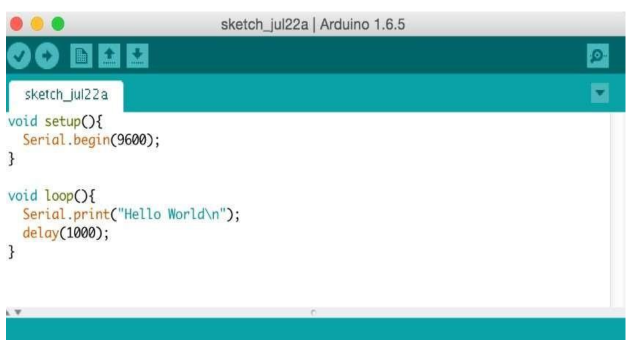

Fig. 3.21 Arduino

3.3.2 PROTEUS*:*

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

3.3.2.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

3.3.2.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc. ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

3.3.2.3 Starting New Design

Step 1: ***Open ISIS software and select New design in File menu***

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

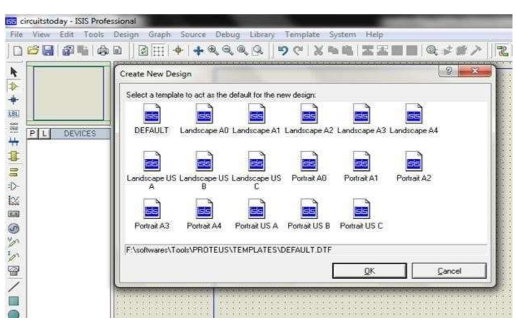

Fig.3.22 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

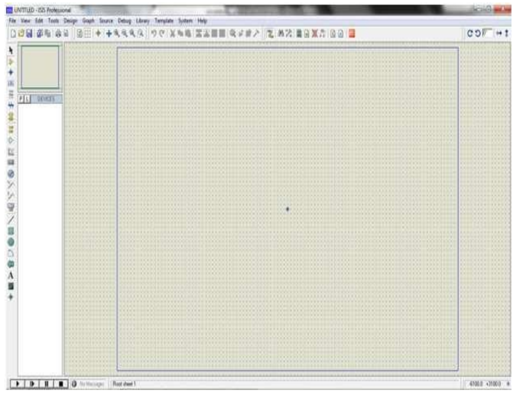

Fig.3.23 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

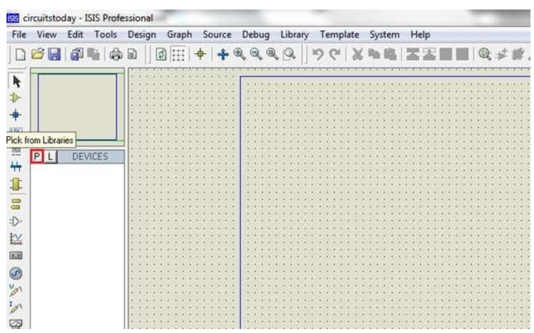

Fig.3.24 Pick From Libraries

Step 6: Select the components from categories or type the part name keyword.

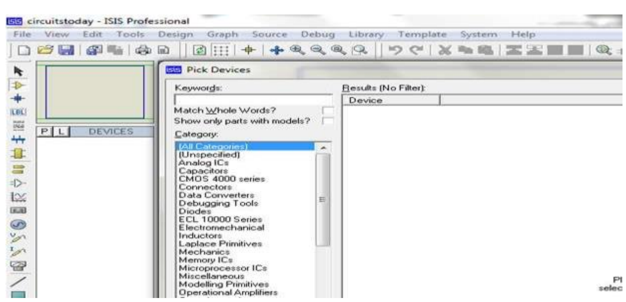

Fig.3.25 Key Word Textbox

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click. Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively. Double click on the component to edit the properties of the components and click on Ok.

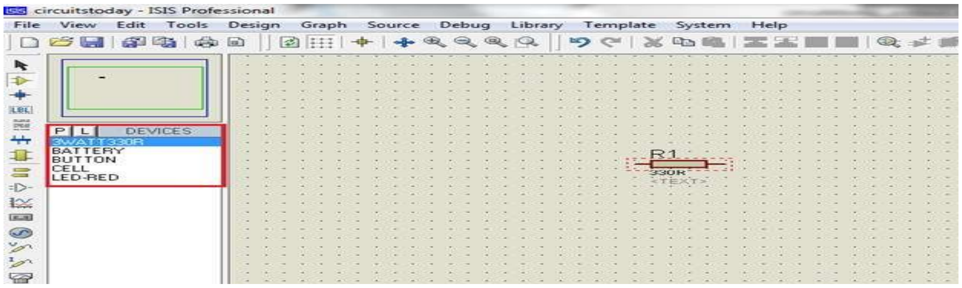

Fig.3.26 Component Selection

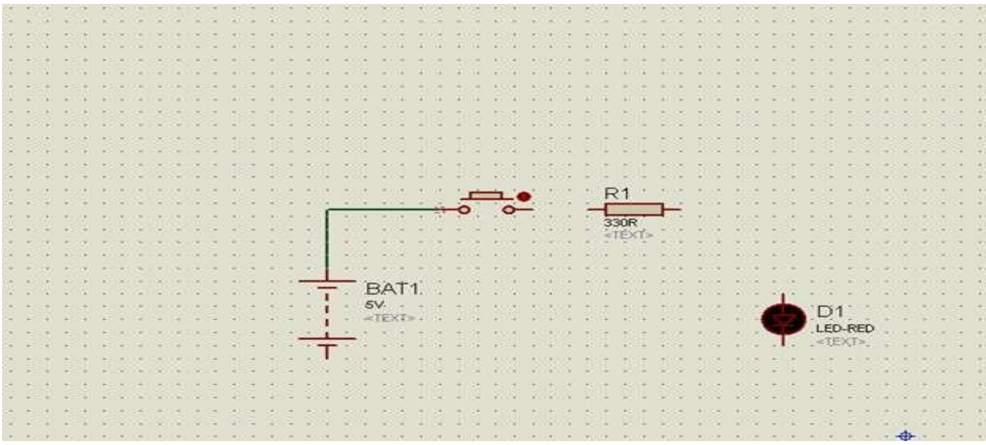

Fig.3.27 Simulation

Step 8: After connecting the circuit, click on the play button to run the simulation. Simulation can be stepped, paused or stopped at any time. In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

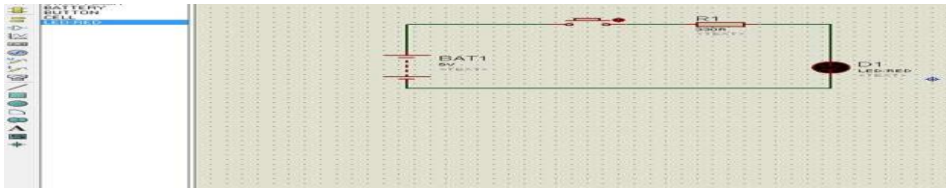

Fig.3.28 Simulation Run

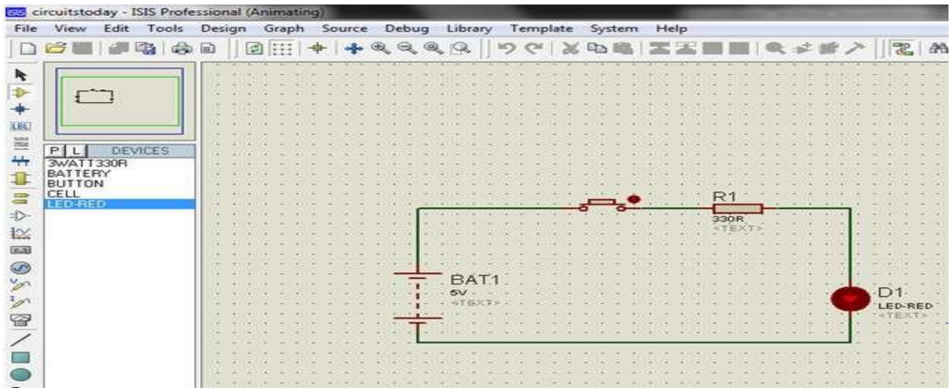

Fig .3.29 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

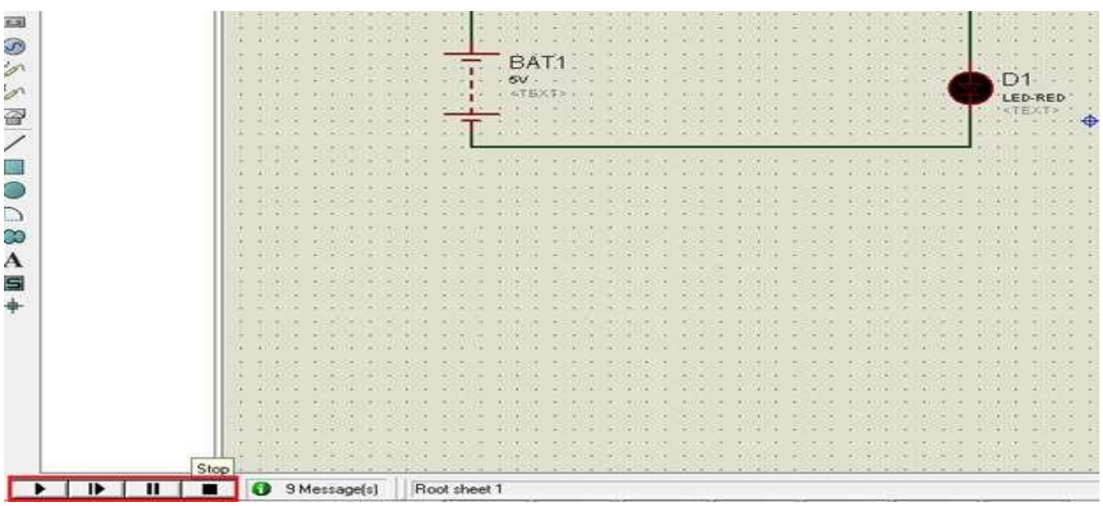

Fig. 3.30 Simulation Step-Pause-Stop Buttons

3.4 DEFINE THE MODULES:

3.4.1 WIFI MODULE

The ESP8266 is a low-cost WiFi module that can be integrated easily into IoT devices. The ESP8266 is a small WiFi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module.

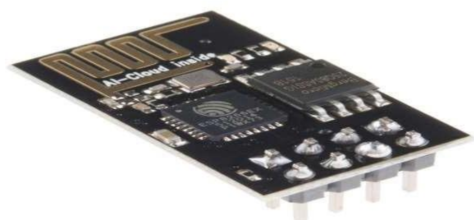

Fig.3.31 ESP8266 ESP-01 Module

3.4.2 ESP-01 Features

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you’ll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you’d like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266’s pins are according to the following diagram:

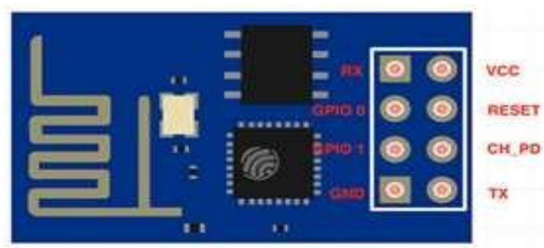

Fig.3.32 ESP8266 Pinout

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we’ll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we’ll have to program include, for example, the SSID and password for the wifi network the module will be connected to. This means that we’ll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino. Use the following diagram to connect the ESP8266 module to the Arduino:

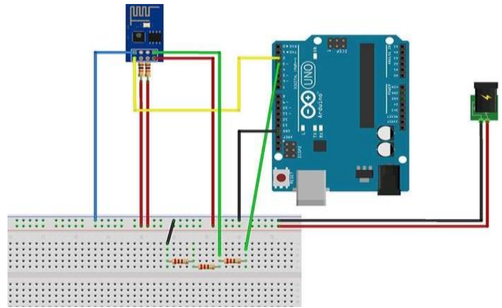

Fig.3.33 Connection Between ESP8266 and Arduino Uno

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino’s 3.3V out pin because the ESP8266 draws a lot of current!)
- Breadboard and jumper wires

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the Vcc and Ground pins to the power supply lines, but also connect the power supply’s ground line to the Arduino’s ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module..

Finally, there are two pull-up resistors on the ESP8266’s CH_PD and RESET pins. These are specified by the module’s creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors. Settings that we’ll have to program include, for example, the SSID and password for the wifi network the module will be connected to. This means that we’ll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino. Use the following diagram to connect the ESP8266 module to the Arduino

3.4.3 STRUCTURE AND CONFIGURATION:

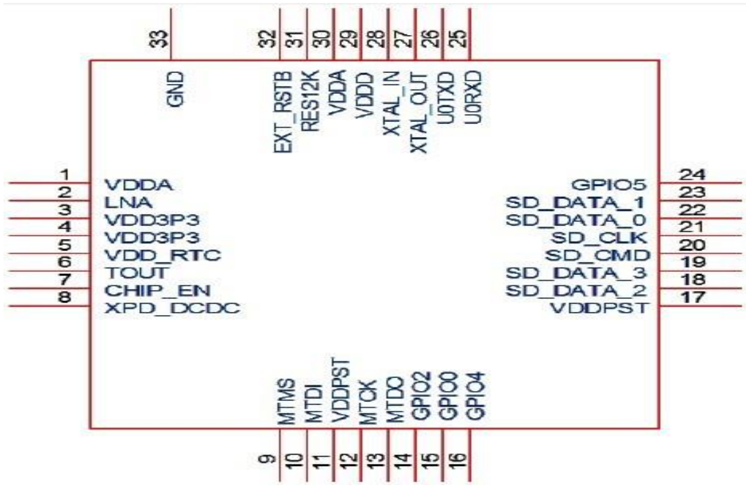

Fig.3.34 Structure and configuration

3.5 MODULE FUNCTIONALITIES:

3.5.1 ESP8266 WIFI MODULE

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either

hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community. This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts. There is an almost limitless fountain of information available for the

ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM

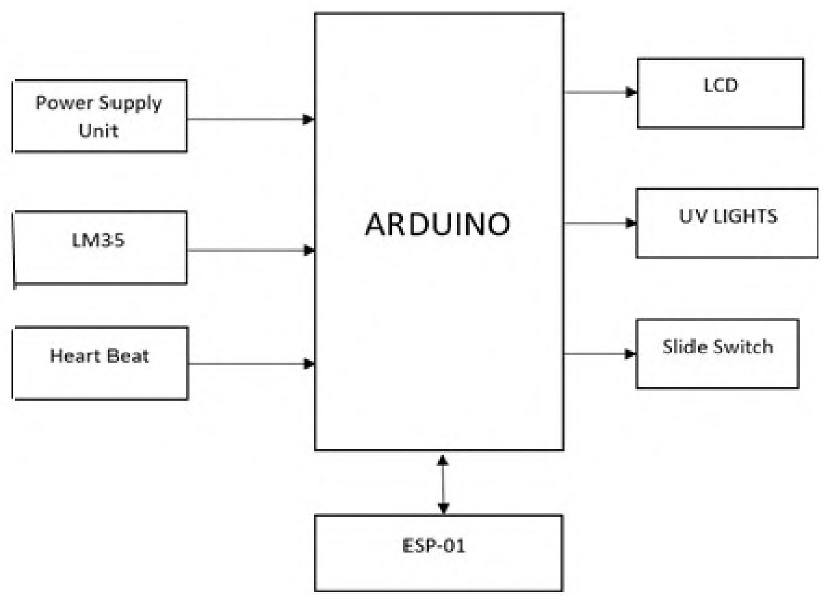

Fig.4.1 Block Diagram

The system consists of two input sensors to detect temperature, and heartbeat sensor, a LCD to display ,Wi-Fi module and slide switch to turn on UV light. At the same time ,data regarding these parameters are sent to IOT module .WiFi module is used to establish connection between microcontroller and the WiFi network connections and sends the data to the IOT.

4.2 IMPLEMENTATION STAGES

Stepwise implementation of IOT covid patient health monitor system is given under:

Step 1: Switch on the kit by giving power supply.

Step 2: Keep the ssid: project, password: project1235 in mobile and turn on Hotspot

Step 3: Kit gets connected to Hotspot using Wi-Fi module.

Step 4: The temperature and heartbeat of patient is measured using LM35 and heartbeat sensors respectively

Step 5: Based on conditions given in code i.e., hbval> 78 and 10< hbval < 50, td > 35.Sensor senses and updates to sever according to conditions.

Step 6: “Thingspeak” is the server where the results are updated.

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

5.1.1 SOFTWARE TESTING

Software Testing is a process of executing the application with intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

5.1.2 TESTING LEVELS

There are various testing levels based on the specificity of test.

• Unit testing: Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.

• Integration Testing: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.

• System Testing: System testing tests a completely integrated system to verify that the system meets its requirements.

• Acceptance testing: Acceptance testing tests the readiness of application, satisfying all requirements.

• Performance testing: Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

5.1.3 SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirement.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

The Internet of Things is considered now as one of the feasible solutions for any remote value tracking especially in the field of health monitoring. The proposed system provides best way to monitor covid patients without any life risk. Moreover, the health can be monitored by any doctor at any distance.

The user (patient) can perform the following basic functions on the system after successful registration:

• Control home devices

• Check for medication and prescription

• Send symptoms of the virus to the doctor while under isolation

• Chat with the doctor or leave a message

• Enter physiological values of measured parameters manually

• Book appointment with the doctor

• View medical data.

In the next level of project other sensors, devices like low cost portable ventilators; ECG can also be connected to this device to monitor respiration rate and blood pressure.Humidity of the room can also be measured in patient's room IOT enabled smart pill boxes keep track of patients medicine schedule .It is used to intimate the patient to take medicine at certain time. An emergency button is kept when a patient is in need of any kind of medical assistance

.

PUBLICATION

Submitted Paper in the Conference ICISECT - 21 with Paper ID (ICISECT21-0027) and got Acceptance for the Paper.

DECLARATION

We, the students of Bachelor of Technology in Department of 'ECE', session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **'Finger Print Based Security System'** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Ms. V.V.S Vasavi	17K81A0459
Ms. A. Kranthi	17K81A0403
Ms. T. Meena	17K81A0454

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision ateach and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **HoD & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Professor** for his involvement with originality has triggered and nourished my intellectualmaturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mrs. A. Soumya,** Department of ECE andour project **Internal guide, Mr.V.V.Ramana Rao, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for theirsupport and co- operation that is difficult to express in words.

1. V.V.S.Vasavi
2. A.Kranthi
3. T.Meena

ABSTRACT

Fingerprint-based security system to authenticate users from entering particular premises. The system is useful for secure sites to provide access only to authorized users automatically. This ensures safety and security at secure sites/premises like military, navy, government as well as corporate premises. For this purpose we here use a Atmega 32 microcontroller circuit. The circuit consists of atmega microcontroller that is interfaced to fingerprint sensor, LCD display and motors to operate a door. Users are allowed to register into the system first. After registration/enrolment the system allows to start monitoring. In monitoring mode, the system monitors for fingerprints. Now if a fingerprint is detected, the system scans the fingerprint against stored ones. If a match is found, the system operates the motors to open the door for those users, else the system does not open the door. Thus we ensure a secure fingerprint authorized security system.

Finger print comparison is one of the tough task, mainly comparing latent finger prints like palm, foot prints will be most difficult part in finger print science. Finger print expert must be well trained and expert to perfectly analyze finger prints.

The comparison of fingerprints, especially latent fingerprints (palm prints, footprints), can be the single most difficult task in all the fingerprint science. No matter how skillful an individual may be in all the related areas, it is the additional ability to accurately compare latent prints against known prints that allows the examiner to be called a fingerprint expert. These utilize fingerprint recognition technology to allow access to only those whose fingerprints you choose. It contains all the necessary electronics to allow you to store, delete, and verify fingerprints with just the touch of a button.

Stored fingerprints are retained even in the event of complete power failure or battery drain. These eliminates the need for keeping track of keys or remembering a combination password, or PIN. It can only be opened when an authorized user is present, since there are no keys or combinations to be copied or stolen, or locks that can be picked.

The main aim of this project is develop a security lock system based on fingerprint scanning. In this project we are using microcontroller for opening and closing lock based on finger print which is stored in microcontroller itself so that only authorized person will access the security lock.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

GLOSSARY OF MOST COMMONLY USED TERMS

FINGERPRINT: A fingerprint is an impression left by the friction ridges of a human finger.There are four groups of whorls: plain (concentric circles), central pocket loop (a loop with a whorl at the end), double loop (two loops that create an S-like pattern) and accidental loop (irregular shaped).

SECURITY: The security which we provide through this system is by using the fingerprints of the user In this system we can enroll our fingerprints and if we attach this to our door so the motor of the system will operate your door based on commands given by Arduino board of this system.

ARDUINO UNO BOARD: This is a microcontroller for this system of version ATMEGA328,this board will control entire operations of the system and act as like heart of the system.

AUTHORIZED USERS: The persons who have enrolled their fingerprints into that system are been considered as authorized users. These people will only be allowed by the system to enter.

UNAUTHORISED USERS: The persons who have not enrolled their fingerprints into that system are been considered as unauthorized users. These people will not be allowed by the system to enter

CHAPTER 1
INTRODUCTION

1.0 OVERVEIW OF THE PROJECT:

In this project at the present age, safety has become a necessary issue for most of the people mainly in the rural and urban areas. Some people are more concern about their safety for them at a expensive thing like jewellery money etc. So, the bank lockers are the safest place to accumulate them but the conventional security system is not providing the higher security because in conventional security system a user can open the lockers using keys. Sometimes the keys could be stolen. Then the user will apply for original keys but the time period is longer to get new keys so in its place of using this security system we have implemented. In this present age, safety has become a necessary issue for biometric based security system which provide more security than conventional system. In this paper we have implemented security of the money in the bank locker, house, and workplace (treasury) by using Fingerprint and GSM technology which will be more protected than other systems. We use only one Fingerprint module scan for no. of only authorized persons to open the separate bank locker. In this project we have designed and implemented a bank locker safety system based on Fingerprint technology. In this system only authentic person can be recovered money from bank locker with password protection method.

The purpose of this project is to increase the security for lockers because conventional banks lockers are not secure so to rectify the problem which we discuss above we are implementing this project. In this project each locker has separate fingerprint module to opening the locker. Users scan their fingerprint. After scanning process complicated user enters their password with the help of keypad then their particular locker is open. After the work has been completed if key is pressed again with help of keypad the locker door will be closed again. If an unauthorized person tries to check his fingerprint image, then a signal will be given by a buzzer which is interfaced to the controller and also if incorrect password is entered by the user again indication will be given by the buzzer.

1.1 OBJECTIVES OF STUDY:

Fingerprint based security system is the most secured system as compared to other systems, Reason is that RFID card or Keys of lock can be stolen, password may be leaked. However, thumbnail of every human being is unique, so lock will not open unless the same person is present to give the impression of fingerprint.

The basic function of every type of scanner is to obtain an image of a person's fingerprint and find a match for it in its database. The measure of the fingerprint image quality is in dots per inch (DPI). Capacitive or CMOS scanners use capacitors and thus electrical current to form an image of the fingerprint. This system was been designed to control thefts in private areas and to provide more security and authenticity to the users, as we are using finger prints for identifying the persons this was one of the most efficient way to identify people because the fingerprints will acts as the unique IDs for persons.

No two person will not be matched with their fingerprints so based on this fact this system was been designed for providing the security for example if a person enrolls his/her fingerprints with the finger print scanner provided in this system then he/her will only be allowed by this system to enter into system protected area. Here we can place this system to operate the door to your private room so as to make the door to open or close according to the system commands, humans cannot open this door by their own because that door will not be provided with any lock or key.

By implementing this project in the public areas like banks and in educational institutes and at offices thefts will be reduced to most extent because the person who have access to that room will only be allowed into the room if any unauthorized person comes and places his finger print and if that finger print was not enrolled in the system, then the door will not open and it will generate a message as a unauthorized person.

1.2 SCOPE OF THE STUDY:

Finger print based security system can be used at many places like Industries, Offices, and Colleges or even at our home. This project is a fine combination of “Biometrics technology” and “Embedded system technology”. ... It makes use of Biometric sensor to detect fingerprint. It is also called as Biometric sensor.

1. We can send this data to a remote location using mobile or internet
2. We can use non-contact fingerprint sensor. Which is also called as touchless 3D fingerprint
3. We can implement other related modules like fire sensor, GSM modem.

Fingerprint based security system is the most secured system as compared to other systems. Reason is that RFID card or Keys of lock can be stolen, password may be leaked. However, thumbnail of every human being is unique, so lock will not open unless the same person is present to give the impression of fingerprint., No need to carry the keys to open the lock. Or even there is no need to remember the password or any Pin number. One of the main advantages is that this system remembers the stored password even if the power supply is turned off. Scientific research and studies have proved that fingerprints do not change as you grow up. Using Fingerprint saves time to gain access as compared to other methods like RFID card, Password or Key.

Since 2000 electronic fingerprint readers have been introduced as consumer electronics security applications. Fingerprint sensors could be used for login authentication and the identification of computer users. However, some less sophisticated sensors have been discovered to be vulnerable to quite simple methods of deception, such as fake fingerprints cast in gels. In 2006, fingerprint sensors gained popularity in the laptop market. Built-in sensors in laptops, such as Think Pads, VAIO, HP Pavilion and EliteBook laptops, and others also double as motion detectors for document scrolling, like the scroll wheel.The use of fingerprints in crime fiction has, of course, kept pace with its use in real-life detection. Sir Arthur Conan Doyle wrote a short story about his celebrated sleuth Sherlock Holmes which features a fingerprint: "The Norwood Builder" is a 1903 short story set in 1894 and involves the discovery of a bloody fingerprint which helps Holmes to expose the real criminal and free his client. The British detective writer R. Austin Freeman's first Thorndyke novel The Red Thumb-Mark was published in 1907 and features a bloody fingerprint left on a piece of paper together with a parcel of diamonds inside a safe-box. These become the center of a medico-legal investigation.

1.3 MATERIALS REQUIREMENT:

1.3.1 HARDWARE COMPONENTS:

- ARDUINO UNO (ATMEGA328) MICROCONTROLLER BOARD

Fig:1.1 Arduino Uno board

The above shown figure is Arduino Uno board.

- FINGER PRINT SCANNER ALONG WITH 3 PUSHBUTTONS

Fig:1.2 Fingerprint Scanner

The above shown figure is fingerprint Scanner.

- LCD DISPLAY (16*2)

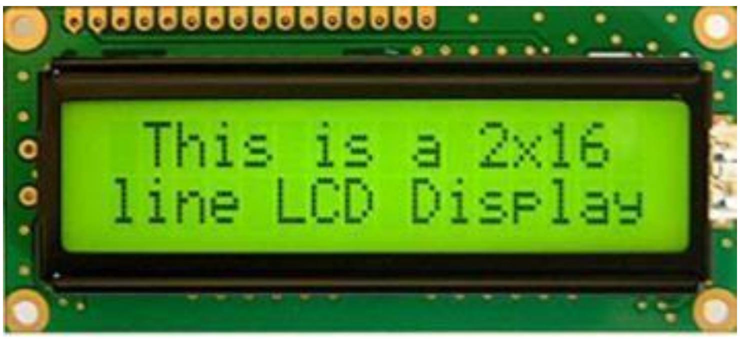

Fig:1.3 LCD Display

The above shown figure is 16x2 LCD Display.

➢ L293D DRIVER IC

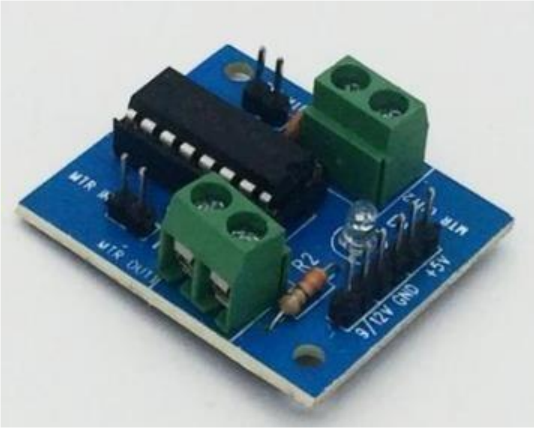

Fig:1.4 Driver IC

The above shown figure is Driver IC

➢ DC MOTOR (5V SUPPLY)

Fig:1.5 DC Motor

The above shown figure is DC Motor

➢ MB27L-12V PIEZO BUZZER

Fig:1.6 Piezo Buzzer

The above shown figure is Piezo Buzzer.

1.3.2 SOFTWARE REQUIREMENTS:

1.3.2.1 ARDUNO IDE SOFTWARE: This software is basically used for giving commands to ARDUNO Microcontroller**.**

STEPS FOR INSTALLING ARDUNO IDE SOFTWARE:

1.Download Arduino IDE Software in your PC.

2. When the download finishes, proceed with the installation.

3. Allow the driver installation process when you get a warning from the operating system.

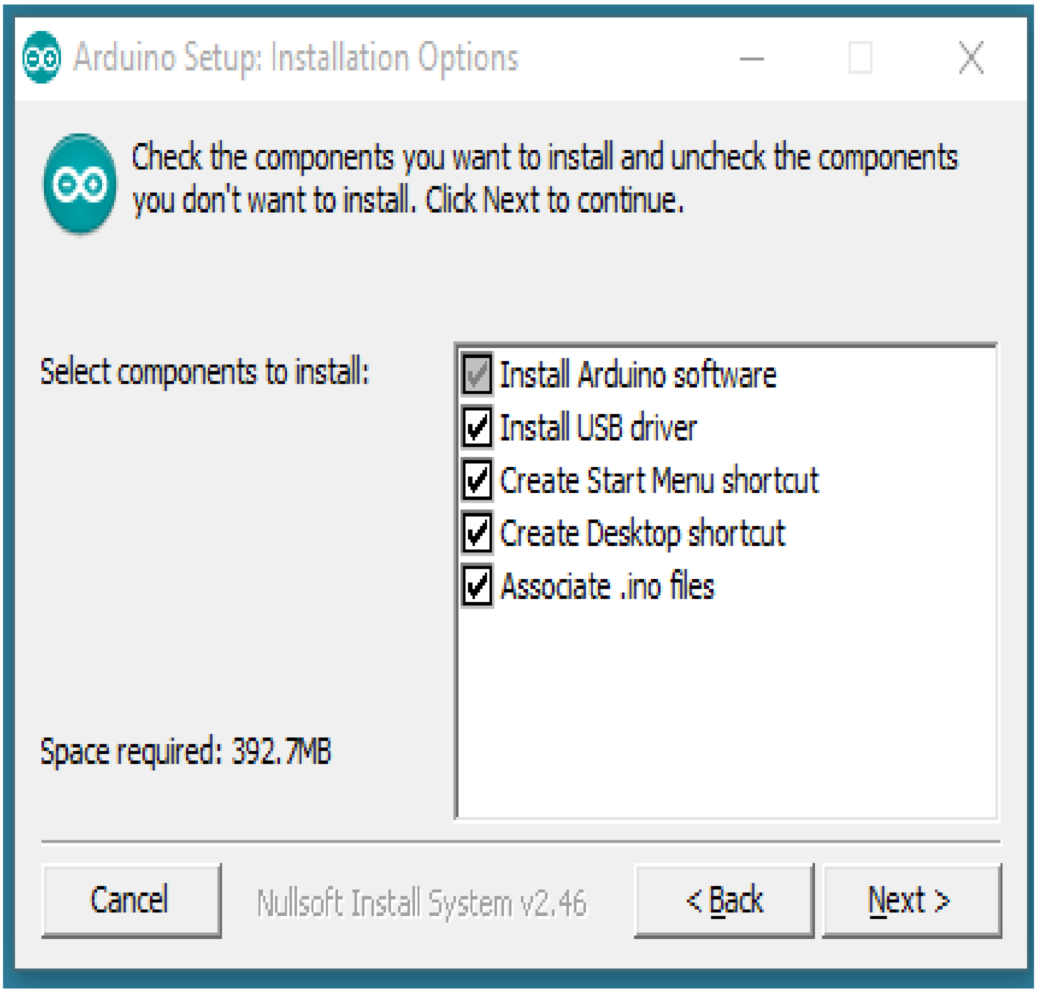

Fig:1.7 Installation process of Driver

4. Choose the components to install

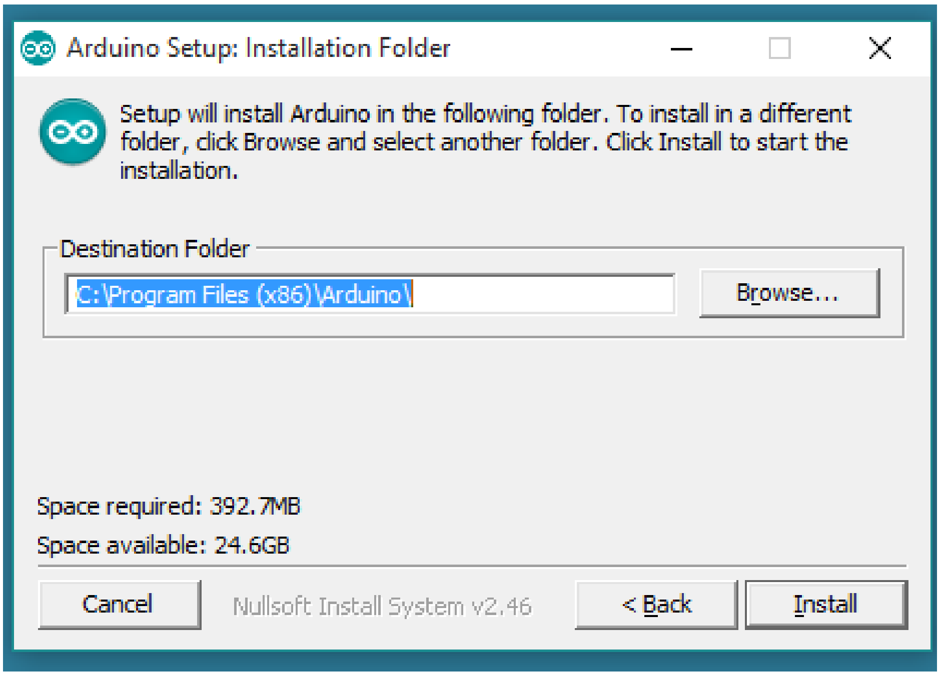

Fig 1.8 Destination folder

5. Choose the installation directory (we suggest to keep the default one)

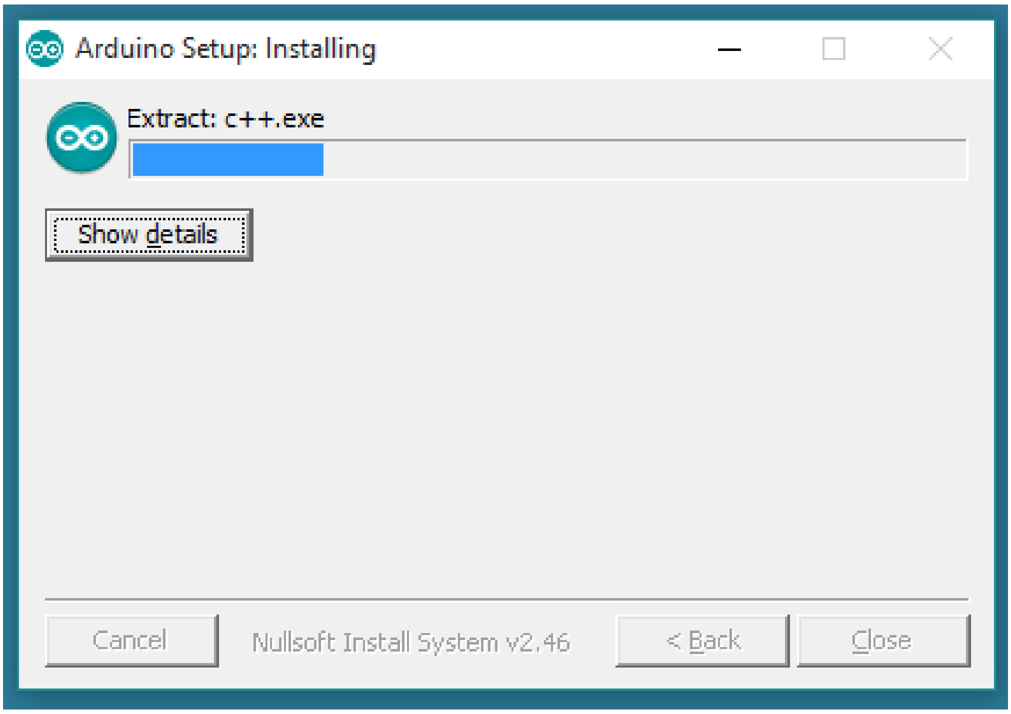

Fig:1.9 Installing directory

6. Successfully completed Installation of Software

7. Writing code on IDE platform

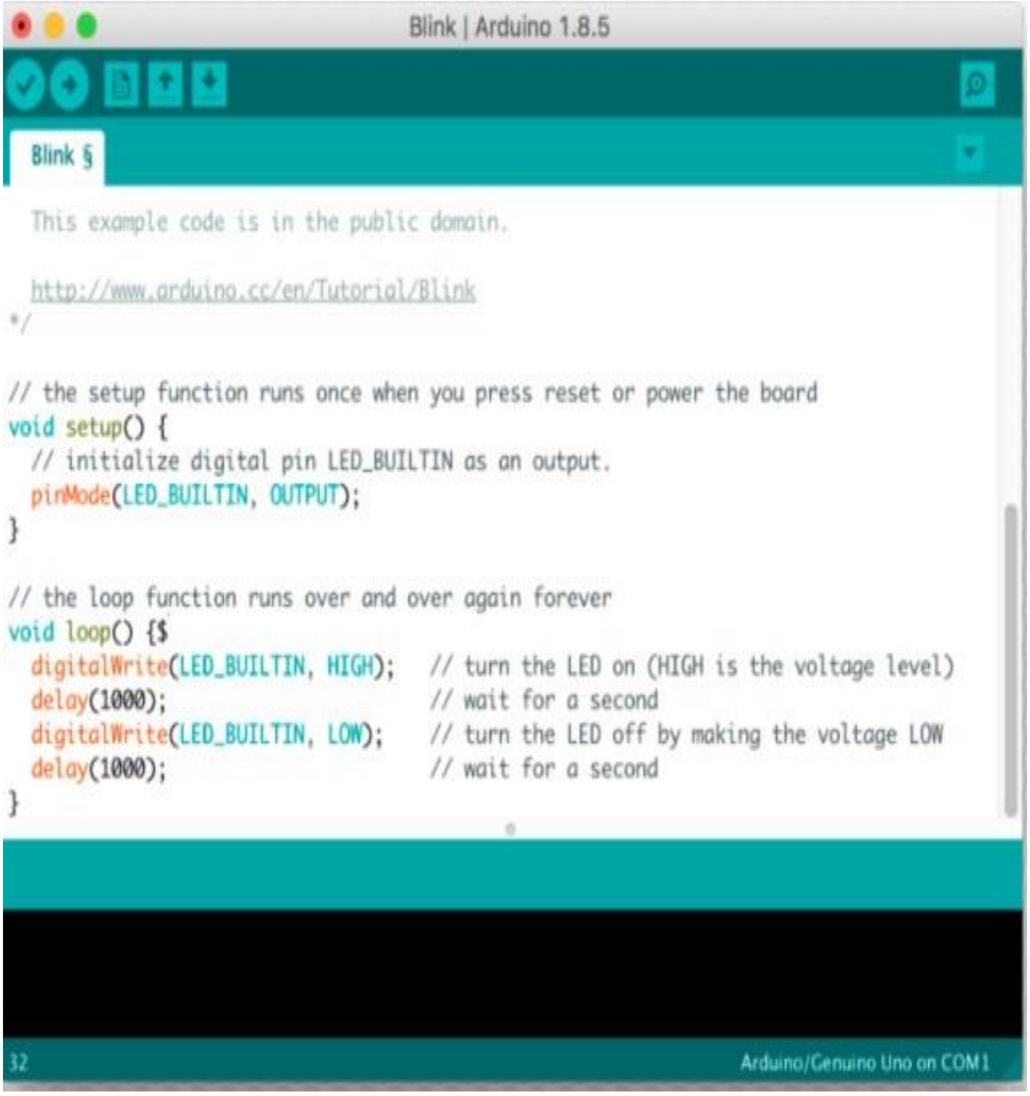

Fig:1.10 Source code written on IDE platform

1.3.2.2 PROTEUS SOFTWARE:

Through this software Schematic implementation of the embedded system will be done.

STEPS FOR DESIGNING SYSTEM ON PROTEUS DESIGN SUITE:

Step 1: Open ISIS software and select new design in File menu

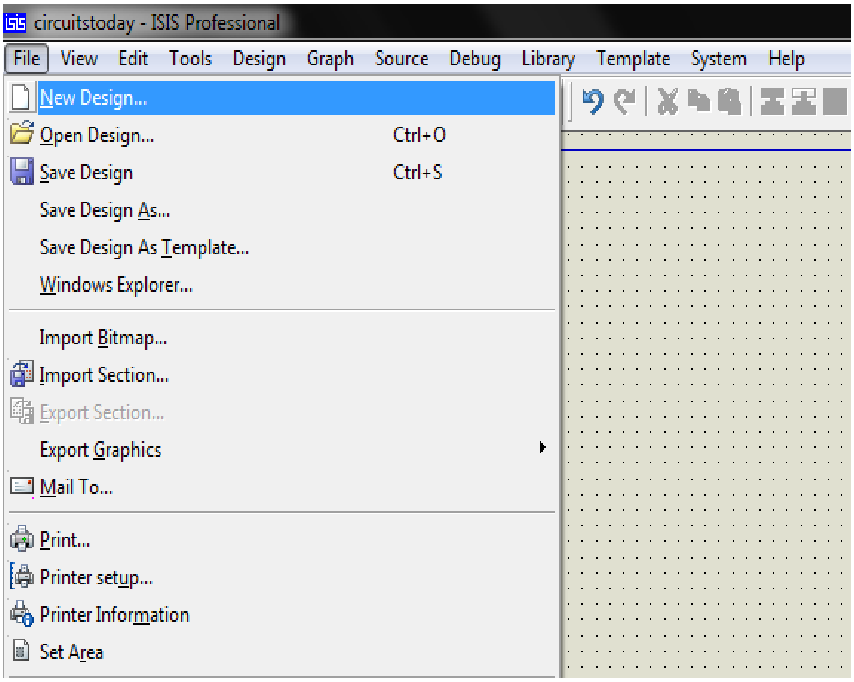

Fig:1.11 Simulation Procedure 1

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

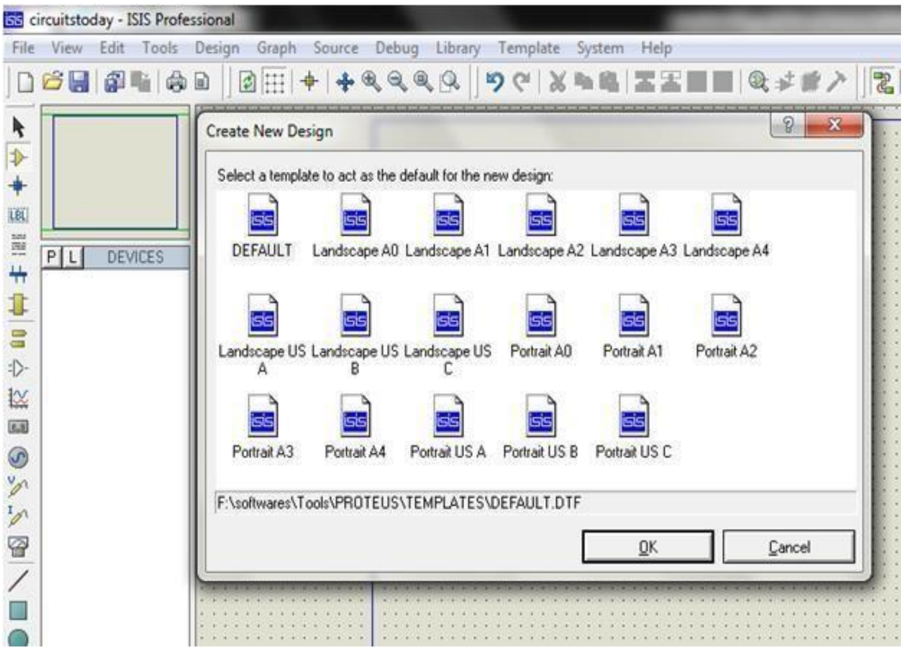

Fig:1.12 Simulation Procedure 2

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create new folder for every layout as it generates other files supporting your design.

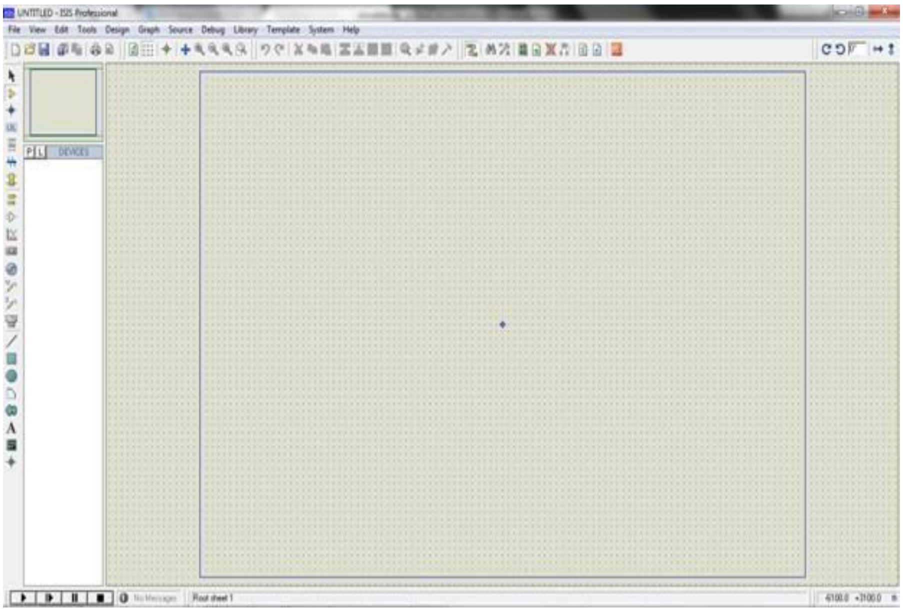

Fig:1.13 Simulation Procedure 3

Step 4: To Select components, Click on the component mode button.

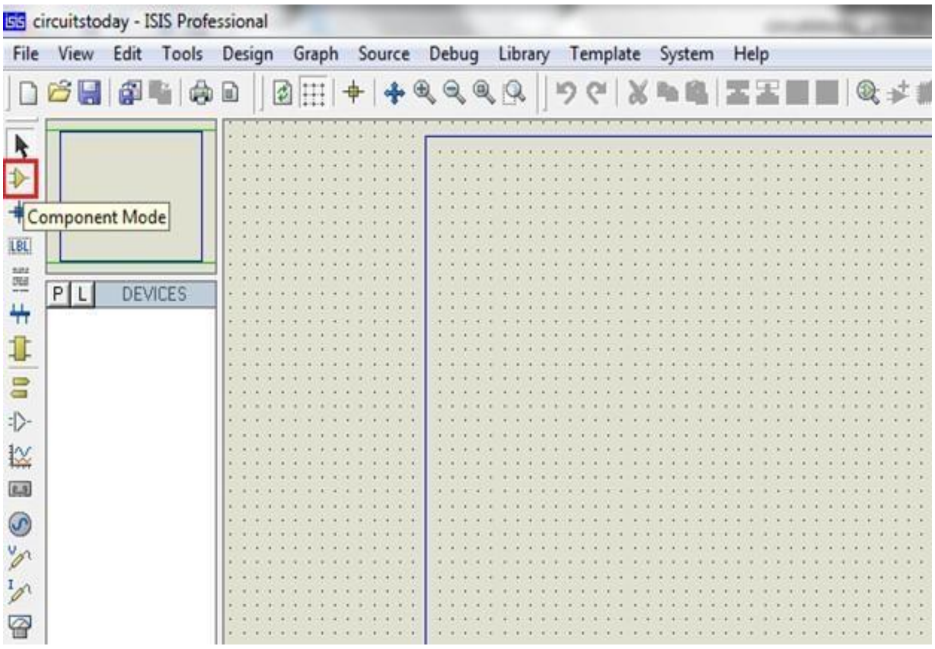

Fig:1.14 Simulation Procedure 4

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

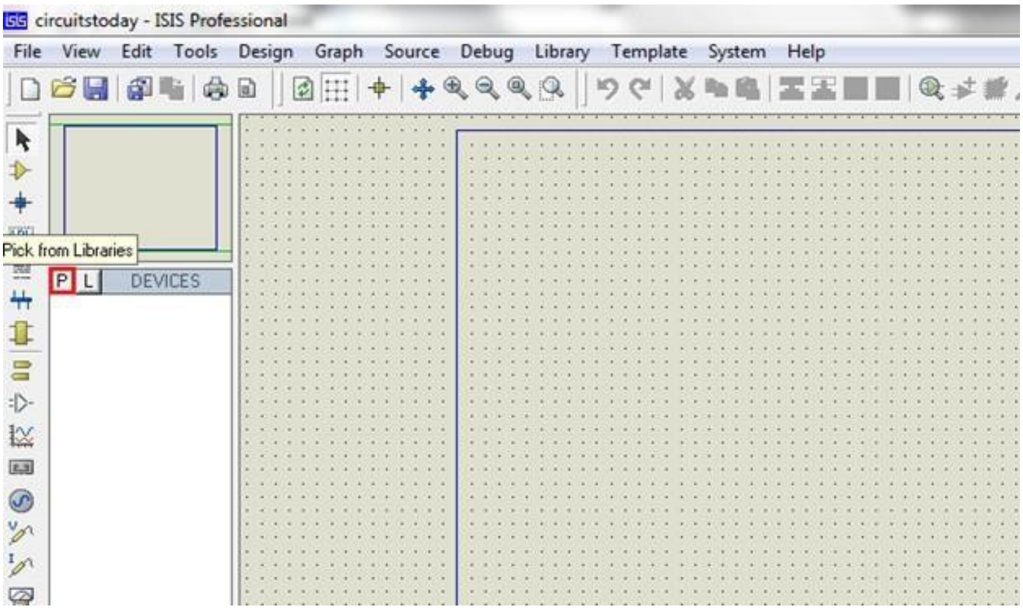

Fig:1.15 Simulation Procedure 5

Step 6: Select the components from categories or type the part name in Keyword's text box.

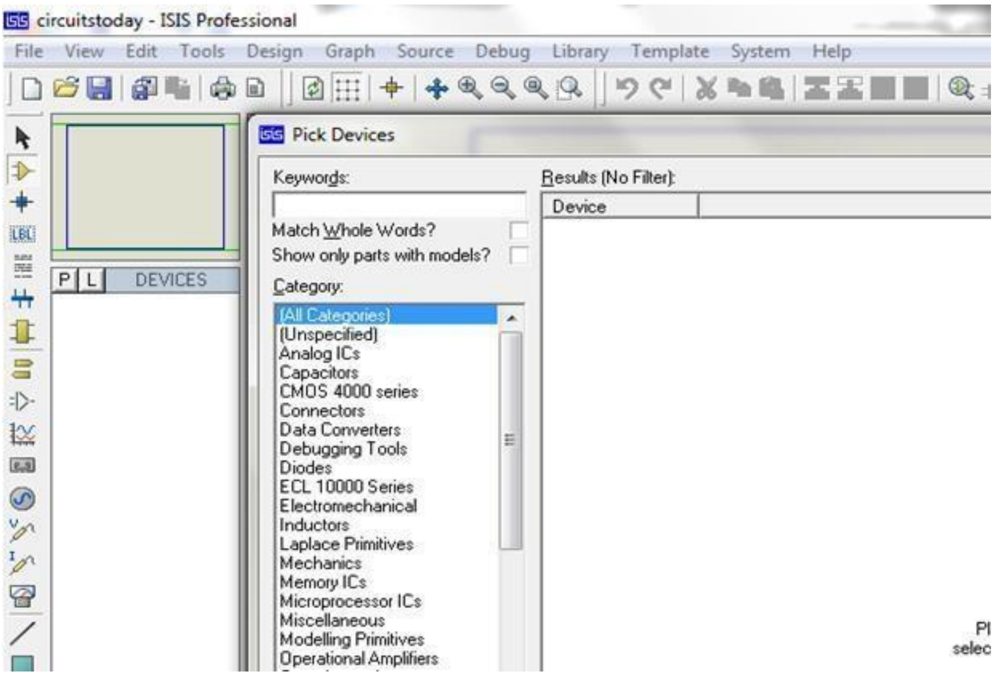

Fig:1.16 Simulation Procedure 6

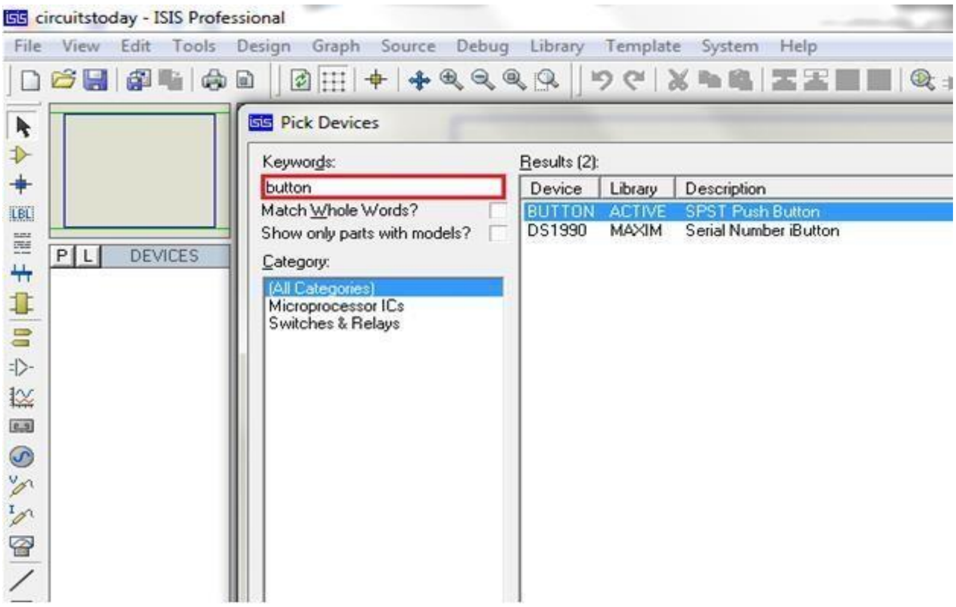

Fig:1.17 Simulation Procedure 7

Step 7**:** The selected components will appear in the devices list. Select the component and place it in the design sheet by left-cl.

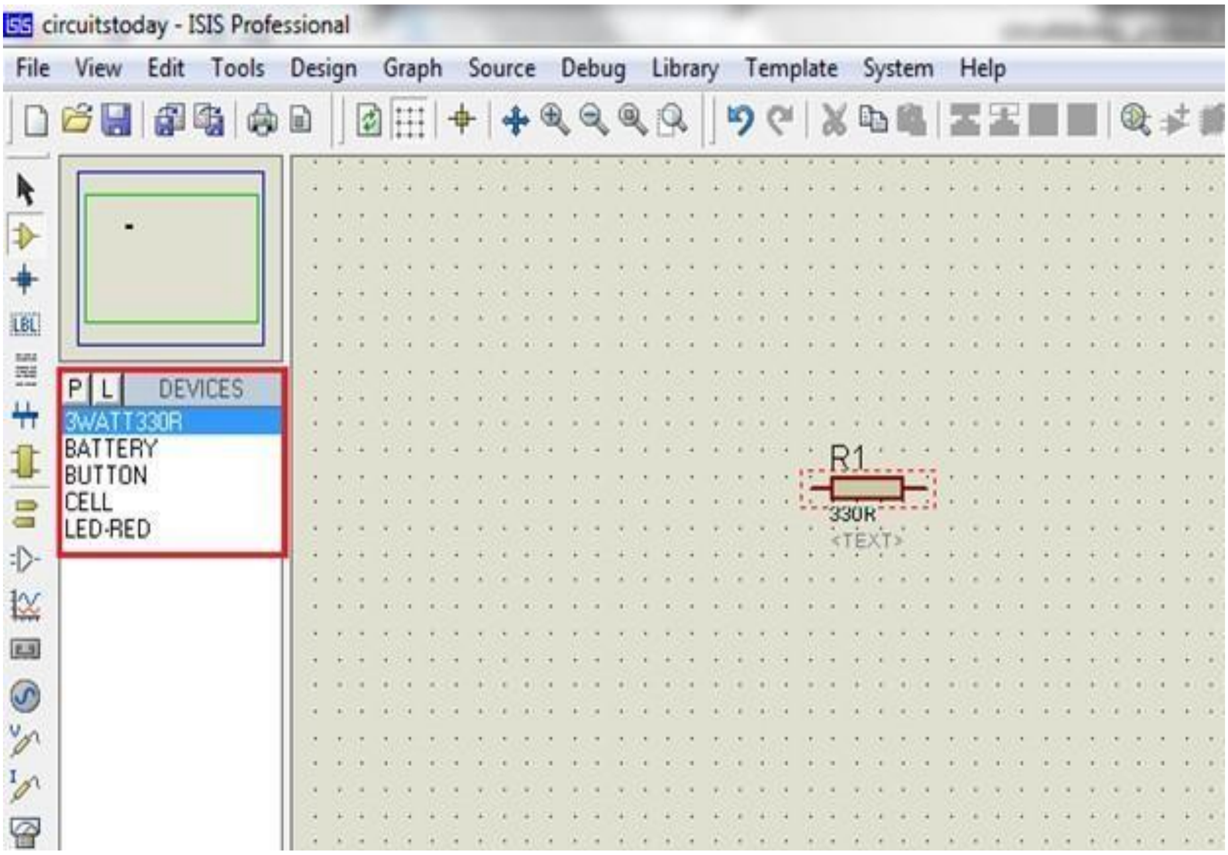

Fig:1.18 Simulation Procedure 8

Step 8: Place all the required components and route the wires i.e., make connections, either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

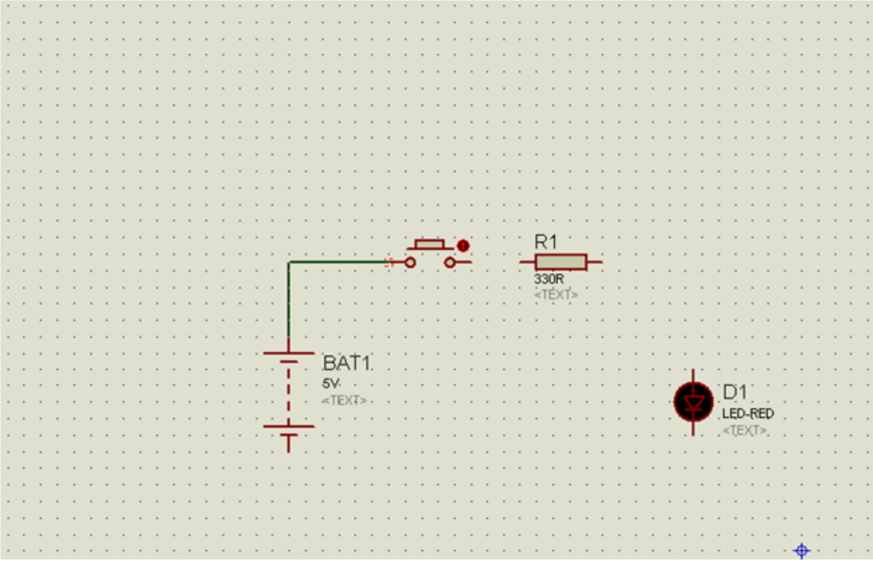

Fig:1.19 Simulation Procedure 9

Step 9: Double click on the component to edit the properties of the components and click on Ok.

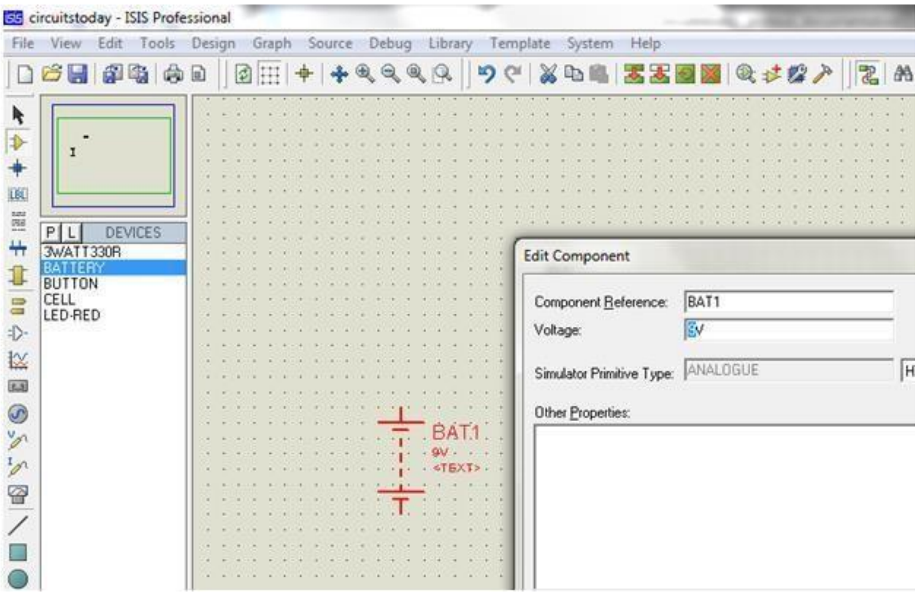

Fig.1.20 Simulation Procedure 10

Step 10: In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

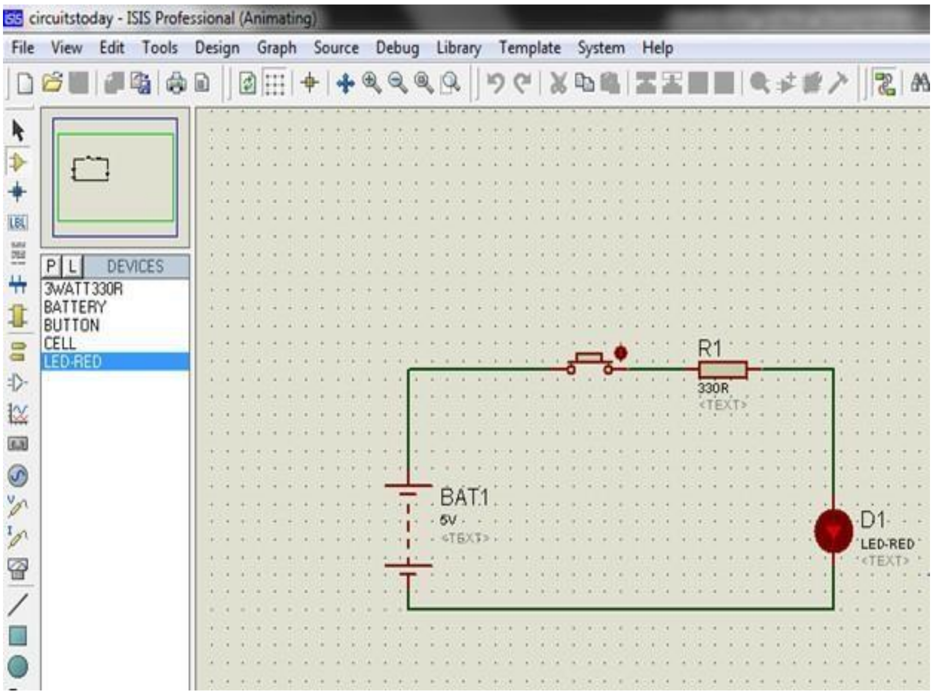

Fig:1.21 Simulation Procedure 11

Step 11: Simulation can be stepped, paused or stopped at any time.

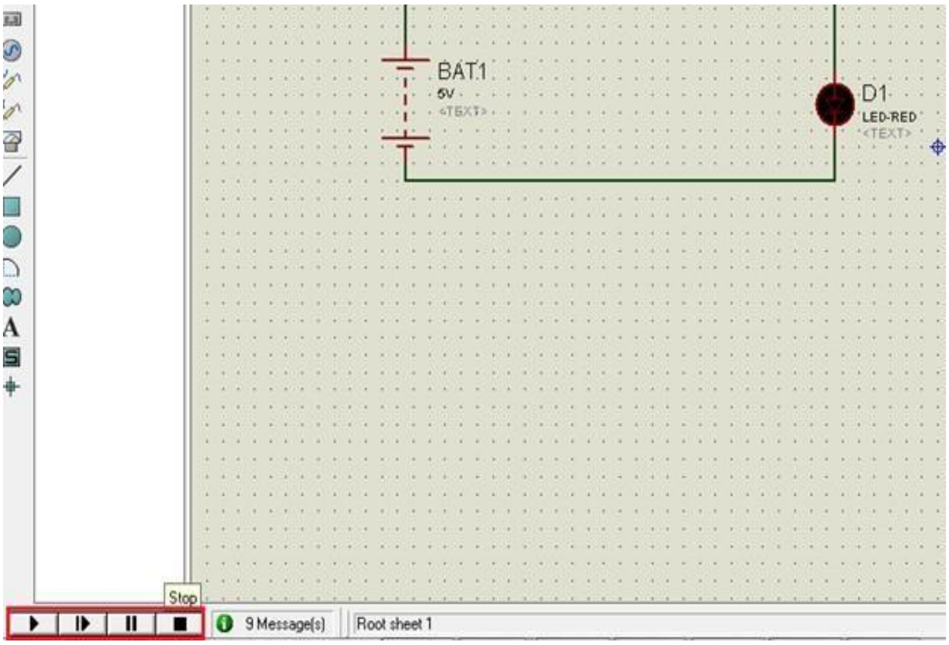

Fig:1.22 Simulation Procedure 12

1.4 PROCURMENT OF EQUIPMENT:

Fingerprints—the small ridges of skin on the fingertips which may enhance texture perception and grip friction—are unique to each person and have been used in identification for more than 100 years. Identification, the process of comparing a set of prints or a single print to others in a database, is used in many aspects of law enforcement and counterterrorism operations and investigations. Fingerprints may be compared to local and national databases for criminal history or to watch lists for border security. Latent prints from crime scenes are used in forensic investigations. Fingerprints can also be used to identify victims and for access control. Each application involves different processes for fingerprint capture and database searching and matching.

1.4.1 Components of Fingerprint Identification Systems

Fig:1.23 Finger print capture device

Fingerprint Capture the first step in fingerprint identification is obtaining an image of prints interest. Fingerprints deliberately collected from an individual are called exemplar prints, and may include simultaneous four finger images or rolled prints, which capture an image of each side the fingernail to the other. Exemplar prints have historically been obtained using paper and ink, which must then be optically scanned for database input. Live scanners electronically capture and store a digital image, eliminating paper and ink. Digitized prints are transmitted electronically for AFIS searches. Most current live scanners are based on optical sensors. Emerging technologies include thermal, capacitive, and ultrasound sensors, and some have to use a striped pattern projected onto the fingertip to obtain a three- dimensional image.

Minutiae Encoding

The second step in fingerprint identification is to extract the fingerprints which are identifible characteristics to be used in a database search. Fingerprints can be sorted into general classification by pattern type, such as arch, loop, or whorl, but minute details such as the ridge endings or burifications are unique to each individual Software identifies.

Recognition Software

An AFIS search involves the interaction of various databases where the minutiae are stored. Depending on the application, proprietary algorithms search segments of the database. For example, software may search the minutiae of two fingerprints of each subject, such as two index fingers, two thumbs, or a combination of finger and thumb. In other cases it may be necessary to search a database of all ten fingers. The simplest type of search is an identity verification used for access control or credentialing applications. Another identifier, such as a username, is submitted with a single fingerprint to specify who is attempting the authentication.

Certifications and Evaluations

A wide variety of fingerprint capture equipment and proprietary matching algorithms are commercially available. Interoperability is critical to the identification process and is achieved through standards and certification. The FBI has established image quality specifications for fingerprint images as well as data compression requirements for storage and transmission. The FBI certifies equipment compatible with the IAFIS, including live scanners, card scanners, and printers are listed.

Standards

Two standards are currently used in FBI certification. The image quality specifications for interoperability with IAFIS for fingerprint scanners and printers are contained in Appendix F of IAFIS- DOC-01078-9.3 Criminal Justice Information Services Electronic Biometric Transmission Specification. Fingerprint verification using 1:1 matching is the focus of the standard PIV-071006.

Development of national and international standards for fingerprint technology is ongoing, and many other standards are available. For example, ANSI/INCITS 381-2004 specifies data compression for image storage and transmission, and ANSI/INCITS 378-2009 defines a fingerprint standard minutiae template.

1.5 ORGANISATION OF THE CHAPTERS

The Overall Overview of Documentation is:

1.5.1 INTRODUCTION

1.5.2 LITERATURE SURVEY

1.5.3 PROJECT DESIGN

1.5.4 PROJECT IMPLEMENTATION

1.5.5 PROJECT TESTING

1.5.6 CONCLUSION AND FUTURE ENHANCEMENT

CHAPTER 2
LITERATURE SURVEY

This chapter gives a brief overview of previous works done related to Fingerprint system.

2.1 INTRODUCTION:

The main idea of our project is to secure the places by using fingerprint sensor used to scan the finger of n the persons, the authorized people have to register their fingerprints to the system by using fingerprint sensor and each person is provided a particular ID which is stored in the data, Authorized people are the only ones who can open the door, while the remaining people can't. For more security, the project is done along with buzzer indicator and GSM system.

2.2 RELATED WORK:

Biometrics is a way used to recognize a person based on his physical nature. The fingerprint, iris, face, voice, etc. are the mainly used biometrics to recognize a person. There are two key functions for biometrics, first is one to one matching and other is one too many matchings. In one to many matching the biometric sample is compared with the already stored samples. In one to one matching, it compares with the previously stored sample. Biometric method results in a faster security, and more convenient method for user verification. Biometric method is better than password security. Fingerprint is unique for each individual so it can be used as a mark of signature, verification and authentication. Fingerprint is the biometric which is used in this project. Finger-print will be different for each individual. In this project, fingerprint is used for the authentication of the user and allows him to cast vote based on his fingerprint image. Finger-print matching can be divided into three types: correlationbased matching, minutiae-based matching, pattern-based (or image-based) matching. In correlationbased matching, two fingerprint images are superimposed and therefore the correlation between corresponding pixels is computed for various alignments. In minutiae- based matching, minutiae from the two fingerprints are extracted and stored in a two-dimensional plane as a set. This matching method consists of finding the alignment between the template and the input minutiae sets that result in the maximum number of minutiae pairings. In pattern-based (or image-based) matching method it compares with stored template and the candidate's fingerprint. This requires that the images to be aligned within the same orientation. To do this, the algorithm finds a central point within the fingerprint image and centers there on. In a pattern-based algorithm, the template contains the sort, size, and orientation of patterns within the aligned fingerprint image. Almost all the sectors are storing data digitally. To create digital India, most of the tasks are made through on-line. When the voting is made on-line, it helps the voters to vote from anywhere in the world. Thingspeak is one of the ways which helps in making voting on-line. Obtaining online result makes the system faster. Traditionally voting was done by marking with stamp casting vote for the corresponding candidate and then dropping the paper to a ballot box. To calculate the number of vote

each vote must be calculated in each ballot box and then sum all the votes for each candidate and candidate who secured largest vote will be selected as the winner.

2.3 EXISTING METHODOLOGY:

In the existing system, most doors are controlled by persons with the use of keys, security cards, password or pattern to open the door. The aim of this project is to help users for improvement of the door security. With the advancement in the technology, Wireless controlling technique is proposed with a fine combination of new technologies and embedded system.

2.4 PROPOSED METHODOLOGY:

In the proposed system, we are introducing finger print module to access door lock. Here we have used MEMS (micro electro mechanical system, this signal is then sent to the Arduino. In this project Arduino act as a master and the remaining acts as slaves. Information from the Arduino is displayed on the LCD. The lock device is connected to the circuit door will be opened or closed depending on the command given. If any unauthorized people try to open the door it gives buzzing sound.

CHAPTER 3

PROJECT DESIGN

3.0 OVERVEIW OF THE SYSTEM DESIGN

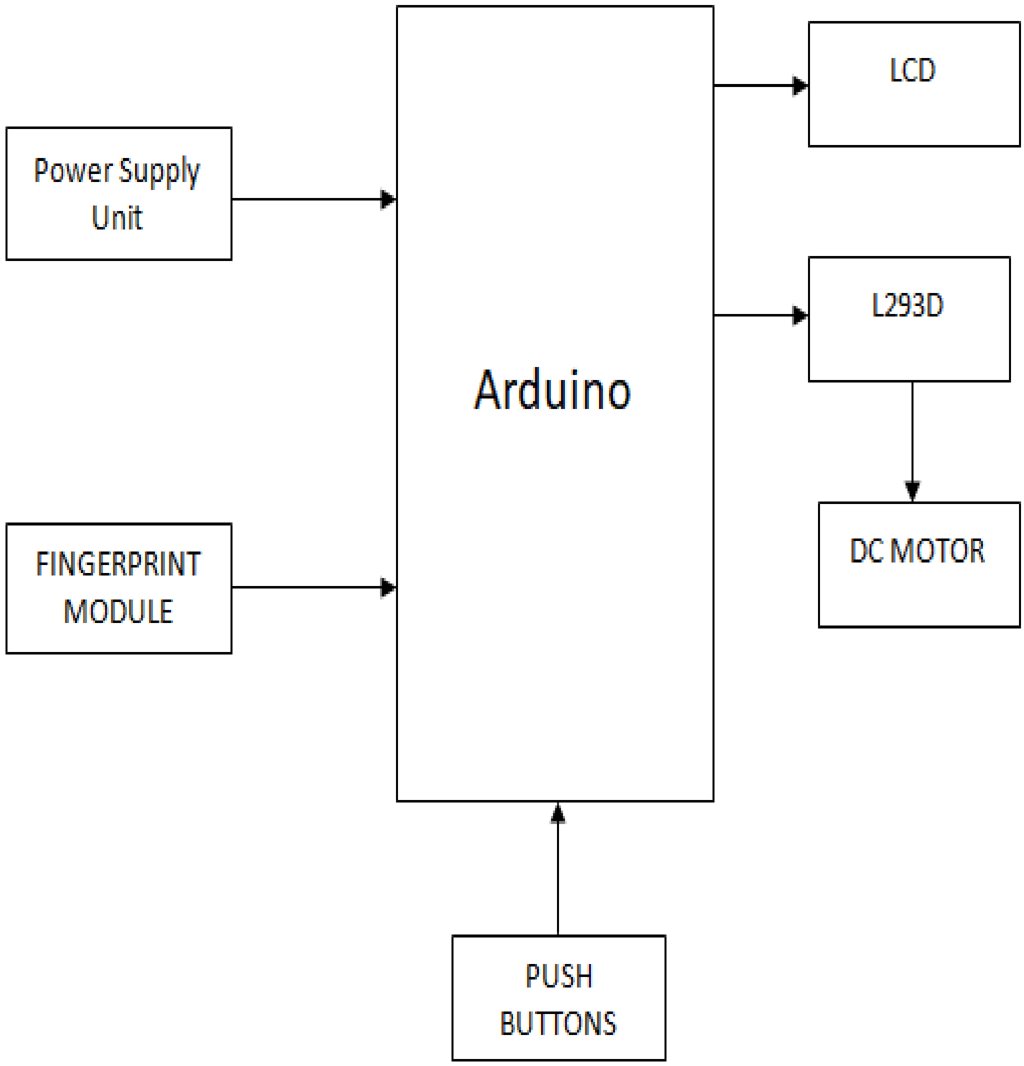

Fig:3.1 Block Diagram of finger print based security system

The block diagram of finger print based security is shown above which consists of fingerprint module, push buttons, Arduino UNO, power supply unit ,L293D IC,DC Motor and power supply unit.

3.1 SCHEMATIC DIAGRAM:

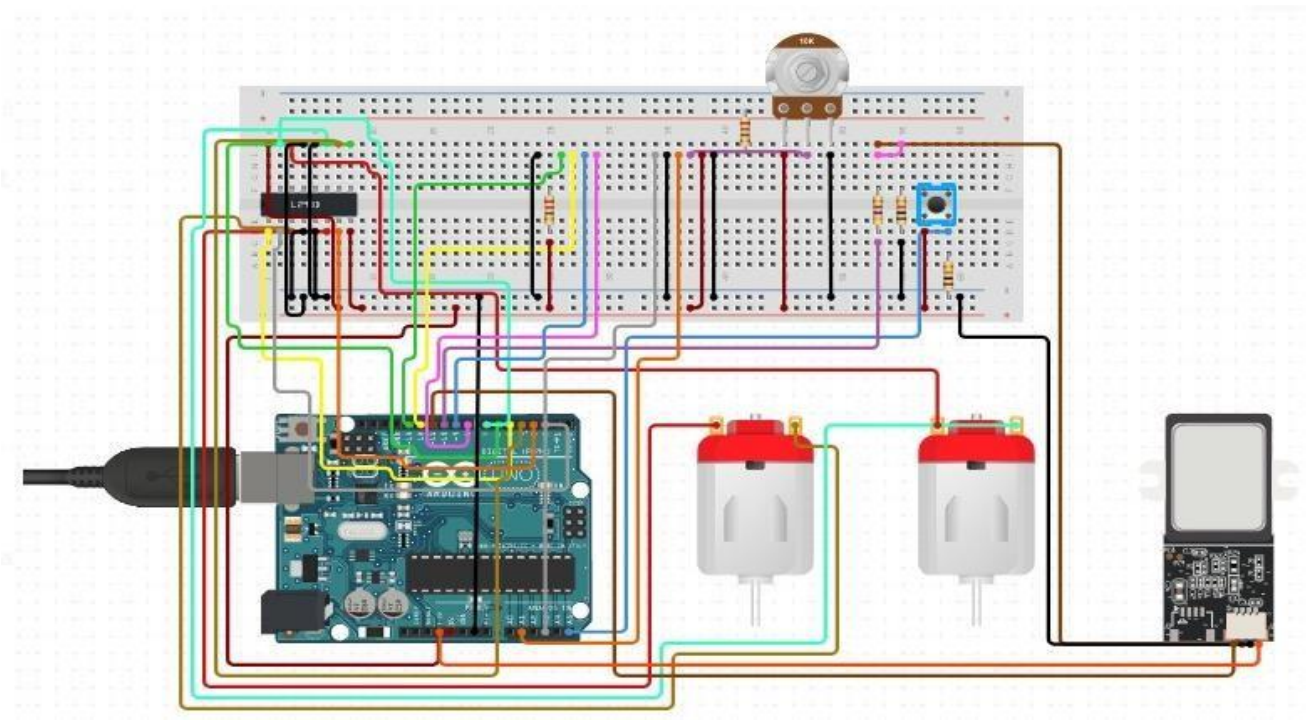

Fig:3.2 Simulation layout

The above schematic diagram of Finger Print Based Security System explains the interfacing section of each component with Arduino uno and input output modules.

3.2 MODULES FUNCTIONALITIES:

3.2.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board. The key features are :

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

3.2.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Table:3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro-3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
Lily pad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

3.2.1.2 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common

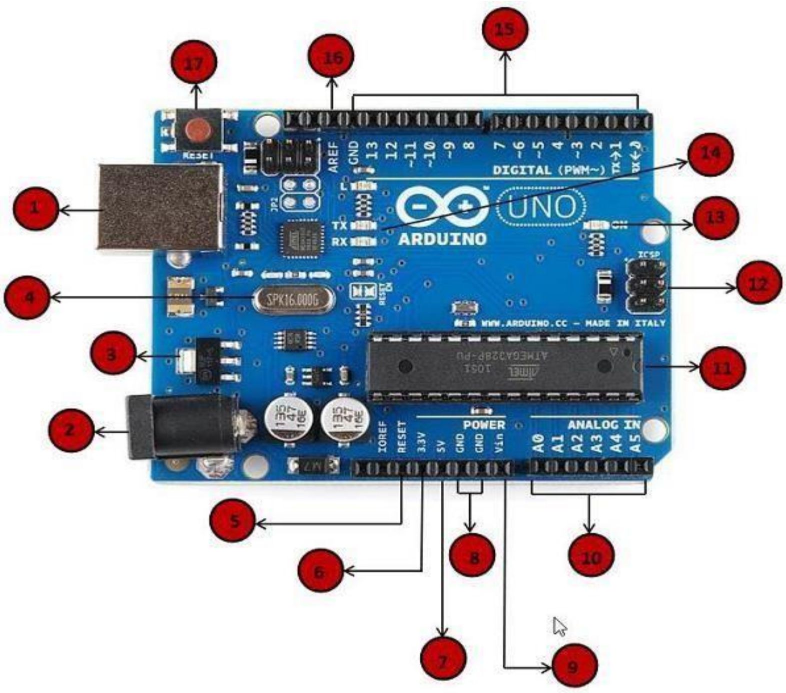

Fig:3.3 Board description of Arduino uno

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. GND (8) (Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.

10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

3.3 Liquid Crystal Display in LCD

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D6).

When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller

3.3.1 Description of 16x2 LCD:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

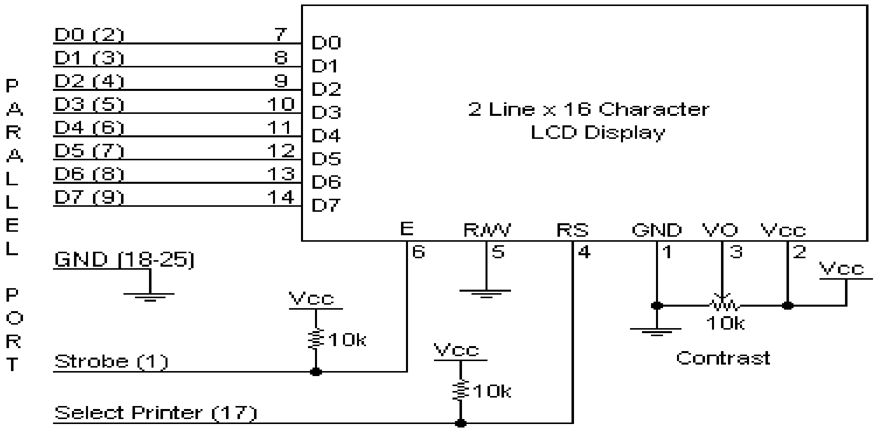

Fig 3.4: Schematic diagram of LCD

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use an onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

3.3.2 16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area.
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line.
- Can display 224 different symbols.
- Low power consumption (1 mA typical).
- Powerful command set and user-produced characters.
- TTL and CMOS compatible.
- Connector for standard 0.1-pitch pin headers.

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H, H->L	Enable

Table:3.5 16x2 LCD Features

3.3.3 FEATURES:

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Table:3.6 Data Location in LCD

3.3.4 Figure Address locations for a 1x16 line LCD

Even limited to character-based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one-, two- and four-line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

3.3.5 Pin Description In LCD:

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers has 16 Pins (two pins are extra in both for back-light LED connections).

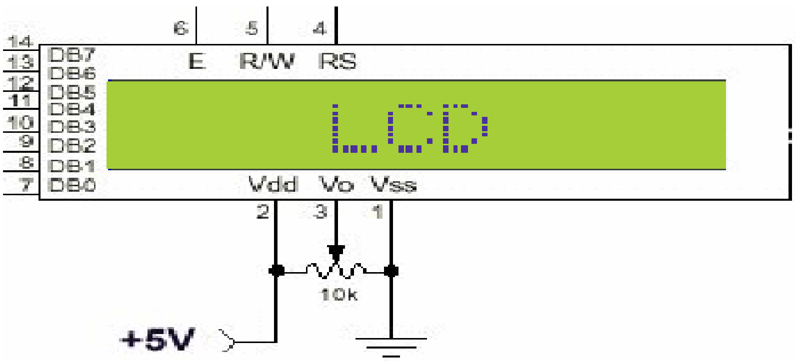

Fig:3.5 Pin Description of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table:3.7 Pin specifications

3.3.6 CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of the selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0-DB8.

Logic status on control lines

- E - 0 Access to LCD disabled.
- 1 Access to LCD enabled.
- R/W - 0 Writing data to LCD.
- 1 Reading data from LCD.
- RS - 0 Instructions.
- 1 Character.

Writing data to the LCD

- Set R/W bit to low.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Read data from data lines (if it is reading) on LCD

- Set R/W bit to high.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Entering Text

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table:3.8 LCD Commands

3.4 Fingerprint Sensor

The fingerprint sensor can read different fingerprints and store in its own flash memory. The sensor can perform three functions namely Add (Enroll), Empty Database or search database and return the ID of stored fingerprint. Any of three functions can be called simply by making the pin low of the sensor or pressing onboard three switches. The response is either error or ok which is indicated by onboard LED. The response is also returned as single serial data byte.

The return byte is a valid ID or error code. The response byte is a single byte at 9600 bps thus making whole sensor very easy to use. We have provided indicating LEDs and function switch already so it’s ready to use when you receive it. Just give power and start using the sensor using onboard switches. Then you can move on making external application using these functions.

3.4.1 Inputs and Outputs of Sensor

Input: Two ways to trigger the function of fingerprint sensor

- Onboard switch: Add, Empty or Search.
- Make pin low from external microcontroller for 5ms as per function required to be executed.

Output: Two ways to monitor output response after a function is executed

- Onboard LEDs: ERROR or OK.
- Read byte after executing function.

3.4.2 Types of Sensor Function

There are namely three functions you can call for the fingerprint sensor. We will see each in brief.

Add (Enroll) Function: Adds a fingerprint to database and return a byte of newly added ID. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function

Search Function: When a finger is put and search function is called, it returns a matching ID if found in its existing memory. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function.

Empty Function: When you wish to empty all fingerprint, data stored on sensor you can use this function. After executing this function, you will get 0xCC as OK or 0xFF in case of error.

3.4.3 Fingerprint Recognition Sensor Module

The sensor is a solid-state fingerprint sensor that reliably captures fingerprint information. It is designed to integrate into devices for improved security and convenience. The sensor provides a reliable, quick and user-friendly alternative to passwords, PIN's and other forms of user authentication.

This fingerprint scanner is capable of gathering and storing unique finger prints. Simply hold your finger on the optical scanner, query the device over serial, and you will be issued a unique ID. Use that ID within your embedded system to determine access levels, time clocks, door locks, etc. Unit includes 4 pin connector cable to connect and read to controller. The outputs are TTL level serial data.

A biometric sensor, fingerprint sensor to be specific, also known as the fingerprint reader, is a fingerprint image capture device, the very front end of the biometric fingerprint identification/verification module. The fingerprint sensor captures the fingerprint images, matches the uniqueness of each print read by the sensor and compares it to the one stored in its module or local system database.

It consists of optical fingerprint sensor, high performance DSP processor and Flash. It boasts of functions such as fingerprint enrollment, deletion,updation,searching,scanning.

3.4.4 Applications

- Computer peripherals – improves security and convenience
- Transportation systems – validation of operators, drivers and inspectors
- Medical equipment – authorization of operator or technician
- Physical access systems – approval for entry
- Kiosks and vending machines – confirmation of person receiving the selection
- Point of Sale terminals – authentication of tellers and cashiers

3.4.5 Features

- Rugged, solid-state optical fingerprint sensor
- High resolution 500 DPI imager
- Adapts to wet/dry fingers
- Simple Interfacing protocol

Fig:3.6 Fingerprint sensor

3.4.6 Specifications of Sensor

- Fingerprint enrollment time <250ms
- Fingerprint search time <1s（100 fingerprint, average value in test） Resolutions 500 DPI
- Security level 5, Adjustable Capacity 768 Templates
- FAR <0.0001%
- FRR <0.01%
- Power Supply 4.3V to 6V Working Current <80mA Peak Current <90mA Communication Interface TTL
- Communication Baud Rate 57600 bps Working Temperature -10 deg C to +40 deg C
- Working Humidity 40% RH to 85% TH (no dew) Module Dimensions 60x21x25 mm (LxWxH)

3.5 BUZZER:

3.5.1 Types of Buzzer

Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

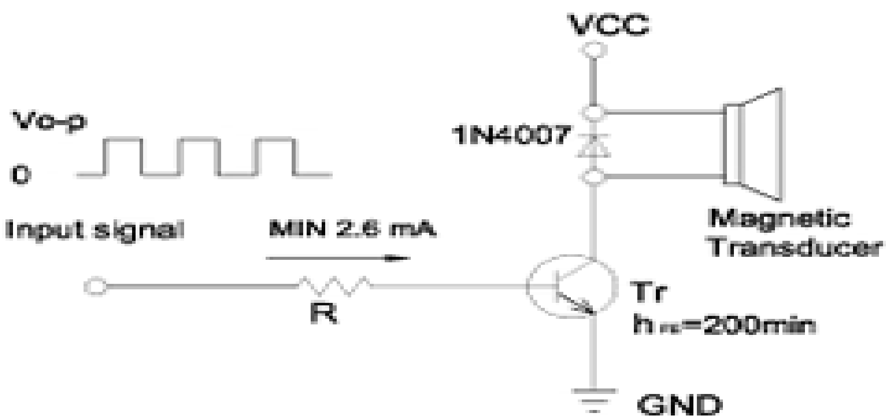

Fig:3.7 Driving Circuit for Magnetic Transducer

3.5.2 Specifications of buzzer:

- **Rated Voltage**: A magnetic buzzer is driven by 1/2 square waves (V o-p). **Operating Voltage**: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
- **Consumption Current**: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
- **Direct Current Resistance**: The direct current resistance is measured by ammeter directly.
- **Sound Output**: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
- **Rated Frequency**: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
- **Operating Temp**: Keep working well between -30℃ and +70℃.
- **Driving methods**: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.
- **Dimension**: Dimension affects frequency, small size result in high frequency.
- **Voltage**: Depend on V o-p (1/2 square waves)
- **Fixed methods**: From the highest cost to the lowest- DIP, wires/ connector, SMD.

3.5.3 How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer starts to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the int set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. to the different work principle, the magnetic buzzer needs to be driven by 1/2 square waves, and the buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of silicon.

The above shown figure is buzzer

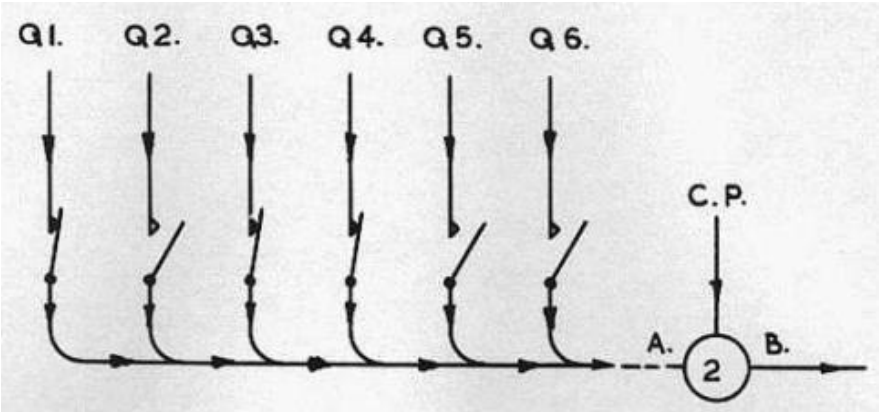

Fig:3.9 Pin Diagram of buzzer

The above shown figure is the diagram of a buzzer

3.6 Switches

A switch is an electrical component that can break an electrical circuit, interrupting the current or diverting it from one conductor to another. The most familiar form of switch is a manually operated electromechanical device with one or more sets of electrical contacts. Each set of contacts can be in one of two states: either 'closed' meaning the contacts are touching and electricity can flow between them, or 'open', meaning the contacts are separated and non-conducting.

Fig:3.10 Switches in a row

Switches with larger numbers of poles or throws can be described by replacing the "S" or "D" with a number or in some cases the letter "T" (for "triple"). In the rest of this article the terms *SPST*, SPDT and intermediate will be used to avoid the ambiguity in the use of the word "way".

3.6.1 Working of Switch

A pair of contacts is said to be "closed" when current can flow from one to the other. When the contacts are separated by an insulating air gap, an air space, they are said to be "open", and no current can flow at typical voltages.

Switches are classified according to the arrangement of their contacts in electronics. Electricians installing building wiring use different nomenclature, such as "one-way", "two- way", "three-way" and "four-way" switches

In a push-button type switch, in which the contacts remain in one state unless actuated, the contacts can either be normally open (abbreviated "no." or "no") until closed by operation of the switch, or normally closed ("n.c. or "nc") and opened by the switch action. A switch with both types of contact is called a changeover switch. These may be "make-before- break" which momentarily connect both circuits, or may be "break-before-make" which interrupts one circuit before closing the other

3.6.1 APPLICATIONS

- They are used for the given instructions to the required device like robot, driving the motor, etc.
- Switches can arrange in the matrix from or in the required from according to the application.
- Reset circuit of the controller, motor also has the switches for its particular functioning.

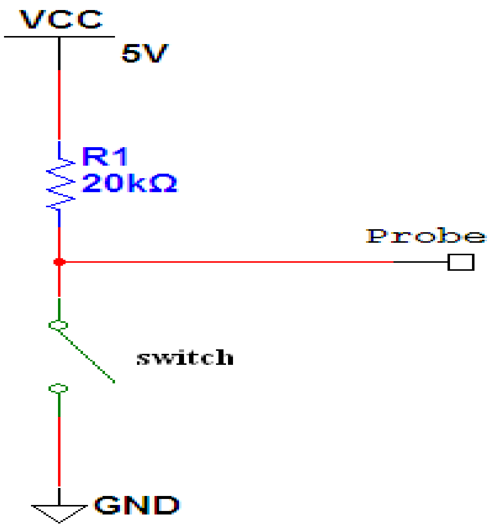

Fig:3.11 Circuit of Switch

From the above circuit it explains the working of the switch when supply is given to the circuit the resistor takes the current and oppose to the certain extend until the switch is pressed. These switches can be connected parallel or serial in required manner.

We can have resistor, capacitor, light resistor diode etc. as the combination of the switch. For example, w the reset circuit in which we the resistor and capacitor as the combination.

CHAPTER 4
PROJECT IMPLEMENTATION

4.0 IMPLEMENTATION STAGES:

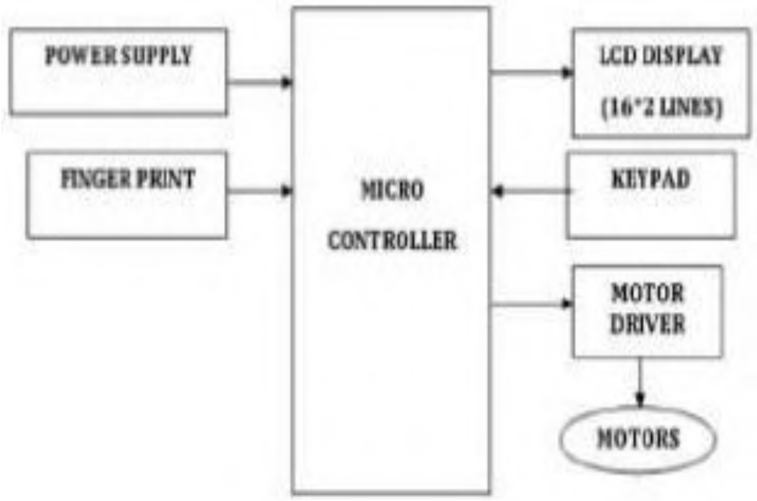

Fig:4.1 Finger print based security sensor

Here we use two microcontrollers to minimize the fee of the locker in view that these microcontrollers are very commercial so that any person can afford the locker. The foremost a part of this venture is the finger print module without which user can't open his/her locker. The fingerprint we used is an optical scanner; the heart of this scanner is a charged coupled gadget (CCD). The CCD has an array of light touchy diodes, referred to as picture sites. These photograph websites generate an electrical in response of light alerts. These alerts are saved in the type of dark and lights pixels for ridges and valleys respectively within the fingerprint module, these darkish and lightweight pixels are used to differentiate between specific fingerprints.

Stepwise implementation of finger print based security system is given under:
Step 1: Enter your password with the keypad.
Step 2: Now, scan your fingerprint on the fingerprint scanner. In case your fingerprint is not matched then snapshot seize by way of the digicam module and retailer in the pc system.
Step 3: If the password and fingerprint are of approved individual then the door attached to the dcmotor will open.
Step 4: Now, that you can entry to your locker.

4.1 WORKING FLOW OF THE PROJECT:

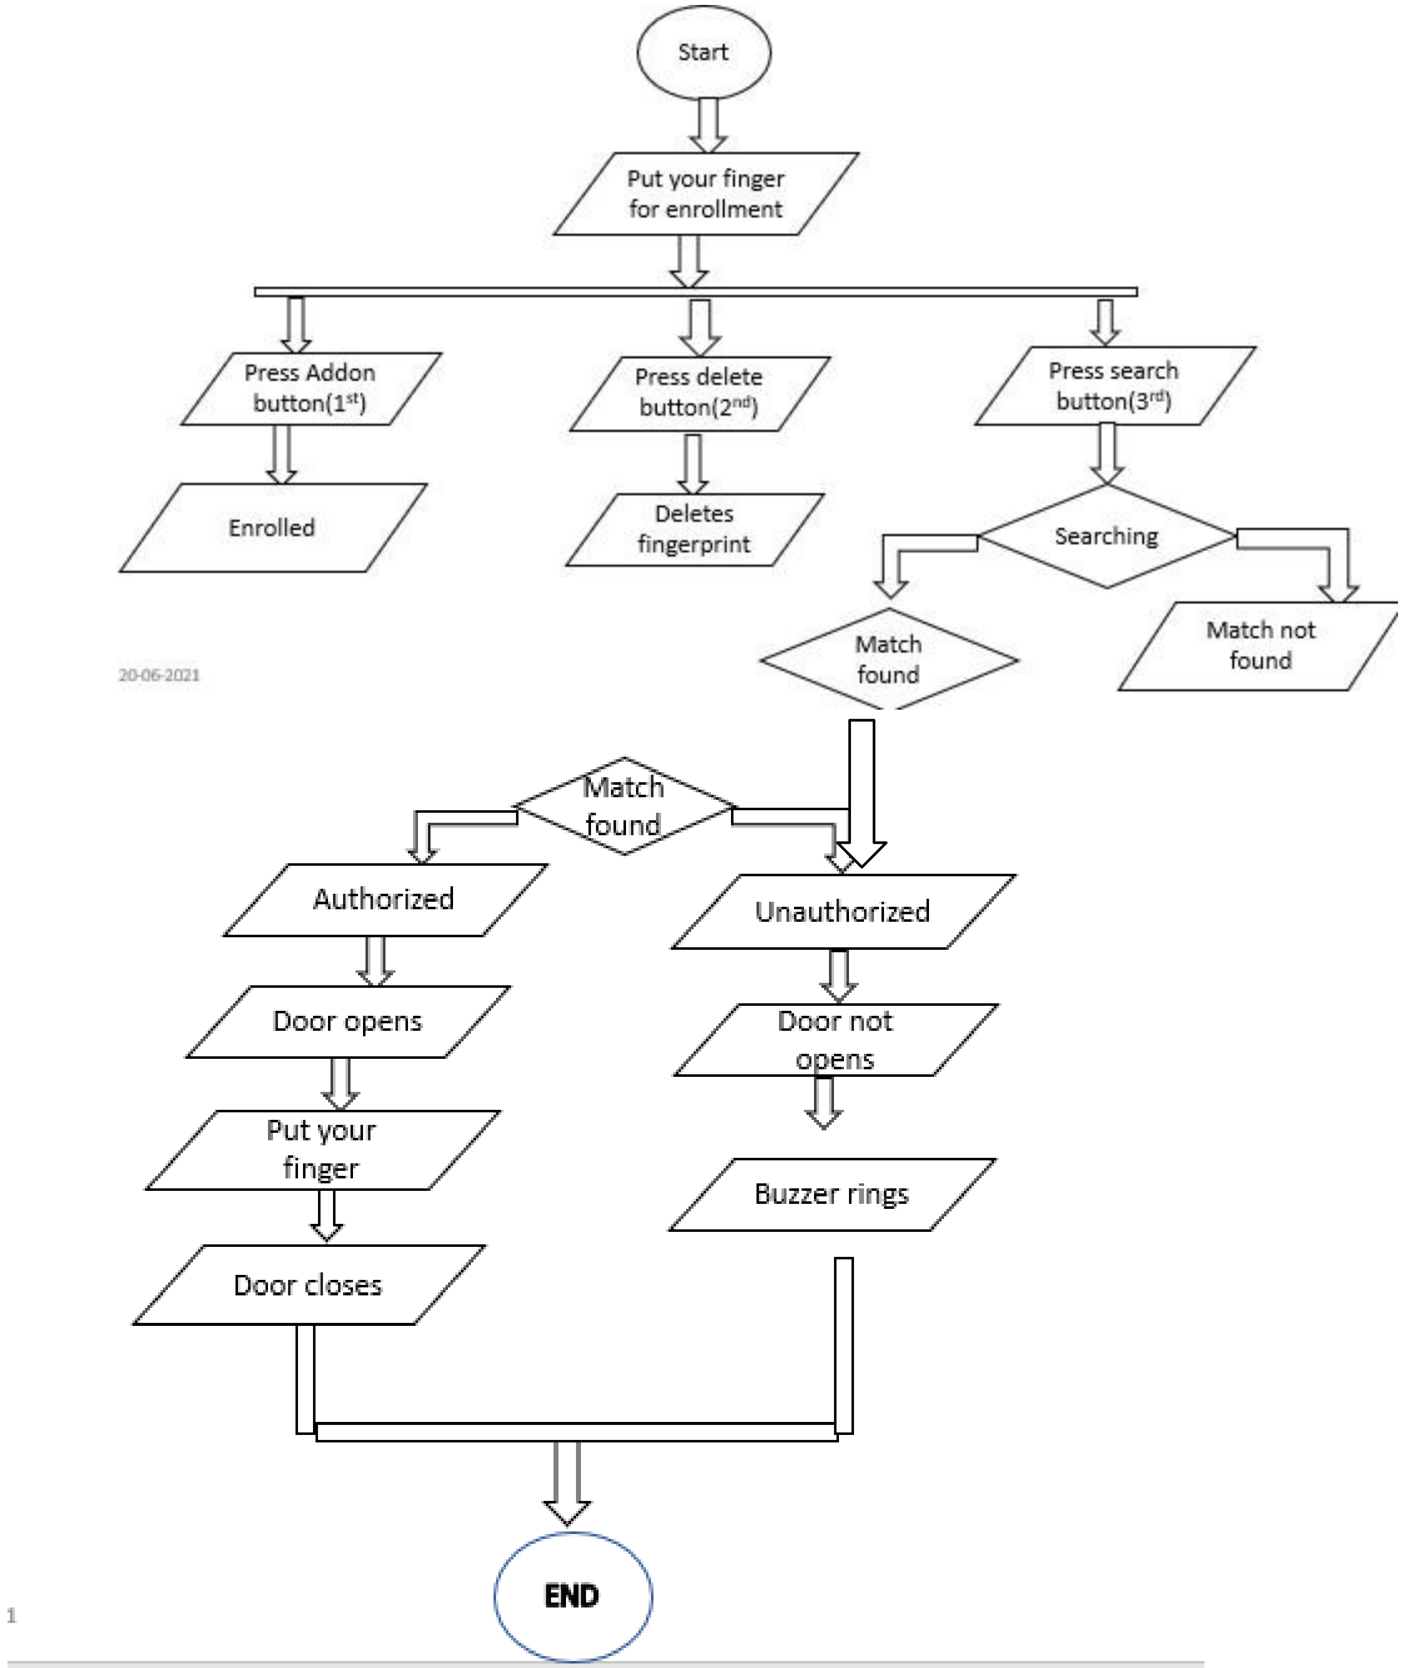

Fig:4.2 Working flow of Finger Print Based Security System

The above figure is the working flow of Finger print based security system.

4.2 EXPERIMENTAL RESULTS:

4.2.1 INTRODUCTION:

Security is a major concern in our day-to-day life, and digital locks have become an important part of these security systems. There are many types of security systems available to secure our place. Some examples are PIR based Security System, RFID based Security System, Digital Lock System, systems, Electronics Code lock. In this post, we will Interface a Fingerprint Sensor Module with Arduino and will build a Fingerprint based Biometric Security System with door locking. Fingerprint is considered one of the safest keys to lock or unlock any system as it can recognize any person uniquely and can't be copied easily. In the proposed system, we are introducing finger print module to access door lock. Here we have used MEMS (micro electro mechanical sensor), which is used to send message to user through GSM if any theft happens. This signal is then sent to the microcontroller. In this project microcontroller Arduino act as a master and the remaining acts as slaves. Information from the micro controller is displayed on the LCD. Fingerprint Sensor Module or Fingerprint Scanner is a module which captures finger's print image and then converts it into the equivalent template and saves them into its memory on selected ID (location) by Arduino.

This is a perfect/optimal solution for saving/protecting one from the hassle of stolen/lost key or an unauthorized entry. Fingerprint is a boon solution for these problems which provides high level of recognition accuracy. The skin on our palms and soles exhibits a flow like pattern of ridges called friction ridges. The pattern of friction ridges on each finger is unique and immutable. This makes fingerprint a unique identification for everyone.

Here all the process is commanded by Arduino like taking an image of fingerprint, convert it into templates and storing location etc. Our proposed system overcomes all the security problems in existing system and provides high security and efficiency.

4.2.2 PROJECT OUTPUT RESPONSE:

The general view of the projected is illustrated in the following figure, followed by the expected performance of the project. each figure summarizes one implementation step that has to take place in the project, each figure shows the output by using LCD, and all the comments appear in the console of LCD, those comments help the user to deal with system.

General view of the Project

The above shown figure is it displays the open door Command in LCD.

Fig:4.7 Command on LCD to close the opened door

The above shown figure is it displays the close door Command in LCD.

CHAPTER 5
ADVANTAGES AND LIMITATIONS

5.1 ADVANTAGES

- Fingerprint based security system is the most secured system as compared to other systems. Reason is that RFID card or Keys of lock can be stolen, password may be leaked. However, thumbnail of every human being is unique, so lock will not open unless the same person is present to give the impression of fingerprint.
- No need to carry the keys to open the lock. Or even there is no need to remember the password or any Pin number.
- One of the main advantages is that this system remembers the stored password even if the power supply is turned off.
- Scientific research and studies have proved that fingerprints do not change as you grow up.
- Using Fingerprint saves time to gain access as compared to other methods like RFID card, Password or Key.

5.2 LIMITATIONS

- **System failures –** Scanners are subject to the same technical failures and limitations as all other electronic identification systems such as power outages, errors and environmental factors.
- **Cost** – it is true that fingerprint recognition systems are more cost effective than ever, but for smaller organisations the cost of implementation and maintenance can still be a barrier to implementation. This disadvantage is lessening as devices become more cost effective and affordable.
- **Exclusions** – while fingerprints remain relatively stable over a person's lifetime there are sections of the population that will be excluded from using the system. For example, older people with a history of manual work may struggle to register worn prints into a system or people who have suffered the loss of fingers or hands would be excluded.

5.3 APPLICATIONS

- **Industrial application:** "Fingerprint-based security system" project can be used by the employees, staff or workers in various industries like Automobile industries, manufacturing industries, Software development companies.

- **Home or domestic application:** This project can be used to automate the door locking process at our home, so the user needs not to carry the door lock keys along with him, he can just use his/her finger to open the door

- **Bank Lockers or security safes:** Many of the banks use key based or password-based locks for their lockers or safes. We can implement Fingerprint based bank locker system using this project.

5.4 FURTHER ENHANCEMENT OF THE PROJECT

- To this project we can add an GSM (global system monitoring) in sending alert messages to the owner if unauthorized person tries to enter the room.

- Touchless fingerprint scanner can be used, so that there is no need to touch the scanner with your finger which ensures some safety on virus attacks.

CHAPTER 6
CONCLUSION AND FUTURE SCOPE

6.1 CONCLUSION

- In our proposed project, the performance is summarized as the following:
- It provides more security compared to the currently used systems.
- It is easy to implement and easy to access by the user.
- It ensures the owner by the range of security provides.
- It Is far better when compared to RFIDs and pattern locking
- No need of remembering of passwords set to the door locks.
- The aim of the work is to design a fingerprint lock system that can be used to lock and unlock a door system but its use can be extended to other electronic locking systems such as vaults.
- Having realized the device and found it working properly according to its design specifications and couple with the facts that relatively cheap components were involved in its realization, the aim of the research can be said to be achieved. The system can be used as an effective security lock.
- Effective Communication with administrators.
- Quick response to accident.
- Quick alert to police and other security services.

6.2 FUTURE SCOPE

- In the future, fingerprint detection can be used for better improvement of home automation and it gives strong security. It can be widely used in the banks, offices and homes…etc.
- It is more interactive by adding a display to show basic information about the vehicle and provides alert system for reporting any kind of trouble occurrences.
- The system could be modified into a web based system.
- Hence, A Vehicle tracking system is becoming increasingly important in rural and urban areas and it is more secured than other systems.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics And Communication for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand kumar** for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide**, Mr. N. Vishwanath, Assistant professor**, Department of ECE and our class project coordinator **Ms. A. Soumya**, **Assistant professor**, Department of ECE for guidance and encouragement in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr. Malayadri, professor in IT,** and **Dr.R. Santhosh kumar Associate Professor in ECE** and for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. R. Sai Krishna
2. M.Sai kumar
3. P. Santhosh kumar

LIST OF ACRONYMS AND DEFINITIONS

RFID: Radio frequency identification

RFID uses an electromagnetic field to identify and track tags attached to objects. An RFID system consists of a tiny radio transponder, a radio receiver and transmitter

ARDUINO: Arduino is an open-source platform used for building electronic projects. Arduino consists of a both physical programmable circuit board and a software used to programme it

EM18 READER: EM 18 reader is the one of the commonly used RFID reader to read 125khz tags.it features low cost, low power consumption, small form factor and easy to use.it can be directly interfaced with microcontrollers using UART and with pc using an RS232 converter

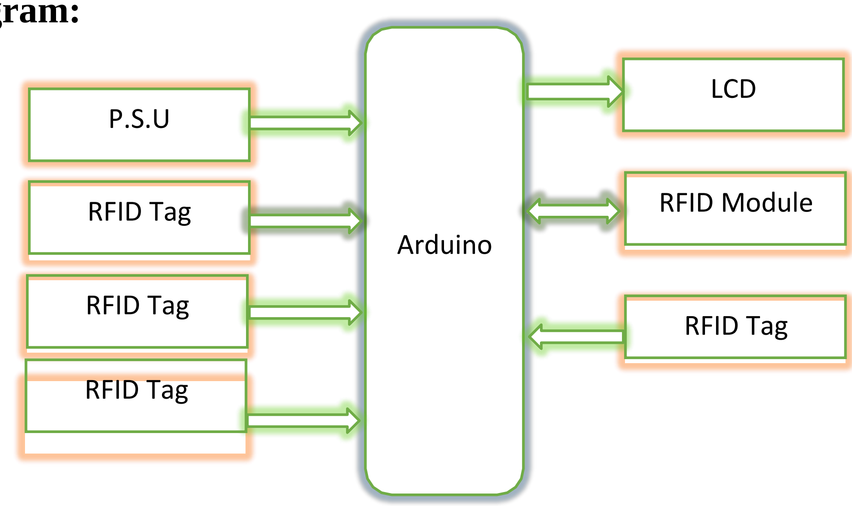
PSU: Power supply unit

RFID BASED SMART MASTER CARD FOR BUS TRAIN METRO TICKETING

Abstract:

Modern cities of today have developed multiple means of communication including Buses, trains, metros and private vehicles. Now each transport system has their own smart card and it becomes a hectic process for users to manage separate smart cards for every transport medium. Thus, we propose a smart master card approach that integrates all these systems together and allows for a single master card and a centralized system for all transportation mediums. To demonstrate this concept, we use three RFID scanners to demonstrate as bus train and metro train smart card scanners respectively. Now we use three smart cards that work particularly on each of the systems viz one RFID card for bus, one for train and one for metro respectively. Now we also provide one more card that is the master smart card that can work on all three scanners thus making it very easy for the user to use any transport as desired using the same card. The system also allows for source and destination selection and based on that deducts particular amount from the user master card.

Block Diagram:



CHAPTER 1
INTRODUCTION

Introduction:

As for the RFID application, it’s been a widespread tool for both tracking the transit transports and for the public ticketing system. It’s already been an outstanding achievement throughout the globe including big cities like London, Helsinki, Shanghai, Istanbul, Moscow, Porto and many more. The system can be implemented for subways, railways and public bus services for the sake of systematic operations in corresponding cases. In the megacities, the conventional system of public transport is based on project-based bus or railway tickets that ultimately lead to chaos among public, system loss, corruption and most of all traffic jam that is responsible for a huge wastage of time. No prior notification of the arrival and departure of the transports are available creating a lot of confusion among the passengers resulting in a rough argument between them and the bus supervisors or the operators.

Again, having no government authority to take control or keep an eye over the whole scenario, the private sectors are creating a monopoly, taking control over the public transport and autocratic raise in bus fare. The tracking and ticketing systems using RFID can be merged to solve the prevailing problems. Even though the GPS based system can be designed, we propose the RFID based tickets for its low cost, easy operation, portability, durability, reliability and being much more user friendly. Also, the high-speed RFID tags and detectors make the tracking system of a running bus merely a child’s play. Public carrying RFID based electronic tickets will have access to any bus service of the city only entering his current location and his destination on the keypad attached to every bus. The data will directly be transferred to the server main database and the equivalent credit will be stored in the corresponding bus account. Also, the screen at every bus stop will notify the passengers, the departure time of the last bus of any route. This automated system will save time, have a higher authoritative inspection and reduce chaos and confusion on the road.

CHAPTER 2

LITERATURE SURVEY

Charlie Fine et. al (2006): RFID technology has generated much hype in the last few years. The major driver for its development has been the tagging of physical objects – people, places, and things – with single chip radios so they can interface with computers. RFID technology is both hailed as the key to the ―Internet of Things,‖ and condemned as invasive surveillance technology, and in more extreme circles it is feared as the Mark of the Beast. An RFID system can be broken down into two key dimensions. The technical infrastructure includes the actual data capture technology comprised of tags, readers, and transmission medium. The logical infrastructure refers to the overall identification (ID) scheme used in representing objects.

Ahuja Sanjay and Potti Pavan (2010) : RFID is still in a developing phase and more is in the pipeline in terms of new applications. Among applications already developed, RFID tags are being used in clothing for billing and security purposes. RFID tags are embedded inside animals for tracking purposes. RFID tags embedded in uniforms can be used to know the number of hours an employee spends to complete a particular task. There are several associations that are pro-testing against the use of RFID to track people fearing the impact on people's social life and privacy.

Matija Bumbak (2005): Considering enormous scale on which RFID will be operating and considering the fact that it will be present everywhere in our lives it is absolutely necessary for it to be a secure system.Even though RFID is still not operational on large scale, some experimental shops, literature written about it is relatively extensive. there are three primary issues surrounding RFID and the need to protect proprietary information: Protecting data stored on the tag; Protecting the integrity of the tag (and thus the product); Securing data related to the serial number on a tag, which may be stored in a network database.

Kamaran Ahsan et. al (2010): Industries use RFID for various applications such as personal/vehicle access control, departmental store security, equipment tracking, baggage, fast food establishments, logistics, etc. The enhancement in RFID technology has brought advantages that are related to resource optimization, increased efficiency within business processes, and enhanced customer care, overall improvements in business operations and healthcare. Other applications includes automatic toll payments, departmental access control in large buildings. personal and vehicle control in a particular area, security of items which shouldn't leave the area, equipment tracking in engineering firms, hospital filing systems.

Srivastav Nandita (2006) : The ―Radio Frequency Identification (**RFID**) is an automatic identification system. RFID uses RF to identify ―tagged‖ items .This data is then collected and transmitted to a host system using an RF Reader. The data transmitted by the tag may provide identification or location information, or specifics about the product tagged, such as price, color, date of purchase; etc.In Bar code the scanner device directs a light beam at the bar code. The device contains a small sensory reading element. This sensor detects the light being reflected back from the bar code, and converts light energy into electrical energy. The result is an electrical signal that can be converted into data.

Daniel M Dobkin et. al (2005): Every form of communication must follow a set of protocols, dealing with such issues as providing access to the communications medium, structure and meaning of the data to be transmitted, and coding and modulation of the data into the transmitted signals. The protocols have been developed somewhat independently and even when standardized are generally mutually inoperable. For example, an ISO15693 tag doesn't detect or understand and ISO11784 reader, and neither can communicate with an EPCGlobal UHF system. **Daniel M Dobkin et. al (2005)**: Every RFID system consists of at least one interrogator, more commonly known as a reader, which uses a radio link to communicate with at least one transponder. The tag generally contains one or more integrated circuits, and a unique identifying number stored in non-volatile memory. The reader is often (though not always) integrated into a network in order to make efficient use of the identification data it collects. There are three key architectural parameters that determine the type of RFID system in use: the frequency (practically equivalent to the mode of coupling), the means of powering the tag, and the communications protocol employed

Juels Ari (2005): RFID raises two main privacy concerns for users: clandestine *tracking* and *inventorying*.RFID tags respond to reader interrogation without alerting their owners or bearers. Thus, where read range permits, clandestine scanning of tags is a plausible threat. Most RFID tags emit unique identifiers, even tags that protect data with cryptographic algorithms In consequence, a person carrying an RFID tag effectively broadcasts a fixed serial number to nearby readers, providing a ready vehicle for clandestine physical tracking. Such tracking is possible even if a fixed tag serial number is random and carries no intrinsic data. The threat to privacy grows when a tag serial number is combined with personal information.

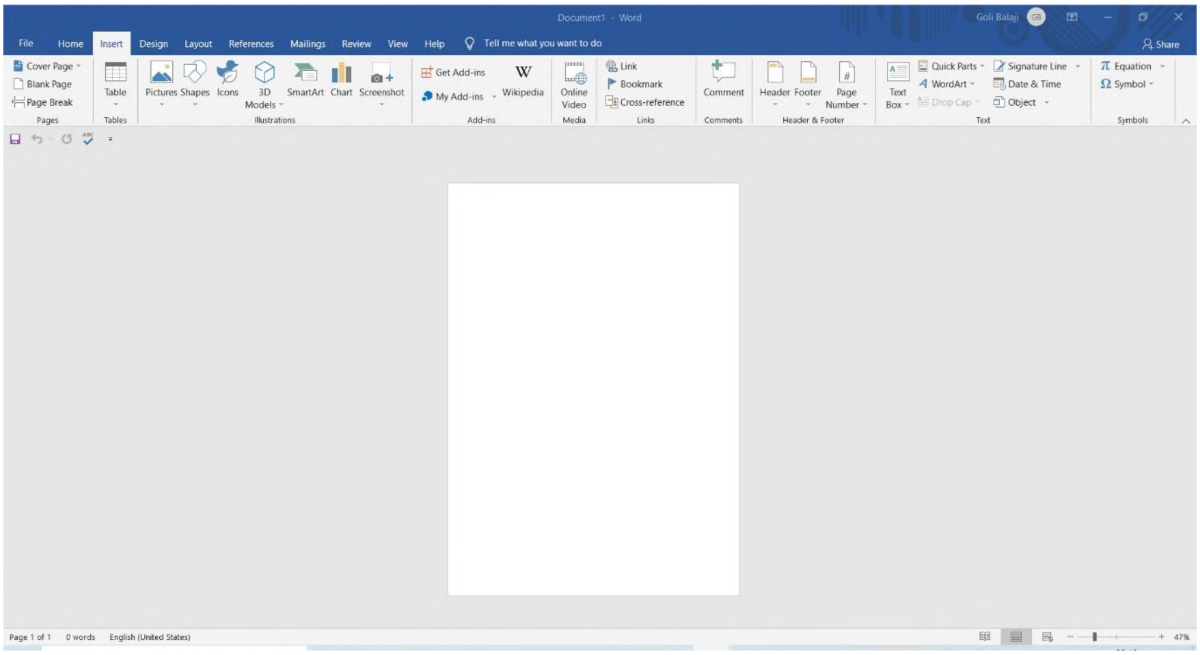
CHAPTER 3

EMBEDDED SYSTEMS

2.1 Embedded System

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.



The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

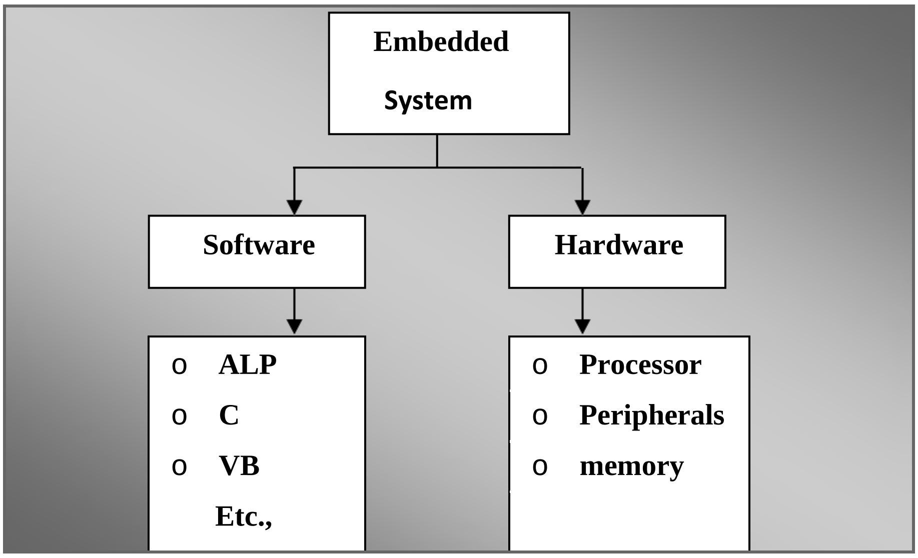


Figure 2.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

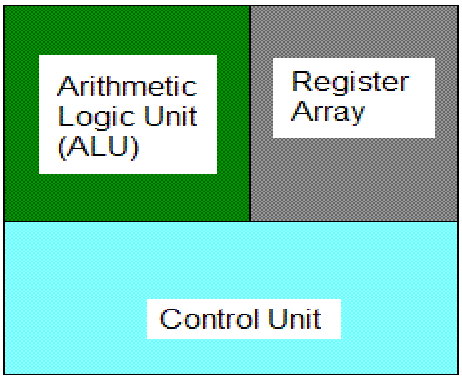

Fig : 2.1.1 Architecture of CPU

Three Basic Elements of a Microprocessor

Micro Controller (μc):

A microcontroller is a small computer on a single **integrated circuit** containing a processor core, memory, and programmable **input/output** peripherals. Program memory in the form of **NOR flash** or **OTP ROM** is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the **microprocessors** used in **personal computers** or other general purpose applications.

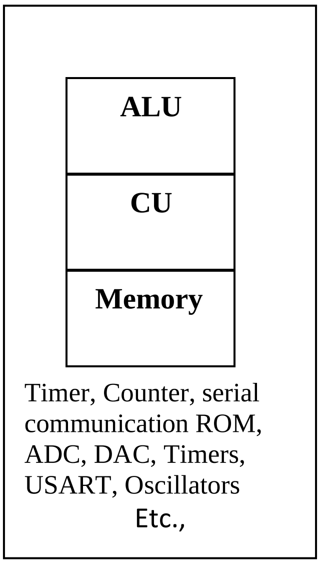

Figure 2.2 Block Diagram of Micro Controller (μc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating-point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program
- Analog circuits to provide clocks and interface to the real world which is analog in nature
- I/O s to connect to external components like LEDs, memories, monitors etc.

2.2 Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

2.2.1 Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.
- The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

2.2.2 RISC characteristics

- **Simple instruction set:**

  In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- **Same length instructions.**

  Each instruction is the same length, so that it may be fetched in a single operation.

- **1machine-cycleinstructions.**

  Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

2.2.3 Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.

- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.
- CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

2.3 Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

2.3.1 Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The **Harvard architecture** is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

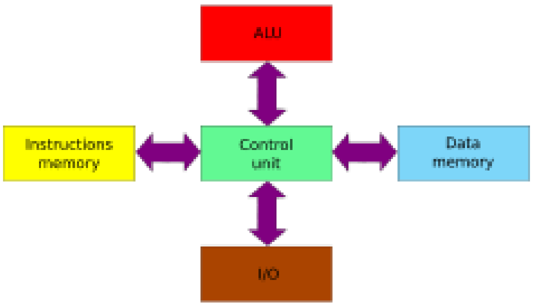

Figure 2.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.3.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

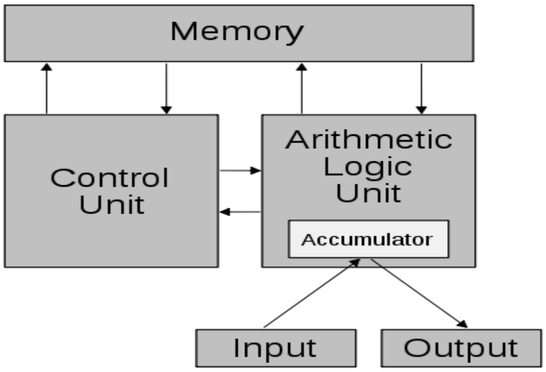

Figure 3.4 Schematic of the Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing,

operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER 4

POWER SUPPLY

4.1 Block Diagram

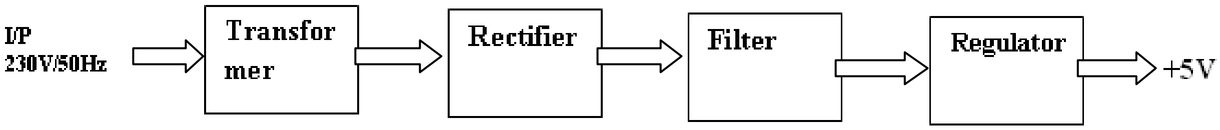

Figure 3.1 Power Supply

4.2 Circuit Diagram

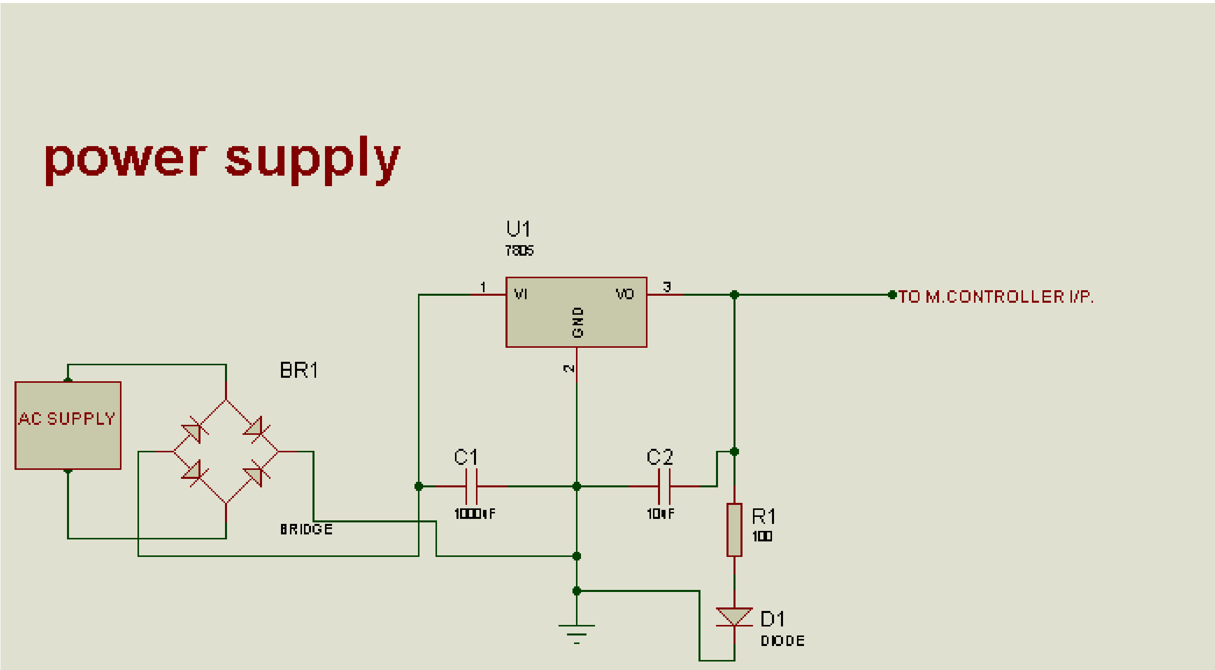

Fig : 4.2 Circuit Diagram

Description

4.2.1 Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

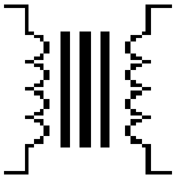

Figure4.2.1: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

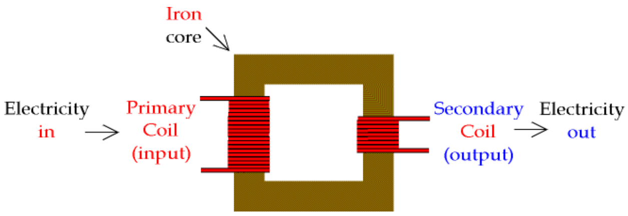

Figure 4.2.2 Transformer

Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

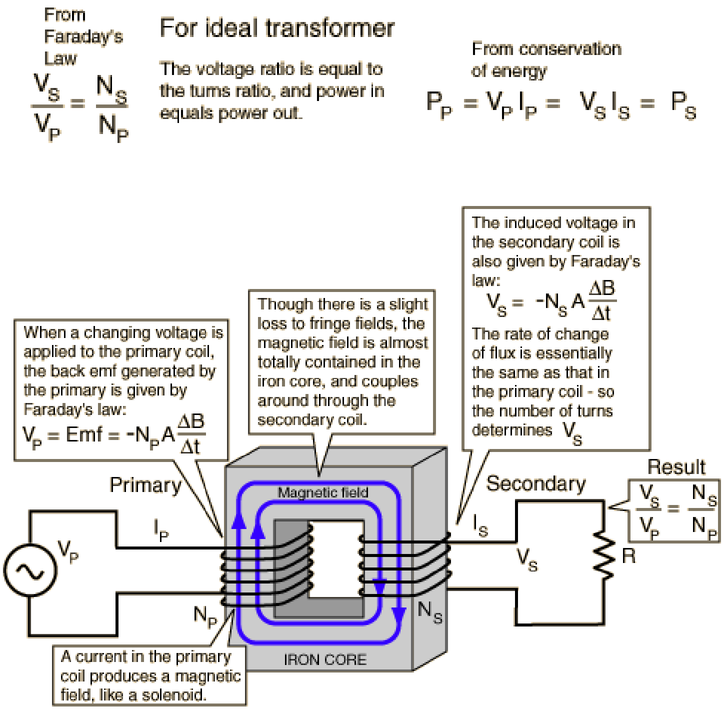

Figure 4.2.3: Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

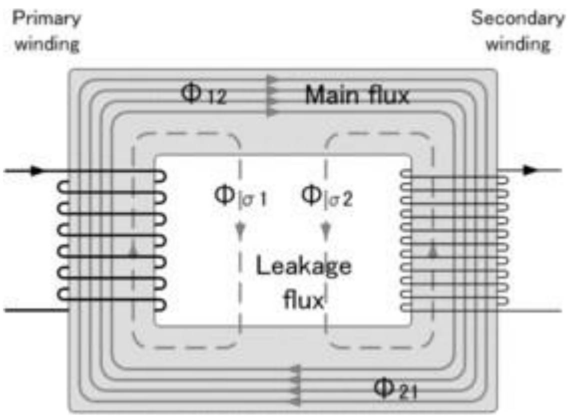

Figure 4.2.4: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

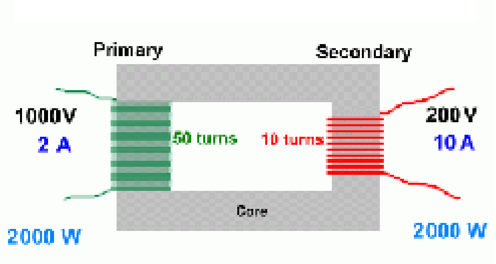
- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.



Figur4.2.5: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

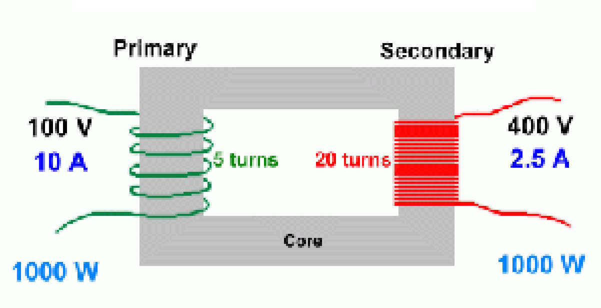


Figure4.2.6: Step-Up Transformer

Applications

Generally these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

4.2.2 Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

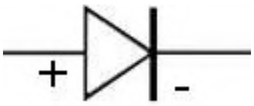

Figure 4.3 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.2.3 Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-wave Rectifier

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure .

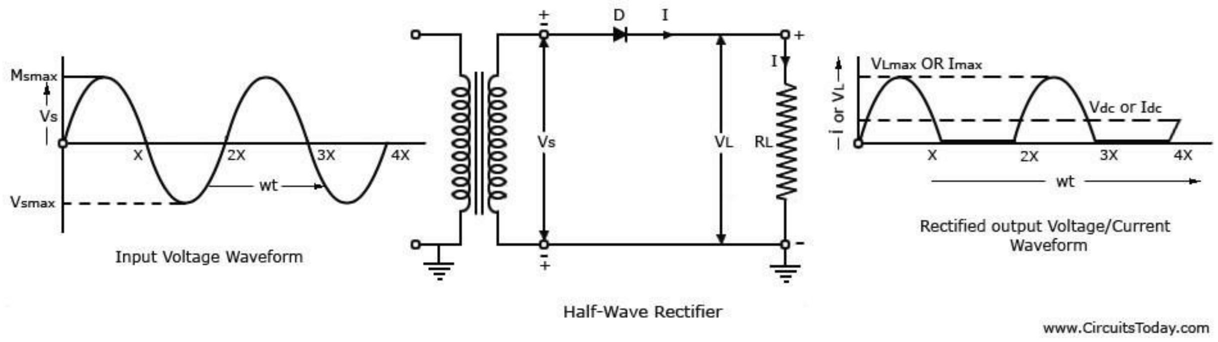

Figure 4.4 Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

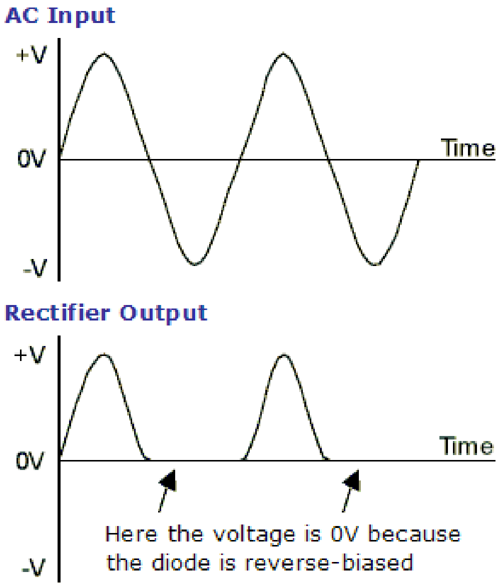

Figure 4.5 Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 4.

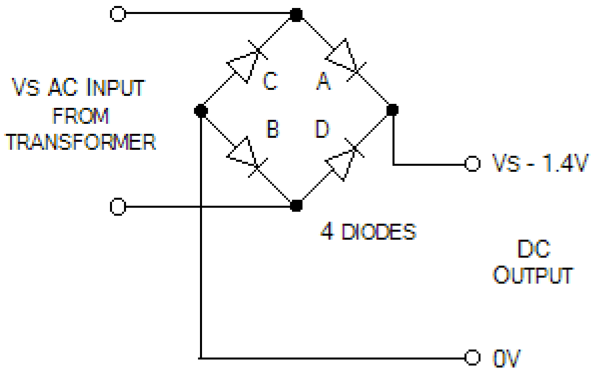

Figure 4.5.1: Full-Wave Rectifier

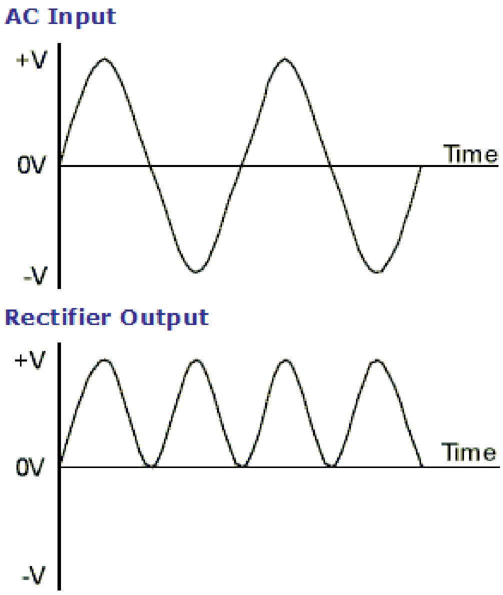

Figure : 4.5.2 : Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

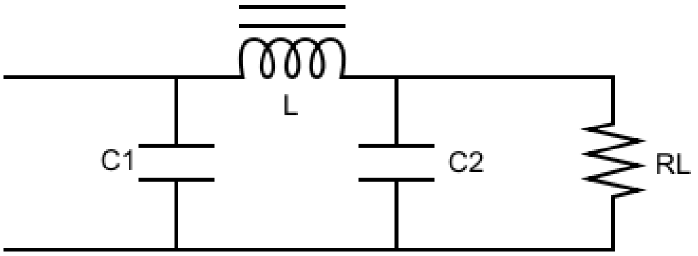

Figure 4.5.3: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L

2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

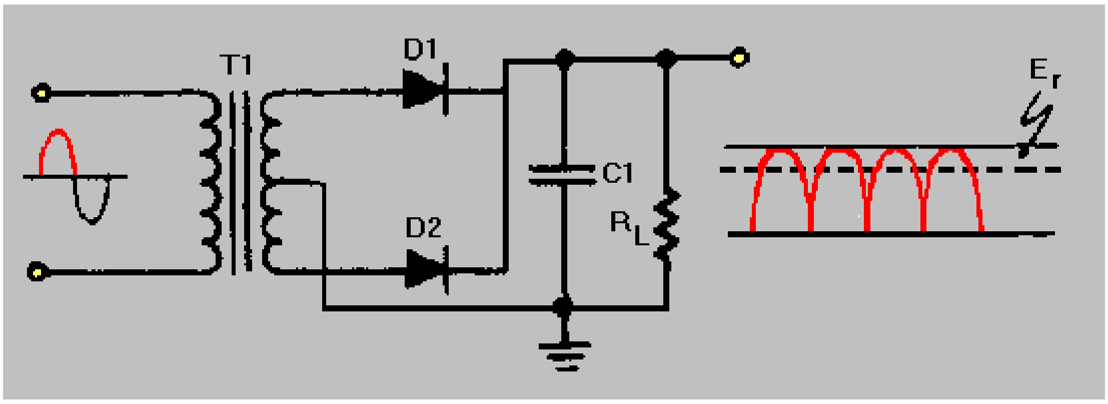

Figure 4.5.4: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

4.2.4 Voltage Regulator:

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

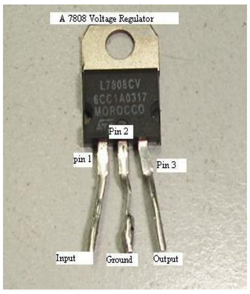

Figure 4.6 Regulator

CHAPTER 5
SOFTWARE

5.1 Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

5.1.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.
ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.
The designer can also develop 2D drawings for the product.

5.1.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

5.2 Starting New Design

Step 1: Open ISIS software and select New design in File menu

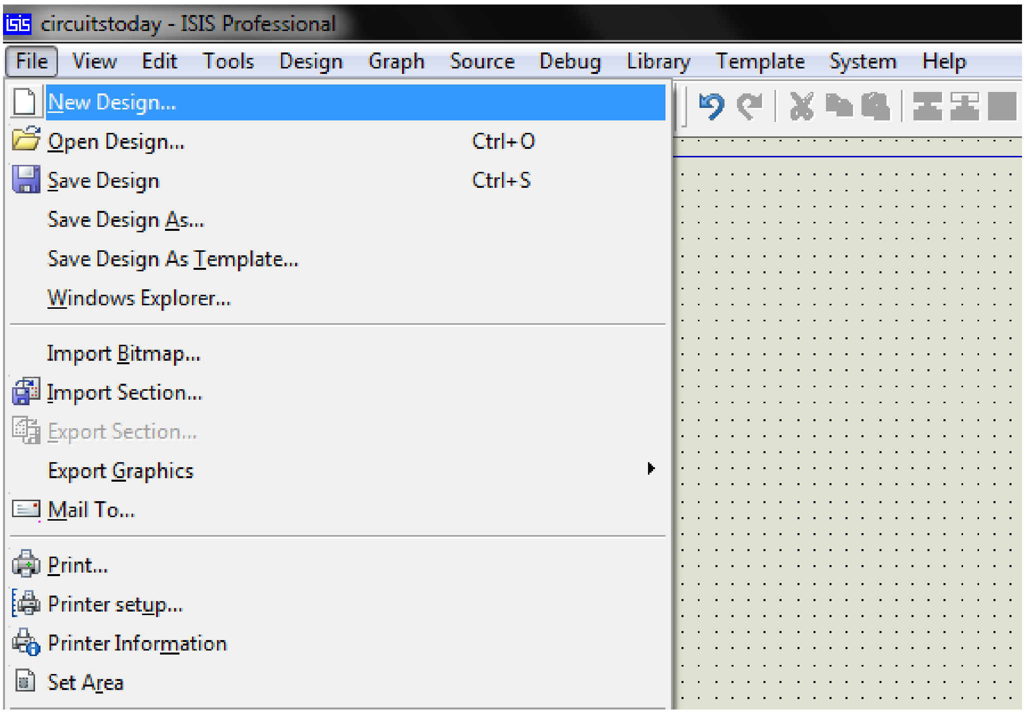

Figure 5.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

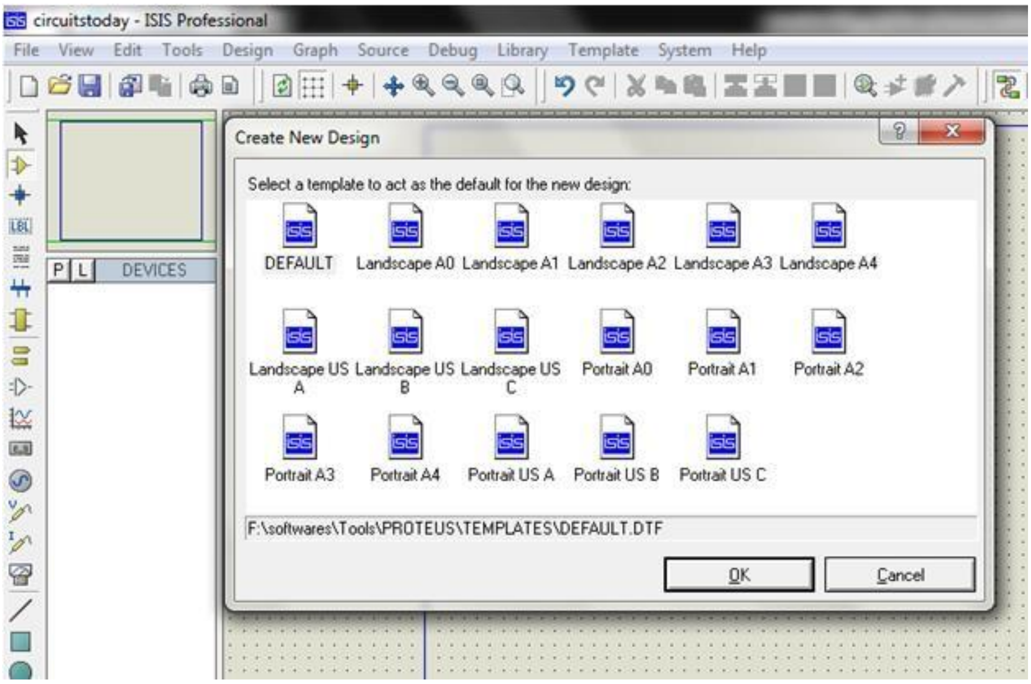

Figure 5.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

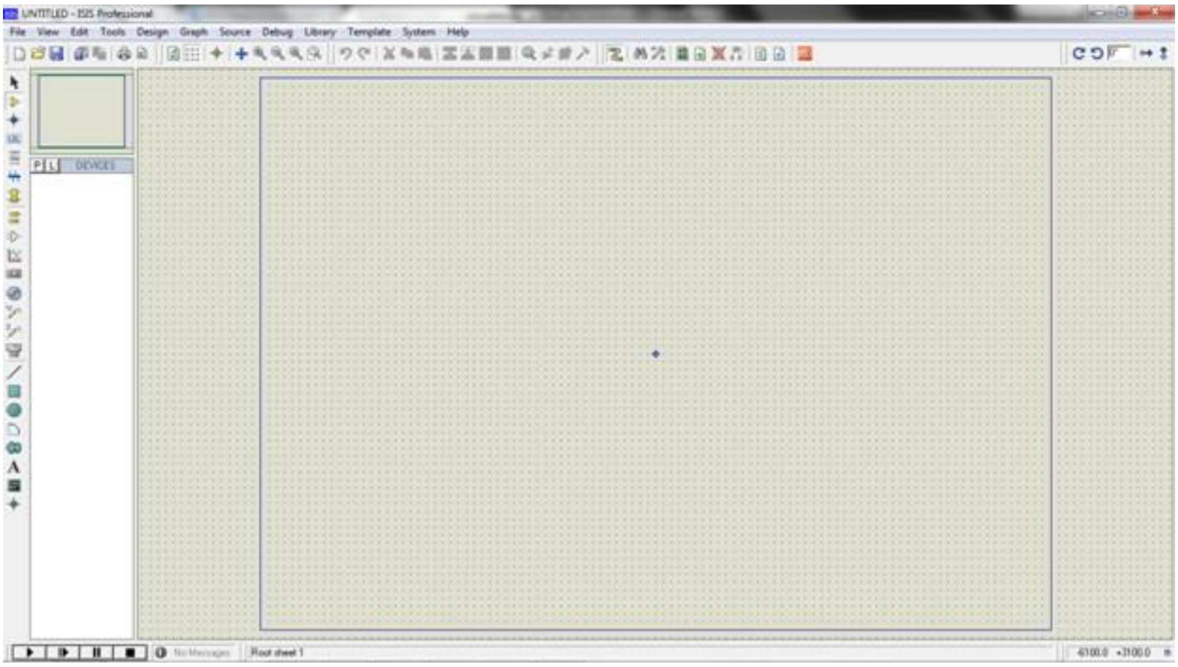

Figure 5.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

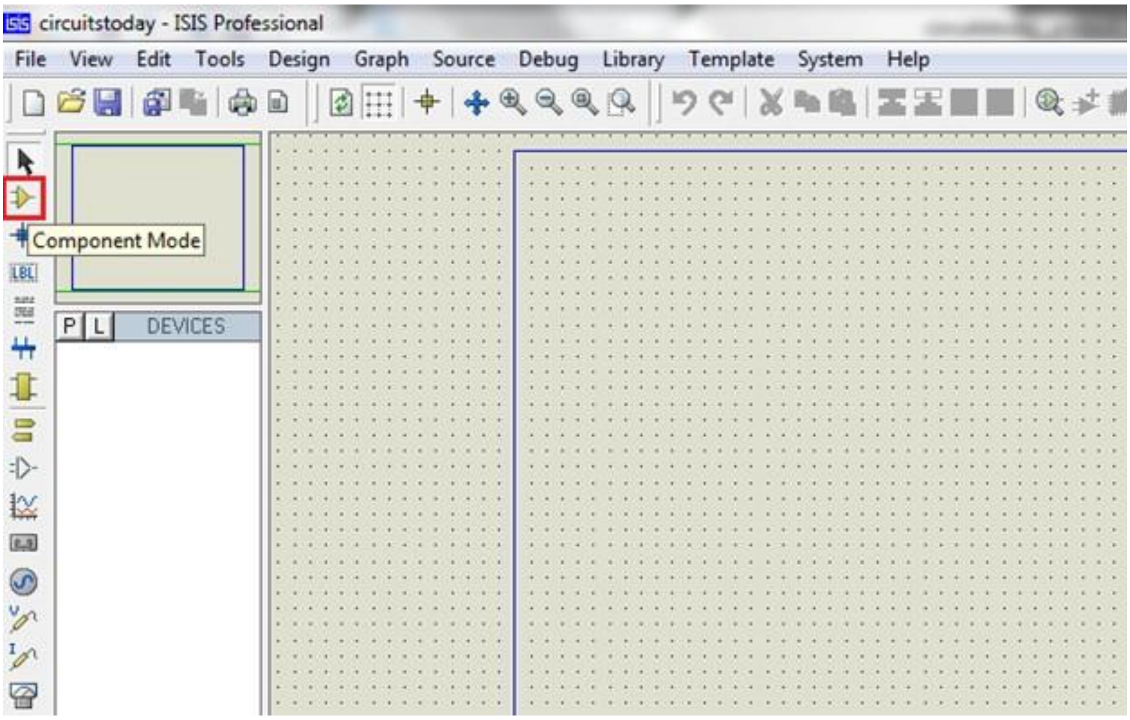

Figure 5.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

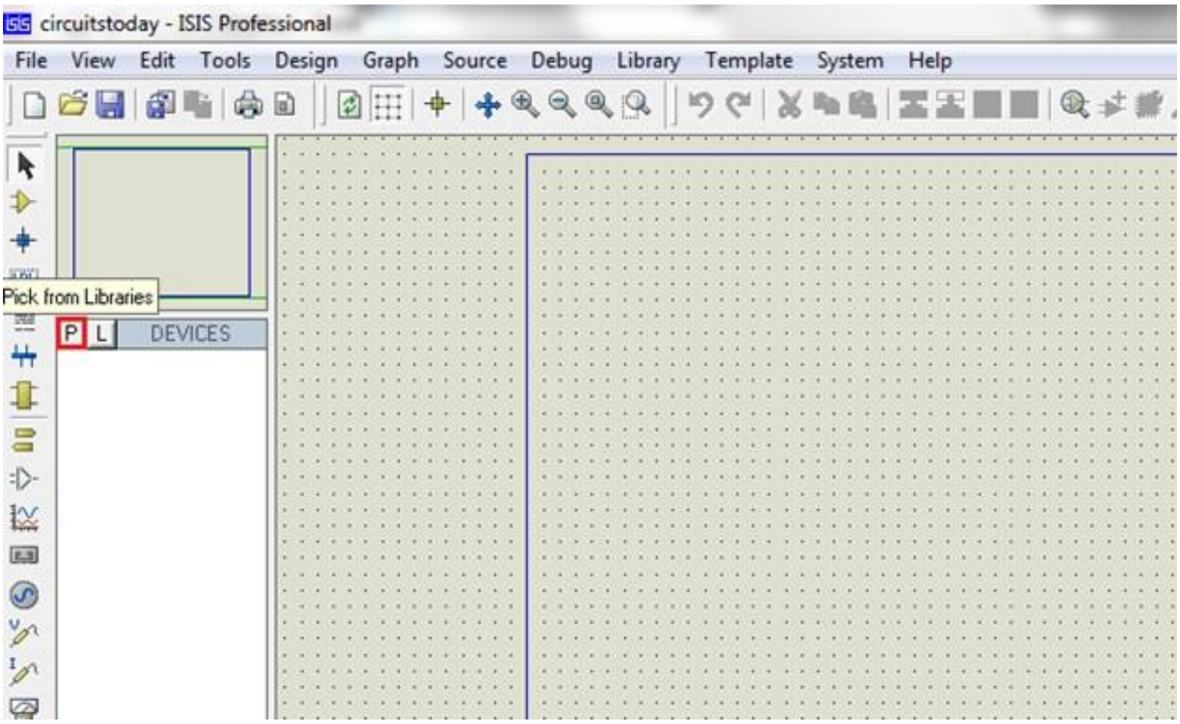

Figure 5.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

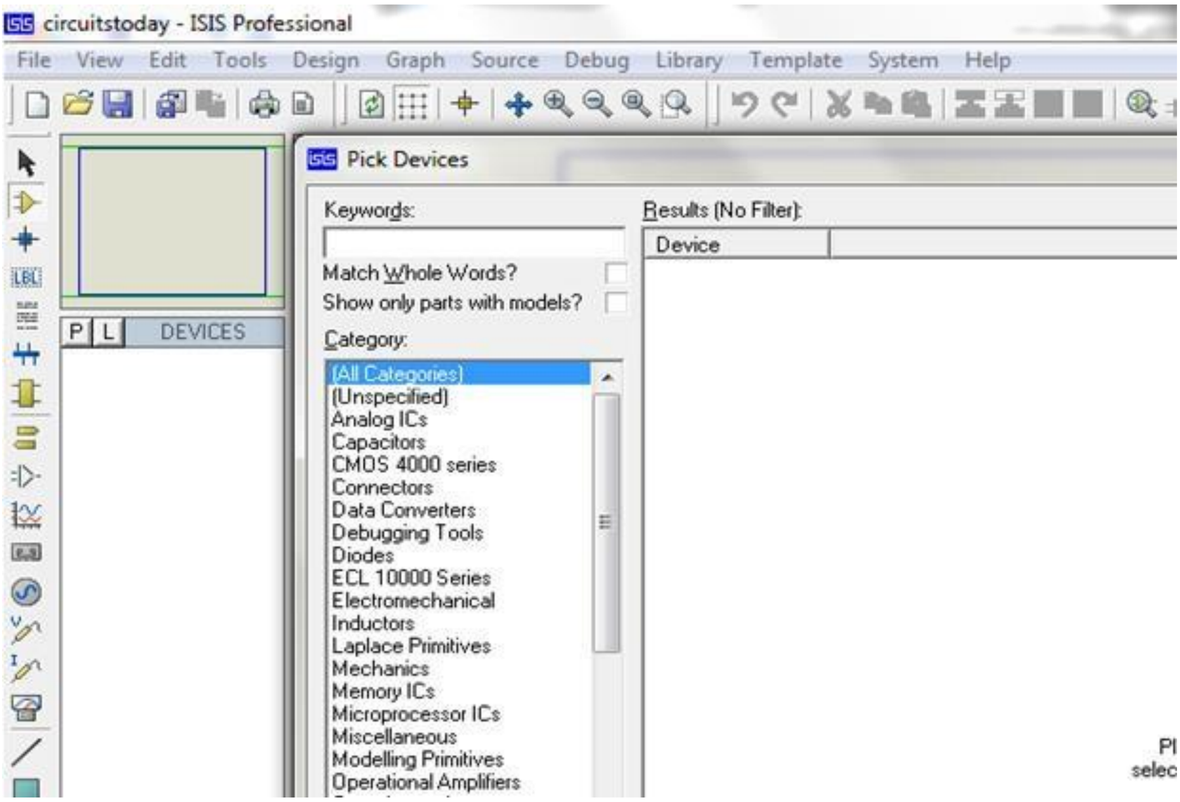

Figure 5.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

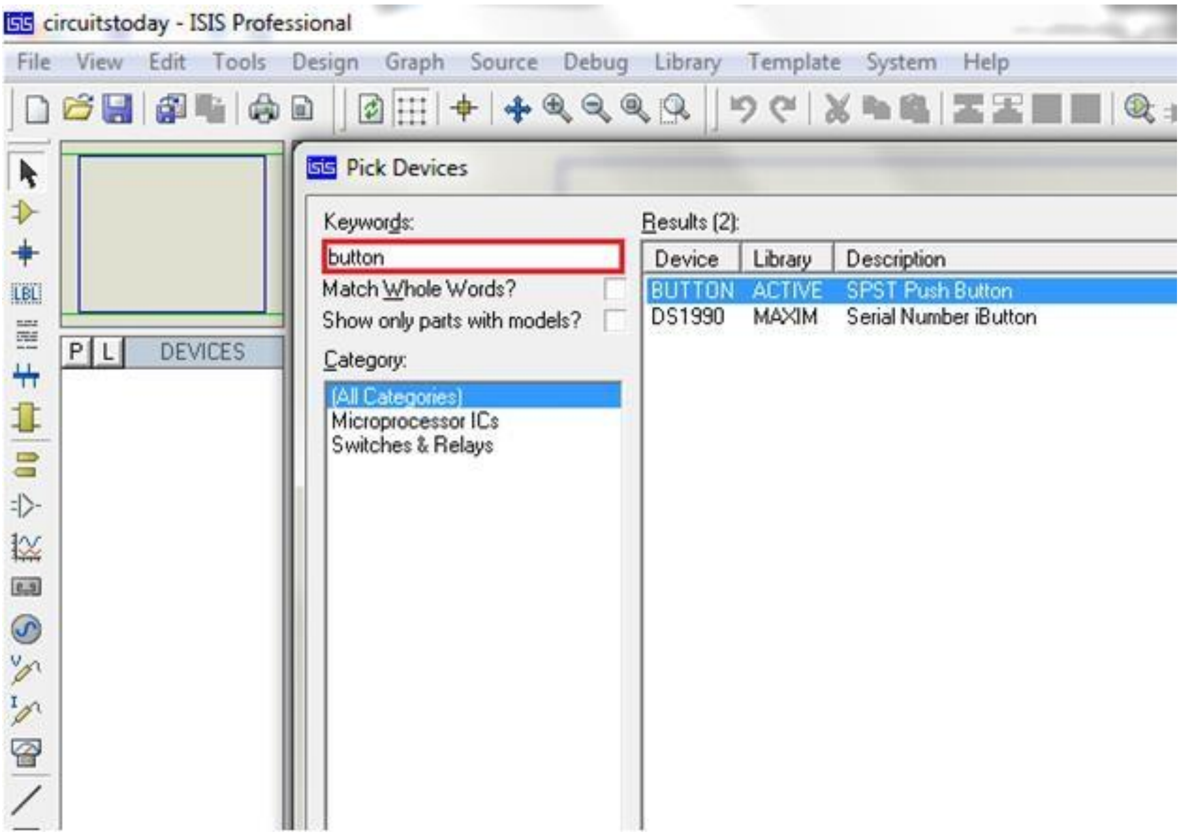

Figure 5.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

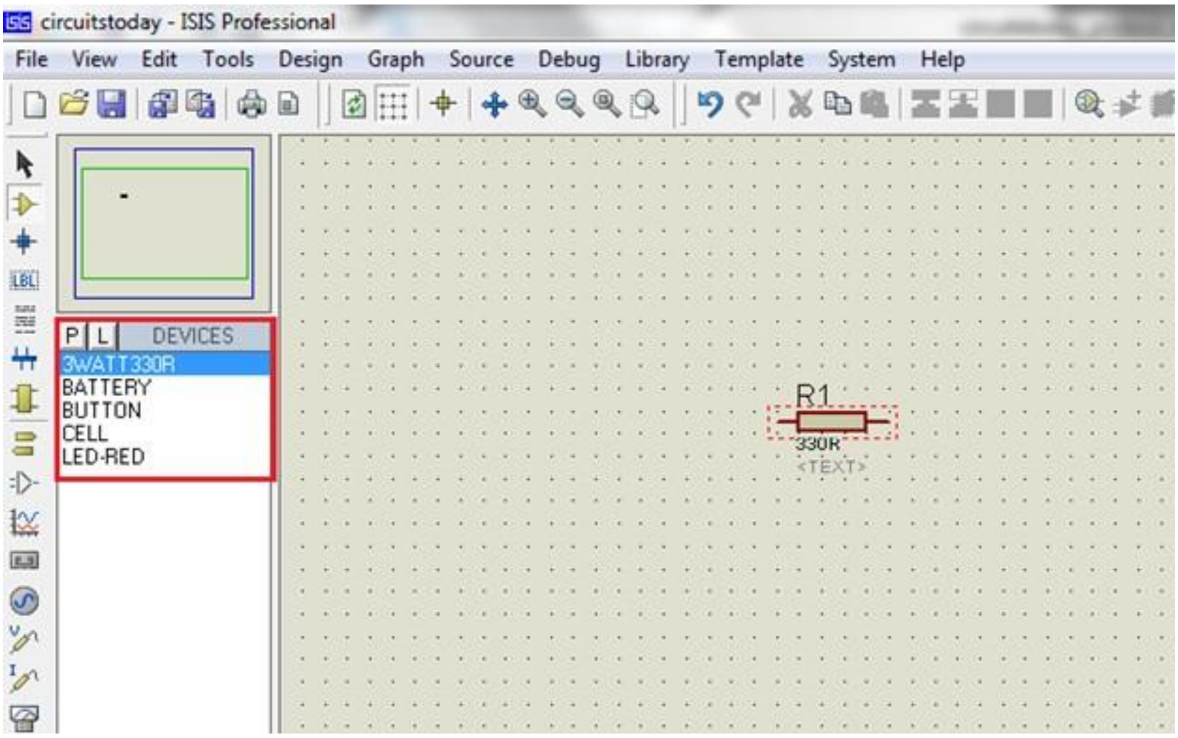

Figure 5.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

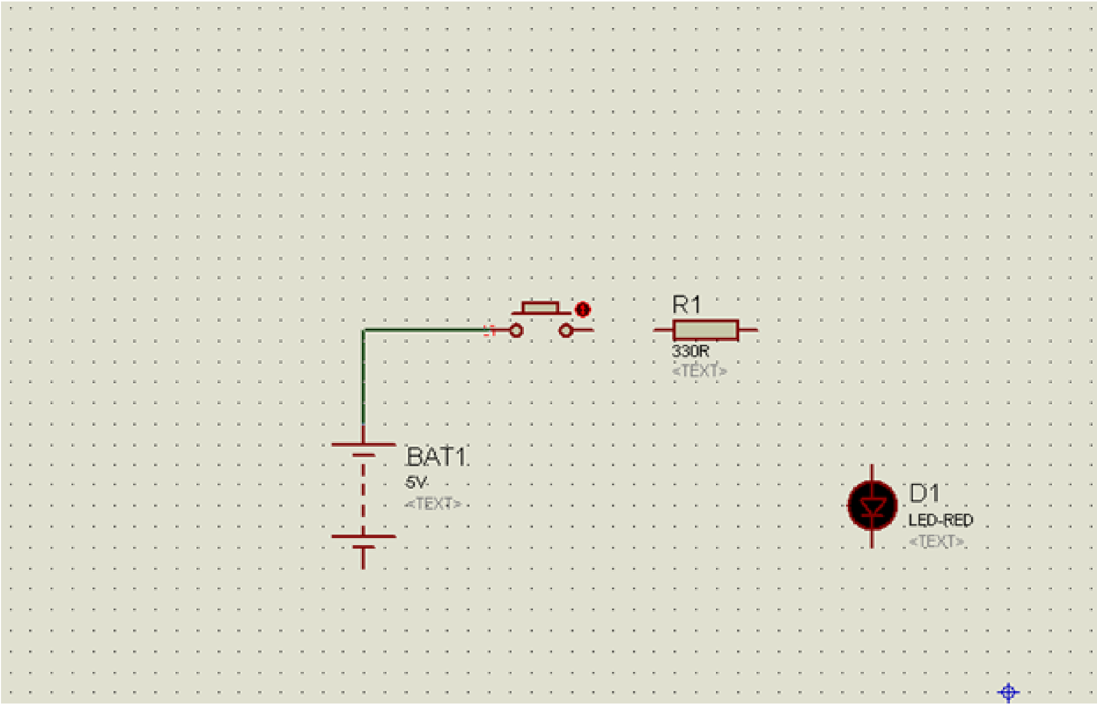

Figure 5.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

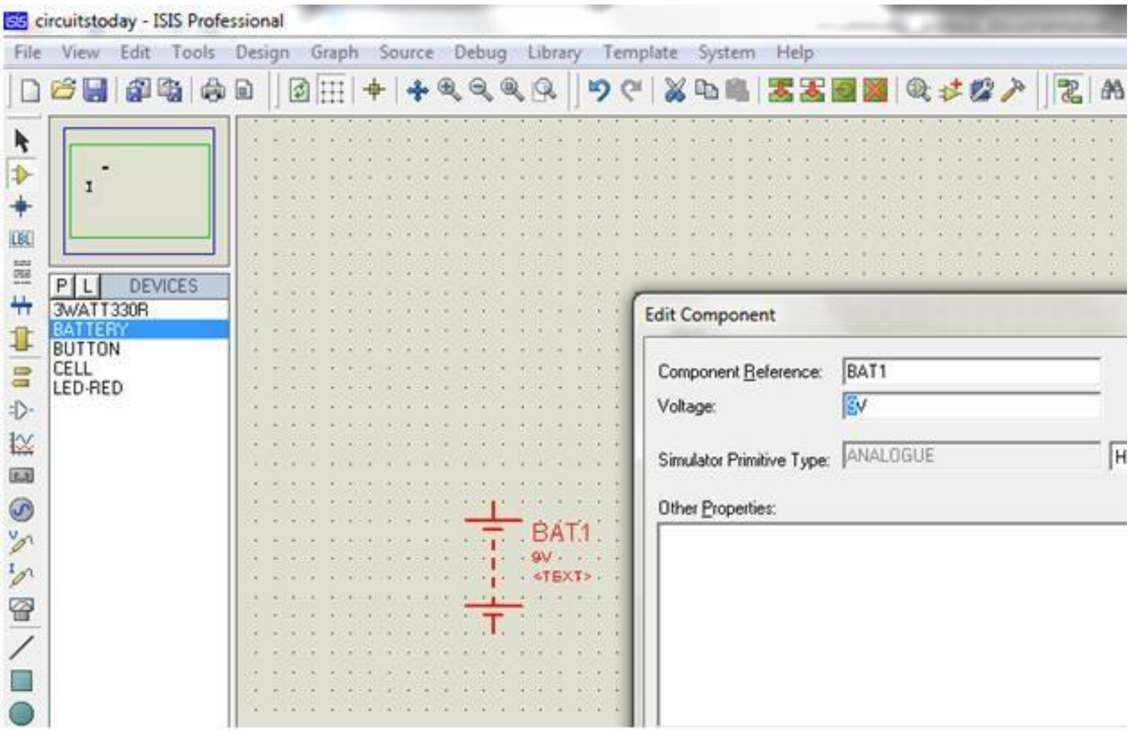

Figure 5.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

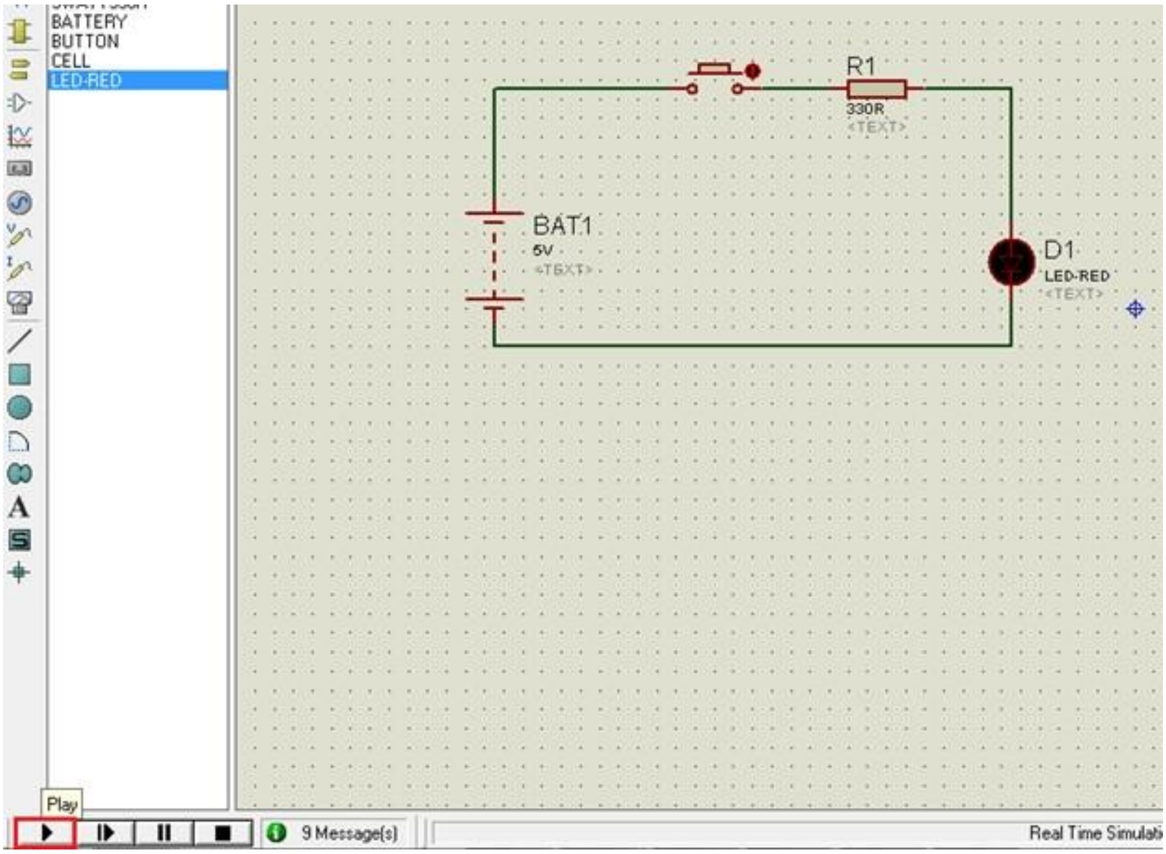

Figure 5.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

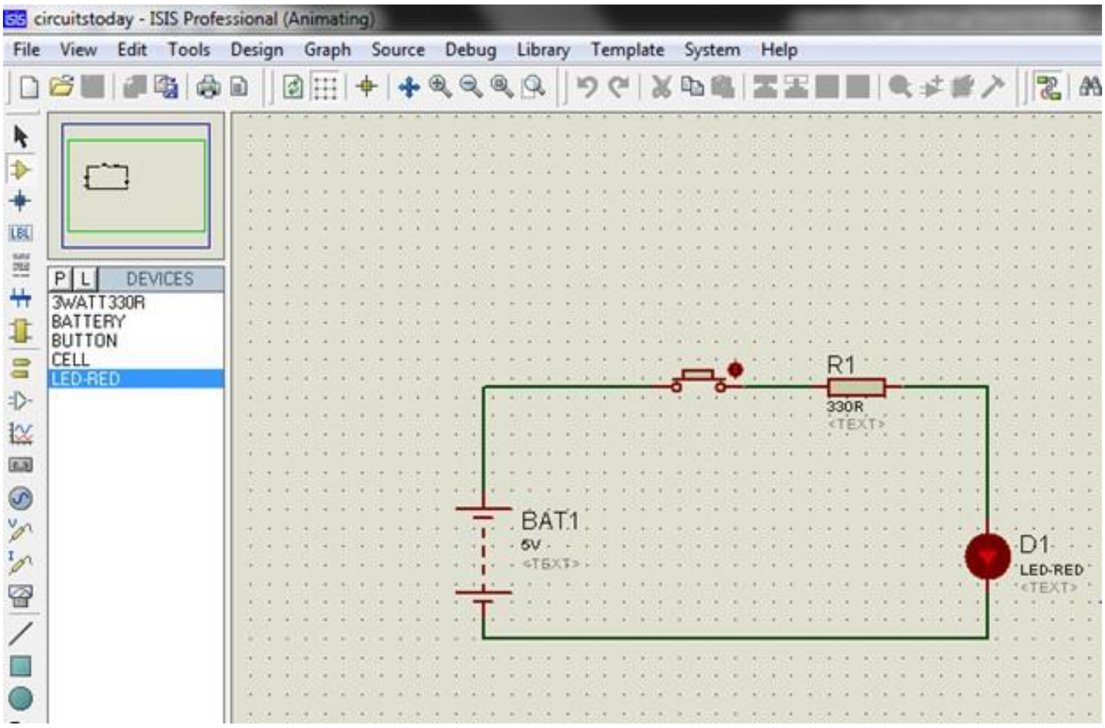

Figure 5.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

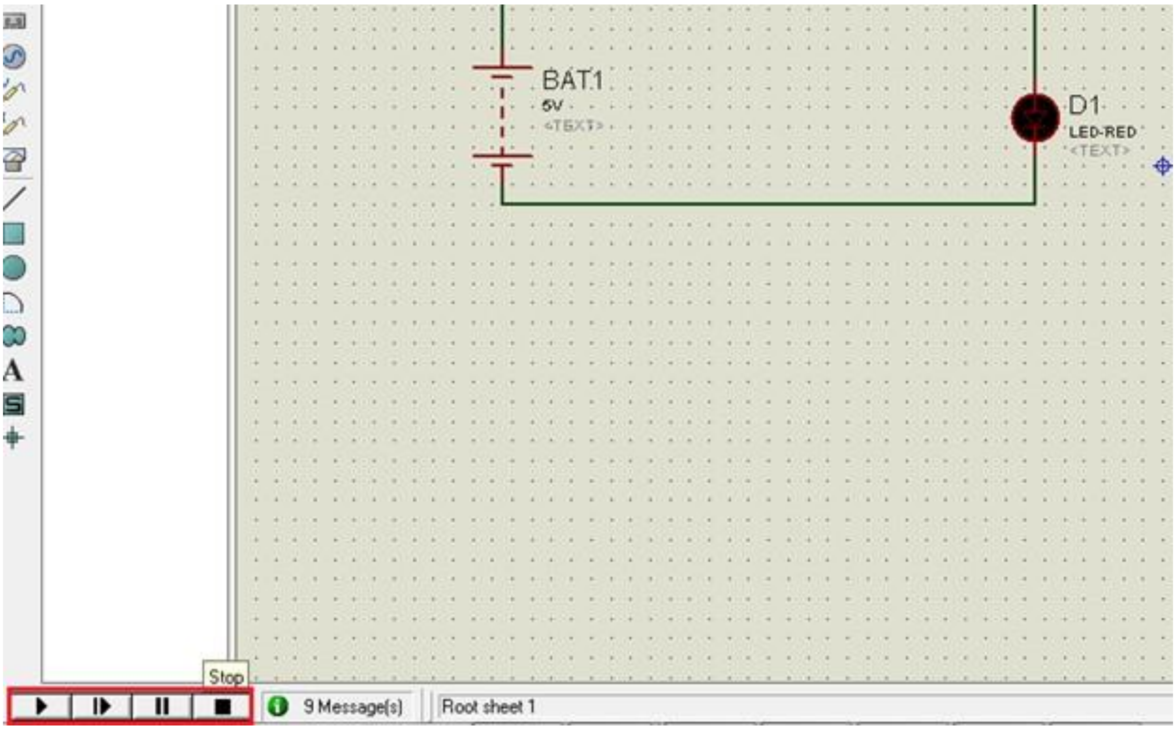

Figure 5.13 Simulation Step-Pause-Stop Buttons

5.3 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]
Repository	github.com/Arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux
Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

5.3.1 Installation

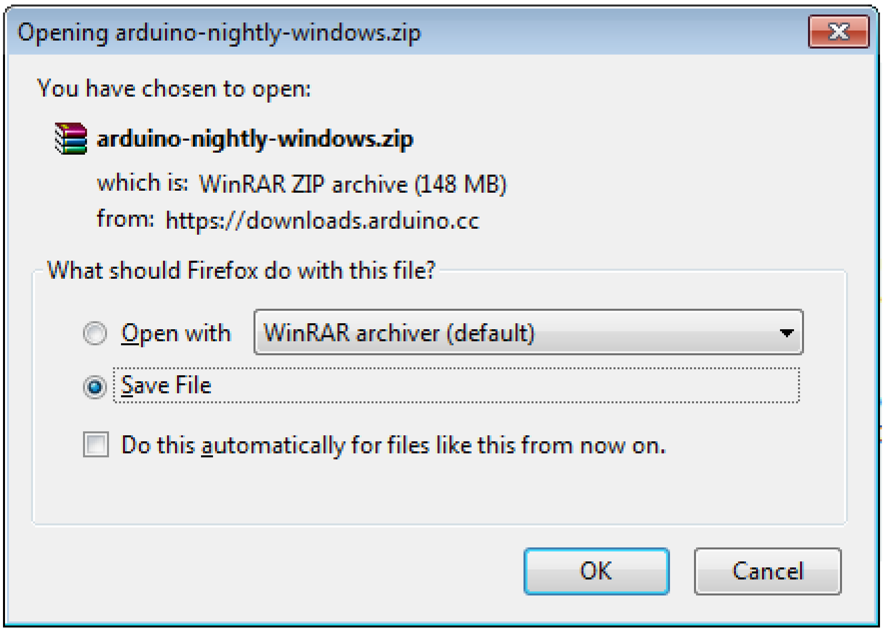
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



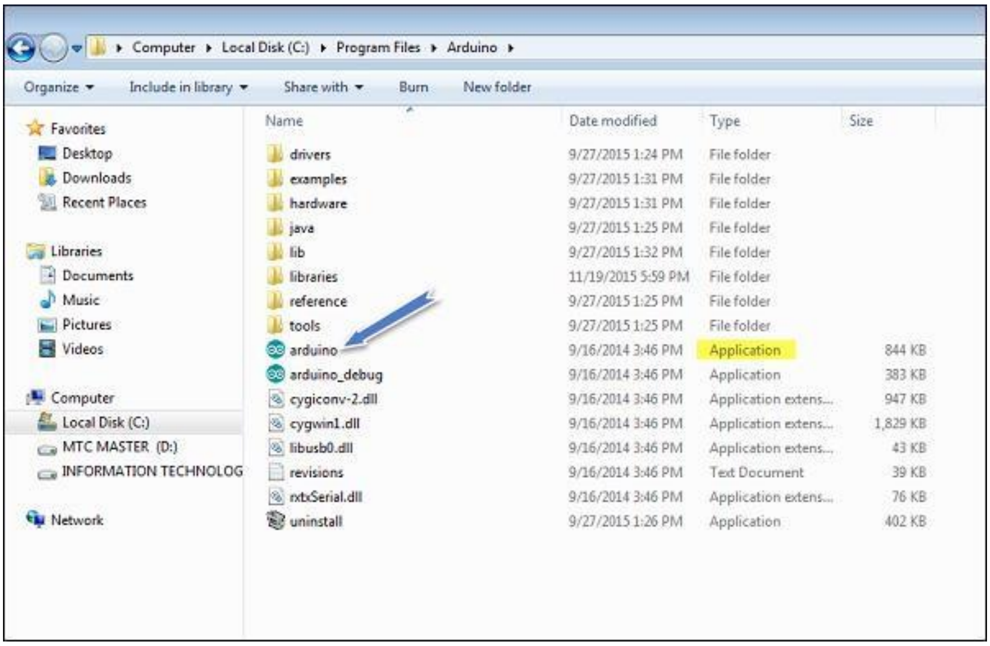
Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

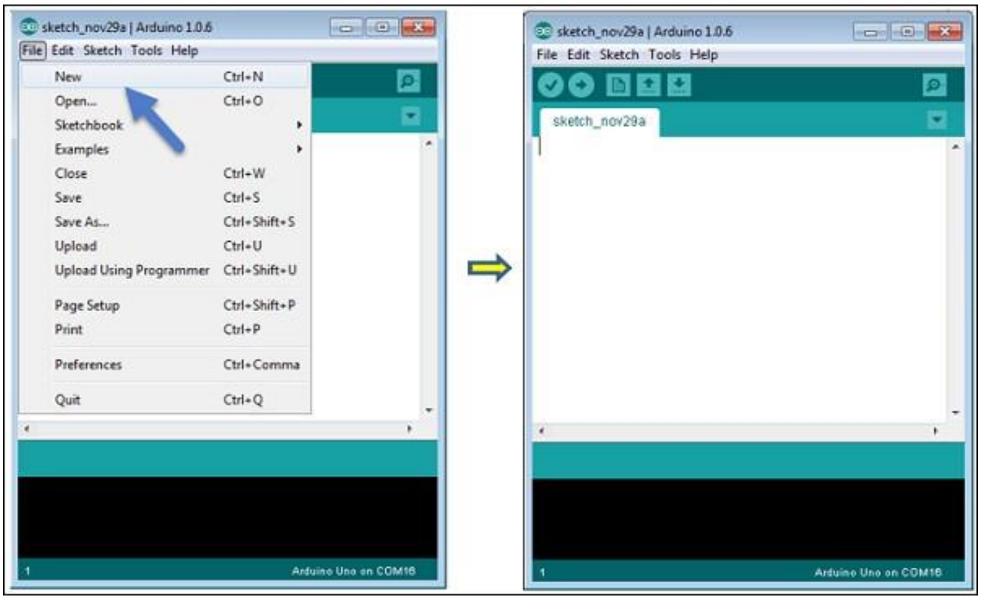


Step 5 − Open your first project.

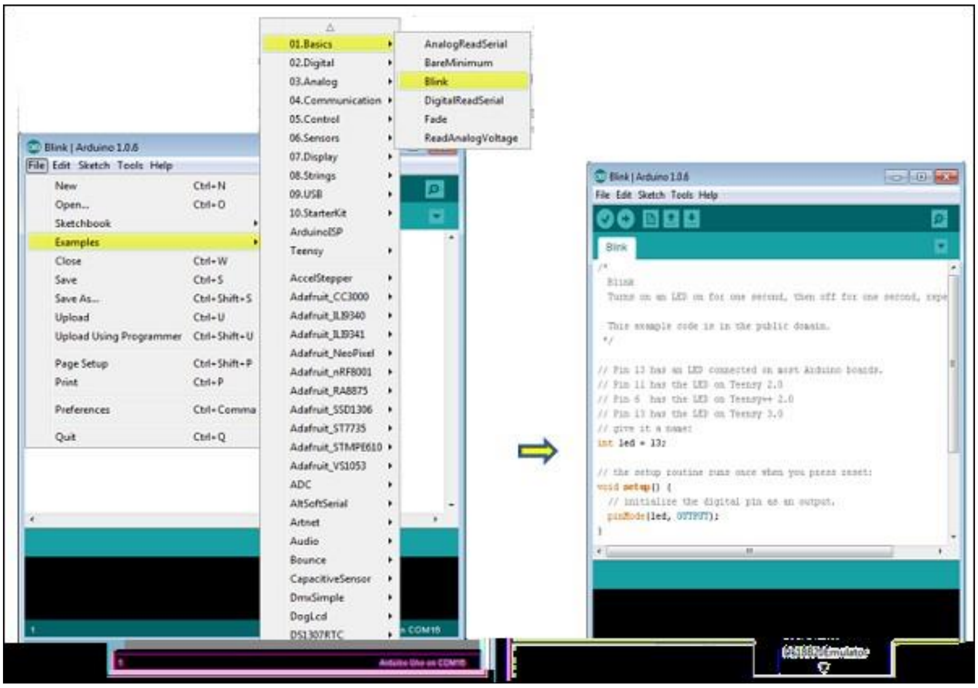
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

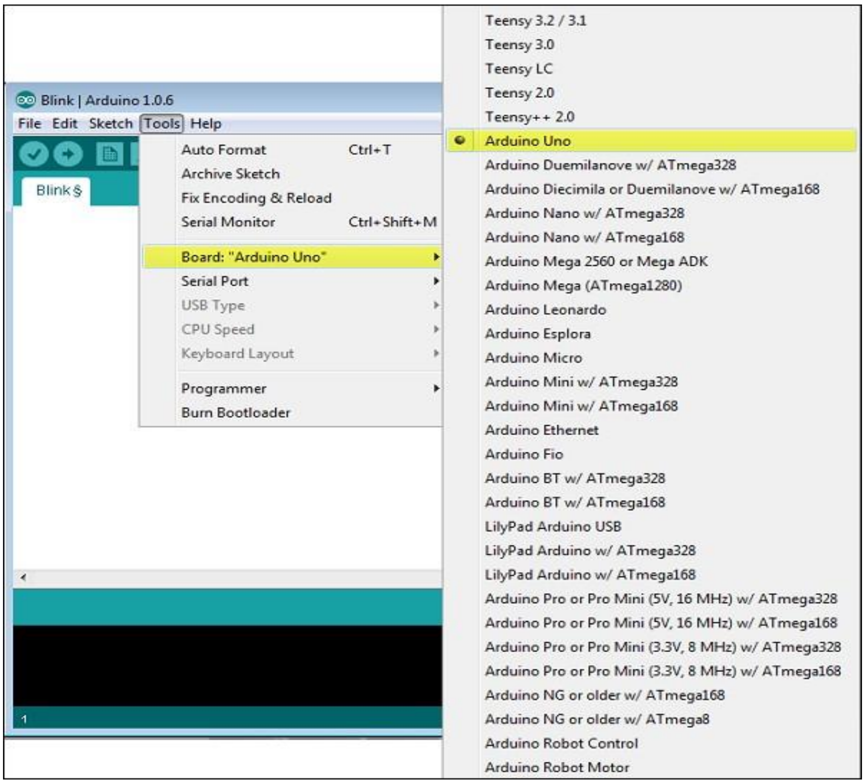


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

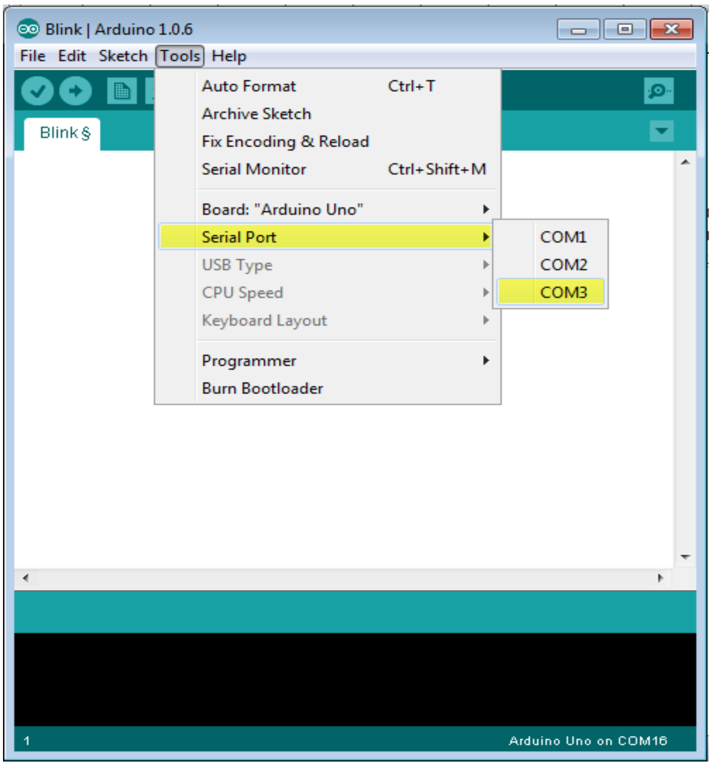
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

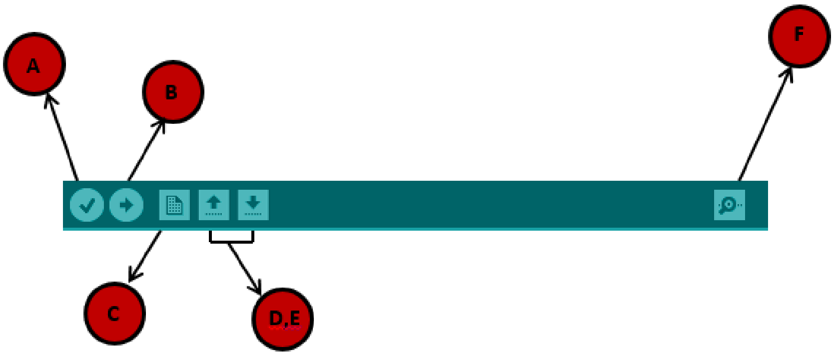
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

CHAPTER 6
HARDWARE

6.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

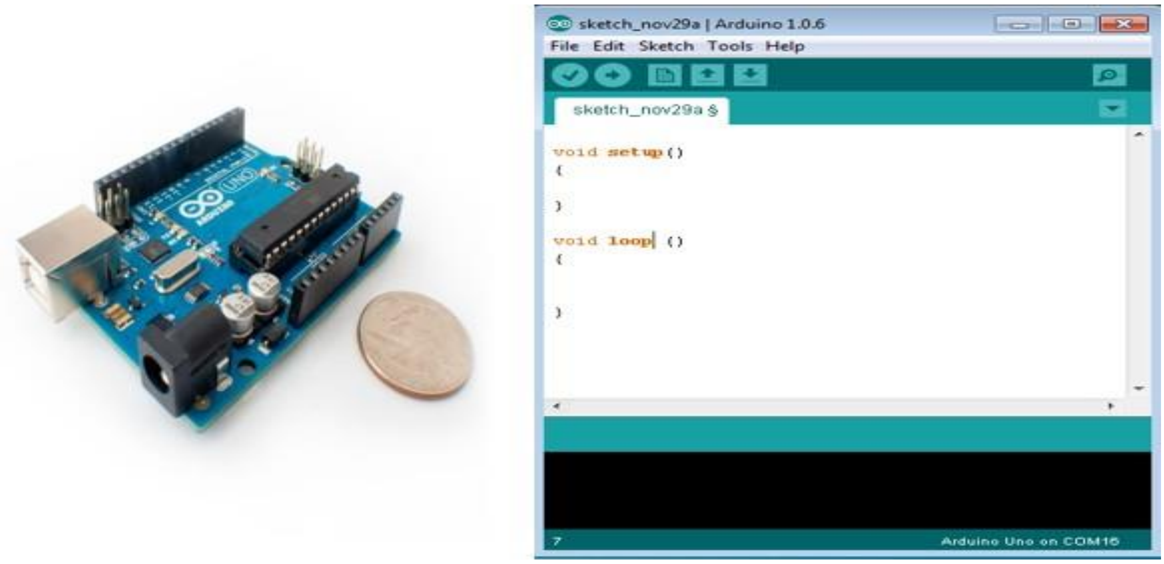


Figure : 6.1 Arduino Board and Dashboard

6.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Table 6.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

6.3 Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

6.4 Arduino boards based on AT91SAM3X8E microcontroller

Board Name	Operating Volt	Clock Speed	Digital I/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

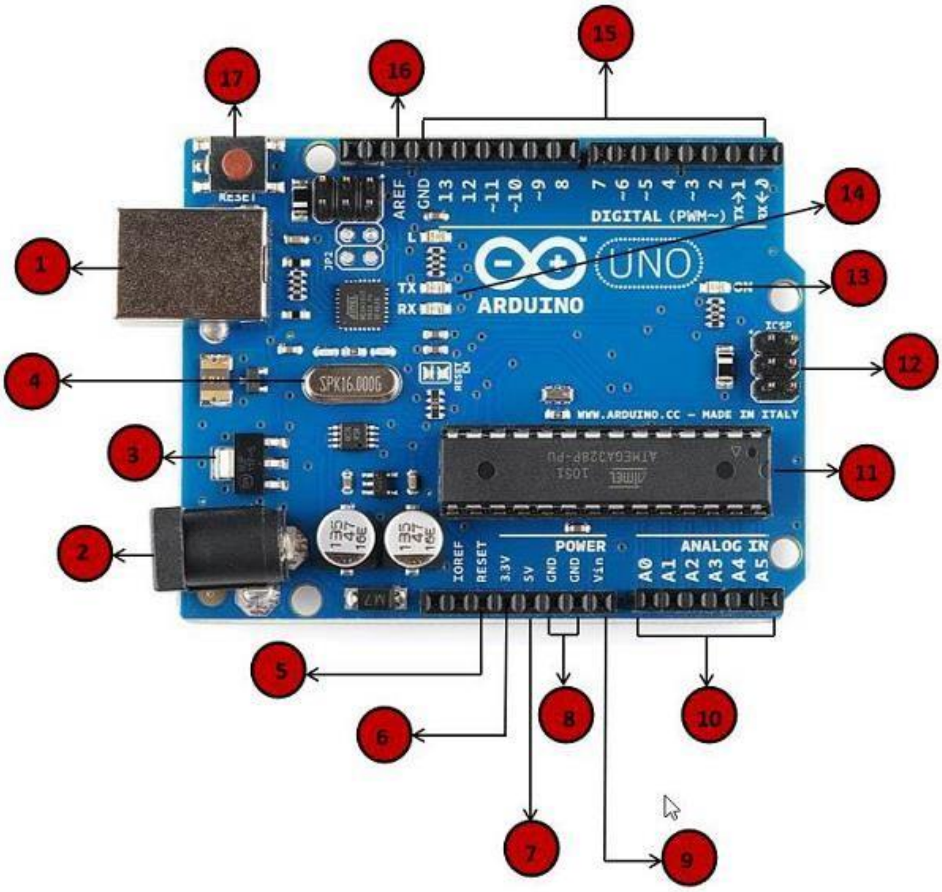

Fig : 6.2 Aurdino Parts

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC.

	For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

6.2 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

5.2.1 Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

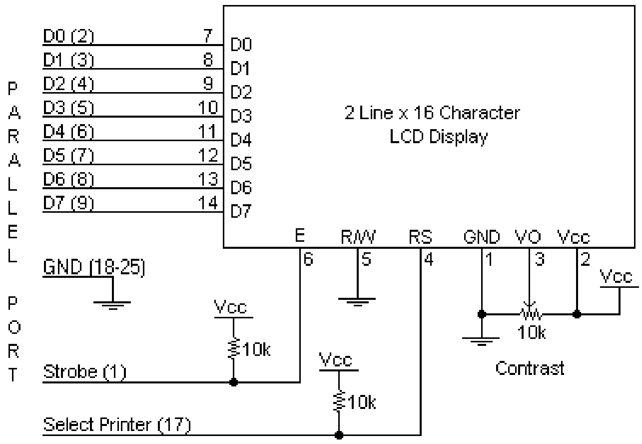

Fig : 6.3 : LCD Panel

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)

6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure 6.4 Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

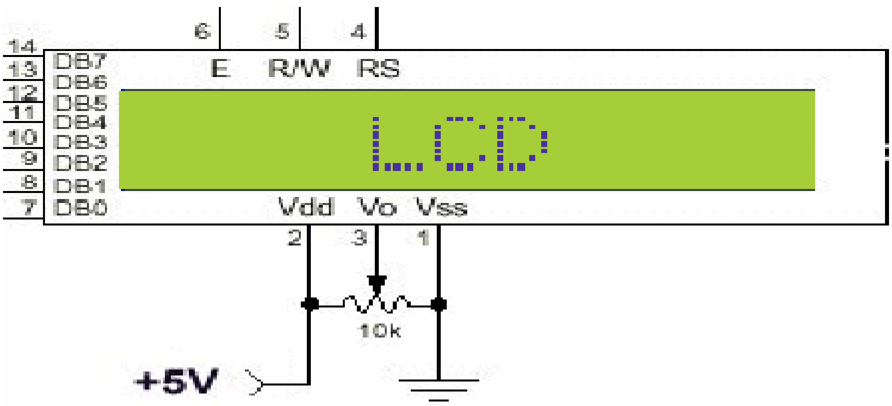

Figure 6.5 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 6.6 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

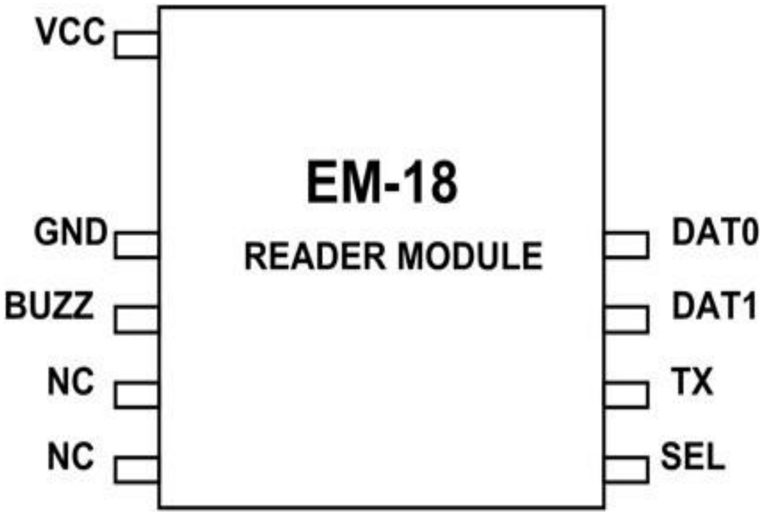
LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 6.5 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

EM18 - RFID Reader Module



EM18 - RFID Reader Module EM18 - RFID Reader Pinout

EM18 RFID Reader is a module which reads the ID information stored in **RFID TAGS**. This ID information is unique for every TAG which cannot be copied.

EM-18 Pin Configuration

EM-18 is a nine-pin device. Among nine pins, 2 pins are not connected, so we basically have to consider seven terminals.

Pin Number	**Description**
VCC	Should be connected to positive of power source.
GND	Should be connected to ground.
BUZZ	Should be connected to BUZZER
NC	No Connection
NC	No Connection
SEL	SEL=1 then o/p =RS232 SEL=0then o/p=WEIGAND
TX	DATA is given out through TX of RS232
DATA1	WEIGAND interface DATA HIGH pin
DATA0	WEIGAND interface DATA LOW pin

EM-18 Features and Specifications

- Operating voltage of EM-18: +4.5V to +5.5V
- Current consumption:50mA
- Can operate on LOW power
- Operating temperature: 0ºC to +80ºC
- Operating frequency:125KHz
- Communication parameter:9600bps
- Reading distance: 10cm, depending on TAG
- Integrated Antenna

How to Use EM-18 RFID Module

EM-18 is used like any other sensor module. First, we choose the mode of communication between MODULE and CONTROLLER. Next, we will program the controller to receive data from module to display. Next power the system. When a tag is brought near the MODULE it reads the ID and sends the information to controller. The controller receives the information and performs action programmed by us.

Step1: Establishing a mode of communication. EM-18 can provide ouput through two communication interfaces. One is RS232 and another is WEIGAND. The form of communication is selected by SEL pin. If SEL pin is selected HIGH then form of communication is RS232 and if SEL pin is pulled LOW then form of communication is WEIGAND. Usually, the RS232 is selected because it's popular so SEL pin is pulled HIGH.

Step2: The output of MODULE bit rate is 9600bps (bit per second). The controller should be programmed to receive information from MODULE at this rate. If bit rate of controller mismatches, then the system will not work correctly.

Now let us consider a **simple EM-18 circuit diagram**,

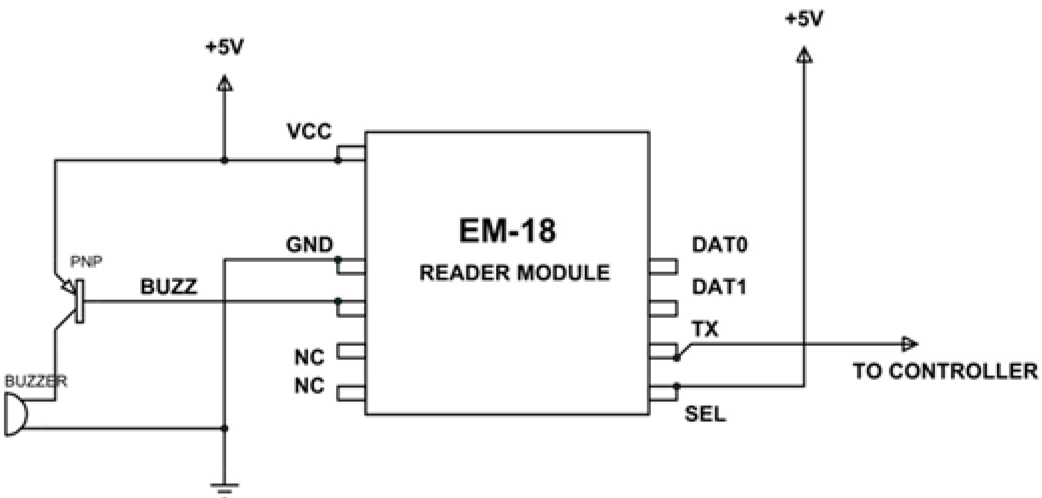


Fig: 6.9: Circuit diagram of EM18 reader module

In the circuit BUZZER is not compulsory. When a TAG is read the BUZZER turns ON. As given in circuit, TX is given to CONTROLLER which is to receive DATA.

Consider a TAG is brought near the MODULE. The MODULE reads the ID and sends the information to controller in 12 ASCII CHARACTERS. In them, 10CHARACTERS represent the TAG ID and 2 CHARACTERS are XOR of previous 10 CHARACTERS.

So, DATA sent = 10ASCII DATA (tag no.) + 2ASCII DATA (XOR result)

Once the Information is sent, the MODULES stop sending DATA. This serial DATA received by the controller though RX pin contains TAG information which is ready for processing. We can program the controller to save the DATA or process it to provide response immediately.

Applications

- Robotics
- Security systems
- Medical tags
- Computer Peripherals
- Package Identification
- Theft protection systems
- Data authorization
- Unique Identity
- Body implants

RFID Tag

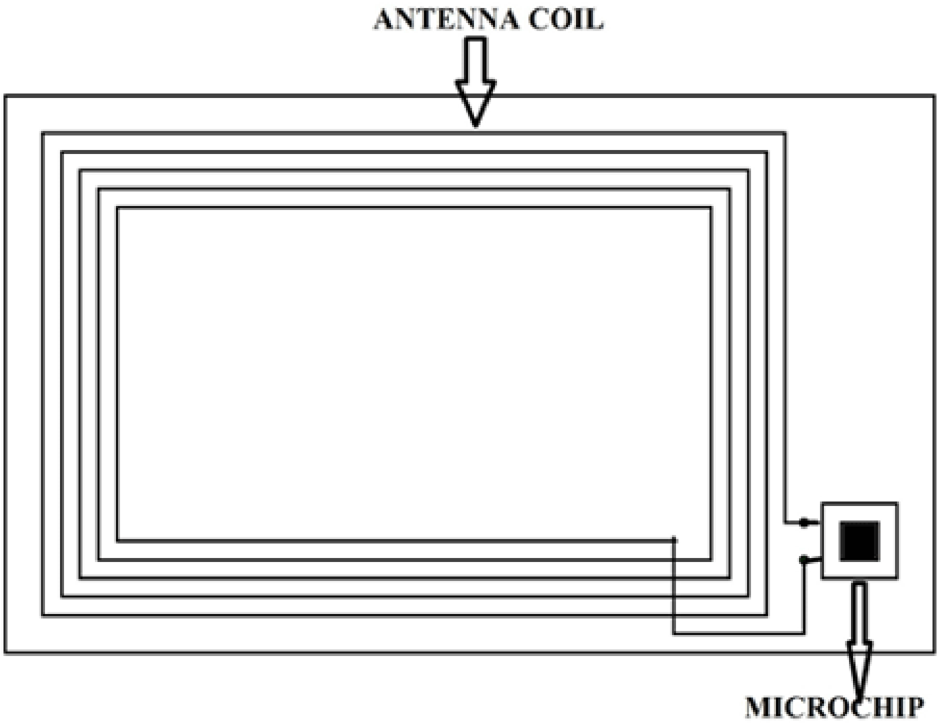

Fig:6.10: RFID Tag

RFID Tag

RFID TAGS are mainly divided in to two **types** - PASSIVE RFID TAGS and ACTIVE RFID TAGS. PASSIVE RFID TAGS are the TAGS with no internal power source. And ACTIVE RFID TAGS are TAGS with their own power source. We will discuss each of them briefly below.

PASSIVE RFID TAGS

In **PASSIVE RFID Tags** we have generally two main components. One is ANTENNA COIL and another is MICROCHIP. As you can see in the above image, there is no BATTERY or any other ACTIVE POWER here.

Working:

With no power source the usually TAG stays ideal. The whole process starts with RFID transmitter. The transmitter generates the electromagnetic radiation through its antenna. When tag gets in range of transmitter, the TAG ANTENNA COIL gets energized through ELECTROMAGNETIC INDUCTION. This energy acts as power source for the MICROCHIP in TAG. This MICROCHIP uses this energy to provide a feedback response for the transmitter. The transmitter receives this response which is unique to the tag and provides the corresponding output.

All PASSIVE TAGS works the same way.

Where PASSIVE TAGS Are Used?

There are various reasons to use PASSIVE TAGS; few are as below:

1. When you want cheaper TAGS. PASSIVE TAGS are very cheap to buy and are available massively. So replacing them will be easy.

2. When TAGS need to be slim. PASSIVE TAGS are very slim. There are available as thin as paper and as small as finger nail.

3. When you need high life. PASSIVE tags do not need any power, so once they are installed in a system they can work for a lifetime.

Types of PASSIVE TAGS

PASSIVE tags are further divided based on operating frequency. As it is known the functioning distance depends on operating frequency, with higher frequency the TAG will be recognized from farther distance. Also with higher frequency the system will be influenced less by other systems.

Low frequency: 125 KHz works up to 10cm.Usually used for ID cards.

Medium frequency: 13.5MHz works up to 1meters. Usually used at airport security.

High frequency: 900MHz works up to 30 meters. Usually used for File tracking and package tracking

How to Use PASSIVE RFID TAGS

Using PASSIVE tags is quite easy. All you need to do is bring the tag near the TRANSMITTERS effective range and all the work will be done by MICROCHIPS present in TRANSMITTER and TAG.

Applications of Passive RFID Tags

- Security systems
- Medical tags
- Package Identification
- Theft protection systems
- Data authorization
- Unique Identity
- Body implants

ACTIVE RFID TAGS

ACTIVE TAGS are tags with power sources fixed internally. So for them there will be usually three main components. One is ANTENNA COIL, second is MICROCHIP and third is power source. For ACTIVE TAGS power sources are usually non rechargeable batteries. These systems usually last for 2-5 years. Once the battery is dead it needs to be replaced for the tag to work again.

There is no standard model for ACTIVE RFID TAGS, they are normally custom made and are available in different sizes and shapes. Appropriate one is chosen depending on requirement. The active tags with battery source on the body are usually bulky.

Where to use ACTIVE TAGS

1. For higher range - Active tags can respond to distances many times higher than passive tags. So ACTIVE TAGS are used for high distance detection.

2. For accurate position - Active tags provide more accurate position then passive ones. Hence active systems are used when direction of system is important.

Types of ACTIVE RFID TAGS

ACTIVE TAGS are divided in to two types based on their working. They are namely Transponders and Beacons.

Transponders: These Tags acts as passive tags and sit ideal under any instance until they receive a signal from transmitter. Once they receive the signal the Transponders turns active and sends a response to the transmitter. By staying ideal these tags save power and usually last longer. These types of tags are used qat tool booths

Beacons: These tags will be ON 24x7 and will be providing specific information for every few seconds. These tags usually have a working range of few hundred meters. These types of tags are used in oil rigs and other industries.

Although they have differences both PASSIVE and ACTIVE TAGS are popular for their own reasons. And both are used extensively.

How to Use ACTIVE RFID TAGS

Using ACTIVE tags is similar to PASSIVE ones. All you need to do is bring the tag near the TRANSMITTER effective range and all the work is will be done by MICROCHIPS present in TRANSMITTER and TAG.

Applications of Active RFID Tags

- Security systems
- Toll booths
- Industrial systems
- Data authorization
- System locating

CHAPTER 7
CONCLUSION AND FUTURE ENHANCEMENT

Conclusion:

The system is expected to be fully automated, reliable, transparent and convenient. The whole system can also be used in vehicle on highways, their toll payment and in the railway ticketing system with small or no modification. The cards being reusable, they are much more convenient compared to the paper-based ticketing system. The card also can be used to be a universal travel pass card that will allow any transportation on any route. Any unwanted events can be avoided as all the person carrying RFID tickets are monitored every time they travel. Also, the possibilities of reducing traffic jams, chaos in the bus stoppage that we usually experienced in Dhaka city are immense.

// ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator,**

Dr. A. Anand Kumar, Professor for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come. We sincerely thank our **Class Project Coordinator, Mrs. A. Soumya,** Department of ECE and our project **Internal guide, Ms. R. Alekya, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr.R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. S KEERTHI SAI

3. K SHINY

ABSTRACT

The rapid increase in the number of subscribers demanding high data rate applications have resulted in maturing of the 4G networks. The next generation (5G) wireless communication networks (WCN's) are required to fulfill these rising requirements, hence aiming to utilize the available spectrum as efficiently as possible. Also this is leading to a detrimental effect on the ecological balance of the environment as the transmit power levels increase correspondingly in the atmosphere.

Hence power optimization has also become a major concern. Various technologies such as massive MIMO, spectrum sharing, device to device communication (D2D), GREEN communication have gained significant attention in aiding spectrum utilization along with power optimization. This proposal intends to optimize power using spectrum sharing for the NGN's to achieve high spectrum and energy efficiency for both the primary and secondary system without introduction of a secondary transmitter. The performance of the proposed model has been compared with the opportunistic spectrum sharing model and other popular resource allocation algorithms. The results obtained confirm the efficiency of the proposed scheme for increased performance of the system

CHAPTER-1

INTRODUCTION

1.0 Overview of the Project

A cellular network or mobile network is a communication network where the link to and from end nodes is wireless. The network is distributed over land areas called "cells", each served by at least one fixed-location transceiver (typically three cell sites or base transceiver stations). These base stations provide the cell with the network coverage which can be used for transmission of voice, data, and other types of content. A cell typically uses a different set of frequencies from neighboring cells, to avoid interference and provide guaranteed service quality within each cell. When joined together, these cells provide radio coverage over a wide geographic area. This enables numerous portable transceivers (e.g., mobile phones, tablets and laptops equipped with mobile broadband modems, pagers, etc.) to communicate with each other and with fixed transceivers and telephones anywhere in the network, via base stations, even if some of the transceivers are moving through more than one cell during transmission.

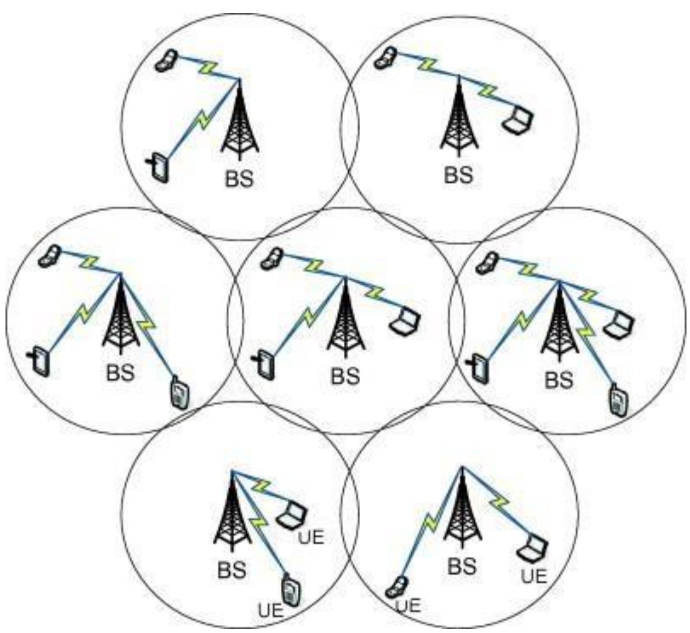

Fig:1.1 Cellular network

5G Cellular Network

5G (from "5th Generation") is the latest generation of cellular mobile communication. It succeeds the 4G (LTE-A, WiMax), 3G (UMTS, LTE) and 2G (GSM) systems. 5G performance targets high data rate, reduced latency, energy saving, cost reduction, higher system capacity, and massive device connectivity. The first phase of 5G specifications in Release-15 will be completed by April 2019 to accommodate the early commercial deployment. The second phase in Release-16 is due to be completed by April 2020 for submission to the International Telecommunication Union (ITU) as a candidate of IMT-2020 technology.

The ITU IMT-2020 specification demands speeds up to 20 Gbit/s, achievable with wide channel bandwidths and massive MIMO. 3rd Generation Partnership Project (3GPP) is going to submit 5G NR (New Radio) as its 5G communication standard proposal. 5G NR can include lower frequencies (FR1), below 6 GHz, and higher frequencies (FR2), above 24 GHz and into the millimeter waves range. However, the speed and latency in early deployments, using 5G NR software on 4G hardware (non-standalone), are only slightly better than new 4G systems, estimated at 15% to 50% better. Simulation of standalone eMBB deployments showed improved throughput between 2.5×, in the FR1 range, and nearly 20×, in the FR2 range.

Like the earlier generation 2G, 3G, and 4G mobile networks, 5G networks are digital cellular networks, in which the service area covered by providers is divided into a mosaic of small geographical areas called *cells*. Analog signals representing sounds and images are digitized in the phone, converted by an analog to digital converter and transmitted as a stream of bits. All the 5G wireless devices in a cell communicate by radio waves with a local antenna array and low power automated transceiver (transmitter and receiver) in the cell, over frequency channels assigned by the transceiver from a common pool of frequencies, which are reused in geographically separated cells. The local antennas are connected with the telephone network and the Internet by a high bandwidth optical fiber or wireless backhaul connection. Like existing cellphones, when a user crosses from one cell to another, their mobile device is automatically “handed off” seamlessly to the antenna in the new cell.

Their major advantage is that 5G networks achieve much higher data rates than previous cellular networks, up to 10 Gbit/s; which is faster than current cable internet, and 100 times faster than the previous cellular technology, 4G LTE. Another advantage is lower network latency (faster response time), below 1 ms (millisecond), compared with 30 - 70 ms for 4G. Because of the higher data rates, 5G networks will serve not just cellphones but are also envisioned as a general home and office networking provider, competing with wired internet providers like cable. Previous cellular networks provided low data rate internet access suitable for cellphones, but a cell tower could not economically provide enough bandwidth to serve as a general internet provider for home computers.

1.1 Objectives of study

5G networks achieve these higher data rates by using higher frequency radio waves, in or near the millimeter wave band from 30 to 300 GHz, whereas previous cellular networks used frequencies in the microwave band between 700 MHz and 3 GHz. A second lower frequency range in the microwave band, below 6 GHz, will be used by some 5G providers, but this will not have the high speeds of the new frequencies. Because of the more plentiful bandwidth at millimeter wave frequencies, 5G networks will use wider frequency channels to communicate with the wireless device, up to 400 MHz compared with 20 MHz in 4G LTE, which can transmit more data (bits) per second. OFDM (orthogonal frequency division multiplexing) modulation is used, in which multiple carrier waves are transmitted in the frequency channel, so multiple bits of information are being transferred simultaneously, in parallel.

Millimeter waves are absorbed by gases in the atmosphere and have shorter range than microwaves, therefore the cells are limited to smaller size; 5G cells will be the size of a city block, as opposed to the cells in previous cellular networks which could be many kilometers across. The waves also have trouble passing through building walls, requiring multiple antennas to cover a cell. Millimeter wave antennas are smaller than the large antennas used in previous cellular networks, only a few inches long, so instead of a cell tower 5G cells will be covered by many antennas mounted on telephone poles and buildings. Another technique used for increasing the data rate is massive MIMO (multiple-input multiple-output). Each cell will have multiple antennas communicating with the wireless device, each over a separate frequency channel, received by multiple antennas in the device, thus multiple bitstreams of data will be transmitted simultaneously, in parallel. In a technique called beamforming the base station computer will continuously calculate the best route for radio waves to reach each wireless device, and will organise multiple antennas to work together as phased arrays to create beams of millimeter waves to reach the device. The smaller, more numerous cells makes 5G network infrastructure more expensive to build per square kilometer of coverage than previous cellular networks. Deployment is currently limited to cities, where there will be enough users per cell to provide an adequate investment return, and there are doubts about whether this technology will ever reach rural areas.

The new 5G wireless devices also have 4G LTE capability, as the new networks use 4G for initially establishing the connection with the cell, as well as in locations where 5G access is not available.

The high data rate and low latency of 5G are envisioned as opening up new applications in the near future. One is practical virtual reality and augmented reality. Another is fast machine-to-machine interaction in the Internet of Things. For example, computers in vehicles on a round continuously communicate with each other,and with the road, by 5G.

Performance Targets

5G systems in line with IMT-2020 specifications are expected to provide enhanced device and network-level capabilities, tightly coupled with intended applications. The following eight parameters are key capabilities for IMT-2020 5G

Capability	Description	5G target	Usage scenario
Peak data rate	Maximum achievable data rate	20 Gbit/s	eMBB
User experienced data rate	Achievable data rate across the coverage area (hotspot cases)	1 Gbit/s	eMBB
User experienced data rate	Achievable data rate across the coverage area	100 Mbit/s	eMBB
Latency	Radio network contribution to packet travel time	1 ms	URLLC
Mobility	Maximum speed for handoff and QoS requirements	500 km/h	eMBB/URLLC
Connection density	Total number of devices per unit area	$10^6/km^2$	MMTC
Energy efficiency	Data sent/received per unit energy consumption (by device or network)	Equal to 4G	eMBB
Spectrum efficiency	Throughput per unit wireless bandwidth and per network cell	3–4x 4G	eMBB
Area traffic capacity	Total traffic across coverage area	1000 (Mbit/s)/m^2	eMBB

Table 1.1 Performance Targets

Note that, for 5G NR, according to 3GPP specification when using spectrum below 6 GHz, the performance would be closer to 4G.

Usage scenario

ITU-R have defined three main types of usage scenario that the capability of 5G is expected to enable. They are Enhanced Mobile Broadband (eMBB), Ultra Reliable Low Latency Communications (URLLC), and Massive Machine Type Communications (mMTC).

Enhanced Mobile Broadband (eMBB)

Enhanced Mobile Broadband (eMBB) refers to the use case of using 5G as an evolution to 4G LTE mobile broadband services with faster connection with higher throughput and more capacity. 5G would need to deliver higher capacity, enhance connectivity, and higher user mobility to match these demands, which would require capabilities in the above table with eMBB mark to deliver.

Ultra Reliable Low Latency Communications (URLLC)

Ultra-Reliable Low-Latency Communications (URLLC) refers to the use case of using 5G in mission-critical applications such as factory automation, where uninterrupted and robust exchange of data is of the utmost importance.

Massive Machine Type Communications (mMTC)

Massive Machine-Type Communications (mMTC) refers to the wide area IoT use cases consisting of large numbers of low-cost devices with high requirements on scalability and increased battery lifetime.

Advantages

Speed

5G promises superior speeds in most conditions to the 4G network. Qualcomm presented a simulation at Mobile World Congress that predicts 490 Mbit/s median speeds for 3.5 GHz 5G Massive MIMO and 1.4 Gbit/s median speed for 28 GHz mmWave. 5G NR speed in sub-6 GHz bands can be slightly higher than the 4G with a similar amount of spectrum and antennas, though some 3GPP 5G networks will be slower than some advanced 4G networks, such as T-Mobile's LTE/LAA network, which achieves 500+ Mbit/s in Manhattan.

The 5G specification allows LAA (License Assisted Access) as well but it has not yet been demonstrated. Adding LAA to an existing 4G configuration can add hundreds of megabits per second to the speed, but this is an extension of 4G, not a new part of the 5G standard.

Low communication latency

Network latency is the time it takes to pass a message from sender to receiver. 5G will have much lower latency than previous cellular networks; below 1 millisecond, compared with 30 - 70 ms for 4G.

New use cases

Features of 5G network, including extreme high bandwidth, ultra low latency, and high density connections, are expected to enable many new use cases that are impossible to be done via older network standards. (See Usage scenario) 5G can also increase the effectiveness of ecommerce vendors' activities.

1.2 Scope of the study

With the massive proliferation in the demand for the mobile wireless communications, smart devices with internet-based applications, the expectation from the from the next generation networks has increased manifolds. Also the next generation networks (NGN) are expected to meet the demands of these rising number of users with improved quality of service. Since we know that we have a limited radio frequency resource to carry out all the wireless and the mobile communications, the main aim of the NGN is to use the available radio resource most efficiently. Also with such humungous rise in the connections and the number of devices there is also a proportional rise in the amount of transmit powers emitted. This has led to a huge rise in the carbon footprint in the ecosystem. Various technologies such as massive MIMO, device-to-device (D2D) communication, spectrum sharing have been suggested to utilize the available spectrum efficiently. Wireless data traffic had been dramatically increasing over the past few ears. None the less, the existing techniques are not satisfying with the users' needs in terms of the emergence of applications for daily routines (e.g., proximity aware services). Therefore, there is a wave of popular interest to seek for new paradigms to deal with this problem. In the coming fifth generation (5G) cellular networks, emerging technologies will lead to both disruptive architectural and component design changes. For instance,in 5G wireless communication systems, diverse researchers study different aspects of millimeter wave transmission, which are plentiful because spectrums have become scarce at microwave frequencies. Massive multiple-input multiple-output, which could increase the system throughput is proposed to utilize a very high number of antennas. We know that 2G–3G–4G cellular networks were built under the design premise of having complete control from the infrastructure side.However, this assumption should be dropped in the 5G systems. The base-station-centric architecture of cellular systems may change, and intelligence at the device side, within different layers of protocol stack, should be exploited, for example, by allowing device-todevice (D2D) connectivity.

Fig1.2 Wireless Communication

Types of Wireless Communication

At present, the usage of mobiles has been increased for different requirements like the internet, talking, multimedia, gaming, photos, video capturing, etc. All these services are available on mobile. Using wireless communication services, we can transfer data, voice, images, videos, and many more.

The different services provided by the wireless communication system is a cellular telephone, Radio¸ paging, TV, video conferencing, etc use different communication services, there are different wireless communications systems are developed based on the application. Some of them are discussed below. A wireless Communication system is classified into Simplex, Half Duplex & Full Duplex. The simple wireless communication system is one-way communication. In this type, the communication can be done in one direction only. The best example is the radio broadcast system.

The half Duplex communication system is two-way communication; however, it is not simultaneous. The best example of this type of communication is walkie – talkie. The full Duplex communication system is also two-way communication & it is simultaneous. The best example of this communication system is the mobile phone. In wireless communication, the devices which are used for communication may change from one service to others because these are available in different shape, size & data throughput. The region enclosed through this type of communication system is an essential factor.

- Infrared Communication
- Broadcast Radio
- Microwave Communication
- Wi-Fi
- Mobile Communication Systems
- Bluetooth Technology
- Satellite communication
- ZigBee

Advantages

- Freedom from wires**:** Can be configured with the use of any physical connection.
- Easy to setup **:**Wireless network is easy to expand and setup
- Better or global coverage**:** It provides global reach by providing networking in places such as rural areas, battlefield, etc… where wiring is not feasible.
- Flexibility**:** Wireless network is more flexible and adaptable compared to wired network.
- Cost-effectiveness**:** Since it is easy to install and doesn't require cables, wireless network is relatively cheaper.
- Mobile and portable**:** Wireless network is easy to carry and re-install in another place.

Disadvantages

- As communication is done through open space, it is less secure.
- Unreliability
- More open to interference.
- Increased chance of jamming.
- Transmission speed is comparably less.

Applications of Wireless Communication

- Satellite system
- Television remote control
- Wi-Fi
- Paging system
- Wi-Max
- Security systems
- Cellphones
- Computer interface devices
- Bluetooth
- GPS
- GSM

1.3 Organization of Chapters

1.3.0 Introduction

Device-to-device communication defined as a direct communication between two mobile users without traversing the base station or the core network is considered to be a promising technique, which also offloads the increasing data traffic into user equipments (UEs). In a traditional cellular network, it is implicitly implied that two parties willing to establish the same call will not be in close proximity to each other. Therefore, all communications must go through the base station. However, in the age of data, mobile users in today's cellular networks are potentially in range for direct communications using high data rate services. Thus, D2D communication, which can decrease latency and increase resource utilization had been proposed as a means of taking advantage of the physical proximity of communicating devices. Figure 1 shows a simple example of D2D communication. The majority of the literatures in D2D communication proposed to use the cellular spectrum for both D2D and cellular communication. Most of these previous studies have focused on issues such as resource allocation and interference mitigation. Although, few existing studies have investigated the D2D access procedure. Here we review the literatures related to device discovery and access procedure. In TR 22.803, the D2D discovery is categorized into several types, which are summarized in. In addition, the D2D discovery procedure and long-term evolution (LTE)-based design are also discussed in. Yanget al. proposed a distributed peer discovery protocol for LTE-A networks.In, they provided an overview of the new agreements in third generation partners hipproject LTE radioaccess networks related to evaluation methodology and channel modeling for D2D discovery and communications. Hong et al. proposed a D2D discovery and link setup procedure and analyzed its performance in terms of energy consumption and delay by utilizing the measurement results of real LTE smartphones. However, all of the existing works lack the overall performance analysis based on the Markov process model. In this work, we will provide the system model based on the Markov process and present the performance analysis. Moreover,we give our proposal on theVienna Matlab platform, which is a system level Matlab simulator developed by Vienna University of Technology and obtain the simulation results.

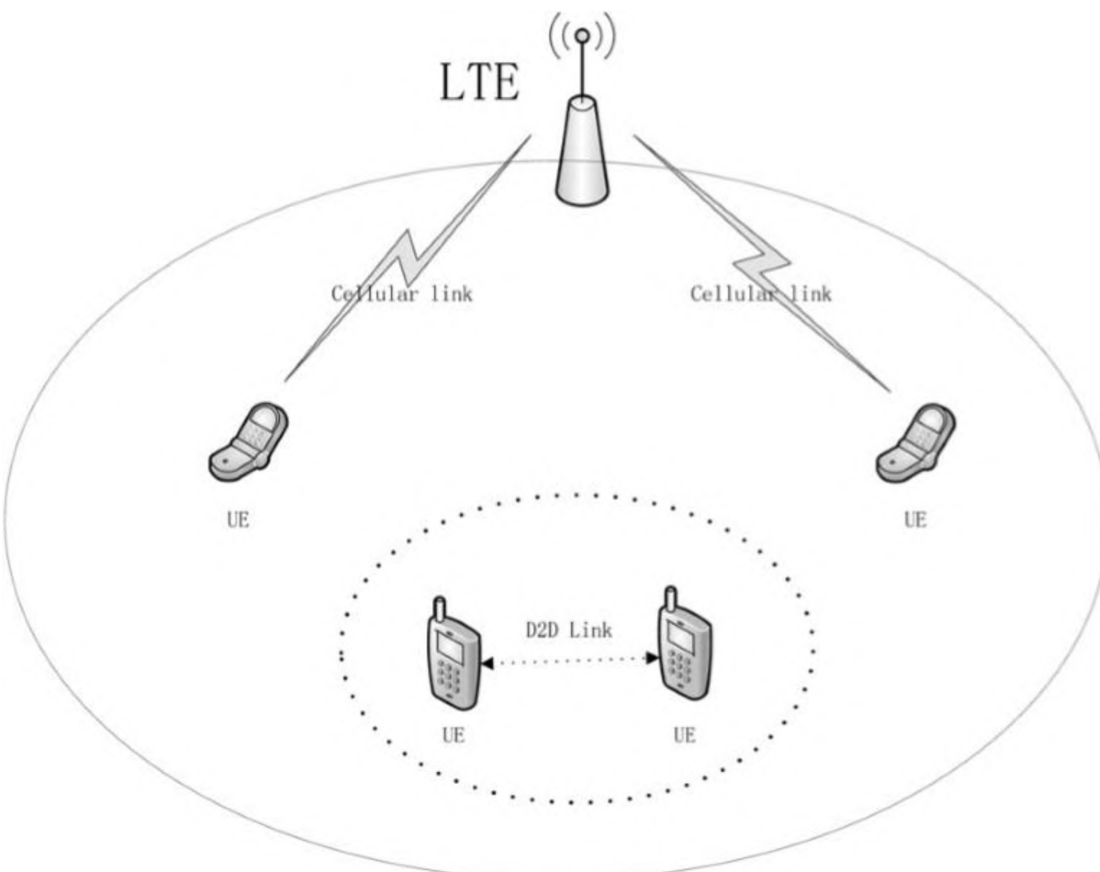

Fig 1.4 An Example of Device-to-Device Communication in a Cellular Network. LTE, Long-Term Evolution.

The rest of this paper is organized as follows: In Section 2, we will describe the system model. After that, we will present the access procedure model and performance analysis in Section 3. In Section 4, the numerical simulation will be provided.Finally,we conclude the paper in Section 5.

The next generation technologies are expected to improve the spectrum utilization along with a reduction in the power levels. Spectrum sharing is gaining popularity with regard to increasing the spectrum and the energy efficiency of the network. Spectrum sharing allows the cooperative use or the simultaneous use of the radio frequency resource by a number of independent entities in a particular geographical area. Spectrum sharing can help in effective utilization of the white spaces or the underutilized parts of the spectrum.

Also there are various power allocation strategies for optimum resource block allocation in a spectrum sharing scenario. The optimum resource block allocation strategies aims at joint optimization of the spectrum and energy efficiency of the system with increase in the quality of service for both the primary and the secondary receivers. The improved spectrum utilization can also aid in supporting the leading technology Internet of things (IoT). So we see that this area is gaining significant attention for improving the spectrum as well as energy efficiency of the network. The suggested proposal discusses both the aspects of increasing the spectrum as well as energy efficiency of the system.

1.3.1 Literature survey

Device-to-Device (D2D) communication in cellular networks is defined as direct communication between two mobile users without traversing the Base Station (BS) or core network. D2D communication is generally non-transparent to the cellular network and it can occur on the cellular frequencies (i.e., inband) or unlicensed spectrum (i.e., outband).

In a traditional cellular network, all communications must go through the BS even if communicating parties are in range for proximity-based D2D communication. Communication through BS suits conventional low data rate mobile services such as voice call and text messaging in which users are seldom close enough for direct communication. However, mobile users in today's cellular networks use high data rate services (e.g., video sharing, gaming, proximity-aware social networking) in which they could potentially be in range for direct communications (i.e., D2D). Hence, D2D communications in such scenarios can greatly increase the spectral efficiency of the network. The advantages of D2D communications go beyond spectral efficiency; they can potentially improve throughput, energy efficiency, delay, and fairness.

1.3.2 Project Design

Devices communicates with each other without intermediate notes.It uses cellular spectrum and proximity of equipments provides

- High bit rates/low delays
- Low energy consumption

Radio resources may be simultaneously used by cellular and D2D links so that the same spectral resources can be used more than once within the same cell.uses the same pre-existing cellular infrastructure supports more services and improves current services and applications.

Data Delivery in Non-Cooperative D2D communication

Existing data delivery protocols in D2D communications mainly assume that mobile nodes willingly participate in data delivery, share their resources with each other, and follow the rules of underlying networking protocols. Nevertheless, rational nodes in real-world scenarios have strategic interactions and may act selfishly for various reasons (such as resource limitations, the lack of interest in data, or social preferences).

For example, if a node has limited battery resources or the cost of the network bandwidth delivered by mobile network operators is high, it would not willingly relay data for others until appropriate incentives are provided. Meanwhile, malicious nodes may attack the network in different ways to disturb the normal operation of the data transmission process. An adversary, for example, may drop received messages but produce forged routing metrics or false information with the aim of attracting more messages or decreasing its detection probability. This issue becomes more challenging when colluding attackers boost their metrics to deceive the attack detection systems. Dealing with non-cooperative mobile nodes is very challenging because of the distributed network model and intermittent access of nodes to central authorities.

D2D applications

D2D Communications is used for

1. Local Services: In local service, user data is directly transmitted directly between the terminals and doesn't involves network side, e.g. social media apps, which are based on proximity service.

2. Emergency communications: In case of natural disasters like hurricanes, earthquakes etc., traditional communication network may not work due to the damage caused. Ad-hoc network can be established via D2D which could be used for such communication in such situations.

3. IoT Enhancement: By combining D2D with Internet of things (IoT), a truly interconnected wireless network will be created. Example of D2D-based IoT enhancement is vehicle-to-vehicle (V2V) communication in the Internet of Vehicles (IoV). When running at high speeds, a vehicle can warn nearby vehicles in D2D mode before it changes lanes or slows down.

Challenges

- Peer Discovery
- Resource Allocation
- Sharing of Spectrum
- Interference Management
- Security Problems

1.3.3 Project Implementation

Step1: start

Step2: It is used to convey an information .It transmits and receives the information

Step3: In this step the data is present after initializing the input channels

Step4: considering all the inputs HMM process starts performing the operation and as a result it produces good access rate, power allocation and throughput.

Step5: All the results are plotted and verified.

Step6: stop

1.3.4 Conclusion and Future Enhancement

The proposal presented aims to achieve joint spectrum efficiency and energy efficiency for the NGN's utilizing spectrum sharing. The model validates its performance when compared to the conventional opportunistic spectrum sharing approach and other popular resource allocation schemes. Significant improvement in the QoS and throughput has been observed in the system when Hidden markov model is used in the proposed model. Spectrum Sharing is highly susceptible to jamming attack along with interference and coverage management issues, which remains an open research field.The next generation technologies are expected to improve the spectrum utilization along with a reduction in the power levels. Spectrum sharing is gaining popularity with regard to increasing the spectrum and the energy efficiency of the network.

CHAPTER-2

LITERATURE SURVEY

2.0 Literature Review on Research Area

The future generation networks (5G) are expected to achieve high data rates, reduced latency, increased spectral efficiency and energy efficiency of the system. Since the available spectrum is a scarce resource, its efficient utilization is the prime focus of the next generation networks. Spectrum Sharing is a key aspect that is gaining significant attention as it can prove to be beneficial in meeting the above requirements. In this paper we present an exhaustive survey of spectrum sharing for future generation networks. We discuss the different techniques and methods of spectrum sharing based on which a general architecture has been presented. Next, we discuss spectrum sensing, network selection and channel allocation, power optimization in spectrum sharing as well as the security issues associated. Based on the survey a four layer architecture has been proposed depicting the complete spectrum sharing scenario from spectrum sensing till the security issues. Modern technologies such as Massive MIMO, SWIPT, spectrum harvesting, spectrum relaying have been incorporated in the architecture for optimizing the power during spectrum sharing. A detailed analysis of security attacks has also been presented in the paper. Two application scenarios have been discussed where in spectrum sharing can offer huge advantages to meet the high bandwidth requirements. The paper also includes a list of the current projects that are being conducted by various research groups and institutions on spectrum sharing, for the next generation networks.

2.1 Review Related On Literature Area

In the present scenario, an energy efficiency has become a matter of prime importance for wireless networks. To meet the demands of an increased capacity, an improved data rate, and a better quality of the service of the next-generation networks, there is a need to adopt energy-efficient architectures. Along with these requirements, it is also our social responsibility to reduce the carbon footprint by reducing the power consumption in a wireless network. Hence, a green communication is an urgent need. In this paper, we have surveyed various techniques for the power optimization of the upcoming 5G networks. The primary focus is on the use of relays and small cells to improve the energy efficiency of the network. We have discussed the various scenarios of relaying for the next-generation networks. Along with this, the importance of simultaneous wireless power and information transfer, massive multiple input multiple output, and millimeter waves has been analyzed for 5G networks.

2.2 Conclusion on Reviews

In the proposed model we have considered a spectrum sharing scenario for the next generation networks. The proposed system model has been presented in Fig. 1. Initially the network is deployed similar to a D2D pair in which the spectrum is being shared. We consider a primary transmitter communicating with ‘n’ number of primary receivers in an urban deployment scenario. The channel coefficients of the different links between the primary transmitter (PT) and primary receiver (PR) are modulated over a subset of ‘K’ subcarriers The maximum rate is achieved over the subcarriers that are OFDM modulated and is given by

$$R_{tr} = \sum_{k=1}^{K} \ln(1 + \beta_n^k p^k)$$

Where depicts the signal to noise ratio for every channel depending on the channel gain and the noise figure and is the allocated power to every channel. In the proposed model spectrum sharing is performed without the introduction of a secondary transmitter in assisting the primary system or the secondary receivers. The primary receiver that is best served assists the secondary system in achieving its target utilizing its own transmit power and the remaining subcarriers left.

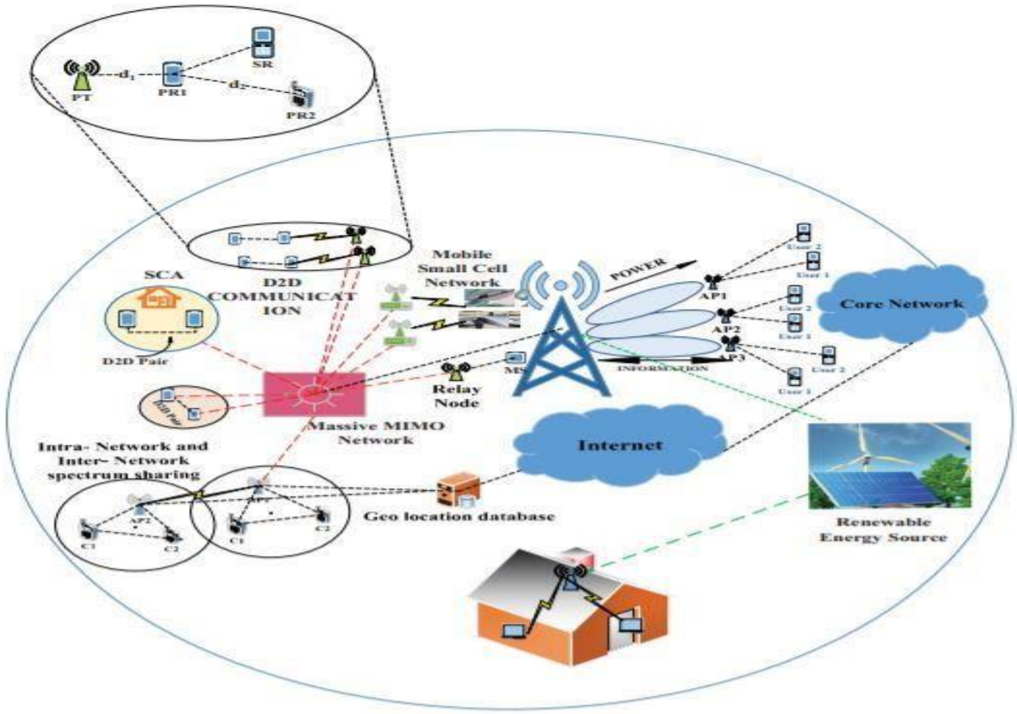

Fig. 2.1 Proposed Model for Power Optimization in a 5G Network using Spectrum Sharing

Different resource allocation techniques to allocate optimum power to the different receivers have been incorporated in the proposed model to make a comparative analysis of the most optimum resource allocation technique.

A comparison has been made with the popular opportunistic spectrum sharing technique based on full duplex cooperative OFDM relaying [13]. The various resource allocation techniques incorporated to study the performance of the model are proportional resource algorithm, water filling algorithm and Hidden Markov model (HMM). Proportional resource algorithm allocates an equal amount of transmit power to all the active users in the network. Water filling algorithm allocates optimum power in the different channels depending on the signal to noise ratio for every channel. The channels with most favorable SNR are allocated the maximum transmit power and vice versa. HMM is a probabilistic method of allocating optimum power to the active users and is based on maximum likelihood criterion. It models both the signal and the noise simultaneously. This model allocates optimum power considering various parameters which are active user distance, SNR and application. The performance of both the opportunistic spectrum sharing model and the proposed model is compared in terms of the power allocated, access rate achieved, throughput and the Mean opinion score (MOS).

The throughput computation for the model is given by the expression where depicts the bandwidth of the resource block. The Mean opinion score gives a measure of the QoE (Quality of Experience) of the users on a scale of 1-5 with 1 depicting the worst experience and 5 the best experience or the quality of the signal. It can be computed with the following expression

$$MOS = 5 - \frac{578}{1 + \left[\frac{B + 541.1}{45.98}\right]^2}$$

Where + is the throughput expressed in Kbps. Following section presents the results and analysis for the proposed model.

CHAPTER-3

PROJECT DESIGN

3.0 Overview of the Design

The players are adverting their network services and presence information through two protocols:

▪ Bonjour

▪ SSDP / UPnP (added in firmware 4.1.0 and Elementi 2018)

Elementi is using the information advertised by the players through any of these two protocols to list the players under Devices tab in Browse panel. If device discovery doesn't work for any reason, the players can be manually added into Elementi.

Both services are using multicast packets, which are restricted to the local area network where the players are located (thus the PC running Elementi must be in the same LAN), might get discarded on WiFi network (especially when crowded) and don't work over VPN connection.

Notes:

● On HMP350, HMP300 and DiVA players, both services can be disabled from Control Center > Network page, should the security policy requires that.

● Discovery across subnetworks is normally prohibited - to activate it, either enable multicast routing of SSDP on the site (applies to SpinetiX players with firmware 4.1.0 or later) or install an mDNS reflector (Avahi has this capability) on the gateway between the subnetworks.

SSDP / UPnP

● Added in firmware 4.1.0 and Elementi 2018.

● Universal Plug and Play (UPnP) is a set of networking protocols that permits networked devices, such as SpinetiX players, personal computers, printers, Internet gateways, Wi-Fi access points and mobile devices to seamlessly discover each other's presence on the network and establish functional network services for data sharing and communications. UPnP discovery protocol, known as Simple Service Discovery Protocol (SSDP), accomplishes the advertisement and discovery of network services and presence information without assistance of server-based configuration mechanisms, such as DHCP or DNS, and without special static configuration of a network host.

● SSDP / UPnP removes the dependency on Bonjour name resolution as IP addresses are used to contact players discovered via UPnP. Furthermore, HMP350, HMP300 and DiVA players show up in the Windows Explorer's Network view in Windows computers when Network Discovery is enabled.

● UPnP uses UDP port 1900 and all used TCP ports are derived from the SSDP alive and response messages.

Bonjour

● Bonjour is Apple Inc's implementation of zero-configuration networking (zeroconf), a group of technologies that includes service discovery, address assignment, and hostname resolution. Bonjour locates devices such as SpinetiX players, printers, other computers, and the services that those devices offer on a local area network using multicast Domain Name System (mDNS) service records and DNS Service Discovery (DNS-SD).

Information Advertised

● The HMP advertises the following services using Bonjour (via mDNS):

http._tcp on port 80 with name "HMP - _device name_";

● This is the standard service web browsers look for.

TXT records:

● path=/ (standard way to signify URL path)

● webdav._tcp on port 81 with name "HMP - _device name_"

This is the standard service WebDAV clients look for.

TXT records:

● path=/ (standard way to signify URL path)

● spx-hmp._tcp on port 80 with name "_device name_"

TXT records:

● txtvers=1 (standard way to support future changes)

● cport=81 (this is the content server port)

● mode= one of

normal when running normally

safe when started in safe mode

recovery when in recovery console

● serial=_serial number_ (e.g., 001d5000001a)

● firmware=_firmware version_ (e.g., 2.1.0-0.1.7844)

● model=_model_ (e.g. HMP100, HMP130 or HMP200)

spx-im._tcp on the port used by the network API (usually 1234)

This is only advertised if the network API is enabled

The device name is the name of the device as configured in Control Center.

Web Browser

Discovery from a web browser is simple if a Bonjour finder is installed (native with Safari). For instance with Internet Explorer open the Bonjour tab, all the HMP devices in the local network will be listed as "HMP - _device name_".

If the Bonjour finder is not available then one can just type spx-hmp-_serial_number_.local. (e.g., spx-hmp-001d5000001a.local.) in the URL bar of the browser, this should open the device's Control Center.

Command Line

If the Bonjour service is installed one can use the command line dns-sd tool to browse the local network.

To discover all HMP devices type (the device names will be listed under the Instance Name column)

dns-sd -B _spx-hmp._tcp

To look up a particular HMP device type (replace instance name by the name returned using the -B option). It will return the device address as spx-hmp-_serial_number_.local

dns-sd -L "instance name" _spx-hmp._tcp

To know the IP address of a device you can use ping like the following (it will show the IP address)

ping spx-hmp-_serial_number_.local.

3.1 Spectrum Sharing

Spectrum sharing is a way to optimize the use of the airwaves, or wireless communications channels, by enabling multiple categories of users to safely share the same frequency bands. Spectrum sharing is necessary because growing demand is crowding the airwaves. Smartphones, the Internet of Things, military and public safety radios, wearable devices, smart vehicles and countless other devices all depend on the same wireless bands of the electromagnetic spectrum to share data, voice and images.

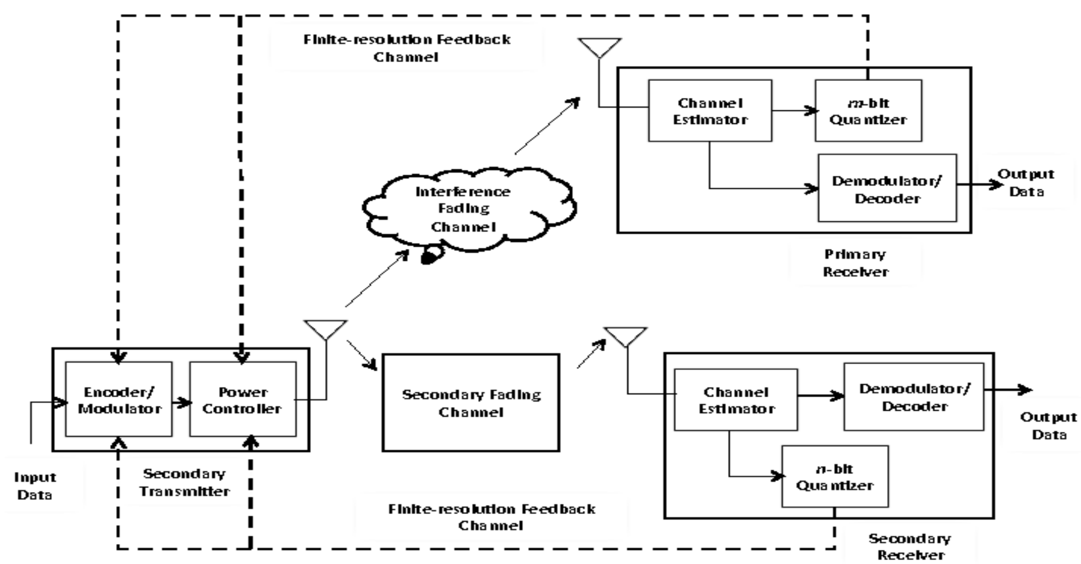

Fig 3.1 Block Diagram of Spectrum Sharing

3.2 Next Generation Network

A next-generation network (NGN) is a packet-based network which can provide services including Telecommunication Services and is able to make use of multiple broadband, quality of service-enabled transport technologies and in which service-related functions are independent from underlying transport-related technologies. It offers unrestricted access by users to different service providers. It supports generalized mobility which will allow consistent and ubiquitous provision of services to users. The next-generation network is a body of key architectural changes in telecommunication core and access networks. The general idea behind the NGN is that one network transports all information and services by encapsulating these into IP packets, similar to those used on the Internet.

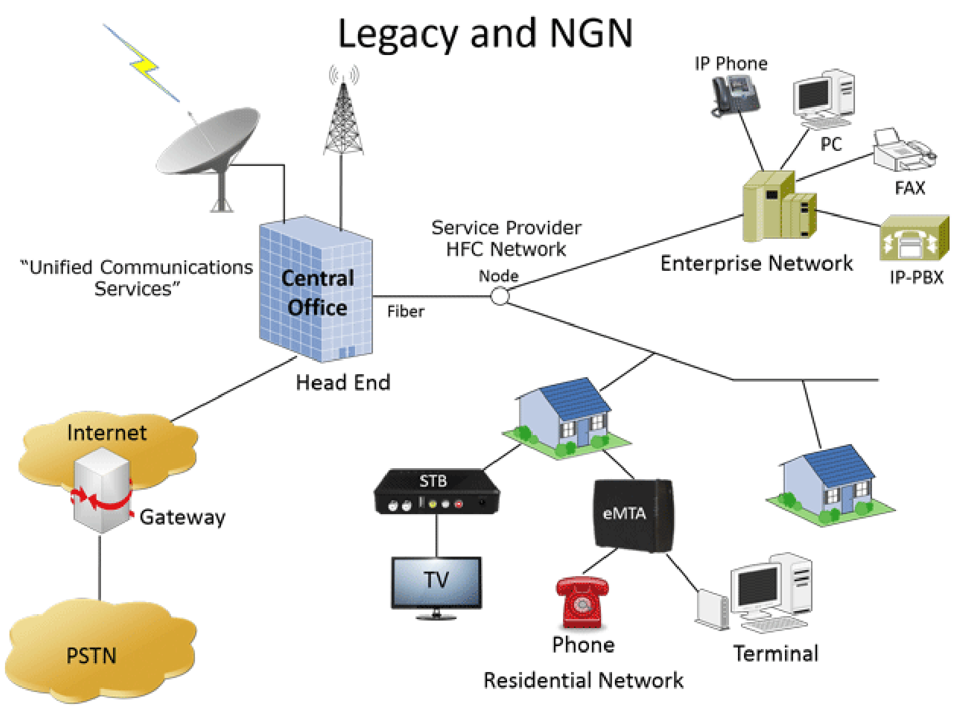

Fig 3.2 Next Generation Network

3.2 5G NR Initial Access Procedure

All the messages exchanged between UE and gNB in 5G NR Initial Access procedure i.e. Random Access Procedure are described. It is also known as initial cell search procedure. 5G NR (New Radio) is the latest cellular wireless technology developed to deliver 10 times fast data rate compare to LTE (i.e. 4G) technology. It follows 3GPP specifications release 15 and above. In this page we will understand initial access procedure i.e. random access procedure. It helps to get the initial uplink grant for UE and helps in performing synchronization with the gNB (i.e. network). It covers Random Access procedure initialization, Random Access Resource selection, Random Access Preamble transmission, Random Access Response reception, Contention Resolution and Completion of the Random Access procedure.

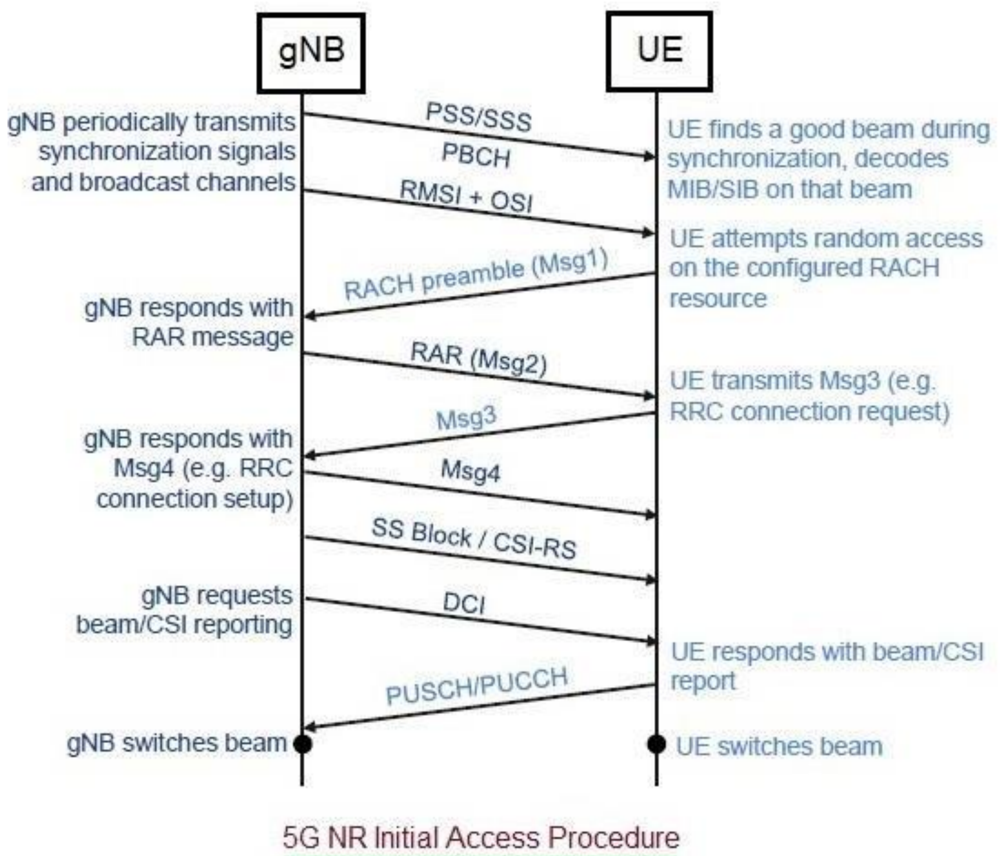

Fig 3.3 5G NR Initial Access Procedure

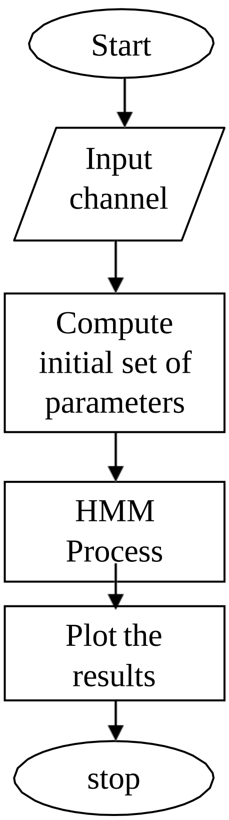
CHAPTER-4

PROJECT IMPLEMENTATION

Flow Chart



4.0 Implementation Stages

Step1: start

Step2: It is used to convey an information .It transmits and receives the information

Step3: In this step the data is present after initializing the input channels

Step4: considering all the inputs HMM process starts performing the operation and as a result it produces good access rate, power allocation and throughput.

Step5: All the results are plotted and verified.

Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

The MATLAB system

The MATLAB system consists of five main parts

- Development Environment

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- The MATLAB Mathematical Function Library

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- The MATLAB Language

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- Graphics

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- The MATLAB Application Program Interface (API)

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

Graphical User Interface (GUI)

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

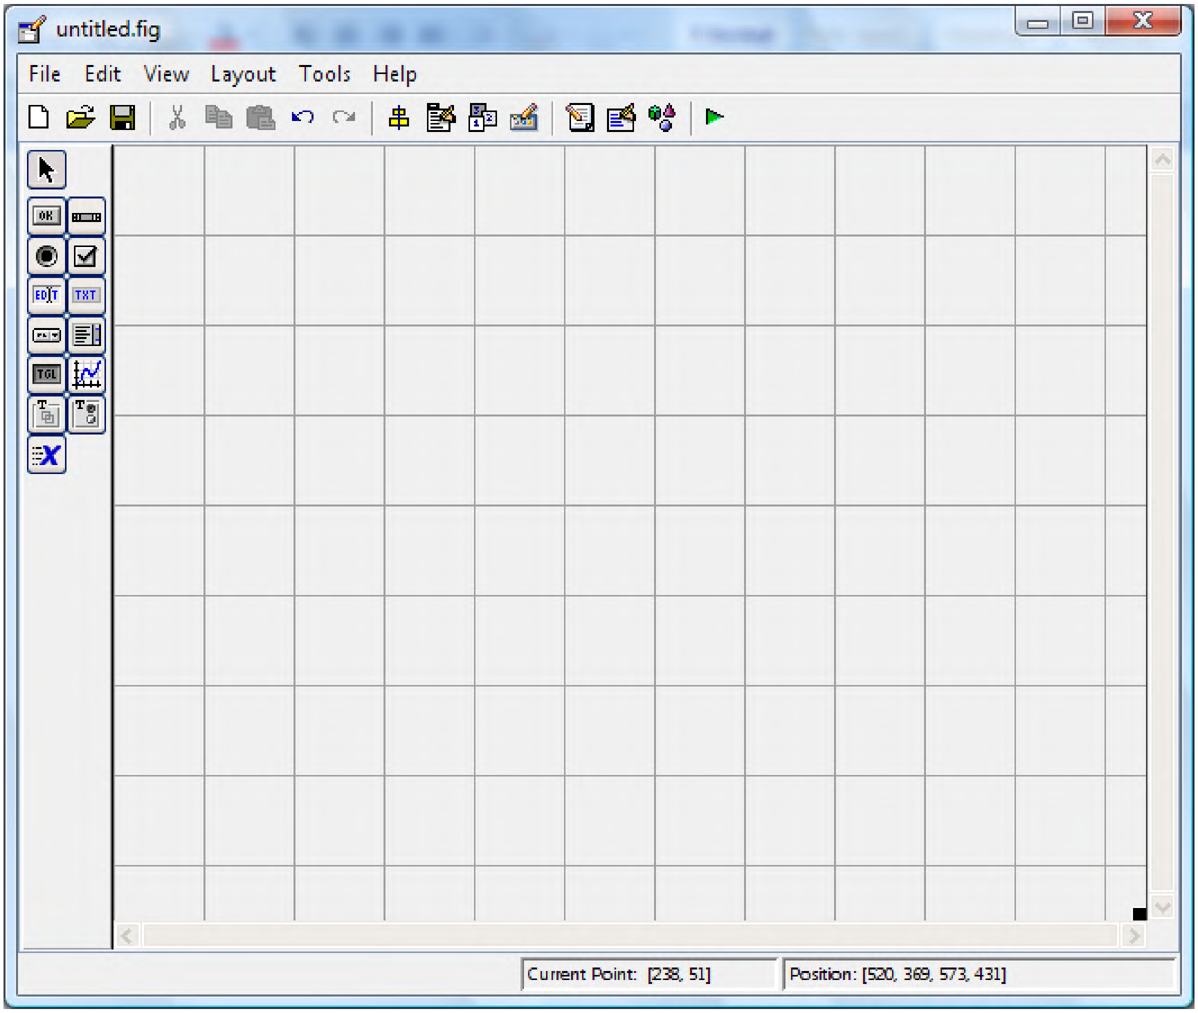

Table 4.1 Creating Matlab GUI

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

Development Environment

Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History:

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

Manipulating Matrices

Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.
- Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =

    16     3     2    13

     5    10    11     8

     9     6     7    12

     4    15    14     1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 4.2 List of Operators

Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 4.3 List of Functions

GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

Creating GUIs with Guide

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

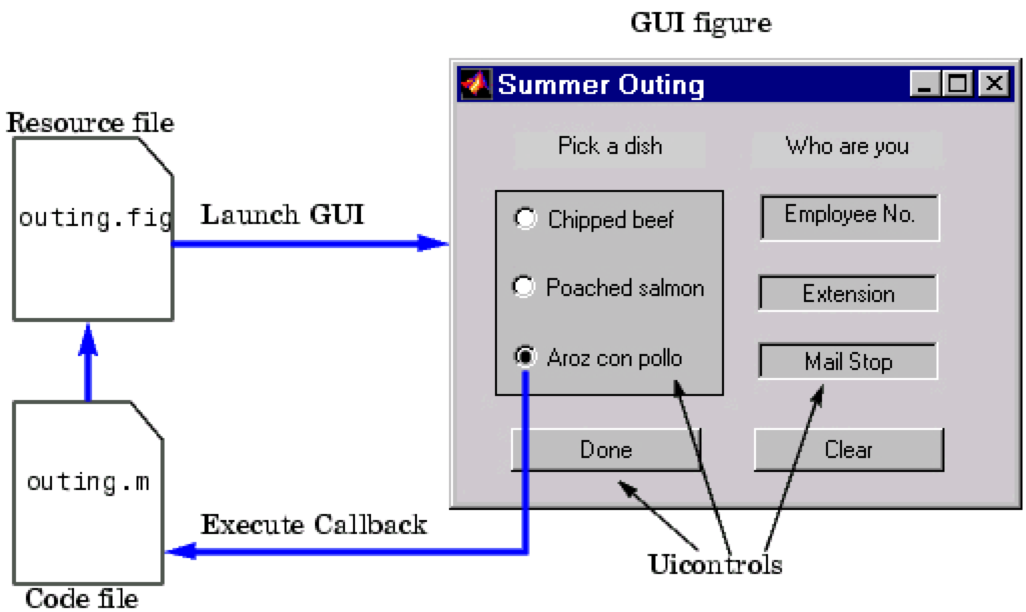

Fig 4.1 Graphical User Blocks

Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes

Checkboxes

- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)
```

```
set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

   .

   .

   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function  edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
```

```
if isnan(user_entry)
    errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer.

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

```
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

4.1 Results

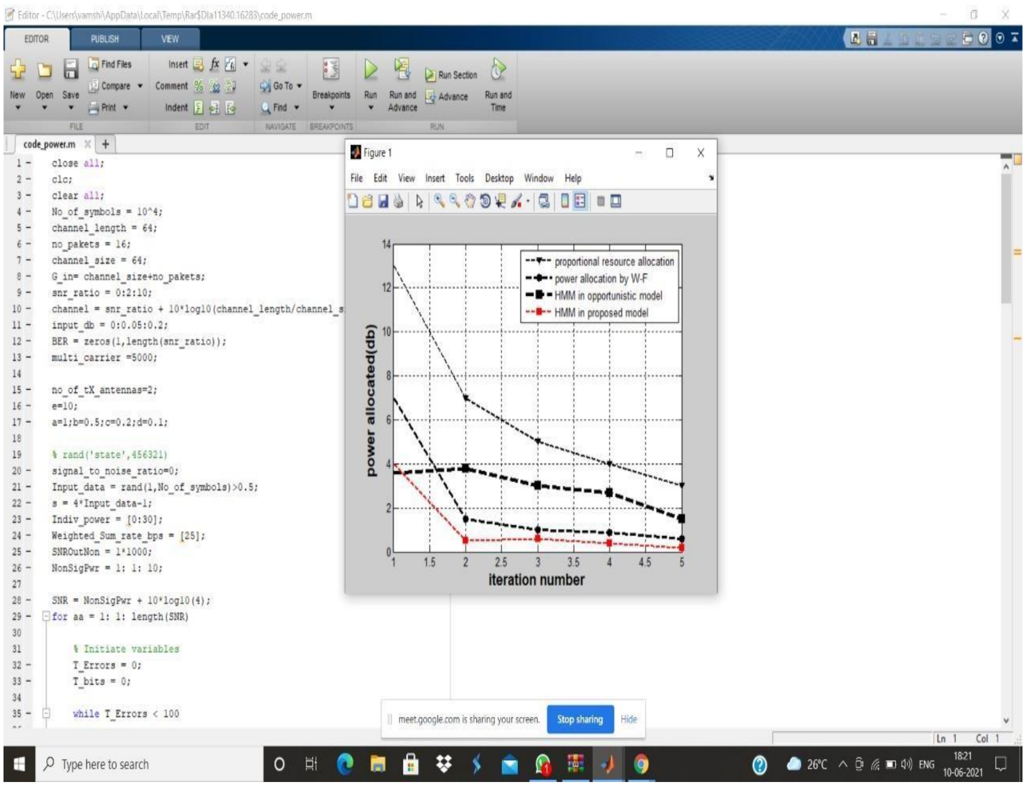

Fig 4.1. Power consumed for different algorithms v/s iteration number

It is clearly observed that it depict the power consumed by the different active pairs using the proportional resource algorithm, waterfilling algorithm, using HMM in opportunistic model and HMM in the proposed model. It is evident from the graph that maximum power is allocated to each pair in the proportional algorithm and least power is utilized in the proposed approach.

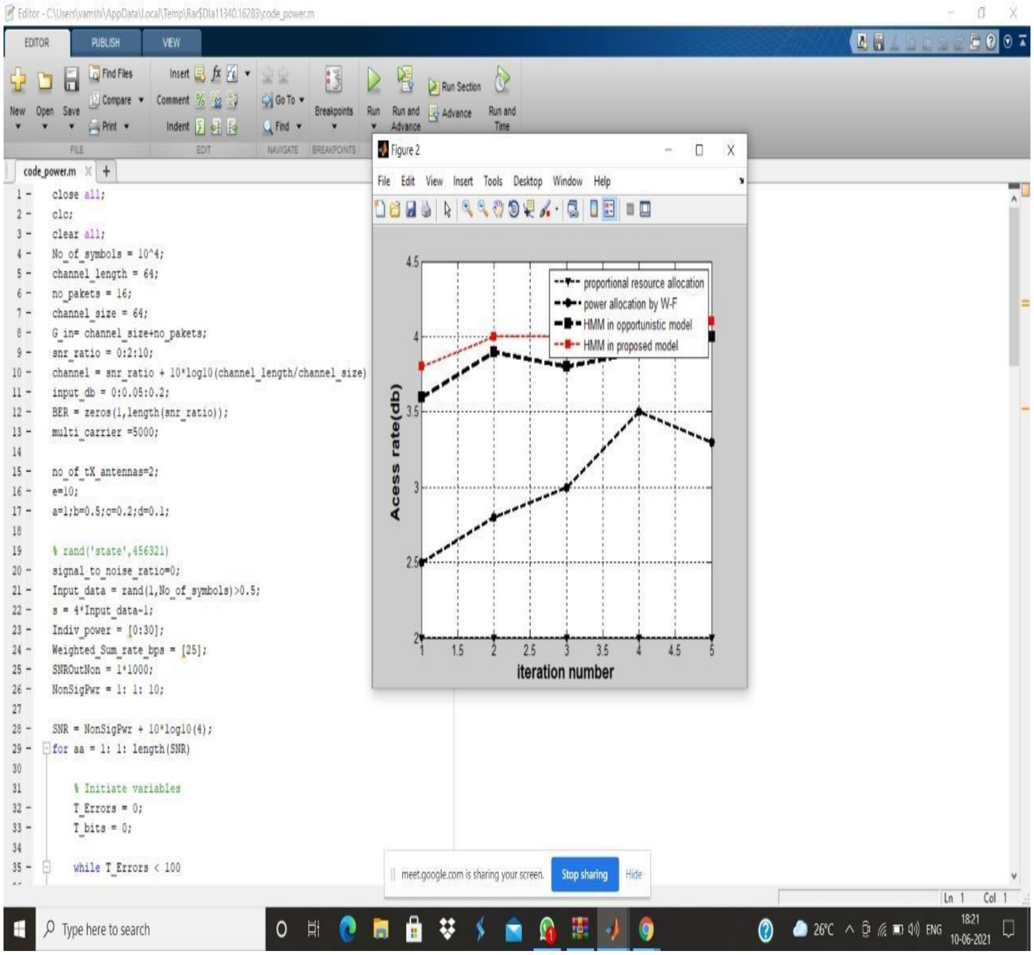

Fig 4.2. Access Rate Achieved in Different Iterations

It presents the access rate achieved for the active pairs with different resource allocation schemes. Highest access rate is achieved using HMM in the proposed model.

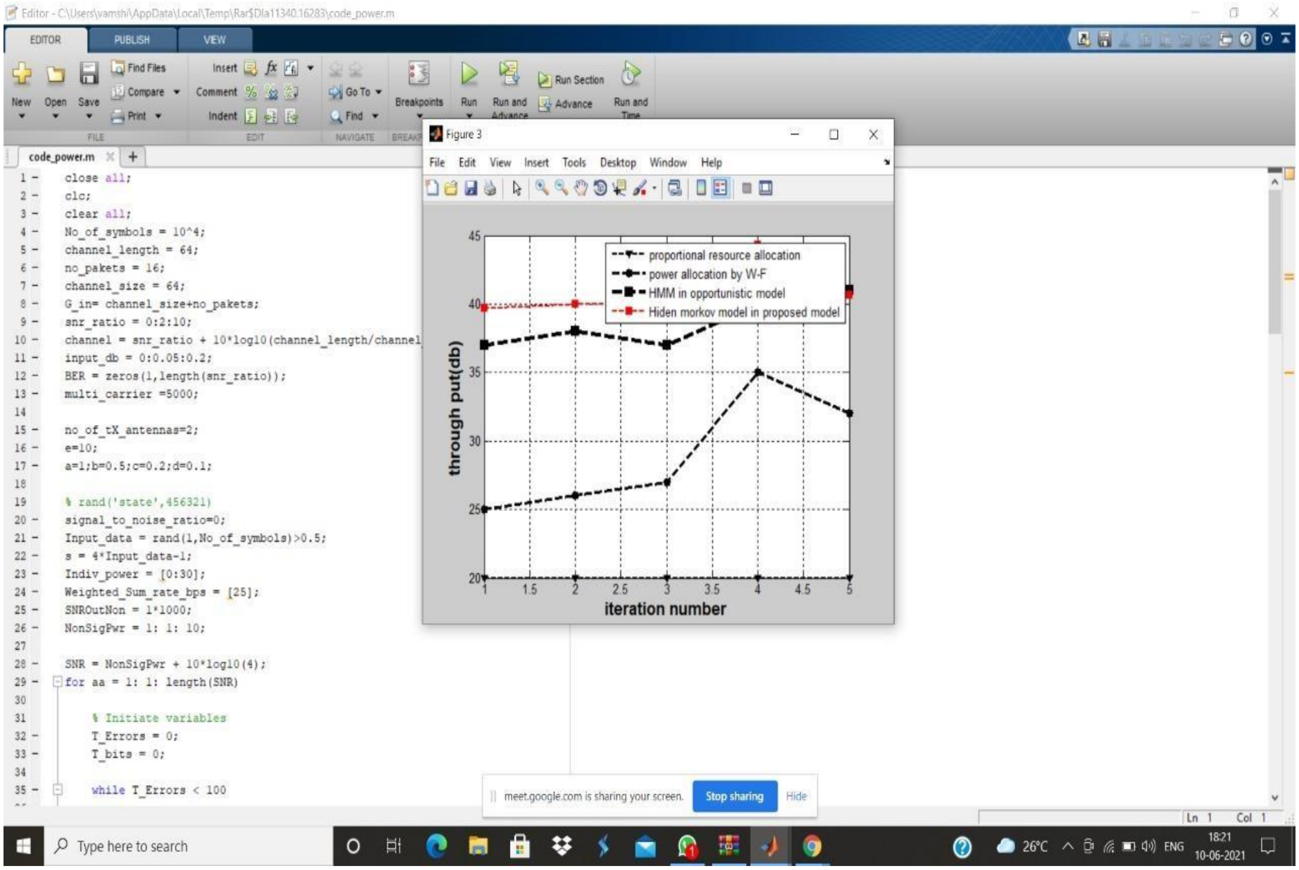

Fig 4.3 Throughput Achieved in Different Iterations

Similar trend has been found in the throughput analysis. Maximum throughput of the network if achieved when power is allocated using HMM in the proposed model.

Advantages

- High resolution and bi-directional large bandwidth shaping.
- Technology to gather all networks on one platform.
- More effective and efficient.
- Technology to facilitate subscriber supervision tools for the quick action.
- Most likely, will provide a huge broadcasting data (in Gigabit), which will support more than 60,000 connections.
- Easily manageable with the previous generations.

- Technological sound to support heterogeneous services (including private network).
- Possible to provide uniform, uninterrupted, and consistent connectivity across the world.

Disadvantages

- Technology is still under process and research on its viability is going on.
- The speed, this technology is claiming seems difficult to achieve (in future, it might be) because of the incompetent technological support in most parts of the world.
- Many of the old devices would not be competent to 5G, hence, all of them need to be replaced with new one — expensive deal.
- Developing infrastructure needs high cost.
- Security and privacy issue yet to be solved.

Applications

- It will make unified global standard for all.
- Network availability will be everywhere and will facilitate people to use their computer and such kind of mobile devices anywhere anytime.
- Because of the IPv6 technology, visiting care of mobile IP address will be assigned as per the connected network and geographical position.
- Its application will make world real Wi Fi zone.
- Its cognitive radio technology will facilitate different version of radio technologies to share the same spectrum efficiently.
- Its application will facilitate people to avail radio signal at higher altitude as well.

CHAPTER-5

CONCLUSION AND FUTURE ENHANCEMENT

5.0 Result

As we consider an urban deployment scenario with the urban macro cell radius of 0.5 km. The active users in the network form spectrum pair depending on a threshold distance criterion. The other users follow conventional cellular communication. Using MATLAB and the parameters in [14], the simulation results for the proposal have been carried out and analyzed. We assume 5 active pairs formed in different iterations. The results in Fig. 2 depict the power consumed by the different active pairs using the proportional resource algorithm, waterfilling algorithm, using HMM in opportunistic model and HMM in the proposed model. It is evident from the graph that maximum power is allocated to each pair in the proportional algorithm and least power is utilized in the proposed approach. Fig. 3 presents the access rate achieved for the active pairs with different resource allocation schemes. Highest access rate is achieved using HMM in the proposed model. Similar trend has been found in the throughput analysis. Maximum throughput of the network if achieved when power is allocated using HMM in the proposed model.

5.1 Conclusion

The proposal presented aims to achieve joint spectrum efficiency and energy efficiency for the NGN's utilizing spectrum sharing. The model validates its performance when compared to the conventional opportunistic spectrum sharing approach and other popular resource allocation schemes. Significant improvement in the QoS and throughput has been observed in the system when Hidden markov model is used in the proposed model. Spectrum Sharing is highly susceptible to jamming attack along with interference and coverage management issues, which remains an open research field.

5.2 Future Scope

The next generation technologies are expected to improve the spectrum utilization along with a reduction in the power levels. Spectrum sharing is gaining popularity with regard to increasing the spectrum and the energy efficiency of the network. Spectrum sharing allows the cooperative use or the simultaneous use of the radio frequency resource by a number of independent entities in a particular geographical area. Spectrum sharing can help in effective utilization of the white spaces or the underutilized parts of the spectrum. Also there are various power allocation strategies for optimum resource block allocation in a spectrum sharing scenario. The optimum resource block allocation strategies aims at joint optimization of the spectrum and energy efficiency of the system with increase in the quality of service for both the primary and the secondary receivers. The improved spectrum utilization can also aid in supporting the leading technology Internet of things (IoT). So we see that this area is gaining significant attention for improving the spectrum as well as energy efficiency of the network. The suggested proposal discusses both the aspects of increasing the spectrum as well as energy efficiency of the system.

5.3 Publications

Paper submitted to online mega international conference on “Smart modernistic in Electronics and Communication”(ICSME-21) with paper ID(ICSMEC21-0072) and got acceptance for the paper.

DECLARATION

We, the student of **Bachelor of Technology** in Department of 'Electronics and Communication Engineering', session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "IOT TECHNOLOGY BASED TRAFFIC SIGNAL AND DENSITY CONTROL" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university foraward of any degree.

A.Nihanth reddy	(17K81A0465)
K.Manasi	(17K81A0484)
U.Jagadish	(17K81A04B6)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, in the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand Kumar**, professor in ECE for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr. K.S.Sagar, Assistant professor,** Department of ECE and our class project coordinator **Mr.K.Karthik, Assistant professor,** Department of ECE for encouragement in carrying out this project work.

Finally, We are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar** , **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

INTRODUCTION

Overview of the Project

In the world of Innovative and automotive world everything isgetting computerized. Each data is in effect effortlessly available. Yet, the movement signals checking is as yet done physically. The activity signals are observed physically from the control room by the executives or a predictable time is settled for signals evolving. Rather than this a computerized controller-based activity checking framework will be useful for controlling the movement. This plan of movement foundation will be useful in decreasing the activity clog issue in urban communities. This paper depicts a framework where IR sensors are incorporated with an Arduino to work for the paths which measure the movement thickness. This incorporated arrangement of movement is Internet of Things (IoT) based which likewise empowers to clear the activity for emergency vehicle by giving a catch in rescue vehicle so the activity gets cleared on that side [1]. It additionally empowers the vehicles tally that move over the sensors. Subsequently, movement controlling gets upgraded effectively, which in the end prompts huge change in rush hour gridlock framework. Keywords Automated traffic monitoring and controlling, Arduino, IR sensors, Traffic congestion and IoT. In this quick moving world everything is mechanized. Beginning from home apparatuses to following of vehicles every last framework is implanted. Installed frameworks are those which are intended for a specific undertaking rather that for broadly useful arrangement of taking care of numerous assignments [2]. Installed frameworks are intended to do some particular errand, as opposed to be a broadly useful PC for different undertakings. Some likewise have continuous execution limitations that must be met, for reason, for example, wellbeing and ease of use; others may have low or no execution prerequisites, enabling the framework equipment to be streamlined to lessen costs. An installed framework isn't generally a different piece - all the time it is physically worked in to the gadget it is controlling. The product composed for implanted frameworks is regularly called firmware and is put away in read-just memory or glimmer convector chips as opposed to a circle drive. It frequently keeps running with constrained PC equipment assets: little or no console, screen, and little memory. Remote correspondence has turned into an essential element for business items and a well known research subject inside the most recent ten years. There are currently more cell phone memberships than wired-line memberships. With new innovations and gadgets come new business exercises, and the requirement for representatives in these mechanical territories. Architects who know about installed frameworks and remote interchanges will be popular. Shockingly, there are couple of cute situations accessible for advancement and classroom utilize, so understudies frequently don't find out about these innovations amid hands-on lab works out.

Objective of the Project

Presently a-days, every one of the works and things are getting to be mechanized and computerized. It began from looking through the notable places and came to home conveyance of anything. Be that as it may, in this quick age the activity framework is still carried on physically. Along these lines, to computerize it we have built up an undertaking. The framework is an IoT based framework which flags the movement lights by thinking about the vehicles thickness. To do this we utilize sensors. The sensors will quantify the activity thickness and isolate it into low, medium and high classifications. In view of that outcome the signs get changed. This task points in planning an IoT based framework in which movement signals are checked and controlled consequently by utilizing sensors. The framework utilizes an Arduino based circuit which controls the signs in view of the thickness of vehicles and transmit the information to the server. The Arduino is a group of microcontroller sheets to improve electronic plan, prototyping and testing for specialists, programmers, specialists, yet additionally numerous experts. Arduinos (we utilize the standard Arduino Uno) are worked around an AtMega microcontroller basically an entire PC with CPU, RAM, Flash memory, and information/yield sticks, all on a solitary chip. The Arduino associates with your PC by means of USB, where you program it in a straightforward dialect (C/C++, like Java) from inside the free Arduino IDE by transferring your arranged code to the board. Once modified, the Arduino can keep running with the USB interface back to your PC, or remain solitary without it — no console or screen required, simply control. The framework measures the thickness of movement utilizing sensors that are set in an interim of separation. This framework likewise gives an alternative to avoid the flag to green at whatever point there a rescue vehicle is going through that course by keeping different sides in Red by giving a catch. Thus the movement signals are observed consequently with the assistance of sensors. In this, we are utilizing IR sensors. IR sensors work by utilizing a particular light sensor to recognize a select light wavelength in the InfraRed (IR) range. By utilizing a LED which creates light at an indistinguishable wavelength from what the sensor is searching. At the point when a question is near the sensor, the light from the LED bobs off the protest and into the light sensor. By utilizing the IR sensors, the thickness is estimated and the signs gets observed and controlled. The information got from the sensors are refreshed at time to time to the server utilizing IoT.

Material Requirement

Hardware Requirements

- Arduino UNO
- IR Sensor
- Wi-Fi Module
- Traffic Signal Module
- LCD
- Power Supply Unit

Software Requirements

- Arduino IDE
- Proteus Software

Procurement of Equipment's

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller board, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software.

Now, we assembled all sensors and interfaced them to Arduino UNO micro-controller board using connecting wires through bread board and we wrote program for the working of all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way.

We monitored traffic signals and checked the display on LCD and also updated on Server. Here we can also monitor the traffic when a VIP vehicle is approaching with the help of TELNET app which works based on internet of things.

Introduction to Embedded System

An embedded system is a combination of computer hardware and software, either fixed in capability or programmable, designed for a specific function or functions within a larger system. Industrial machines, agricultural and process industry devices, automobiles, medical equipment, cameras, household appliances, airplanes, vending machines and toys, as well as mobile devices, are possible locations for an embedded system. An embedded system is a dedicated computer system designed for one or two specific functions. This system is embedded as a part of a complete device system that includes, such as electrical and mechanical components[1]. The embedded system is unlike the generalpurpose computer, which is engineered to manage a wide range of processing tasks. Because an embedded system is engineered to perform certain tasks only, design engineers may optimize size, cost, power consumption, reliability and performance. Embedded systems are typically produced on broad scales and share across a variety of environments and applications. An embedded system is one that has computer-hardware with software embedded in it as one of its most important components. It is a dedicated computer-based system for an application or product. An embedded system has three main components.

- It has hardware
- It has main application software.
- It has a real time operating system (RTOS)

An embedded system has software designed to keep in view three constraints:

(i) Available system memory.

(ii) Available processor speed.

(iii) The need to limit power dissipation when running the system .

An2 embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer

may be used to control the operation of a large complex processing plant, and its presence will be obvious. Some of these computers are however very simple systems as compared with a personal computer[2]. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes[2]. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware. The simplest devices consist of a single microprocessor (often called a chip)
which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine[3]. As the embedded system is the combination of both software and hardware.

History of Embedded Systems

Embedded systems date back to the 1960s. Charles Stark Draper developed an integrated circuit (IC) in 1961 to reduce the size and weight of the Apollo Guidance Computer, the digital system installed on the Apollo Command Module and Lunar Module. The first computer to use ICs, it helped astronauts collect realtime flight data. In 1965, Auto now a part of Boeing, developedthe D-17B, the computer used in the Minuteman I missile guidance system.

Block Diagram of Embedded System

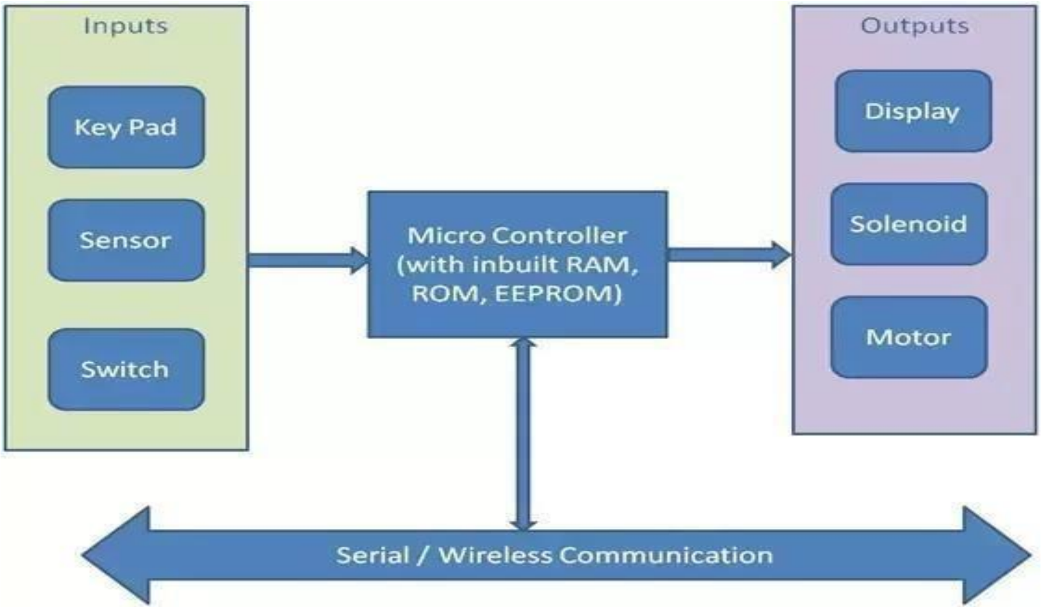

Fig.1.5.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Embedded System Hardware

Embedded system hardware can be microprocessor- or microcontroller-based. In either case, an integrated circuit is at the heart of the product that is generally designed to carry out computation for real-time operations[4]. Microprocessors are visually indistinguishable from microcontrollers, but while the microprocessor only implements a central processing unit (CPU) and, thus, requires the addition of other components such as memory chips, microcontrollers are designed as self contained systems.

Embedded System Software

A typical industrial microcontroller is unsophisticated compared to the typical enterprise desktop computer and generally depends on a simpler, less-memory intensive program environment. The simplest devices run on bare metal and are programmed directly using the chip CPU's machine code language. Often, embedded systems use operating systems or language platforms tailored to embedded use, particularly where real-time operating environments must be served. At higher levels of chip capability, such as those found in SoCs designers have increasingly decided the systems are generally fast enough and the tasks tolerant of slight variations in reaction time that near-real-time approaches are suitable.

Examples of Embedded System

- ATM
- Digital Cameras
- Microwave ovens
- Factory controllers
- Washing machine
- Calculator
- TV remote
- Traffic lights
- Digital watches
- Mp3 player

Applications of Embedded Systems

- Manufacturing and process control
- Construction industry
- Transport
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical Systems
- Robotics
- Instrumentation
- Military Application

Microcontroller

A microcontroller is a small computer on a single metal oxide semiconductor (MOS) integrated circuit (IC) chip. A microcontroller contains one or more CPUs along with memory and programmable input/output peripherals. Program memory in the form of ferroelectric RAM, NOR flash or OTP ROM is also often included on chip, as well as a small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications consisting of various discrete chips[7]. In modern terminology, a microcontroller is similar to, but less sophisticated than, a system on a chip (SoC). SoC may include a microcontroller as one of its components, but usually integrates it with advanced peripherals like graphics processing unit (GPU), Wi-Fi module, or one or more coprocessors.

Fig.1.6.1: Microcontroller

Microcontrollers are used in automatically controlled products and devices, such as automobile engine control systems, implantable medical devices, remote controls, office machines, appliances, power tools, toys and other embedded systems. By reducing the size and cost compared to a design that uses a separate microprocessor, memory, and input/output devices, microcontrollers make it economical to digitally control even more devices and processes. Mixed signal microcontrollers are common, integrating analog components needed to control non-digital electronic systems. In the context of the internet of things, microcontrollers are an economical and popular means of data collection, sensing and actuating the physical world as edge devices.

Some microcontrollers may use four-bit words and operate at frequencies as low as 4 kHz for low power consumption (single-digit milliwatts or microwatts). They generally have the ability to retain functionality while waiting for an event such as a button press or other interrupt; power consumption while sleeping (CPU clock and most peripherals off) may be just nanowatts, making many of them well suited for long lasting battery applications[8]. Other microcontrollers may serve performance-critical roles, where they may need to act more like a digital signal processor (DSP), with higher clock speeds and power consumption.

Microprocessor	Microcontroller
CPU is stand alone, RAM,ROM, I/O & timer are separate.	CPU, RAM,ROM, I/O & timer all are on single chip.
Designer can decide amount of RAM,ROM, & I/O ports.	Fixed amount of on-chip RAM,ROM, & I/O ports.
High processing power	Low processing power
High power consumption	Low power consumption
Typically 32/64 bit	8/16 bit
General purpose	Single purpose(control oriented)
Less reliable	Highly reliable
Eg.- 8086,8085	8051

Table 1.6.1: Difference between microprocessor and microcontroller

History

The origins of both the microprocessor and the microcontroller can be traced back to the invention of the MOSFET (metal-oxide-semiconductor field-effect transistor), also known as the MOS transistor. It was invented by Mohamed M. Atalla and Dawon Kahng at Bell Labs in 1959, and first demonstrated in 1960.

The same year, Atalla proposed the concept of the MOS integrated circuit, which was an integrated circuit chip fabricated from MOSFETs. By 1964, MOS chips had reached higher transistor density and lower manufacturing costs than bipolar chips[2]. MOS chips further increased in complexity at a rate predicted by Moore's law, leading to large-scale integration (LSI) with hundreds of transistors on a single MOS chip by the late 1960s. The application of MOS LSI chips to computing was the basis for the first microprocessors, as engineers began recognizing that a complete computer processor could be contained on a single MOS LSI chip.

Fig.1.6.2: 8051 Microcontroller Board

Most microcontrollers at this time had concurrent variants. One had EPROM program memory, with a transparent quartz window in the lid of the package to allow it to be erased by exposure to ultraviolet light. These erasable chips were often used for prototyping. The other variant was either a mask programmed ROM or a PROM variant which was only programmable once. For the latter, sometimes the designation OTP was used, standing for "one-time programmable". In an OTP microcontroller, the PROM was usually of identical type as the EPROM, but the chip packagehad no quartz window; because there was no way to expose the EPROM to ultraviolet light, it could not be erased. Because the erasable versions required ceramic packages with quartz windows, they were significantly more expensive than the OTP versions, which could be made in lower-cost opaque plastic packages. For the erasable variants, quartz was required, instead of less expensive glass, for its transparency to ultraviolet light— to which glass is largely opaque—but the main cost differentiator was the ceramic package itself.

In 1993, the introduction of EEPROM memory allowed microcontrollers (beginning with the Microchip PIC16C84) to be electrically erased quickly without an expensive package as required for EPROM, allowing both rapid prototyping, and in-system programming. (EEPROM technology had been available prior to this time, but the earlier EEPROM was more expensive and less durable, making it unsuitable for low-cost mass-produced microcontrollers.) The same year, Atmel introduced the first microcontroller using Flash memory, a special type of EEPROM. Other companies rapidly followed suit, with both memory types.

IoT Technology

The Internet of things (IoT) describes the network of physical objects—a.k.a. "things"—that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the Internet.[20][21]

Things have evolved due to the convergence of multiple technologies, realtime analytics, machine learning, ubiquitous computing, commodity sensors, and embedded systems[20]. Traditional fields of embedded systems, wireless sensor networks, control systems, automation (including home and building automation), and others all contribute to enabling the Internet of things. In the consumer market, IoT technology is most synonymous with products pertaining to the concept of the "smart home", including devices and appliances (such as lighting fixtures, thermostats, home security systems and cameras, and other home appliances) that support one or more common ecosystems, and can be controlled via devices associated with that ecosystem, such as smartphones and smart speakers. The IoT can also be used in healthcare systems.

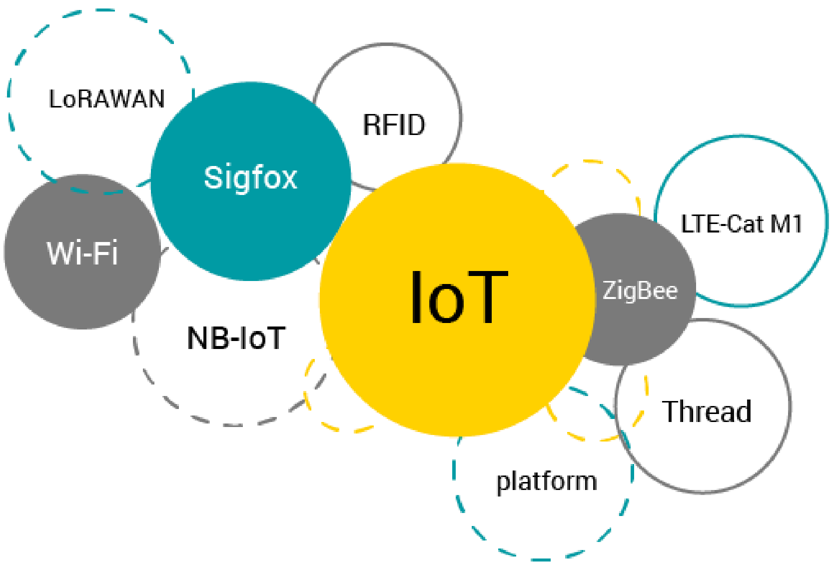

Fig 1.7.1: IoT Technology

There are a number of serious concerns about dangers in the growth of the IoT, especially in the areas of privacy and security, and consequently industry and governmental moves to address these concerns have begun including the development of international standards.

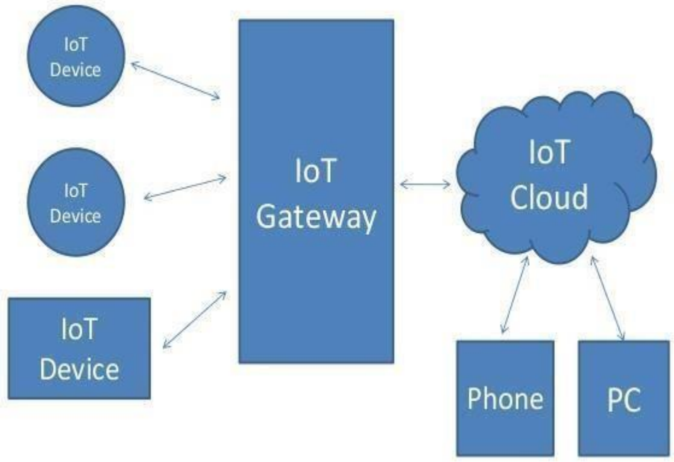

Fig 1.7.2: IoT Block diagram

The IoT technology stack and its Connectivity Solutions

It can prove a hard task if you'd like to find your way through the IoT technological maze given the diversity and sheer numerousness of the technology solutions that surround it. However, for matters of simplicity, we could break down the IoT technology stack into four basic technology layers involved in making the Internet of Things work. These are the following:

Fig 1.7.3: IoT technology stack

1. Device Hardware

Devices are objects which actually constitute the 'things' within the Internet of Things. Acting as an interface between the real and the digital worlds, they may take different sizes, shapes and levels of technological complexity depending on the task they are required to perform within the specific IoT deployment. Whether pinhead sized microphones or heavy construction machines, practically every material object (even the animate ones, like animals or humans) can be turned into a connected device by the addition of necessary instrumentation (by adding sensors or actuators along with the appropriate software) to measure and collect the necessary data. Obviously, sensors, actuators or other telemetry gear can also constitute standalone smart devices by themselves. The only limitation to be encountered here is the actual IoT use case and its hardware requirements (size, ease of deployment and management, reliability, useful lifetime, cost-effectiveness)

2. Device Software

This is what actually makes the connected devices 'smart'. Software is responsible for implementing the communication with the Cloud, collecting data, integrating devices as well as performing real-time data analysis within the IoT network. What is more, it is device software that also caters for application-level capabilities for users to visualize data and interact with the IoT system.

3. Communications

Having the device hardware and software in place, there must be another layer which will provide the smart objects with ways and means of exchanging information with the rest of the IoT world. While it is true that communications mechanisms are strongly tied to device hardware and software, it is vital to consider them as a separate layer. Communication layer includes both physical connectivity solutions (cellular, satellite, LAN) and specific protocols used in varying IoT environments (ZigBee, Thread, Z-Wave, MQTT, LwM2M). Choosing the relevant communications solution is one of the vital parts in constructing every IoT technology stack. The technology chosen will determine not only the ways in which data is sent to/received from the Cloud, but also how the devices are managed and how they communicate with third party devices. For the purpose of the present article, we will go into the details of some of the present-day communications solutions later in the text.

4. Platform

As mentioned earlier, thanks to the 'smart' hardware and the software installed the device is able to 'sense' what is going on around it and communicate that to the user via a specific communications channel. An IoT platform is the place where all of these data is gathered, managed, processed, analysed and presented in a user-friendly way. Thus, what makes such a solution especially valuable is not merely its data collection and IoT device management capabilities, but rather its ability to analyse and find useful insights from the portions of data provided by the devices via the communications layer. Again, there is quite a number of IoT platforms on the market, with choice depending on the requirements of the specific IoT project and such factors as architecture and IoT technology stack, reliability, customization properties, protocols used, hardware agnosticism, security and cost-effectiveness. It is also worth mentioning that platforms can be either installed on-premise or cloud-based. Coiote IoT Device Management platform is a good example of such a platform as it can be deployed on-site as well as in the cloud. The same applies to another IoT platform by AVSystem — Coiote IoT Data Orchestration.

Connectivity solutions

As many as there are possible real-life applications of the IoT technologies, there is no shortage of connectivity solutions behind them. Depending on the specifications of a given IoT use case, each communications option may offer different service enablement scenarios while having tradeoffs between power consumption, range and bandwidth. With this multiplicity and diversity of communication standards and protocols in mind, one may raise a question about the actual need for developing new solutions while there are some well-proven Internet protocols that have been in use already for decades. The reason for this is that existing Internet protocols, such as Transmission Control Protocol / Internet Protocol (TCP/IP), are often not effective enough and too power-consuming to be able to work efficiently within the emerging IoT technology applications. This section will present a short overview of the major alternative Internet protocols specially dedicated for use by IoT systems.

The overview concerns the most popular IoT radio technologies broken down by radio-frequency range achieved by each of the solutions: short range IoT radio solutions, medium range solutions, and long-range Wide Area Networks solutions.

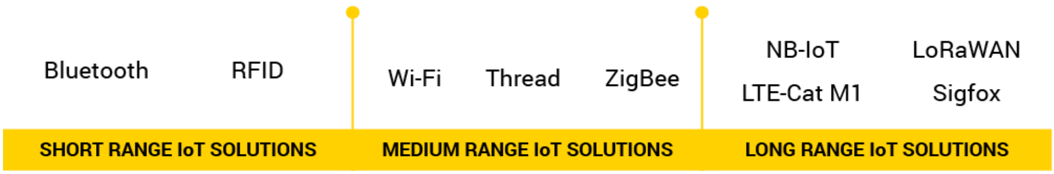

Fig 1.7.4: Connectivity Solutions

Short range IoT radio solutions

1. Bluetooth

As a well-established short-range connectivity technology, Bluetooth is considered to be the key solution particularly for the future of the wearable electronics market such as wireless headphones or geolocation sensors, especially given its widespread integration with smartphones. Designed with cost-effectiveness and reduced power consumption in mind, the Bluetooth Low-Energy (BLE) protocol requires very little power from the device. Yet, this comes with a compromise: when transferring frequently higher amounts of data, BLE may not be the most effective solution.

2. RFID

Being among the first IoT applications ever implemented, Radio-frequency identification (RFID) offers positioning solutions for IoT applications, especially in supply chain management and logistics, which require the ability of determining the object position inside buildings. The future of RFID technology clearly goes far beyond the simple localisation services, with possible applications ranging from tracking hospital patients to improving efficiency in healthcare to providing real-time merchandise location data to minimize out-of-stock situations for retail stores.

Medium Range Solutions

1. Wi-Fi

Developed based on IEEE 802.11, it remains the most widespread and generally known wireless communications protocol. Its broad usage across the IoT world is mainly limited by higher-than-average power consumption resulting from the need of retaining high signal strength and fast data transfer for better connectivity and reliability. As a key technology in the development of IoT, WiFi provides a wide-ranging ground to staggering number of IoT solutions, yet it also needs to be managed and used in terms of marketing to yield profits to service providers and users alike. A fine example of a WiFi management platform that offers a value-added service empowering public WiFi access points is Linkify. As one of AVSystem's cutting-edge solutions, Linkify allows for practically limitless guest WiFi customization and marketing options.

2. Zigbee

This popular wireless mesh networking standard finds its most frequent applications in traffic management systems, household electronics, and machine industry. Built on top of the IEEE 802.15.4 standard, Zigbee supports low data exchange rates, low power operation, security, and reliability.

Long Range Wide Area Networks (WAN) solutions:

1. NB-IOT

A product of existing 3GPP technologies, Narrowband IoT is a brand-new radio technology standard that ensures extremely low power consumption (10 years of battery power operation) and provides connectivity with signal strength approx. 23 dB lower than in the case of 2G. What is more, it uses existing network infrastructure, which ensures not only global coverage in LTE networks, but also guaranteed signal quality. In many cases, this fact allows for implementing NB-IoT instead of solutions that required the construction of local networks, such as LoRa or Sigfox.

2. LoRaWAN

LoRaWAN is a low-power Long Range Wide-Area Networking protocol optimized for low-power consumption and supporting large networks with millions of devices. Aiming at wide-area network (WAN) applications, LoRaWAN is designed to furnish low-power WANs with features required to support low-cost, mobile and secure bi-directional communication within IoT, M2M, smart city, and industrialapplications.

3. Sigfox

The concept behind Sigfox is to provide an effective connectivity solution for low-power M2M applications requiring low levels of data transfer for which the WiFi range is too short, and cellular range is too expensive and too power-hungry. Sigfox employs UNB, a technology that enables it to handle low data-transfer speeds of 10 to 1,000 bits per second. Consuming up to 100 times less energy compared to cellular communication solutions, it delivers a typical stand-by time of 20 years for a 2.5Ah battery. Offering a robust, energy-efficient and scalable network able to support communication between thousands of thousands of battery-operated devices across areas of several square kilometres, Sigfox proves suitable for various M2M applications, including smart street lighting, intelligent meters, patient monitors, security devices, and environmental sensors

4. LTE-Cat M1

LTE-Cat M1 is a low-power wide-area (LPWA) connectivity standard that connects IoT and M2M devices with medium data rate requirements. It supports longer battery lifecycles and offers enhanced in-building range as compared to cellular technologies such as 2G, 3G, or LTE-Cat 1. Being compatible with the existing LTE network, CAT M1 doesn't require the carriers to build new infrastructure to implement it. As compared to NB-IoT, LTE Cat M1 proves to be perfect for mobile use cases, as its handling of hand-over between cell sites is significantly better and is very similar to high speed LTE.

IoT vs Embedded Systems

	IoT	Embedded System
Definition	Things that contain computer, software and networking capabilities	Things that contain computers and software.
Example	A talking doll that accepts voice commands and regularly learns new words	A talking doll that never learns but that isn't a privacy concern because it transmits no data.

Table 1.7.1: IoT vs Embedded system

IoT Technology in Transportation

The IoT can assist in the integration of communications, control, and information processing across various transportation systems. Application of the IoT extends to all aspects of transportation systems (i.e. the vehicle, the infrastructure, and the driver or user). Dynamic interaction between these components of a transport system enables inter- and intra-vehicular communication, smart traffic control, smart parking, electronic toll collection systems, logistics and fleet management, vehicle control, safety, and road assistance.

Motivation of the Project

In the present day's scenario, with growing technologies and adverse development in the metropolitan cities, traffic administration has become one of the most important fields to be dealt with. The main role of a traffic administration is to constantly improve the traffic control system and effectively regulate the same. With the number of vehicle users constantly increasing, the facility provided by the current system is limited and inefficient concerning the energy and time consumed. The objective of the project is that we focus on the traffic density rather than just giving control tothe signals on a fixed time basics. It is based on vehicle detection by IR sensors, analysis, and communicates the scenarios to the Arduino UNO and it gives the control depending on the control time. On a whole, this system senses the presence of the vehicle in that given lane and suitably gives control to the signals which help in controlling traffic.

CHAPTER 2

LITERATURE SURVEY

Literature review on research area

As per the exploration paper by G.Kavya and B.Saranya , Density Based Traffic Signal System Using Microcontroller, the enhancement of activity light controller in a city utilizing sensors and microcontroller. By utilizing this framework setup the potential outcomes of congested roads are lessened to some degree which are caused by activity lights, and effectively gets the outcomes. Number of passing vehicles in the settled availability out and about chooses the thickness scope of movement .The recorded information can be downloaded to the PC through correspondenceamongst microcontroller and the PC. Pramod Sharma et al proposed a density based intelligent traffic control system using IR sensors using the ATMEL 89C51 Microcontroller were IR sensors are used for the vehicle detection and the control of the signals are taken over by the microcontroller [5]. As per Shwetha N. Pable, Density, speed, and stream are the three basic parameters for street movement examination. Superior street movement administration and control require ongoing estimation of room, mean speed and thickness as contribution for substantial spatial and fleeting scope of the roadway organize. As Saiba P A et al proposed a density based traffic control system using PIC microcontroller were three IR sensors are employed in each road for the detection of the presence of the automobile and the density is identified in different levels such as low, medium and high. Based on the density recorded, the duration of the green light is decided by the microcontroller [4]. As indicated by K.Vidhya and A.Bazila Banu , utilize the Density estimation by utilizing open instrument as programming for picture preparing by simply showing the different change of picture in the screen lastly encompassing the container on the vehicle in the given picture, the quantity of vehicles are computed. They can figure the thickness of the vehicle by utilizing mat lab device by looking at the four side of the picture which is given as an information. D. D. Pukale et al proposed a density based traffic control system using video processing. With the help of Arduino, the implementation is carried out by analysing the video recordings and extracting the frames using which the vehicle densities is found. Corresponding the density present, the time duration for the specific control of the signal is decided [6].

Review on Literature Survey

The purpose of this project is to control the traffic based on density control and also to reduce the manpower required for controlling. In today's world traffic regulation is one of the biggest problems that need to be solved. Our project helps in controlling the traffic by checking the density present at roads and accordingly changing the traffic signals for smooth flow of vehicles.

Existing Models

Under present scenario, traffic control is achieved by the use of a system of hand signs by traffic police personnel, traffic signals, and markings. Under current circumstances, traffic lights are set on in the different directions with fixed time delay, following a particular cycle while switching from one signal to other creating unwanted and wasteful congestion on one lane while the other lanes remain vacant.

Drawbacks in the existing models:

- The presence of a fixed time period of signal operation irrespective of the lack of comparison of the vehicle densities in the different parts of the road at a junction.
- Even if the road is empty and lacks the presence of vehicles, still receives a fixed time period of green signal which is of no use.
- This can lead to a large levels of traffic congestion since there is no uniform flow of vehicles from all the roads at the junction.
- Human irritability increases and this can be one of the main reasons forsome of the traffic violations such as jumping signals, over speeding, etc. [4]

Proposed model

The main aim of the proposed model is to constantly monitor the vehicle density present in all parts of the road at the junction. The basic flow of operation is as follows: collection of vehicle density data from the roads; next is to send the same data to the device which compares the same and arrives at a particular characteristic output pattern; then the execution of the output pattern which is reflected in the signal pattern. In this model, the IR sensors are used to detect the presence of any vehicle in that part of the road. When detected it sends a triggered output to Arduino UNO which is the heart of the project. Then Arduino analyses the number of such triggered outputs from the set of sensors placed in the different roads at the junction and correspondingly triggers the different LED lights in the signals in order to felicitate the vehicle movement

Advantages in the proposed model

- Traffic can be cleared without any difficulty
- Time can be shared evenly for all intersections
- Effective time management

Conclusion on review

To Overcome all the problems in the existing system in monitoring traffic signals based on density control, in the proposed system we introduced IoT based traffic signal and density control system using Arduino.

Proposed system, consists of mainly two units- in the first unit, we connect the sensors to monitor the traffic and get the information regarding density at roads and Arduino UNO microcontroller board will analyse all those information and change the traffic signals based on the information obtained.

In the second unit, after analysing all the information by the Arduino UNO, It will display the information regarding traffic signals on LCD and also updates all information in the Sever

Here we can monitor the traffic for VIP vehicles by controlling the traffic signals from telnet app that works with the help of IoT technology.

CHAPTER 3

PROJECT DESCRIPTION

Block Diagram

In the present day's scenario, with growing technologies and adverse developmentin the metropolitan cities, traffic administration has become one of the most important fields to be dealt with. The main role of a traffic administration is to constantly improve the traffic control system and effectively regulate the same. With the number of vehicle users constantly increasing, the facility provided by the current system is limited and inefficient concerning the energy and time consumed. The objective of the project is that we focus on the traffic density rather than just giving control to the signals on a fixed time basics. It is based on vehicle detection by IR sensors, where it analysis, and communicates the scenarios to the Arduino UNO and it gives the control depending on the control time. On a whole, this system senses the presence of the vehicle in that given lane and suitably gives control to the signals which help in controlling traffic.

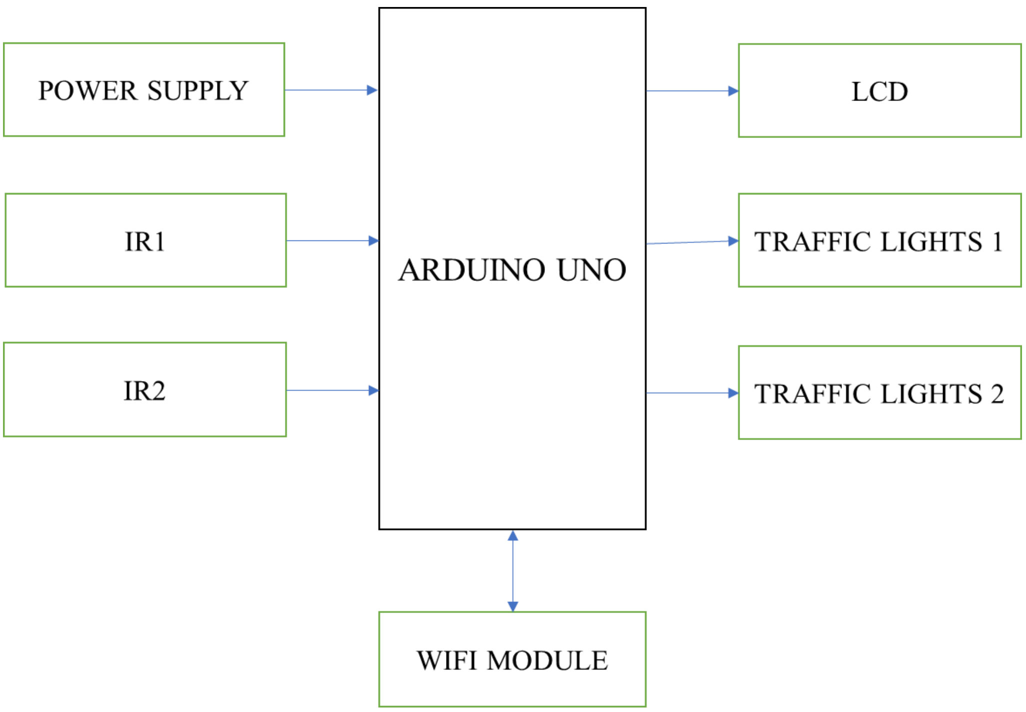

Fig 3.1.1: Block diagram

The blocks of the circuit are:

1. Arduino UNO

2. IR Sensor

3. Traffic Signal module

4. Power supply

5. LCD

6. Wi-Fi Module

1. Arduino UNO

Arduino is open source platform based on easy to use hardware and software. Arduino Uno is a microcontroller board, which has ATmega328P microcontroller in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2. IR Sensor

IR sensor is an electronic device, that emits the light in order to sense some object of the surroundings. IR Infrared Obstacle Avoidance Sensor Module has a pair of infrared transmitting and receiving tubes. When the transmitted light waves are reflected back, the reflected IR waves will be received by the receiver tube. Here the IR Sensor is used to detect the density present at the roads and send the information to the Arduino UNO.

3. Traffic Lights module

The LED Traffic Lights Signal Module / Digital Signal Output Traffic Light Module is a mini-traffic light display module with high brightness and very suitable for the production of a traffic light system model. Here this module is helping us to control the flow of traffic in different lanes by changing the led lights depending upon the density present at the roads.

4. Wi-Fi Module

The ESP8266 Wi-Fi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much Wi-Fi-ability.

5. LCD

The LCD here is used to display us the information regarding the traffic density present at roads. When the traffic density is detected by IR sensor at road 1, the LCD is going to display us ‘Density at Road 1’ and similarly when density is detected at road 2 then the LCD is going to display us that ‘Density at Road 2’. It is also going to display us regarding the manual control for VIP vehicles like ‘VIP vehicle on road 1’ or ‘VIP vehicle on road 2’.

6. Power Supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices.

Schematic Diagram

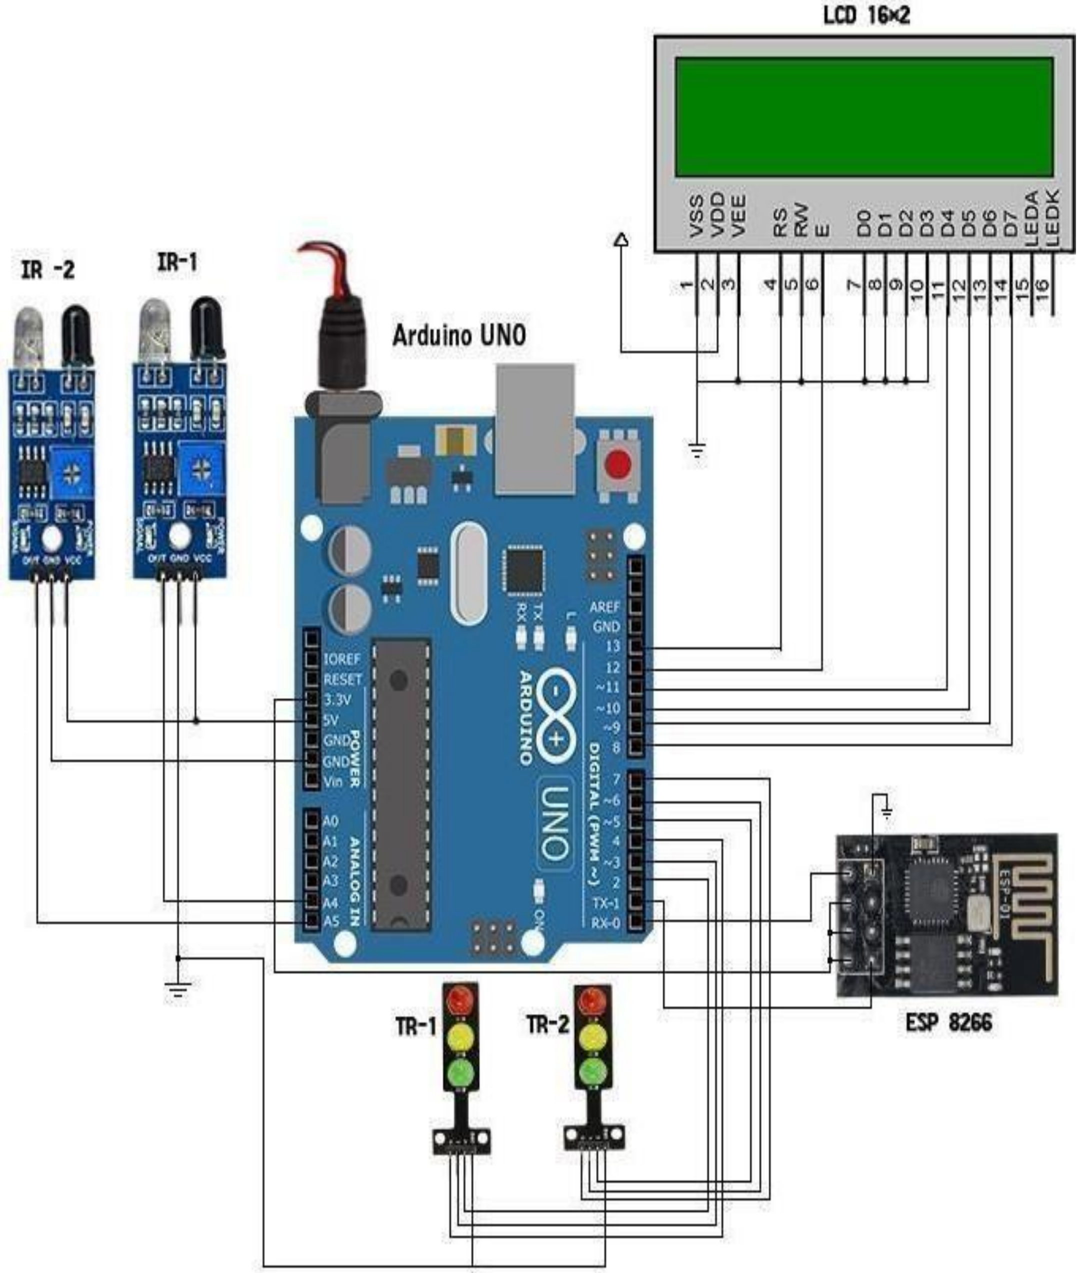

Fig 3.2.1: Schematic Diagram

3.2.1 Schematic Explanation

Arduino UNO has 28 pins among which we has 6 analog pins i.e A0-A5 to which we connect the input and 14 digital pins i.e D0 - D15 where the output devices are connected. The two IR sensors which are our input device has 3 pins each i.e vcc, gnd, out and vcc is connected to 5v supply pin of Arduino, gnd is given to the common ground and out pin is given to the input pin of Arduino A5 and A4 one from each sensor. We use two output devices like traffic lights module which has 4 pins each gnd and other 3 pins are voltage pins of each LED present in it red, yellow, green. So the gnd pin of both the modules are again connected to the common ground and 3 voltage pins of traffic signal module 1 is connected to 2,3,4 digital pins of Arduino and similarly 3 pins of traffic signal module 2 pins are connected to 5,6,7 digital pins of Arduino. We have a Wi-Fi module here where tx pin and rx pin are connected to rx and tx pin the Arduino respectively. Here reset pin, chip enable pin and vcc are connected to Arduino 3.3v pin. We also has a LCD whose data pins 14,13,12,11 are connected to 8,9,10,11 pins of Arduino respectively.

CHAPTER-4

HARDWARE AND SOFTWARE DESCRIPTION

Hardware Components

The hardware components used for the implementation of "IoT Technology based Traffic signal and Density control" are

1. Arduino UNO
2. Power Supply
3. IR sensor
4. LCD
5. Wi-Fi module
6. Traffic lights

Arduino UNO

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message and turn it into an output activating a motor, turning on an led, publishing as it reached a wider community, the Arduino board started something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board.

To do so you use the Arduino programming language (based Wiring), the Arduino Software (IDE), based on Processing. Arduino was born at the area Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming wearable, 3dprinting, and embedded environments. All Arduino boards are completely open-source, empowering from everyday objects to complex scientific instruments.

Professional gathered around open-source plat form, the software too is open-source, it is growing through the contributions of users worldwide, the Arduino board is shown in below figure.

Fig.4.1.1: Arduino uno board

Why Arduino?

Arduino Uno is inexpensive. Arduino is cross platform, its IDE can run on multiple Operating Systems such as Windows, Macintosh, Linux and many more. It has simple and clear programming environment. Its software and hardware are open-source and extensible, that is, Arduino programming can be expanded through C++ libraries and can also leap to AVR ‘C’ language programming.

It is simple and accessible to user experience; Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove the chemistry and physics principles or to get started with programming and robotics.

Designers and the architects build interactive prototypes, musicians, artists use it for installations and to experiment with new musical instruments. Makers of course use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers can start tinkering just following the step by step I constructions of a kit or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers platforms available for physical computing. Parallax Basic Stamp, Netmedia's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-touse package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems.

- **Inexpensive**
  Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50
- **Cross-platform**
  The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux-operating systems. Most microcontroller systems are limited to Windows.
- **Simple, clear programming environment**
  The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- **Open source and extensible software**
  The Arduino software is published as opensource tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- **Open source and extensible hardware**
  The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money and the parts of Arduino board is shown below.

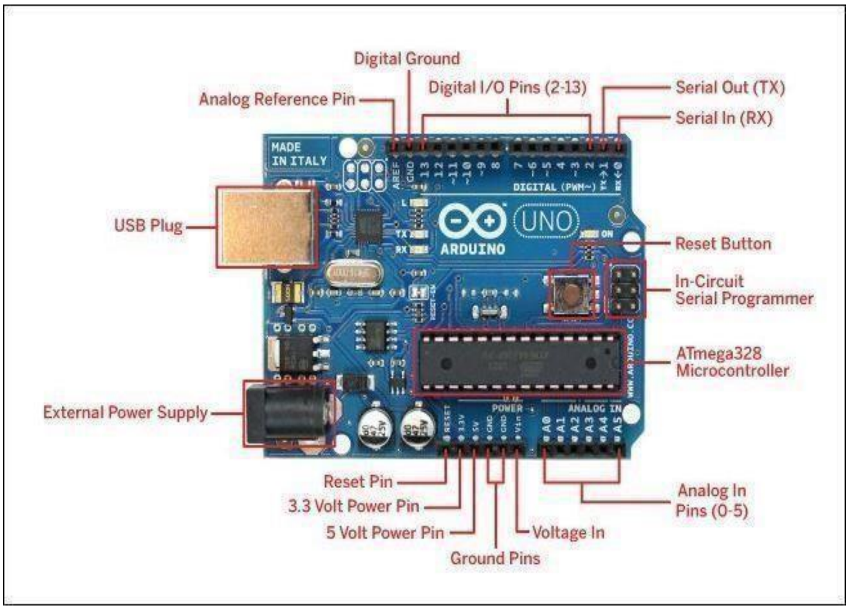

Fig.4.1.2: Arduino board description

Features of Arduino

Micro controller	Atmega328
Operating voltage	5V
Input Voltage(recommended)	7-12V
Input Voltage	6-20V
Digital I/O	14(of which 6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 Ma
DC Current for 3.3V Pin	50 Ma
Flash Memory	32 KB(Atmega328 of which 0.5 KB used by bootloader)
SRAM	2 KB (ATmega32)
EEPROM	1 KB(ATmeha328)
Clock Speed	16 MHz

Table 4.1.1: Features of Arduino uno

- It is an easy USB interface. This allows interface with USB as this is like a serial device.
- The chip on the board plugs straight into your USB port and supports on your computer as a virtual serial port. The benefit of this setup is that serial communication is an extremely easy protocol which is time-tested and USB makes connection with modern computers and makes it comfortable.
- It is easy-to-find the microcontroller brain which is the ATmega328 chip. It has more number of hardware features like timers, external and internal interrupts, PWM pins and multiple sleep modes.
- It is an open source design and there is an advantage of being open source is that it has a large community of people using and troubleshooting it. This makes easy to help in debugging projects.
- It is 16MHz clock which is fast enough for most applications and does not speeds up the microcontroller.
- It is very convenient to manage power inside it and it had a feature of builtin voltage regulation. This also be powered directly off a USB port without any external power. You can connect an external power source of up to 12v and this regulates it to both 5v and 3.3v.
- 14 digital pins and 6 analog pins. This sort of pins allows you to connect hardware to your Arduino Uno board externally. These pins areused as a key for extending the computing capability of the Arduino Uno into the real world. This has an ICSP connector for bypassing the USB port and interfacing the Arduino directly as a serial device. This port is necessary to re-boot load your chip if it corrupts and can no longer used to your computer.
- It has a 32 KB of flash memory for storing your code.
- An on-board led is attached to digital pin 13 to make fast the debugging of code and to make the debug process easy finally it has the button to reset.

Pin Configuration of Arduino UNO

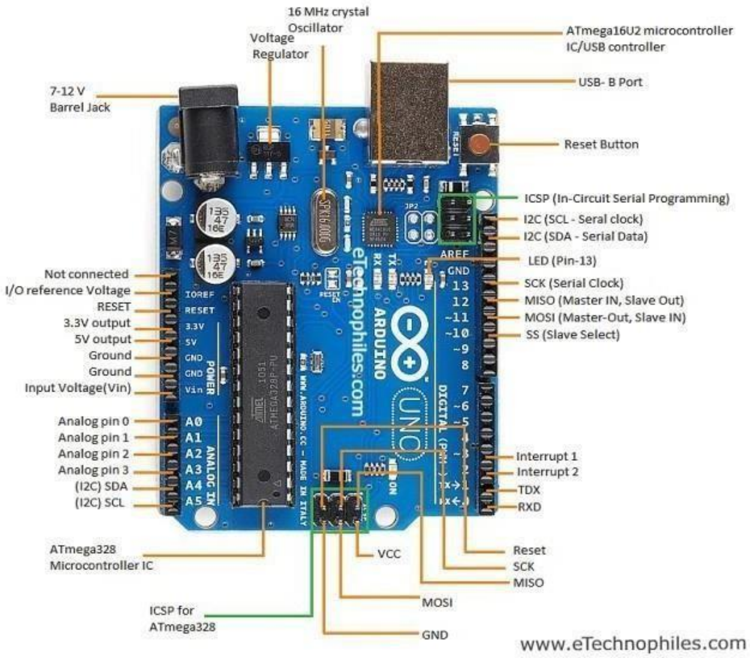

Fig 4.1.3: Pin configuration

- **Reset Pin:** resets the microcontroller.
- **GND :** used to connect the circuit to Ground
- **A0-A5:** used to provide analog input in the range of 0-5V.
- **Digital pins(0-13) :** can be used as input or output pins.
- **0(RX),1(TX) :** used to receive and transmit TTL serial data.
- **AREF :** To provide reference voltage for input voltage.
- **SPI :** used for SPI communication.

Working of Arduino Uno

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The 14 digital input/output pins can be used as input or output pins by using pinMode(), digitalRead() and digitalWrite() functions in arduino programming.

Each pin operate at 5V and can provide or receive a maximum of 40mA current, and has an internal pull-up resistor of 20-50 KOhms which are disconnected by default. Out of these 14 pins, some pins have specific functions as listedbelow:

- **Serial Pins 0 (Rx) and 1 (Tx):** Rx and Tx pins are used to receive andtransmit TTL serial data. They are connected with the corresponding ATmega328P USB to TTL serial chip.
- **External Interrupt Pins 2 and 3:** These pins can be configured to trigger an interrupt on a low value, a rising or falling edge, or a change in value.
- **PWM Pins 3, 5, 6, 9 and 11:** These pins provide an 8-bit PWM output by using analogWrite() function.
- **SPI Pins 10 (SS), 11 (MOSI), 12 (MISO) and 13 (SCK):** These pins are used for SPI communication.
- **In-built LED Pin 13:** This pin is connected with an built-in LED, when pin 13 is HIGH – LED is on and when pin 13 is LOW, its off.
- **Analog pins (A0-A5) :** used to provide analog inputs in the range of 0-5V.

- Analog pin 4 (SDA) and pin 5 (SCA) also used for TWI communication using Wire library.

Arduino Uno has a couple of other pins as explained below:

- **AREF:** Used to provide reference voltage for analog inputs with analog Reference() function.
- **Reset Pin:** resets the microcontroller.

Power

The Arduino Uno can be powered via through USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter (wallwart) or battery. The adapter can be connected by plugging a 2.1mm centrepositive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and Vin pin headers of the POWER connector.

The board can operate on an external supply of 6 to 20 volts. If supplied with less than 7V, however, the 5V pin may supply less than five volts and the board may be unstable. If using more than 12V, the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. the power pins are as follows.

- **VIN.** The input voltage to the Arduino board when it's using an external power source (as opposed to 5 volts from the USB connection or other regulated power source). You can supply voltage through this pin, or, if supplying voltage via the power jack, access it through this pin.
- **5V.** The regulated power supply used to power the microcontroller and other components on the board. This can come either from VIN via an onboard regulator, or be supplied by USB or another regulated 5V supply.
- **3.3V.** A 3.3volt supply generated by the on-board regulator. Maximum current draw is 50 mA.
- GND. Ground pins.

Programming

The Arduino Uno can be programmed with the Arduino Software (IDE). Select Arduino Uno from the Tools Board After your code is compiled using Arduino IDE, it should be uploaded to the main microcontroller of the Arduino UNO using a USB connection. Because the main microcontroller doesn’t have a USB transceiver, you need a bridge to convert signals between the serial interface (UART interface) of the microcontroller and the host USB signals. The ATmega328 on the Arduino Uno comes pre-programmed with a boot loader that allows you to upload new code to it without the use of an external hardware programmer. It communicates using the original STK500 protocol. You can also bypass the bootloader and program the microcontroller through the ICSP (In-Circuit Serial Programming) header using Arduino are similar. The ATmega16U2 (or 8U2 in the rev1&rev2 boards) firmware source code is available in the Arduino repository. The ATmega16U2 or 8U2 is loaded with a DFU bootloader, which can be activated by On Rev1 boards connecting the solder jumper on the back of the board and then resetting the 8U2.

You can then use Atmel's FLIP software (Windows) or the DFU programmer (Mac OS X and Linux) to load a new firmware. Or you can use the ISP header with an external programmer (overwriting the DFU bootloader). Arduino is an open-source hardware platform that is being used by people around the globe for building electronics projects. It is an integrated platform which contains both the physical and programmable circuit otherwise known as microcontroller and a software (or IDE) that you can run on your computer to write and upload the code onto the physical board.

Arduino Board is quite popular among many people who want to get started with electronics, and unlike other embedded system boards Arduino does not require any additional hardware to upload the code (generally known as programmer). Here we will try to understand about the Arduino Architecture and its functionalities. The processor of the Arduino Board uses Harvard Architecture for which the program code and program data have separate memory. The memory of it is divided into two namely program memory and data memory. The data will be stored in the data memory whereas the program code will be stored in the flash program memory. For ex: The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM, 1kb of EPROM and operates at 16MHz clock speed. Some of the other basic functions of Arduino are:

- **Digital write pin** is used to write the digital value of the given pin.
- **Pin mode pin** is used to set the pin to I/O mode.
- **Analog read pin** Reads the value from the specified Analog pin.
- **Analog write pin** writes the value from the specified Analog pin
- **Serial. Begins pin** sets the beginning of serial communication by setting the rate of bit
- **Digital read pin** reads the digital value of given pin.

Advantages

Inexpensive -Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50.

1. Cross-platform - The Arduino software runs on Windows, Macintosh OSX, and the Linux operating systems. Most microcontroller systems are limited to Windows.
2. Simple programming environment- Here the Arduino programming environment is easy-to-use for beginners, yet flexible enough for advanced

users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with the look and feel of Arduino.

3. Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you canadd AVR-C code directly into your Arduino programs if you want to.

Arduino UNO Atmega328

The Arduino UNO is a micro controller board based on the ATmega. UNP means one in Italian and is named to mark the upcoming release of the given Arduino 1.0 it has 14 digital input/output pins, 6 analog inputs, 16MHz ceramic resonator. A USB connection. A power jack, An ICSP header and a reset button.it contains information everything needed to support the microcontroller. simply connect it to a computer with a USB cable or power it with a ac-to-dc adapter or battery to get started.

The UNO differs from all preceding boards in that it does not use the FTDI USB-to serial driver chip. Instead it features the ATMega 16U2ATMega 8U2 up to version instead R2) programmed as a USB to-serial converter

Introduction to Atmega328

ATmega328 is an eight (8) bit Microcontroller. It can handle the data sized of up to eight (8) bits. It is an AVR based micro-controller. Its built-in internal memory is around 32KB. It operates ranging from 3.3V to 5V. It has an ability to store the data even when the electrical supply is removed from its biasing terminals. it is the excellent features include the cost efficiency and low power dissipation, programming lock for security purposes, real timer counter with the separate oscillator and It is generally or normally used in Embedded Systems applications. ATmega-328 is shown in the figure given below.

Fig.4.1.4: ATMega328P Microcontroller

Atmega328 Pin Description

Functions associated with the pins must be known in order to use the device appropriately. ATmega-328 pins are divided into different ports which are given in detail below.

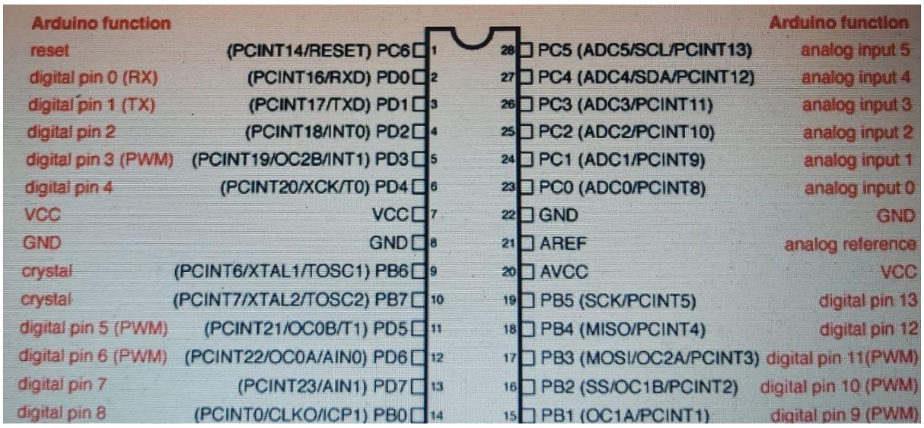

Fig.4.1.5: Arduino UNO to ATmega328P mapping

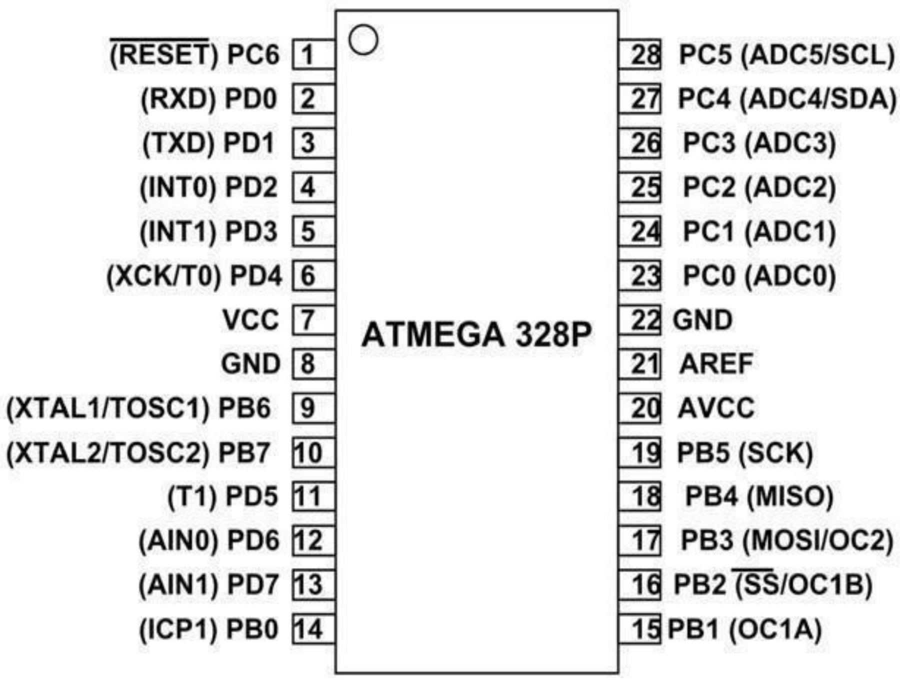

Fig.4.1.6: ATmega328P Ports

AVCC is a supply voltage pin for analog to digital converter.

VCC is a digital voltage supply

GND denotes Ground and it has a 0V.

AREF AREF is the analog reference pin for the A/D converter.

Port B consists of the pins from PB0 to PB5. This port is an 8-bit bidirectional I/O port having an internal pull-up resistor.

Port C consists of the pins from PC0 to PC6. This port is an 7-bit bidirectional I/O port, where PC6 is used as a reset input.

Port D consists of the pins from PD0 to PD7. It is also an 8bit input/output port having an internal pull-up resistor.

Applications of Arduino Uno

- Arduino Uno is used in Do-it-Yourself projects prototyping.
- In developing projects based on code-based control
- Development of Automation System
- Designing of basic circuit designs.

Power Supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices.

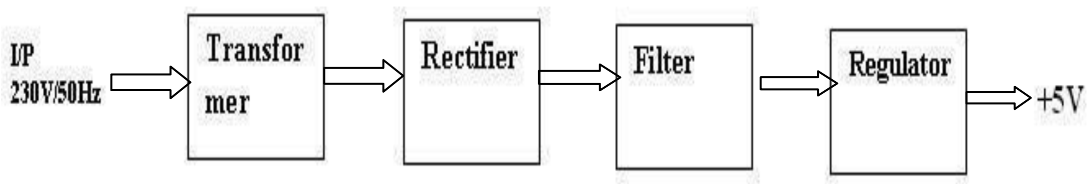

Fig 4.1.7: Block Diagram of Power supply

There are various types of power electronic converters such as step-down converter, step-up converter, voltage stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply

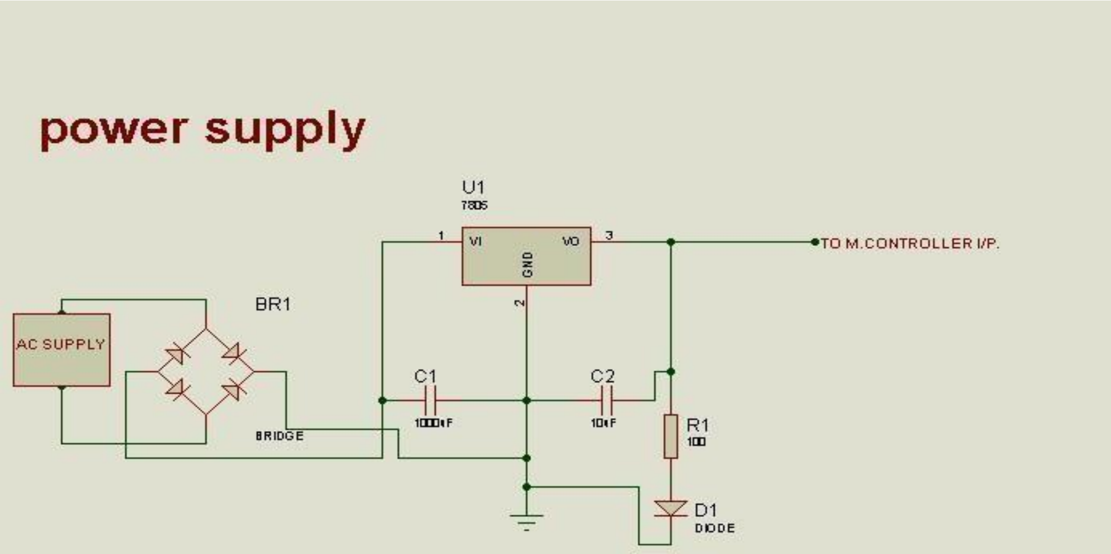

Fig 4.1.8: Circuit diagram of Power supply

IR SENSOR

Infrared technology addresses a wide variety of wireless applications. The main areas are sensing and remote controls. In the electromagnetic spectrum, the infrared portion is divided into three regions: near infrared region, mid infrared region and far infrared region.

The wavelengths of these regions and their applications are shown below.

- Near infrared region — 700 nm to 1400 nm — IR sensors, fibre optic
- Mid infrared region — 1400 nm to 3000 nm — Heat sensing
- Far infrared region — 3000 nm to 1 mm — Thermal imaging

The frequency range of infrared is higher than microwave and lesser than visible light.

For optical sensing and optical communication, photo optics technologies are used in the near infrared region as the light is less complex than RF when implemented as a source of signal. Optical wireless communication is done with IR data transmission for short range applications

An infrared sensor emits and/or detects infrared radiation to sense its surroundings. The working of any Infrared sensor is governed by three laws: Planck's Radiation law, Stephen – Boltzmann law and Wien's Displacement law. Planck's law states that "every object emits radiation at a temperature not equal to 0^0K". Stephen – Boltzmann law states that "at all wavelengths, the total energy emitted by a black body is proportional to the fourth power of the absolute temperature". According to Wien's Displacement law, "the radiation curve of a black body for different temperatures will reach its peak at a wavelength inversely proportional to the temperature".

The basic concept of an Infrared Sensor which is used as Obstacle detector is to transmit an infrared signal, this infrared signal bounces from the surface of an object and the signal is received at the infrared receiver. There are five basic elements used in a typical infrared detection system: an infrared source, a transmission medium, optical component, infrared detectors or receivers and signal processing. Infrared lasers and Infrared LED's of specific wavelength can be used as infrared sources. The three main types of media used for infrared transmission are vacuum, atmosphere and optical fibres. Optical components are used to focus the infrared radiation or to limit the spectral response.

Optical lenses made of Quartz, Germanium and Silicon are used to focus the infrared radiation. Infrared receivers can be photodiodes, phototransistors etc. some important specifications of infrared receivers are photosensitivity, detectivity and noise equivalent power. Signal processing is done by amplifiers as the output of infrared detector is very small.

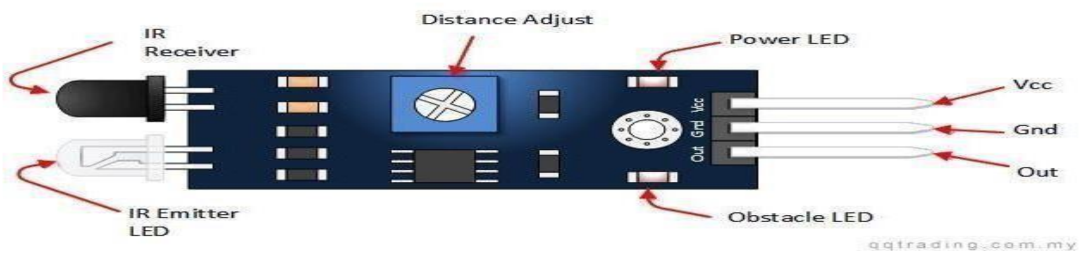

Fig 4.1.9: Basic parts of IR Sensor

Types of IR Sensors

Infrared sensors can be passive or active. Passive infrared sensors are basically Infrared detectors. Passive infrared sensors do not use any infrared source and detects energy emitted by obstacles in the field of view. They are of two types: quantum and thermal. Thermal infrared sensors use infrared energy as the source of heat and are independent of wavelength. Thermocouples, pyroelectric detectors and bolometers are the common types of thermal infrared detectors.

Quantum type infrared detectors offer higher detection performance and are faster than thermal type infrared detectors. The photosensitivity of quantum type detectors is wavelength dependent. Quantum type detectors are further classified into two types: intrinsic and extrinsic types. Intrinsic type quantum detectors are photoconductive cells and photovoltaic cells.

Active infrared sensors consist of two elements: infrared source and infrared detector. Infrared sources include an LED or infrared laser diode. Infrared detectors include photodiodes or phototransistors. The energy emitted by the infrared source is reflected by an object and falls on the infrared detector.

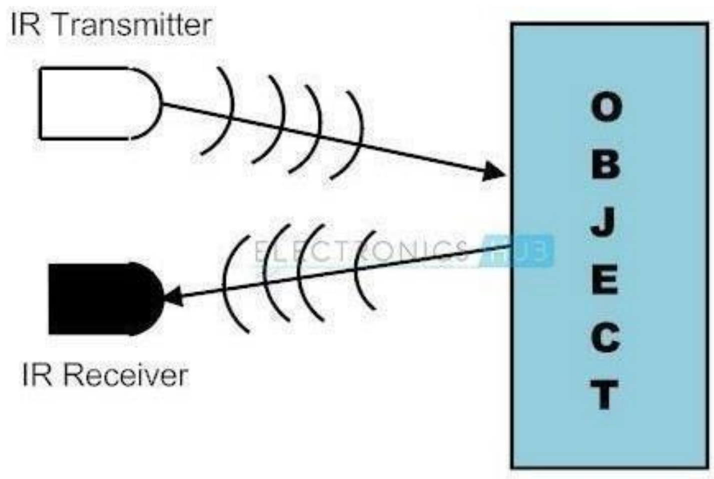

Fig 4.1.10: IR Sensor

IR Transmitter

Infrared Transmitter is a light emitting diode (LED) which emits infrared radiations. Hence, they are called IR LED's. Even though an IR LED looks like a normal LED, the radiation emitted by it is invisible to the human eye.

Fig 4.1.11: IR Transmitter

There are different types of infrared transmitters depending on their wavelengths, output power and response time. A simple infrared transmitter can be constructed using an infrared LED, a current limiting resistor and a power supply.

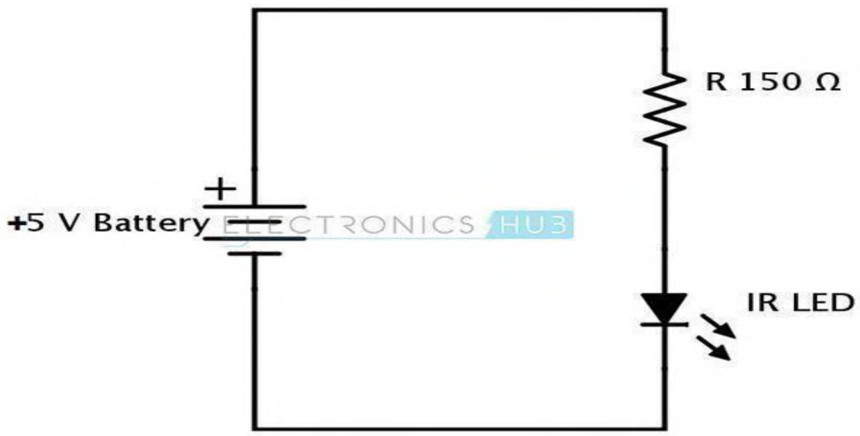

Fig.4.1.12: Schematic of IR Transmitter

When operated at a supply of 5V, the IR transmitter consumes about 3 to 5 mA of current. Infrared transmitters can be modulated to produce a particular frequency of infrared light. The most commonly used modulation is OOK (ON – OFF – KEYING) modulation.

IR transmitters can be found in several applications. Some applicationsrequire infrared heat and the best infrared source is infrared transmitter. When infrared emitters are used with Quartz, solar cells can be made.

IR Receiver

Infrared receivers are also called as infrared sensors as they detect the radiation from an IR transmitter. IR receivers come in the form of photodiodes and phototransistors. Infrared Photodiodes are different from normal photo diodes as they detect only infrared radiation.

Fig.4.1.13: IR Receiver

Different types of IR receivers exist based on the wavelength, voltage, package, etc. When used in an infrared transmitter – receiver combination, the wavelength of the receiver should match with that of the transmitter.

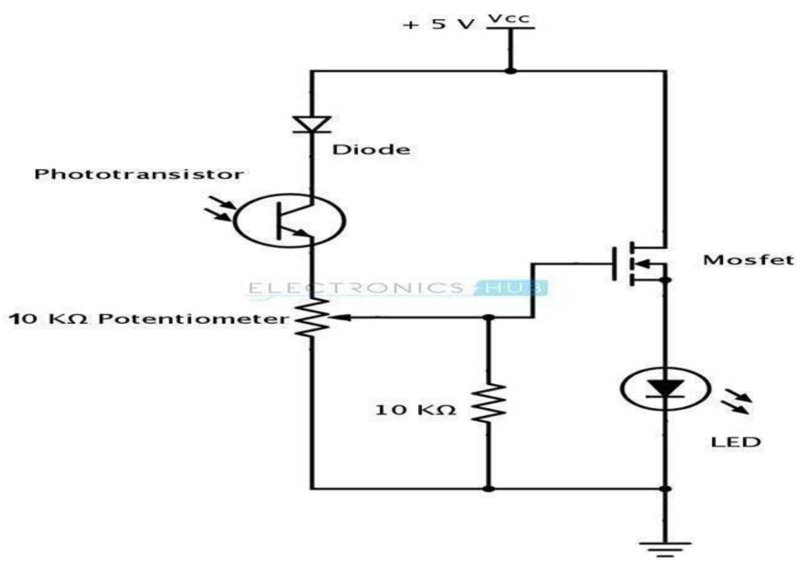

Fig.4.1.14: Infrared Receiver circuit using a phototransistor

It Consist of an IR phototransistor, a diode, a MOSFET, a potentiometer and an LED. When the phototransistor receives any infrared radiation, current flows through it and MOSFET turns on. This in turn lights up the LED which acts as a load. The potentiometer is used to control the sensitivity of the phototransistor.

Principle of Working

The principle of an IR sensor working as an Object Detection Sensor can be explained using the following figure. An IR sensor consists of an IR LED and an IR Photodiode; together they are called as Photo – Coupler or Opto – Coupler.

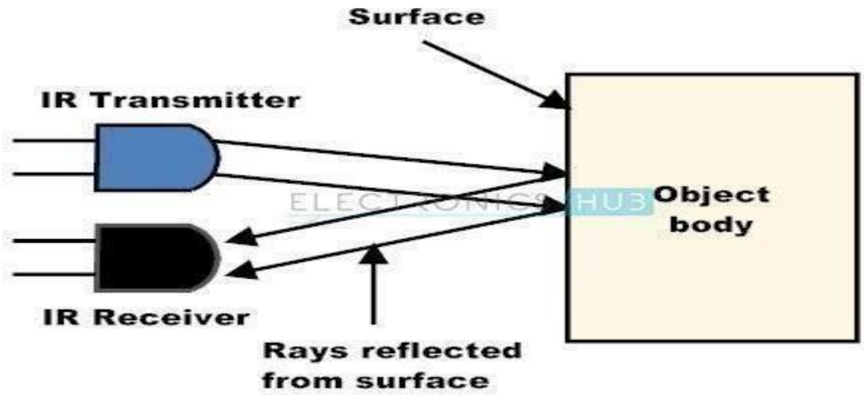

Fig.4.1.15: Working of IR Sensor

When the IR transmitter emits radiation, it reaches the object and some of the radiation reflects back to the IR receiver. Based on the intensity of the reception by the IR receiver, the output of the sensor is defined.

Pin Configuration

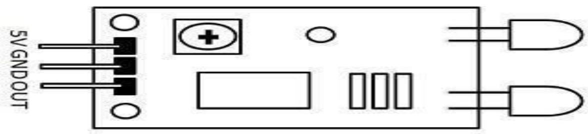

Fig 4.1.16: Pin Configuration

- Vcc – Power supply input of 5v
- GND – Power supply ground
- OUT - Active high output

Features

- 5VDC Operating voltage
- I/O pins are 5V and 3.3V compliant
- Range: Up to 20cm
- Adjustable Sensing range
- Built-in Ambient Light Sensor
- 20mA supply current

Applications

- Obstacle Detection
- Industrial safety devices
- Wheel encode

LCD (Liquid Crystal Display)

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0) For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Pin	Symbol	I/O	Description
1	GND	-	Ground
2	Vcc	-	+5V power supply
3	VEE	-	Contrast control
4	RS	I	command/data register selection
5	R/W	I	write/read selection
6	E	I/O	Enable
7	DB0	I/O	The 8-bit data bus
8	DB1	I/O	The 8-bit data bus
9	DB2	I/O	The 8-bit data bus
10	DB3	I/O	The 8-bit data bus
11	DB4	I/O	The 8-bit data bus
12	DB5	I/O	The 8-bit data bus
13	DB6	I/O	The 8-bit data bus
14	DB7	I/O	The 8-bit data bus

Table.4.1.2: LCD Pin Description

Pin Description Of 16x2:

- Pin1 (Ground/Source Pin): This is a GND pin of display, used to connect the GND terminal of the microcontroller unit or power source.
- Pin2 (VCC/Source Pin): This is the voltage supply pin of the display, used to connect the supply pin of the power source.
- Pin3 (V0/VEE/Control Pin): This pin regulates the difference of the display, used to connect a changeable POT that can supply 0 to 5V.
- Pin4 (Register Select/Control Pin): This pin toggles among command or data register, used to connect a microcontroller unit pin and obtains either 0 or 1(0 = data mode, and 1 = command mode).
- Pin5 (Read/Write/Control Pin): This pin toggles the display among the read or writes operation, and it is connected to a microcontroller unit pin to get either 0 or 1 (0 = Write Operation, and 1 = Read Operation).

- Pin 6 (Enable/Control Pin): This pin should be held high to execute Read/Write process, and it is connected to the microcontroller unit & constantly held high.
- Pins 7-14 (Data Pins): These pins are used to send data to the display. These pins are connected in two-wire modes like 4-wire mode and 8-wire mode. In 4-wire mode, only four pins are connected to the microcontroller unit like 0 to 3, whereas in 8-wire mode, 8-pins are connected to microcontroller unit like 0 to 7.
- Pin15 (+ve pin of the LED): This pin is connected to +5V
- Pin 16 (-ve pin of the LED): This pin is connected to GND.

Schematic Diagram

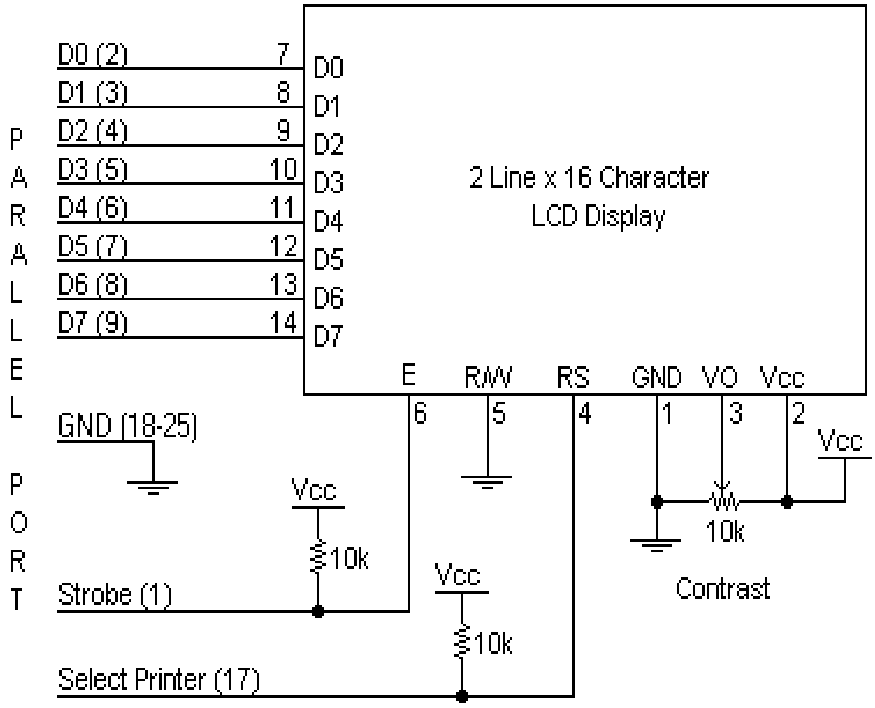

Fig.4.1.17: Schematic Diagram of LCD

- Above is the quite simple schematic. The LCD panel's Enable and register select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit ismore portable for a wider range of computers, some of which may have no internal pull up resistors.

- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you havetrouble with the circuit working properly.

Code (hex)	Command to LCD Instruction Register
1	Clear display screen
2	Return home
4	Shift cursor to left
5	Shift display right
6	Shift cursor to right
7	Shift display left
8	Display off, Cursor off
A	Display off, Cursor on
C	Display on, cursor off
E	Display on, cursor blinking
F	Display on, cursor blinking
10	Shift cursor position to left
14	Shift cursor position to right
18	Shift the entire display to the left
1C	Shift the entire display to the right
80	Force cursor to beginning of 1st line
C0	Force cursor to beginning of 2nd line
38	2 lines and 5x7 matrix

Table 4.1.3: LCD commands

Features

- Operating Voltage is 4.7V to 5.3V
- Current consumption is 1mA without backlight
- Alphanumeric LCD display module, meaning can display alphabets
- Consists of two rows and each row can print 16 characters.
- Each character is build by a 5×8 pixel box
- Can work on both 8-bit and 4-bit mode
- It can also display any custom generated characters
- Available in Green and Blue Backlight

Applications

- In most of the applications that’s have only small values to show, uses the LCD.
- Most of the commercial meters use this module to represent the data output.
- In the toys and developing projects, it is still vastly in use.
- In black and white printers, it helps to show the printer settings and status.

Wi-Fi Module ESP8266

ESP8266 is a complete and self-contained Wi-Fi network solutions that can carry software applications, or through Another application processor uninstall all Wi-Fi networking capabilities. ESP8266 when the device is mounted and as the only application of the application processor, the flash memory can be started directly from an external Move. Built-in cache memory will help improve system performance and reduce memory requirements. Another situation is when wireless Internet access assume the task of Wi-Fi adapter, you can add it to any microcontroller-based design, the connection is simple, just by SPI / SDIO interface or central processor AHB bridge interface. Processing and storage capacity on ESP8266 powerful piece, it can be integrated via GPIO ports sensors and other applications specific equipment to achieve the lowest early in the development and operation of at least occupy system resources. The ESP8266 highly integrated chip, including antenna switch balun, power management converter, so with minimal external circuitry, and includes front-end module, including the entire solution designed to minimize the space occupied by PCB. The system is equipped with ESP8266 manifested leading features are: energy saving VoIP quickly switch between the sleep / wake patterns, with low-power operation adaptive radio bias, front-end signal processing functions, troubleshooting and radio systems coexist characteristics eliminate cellular / Bluetooth / DDR / LVDS / LCD interference.

Fig 4.1.18: Wi-fi Module

Pin Configuration

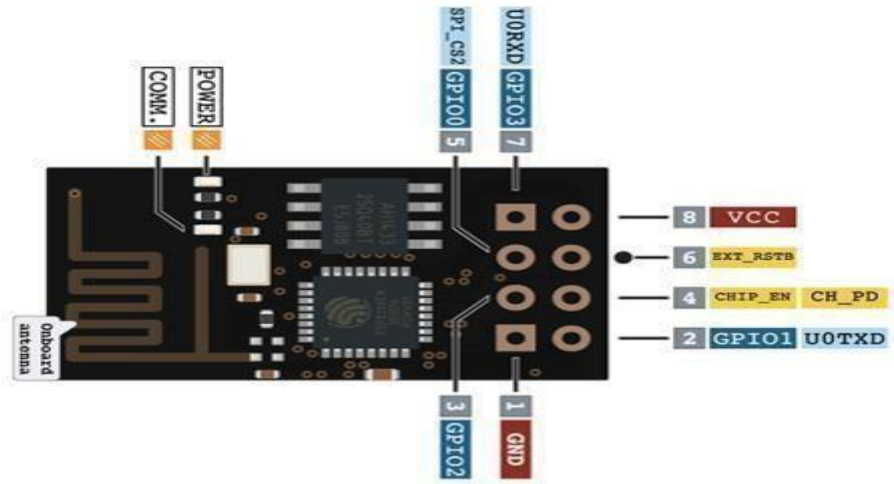

Fig 4.1.19: Pin Configuration

- Ground - Connected to the ground of the circuit
- Tx - Connected to Rx pin of programmer/microcontroller to upload program
- GPIO 2 - General purpose Input/output pin
- CH_EN - Chip Enable – Active high
- GPIO 0 - General purpose Input/output pin
- Reset – Reset pin is the Active low pin that resets the Wi-Fi module
- Rx - Connected to Tx pin of microcontroller to collect the data
- Vcc - Connect to +3.3V only

Ultra-low power technology

ESP8266 specifically for mobile devices, wearable electronics and networking applications design and make the machine to achieve the lowest energy consumption, together with several other patented technology. This energyefficient construction in three modes: active mode, sleep mode and deep sleep mode type. When ESP8266 using high-end power management technology and logic systems to reduce non-essential functions of the power conversion regulate sleep patterns and work modes, in sleep mode, it consumes less than the current 12uA, is connected, it consumes less power to 1.0mW (DTIM = 3) or 0.5mW (DTIM = 10). Sleep mode, only calibrated real-time clock and watchdog in working condition. Real-time clock can be programmed to wake ESP8266 within a specific period of time. Through programming, ESP8266 will automatically wake up when detected certain to happen. ESP8266 automatic wake-up in the shortest time, this feature can be applied to the SOC for mobile devices, so before you turn Wi- Fi SOC are in a low-power standby mode. To meet the power requirements of mobile devices and wearable electronics products, ESP8266 at close range when the PA output power can be reduced through software programming to reduce overall power consumption in order to adapt to different applications.

Specifications

- 802.11 b / g / n
- Wi-Fi Direct (P2P), soft-AP
- Built-in TCP / IP protocol stack
- Built-in TR switch, balun, LNA, power amplifier and matching network
- Built-in PLL, voltage regulator and power management components
- 802.11b mode + 19.5dBm output power
- Built-in temperature sensor
- Support antenna diversity
- off leakage current is less than 10uA
- Built-in low-power 32-bit CPU: can double as an application processor

- SDIO 2.0, SPI, UART
- STBC, 1x1 MIMO, 2x1 MIMO
- A-MPDU, A-MSDU aggregation and the 0.4 Within wake
- 2ms, connect and transfer data packets
- standby power consumption of less than 1.0mW (DTIM3)

Applications

- Smart Power Plug
- Home Automation
- mesh network
- industrial wireless control
- Baby Monitor
- Network Camera
- sensor networks
- wearable electronics
- wireless location-aware devices
- Security ID tag

Traffic Signal Module

The LED Traffic Lights Signal Module / Digital Signal Output Traffic Light Module is a mini-traffic light display module, high brightness, very suitable for the production of a traffic light system model.

Fig 4.1.20: Traffic Signal Module

1. GND – connected to the ground of the circuit
2. R – Red LED voltage pin

3. Y – Yellow LED voltage pin
4. G – Green LED voltage pin

Specifications

- PCB Size: 60 x 20 x 13.5 (LxWxH)mm.
- Colour: red, yellow, green
- LED Size: 10mm x 7.
- Brightness: Normal brightness.
- Voltage: 5V.
- Interface: common cathode red yellow green control

Application

- Analog traffic signal system
- Teaching demonstration
- Indication sign
- Light alarm system

Software Requirement

- Arduino IDE software
- Proteus

Arduino IDE software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually. When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.2.1: USB Cable A plug to B plug

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.4.2.2: USB Cable A plug to Mini-B plug

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

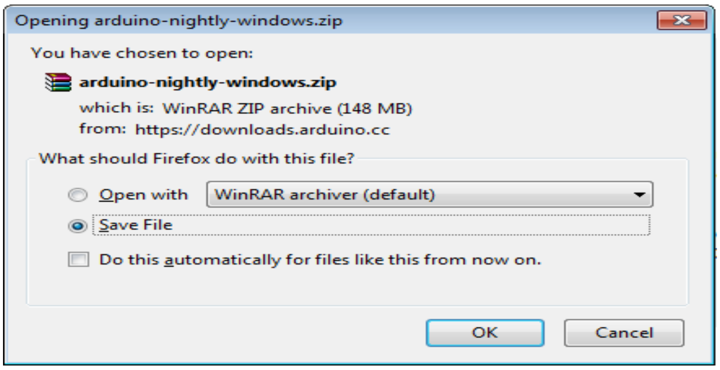

Fig.4.2.3: Unzip of Arduino IDE software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port. Connect the Arduino board to your computer using the USB cable. The green power LED (labelled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

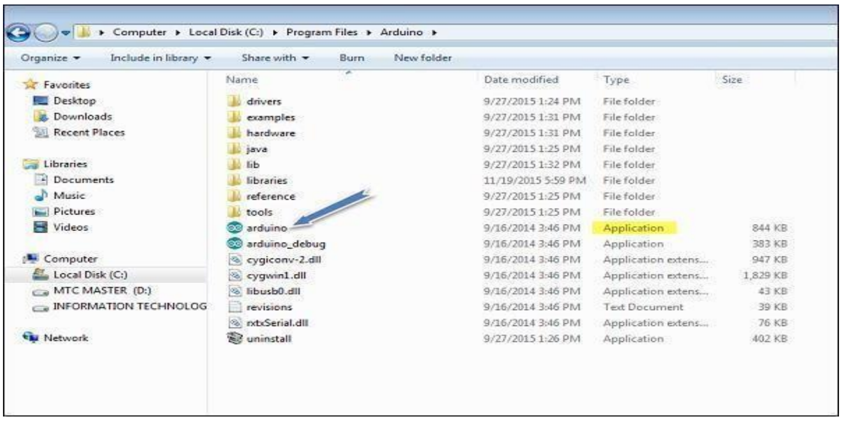

Fig.4.2.4: Open IDE software

Step 5 − Open your first project.

Once the software starts, you have two options:

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

To open an existing project example, select

File → Example → Basics → Blink.

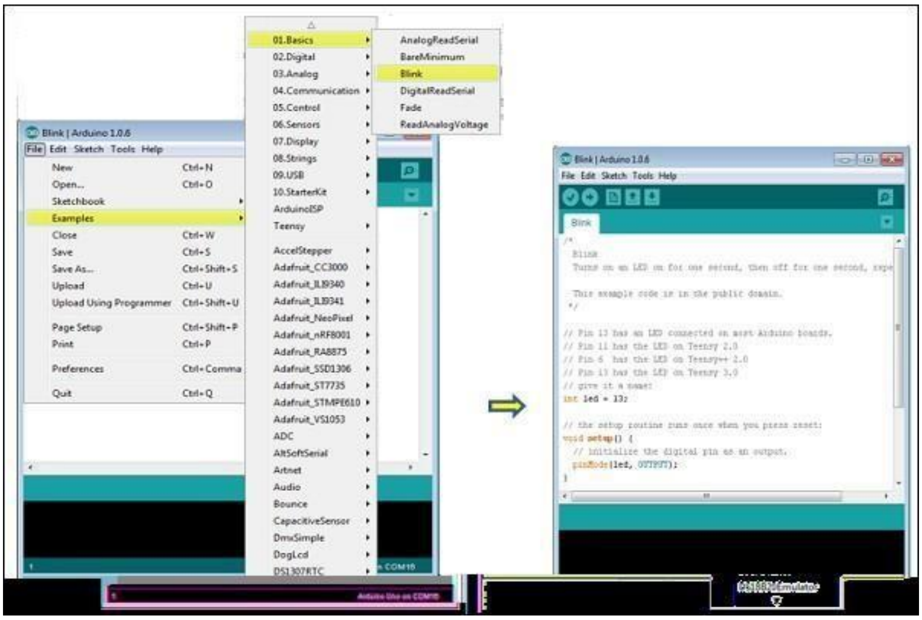

Fig.4.2.5: Open existing Project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

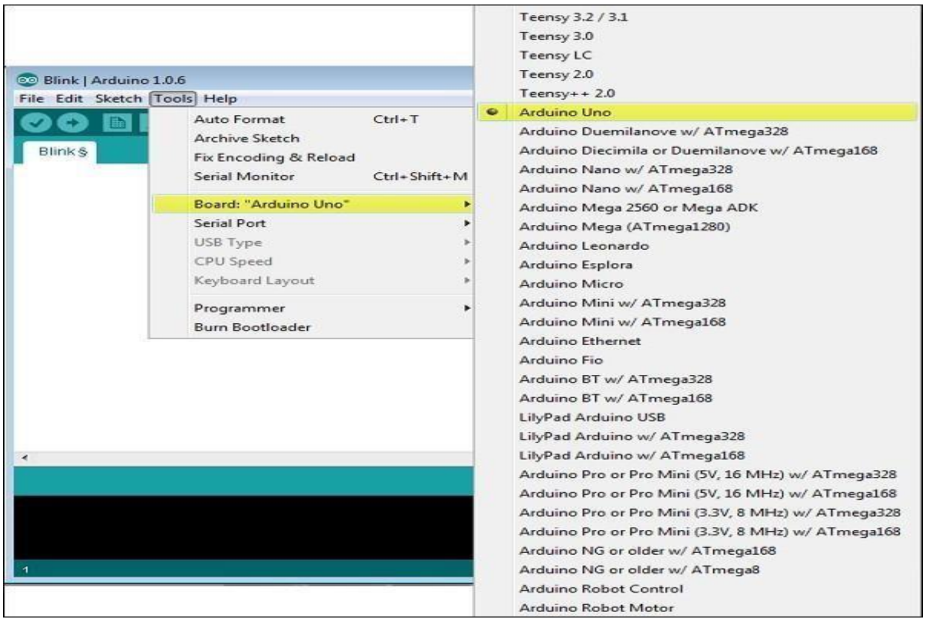

Fig.4.2.6: Selection of Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

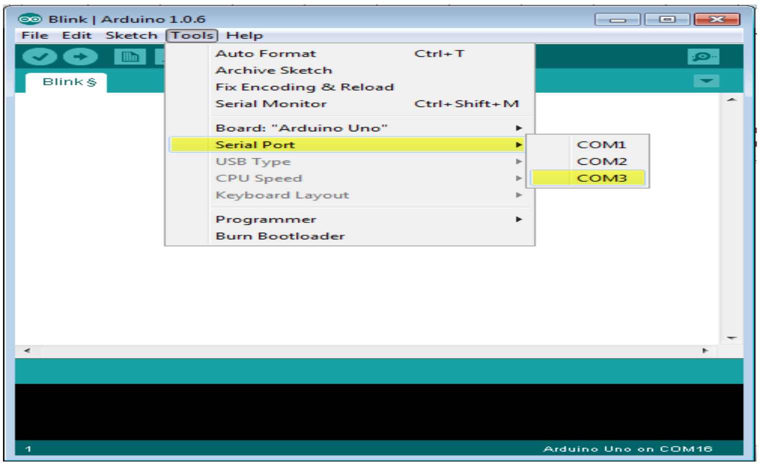

Fig.4.2.7: Selection of Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

Fig.4.2.8: Uploading the program to board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. Here is what this looks like.

Fig.4.2.9: Battery connected to Arduino

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving on

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

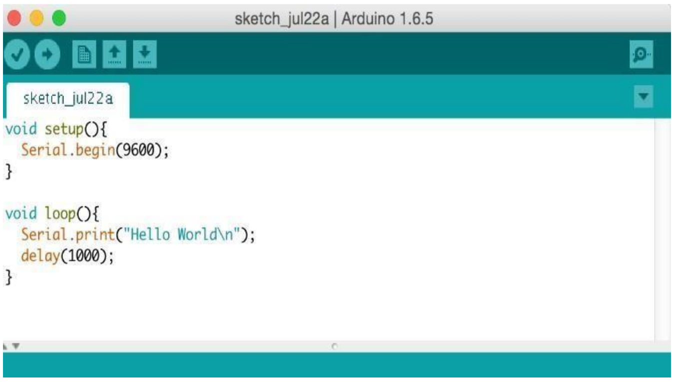

Fig.4.2.10: Program in Arduino-speak

Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion" .

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

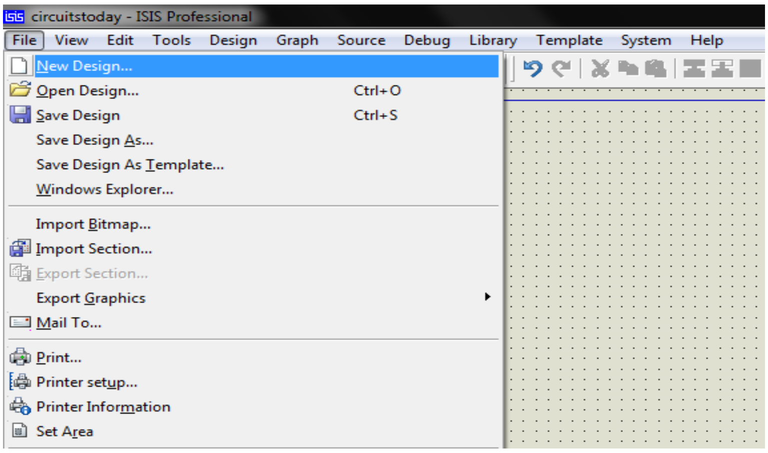

Fig.4.2.11: Proteus file menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

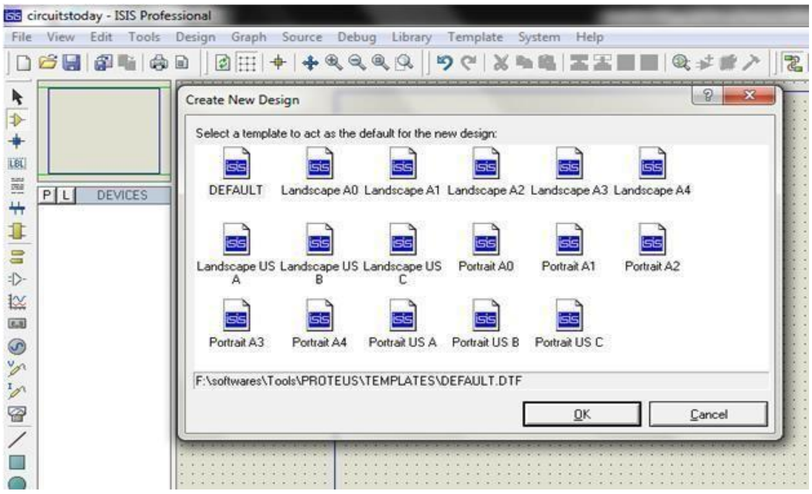

Fig. 4.2.12: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout.

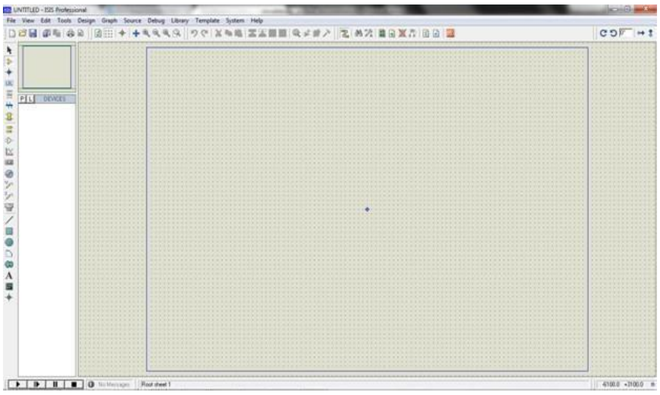

Fig. 4.2.13: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

Step 6: Select the components from categories or type the part name in Keywords text box.

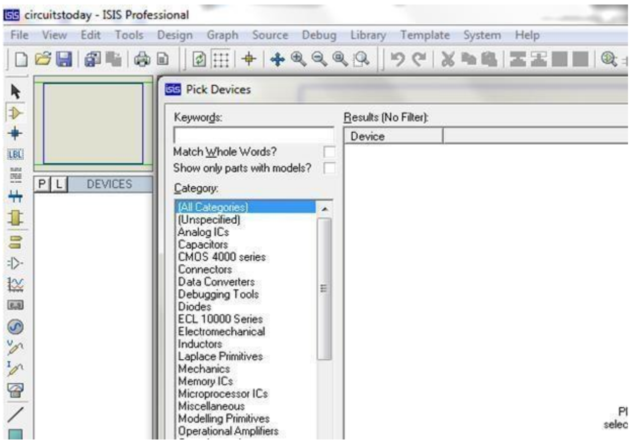

Fig.4.2.14: Keywords Textbox

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

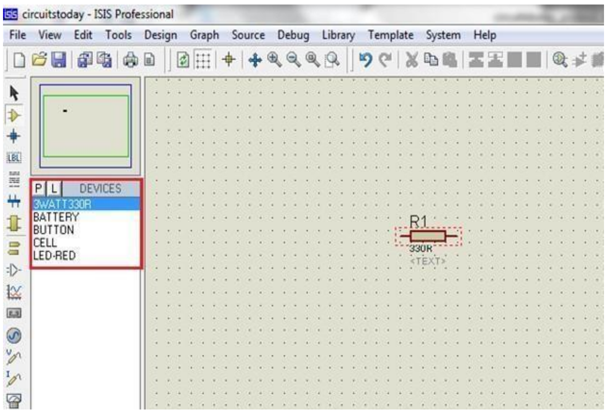

Fig. 4.2.15: Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

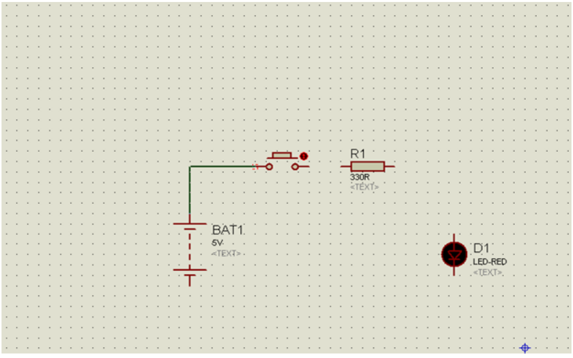

Fig.4.2.16: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

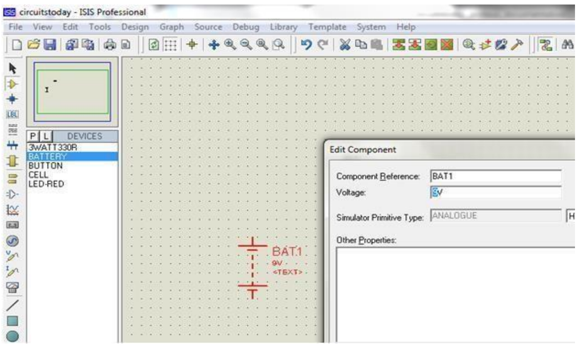

Fig.4.2.17: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

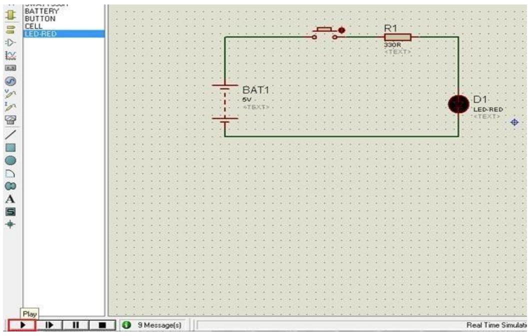

Fig.4.2.18: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

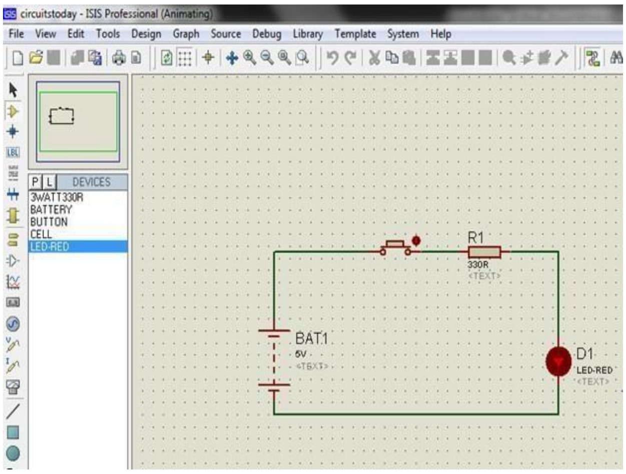

Fig.4.2.19: Simulation Animating

Simulation can be stepped, paused or stopped at any time

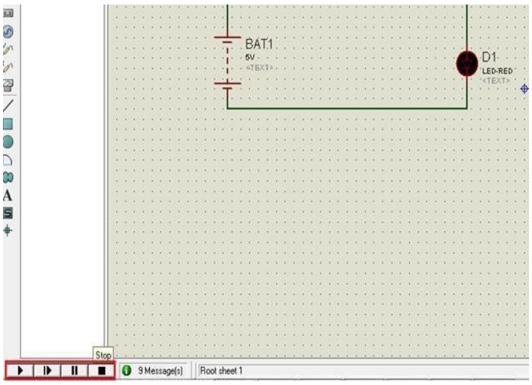

Fig.4.2.20: Simulation Step-Pause-Stop Buttons

CHAPTER 5

SOFTWARE TESTING AND CODE IMPLEMENTATION

Software Testing

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

Testing Levels

There are various testing levels based on the specificity of test.

- **Unit testing:** Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.
- **Integration Testing:** Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.
- **System Testing:** System testing tests a completely integrated system to verify that the system meets its requirements.
- **Acceptance testing:** Acceptance testing tests the readiness of application, satisfying all requirements.
- **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

System Test Cases

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement.

We have designed and executed a few test cases to check if the project meets the functional requirements.

Code Implementation

5.4.1 Project Code

```
#include"LiquidCrystal.h"

LiquidCrystal lcd(13,12,11,10,9,8);

int
red_led_road_1=2,yellow_led_road_1=3,green_led_road_1=4,red_led_road_2=5,yellow_le
d_road_2=6,green_led_road_2=7;

int sensor_road_1=A4,sensor_road_2=A5;

#include<SoftwareSerial.h>

char inputByte;

void setup()

{

  Serial.begin(9600);

  lcd.begin(16,2);

  lcd.clear();

  lcd.setCursor(0,0);

  lcd.print("IOT Based");

  delay(200);

  lcd.setCursor(0,1);

  lcd.print("Traffic Control");

  delay(3000);

CHAPTER 6

RESULT ANALYSIS

Working of traffic lights at normal condition

This hardware setup gives a brief idea as to how the project “IoT Technology based Traffic Signal and Density Control” works. As Initially when there is normal flow of traffic then this system works normally with a fixed time delay that we have set. The LCD which we have used displays us that is it working in normal condition.

The code below is the condition for normal functioning of traffic signals.

Fig 6.1.1: LCD display for Normal condition

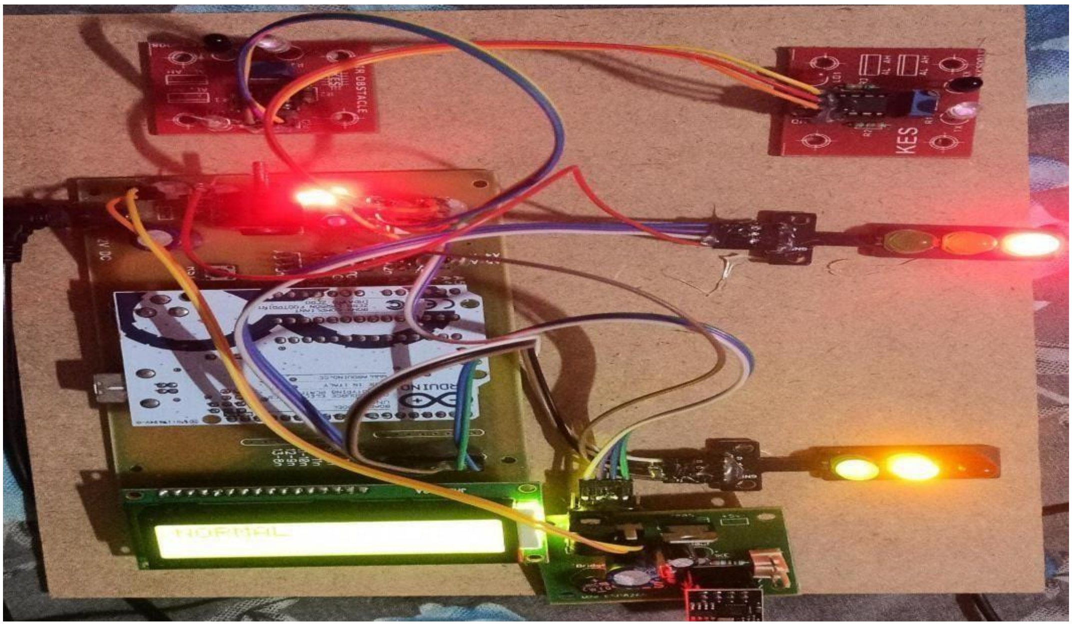

Fig 6.1.2: Normal functioning of the traffic signal

Working of traffic lights based on Density

When the IR Sensor senses that there is density present at 1 road and not in the other, then we use this kind of condition depending on the density present on which road.

Density at road 1

- When the IR Sensor senses that there is density present at road 1 and not in the road 2, then we use this kind of condition for working of traffic signals.
- Condition for the working of traffic signal when density is present in road 1

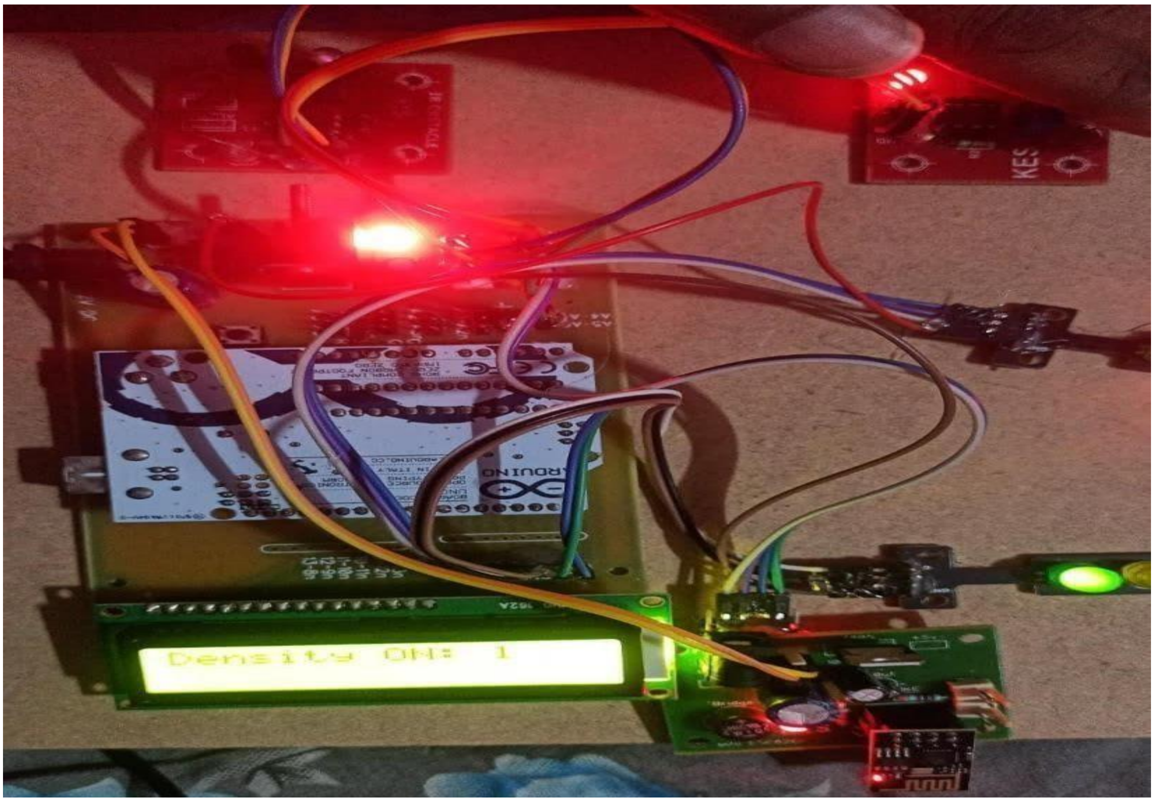

Fig 6.2.1: Working of traffic signals when Density is at road 1

Fig 6.2.2: LCD display when Density is at road 1

Density at road 2

- When the IR Sensor senses that there is density present at road 2 and not in the road 1, then we use this kind of condition for working of traffic signals.
- Condition for the working of traffic signal when density is present in road 2

Fig 6.2.3: LCD display when Density is at road 2

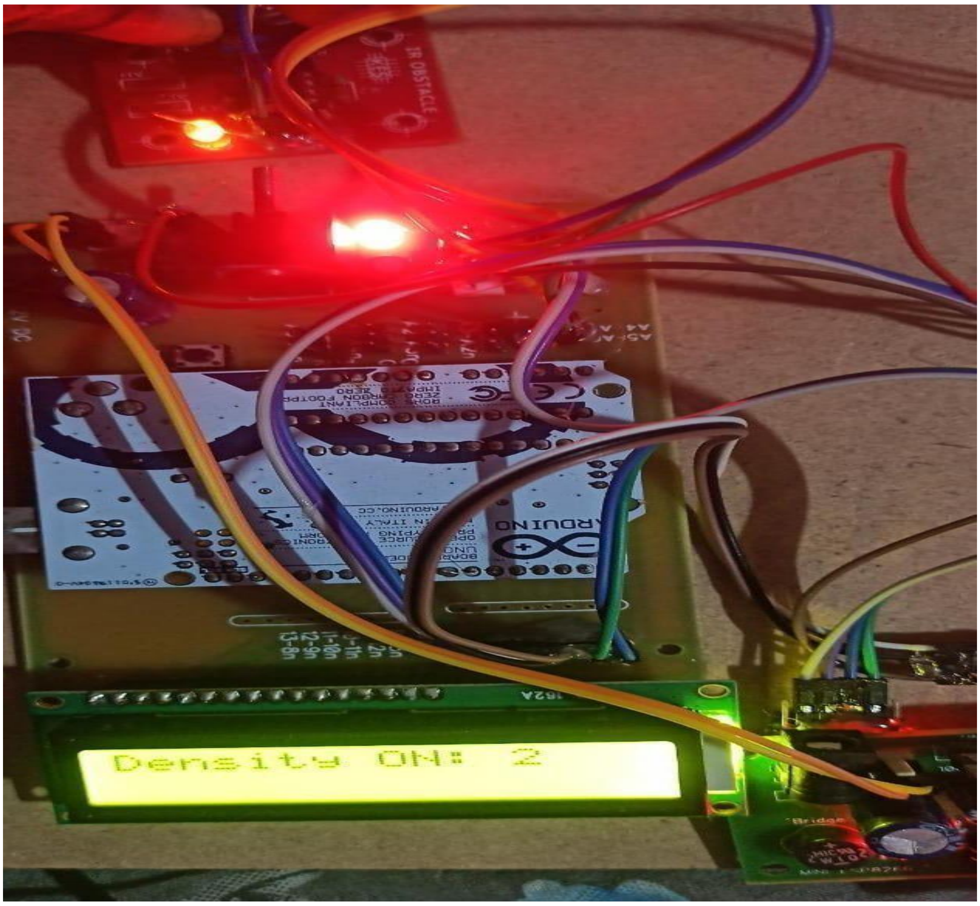

Fig 6.2.4: Working of traffic signals when Density is at road 2

Manually monitoring for VIP Vehicle

- Here we are manually monitoring the control for VIP vehicles using TELNET app through the mobile phone.

VIP vehicle at road 1

- This condition is used where ever we want to manually allow any VIP vehicle that is struck at road 1. This condition allows us to clear the lane when we spot a VIP vehicle on the road 1.
- Here we need to click * in the Telnet app so that green signal is at road 1 and red signal at road 2.
- Condition for the working of traffic signal when VIP vehicle is present at road 1

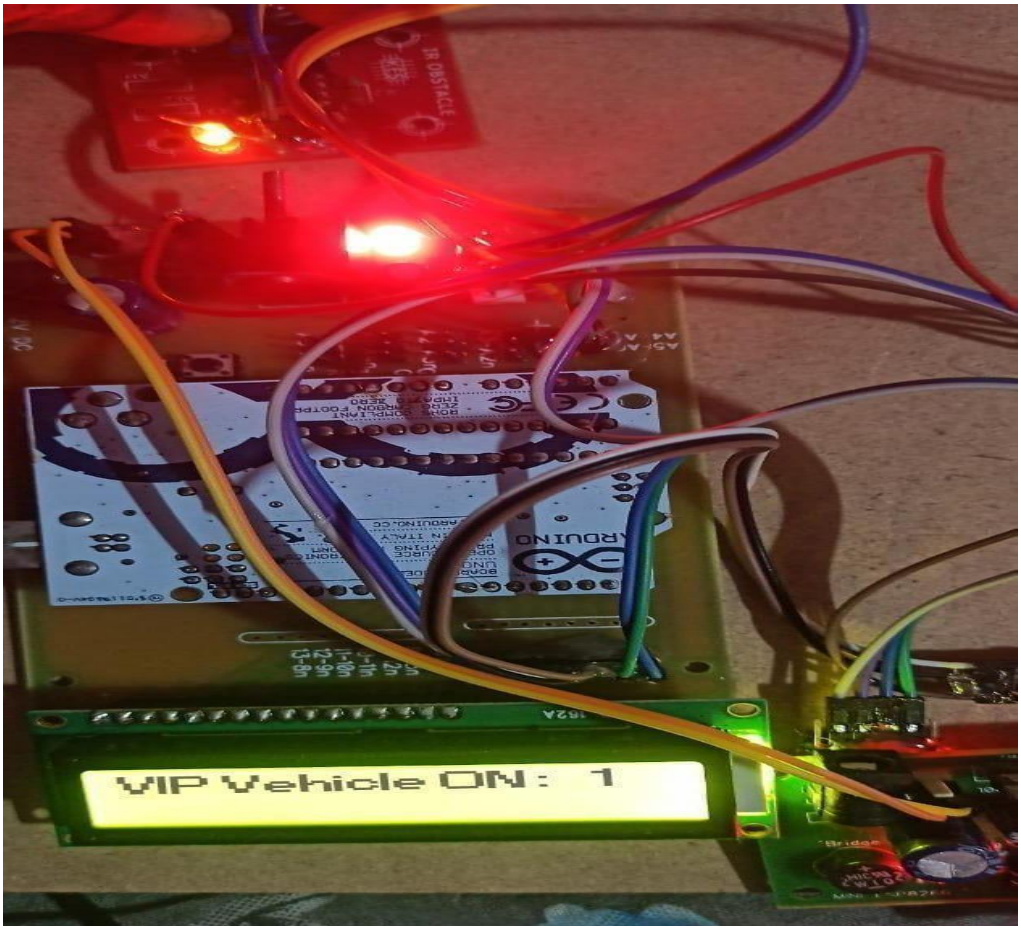

Fig 6.3.1: Working of traffic signals when VIP Vehicle is at road 1

VIP vehicle at road 2

- This condition is used where ever we want to manually allow any VIP vehicle that is struck at road 2. This condition allows us to clear the lane when we spot a VIP vehicle on the road 2.

- Here we need to click # in the Telnet app so that green signal is at road 2 and red signal at road 1.
- Condition for the working of traffic signal when VIP vehicle is present at road 2.

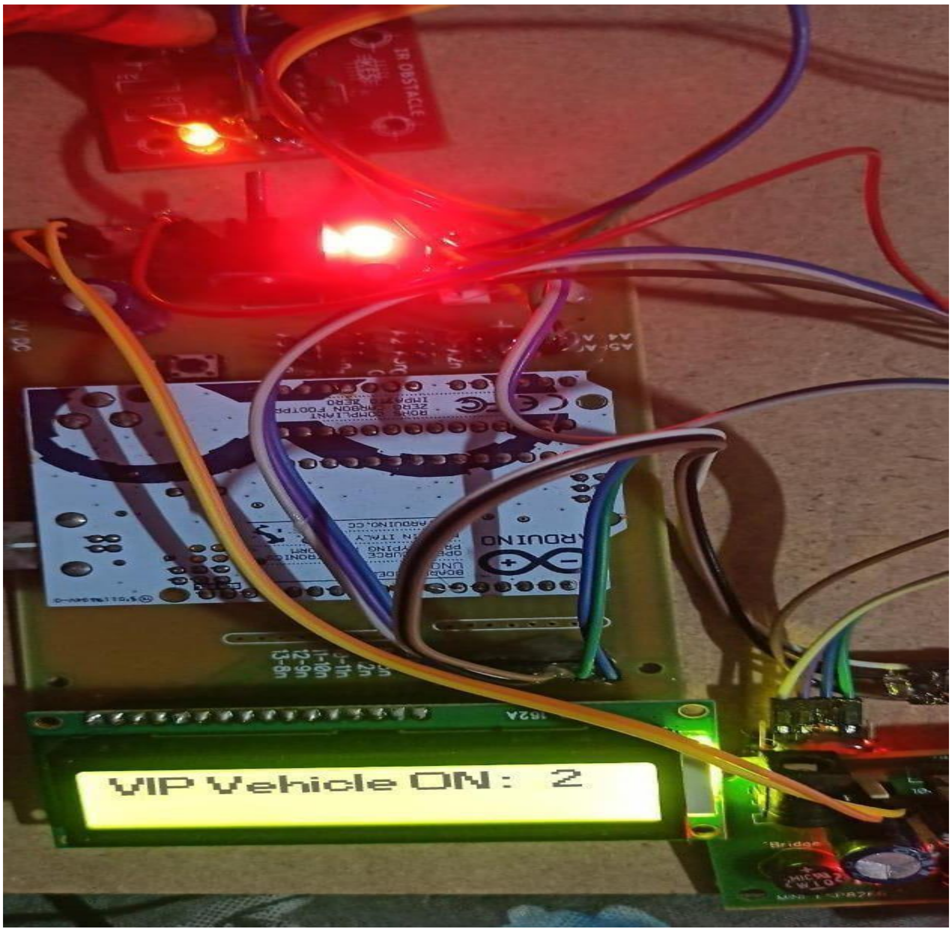

Fig 6.3.2: Working of traffic signals when VIP Vehicle is at road 2

CHAPTER 7

LIMITATIONS AND ADVANTAGES

Limitations

- Power Supply must be 5V.
- Manual errors are possible

Advantages

- Reduces traffic jams at the signals and on the streets
- A large chunk of vehicles can transit the signals efficiently
- Instant traffic clearance for emergency vehicle
- Effective time management
- Time can be shared evenly for all intersections

CHAPTER 8
CONCLUSION AND FUTURE SCOPE

Conclusion

There is exigent need of efficient traffic management system in our country, as India meets with many road accidents every day. To reduce this congestion and unwanted time delay in traffic an advanced system is designed here in this project. With field application of this technology, the maddening chaos of traffic can be effectively channelized by distributing the time slots based on the merit of the vehicle load in certain lanes of multi junction crossing.

The proposed system aims to save the number of manhours wasted at the signals and hence making effective utilization of time.

So in this way, apart from operating the signal manually or by keeping them constant, the signal can be monitored and traffic can be controlled using the sensors and by controlling the density of traffic. Even, instead of clearing the traffic by the traffic police, the green will be signaled automatically, to give way for the ambulance by clicking the button provided.

Future Scope

Though the prototype model worked very efficiently with remarkable outputs, the real-life situation is going to be way more challenging and demanding.

Few of the challenges that should be taken into account are listed as follows

- Low range IR sensors may not be an answer for long range signaling system. We may resort to ultrasound or radar techniques for big scale set-ups.
- Next is the influence of stray signals that may alter the reading of sensor receptors and lead to conveying false information to the microcontroller

Safety has to be absolutely made sure that no compromise is being made on safety issues, i.e. a secondary stand-by set-up that can switch over from automated to manual mode, should be provided in case of sensor or circuit malfunctions so that vehicular crowd does not go beyond control.

As part of future advancements, the traffic check post may be connected by wireless transmitters by which the crossings ahead may be an anticipation of the traffic that is approaching. This may be achieved the connecting the sensor network with GPS connectivity and shortwave radio transmission signals. This will act as a feed forward system making the signaling system even more smooth and congestion free.

ABSTRACT

Recently, low-dose computed tomography (CT) was considered by many researchers to be a good solution to reduce radiation risks of patients. However, lowering X-ray tube current will make reconstructed images quality be significantly degraded. To improve image quality, in this paper, we proposed a modified dual-domain U-net (MDD-U-net) that combines the projection domain and image domain losses. The proposed MDD-U-net can effectively suppress the projection domain noise and reduce the error in reconstructed images. The simulation experiment results showed that the proposed method effectively reduce the noise in the low-dose CT images while preserved images details information.

CHAPTER 1

INTRODUCTION

1.1 OBJECTIVE OF THEPROJECT

Recently, low-dose computed tomography (CT) was considered by many researchers to be a good solution to reduce radiation risks of patients. However, lowering X-ray tube current will make reconstructed images quality be significantly degraded. To improve image quality, in this paper, we proposed a modified dual-domain U-net (MDD-U-net) that combines the projection domain and image domain losses. The proposed MDD-U-net can effectively suppress the projection domain noise and reduce the error in reconstructed images. The simulation experiment results showed that the proposed method effectively reduce the noise in the low-dose CT images while preserved images details information.

1.2 Introduction:

MATLAB is a programming language developed by MathWorks. It started out as a matrix programming language where linear algebra programming was simple. It can be run both under interactive sessions and as a batch job. This tutorial gives you aggressively a gentle introduction of MATLAB programming language. It is designed to give students fluency in MATLAB programming language. Problem-based MATLAB examples have been given in simple and easy way to make your learning fast and effective.

This tutorial has been prepared for the beginners to help them understand basic to advanced functionality of MATLAB. After completing this tutorial you will find yourself at a moderate level of expertise in using MATLAB from where you can take yourself to next levels.

We assume you have a little knowledge of any computer programming and understand concepts like variables, constants, expression, statements, etc. If you have done programming in any other high-level programming language like C, C++ or Java, then it will be very much beneficial and learning MATLAB will be like a fun for you.

MATLAB (matrix laboratory) is a fourth-generation high-level programming language and interactive environment for numerical computation, visualization and programming.

It allows matrix manipulations; plotting of functions and data; implementation of algorithms; creation of user interfaces; interfacing with programs written in other languages, including C, C++, Java, and FORTRAN; analyze data; develop algorithms; and create models and applications.

It has numerous built-in commands and math functions that help you in mathematical calculations, generating plots, and performing numerical methods.

MATLAB is used in every facet of computational mathematics. Following are some commonly used mathematical calculations where it is used most commonly −

- Dealing with Matrices and Arrays
- 2-D and 3-D Plotting and graphics
- Linear Algebra
- Algebraic Equations

- Non-linear Functions
- Statistics
- Data Analysis
- Calculus and Differential Equations
- Numerical Calculations
- Integration
- Transforms
- Curve Fitting
- Various other special functions

Features of MATLAB

Following are the basic features of MATLAB −

It is a high-level language for numerical computation, visualization and application development.

It also provides an interactive environment for iterative exploration, design and problem solving.

It provides vast library of mathematical functions for linear algebra, statistics, Fourier analysis, filtering, optimization, numerical integration and solving ordinary differential equations.

It provides built-in graphics for visualizing data and tools for creating custom plots.

MATLAB's programming interface gives development tools for improving code quality maintainability and maximizing performance.

It provides tools for building applications with custom graphical interfaces.

It provides functions for integrating MATLAB based algorithms with external applications and languages such as C, Java, .NET and Microsoft Excel.

Uses of MATLAB

MATLAB is widely used as a computational tool in science and engineering encompassing the fields of physics, chemistry, math and all engineering streams. It is used in a range of applications including −

- Signal Processing and Communications
- Image and Video Processing
- Control Systems
- Test and Measurement
- Computational Finance
- Computational Biology

In recent decades, computed tomography (CT) has been widely used in the diagnosis and intervention tasks of modern hospitals and clinics. Given the potential radiation risk of CT scans, there is growing concern about the harm caused by radiation dose to humans. In order to reduce the radiation dose received by patients and the risk of related diseases, low-dose CT has gradually become the focus of researchers in the field of CT imaging. At present, there are two main ways to reduce the radiation dose. The first method is to reduce time of CT scans, and the second method is to lower the operating current of the X-ray source tube. Because the second way is simple and effective, it has become one of the most popular methods to reduce theradiation dose. However, directly lowering the tube current will severely degrade the images quality due to the excessive quantum noise caused by an insufficient number of photons in the projections, thereby affecting the doctor’s diagnosis of thedisease. Many different methods have been proposed to improve the quality of low-dose CT imaging. In 2008, Sidkyet al.[1] integrated the total variation (TV) regularization into traditional projection onto convex sets (POCS) and proposed the adaptive-steepest-descent POCS (ASD-POCS) algorithm to suppress images noise. In 2012, Chen et al.[2] proposed a processing scheme called 'artifact suppressed large-scale nonlocal means' for suppressing both noise and artifact in low-dose CT images. In 2016, Chen et al.[3] proposed an improved context-based block matching and three-dimension (BM3D) filtering method to reduce the noise of low-dose CT and improve the images quality. However, the above methods belong to the general denoising method, and using them may not be enough to suppress strong and widelydistributed noise in low-dose CTimages. In recent years, deep learning methods have been widely used in the field of low-dose CT images noise reduction. In 2017, Chen et al.[4] proposed residual encoder-decoder convolutional neural network (RED-CNN) that combines the auto-encoder, the deconvolution network, and shortcut connections for improving low-dose CT imaging quality. In 2017, Kang et al.[5] proposed a deep convolution neural network using a directional wavelet transform to extract the directional component of noise to suppress low-dose CT images noise. In 2018, Lee et al.[6] proposed a deep-neuralnetwork for interpolating sparsely-sampled sinogram to reduce low-dose CT images noise. Although this method have shown impressive performance capabilities, there are still errors between the processed projection and the real projection. During the image reconstruction process, these errors will be magnified, resulting in blurred details in the reconstructed images. In this paper, we proposed a modified dual-domain U-net (MDD-U-net) to preprocess the projection data to effectively suppress the projection domain noise. In addition, in order to reduce the error of the low-dose CT reconstructed images, a filtered back-projection (FBP) module with backpropagation capability is added into the network structure to implement image domain constraints. The trained network model can be directly applied to low-dose CT projection denoising, which greatly reduces the calculation time and improving the quality of low-dose CT reconstructed images.

II. METHODS

A. Noise Model X-ray photon statistical noise and electronic background noise are the two main types of noise in the process of lowdose CT imaging. They approximately obey the Poisson distribution and Gaussian distribution, respectively.[7] Zheng et al.conducted a detailed study for the noise in the low-dose CT images and showed that the Poisson-Gaussian mixed noise is closerto the real noise in the low-dose CT images[8]. Therefore, in order to simulate the low-dose CT images more exactly, the Poisson-Gaussian mixed noise was used to 223 2020 3rd International Conference on Artificial Intelligence and Big Data

 simulate the real low-dose CT projection data acquisition process in this paper. The specific noise model is shown as follow: (1) where is the path of the X-ray, parameter is used to simulate the conversion gain of x-ray photons to electrons, is the initial incident intensity of X-rays, and is the variance of Gaussian noise. In our study, was set to 10000 and was set to 25. *B. Network Architecture* Recently, the U-net proposed by Ronnebergeret al.[9] not only have achieved good performance on many different kinds of biomedical segmentation applications but also have been applied in CT image denoising tasks[10].

Inspired by the successful application of the U-net, we proposed a novel low-dose CT images denoising network that can be directly applied to the projection denoising of low-dose CT. In order to further improve the performance of the network in suppressing noise of the projection domain, we proposed a MDD-U-net to more effectively extract projection domain features.

The proposed network structure consists of an encoding structure (left side) and a decoding structure (right side) is illustrated in Fig. 1. In contrast to the U-net architecture composed of four convolutional layers and four deconvolution layers in the original paper, the MDD-U-net encoding structure contains five convolution layers (CONV) and the decoding structure contains five deconvolution layers (DECONV). All layers have a 3×3 kernel, and each layer is followed by a rectified linear unit (ReLU) to prevent vanish of gradient and accelerate the convergence rate. Downsampling operate in the encoding structure and up-sampling operate in the decoding structure are implemented by 2×2 max-pooling operation and 2×2 up-convolution operation, respectively. The number of feature channels doubles with each down-sampling operation, however, the number of feature channels is halved after each up-sampling operation. We added five shortcut connections to the network to reduce the loss of pixels caused by each convolution. Due to sinogram edge vanish after each convolution, we used the zero-padding scheme to maintain sinogram size. The proposed network reduces noise by learning an endto-end mapping from containing noise low-dose CT sinogram (input) to its corresponding noise-free normal-dose CT sinogram (label). The deconvolution layers use the projection features extracted from the input by the convolution layers to construct the predicted output.

C. Objective Function

For the purpose of improving imaging quality, different loss functions were used in the proposed method. We reduced the projection domain noise by minimizing the projection domain loss. Let be a low-dose CT sinogram as an input and be a normal-dose CT sinogram as a label. The MDD-U-net obtains the predicted output by learning the end-to-end mapping from to . And we minimized image domain loss to further reduce the error of low-dose CT reconstruction image. To achieve the constraint on the image domain, the ASTRA-toolbox[11] was used for implementing the FBP module with the ability for error backward-propagation from image to sinogram. Let be a FBP image of the predicted output and be a FBP image of the label . Given the good noise suppression capability of the TV regularization term, in this work, TV loss is added to the objective function. The reduction of TV loss can decrease the difference between adjacent pixel values in the low-dose CT images[12]. TV regularization model can describe the sparsity of gradient magnitude images. TV of an image is defined asfollow[13]:

(2) where represents discrete directional gradient operators. Specifically, the objective function is expressed as follow: (3)

where represents the loss of the projection domain, represents the loss of the image domain, both are based on norm loss function, and represent the parameters of the projection domain loss and the image domain loss, respectively. represents the TV loss.

.

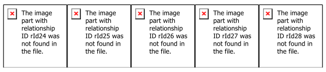
D. Network Training

In this study, network training is implemented by minimizing the objective function (2). Parameter $\lambda 1$ and $\lambda 2$ values were set to 1 and 100, respectively. The $\lambda 3$ was set to 0.5. We used the adaptive momentum estimator (Adam) optimizer[14] to optimize our proposed network. It is a gradient-based optimizer that considers first-order moment estimation and second-order moment estimation of a gradient. We set the first momentum to 0.9 and the second momentum to 0.999 and ε to 10-8 , respectively, the same setting as in the original paper. We set the initial learning rate to 0.0001. We used the Tensorflow deep learning framework to train the proposed network on a GPU (NVIDIA TITAN V, 12GB). The proposed network model was trained for approximately 17 hours.

Matlab can be used as a tool for simulating various electrical networks but the recent developments in matlab make it a very competitive tool for Artificial Intelligence, Robotics, Image processing, Wireless communication, Machine learning, Data analytics and whatnot. Though its mostly used by circuit branches and mechanical in the engineering domain to solve a basic set of problems its application is vast. It is a tool that enables computation, programming and graphically visualizing the results.

The basic data element of MATLAB as the name suggests is the Matrix or an array. MATLAB toolboxes are professionally built and enable you to turn your imaginations into reality. MATLAB programming is quite similar to C programming and just requires a little brush up of your basic programming skills to start working with.

1.3 Block diagram of embeddedsystem:



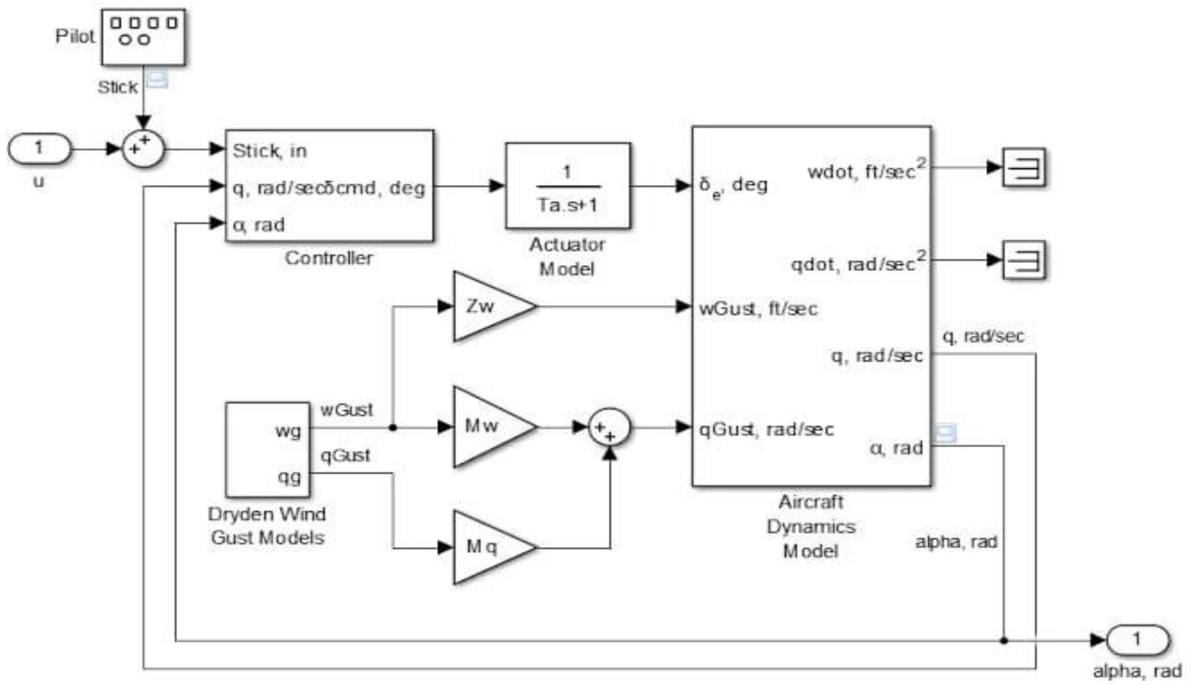


Fig.1.1: Block diagram of Matlab

1.4 Applications of Matlab:

- Math and computation.
- Algorithm development.
- Modeling, simulation, and prototyping.
- Data analysis, exploration, and visualization.
- Scientific and engineering graphics.
- **Application** development, including Graphical User Interface building.

1.5 Matlab Parts

The **Matlab** screen mainly include 4 **parts**:Command Window, Workspace window,Command History window and Current Directory window.

1.5.1 Command window

The MATLAB Command Window is the main window where you type commands directly to the MATLAB interpreter. The MATLAB Editor Window is a simple text editor where you can load, edit and save complete MATLAB programs. The Editor window also has a menu command (Debug/Run) which allows you to submit the program to the command window. The MATLAB Help Window gives you access to a great deal of useful information about the MATLAB language and MATLAB computing environment. It also has a number of example programs and tutorials.

The Command Window is always open. To restore the Command Window to the default location, go to the Home tab, and in the Environment section, click Layout. Then, select from one of the default layout options. To bring focus to the Command Window from another tool such as the Editor, type commandwindow .

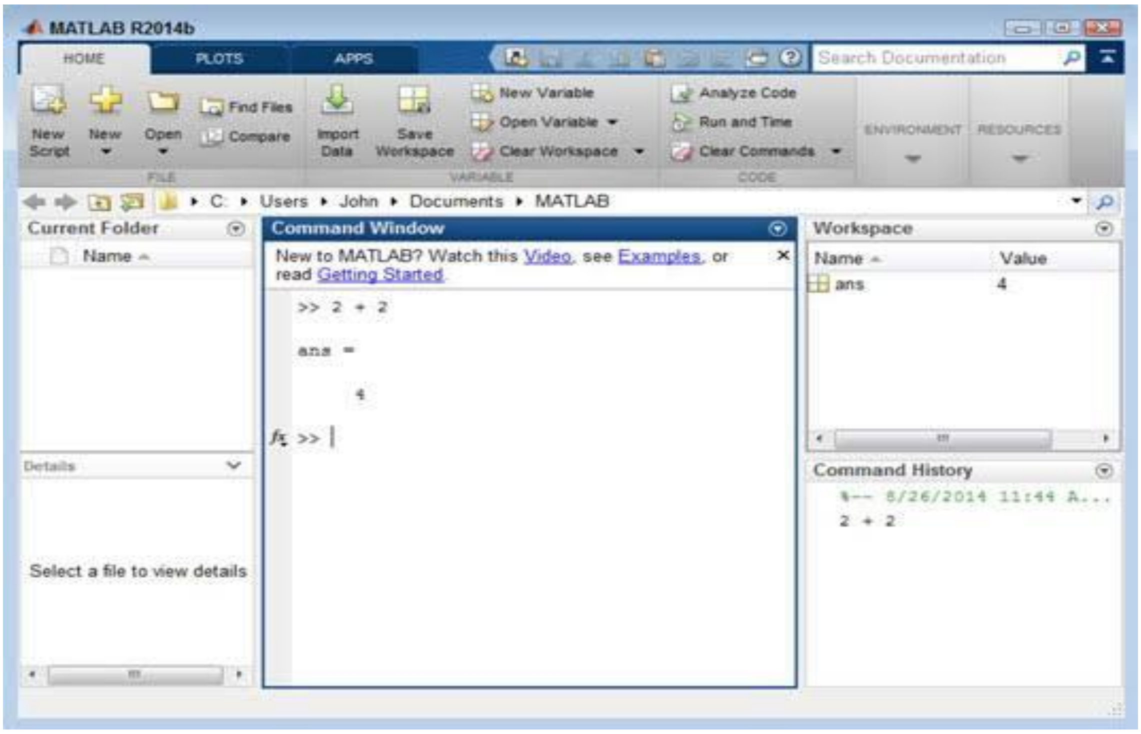

Fig:1.2: Command window

1.5.2 Workspace window

The workspace contains variables that you create or import into MATLAB from data files or other programs. You can view and edit the contents of the workspace in the Workspace browser or in the Command Window. For more information, see Create and Edit Variables. Workspace variables do not persist after you exit MATLAB.

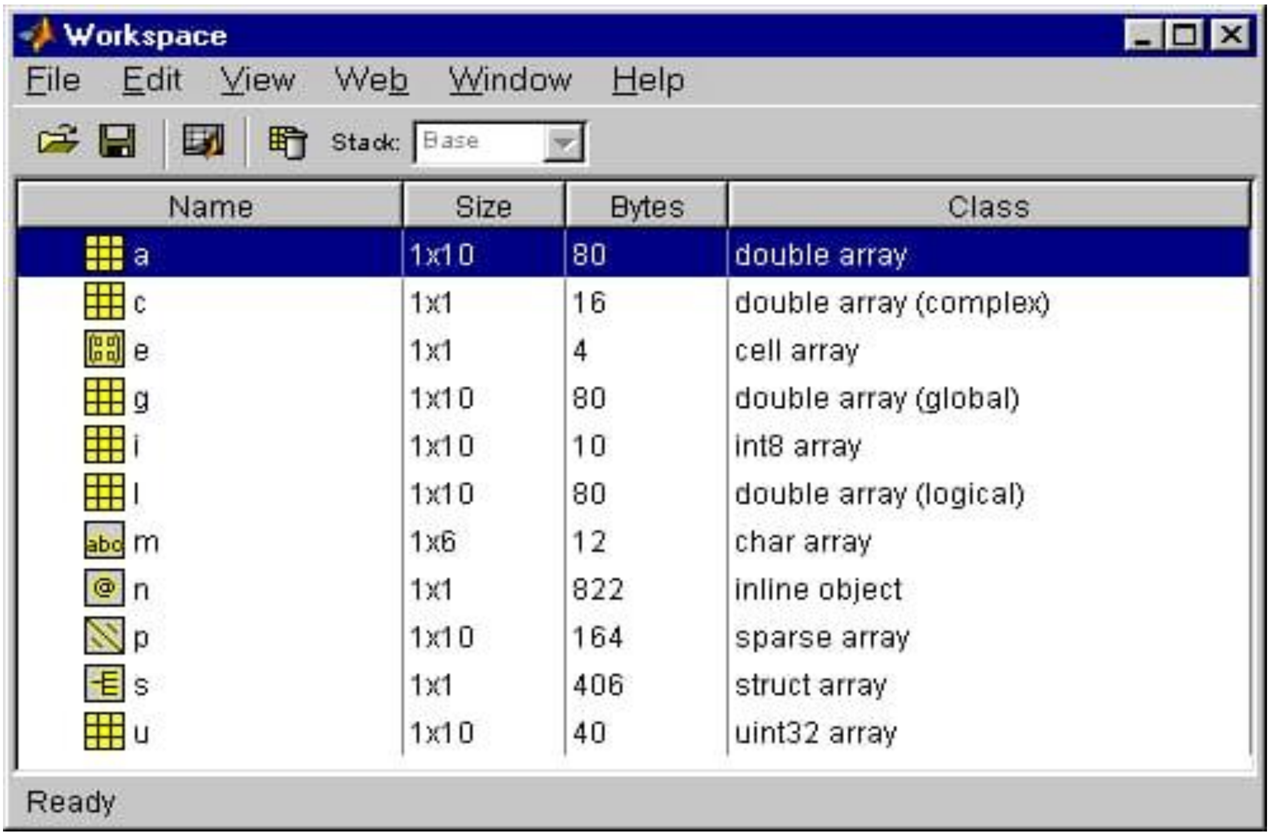

Fig:1.3:Work space in matlab

1.5.3 Command History Window

To open the **Command History** window with all **history** showing, in the **Command** Window, press the Up Arrow key (↑) or enter commandhistory . To open the **Command History** window and display a specific statement, type any part of the statement at the prompt and then press the Up Arrow key.

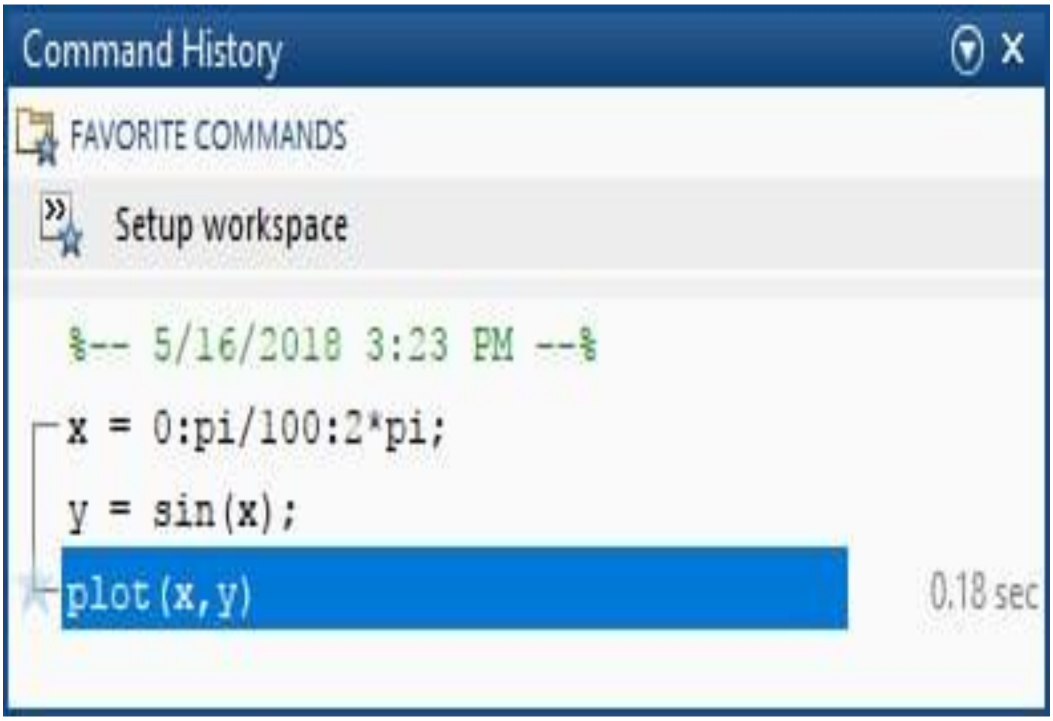

Fig:1.3:Command history window

.

1.5.4 Current Directory Window

To open the Current Folder browser if it is not currently visible, do one of the following: MATLAB Toolstrip: On the Home tab, in the Environment section, click Layout. Then, in the Show section, select Current Folder. MATLAB command prompt: Enter filebrowser .

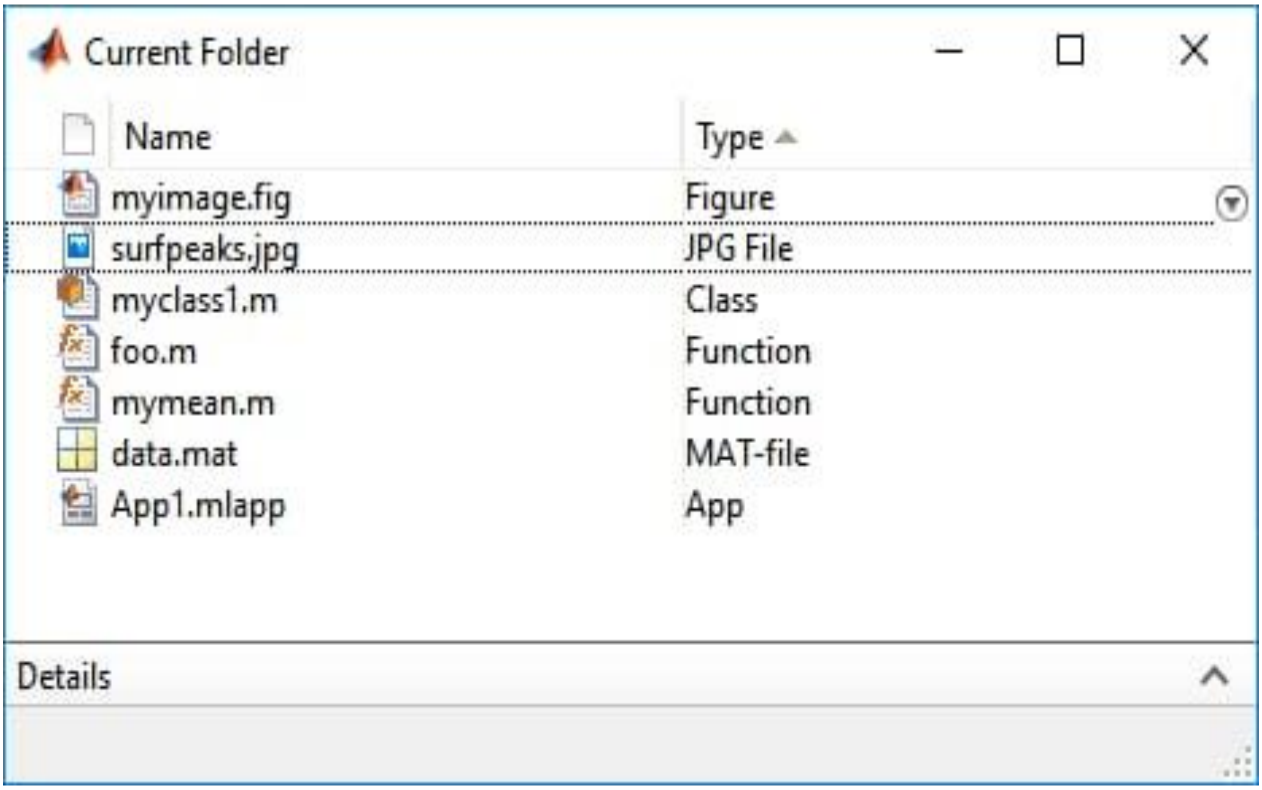

Fig:1.5: Command Directory Window

CHAPTER-2 LITERATURE SURVEY

2.1 Literature survey:

This literature review focused on the use of MATLAB, a computer algebra system, as a didactical tool for mathematics. It has also looked at some theories of learning related to the teaching and learning of mathematics with the computer technology. The review aimed at summarizing the different ways in which the software has been used as a tool for visualization, computation, problem-solving, fostering positive attitudes and math confidence, increasing motivation & math performance, and projects. It has also included the proposals in which the software has been recommended to be used. It is our hope that this review could be useful for those interested in integrating MATLAB in mathematics curriculum. Keywords: CAS, MATLAB, Teaching & Learning, Mathematics, Literature Review. Introduction The Computer Algebra System, popularly known as CAS, is a modern computing technology that provides great learning and teaching opportunities to both students as well as instructors. MATLAB is one of the most popular CAS programs that is widely used in mathematics classrooms especially at the university level. As more and more universities are adopting its use in education, it is necessary to study and analyze how the software could be used in teaching and learning of mathematics. In this literature, focus has been given on how MATLAB has been used in problem solving, computation, and visualization of mathematics through mathematical explorations etc. It has been shown to be a technology that could be used for developing mathematical thinking, concepts and skills, and a source of motivating students for learning mathematics. It is also a very useful tool in demonstrating connections in various underlying mathematical concepts in the teaching and learning processes. 23 24 M. Abdul Majid et al. The modern computer algebra systems are cognitive tools, Heid (2001). According to Pea (1987, p. 91), a cognitive technology is “any medium that helps transcend the limitations of the mind in thinking, learning, and problem-solving activities”. Cognitive tools are both mental and computational devices that support, guide, and extend the thinking processes of their users, Derry (1990). They are used as a didactical tool to enhance students' mathematical learning and to provide them with essential career-related skills. Both advantages and disadvantages of using computer technology are reported in the literature. Those who oppose the didactical use of computer tools voice the declining mental and manual mathematical skills of students. However, those who support its use believe that these tools would not only enhance the presentation of mathematics but also could provide the necessary skills needed in the 21st century. Undoubtedly, technology has become ubiquitous in mathematics education. According to National Council of Teachers’ of Mathematics (2006), “Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning”. Does the use of computer tools or technologies per se enhance students learning? What factors influence classroom-based math learning? The positive change in the teaching and learning lies in several factors. “Education technology is neither inherently effective nor inherently ineffective; instead, its degree of effectiveness depends upon the congruence among the goals of instruction, characteristics of the learners, design of the software, and educator training and decision-making, among other factors", Schneider (2000). However, for some, its use is still questionable. The research question which will guide this review is the following: "In what ways MATLAB has been used in the literature for teaching and learning of mathematics in the university education?" MATLAB MATLAB, the product of Mathworks Company, is the general purpose computing software. It contains a vast range of specialized toolboxes and also works as the computer algebra system through its symbolic math toolbox. This toolbox performs symbolic algebraic/mathematical manipulative operations with a lot of built-in interactivity. MATLAB undoubtedly is popular among computer and multi-disciplinary scientists, engineers and particularly with experts in the area of computational mathematics. It integrates numerical, symbolic and the state-of-the-art graphic visualization capabilities with quite intuitive computer programming environment. Methodology The systematically classified and integrated methods were used to summarize the relevant articles and presented them in a narrative manner. A literature review for the publications between 1988 and 2012 was carried out from the sources such as mathwork.com, ERIC, IEEE xplore, ProQuest, Academic Search, Springer Link, Taylor and Francis, Science Direct, Proceedings for the conferences, the Google and the Google scholar search. The keywords used for the search were "CAS and mathematics education", and "CAS/MATLAB as a teaching & learning tool for math", "CAS/MATLAB as a visualization tool for math", "CAS/MATLAB as problem-solving tool in math" etc. Our primary focus was the empirical studies based on classroom and computer-lab where MATLAB was used as a pedagogical tool for mathematics. MATLAB as a Teaching and Learning Tool for Mathematics... 25 Theories of Learning and CAS It is important to know how theories may help in technology integration for mathematics instruction. The theoretical and conceptual basis of using computer technology in the teaching and learning of mathematics can be linked with the Constructivist Theory. According to this theory, a learner cognitively constructs a mathematical concept through the active involvement in the processes of experimenting, conjecturing, proving, and applying. Using CAS, students actively construct and acquire knowledge in mathematics rather than being passive receivers of knowledge. There are a number of other theories derived from the cognitive psychology relating to cognitive and technology-aided cognitive processes such as Cognitive Load Theory, Cognitive Theory for Multimedia Learning and Distributed Cognition Theory. According to Sweller (2004), Cognitive Load Theory suggests the learning activities to be aligned with the human cognitive structure. The structure of human cognitive architecture, while not known precisely, is discernible through the results of experimental research. According to Hutchins (1990), “Distributed cognition is a branch of cognitive science that proposes cognition and knowledge are not confined to an individual; rather, it is distributed across objects, individuals, artefacts, and tools in the environment.” According to Cognitive Multimedia Theory, the information presented through the integration of limited visual and auditory channels will be filtered, selected, organized, and integrated by the learner actively, figure 1, Mayer & Moreno (2003). However, an understanding of the human cognitive processes in a mathematics teaching and learning environment which involves human computer interaction still needs much exploration. Figure 1: Cognitive Multimedia Theory by Mayer & Moreno, (2003). Duval (1993) suggested an absolute necessity of the application of different semiotic representations for a solid understanding of mathematical concepts. This can be achieved in a technology-enriched teaching and learning environment. The theoretical framework in figure 2 is based on the notion of 'procept' given by Gray and Tall (1994) and the semiotic representation of mathematical concepts by Duval (1993). This theoretical framework was used by Abdul Majid et al (2012). 26 M. Abdul Majid et al. Figure 2: A theoretical framework for teaching and learning of mathematics with CAS. Literature Review Summary The literature review search has not revealed any study which focused specifically on the review of literature on MATLAB as a teaching and learning tool for math. The selected articles and papers that were reviewed, compiled and summarized are as follows: Proposals to use MATLAB as a Teaching and Learning Tool for Mathematics A number of articles have been written proposing the use of MATLAB in teaching and learning of mathematics, Kazimovich et al (2012), Tahir et al (2010), Chaamwe (2010), Mckenzie (2008), Friedrich et al (2008), Stanoyevitch (2005), Shi (2004), Wu (2004), Colgan (2000), Kawski (2003), Dunn et al (2002), Pester et al (2001), Markanda (1995) and Katende in his unpublished paper. Kazimovich et al (2012) illustrated the capabilities of the applications of symbolic computation techniques of MATLAB for engineering students. The capabilities of MuPAD and its combination with MATLAB were described for writing formulas, factorizing an expression, solving equations, solving systems of equations and differential equations, finding derivatives and antiderivatives as well as plotting functions. In addition, some of the useful functions like computing Fourier transforms and their inverses have also been given. The paper also provided sketches of the transfer between MuPAD and MATLAB. Tahir et al (2010) proposed the integration of MATLAB into science, technology and engineering disciplines as a teaching and learning tool for undergraduate studies to the Ministry of Science and Technology, Iraq. The graphical user interface programs created for Math 1 and Math 2 courses were proposed to be used in teaching linear algebra, graphing, Laplace Transform, differential and integral calculus courses. The proposed programs were aimed at motivating students and demonstrating the relationships between pure mathematical concepts to the real world. The authors planned to develop a supplemental booklet for using computer programs in tutorial sessions. The authors also recommended the use of the software throughout the science and engineering institutions in the country and also emphasized the need for providing necessary training on the use of MATLAB to the teaching faculty. Chaamwe (2010) provided a few illustrations for sketching mathematical graphs of functions using MATLAB. The study highlighted some general benefits of integrating the software. Students motivation to learning can be enhanced, they can work collaboratively in teams. It could provide a problem-centered approach in teaching and learning. Their skills could be honed. The software can also be used for demonstrating a connection between the theory and MATLAB as a Teaching and Learning Tool for Mathematics... 27 the practice and as well as students actively participate in the learning process. The study also highlighted some relevant studies on the role of Information and Computer Technology. In this report by Mckenzie (2008), MATLAB has been recommended to be used as a new pedagogical model for illustrating and reinforcing mathematical concepts to students at the Oregon Institute of Technology. This recommendation was for a replacing the existing system of math instruction. The purpose was to provide interactive demonstrations and visualizations into mathematics classes. Primarily, two objectives were aimed at, firstly, to demonstrate the link between the use of MATLAB to the enhancement of the understanding of the math and secondly, to equip students with the necessary professional software skills in their careers. To make the efficient use of the new model, the report also recommended creating a website for MATLAB, integrating teaching of the software as a one-credit course into the math curriculum and also providing the information on the website about the connection of mathematical contents to students' specific engineering fields. The report concluded that students' motivation, interest, their appreciation to the software, communications and critical thinking would be positive. Computer tools could also be used to overcome math-phobia as termed by Pappert (1993). Friedrich et al (2008) described the cognitive role of computer technologies such as MATLAB in the development of students' mathematical reasoning, logic and problem solving skills. The graphing capabilities of various CAS programs such as Maxima, Scilab, Micro Worlds, Dynamic and Interactive Geometry as well as MATLAB have been given. The study concluded that the issue of declining interest in math and in its allied disciplines such as engineering is due to the lack of well-educated technical experts in cognitive technologies. In this paper, the author Stanoyevitch (2005) presented the benefits and versatility of introducing MATLAB into university mathematics programs and how the software could be incorporated. A detailed description was given on how the implementation of the software could enhance mathematics courses both from the academic aspect as well as opening up the employment prospects for graduates. Students could achieve a higher level of learning in courses like abstract algebra with the incorporation of MATLAB into it. The issues such as licensing the software, using it as an isolated technology, from a minimal lower level to an advance levels, have also been raised in the study. Some illustrations of its use such as logistics of air shipping and computation of worst-case-scenario number of a directed network were provided in detail. The study by Shi (2004) was aimed at implementing MATLAB as a tool into teaching and learning of calculus for students majoring in Physics. It was also suggested dividing students into normal and advanced levels based upon their aptitudes as well as including the group work for them. The need for the change in the pedagogy was felt due to a host of problems related to students learning of mathematics. The focus for the normal group of students was given for learning the basic underlying concepts and principles of mathematics with less emphasis on the subject’s rigor. The advanced group of students would have the normal course without providing them the details of the course putting greater self-responsibility for learning. A number of illustrations of the visualization of the graphs of the mathematical functions were given with explanation of how they could be used in teaching. The software tool was also recommeded to be used for enhancing the key concepts such as tangent line of a curve at some point, geometric interpretation of the definite integral as well as some examples of mathematical modelling. The study also highlighted the importance of group work and suggested to form a group of 4 to 5 students to cultivate necessary communication and collaborative skills among them. The assessment scheme to the new approach was suggested to be in place. The author believed that 28 M. Abdul Majid et al. the proposed new approach would be more student-centered and it would provide necessary important skills to students. In this study, Wu (2004) proposed MATLAB to be used as a teaching and learning tool at the School of Science, Beijing Institute of Technology. The study aimed at improving the teaching and learning of linear algebra and to equip students with modern computing technology. The proposal also suggested establishing the website for the course. It was also highlighted that the software could be used as a data visualization tool to promote deeper understanding of the concepts. Dunn et al (2002) used MATLAB for teaching and learning of introductory calculus at the University of Southern Queensland, Australia. Five MATLAB based graphical interface programs were used to demonstrate the mathematical concepts such as Newton's Method, differentiation and integration. The programs present some unusual and important cases of the calculus concepts. The authors argued that MATLAB could be incorporated into learning of mathematics in three ways, namely, firstly as a numerical and graphical tool, secondly as an aid to learning of ideas and concepts and thirdly to show the procedure or concept in a more sophisticated way. In this work, the authors have used MATLAB using the third approach. The main focus of the use of these programs was to demonstrate mathematical concepts rather than doing a particular task. The study also suggested that the computer technology should be used a supplement to the traditional teaching and learning. In this proposal, Kawski (2003) compared the arguments of the integration of MATLAB with that of the other CAS programs such as Maple and Mathematica in the first year college mathematics. The author comparatively put forward the argument that integrating a CAS in mathematics curriculum is much easier than MATLAB due to the pedagogical and planning related challenges with the later. The study further stated that the traditional calculus is still an "algebra course" whereas MATLAB provides numeric computing in which "almost everything is a matrix". Katende in his unpublished paper reviewed the role of MATLAB and other symbolic algebra systems for engineering mathematics with some illustrations. The study outlined some of the potentials and challenges in undergraduate engineering mathematics. Illustrations such as expanding cos(7x), differentiating sin(E^x(x^2+1)) and integration problems were given and how quickly the algebra systems provided output to such complicated computations. Some examples of 2-D and 3-D graphical visualization were also provided in the paper. The study concluded highlighting the need to change the curriculum or the approach to teaching engineering mathematics. MATLAB Web Server was proposed to be used in this study by Pester et al (2001) for electrical engineering and mathematical modeling. The interactive software could be used to save students' time and to increase their motivation. It could be used for simulation and visualization of 2 and 3-dimension graphs. A few illustrations of how the software could be used were given as well as with some advantages and disadvantage of using web-based MATLAB. Solutions to some network related problems were also proposed. Markanda (1995) described how the students' version of MATLAB could be used to compare several direct, elimination, and iterative methods for solving efficiently and with less calculations systems of n equations in n variables. The illustrations of Jacobi and Gauss-Seidel methods using the software were given in the paper. In a study by Dios et al (2012), MATLAB and Learning Management System "Moodle" were introduced in the traditional teaching and learning of graduate engineering mathematics course. The aim was to give students a better understanding of the course contents. The paper MATLAB as a Teaching and Learning Tool for Mathematics... 29 discussed the mechanism of the new structure of the course including the web-based assessment. The Learning Management System "Moodle" was created as a virtual learning environment to work as a pedagogical model. The online quizzes were used using WIRIS, an editor to write symbols and formulas. Kovacheva (2008) outlined the main features of many popular mathematical application packages including MATLAB. The capabilities of these programs for research as well as for teaching were described briefly. MATLAB as a Tool for Graphing and Visualization of Mathematical Data and Concepts One of the greatest benefits of computer technology is the accessibility of the mathematical concepts through visualization. MATLAB is one of the best known software which contains mathematical data visualization capabilities, Palais (1999). MATLAB as a visualization tool has been used in the courses like linear algebra, calculus and differential equations etc. Szurley (2007) used MATLAB as a visualization tool for applications of linear algebra course. Two examples of population modeling and one example of Genetics were used in this study. The aim of the study was to provide students with the graphing capabilities for illustrating the insights into the material. In an extension of the study, the author created some graphical user interfaces in MATLAB to address students' unsatisfactory responses to the use of the software in an earlier study. The aim was to provide interactivity and visuals for presenting mathematical concepts. Palmer (2008) also aimed at visualization of linear algebra concepts through the writing and the development of simple animation programs in MATLAB. The author claimed that creating animation programs is possible with little knowledge of linear algebra, no computer programming experience and without MATLAB's familiarity. The study concluded that students' learning of matrices enhanced, however, no students' feedback was given. In a collaborative project between Swedish and British instructors (two mathematicians and one didactic expert), MATLAB was used to teach undergraduate engineering mathematics students, Burton et al (2004). The aims of the project were to support students' visual and graphical understanding of mathematics and their access to the numerical computation of the course. Individual interviews were conducted to get the feedback from students. Their overall feelings were mixed on their experience of using the software. To achieve effective software integration, the study has also provided suggestions such as ensuring clarity in learning goals, adequate number of MATLAB classes, and the preparation of a manual to support MATLAB programming by providing necessary reference material on the web. Students expressed their dissatisfaction with their experiences of using MATLAB as there was too much elapsed time between two MATLAB sessions consequently students had to learn the material over and over again. The study concluded that the integration of the software should be planned thoroughly with enough software documentation. In several studies, MATLAB was integrated into the mathematics curriculum as an add-on teaching and learning tool. In a slightly different approach, it was integrated to an interactive "Adaptive Book" system with the aim to demonstrate the linear algebra concepts and as well as the course's algorithms, Gunawardena and Jain (2002). The concepts were presented both in the mathematics classroom/laboratory followed by the software demonstrations. In this study, MATLAB was also used as a drill and practice tool in which a combination of text and visuals were presented in multiple forms. The project such as Singular Value Decomposition for performing data compression was based on practical applications. The study described linear algebra as an ideal course for integrating technology to enhance the teaching and learning processes. It was concluded that the software 30 M. Abdul Majid et al. like MATLAB could provide a good platform for not only visualization but also for numerical computation. Stewart et al (2005) used MATLAB to assess the process of students' instrumentation of technology in the teaching of mathematics courses. The authors' called the instrumentation as a student's transformation and adaptation of computer technology to the assigned mathematical task and "it is through the actions and decisions that the student makes that the CAS tool or artefact is transformed into an instrument". The case study involved first and second year students enrolled in scientific and engineering disciplines at the University of Canterbury. The second year students used MATLAB in tutorials and computer laboratory sessions for an advance linear algebra course. The aim of the software use was to solve problems but the main focus was to help students with understanding the steps involved in the solution. The data were collected through a questionnaire in which questions were given relating to students' attitudes to the use of computers in learning math; use of computers in linear algebra course and some openended questions on the value of computers for the course. Students' feedback to the benefits of using MATLAB for visualization, conceptualization, and problem-solving was positive. In the analysis, the study reported three students' types regarding the instrumentation of computer technology for university mathematics courses. These types were firstly, those who opposed to the computer work, secondly those who were happy to use computer with a limited instrumentation, and thirdly those who exhibited too much reliance on the use of computer for mathematics. The study concluded with the recommendation of the Leigh-Lancaster's view of achieving the integration of computer technology through the process of having congruency between curriculum, pedagogy and assessment making it clear that CAS must be specified in the curriculum, teaching as well as assessment. The assessment in mathematics must be in tandem with its teaching and learning. In a study, Colgan (2000) described the integration of MATLAB to the teaching of traditional engineering mathematics course at the University of South Australia. The course included elementary linear algebra, the differential and the integral calculus. The need for the software integration was felt due to the decline in the mathematical skills of students entering into the engineering disciplines. MATLAB was chosen because of two reasons, firstly it was extensively used in some of the engineering programs at the university and secondly it was believed to increase students' employability after graduation. A MATLAB guide specifically covering the course contents was prepared to incorporate the software into the teaching. This was considered a major component of integrating software into the syllabus. The software use was demonstrated in the classroom lectures. The graphing capability of the MATLAB was shown to the students illustrating graphs of functions including features such as zoom on and multiple commands for plotting functions etc. MATLAB was used to improve students understanding of the mathematical concepts such as limits, continuity, differentiability, multiple representations of the Mean Value Theorem, Riemann Sums, and finding the volumes of revolution etc. The methodologies of teaching the course were redesigned keeping in view of the qualities of the engineering programs mentioned by the professional engineering body of Australia. The syllabus was rewritten outlining clearly the delivery and the assessment criteria. Weekly five contact hours were allocated for the course in which three hours of regular lecture, one hour of tutorial and one hour was dedicated for working with the software. Apart from the software guide, the syllabus also included the engineering applied examples relevant to the course. The emphasis throughout the process of technology integration was to enhance students' understanding of mathematics. The paper also provided some of the illustration of the engineering examples such as the classical problem of Snell's Law and the minimization of the MATLAB as a Teaching and Learning Tool for Mathematics... 31 time in the refraction of light. To inculcate collaborative spirit among students, they worked in groups of four on MATLAB sessions and the engineering projects/assignments. A part of the group's work was performing the analysis of the engineering project and presenting that in the form of a report. The projects involved the knowledge of the engineering as well as the use of the mathematical formulas. The study concluded that the course was considered to be the most successful without providing any data. The author highlighted the need for striking a good balance between the amounts of time to be spent on MATLAB to the course requirement. Schlatter (1999) described the visualization benefits of using MATLAB in a multivariable calculus for various concepts such as three-dimensional surfaces, contours plots, gradient fields and parametric curves etc. The software, to some extent, was also used for symbolic integration and for setting up integrals. The author developed two- and three- dimensional interactive packages in MATLAB and they were used; firstly to help students in visualization of mathematical objects and surfaces and; secondly to familiarize them with the use of MATLAB. The study concluded that the students could cover a more variety of integrals when the software would be used as a pedagogical tool. Apart from linear algebra and multivariable calculus courses, the software was also used for teaching concepts such as series convergence and numerical computation and visualization of power series approximations. Moore (1988) used MATLAB to teach "Series and Differential Equations" at the Grinnell College. The goal was to provide graphic visualization through the experimentation of various functions, and numeric computations for Taylor polynomials approximations, partial sums of power series, definite integrals and differential equations. Students' used MATLAB-based programs. The study concluded that the software tools not only widen students' problem-solving ability, insight, flexibility but also their ability to use them. However, the study has not provided any students' feedback. In addition to the above studies, the software was also reported to be effective tool in the visualization of mathematical concepts, (Abdul Majid et al 2012, Puhak 2011, Liang 2009, Stewart 2005, Henderson 2002, Smits 1992). MATLAB as a Computational Tool Another extremely powerful feature of MATLAB is its interactive numerical computation environment which is based on the matrix structure. Computational methods and skills of students in topics such as matrix computation, numerical differentiation and integration, and differential equations etc. can be enhanced with the use of the software. Particularly, engineering students need this skill to solve many engineering problems, Canfield (2012). Addabbo (2010) presented the approach that was used for teaching Introduction to MATLAB course for engineering students of Vaughn College who had completed calculus as one of the requirements. The course was divided into two parts; part 1 was related with programming techniques based on calculus problems, and the part 2 was the study of the numerical solutions of differential equations studied through linear and non-linear physical models. This approach was developed to demonstrate the relationship between the pre-requisite courses such as physics, statics, dynamics, writing and the vibration with that of calculus as well as to encourage higher order learning. Several projects such as matrix operations, summing series, Newton's Root Finding Method, Weather Data, and the numerical integration were given to students. Students were expected to do projects in groups of maximum three students. Upon completion, they were required to give a presentation and their performance was assessed on a set criteria. However, the study has not reported the effects of the approach and no conclusions were drawn. In a similar study, MATLAB was used for teaching computational modules at Southern Queensland University, Tonkes (2005). The learning model was developed and integrated for the first year mathematics courses. The aim of the study was to primarily reinforce traditional mathematical 32 M. Abdul Majid et al. learning, teaching concepts in numerical math and as well as for engaging students in computer aided problem solving. The model development included an interactive workbook, web-based solutions, Graphical User Interfaces and programs developed in MATLAB. The study highlighted some of the challenges encountered in the integration of the software in the mathematics curriculum. They were time allocation for the software use, students' efforts in learning it, numeric nature of the software, its syntax, and differences in the meaning of some of the signs in computers and math as well as the attitudes of teachers using it. Students progressed through their use of the software in stages through the single line commands environment to launching MATLAB's GUIs and then to developing their own MATLAB code. All assignments/exercises and experiments were performed in pairs. The outcome of the study was assessed through students' feedback survey and the programs downloads log. The students demonstrated an enhanced understanding of math, interaction with the tutors increased, and students' retention improved. The model had been reportedly successful from all stake-holders; students, lecturers, and tutors. Linear Algebra course was among the most popular courses in which MATLAB was used as reinforcement to classrooms lecture. At the University of Sydney, MATLAB was used as a supplement for teaching an undergraduate linear algebra course, Henderson (2002). The aims were to familiarize students with basic MATLAB commands so as to improve their conceptual understanding of the course. In this study, students used MATLAB to solve 4 to 5 problems in a week over one full semester. The use was mainly towards mathematical exploration, visualization of graphs and multiple representations of mathematical concepts. The study recommended maintaining an appropriate balance between the use of the software for learning mathematics and the traditional learning of mathematics. The data were collected through a questionnaire which contained both open-ended and closed-ended questions. The feedback to students' attitudes toward mathematics have also been discussed. The study reported positive and negative views toward the use of the software for learning mathematics. The software had also been used to study some mathematical functions such as Weirstrass function and to study numerical approximation of ʌ, Feng (2011). In this study, the author has also used the software for testing the convergence of an infinite series using ratio test, root test and the integral test. Liang 2009, Burton 2004, Gunawardana 2002, Smits 1992, & Moore 1988 have also reported the benefits of using MATLAB as a computational tool. MATLAB as a Tool for Improving Math Performance/Math Achievement The positive impact of computer technology on students' learning and performance has also been examined and reported, Abdul Majid et al (2012), Strayhorn (2006), Kulik & Kulik (1991). Abdul Majid et al (2012) have used MATLAB as a supplement for teaching Integral Calculus course to 77 engineering students at the University of Ha'il. The study aimed at firstly, to enhance students' conceptual understanding, their performance in mathematics and secondly, to foster positive attitudes towards mathematics and attitudes toward the computer technology. The case study involved an experimental group and a control group. Among the important objectives of incorporating the software were to address the declining mathematical skills of students needed for their core engineering courses as well as establishing a smooth transition to the upper level courses. The software had been used for a number of instructional objectives such as for visualization of graphs of mathematical functions, for identifying and exploring mathematical patterns in evaluating definite integrals, for multiple representations of a mathematical concept, and as well as for computation. The study reported the positive effects on students' math achievement compared to the performance of control group of students in the final examination. MATLAB as a Teaching and Learning Tool for Mathematics... 33 The conclusions drawn from the study were that the integration of MATLAB could be effective through the appropriate instructional design combined with students using the software in groups of 2-3. The integration of MATLAB has also been reportedly positive on students' performance in mathematics with "Moodle" an e-learning management system. The MATLAB was integrated with Moodle as a supplement to the classroom lecture for teaching calculus to undergraduate students in Geodesy at the Vienna University of Technology, Judex et al (2008). The blended teaching and learning approach was used to address the issue of students' lack of interest in mathematics and their weak background in the subject. To integrate MATLAB into the course, the software was used as an instructional tool and its basic course was included into the exercises of the mathematics courses. Specifically, the software was used for the large geometric mathematical drawings used in the geo science. Over 90 examples were developed and were made available via "Moodle" for students. The blended approach proved to be successful for the presentation of the heavy calculus course contents in a short time without sacrificing the true comprehension of the course. It enhanced the quality of lectures, improved students average grades as well as their programming skills. The integration of MATLAB would not only provide students a familiarity with modern learning tool but also an added advantage in their careers. The linear algebra course is among the most popular courses in which MATLAB has been integrated in its teaching. Smits et al (1992) described the impact of the use of MATLAB on mathematics achievement of the first year linear algebra students at the Eindhoven University of Technology. A detailed overview was given on how the course contents were presented in lectures and tutorials. In their study, the first nine weeks of the term, linear algebra was taught in which a 3-hour lecture with a tutorial were given. During the second half of the term, the course primarily focused on eigenvalues and eigenvectors followed by the last 3-weeks of the course on ordinary differential equations. MATLAB was used for time-consuming calculations, for motivating students, the interpretation of the row-echelon form, for doing more practice with the problems, for illustrating some aspects of the theory, geometric interpretation of the matrix of a linear transformation, and for introducing unknown techniques or concepts. Students played an active role in learning, conjecturing through guided experiments, and acquainted themselves with the real use of the mathematical techniques. An analysis of the results revealed that students' performance was better in the first term compared to the second term due to the complex nature of the concepts dealt with in the second. The study described the positive effects of the use of the software on students' performance as well as on equipping them with modern computing skills. MATLAB as a Tool for Fostering Positive Attitudes Towards Math, Math Confidence, and Enhancing Motivation Towards Learning Math Attitudes are defined as positive or negative emotional dispositions, McLeod, D. B. (1992) & Aiken (2000). Students' attitudes toward mathematics are complex and a number of measurement tools and constructs are reported in the literature. According to Willis (1995), "Human-computer interaction is a complex phenomenon and the attitudes and feelings involved with this relationship are difficult to identify" and the author has also reported the positive attitudes towards computer technology. This positive change in attitudes also reported to have motivated students in mastering the necessary computer skills quickly. Confidence in learning mathematics, mathematics anxiety, and perceived usefulness of mathematics as the most frequently studied and identified affective variables associated with student achievement in mathematics, Reyes (1984). One of the strategies indicated by Bretscher (1989) is the use of a computer lab with 34 M. Abdul Majid et al. tutors providing individual instruction and hands-on practice in concepts and skills. This strategy may help enhancing students' motivation and overcoming their math anxiety. The computer technology fosters positive attitudes towards mathematics, Lim et al (2009), Yashau (2006), Ocak (2006) &Gorev et al (2004), Cretchley et al (2000), increases students confidence in math, Brake (2007) and as well as it enhances their motivation towards learning math, Puhak (2011) & Carol (2012) . Figure 3: Ernest (2003) on failure and success cycles in math. Yushau (2006) used a blended learning approach in which MATLAB was used as a learning tool by 70 pre-calculus students at King Fahd University of Petroleum & Minerals. Students used MATLAB in weekly computer lab sessions. Some related online learning resources were also provided to students. The study was conducted over a semester and the pre- and post-study students' attitude towards mathematics and computers were examined. The concluding results reported a statistical significance of students' positive attitude towards mathematics and computers. The use of technology had reportedly positive effects on students' attitudes for a variety of courses such as single and multivariable calculus and courses which require solid background in mathematics such as engineering and technology. However, some studies such as the one on mathematical modeling by Lim et al (2009) reported no change in students' attitudes. In this study, the effects on students' attitudes were examined when applied mathematical modeling project was introduced with MATLAB. The project was concerning the volcanic ash fall after an eruption. The study involved third year students of Earth Science at the National Taiwan Normal University. It aimed at assessing students' attitudes towards mathematics in the pre- and post-modeling project. Some of the anticipated benefits of the projects were making the learning of the course interesting, providing a link between mathematical theory and the practical applications thereby reinforcing the bond with the real world, in addition to the fact that the computer modeling is cheaper as it does not require expensive equipment. The partial differential equation of the advection-dispersion model was used for the study. Due to the time constraints, students were involved only in the graphical interpretation of the solution by writing programs in MATLAB. The study highlighted that for practical purposes, the experts require the graphical interpretation of the solution rather than the methods which are employed. Students were also required to orally present and report their findings. Data were collected through preand post-study questionnaires and the post-study semi-structured individual interview with 7 students to assess their attitudes towards the project. Questionnaires consisted of four categories of questions relating to students beliefs, usefulness, enjoyment and anxiety. The study, however, concluded that there was no significant change in the attitudes of students due to a relatively short period of time. Nevertheless, students' enjoyment and interest towards the project and the use of MATLAB had reportedly positive. MATLAB as a Teaching and Learning Tool for Mathematics... 35 Computers have also been used for motivating students toward mathematics and their use reportedly had positive impact. Puhak (2011) used MATLAB as a teaching tool to enhance students' motivation and understanding of applied mathematics. The method used for the implementation of the software included choosing one traditional calculus concept, using its application in related areas, performing related calculations for enhanced understanding, and dealing with associated questions to further students comprehension. This method was illustrated with the example 'Center of Mass' with details of the role of MATLAB in the activity with the needed programming code and its visualization. The study has not used the formal measurement techniques, but recommended, to assess the effects of the use of the approach on students' learning. However, routine course evaluations and volunteered feedback were received. In another study by Carol (2012), MATLAB was used for students of Sports Technology who were enrolled into a first year mathematics course at Loughborough University. The aim of the study was to enhance students' motivation and engagement towards learning of mathematics through the introduction of appropriate sports-related group projects and applications. The need for the study was to address the problem of students' lack of engagement and motivation in the learning of mathematics, their poor attendance and high failure rate. An electronic voting system was also used to increase students' engagement and interaction with the lectures. The study highlighted the importance of the group projects and the use of the computer software for realistic problems for engineering students. The author compared the outcome of the initiative which included students' attendance record, motivation and their post-study results with the previous historical data. In the post-study analysis, the students' attendance had reportedly increased compared to the previous data. This increase was attributed to the change in the tutorial classes from the traditional math tutorial to the tutorial held in the computer laboratory where the active learning took place. The change was also evident in their quality of work and the feedback given through the questionnaire. Moreover, a noticeable jump of 33% in the students' success rate was reported. However, the study lacked the control group. Brake (2007) used MATLAB with the aim to increase the math self-confidence and the math ability of freshmen engineering technology students at the School of Engineering Technology, Eastern Michigan University. The software was used to see if this could improve students’ learning. The author believed that self-confident students could be transformed from novice learners to expert learners and MATLAB would increase that self-confidence in them in analyzing problems in mathematics. In this study, the researcher taught two sections of ET 100, Introduction to Engineering Technology, a freshmen engineering pre-requisite course for electronics engineering technology, mechanical engineering technology, and computer engineering technology. MATLAB was introduced into the curriculum, not just as a tool, but to be able to solve engineering problems. The number of students enrolled in this course was 38. A survey was carried out to obtain demographic information as well as data on students past mathematical training including how confident they felt in solving two rather difficult problems relating to finding roots of numbers and applying the math to a real world. A second survey was conducted at the end of the semester and a record of quiz, midterm and final grades on specific questions using MATLAB was kept. Since one of the goals was to turn the inexperienced students into expert learners, it was found that graphing helped many students learn to think more deeply about problems, however, further interpretation skills could not be enhanced due to the insufficient time of using the software. Nevertheless, this study touched upon a very important issue of incorporating computational package into the learning of engineering technology course which requires a thorough understanding of underlying mathematical principles. There are some issues unaddressed relating to the low class size of students, improper 36 M. Abdul Majid et al. brushing up of students skills in learning MATLAB, inadequate background of students in mathematics, and hence statistical insignificance in terms of its applicability to a wider audience and areas. There is a need for more research on the use of MATLAB as a tool to increase self confidence and math ability in freshmen engineering students which the author also felt strongly about. The skills acquired through the use of MATLAB in the teaching and learning will prepare future engineers to meet the demands of the 21st century. Ocak (2006) investigated the relationship between gender and students' attitudes and their prior experience of using MATLAB. Three calculus I classes comprising of 23 female and 37 male students from three different colleges were chosen for this study. All students of these classes had used MATLAB. Students' attitudes were assessed with an attitudes survey instrument and the prior experience with MATLAB was measured with a closed-ended response format questions. The author found a slightly positive correlation between students' attitudes and a prior experience on using the mathematical software program. The study concluded that there was no correlation between gender differences, students' attitude and the software program experience. The study also suggested that an assessment of the students' attitudes should be taken into consideration while using programs like MATLAB. Students' familiarity with features of the software program and their ease of use also affect their enthusiasm and curiosity. This study was conducted by Gorevet al (2004) to examine the effectiveness of the use of computer technologies in solving and doing mathematical problems by pre-service teachers. In addition, the assessments of teachers' skills in using these computer tools; their attitudes toward them; and their willingness to use these tools in their careers as teachers were also considered. MATLAB was also used among the many other computer software tools. Students were given assignment sheets which included both routine and non-routine questions without the use of computers. They were further encouraged to use the computerized tools to solve the problems which they could not solve by hand as well as to enhance their previous solutions. Students' solutions were analyzed using Van Hiele theory to understand the development of their insights. This theory defines insight as a combination of the ability to perform in a possible unfamiliar situation, to perform competently as per the requirement, and resolving the solution consciously and deliberately. Their responses were also collected through their opinions on the use of computer tools in their careers. A vast majority of students expressed strong support to the use of computerized tools for improving their understanding and as well as to find solutions to problems. Some qualitative responses were also provided in the study which, by and large, favored their strong willingness to the use of these tools in their careers despite some unanticipated technical problems that may come in the way. Cretchley et al (2000) investigated the effects of the use of MATLAB on the attitudes and learning of undergraduate mathematics students at the University of Southern Queensland. The study also highlighted the relationships between attitudinal effects and performance. The student body had comprised of a diverse group, on-campus and distance learners, registered in the first semester Algebra and Calculus course. MATLAB was used in lectures, tutorial and assignments. In order to develop mathematical concepts and necessary skills, tasks were designed and a MATLAB manual was written. The use of the software was demonstrated in lectures and oncampus students attended weekly two-hour small group tutorials conducted by tutors and the distance learners used scheduled tutorial on telephones, emails and newsgroups. To encourage and motivate students, small prize money was announced. The data collection instruments used were a pre-study diagnostic test, two post-study examinations, questionnaires related to MATLAB-based assignments, interviews and focus groups, and a pre- and post-study survey questionnaire. The study reported that students' appreciation of the use of the software gradually MATLAB as a Teaching and Learning Tool for Mathematics... 37 increased over time and their ease of use developed as they overcome frustration and difficulty. The assessment of students' knowledge was based on an open book examination without the use of the computers to maintain equity. Students were not examined on their knowledge of the software. Pre- and post-study tests and assignments were conducted to evaluate students' mathematics learning experience, their opinions, skills and interviews were also conducted through focus discussion groups and case studies. Students' opinions were sought on categories such as their learning of mathematics, their experience of using computer software in the learning of mathematics, and self-efficacy in math. MATLAB based tasks particularly explorations were reportedly successful and students reported their positive experiences such as visualizing and computing areas under curves, and the concept of definite integral by taking Riemann sums. The study also reported a wide acceptance, by both on-campus and external students, of the use of technology as an aid for learning and, in particular, of MATLAB as an appropriate software package. The authors reported a strong positive reaction to the experience of using MATLAB to support students learning of mathematics where inculcating motivation towards the study of mathematics many a times is a hardest job. Another motivating factor towards the use of the MATLAB was students' need and importance of its familiarity would help in their relevant engineering subjects. The software's graphical capacity, power and novelty were much appreciated by students. Other features students liked were MATLAB's speed in performing computation with ease, clarity in understanding through explorations, and use the software as a technology check for confirmation of their answers. MATLAB was favoured over graphing calculators due to the computer power with large screen and 3-D graphing capacity. Several others studies have also reported the benefits of using the software as a tool for increasing motivation (Pennel 2009, Ohrstrom 2005, Smits 1992) and fostering positive attitudes, Abdul Majid et al 2012. MATLAB as a Tool for Projects Han (2008) used MATLAB to teach elementary linear algebra to a class of 23 students at the Eastern Michigan University. Three software-based projects and some homework assignments problems were given to students. This innovation was used as a supplement to the traditional method of instruction and its aim was to examine students' perceptions of its usefulness in learning the course material. The approach provided an opportunity to students to solve realworld application problems. MATLAB was chosen to be the right choice over the other software due to its wide popularity in science and engineering, interactive calculations, visualizations capabilities together with its broader applications and audiences. A MATLAB manual was written and the tutorial sessions were held to familiarize students of its use. The three projects designed for the study were; firstly the application of Gaussian elimination, secondly inverse computing methods to solve large linear systems of equations, solving linear systems using Cramer's rule and thirdly the application of the singular value decomposition method. Students performed these projects individually and as well as in groups of 2 to 3. Students' feedback was received through a survey using yes/no types of questions and their opinions were also taken. More than 3/4th of the students expressed their overall satisfaction with the software and more than 57% thought that the software helped them in their learning. Chapin et al (2004) supplemented MATLAB with the standard calculus course for giving simple homework assignments to students at Ohio University. The authors outlined three categories, integrated use, project format and textbook add-on, of the uses of technology in the literature. They, however, implemented the use of the software for simple assignments for 38 M. Abdul Majid et al. making its application easy and practical for both students and instructors. The study highlighted the incorporation of the technology through firstly, use of simple and basic calculations; secondly, giving very clear instructions on assignments; and thirdly, giving very clear and concise technical information. In conclusion, the authors proposed the use of software in undergraduate mathematics courses for simple homework and included a sample MATLAB assignment. The study has not discussed its effects on students learning. Horwitz (2002) described collaborative engineering and science projects between mathematics and engineering departments for the purpose of enhancing first year differential and integral calculus courses. Students used MATLAB in projects individually and in teams and some real data were used. The first semester projects were Hydraulic Engineering, designing a pipeline with minimum cost, optimization of irrigation channel and the second semester projects were Exponential Decay, Skydiver free fall, Wrecking ball, and the Automobile velocity data. A students survey was carried out and they were asked to rate the projects on the scale of 1 to 5. Students reported some complains on the difficulty level of the projects. Some variation was observed in the comments of students belonging to engineering disciplines compared with the science majors. In addition, some students did take part in the projects but did not fully understand the mathematics involved. The study concluded firstly that the students' motivation for doing projects did not seem to have increased at the end of the study, secondly, they were simply involved in the project without themselves understanding the process, and thirdly, in depth project understanding could not be achieved due to the pressure of covering the regular syllabus of the courses. The authors suggested offering one extra credit hour course which could enhance the calculus program. The positive feedback was received from students as they enjoyed doing the projects with MATLAB and they saw a connection of mathematics with the real world. A thorough understanding of mathematical concepts with their applications in engineering and science proved useful to students. Szurley (2011) discussed the application of MATLAB for providing simulation to the projects involving solution of Differential Equations. The modeling projects involved the simulation of the industrial process of film casting and the conduction of heat. The projects were aimed at exposing students to real world applications, familiarizing them with MATLAB, demonstrating the need for numerical computation, and providing the necessary presentation skills. The study reported positive responses from students about real-world applications and in general considered a success. However, the use of MATLAB and the numerical schemes were not much favoured by them. In another study, the author incorporated MATLAB within mathematics courses at Francis Marion University. MATLAB was used for Calculus III projects involving numerical solutions and also for understanding the software's programming concepts. The projects involved L'Hopital Rule, improper integrals, sequences, power series, Taylor and Maclaurin series and as well as Linear Programming and Linear Algebra. The study concluded that students' responses were not very positive about the use of MATLAB partly due to nongraphical interfaces provided to them but in the long run this exposure was believed to help them. The future plan was set up to develop interactive graphical interfaces. Hailan et al (2012) highlighted various benefits of using MATLAB in applications of engineering as an innovative and scientific tool. The author illustrated with examples of how the software could be used as a tool for exploration and experimentation in courses like linear algebra and higher mathematics. The software's commands for finding reduced row echelon form and solving linear equations are used with examples including examples from statistics. Some applications in textile engineering and textile materials have also been given in this paper. MATLAB as a Teaching and Learning Tool for Mathematics... 39 Ohrstrom et al (2005) conducted a study at Chalmers University of Technology. An integrated approach to using MATLAB in chemistry and mathematics courses was introduced and its impact on students learning of solving chemical problems was evaluated. This curriculum reform approach was developed by experts in math, chemistry and education. Students used MATLAB-based assignments individually and in groups in the laboratory. The process of integration of the software into the course was achieved through the exchange of teachers and course material, schedules and planning together with the number of MATLABrelated projects and exercises/assignments. The projects were meant to teach mathematical concepts and skills followed by the development of MATLAB programs. The projects included were the introduction of the 3d geometry of molecules and mathematics, differential equations and kinetics, systems of nonlinear equations and equilibrium analysis as well as computer laboratory on acids and bases. Various pedagogical benefits of using the software were highlighted in the paper. The process of evaluation of its impact involved students, teachers and the educational consultants. The new reform resulted in a positive impact on students learning, and their motivation towards the subject increased. One of the main challenges highlighted by the study was maintaining a right balance in providing the necessary MATLAB skills to students for the future courses. MATLAB as a Tool for Business and Engineering-Related Applications The study conducted by Liang et al (2009) at the University of New Haven is an illustration and a summary of the use of MATLAB for teaching mathematics. The software use aimed at helping students' learning of calculus-based business mathematics and apply the calculus principles to find solutions to real quantitative business problems. The software was implemented to address students' varying levels of algebraic knowledge and skills and the challenge of completing the course in one semester. MATLAB was used to teach topics such as limits, derivatives, optimization, integration and their applications in business as well as the introduction to multivariate calculus and partial derivatives. MATLAB-aided solutions to the mathematical problems were presented step-by-step. The researchers concluded that the software use had helped students in focusing on key objectives of the course through the visualization of the examples and quick numerical computation. The study concluded with the statement that the application of computer technology would prepare students for modern day challenging careers in the workplace. An innovative approach, in the study by Pennell et al (2009), was introduced to the traditionally taught Differential Equations course for the students of engineering majors. The need for innovation was felt due to the fact that most engineering students were unaware of the relationship between mathematics courses and the their core engineering courses as well as the importance of mathematics in their careers as engineers. The new interdisciplinary project was designed in collaboration between mathematicians and engineers in an attempt to overcome students' lack of motivation towards mathematics and to address their poor retention of the material. The lack of engineering-orientation in the traditional teaching of a course like differential equations was highlighted. For instance the main focus was given on techniques for generating solution formulas. From the practical engineering application view point, the system under consideration was to understand how it responds to classes of inputs. The methods of incorporating engineering points of views of first and second order differential equations were given through the illustrations of circuit series, a mass-spring system and the Laplace transform. For students to investigate the behavior of the systems, authors prepared a brief theoretical 40 M. Abdul Majid et al. description together with the software tool developed using MATLAB and its allied toolboxes. MATLAB's GUI was prepared for students to interactively investigate various plots and behaviors of the systems. No feedback on the approach has been given. Naimark (2002) pointed the problems of a lack of connection in mathematics curriculum with the engineering disciplines which are applications oriented. The author alternatively presented the argument of what he called modernizing the mathematics courses by introducing modern computing-based applications by incorporating MATLAB. Mathematics syllabus should be viewed and taught as a central concept and a unified picture, "concepts as unifying vehicles". The illustrations of the use of MATLAB's Polyfit, MATLAB's view and Fourier Transforms were given. The linear Algebra course was taught using MATLAB in this study. Some of the software-based applications were the visualization of parametric equations, matrix of Linear Operator, matrix multiplication, Gaussian elimination method, rotations, projections, eigenvalues and eigenvectors etc. The study highlighted some pedagogical benefits of the new approach such as making the theory more transparent; students could concentrate on the structure of operations and as well as an additional method of memorization of concepts and procedures for students. The effects of the modern approach enhanced students understanding. The course objectives were achieved through the internalization of the central concept of the general linear operator. The use of the equality of inverse matrices, systems of linear equations, and the associative property of matrix multiplication improved students learning. Some of the challenges noted in the study were: the amount of time required for MATLAB-based exercises, instantaneous rectification of students' errors and the delay caused in teaching concepts like determinants and eigenvectors. In a study by Brown et al (2012), MATLAB has been used as a complementary tool to the traditional lecture for exploring mathematical concepts for the 1st year Electrical Engineering students at the University of Manchester. The introduction of the software was to provide mathematics contextually to see the connection with engineering concepts and to do calculations with varied parameters. Students used the software notebooks developed in Mupad-MATLAB. The study has not described the effects on students learning. MATLAB as a Tool for Improving Problem-Solving Techniques Talbert (2011) used MATLAB to teach problem-solving techniques to first-year Liberal Arts students who were enrolled in Calculus III at the Franklin College. Students spent most of the classtime doing hands-on lab exercises, watching video lectures and completing online tutorial work. The inverted classroom model was used in this study. This model provided students the ability to learn on their own and to apply new concepts. Students took some time adjusting to the innovative learning model, however, their feedback was reportedly positive. Legua et al (2001) in their study provided a comparison of the use of DERIVE, Mathematica and MATLAB to solve the line integral, an engineering mathematical problem. The aim of the study was to harmonize the use of the software with the teaching of mathematics at the Escuela Universitaria de IngenieraTcnica Industrial. A comparison of how the line integral concept could be explained using DERIVE, Mathematica and MATLAB was given with screenshots. The study concluded the DERIVE software as the most efficient of the other programs for evaluating line integrals. The study has not reported the effects of the use of this approach in the classroom teaching. Nyondo (1992) used MATLAB as a problem-solving tool for teaching some topics in linear algebra course at The Papua New Guinea University of Technology. The software was used to MATLAB as a Teaching and Learning Tool for Mathematics... 41 reinforce theoretical concepts taught in conventional lectures. The instructors had designed exercises and problems appropriate to the level of the course and suitable to the students' engineering specialization. The emphasis was also given on using MATLAB and mathematics as problem solving tools for engineering. Using the software, students practiced a variety of problems through experimentation. The study, however, has not reported the effects of the use of MATLAB on students' learning. Conclusion In this review, we have shown the different ways in which MATLAB was used as a teaching and learning tool for mathematics. It has been used as a tool for the visualization of the graphs of mathematical functions, computation, problem-solving, increasing motivation and selfconfidence and as well as fostering positive attitudes toward mathematics. However, a number of factors need to be taken into consideration concerning the technology integration in the teaching and learning of mathematics as highlighted by Schneider (2000). A vast majority of studies have used MATLAB as a supplement to the traditional teaching and learning of mathematics. References Abdul Majid, M., Huneiti, Z. A., Balachandran, W., & Al-Naafa, M. A. 3.2 BLOCK DIAGRAM OF PROJECT:

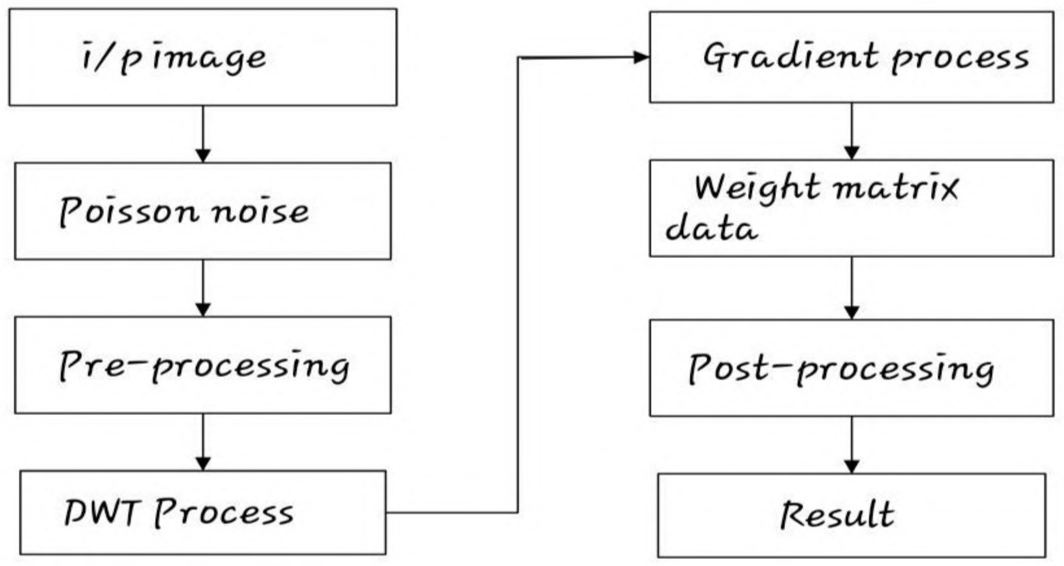

Fig.3.1: Block diagram of the project

Matlab

MATLAB is a programming language developed by MathWorks. It started out as a matrix programming language where linear algebra programming was simple. It can be run both under interactive sessions and as a batch job. This tutorial gives you aggressively a gentle introduction of MATLAB programming language. It is designed to give students fluency in MATLAB programming language. Problem-based MATLAB examples have been given in simple and easy way to make your learning fast and effective.

This tutorial has been prepared for the beginners to help them understand basic to advanced functionality of MATLAB. After completing this tutorial you will find yourself at a moderate level of expertise in using MATLAB from where you can take yourself to next levels.

We assume you have a little knowledge of any computer programming and understand concepts like variables, constants, expression, statements, etc. If you have done programming in any other high-level programming language like C, C++ or Java, then it will be very much beneficial and learning MATLAB will be like a fun for you.

MATLAB (matrix laboratory) is a fourth-generation high-level programming language and interactive environment for numerical computation, visualization and programming.

It allows matrix manipulations; plotting of functions and data; implementation of algorithms; creation of user interfaces; interfacing with programs written in other languages, including C, C++, Java, and FORTRAN; analyze data; develop algorithms; and create models and applications.

It has numerous built-in commands and math functions that help you in mathematical calculations, generating plots, and performing numerical methods.

MATLAB is used in every facet of computational mathematics. Following are some commonly used mathematical calculations where it is used most commonly.

Following are the basic features of MATLAB −

It is a high-level language for numerical computation, visualization and application development.

It also provides an interactive environment for iterative exploration, design and problem solving.

It provides vast library of mathematical functions for linear algebra, statistics, Fourier analysis, filtering, optimization, numerical integration and solving ordinary differential equations.

It provides built-in graphics for visualizing data and tools for creating custom plots.

MATLAB's programming interface gives development tools for improving code quality maintainability and maximizing performance.

It provides tools for building applications with custom graphical interfaces.

It provides functions for integrating MATLAB based algorithms with external applications and languages such as C, Java, .NET and Microsoft Excel.

The positive change in the teaching and learning lies in several factors. “Education technology is neither inherently effective nor inherently ineffective; instead, its degree of effectiveness depends upon the congruence among the goals of instruction, characteristics of the learners, design of the software, and educator training and decision-making, among other factors", Schneider (2000). However, for some, its use is still questionable. The research question which will guide this review is the following: "In what ways MATLAB has been used in the literature for teaching and learning of mathematics in the university education?" MATLAB MATLAB, the product of Mathworks Company, is the general purpose computing software. It contains a vast range of specialized toolboxes and also works as the computer algebra system through its symbolic math toolbox. This toolbox performs symbolic algebraic/mathematical manipulative operations with a lot of built-in interactivity. MATLAB undoubtedly is popular among computer and multi-disciplinary scientists, engineers and particularly with experts in the area of computational mathematics. It integrates numerical, symbolic and the state-of-the-art graphic visualization capabilities with quite intuitive computer programming environment. Methodology The systematically classified and integrated methods were used to summarize the relevant articles and presented them in a narrative manner. A literature review for the publications between 1988 and 2012 was carried out from the sources such as mathwork.com, ERIC, IEEE xplore, ProQuest, Academic Search, Springer Link, Taylor and Francis, Science Direct, Proceedings for the conferences, the Google and the Google scholar search. The keywords used for the search were "CAS and mathematics education", and "CAS/MATLAB as a teaching & learning tool for math", "CAS/MATLAB as a visualization tool for math", "CAS/MATLAB as problem-solving tool in math" etc. Our primary focus was the empirical studies based on classroom and computer-lab where MATLAB was used as a pedagogical tool for mathematics. MATLAB as a Teaching and Learning Tool for Mathematics... 25 Theories of Learning and CAS It is important to know how theories may help in technology integration for mathematics instruction. The theoretical and conceptual basis of using computer technology in the teaching and learning of mathematics can be linked with the Constructivist Theory. According to this theory, a learner cognitively constructs a mathematical concept through the active involvement in the processes of experimenting, conjecturing, proving, and applying. Using CAS, students actively construct and acquire knowledge in mathematics rather than being passive receivers of knowledge. There are a number of other theories derived from the cognitive psychology relating to cognitive and technology-aided cognitive processes such as Cognitive Load Theory, Cognitive Theory for Multimedia Learning and Distributed Cognition Theory. According to Sweller (2004), Cognitive Load Theory suggests the learning activities to be aligned with the human cognitive structure. The structure of human cognitive architecture, while not known precisely, is discernible through the results of experimental research. According to Hutchins (1990), "Distributed cognition is a branch of cognitive science that proposes cognition and knowledge are not confined to an individual; rather, it is distributed across objects, individuals, artefacts, and tools in the environment." According to Cognitive Multimedia Theory, the information presented through the integration of limited visual and auditory channels will be filtered, selected, organized, and integrated by the learner actively, figure 1, Mayer & Moreno (2003). However, an understanding of the human cognitive processes in a mathematics teaching and learning environment which involves human computer interaction still needs much exploration. Figure 1: Cognitive Multimedia Theory by Mayer & Moreno, (2003). Duval (1993) suggested an absolute necessity of the application of different semiotic representations for a solid understanding of mathematical concepts. This can be achieved in a technology-enriched teaching and learning environment. The theoretical framework in figure 2 is based on the notion of 'procept' given by Gray and Tall (1994) and the semiotic representation of mathematical concepts by Duval (1993). This theoretical framework was used by Abdul Majid et al (2012). 26 M. Abdul Majid et al. Figure 2: A theoretical framework for teaching and learning of mathematics with CAS. Literature Review Summary The literature review search has not revealed any study which focused specifically on the review of literature on MATLAB as a teaching and learning tool for math. The selected articles and papers that were reviewed, compiled and summarized are as follows: Proposals to use MATLAB as a Teaching and Learning Tool for Mathematics A number of articles have been written proposing the use of MATLAB in teaching and learning of mathematics, Kazimovich et al (2012), Tahir et al (2010), Chaamwe (2010), Mckenzie (2008), Friedrich et al (2008), Stanoyevitch (2005), Shi (2004), Wu (2004), Colgan (2000), Kawski (2003), Dunn et al (2002), Pester et al (2001), Markanda (1995) and Katende in his unpublished paper. Kazimovich et al (2012) illustrated the capabilities of the applications of symbolic computation techniques of MATLAB for engineering students. The capabilities of MuPAD and its combination with MATLAB were described for writing formulas, factorizing an expression, solving equations, solving systems of equations and differential equations, finding derivatives and antiderivatives as well as plotting functions. In addition, some of the useful functions like computing Fourier transforms and their inverses have also been given. The paper also provided sketches of the transfer between MuPAD and MATLAB. Tahir et al (2010) proposed the integration of MATLAB into science, technology and engineering disciplines as a teaching and learning tool for undergraduate studies to the Ministry of Science and Technology, Iraq. The graphical user interface programs created for Math 1 and Math 2 courses were proposed to be used in teaching linear algebra, graphing, Laplace Transform, differential and integral calculus courses. The proposed programs were aimed at motivating students and demonstrating the relationships between pure mathematical concepts to the real world. The authors planned to develop a supplemental booklet for using computer programs in tutorial sessions. The authors also recommended the use of the software throughout the science and engineering institutions in the country and also emphasized the need for providing necessary training on the use of MATLAB to the teaching faculty. Chaamwe (2010) provided a few illustrations for sketching mathematical graphs of functions using MATLAB. The study highlighted some general benefits of integrating the software. Students motivation to learning can be enhanced, they can work collaboratively in teams. It could provide a problem-centered approach in teaching and learning. Their skills could be honed. The software can also be used for demonstrating a connection between the theory and MATLAB as a Teaching and Learning Tool for Mathematics... 27 the practice and as well as students actively participate in the learning process. The study also highlighted some relevant studies on the role of Information and Computer Technology. In this report by Mckenzie (2008), MATLAB has been recommended to be used as a new pedagogical model for illustrating and reinforcing mathematical concepts to students at the Oregon Institute of Technology. This recommendation was for a replacing the existing system of math instruction. The purpose was to provide interactive demonstrations and visualizations into mathematics classes. Primarily, two objectives were aimed at, firstly, to demonstrate the link between the use of MATLAB to the enhancement of the understanding of the math and secondly, to equip students with the necessary professional software skills in their careers. To make the efficient use of the new model, the report also recommended creating a website for MATLAB, integrating teaching of the software as a one-credit course into the math curriculum and also providing the information on the website about the connection of mathematical contents to students' specific engineering fields. The report concluded that students' motivation, interest, their appreciation to the software, communications and critical thinking would be positive. Computer tools could also be used to overcome math-phobia as termed by Pappert (1993). Friedrich et al (2008) described the cognitive role of computer technologies such as MATLAB in the development of students' mathematical reasoning, logic and problem solving skills. The graphing capabilities of various CAS programs such as Maxima, Scilab, Micro Worlds, Dynamic and Interactive Geometry as well as MATLAB have been given. The study concluded that the issue of declining interest in math and in its allied disciplines such as engineering is due to the lack of well-educated technical experts in cognitive technologies. In this paper, the author Stanoyevitch (2005) presented the benefits and versatility of introducing MATLAB into university mathematics programs and how the software could be incorporated. A detailed description was given on how the implementation of the software could enhance mathematics courses both from the academic aspect as well as opening up the employment prospects for graduates. Students could achieve a higher level of learning in courses like abstract algebra with the incorporation of MATLAB into it. The issues such as licensing the software, using it as an isolated technology, from a minimal lower level to an advance levels, have also been raised in the study. Some illustrations of its use such as logistics of air shipping and computation of worst-case-scenario number of a directed network were provided in detail. The study by Shi (2004) was aimed at implementing MATLAB as a tool into teaching and learning of calculus for students majoring in Physics. It was also suggested dividing students into normal and advanced levels based upon their aptitudes as well as including the group work for them. The need for the change in the pedagogy was felt due to a host of problems related to students learning of mathematics. The focus for the normal group of students was given for learning the basic underlying concepts and principles of mathematics with less emphasis on the subject’s rigor. The advanced group of students would have the normal course without providing them the details of the course putting greater self-responsibility for learning. A number of illustrations of the visualization of the graphs of the mathematical functions were given with explanation of how they could be used in teaching. The software tool was also recommeded to be used for enhancing the key concepts such as tangent line of a curve at some point, geometric interpretation of the definite integral as well as some examples of mathematical modelling. The study also highlighted the importance of group work and suggested to form a group of 4 to 5 students to cultivate necessary communication and collaborative skills among them. The assessment scheme to the new approach was suggested to be in place. The author believed that 28 M. Abdul Majid et al. the proposed new approach would be more student-centered and it would provide necessary important skills to students. In this study, Wu (2004) proposed MATLAB to be used as a teaching and learning tool at the School of Science, Beijing Institute of Technology. The study aimed at improving the teaching and learning of linear algebra and to equip students with modern computing technology. The proposal also suggested establishing the website for the course. It was also highlighted that the software could be used as a data visualization tool to promote deeper understanding of the concepts. Dunn et al (2002) used MATLAB for teaching and learning of introductory calculus at the University of Southern Queensland, Australia. Five MATLAB based graphical interface programs were used to demonstrate the mathematical concepts such as Newton’s Method, differentiation and integration. The programs present some unusual and important cases of the calculus concepts. The authors argued that MATLAB could be incorporated into learning of mathematics in three ways, namely, firstly as a numerical and graphical tool, secondly as an aid to learning of ideas and concepts and thirdly to show the procedure or concept in a more sophisticated way. In this work, the authors have used MATLAB using the third approach. The main focus of the use of these programs was to demonstrate mathematical concepts rather than doing a particular task. The study also suggested that the computer technology should be used a supplement to the traditional teaching and learning. In this proposal, Kawski (2003) compared the arguments of the integration of MATLAB with that of the other CAS programs such as Maple and Mathematica in the first year college mathematics. The author comparatively put forward the argument that integrating a CAS in mathematics curriculum is much easier than MATLAB due to the pedagogical and planning related challenges with the later. The study further stated that the traditional calculus is still an "algebra course" whereas MATLAB provides numeric computing in which "almost everything is a matrix". Katende in his unpublished paper reviewed the role of MATLAB and other symbolic algebra systems for engineering mathematics with some illustrations. The study outlined some of the potentials and challenges in undergraduate engineering mathematics. Illustrations such as expanding cos(7x), differentiating sin(E^x(x^2+1)) and integration problems were given and how quickly the algebra systems provided output to such complicated computations. Some examples of 2-D and 3-D graphical visualization were also provided in the paper. The study concluded highlighting the need to change the curriculum or the approach to teaching engineering mathematics. MATLAB Web Server was proposed to be used in this study by Pester et al (2001) for electrical engineering and mathematical modeling. The interactive software could be used to save students' time and to increase their motivation. It could be used for simulation and visualization of 2 and 3-dimension graphs. A few illustrations of how the software could be used were given as well as with some advantages and disadvantage of using web-based MATLAB. Solutions to some network related problems were also proposed. Markanda (1995) described how the students' version of MATLAB could be used to compare several direct, elimination, and iterative methods for solving efficiently and with less calculations systems of n equations in n variables. The illustrations of Jacobi and Gauss-Seidel methods using the software were given in the paper. In a study by Dios et al (2012), MATLAB and Learning Management System "Moodle" were introduced in the traditional teaching and learning of graduate engineering mathematics course. The aim was to give students a better understanding of the course contents. The paper MATLAB as a Teaching and Learning Tool for Mathematics... 29 discussed the mechanism of the new structure of the course including the web-based assessment. The Learning Management System "Moodle" was created as a virtual learning environment to work as a pedagogical model. The online quizzes were used using WIRIS, an editor to write symbols and formulas. Kovacheva (2008) outlined the main features of many popular mathematical application packages including MATLAB. The capabilities of these programs for research as well as for teaching were described briefly. MATLAB as a Tool for Graphing and Visualization of Mathematical Data and Concepts One of the greatest benefits of computer technology is the accessibility of the mathematical concepts through visualization. MATLAB is one of the best known software which contains mathematical data visualization capabilities, Palais (1999). MATLAB as a visualization tool has been used in the courses like linear algebra, calculus and differential equations etc. Szurley (2007) used MATLAB as a visualization tool for applications of linear algebra course. Two examples of population modeling and one example of Genetics were used in this study. The aim of the study was to provide students with the graphing capabilities for illustrating the insights into the material. In an extension of the study, the author created some graphical user interfaces in MATLAB to address students' unsatisfactory responses to the use of the software in an earlier study. The aim was to provide interactivity and visuals for presenting mathematical concepts. Palmer (2008) also aimed at visualization of linear algebra concepts through the writing and the development of simple animation programs in MATLAB. The author claimed that creating animation programs is possible with little knowledge of linear algebra, no computer programming experience and without MATLAB’s familiarity. The study concluded that students' learning of matrices enhanced, however, no students' feedback was given. In a collaborative project between Swedish and British instructors (two mathematicians and one didactic expert), MATLAB was used to teach undergraduate engineering mathematics students, Burton et al (2004). The aims of the project were to support students' visual and graphical understanding of mathematics and their access to the numerical computation of the course. Individual interviews were conducted to get the feedback from students. Their overall feelings were mixed on their experience of using the software. To achieve effective software integration, the study has also provided suggestions such as ensuring clarity in learning goals, adequate number of MATLAB classes, and the preparation of a manual to support MATLAB programming by providing necessary reference material on the web. Students expressed their dissatisfaction with their experiences of using MATLAB as there was too much elapsed time between two MATLAB sessions consequently students had to learn the material over and over again. The study concluded that the integration of the software should be planned thoroughly with enough software documentation. In several studies, MATLAB was integrated into the mathematics curriculum as an add-on teaching and learning tool. In a slightly different approach, it was integrated to an interactive "Adaptive Book" system with the aim to demonstrate the linear algebra concepts and as well as the course's algorithms, Gunawardena and Jain (2002). The concepts were presented both in the mathematics classroom/laboratory followed by the software demonstrations. In this study, MATLAB was also used as a drill and practice tool in which a combination of text and visuals were presented in multiple forms. The project such as Singular Value Decomposition for performing data compression was based on practical applications. The study described linear algebra as an ideal course for integrating technology to enhance the teaching and learning processes. It was concluded that the software 30 M. Abdul Majid et al. like MATLAB could provide a good platform for not only visualization but also for numerical computation. Stewart et al (2005) used MATLAB to assess the process of students' instrumentation of technology in the teaching of mathematics courses. The authors' called the instrumentation as a student's transformation and adaptation of computer technology to the assigned mathematical task and "it is through the actions and decisions that the student makes that the CAS tool or artefact is transformed into an instrument". The case study involved first and second year students enrolled in scientific and engineering disciplines at the University of Canterbury. The second year students used MATLAB in tutorials and computer laboratory sessions for an advance linear algebra course. The aim of the software use was to solve problems but the main focus was to help students with understanding the steps involved in the solution. The data were collected through a questionnaire in which questions were given relating to students' attitudes to the use of computers in learning math; use of computers in linear algebra course and some openended questions on the value of computers for the course. Students' feedback to the benefits of using MATLAB for visualization, conceptualization, and problem-solving was positive. In the analysis, the study reported three students' types regarding the instrumentation of computer technology for university mathematics courses. These types were firstly, those who opposed to the computer work, secondly those who were happy to use computer with a limited instrumentation, and thirdly those who exhibited too much reliance on the use of computer for mathematics. The study concluded with the recommendation of the Leigh-Lancaster's view of achieving the integration of computer technology through the process of having congruency between curriculum, pedagogy and assessment making it clear that CAS must be specified in the curriculum, teaching as well as assessment. The assessment in mathematics must be in tandem with its teaching and learning. In a study, Colgan (2000) described the integration of MATLAB to the teaching of traditional engineering mathematics course at the University of South Australia. The course included elementary linear algebra, the differential and the integral calculus. The need for the software integration was felt due to the decline in the mathematical skills of students entering into the engineering disciplines. MATLAB was chosen because of two reasons, firstly it was extensively used in some of the engineering programs at the university and secondly it was believed to increase students' employability after graduation. A MATLAB guide specifically covering the course contents was prepared to incorporate the software into the teaching. This was considered a major component of integrating software into the syllabus. The software use was demonstrated in the classroom lectures. The graphing capability of the MATLAB was shown to the students illustrating graphs of functions including features such as zoom on and multiple commands for plotting functions etc. MATLAB was used to improve students understanding of the mathematical concepts such as limits, continuity, differentiability, multiple representations of the Mean Value Theorem, Riemann Sums, and finding the volumes of revolution etc. The methodologies of teaching the course were redesigned keeping in view of the qualities of the engineering programs mentioned by the professional engineering body of Australia. The syllabus was rewritten outlining clearly the delivery and the assessment criteria. Weekly five contact hours were allocated for the course in which three hours of regular lecture, one hour of tutorial and one hour was dedicated for working with the software. Apart from the software guide, the syllabus also included the engineering applied examples relevant to the course. The emphasis throughout the process of technology integration was to enhance students' understanding of mathematics. The paper also provided some of the illustration of the engineering examples such as the classical problem of Snell's Law and the minimization of the MATLAB as a Teaching and Learning Tool for Mathematics... 31 time in the refraction of light. To inculcate collaborative spirit among students, they worked in groups of four on MATLAB sessions and the engineering projects/assignments. A part of the group's work was performing the analysis of the engineering project and presenting that in the form of a report. The projects involved the knowledge of the engineering as well as the use of the mathematical formulas. The study concluded that the course was considered to be the most successful without providing any data. The author highlighted the need for striking a good balance between the amounts of time to be spent on MATLAB to the course requirement. Schlatter (1999) described the visualization benefits of using MATLAB in a multivariable calculus for various concepts such as three-dimensional surfaces, contours plots, gradient fields and parametric curves etc. The software, to some extent, was also used for symbolic integration and for setting up integrals. The author developed two- and three-dimensional interactive packages in MATLAB and they were used; firstly to help students in visualization of mathematical objects and surfaces and; secondly to familiarize them with the use of MATLAB. The study concluded that the students could cover a more variety of integrals when the software would be used as a pedagogical tool. Apart from linear algebra and multivariable calculus courses, the software was also used for teaching concepts such as series convergence and numerical computation and visualization of power series approximations. Moore (1988) used MATLAB to teach "Series and Differential Equations" at the Grinnell College. The goal was to provide graphic visualization through the experimentation of various functions, and numeric computations for Taylor polynomials approximations, partial sums of power series, definite integrals and differential equations. Students' used MATLAB-based programs. The study concluded that the software tools not only widen students' problem-solving ability, insight, flexibility but also their ability to use them. However, the study has not provided any students' feedback. In addition to the above studies, the software was also reported to be effective tool in the visualization of mathematical concepts, (Abdul Majid et al 2012, Puhak 2011, Liang 2009, Stewart 2005, Henderson 2002, Smits 1992). MATLAB as a Computational Tool Another extremely powerful feature of MATLAB is its interactive numerical computation environment which is based on the matrix structure. Computational methods and skills of students in topics such as matrix computation, numerical differentiation and integration, and differential equations etc. can be enhanced with the use of the software. Particularly, engineering students need this skill to solve many engineering problems, Canfield (2012). Addabbo (2010) presented the approach that was used for teaching Introduction to MATLAB course for engineering students of Vaughn College who had completed calculus as one of the requirements. The course was divided into two parts; part 1 was related with programming techniques based on calculus problems, and the part 2 was the study of the numerical solutions of differential equations studied through linear and non-linear physical models. This approach was developed to demonstrate the relationship between the pre-requisite courses such as physics, statics, dynamics, writing and the vibration with that of calculus as well as to encourage higher order learning. Several projects such as matrix operations, summing series, Newton's Root Finding Method, Weather Data, and the numerical integration were given to students. Students were expected to do projects in groups of maximum three students. Upon completion, they were required to give a presentation and their performance was assessed on a set criteria. However, the study has not reported the effects of the approach and no conclusions were drawn. In a similar study, MATLAB was used for teaching computational modules at Southern Queensland University, Tonkes (2005). The learning model was developed and integrated for the first year mathematics courses. The aim of the study was to primarily reinforce traditional mathematical 32 M. Abdul Majid et al. learning, teaching concepts in numerical math and as well as for engaging students in computer aided problem solving. The model development included an interactive workbook, web-based solutions, Graphical User Interfaces and programs developed in MATLAB. The study highlighted some of the challenges encountered in the integration of the software in the mathematics curriculum. They were time allocation for the software use, students' efforts in learning it, numeric nature of the software, its syntax, and differences in the meaning of some of the signs in computers and math as well as the attitudes of teachers using it. Students progressed through their use of the software in stages through the single line commands environment to launching MATLAB's GUIs and then to developing their own MATLAB code. All assignments/exercises and experiments were performed in pairs. The outcome of the study was assessed through students' feedback survey and the programs downloads log. The students demonstrated an enhanced understanding of math, interaction with the tutors increased, and students' retention improved. The model had been reportedly successful from all stake-holders; students, lecturers, and tutors. Linear Algebra course was among the most popular courses in which MATLAB was used as reinforcement to classrooms lecture. At the University of Sydney, MATLAB was used as a supplement for teaching an undergraduate linear algebra course, Henderson (2002). The aims were to familiarize students with basic MATLAB commands so as to improve their conceptual understanding of the course. In this study, students used MATLAB to solve 4 to 5 problems in a week over one full semester. The use was mainly towards mathematical exploration, visualization of graphs and multiple representations of mathematical concepts. The study recommended maintaining an appropriate balance between the use of the software for learning mathematics and the traditional learning of mathematics. The data were collected through a questionnaire which contained both open-ended and closed-ended questions. The feedback to students' attitudes toward mathematics have also been discussed. The study reported positive and negative views toward the use of the software for learning mathematics. The software had also been used to study some mathematical functions such as Weirstrass function and to study numerical approximation of ʌ, Feng (2011). In this study, the author has also used the software for testing the convergence of an infinite series using ratio test, root test and the integral test. Liang 2009, Burton 2004, Gunawardana 2002, Smits 1992, & Moore 1988 have also reported the benefits of using MATLAB as a computational tool. MATLAB as a Tool for Improving Math Performance/Math Achievement The positive impact of computer technology on students' learning and performance has also been examined and reported, Abdul Majid et al (2012), Strayhorn (2006), Kulik & Kulik (1991). Abdul Majid et al (2012) have used MATLAB as a supplement for teaching Integral Calculus course to 77 engineering students at the University of Ha'il. The study aimed at firstly, to enhance students' conceptual understanding, their performance in mathematics and secondly, to foster positive attitudes towards mathematics and attitudes toward the computer technology. The case study involved an experimental group and a control group. Among the important objectives of incorporating the software were to address the declining mathematical skills of students needed for their core engineering courses as well as establishing a smooth transition to the upper level courses. The software had been used for a number of instructional objectives such as for visualization of graphs of mathematical functions, for identifying and exploring mathematical patterns in evaluating definite integrals, for multiple representations of a mathematical concept, and as well as for computation. The study reported the positive effects on students' math achievement compared to the performance of control group of students in the final examination. MATLAB as a Teaching and Learning Tool for Mathematics... 33 The conclusions drawn from the study were that the integration of MATLAB could be effective through the appropriate instructional design combined with students using the software in groups of 2-3. The integration of MATLAB has also been reportedly positive on students' performance in mathematics with "Moodle" an e-learning management system. The MATLAB was integrated with Moodle as a supplement to the classroom lecture for teaching calculus to undergraduate students in Geodesy at the Vienna University of Technology, Judex et al (2008). The blended teaching and learning approach was used to address the issue of students' lack of interest in mathematics and their weak background in the subject. To integrate MATLAB into the course, the software was used as an instructional tool and its basic course was included into the exercises of the mathematics courses. Specifically, the software was used for the large geometric mathematical drawings used in the geo science. Over 90 examples were developed and were made available via "Moodle" for students. The blended approach proved to be successful for the presentation of the heavy calculus course contents in a short time without sacrificing the true comprehension of the course. It enhanced the quality of lectures, improved students average grades as well as their programming skills. The integration of MATLAB would not only provide students a familiarity with modern learning tool but also an added advantage in their careers. The linear algebra course is among the most popular courses in which MATLAB has been integrated in its teaching. Smits et al (1992) described the impact of the use of MATLAB on mathematics achievement of the first year linear algebra students at the Eindhoven University of Technology. A detailed overview was given on how the course contents were presented in lectures and tutorials. In their study, the first nine weeks of the term, linear algebra was taught in which a 3-hour lecture with a tutorial were given. During the second half of the term, the course primarily focused on eigenvalues and eigenvectors followed by the last 3-weeks of the course on ordinary differential equations. MATLAB was used for time-consuming calculations, for motivating students, the interpretation of the row-echelon form, for doing more practice with the problems, for illustrating some aspects of the theory, geometric interpretation of the matrix of a linear transformation, and for introducing unknown techniques or concepts. Students played an active role in learning, conjecturing through guided experiments, and acquainted themselves with the real use of the mathematical techniques. An analysis of the results revealed that students' performance was better in the first term compared to the second term due to the complex nature of the concepts dealt with in the second. The study described the positive effects of the use of the software on students' performance as well as on equipping them with modern computing skills. MATLAB as a Tool for Fostering Positive Attitudes Towards Math, Math Confidence, and Enhancing Motivation Towards Learning Math Attitudes are defined as positive or negative emotional dispositions, McLeod, D. B. (1992) & Aiken (2000). Students' attitudes toward mathematics are complex and a number of measurement tools and constructs are reported in the literature. According to Willis (1995), "Human-computer interaction is a complex phenomenon and the attitudes and feelings involved with this relationship are difficult to identify" and the author has also reported the positive attitudes towards computer technology. This positive change in attitudes also reported to have motivated students in mastering the necessary computer skills quickly. Confidence in learning mathematics, mathematics anxiety, and perceived usefulness of mathematics as the most frequently studied and identified affective variables associated with student achievement in mathematics, Reyes (1984). One of the strategies indicated by Bretscher (1989) is the use of a computer lab with 34 M. Abdul Majid et al. tutors providing individual instruction and hands-on practice in concepts and skills. This strategy may help enhancing students' motivation and overcoming their math anxiety. The computer technology fosters positive attitudes towards mathematics, Lim et al (2009), Yashau (2006), Ocak (2006) &Gorev et al (2004), Cretchley et al (2000), increases students confidence in math, Brake (2007) and as well as it enhances their motivation towards learning math, Puhak (2011) & Carol (2012) . Figure 3: Ernest (2003) on failure and success cycles in math. Yushau (2006) used a blended learning approach in which MATLAB was used as a learning tool by 70 pre-calculus students at King Fahd University of Petroleum & Minerals. Students used MATLAB in weekly computer lab sessions. Some related online learning resources were also provided to students. The study was conducted over a semester and the pre- and post-study students' attitude towards mathematics and computers were examined. The concluding results reported a statistical significance of students' positive attitude towards mathematics and computers. The use of technology had reportedly positive effects on students' attitudes for a variety of courses such as single and multivariable calculus and courses which require solid background in mathematics such as engineering and technology. However, some studies such as the one on mathematical modeling by Lim et al (2009) reported no change in students' attitudes. In this study, the effects on students' attitudes were examined when applied mathematical modeling project was introduced with MATLAB. The project was concerning the volcanic ash fall after an eruption. The study involved third year students of Earth Science at the National Taiwan Normal University. It aimed at assessing students' attitudes towards mathematics in the pre- and post-modeling project. Some of the anticipated benefits of the projects were making the learning of the course interesting, providing a link between mathematical theory and the practical applications thereby reinforcing the bond with the real world, in addition to the fact that the computer modeling is cheaper as it does not require expensive equipment. The partial differential equation of the advection-dispersion model was used for the study. Due to the time constraints, students were involved only in the graphical interpretation of the solution by writing programs in MATLAB. The study highlighted that for practical purposes, the experts require the graphical interpretation of the solution rather than the methods which are employed. Students were also required to orally present and report their findings. Data were collected through preand post-study questionnaires and the post-study semi-structured individual interview with 7 students to assess their attitudes towards the project. Questionnaires consisted of four categories of questions relating to students beliefs, usefulness, enjoyment and anxiety. The study, however, concluded that there was no significant change in the attitudes of students due to a relatively short period of time. Nevertheless, students' enjoyment and interest towards the project and the use of MATLAB had reportedly positive. MATLAB as a Teaching and Learning Tool for Mathematics... 35 Computers have also been used for motivating students toward mathematics and their use reportedly had positive impact. Puhak (2011) used MATLAB as a teaching tool to enhance students' motivation and understanding of applied mathematics. The method used for the implementation of the software included choosing one traditional calculus concept, using its application in related areas, performing related calculations for enhanced understanding, and dealing with associated questions to further students comprehension. This method was illustrated with the example 'Center of Mass' with details of the role of MATLAB in the activity with the needed programming code and its visualization. The study has not used the formal measurement techniques, but recommended, to assess the effects of the use of the approach on students' learning. However, routine course evaluations and volunteered feedback were received. In another study by Carol (2012), MATLAB was used for students of Sports Technology who were enrolled into a first year mathematics course at Loughborough University. The aim of the study was to enhance students' motivation and engagement towards learning of mathematics through the introduction of appropriate sports-related group projects and applications. The need for the study was to address the problem of students' lack of engagement and motivation in the learning of mathematics, their poor attendance and high failure rate. An electronic voting system was also used to increase students' engagement and interaction with the lectures. The study highlighted the importance of the group projects and the use of the computer software for realistic problems for engineering students. The author compared the outcome of the initiative which included students' attendance record, motivation and their post-study results with the previous historical data. In the post-study analysis, the students' attendance had reportedly increased compared to the previous data. This increase was attributed to the change in the tutorial classes from the traditional math tutorial to the tutorial held in the computer laboratory where the active learning took place. The change was also evident in their quality of work and the feedback given through the questionnaire. Moreover, a noticeable jump of 33% in the students' success rate was reported. However, the study lacked the control group. Brake (2007) used MATLAB with the aim to increase the math self-confidence and the math ability of freshmen engineering technology students at the School of Engineering Technology, Eastern Michigan University. The software was used to see if this could improve students' learning. The author believed that self-confident students could be transformed from novice learners to expert learners and MATLAB would increase that self-confidence in them in analyzing problems in mathematics. In this study, the researcher taught two sections of ET 100, Introduction to Engineering Technology, a freshmen engineering pre-requisite course for electronics engineering technology, mechanical engineering technology, and computer engineering technology. MATLAB was introduced into the curriculum, not just as a tool, but to be able to solve engineering problems. The number of students enrolled in this course was 38. A survey was carried out to obtain demographic information as well as data on students past mathematical training including how confident they felt in solving two rather difficult problems relating to finding roots of numbers and applying the math to a real world. A second survey was conducted at the end of the semester and a record of quiz, midterm and final grades on specific questions using MATLAB was kept. Since one of the goals was to turn the inexperienced students into expert learners, it was found that graphing helped many students learn to think more deeply about problems, however, further interpretation skills could not be enhanced due to the insufficient time of using the software. Nevertheless, this study touched upon a very important issue of incorporating computational package into the learning of engineering technology course which requires a thorough understanding of underlying mathematical principles. There are some issues unaddressed relating to the low class size of students, improper 36 M. Abdul Majid et al. brushing up of students skills in learning MATLAB, inadequate background of students in mathematics, and hence statistical insignificance in terms of its applicability to a wider audience and areas. There is a need for more research on the use of MATLAB as a tool to increase self confidence and math ability in freshmen engineering students which the author also felt strongly about. The skills acquired through the use of MATLAB in the teaching and learning will prepare future engineers to meet the demands of the 21st century. Ocak (2006) investigated the relationship between gender and students' attitudes and their prior experience of using MATLAB. Three calculus I classes comprising of 23 female and 37 male students from three different colleges were chosen for this study. All students of these classes had used MATLAB. Students' attitudes were assessed with an attitudes survey instrument and the prior experience with MATLAB was measured with a closed-ended response format questions. The author found a slightly positive correlation between students' attitudes and a prior experience on using the mathematical software program. The study concluded that there was no correlation between gender differences, students' attitude and the software program experience. The study also suggested that an assessment of the students' attitudes should be taken into consideration while using programs like MATLAB. Students' familiarity with features of the software program and their ease of use also affect their enthusiasm and curiosity. This study was conducted by Gorev et al (2004) to examine the effectiveness of the use of computer technologies in solving and doing mathematical problems by pre-service teachers. In addition, the assessments of teachers' skills in using these computer tools; their attitudes toward them; and their willingness to use these tools in their careers as teachers were also considered. MATLAB was also used among the many other computer software tools. Students were given assignment sheets which included both routine and non-routine questions without the use of computers. They were further encouraged to use the computerized tools to solve the problems which they could not solve by hand as well as to enhance their previous solutions. Students' solutions were analyzed using Van Hiele theory to understand the development of their insights. This theory defines insight as a combination of the ability to perform in a possible unfamiliar situation, to perform competently as per the requirement, and resolving the solution consciously and deliberately. Their responses were also collected through their opinions on the use of computer tools in their careers. A vast majority of students expressed strong support to the use of computerized tools for improving their understanding and as well as to find solutions to problems. Some qualitative responses were also provided in the study which, by and large, favored their strong willingness to the use of these tools in their careers despite some unanticipated technical problems that may come in the way. Cretchley et al (2000) investigated the effects of the use of MATLAB on the attitudes and learning of undergraduate mathematics students at the University of Southern Queensland. The study also highlighted the relationships between attitudinal effects and performance. The student body had comprised of a diverse group, on-campus and distance learners, registered in the first semester Algebra and Calculus course. MATLAB was used in lectures, tutorial and assignments. In order to develop mathematical concepts and necessary skills, tasks were designed and a MATLAB manual was written. The use of the software was demonstrated in lectures and oncampus students attended weekly two-hour small group tutorials conducted by tutors and the distance learners used scheduled tutorial on telephones, emails and newsgroups. To encourage and motivate students, small prize money was announced. The data collection instruments used were a pre-study diagnostic test, two post-study examinations, questionnaires related to MATLAB-based assignments, interviews and focus groups, and a pre- and post-study survey questionnaire. The study reported that students' appreciation of the use of the software gradually MATLAB as a Teaching and Learning Tool for Mathematics... 37 increased over time and their ease of use developed as they overcome frustration and difficulty. The assessment of students' knowledge was based on an open book examination without the use of the computers to maintain equity. Students were not examined on their knowledge of the software. Pre- and post-study tests and assignments were conducted to evaluate students' mathematics learning experience, their opinions, skills and interviews were also conducted through focus discussion groups and case studies. Students' opinions were sought on categories such as their learning of mathematics, their experience of using computer software in the learning of mathematics, and self-efficacy in math. MATLAB based tasks particularly explorations were reportedly successful and students reported their positive experiences such as visualizing and computing areas under curves, and the concept of definite integral by taking Riemann sums. The study also reported a wide acceptance, by both on-campus and external students, of the use of technology as an aid for learning and, in particular, of MATLAB as an appropriate software package. The authors reported a strong positive reaction to the experience of using MATLAB to support students learning of mathematics where inculcating motivation towards the study of mathematics many a times is a hardest job. Another motivating factor towards the use of the MATLAB was students' need and importance of its familiarity would help in their relevant engineering subjects. The software's graphical capacity, power and novelty were much appreciated by students. Other features students liked were MATLAB's speed in performing computation with ease, clarity in understanding through explorations, and use the software as a technology check for confirmation of their answers. MATLAB was favoured over graphing calculators due to the computer power with large screen and 3-D graphing capacity. Several others studies have also reported the benefits of using the software as a tool for increasing motivation (Pennel 2009, Ohrstrom 2005, Smits 1992) and fostering positive attitudes, Abdul Majid et al 2012. MATLAB as a Tool for Projects Han (2008) used MATLAB to teach elementary linear algebra to a class of 23 students at the Eastern Michigan University. Three software-based projects and some homework assignments problems were given to students. This innovation was used as a supplement to the traditional method of instruction and its aim was to examine students' perceptions of its usefulness in learning the course material. The approach provided an opportunity to students to solve realworld application problems. MATLAB was chosen to be the right choice over the other software due to its wide popularity in science and engineering, interactive calculations, visualizations capabilities together with its broader applications and audiences. A MATLAB manual was written and the tutorial sessions were held to familiarize students of its use. The three projects designed for the study were; firstly the application of Gaussian elimination, secondly inverse computing methods to solve large linear systems of equations, solving linear systems using Cramer's rule and thirdly the application of the singular value decomposition method. Students performed these projects individually and as well as in groups of 2 to 3. Students' feedback was received through a survey using yes/no types of questions and their opinions were also taken. More than 3/4th of the students expressed their overall satisfaction with the software and more than 57% thought that the software helped them in their learning. Chapin et al (2004) supplemented MATLAB with the standard calculus course for giving simple homework assignments to students at Ohio University. The authors outlined three categories, integrated use, project format and textbook add-on, of the uses of technology in the literature. They, however, implemented the use of the software for simple assignments for 38 M. Abdul Majid et al. making its application easy and practical for both students and instructors. The study highlighted the incorporation of the technology through firstly, use of simple and basic calculations; secondly, giving very clear instructions on assignments; and thirdly, giving very clear and concise technical information. In conclusion, the authors proposed the use of software in undergraduate mathematics courses for simple homework and included a sample MATLAB assignment. The study has not discussed its effects on students learning. Horwitz

(2002) described collaborative engineering and science projects between mathematics and engineering departments for the purpose of enhancing first year differential and integral calculus courses. Students used MATLAB in projects individually and in teams and some real data were used. The first semester projects were Hydraulic Engineering, designing a pipeline with minimum cost, optimization of irrigation channel and the second semester projects were Exponential Decay, Skydiver free fall, Wrecking ball, and the Automobile velocity data. A students survey was carried out and they were asked to rate the projects on the scale of 1 to 5. Students reported some complains on the difficulty level of the projects. Some variation was observed in the comments of students belonging to engineering disciplines compared with the science majors. In addition, some students did take part in the projects but did not fully understand the mathematics involved. The study concluded firstly that the students' motivation for doing projects did not seem to have increased at the end of the study, secondly, they were simply involved in the project without themselves understanding the process, and thirdly, in depth project understanding could not be achieved due to the pressure of covering the regular syllabus of the courses. The authors suggested offering one extra credit hour course which could enhance the calculus program. The positive feedback was received from students as they enjoyed doing the projects with MATLAB and they saw a connection of mathematics with the real world. A thorough understanding of mathematical concepts with their applications in engineering and science proved useful to students. Szurley (2011) discussed the application of MATLAB for providing simulation to the projects involving solution of Differential Equations. The modeling projects involved the simulation of the industrial process of film casting and the conduction of heat. The projects were aimed at exposing students to real world applications, familiarizing them with MATLAB, demonstrating the need for numerical computation, and providing the necessary presentation skills. The study reported positive responses from students about real-world applications and in general considered a success. However, the use of MATLAB and the numerical schemes were not much favoured by them. In another study, the author incorporated MATLAB within mathematics courses at Francis Marion University. MATLAB was used for Calculus III projects involving numerical solutions and also for understanding the software's programming concepts. The projects involved L'Hopital Rule, improper integrals, sequences, power series, Taylor and Maclaurin series and as well as Linear Programming and Linear Algebra. The study concluded that students' responses were not very positive about the use of MATLAB partly due to nongraphical interfaces provided to them but in the long run this exposure was believed to help them. The future plan was set up to develop interactive graphical interfaces. Hailan et al (2012) highlighted various benefits of using MATLAB in applications of engineering as an innovative and scientific tool. The author illustrated with examples of how the software could be used as a tool for exploration and experimentation in courses like linear algebra and higher mathematics. The software's commands for finding reduced row echelon form and solving linear equations are used with examples including examples from statistics. Some applications in textile engineering and textile materials have also been given in this paper. MATLAB as a Teaching and Learning Tool for Mathematics... 39 Ohrstrom et al (2005) conducted a study at Chalmers University of Technology. An integrated approach to using MATLAB in chemistry and mathematics courses was introduced and its impact on students learning of solving chemical problems was evaluated. This curriculum reform approach was developed by experts in math, chemistry and education. Students used MATLAB-based assignments individually and in groups in the laboratory. The process of integration of the software into the course was achieved through the exchange of teachers and course material, schedules and planning together with the number of MATLABrelated projects and exercises/assignments. The projects were meant to teach mathematical concepts and skills followed by the development of MATLAB programs. The projects included were the introduction of the 3d geometry of molecules and mathematics, differential equations and kinetics, systems of nonlinear equations and equilibrium analysis as well as computer laboratory on acids and bases. Various pedagogical benefits of using the software were highlighted in the paper. The process of evaluation of its impact involved students, teachers and the educational consultants. The new reform resulted in a positive impact on students learning, and their motivation towards the subject increased. One of the main challenges highlighted by the study was maintaining a right balance in providing the necessary MATLAB skills to students for the future courses. MATLAB as a Tool for Business and Engineering-Related Applications The study conducted by Liang et al (2009) at the University of New Haven is an illustration and a summary of the use of MATLAB for teaching mathematics. The software use aimed at helping students' learning of calculus-based business mathematics and apply the calculus principles to find solutions to real quantitative business problems. The software was implemented to address students' varying levels of algebraic knowledge and skills and the challenge of completing the course in one semester. MATLAB was used to teach topics such as limits, derivatives, optimization, integration and their applications in business as well as the introduction to multivariate calculus and partial derivatives. MATLAB-aided solutions to the mathematical problems were presented step-by-step. The researchers concluded that the software use had helped students in focusing on key objectives of the course through the visualization of the examples and quick numerical computation. The study concluded with the statement that the application of computer technology would prepare students for modern day challenging careers in the workplace. An innovative approach, in the study by Pennell et al (2009), was introduced to the traditionally taught Differential Equations course for the students of engineering majors. The need for innovation was felt due to the fact that most engineering students were unaware of the relationship between mathematics courses and the their core engineering courses as well as the importance of mathematics in their careers as engineers. The new interdisciplinary project was designed in collaboration between mathematicians and engineers in an attempt to overcome students' lack of motivation towards mathematics and to address their poor retention of the material. The lack of engineering-orientation in the traditional teaching of a course like differential equations was highlighted. For instance the main focus was given on techniques for generating solution formulas. From the practical engineering application view point, the system under consideration was to understand how it responds to classes of inputs. The methods of incorporating engineering points of views of first and second order differential equations were given through the illustrations of circuit series, a mass-spring system and the Laplace transform. For students to investigate the behavior of the systems, authors prepared a brief theoretical 40 M. Abdul Majid et al. description together with the software tool developed using MATLAB and its allied toolboxes. MATLAB's GUI was prepared for students to interactively investigate various plots and behaviors of the systems. No feedback on the approach has been given. Naimark (2002) pointed the problems of a lack of connection in mathematics curriculum with the engineering disciplines which are applications oriented. The author alternatively presented the argument of what he called modernizing the mathematics courses by introducing modern computing-based applications by incorporating MATLAB. Mathematics syllabus should be viewed and taught as a central concept and a unified picture, "concepts as unifying vehicles". The illustrations of the use of MATLAB's Polyfit, MATLAB's view and Fourier Transforms were given. The linear Algebra course was taught using MATLAB in this study. Some of the software-based applications were the visualization of parametric equations, matrix of Linear Operator, matrix multiplication, Gaussian elimination method, rotations, projections, eigenvalues and eigenvectors etc. The study highlighted some pedagogical benefits of the new approach such as making the theory more transparent; students could concentrate on the structure of operations and as well as an additional method of memorization of concepts and procedures for students. The effects of the modern approach enhanced students understanding. The course objectives were achieved through the internalization of the central concept of the general linear operator. The use of the equality of inverse matrices, systems of linear equations, and the associative property of matrix multiplication improved students learning. Some of the challenges noted in the study were: the amount of time required for MATLAB-based exercises, instantaneous rectification of students' errors and the delay caused in teaching concepts like determinants and eigenvectors. In a study by Brown et al (2012), MATLAB has been used as a complementary tool to the traditional lecture for exploring mathematical concepts for the 1st year Electrical Engineering students at the University of Manchester. The introduction of the software was to provide mathematics contextually to see the connection with engineering concepts and to do calculations with varied parameters. Students used the software notebooks developed in Mupad-MATLAB. The study has not described the effects on students learning. MATLAB as a Tool for Improving Problem-Solving Techniques Talbert (2011) used MATLAB to teach problem-solving techniques to first-year Liberal Arts students who were enrolled in Calculus III at the Franklin College. Students spent most of the classtime doing hands-on lab exercises, watching video lectures and completing online tutorial work. The inverted classroom model was used in this study. This model provided students the ability to learn on their own and to apply new concepts. Students took some time adjusting to the innovative learning model, however, their feedback was reportedly positive.Legua et al (2001) in their study provided a comparison of the use of DERIVE, Mathematica and MATLAB to solve the line integral, an engineering mathematical problem. The aim of the study was to harmonize the use of the software with the teaching of mathematics at the Escuela Universitaria de IngenieraTcnica Industrial. A comparison of how the line integral concept could be explained using DERIVE, Mathematica and MATLAB was given with screenshots. The study concluded the DERIVE software as the most efficient of the other programs for evaluating line integrals. The study has not reported the effects of the use of this approach in the classroom teaching. Nyondo (1992) used MATLAB as a problem-solving tool for teaching some topics in linear algebra course at The Papua New Guinea University of Technology. The software was used to MATLAB as a Teaching and Learning Tool for Mathematics... 41 reinforce theoretical concepts taught in conventional lectures. The instructors had designed exercises and problems appropriate to the level of the course and suitable to the students' engineering specialization. The emphasis was also given on using MATLAB and mathematics as problem solving tools for engineering. Using the software, students practiced a variety of problems through experimentation. The study, however, has not reported the effects of the use of MATLAB on students' learning. Conclusion In this review, we have shown the different ways in which MATLAB was used as a teaching and learning tool for mathematics. It has been used as a tool for the visualization of the graphs of mathematical functions, computation, problem-solving, increasing motivation and selfconfidence and as well as fostering positive attitudes toward mathematics. However, a number of factors need to be taken into consideration concerning the technology integration in the teaching and learning of mathematics as highlighted by Schneider (2000). A vast majority of studies have used MATLAB as a supplement to the traditional teaching and learning of mathematics

CT Images

A computerized tomography scan (CT or CAT scan) uses computers and rotating X-ray machines to create cross-sectional images of the body. These images provide more detailed information than normal X-ray images. They can show the soft tissues, blood vessels, and bones in various parts of the body. A CT scan may be used to visualize the:

- head
- shoulders
- spine
- heart
- abdomen
- knee
- chest

During a CT scan, you lie in a tunnel-like machine while the inside of the machine rotates and takes a series of X-rays from different angles. These pictures are then sent to a computer, where they're combined to create images of slices, or cross-sections, of the body. They may also be combined to produce a 3-D image of a particular area of the body.

Why Is a CT Scan Performed?

A CT scan has many uses, but it's particularly well-suited for diagnosing diseases and evaluating injuries. The imaging technique can help your doctor:

- diagnose infections, muscle disorders, and bone fractures
- pinpoint the location of masses and tumors (including cancer)
- study the blood vessels and other internal structures
- assess the extent of internal injuries and internal bleeding
- guide procedures, such as surgeries and biopsies
- monitor the effectiveness of treatments for certain medical conditions, including cancer and heart disease

The test is minimally invasive and can be conducted quickly.

How Is a CT Scan Performed?

Your doctor may give you a special dye called a contrast materialto help internal structures show up more clearly on the X-ray images. The contrast material blocks X-rays and appears white on the images, allowing it to highlight the intestines, blood vessels, or other structures in the area being examined. Depending on the part of your body that's being inspected, you may need to drink a liquid containing the contrast. Alternatively, the contrast may need to be injected into your arm or administered through your rectum via an enema. If your doctor plans on using a contrast material, they may ask you to fast for four to six hours before your CT scan.

When it comes time to have the CT scan, you'll be asked to change into a hospital gown and to remove any metal objects. Metal can interfere with the CT scan results. These items include jewelry, glasses, and dentures. Your doctor will then ask you to lie face up on a table that slides into the CT scanner. They'll leave the exam room and go into the control room where they can see you and hear you. You'll be able to communicate with them via an intercom.

While the table slowly moves you into the scanner, the X-ray machine will rotate around you. Each rotation produces numerous images of thin slices of your body. You may hear clicking, buzzing, and whirring noises during the scan. The table will move a few millimeters at a time until the exam is finished. The entire procedure may take anywhere from 20 minutes to one hour.

It's very important to lie still while CT images are being taken because movement can result in blurry pictures. Your doctor may ask you to hold your breath for a short period during the test to prevent your chest from moving up and down. If a young child needs a CT scan, the doctor may recommend a sedative to keep the child from moving.

Once the CT scan is over, the images are sent to a radiologist for examination. A radiologist is a doctor who specializes in diagnosing and treating conditions using imaging techniques, such as CT scans and X-rays. Your doctor will follow-up with you to explain the results.

What Are the Risks Associated with a CT Scan?

There are very few risks associated with a CT scan. Though CT scans expose you to more radiation than typical X-rays, the risk of cancer caused by radiation is very small if you only have one scan. Your risk for cancer may increase over time if you have multiple X-rays or CT scans. The risk of cancer is increased in children receiving CT scans, especially to the chest and abdomen.

Some people have an allergic reaction to the contrast material. Most contrast material contains iodine, so if you've had an adverse reaction to iodine in the past, make sure to notify your doctor. Your doctor may give you allergy medication or steroids to counteract any potential side effects if you're allergic to iodine but must be given contrast.

It's also important to tell your doctor if you're pregnant. Though the radiation from a CT scan is unlikely to harm your baby, your doctor may recommend another exam, such as an ultrasound or MRI scan, to minimize risk.

What Do CT Scan Results Mean?

CT scan results are considered normal if the radiologist didn't see any tumors, blood clots, fractures, or other abnormalities in the images. If any abnormalities are detected during the CT scan, you may need further tests or treatments, depending on the type of abnormality found.

A computerized tomography scan (CT or CAT scan) uses computers and rotating X-ray machines to create cross-sectional images of the body. These images provide more detailed information than normal X-ray images. They can show the soft tissues, blood vessels, and bones in various parts of the body. A CT scan may be used to visualize the:

They'll leave the exam room and go into the control room where they can see you and hear you. You'll be able to communicate with them via an intercom.

While the table slowly moves you into the scanner, the X-ray machine will rotate around you. Each rotation produces numerous images of thin slices of your body. You may hear clicking, buzzing, and whirring noises during the scan. The table will move a few millimeters at a time until the exam is finished. The entire procedure may take anywhere from 20 minutes to one hour.

It's very important to lie still while CT images are being taken because movement can result in blurry pictures. Your doctor may ask you to hold your breath for a short period during the test to prevent your chest from moving up and down. If a young child needs a CT scan, the doctor may recommend a sedative to keep the child from moving.

Once the CT scan is over, the images are sent to a radiologist for examination. A radiologist is a doctor who specializes in diagnosing and treating conditions using imaging techniques, such as CT scans and X-rays. Your doctor will follow-up with you to explain the results.

What Are the Risks Associated with a CT Scan?

There are very few risks associated with a CT scan. Though CT scans expose you to more radiation than typical X-rays, the risk of cancer caused by radiation is very small if you only have one scan. Your risk for cancer may increase over time if you have multiple X-rays or CT scans. The risk of cancer is increased in children receiving CT scans, especially to the chest and abdomen.

Some people have an allergic reaction to the contrast material. Most contrast material contains iodine, so if you've had an adverse reaction to iodine in the past, make sure to notify your doctor. Your doctor may give you allergy medication or steroids to counteract any potential side effects if you're allergic to iodine but must be given contrast.

It's also important to tell your doctor if you're pregnant. Though the radiation from a CT scan is unlikely to harm your baby, your doctor may recommend another exam, such as an ultrasound or MRI scan, to minimize risk.

What Do CT Scan Results Mean?

CT scan results are considered normal if the radiologist didn't see any tumors, blood clots, fractures, or other abnormalities in the images. If any abnormalities are detected during the CT scan, you may need further tests or treatments, depending on the type of abnormality found.

What is a cranial CT scan?

A cranial CT scan is a diagnostic tool used to create detailed pictures of features inside your head, such as your skull, brain, paranasal sinuses, ventricles, and eye sockets. CT stands for computed tomography, and this type of scan is also referred to as a CAT scan. A cranial CT scan is known by a variety of names as well, including brain scan, head scan, skull scan, and sinus scan.

This procedure is noninvasive, meaning it doesn’t require surgery. It’s usually suggested to investigate various symptoms involving the nervous system before turning to invasive procedures.

Reasons for a cranial CT scan

The pictures created by a cranial CT scan are far more detailed than regular X-rays. They can help diagnose a range of conditions, including:

- abnormalities of the bones of your skull
- arteriovenous malformation, or abnormal blood vessels
- atrophy of brain tissue
- birth defects
- Brain eneurysm
- hemorrhage, or bleeding, in your brain
- hydrocephalus, or fluid buildup in your skull
- infections or swelling
- injuries to your head, face, or skull
- stroke
- tumors
- Your doctor may order a cranial CT scan if you’ve had an injury or display any of these symptoms with no apparent cause:
- fainting
- headache
- seizures, especially if any occurred recently
- sudden behavioral changes or changes in thinking
- Hearing loss
- vision loss
- muscle weakness or numbness and tingling
- speech difficulty
- difficulty swallowing
- A cranial CT scan can also be used to guide other procedures such as surgery or biopsy.

What happens during a cranial CT scan

A cranial CT scanner takes a series of X-rays. A computer then puts these X-ray images together to create detailed pictures of your head. These images help your doctor make a diagnosis.

The procedure is usually done in a hospital or outpatient imaging center. It should take only about 15 minutes to complete your scan.

On the day of the procedure, you must remove jewelry and other metal objects. They can damage the scanner and interfere with the X-rays.

You’ll probably be asked to change into a hospital gown. You’ll lie on a narrow table either face up or face down, depending on the reasons for your CT scan.

It’s very important that you remain completely still during the exam. Even a little movement can blur the images.

Some people find the CT scanner stressful or claustrophobic. Your doctor may suggest a sedative to keep you calm during the procedure. A sedative will also help keep you still. If your child is having the CT scan, their doctor may recommend a sedative for these same reasons.

The table will slowly slide so that your head is inside the scanner. You may be asked to hold your breath for a short period. The scanner’s X-ray beam will rotate around your head, creating a series of images of your head from different angles. The individual images are called slices. Stacking the slices creates three-dimensional images.

Images can be seen immediately on a monitor. They will be stored for later viewing and printed. For your security, the CT scanner has a microphone and speakers for two-way communication with the scanner operator.

Contrast dye and cranial CT scans

Contrast dye helps highlight some areas better on CT images. For example, it can highlight and emphasize blood vessels, intestines, and other areas. The dye is given through an intravenous line inserted into a vein of your arm or hand.

Often, images are first taken without contrast, and then again with contrast. However, use of contrast dye isn’t always necessary. It depends on what your doctor is looking for.

Your doctor may direct you not to eat or drink for several hours before the test if you’re going to receive contrast dye. This depends on your particular medical condition. Ask your doctor for specific instructions for your CT scan.

Preparation and precautions to consider

The scanner table is very narrow. Ask if there is a weight limit for the CT scanner table if you weigh more than 300 pounds.

Be sure to tell your doctor if you’re pregnant. X-rays of any kind aren’t recommended for pregnant women.

You’ll want to be aware of some extra precautions if contrast dye will be used. For example, special measures must be taken for people on the diabetes medicine metformin (Glucophage). Be sure to let your doctor know if you take this drug. Also tell your doctor if you’ve ever suffered an adverse reaction to contrast dye.

Possible side effects or risks

Side effects and risks for a cranial CT scan involve discomfort, exposure to radiation, and allergic reaction to the contrast dye.

Discuss any concerns with your doctor before the test so you can assess the potential risks and benefits for your medical condition.

Discomfort

The CT scan itself is a painless procedure. Some people feel uncomfortable on the hard table or have difficulty remaining still.

You may feel a slight burning when the contrast dye enters your vein. Some people experience a metal taste in their mouths and a warm sensation throughout their bodies. These reactions are normal and generally last less than a minute.

Radiation exposure

CT scans expose you to some radiation. Doctors generally agree that the risks are low compared to the potential risk of not being diagnosed with a dangerous health problem. The risk from a single scan is small, but it increases if you have many X-rays or CT scans over time. Newer scanners may expose you to less radiation than older models.

Tell your doctor if you're pregnant. Your doctor may be able to avoid exposing your baby to radiation by using other tests. These may include a head MRI scan or ultrasound, which don't use radiation.

Allergic reaction to contrast

Tell your doctor before the scan if you've ever had an allergic reaction to contrast dye.

Contrast dye commonly contains iodine and may cause nausea, vomiting, rash, hives, itching, or sneezing in people who are allergic to iodine. You may be given steroids or antihistamines to help with these symptoms before you receive the dye injection. after the test, you may need to drink extra fluids to help flush the iodine from the body if you have diabetes or kidney disease.

In very rare cases, contrast dye can cause anaphylaxis, a whole-body allergic reaction that can be life-threatening. Notify the scanner operator immediately if you have trouble breathing.

Results of your cranial CT scan and follow-up

You should be able to return to your normal routine after the test. Your doctor may give you special instructions if contrast was used in your test.

A radiologist will interpret the results of the test and send a report to your doctor. The scans are stored electronically for future reference.

Your doctor will discuss the radiologist's report with you. Depending on the results, your doctor might order more tests. Or if they're able to reach a diagnosis, they will go over next steps with you, if any.

Chapter 4 SOFTWARE DESCRIPTION

4.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include • Math and computation • Algorithm development • Data acquisition • Modeling, simulation, and prototyping • Data analysis, exploration, and visualization • Scientific and engineering graphics • Application development, including graphical user interface building MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN. The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation. MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis. 49 MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others. 4.2 The MATLAB system: The MATLAB system consists of five main parts • Development Environment: This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path. • The MATLAB Mathematical Function Library: This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms. • The MATLAB Language: This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs. • Graphics: MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. 50 It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes lowlevel functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications. • The MATLAB Application Program Interface (API): This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling

MATLAB as a computational engine, and for reading and writing MAT-files. Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox. 4.3 GRAPHICAL USER INTERFACE (GUI): MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files: • A file with extension. fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed. • A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed. 51 To launch GUIDE from the MATLAB command window, type guide filename Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window. Fig:4.3 Blank Window A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed. GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few 4.4 Getting Started If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos. 52 At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work. 4.4.1 Introduction - describes the components of the MATLAB system. 4.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop. 4.4.3 Manipulating Matrices- introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices. 4.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images. 4.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays. 4.5 DEVELOPMENT ENVIRONMENT 4.5.1Introduction This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print. Starting and Quitting MATLAB 4.5.2 Starting MATLAB On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. 53 On a UNIX platform, to start MATLAB, type MATLAB at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop. You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations. 4.5.3 Quitting MATLAB To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script. 4.5.4 MATLAB Desktop When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries. You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts. You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box. 54 4.5.5 Desktop Tools This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are: • Current Directory Browser • Workspace Browser • Array Editor • Editor/Debugger • Command Window • Command History • Launch Pad • Help Browser Command Window Use the Command Window to enter variables and run functions and M-files. Command History Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function. Running External Programs You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example, emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB. 55 Launch Pad MATLAB's Launch Pad provides easy access to tools, demos, and documentation. Help Browser Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information. Help Navigator Use to Help Navigator to find information. It includes: Product filter - Set the filter to show documentation only for the products you specify. Content's tab - View the titles and tables of contents of documentation for your products. Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products. Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name. Favorite's tab - View a list of documents you previously designated as favorites. Display Pane-After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can: Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar. Bookmark pages - Click the Add to Favorites button in the toolbar. Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go. Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages Current Directory Browser MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path. Search Path To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path. Workspace Browser The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces. To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace as from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a. mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function 57 Array Editor Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace. Editor/Debugger Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical userinterface for basic text editing, as well as for M-file debugging. You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint. If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function. 4.6 MANIPULATING MATRICES 4.6.1 Entering Matrices The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example. You can enter matrices into MATLAB in several different ways: Enter an explicit list of elements.Load matrices from external data files. • Generate matrices using built-in functions. Create matrices with your own functionsin M-files. 58 Start by entering Durer's matrix as a list of its elements. You have only to follow a few basic conventions: Separate the elements of a row with blanks or commas. Use a semicolon, ; , to indicate the end of each row. Surround the entire list of elements with square brackets, [ ]. To enter Dürer's matrix, simply type in the Command Window A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1] MATLAB displays the matrix you just entered. ` A = 16 3 2 13 5 10 11 8 9 6 7 12 4 15 14 1 This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A. 4.6.2 Expressions Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are: • Variables • Numbers • Operators • Functions 59 Variables MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example, num_students = 25 Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element. Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned toany variable, simply enter the variable name. Numbers MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are 3 -99 0.0001 9.6397238 1.60210e-20 6.02252e23 1i -3.14159j 3e5i All numbers are stored internally using the long format specified by the IEEE floatingpoint standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308. 60 4.6.3 Operators Expressions use familiar arithmetic operators and precedence rule. + Addition - Subtraction * Multiplication / Division \ Left division (described in "Matrices and Linear Algebra" in Using MATLAB) ^ Power ' Complex conjugate transpose ( ) Specify evaluation order 4.6.3 Table: Operators 4.6.4 Functions MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, for a list of more advanced mathematical and matrix functions, type help specfun help elmat. 61 Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants. Pi 3.14159265... I Imaginary unit, √-1 I Same as i Eps Floating-point relative precision, 2-52 Realmin Smallest floating-point number, 2-1022 Realmax Largest floating-point number, (2- ε)21023 Inf Infinity NaN Not-a-number 4.6.4 Table: Functions 4.7 GUI A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components. Applications thatprovide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface. 62 The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include: 4.7.1 Creating GUIs with GUIDE MATLAB implements GUIs as figure windows containing various styles of uncontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must beable to save and launch your GUI. All ofthese tasks are simplified by GUIDE, MATLAB's graphical user interface developmentenvironment. 4.7.2 GUI Development Environment The process of implementing a GUI involves two basic tasks. • Laying out the GUI components • Programming the GUI components GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI. The Implementation of a GUI While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI: A FIG-file - contains a complete description of the GUI figure and all of its children (uncontrol and axes), as well as the values of all object properties. 63 An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation. Note that the application M-file does not contain the code that lays out the uncontrol's; this information is saved in the FIG-file. The following diagram illustrates the parts of a GUI implementation. FIG 4.7.2 graphical user blocks 4.7.3 Features of the GUIDE-Generated Application M-Fil GUIDE simplifies the creation of GUI applications by automatically generating an Mfile framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages: The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). 64 The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information). The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments. You can elect to have GUIDE generate only the FIG-file and write the application Mfile yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor. 4.7.4 Beginning the Implementation Process To begin implementing your GUI, proceed to the following sections: Getting Started with GUIDE - the basics of using GUIDE. Selecting GUIDE Application Options - set both FIG-file and M-file options. Using the Layout Editor - begin laying out the GUI. Understanding the Application M-File - discussion of programming techniques used in the application M-file. Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs. Command-Line Accessibility When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as find obj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes. 65 GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI. In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access. 4.7.5 User Interface Control The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components. ➢Push Buttons ➢ Sliders ➢Toggle Buttons ➢Frames ➢Radio Buttons ➢List boxes ➢Checkboxes ➢Popup Menus ➢Edit Text ➢Axes ➢Static Text ➢Figures Push Buttons Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event. 66 Properties to Set String - set this property to the character string you want displayed on the push button. Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close button) before activating the GUI. Programming the Callback When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state. Toggle Buttons Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback. Programming the Callback The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default). From the GUIDE Application M-File The following code illustrates how to program the callback in the GUIDE application Mfile. function varargout = togglebutton1_Callback(h,eventdata,handles,varargin) button_state = get(h,'Value'); if button_state == get(h,'Max') % Toggle button is pressed elseif button_state == get(h,'Min') % toggle button is not pressed end 67 Adding an Image to a Push Button or Toggle Button Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand). a(:,:,1) = rand (16,128); a(:,:,2) = rand (16,128); a(:,:,3) = rand(16,128); set (h,'CData’, a) Radio Buttons Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button. Implementing Mutually Exclusive Behavior Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property: Value = Max, button is selected. Value = Min, button is not selected. To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user. 68 The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected. function mutual exclude(off) set(off,'Value',0) Obtaining the Radio Button Handles. The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks. The following code shows the call to mutual exclude being made from the first radio button's callback in a group of four radio buttons. function varargout = radiobutton1_Callback (h, event data, handles, varargin) off = [handles. radiobutton2, handles. radiobutton3, handles. radiobutton4]; mutual exclude(off) % Continue with callback.

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks. Checkboxes Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes). 69 The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default): Value = Max, box is checked. Value = Min, box is not checked. You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example: function checkbox1_Callback (h, eventdata, handles, varargin) if (get(h,'Value') == get(h,'Max')) % Then checkbox is checked-take appropriate action else % Checkbox is not checked-take appropriate action end Edit Text Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user. To obtain the string typed by the user, get the String property in the callback. function edittext1_Callback (h, event data, handles,varargin) user string = get(h,'string'); % Proceed with callback... 70 4.7.6 Obtaining Numeric Data from an Edit Test Component MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns Nan. You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is Nan, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg). function edittext1_Callback(h,eventdata, handles,varargin) user entry = str2double(get(h,'string')); if isnan(user_entry) errordlg ('You must enter a numeric value','BadInput','modal') end % Proceed with callback... Triggering Callback Execution On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback. Static Text Static text controls display lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it 71 Frames Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot). Placing Components on Top of Frames Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose. List Boxes List boxes display a list of items and enable users to select one or more items. The String property contains the list of strings displayed in the list box. The first item in the list has an index of The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty. The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer Single or Multiple Selection The values of the Min and Max properties determine whether users can make single or multiple selections: If Max - Min > 1, then list boxes allow multiple item selection. If Max - Min <= 1, then list boxes do not allow multiple item selection. 72 Selection Type List boxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection. Triggering Callback Execution MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either: Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items. The first choice is best if you are sure, you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file. Popup Menus Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1. 73 Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires. Programming the Popup Menu You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item. This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu are fixed, then you can use this approach. function varargout = popupmenu1_Callback (h, event data, handles, varargin) val = get(h,'Value'); switch val case 1 % The user selected the first item case 2 % The user selected the second item % etc. This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string. 74 function varargout = popupmenu1_Callback (h, event data, handles,varargin) val = get(h,'Value'); string_list = get(h,'String'); selected_string = string_list{val}; % convert from cell array to string % etc. Enabling or Disabling Controls You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states: on - The control is operational off - The control is disabled and its label (set by the string property) is grayed out. inactive - The control is disabled, but its label is not grayed out. When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's Button-down callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details. Axes Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects. 75 Axes Callbacks Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button-down property to define the callback. 4.7.7 Plotting to Axes in GUIs GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes. GUIs with Multiple Axes If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example, axes (handles. axes1) makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axis. See GUI with Multiple Axes for an example that uses two axes. Figure Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control. 76 Chapter 5 RESULT ANALYSIS 5.1 Results: Experiments conducted in this research using grayscale image as the cover image, and binary image as a message, see Figure as cover images and as a message. The cover image and message image have the same size, 256 * 256 in size. Here is a cover image used in this study: Fig 5.1.1 Original Image The hidden data should be robust against unauthorized extraction / viewing. In the simplest scenario, the attacker has the knowledge about the proposed method as well as the fact that only one fixed pixel pair with 2 partitions is used throughout the image to hide data. The number of possible cases (i.e., correctly guessing the threshold value used during the filter embedding step) to consider can be formulated as: $\Lambda = [\ w2/r \times (w2/r + 1)] \times 2$ where in these two partitions, each consists of w2/r pixels and (w2/r + 1) pixels, respectively. The value 2 signifies that there is r = 2 cases to consider.

CHAPTER 5 RESULT ANALYSIS

Here we take a low dose CT image which is not a clear image and contains noise.Input image is taken and noise is removed in several steps.

CHAPTER 6 APPLICATIONS AND ADVANTAGES

APPLICATIONS

→The application requirements for CT have almost covered all clinical departments, and have been commonly used in medical institutions.

→ Denoising can be a very effective approach to improving the quality of low-dose CT images.

→ Electronic surveillance The application concerns passive detection and finger printing of incoming radar signatures from an electronic surveillance platform.

ADVANTAGES

- It can be done faster with large amount of software.
- This method featured security, capacity and robustness, the three needed aspects of steganography that makes it useful in hidden exchange of information through text documents and establishing secrets communication.

CONCLUSION AND FUTURE SCOPE

CONCLUSION

→ Denoising of the projections with the proposed idea leads to a substantial improvement of the reconstructed image in terms of noise level, spatial resolution, and visual quality.

→ Low dose images on the other hand have poor quality due to the presence of AWGN noise.

→ CT scan imaging is one of the most widely used imaging modality. The quality of the CT images improves as the radiation dose.

FUTURE SCOPE

→ Ultra low dose CT Scan:researchers pay attention to the reconstruction algorithms for high-quality ultra low dose CT scan.

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to Dr. B. Hari Krishna, **Head &Professor**, in the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand**, professor in ECE for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide **Mrs.K.Anitha**, **Assistant professor**,Department of ECE and our class project coordinator **Mr.Karthik,Assistant professor**,Department of ECE for guidance and encouragement in carrying out this project work.

Finally, We are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar** , **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

In the present era, air and noise pollution is the growing hazardous issue. It is necessary to monitor air quality and keep it under control for a better future and healthy living for all. Here we propose an air quality as well as sound pollution monitoring system that allows us to monitor and check live air quality as well as sound pollution in a particular area through IOT. System uses air sensors to sense presence of harmful gases/compounds in the air and constantly transmit this data to microcontroller. Also, system keeps measuring sound level and reports it to the online server over IOT. The sensors interact with microcontroller which processes this data and transmits it over internet. This allows authorities to monitor air pollution in different areas and take action against it. Also, authorities can keep a watch on the noise pollution near schools, hospitals and no honking areas, and if system detects air quality and noise issues it alerts authorities so they can take measures to control the issue.

CHAPTER 1

INTRODUCTION

OVERVIEW TO THE PROJECT

Air and sound pollution is a growing issue these days. It is necessary to monitor air quality and keep it under control for a better future and healthy living for all. Here we propose an air quality as well as sound pollution monitoring system that allows us to monitor and check live air quality as well as sound pollution in a particular areas through IOT. System uses air sensors to sense presence of harmful gases/compounds in the air and constantly transmit this data to microcontroller. Also system keeps measuring sound level and reports it to the online server over IOT. The sensors interact with microcontroller which processes this data and transmits it over internet. This allows authorities to monitor air pollution in different areas and take action against it. Also authorities can keep a watch on the noise pollution near schools, hospitals and no honking areas, and if system detects air quality and noise issues it alerts authorities so they can take measures to control the issue.

In infrastructure and industrial plants the rapid growth creating environmental issues like pollution (Air, Water, Noise), climate change, malfunctioning and has greatly consequence for the requirement of an, operationally adaptable, efficient, cheap and smart monitoring systems. In this context where combination of many challenges of computer science, wireless communication and electronics; the Smart Sensor Networks are an emerging field of research. In this paper a solution to monitor the air and noise pollution levels in industrial environment or by using wireless embedded computing system a particular area of interest is proposed. The technology like Internet of Things (IoT) is included in the form of solution which is outcome of merged field of computer science and electronics. For monitoring the fluctuation of parameters like noise and air pollution levels from their normal levels in this case the sensing devices are connected to the embedded computing system. For the requirement of continuous monitoring, controlling and behavior analysis this model is adaptable and distributive for any infrastructural environment. For two or three parameters like noise, CO and radiation levels the implementation is tested with respect to the normal behavior levels or given specifications which provide a monitoring over the pollution control to make the environment smart and Eco-friendly.

MATERIAL REQUIREMENT:

HARDWARE REQUIREMENT:

1.Arduino uno

2.MQ2 gas sensor

3.Sound sensor

4.LCD Display

5.ESP8266 Wi-Fi Module

6.Power supply unit

SOFTWARE REQUIREMENT :

- Arduino IDE
- Proteus software

PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in a electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software. Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way. We calculated all the threshold limit for the harmful gases and sound intensity and all the information is sent to the online server.

INTRODUCTION TO EMBEDDED SYSTEM

An embedded system is a combination of computer hardware and software, either fixed in capability or programmable, designed for a specific function or functions within a larger system. Industrial machines, agricultural and process industry devices, automobiles, medical equipment, cameras, household appliances, airplanes, vending machines and toys, as well as mobile devices, are 2 possible locations for an embedded system. An embedded system is a dedicated computer system designed for one or two specific functions. This system is embedded as a part of a complete device system that includes, such as electrical and mechanical components[1]. The embedded system is unlike the generalpurpose computer, which is engineered to manage a wide range of processing tasks. Because an embedded system is engineered to perform certain tasks only, design engineers may optimize size, cost, power consumption, reliability and performance. Embedded systems are typically produced on broad scales and share across a variety of environments and applications. An embedded system is one that has computer-hardware with software embedded in it as one of its most important components. It is a dedicated computer-based system for an application or product. An embedded system has three main components. 1. It has hardware 2. It has main application software. 3. It has a real time operating system (RTOS) An embedded system has software designed to keep in view three constraints: (i) Available system memory. (ii) Available processor speed. (iii) The need to limit power dissipation when running the system . An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious. Some of these computers are however very simple systems as compared with a personal computer[2]. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a 3 variety of different purposes[2]. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware. The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine[3]. As the embedded system is the combination of both software and hardware.

HISTORY OF EMBEDDED SYSTEM

Embedded systems date back to the 1960s. Charles Stark Draper developed an integrated circuit (IC) in 1961 to reduce the size and weight of the Apollo Guidance Computer, the digital system installed on the Apollo Command Module and Lunar Module. The first computer to use ICs, it helped astronauts collect realtime flight data. In 1965, Auto now a part of Boeing, developed the D-17B, the computer used in the Minuteman I missile guidance system.

BLOCK DIAGRAM OF EMBEDDED SYSTEM

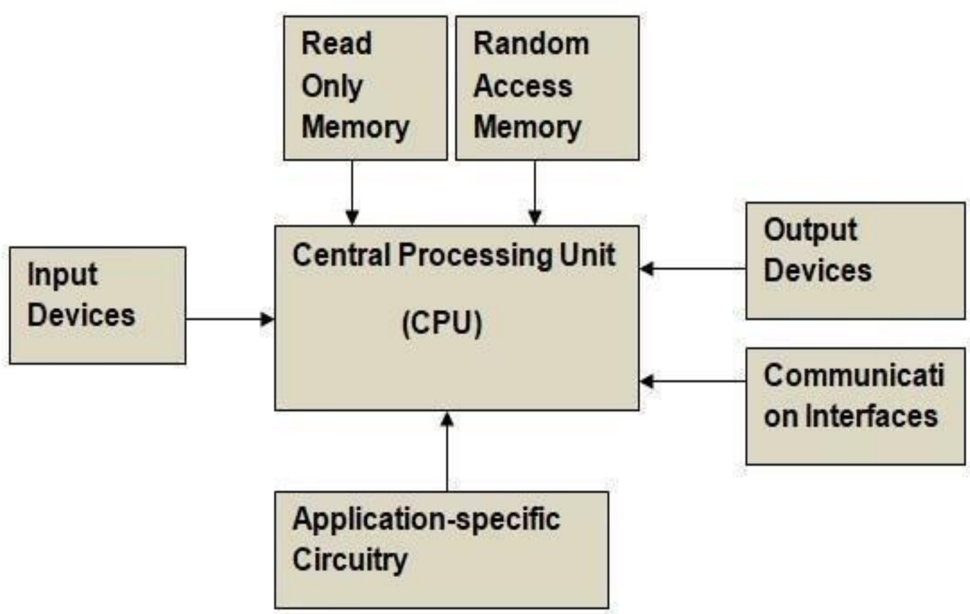

Fig.1.2.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

EMBEDDED SYSTEM HARDWARE:

Embedded system hardware can be microprocessor- or microcontroller-based. In either case, an integrated circuit is at the heart of the product that is generally designed to carry out computation for real-time operations[4]. Microprocessors are visually indistinguishable from microcontrollers, but while the microprocessor only implements a central processing unit (CPU) and, thus, requires the addition of other components such as memory chips, microcontrollers are designed as self contained systems.

EMBEDDED SYSTEM SOFTWARE:

A typical industrial microcontroller is unsophisticated compared to the typical enterprise desktop computer and generally depends on a simpler, less-memory intensive program environment. The simplest devices run on bare metal and are programmed directly using the chip CPU's machine code language. Often, embedded systems use operating systems or language platforms tailored to embedded use, particularly where real-time operating environments must be served. At higher levels of chip capability, such as those found in SoCs designers have increasingly decided the systems are generally fast enough and the tasks tolerant of slight variations in reaction time that near-real-time approaches are suitable.

EXAMPLES OF EMBEDDED SYSTEM

Some examples of embedded systems are below

- ATM
- Digital Cameras
- Microwave ovens
- Factory controllers
- Washing machine 5
- Calculator

- TV remote
- Traffic lights
- Digital watches
- Mp3 player
- Video games consoles
- Printers
- GPS receivers
- Dishwashers
- Thermostats
- Anti-lock banking system
- Medical imaging

TYPES OF EMBEDDED SYSTEM

1. Real Time Systems

Real-time systems are those which give a quick response to critical situations. They are used in military, medical and industrial applications. Engineers working in these systems have high demand is current days. To develop the real-time embedded system we require timing analysis, multitasking design, debugging, cross-platform testing and architecture design. In these systems, quick response is very important.

2. Standalone Embedded System

This type of embedded system works for itself as a device without needing any interconnected computer. It can take data in the form of Analog or digital signals. This system first process data and then outputs data by displaying on the screen.

3. Networked Embedded System

Networked embedded systems are those systems which are connected to the network to give output to the attached resources[5]. The devices in the networked embedded system are connected to the network with network interfaces. The network can be either a local area network (LAN) or a wide area network (WAN).

4. Mobile Embedded System

Mobile embedded systems are limited in resources including memory. Examples of mobile embedded systems include

- Personal digital assistants (PDA)
- Cellular phones
- Mp3 players
- Digital cameras

5. Small-Scale Embedded System

Small-scale embedded systems consist of 8-16 bit microcontroller. This system can perform tasks at a small level. They have on-chip ROM and RAM. Small scale systems can be even activated by the battery. The tools used to develop small-scale embedded systems are an editor, cross assembler, assembler and integrated development environment (IDE). The purpose of this system is not computation but to control as a computer embedded inside it. It behaves as a component of a computer and its function is not to compute. The small-scale system is dedicated to some specific task.

6. Medium Scale Embedded System

This embedded system has 16-32 bit microprocessor or microcontroller with external RAM and ROM They can perform medium to complex level works. The integration between hardware and software is complex in these embedded systems. Programming languages used to develop medium scale embedded systems include Java, C, Visual C++, debugger, C++, RTOS, simulator, source code engineering tool and IDE.

7. Sophisticated Embedded System

The embedded system which can do large-scale works with multiple 32-64 bit chips is known as sophisticated embedded systems[6]. They can perform distributed work on a large scale. The complexity of hardware and software is very high in these systems. In sophisticated embedded systems, hardware and software are assembled together on large scale and designing of hardware products is also included in these systems.

APPLICATIONS OF EMBEDDED SYSTEM

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

MICROCONTROLLER

A microcontroller is a small computer on a single metal oxide semiconductor (MOS) integrated circuit (IC)chip. A microcontroller contains one or more CPUs along with memory and programmable input/output peripherals. Program memory in the form of ferroelectric RAM, NOR flash or OTP ROM is also often included on chip, as well as a small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications consisting of various discrete chips[7]. In modern terminology, a microcontroller is similar to, but less sophisticated than, a system on a chip (SoC). SoC may include a microcontroller as one of its components, but usually integrates it with advanced peripherals like graphics processing unit (GPU), Wi-Fi module, or one or more coprocessors.

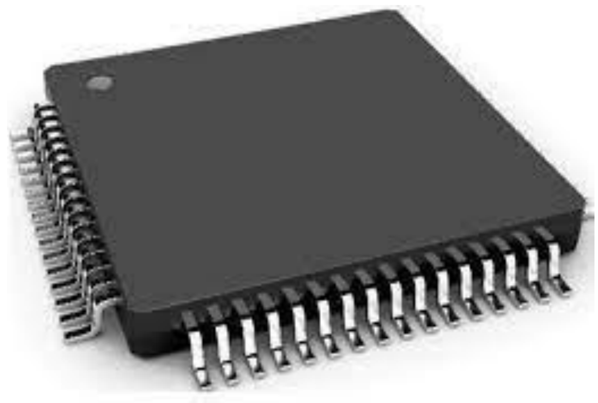

Fig.1.3.1: Microcontroller

Microcontrollers are used in automatically controlled products and devices, such as automobile engine control systems, implantable medical devices, remote controls, office machines, appliances, power tools, toys and other embedded systems. By reducing the size and cost compared to a design that uses a separate microprocessor, memory, and input/output devices, microcontrollers make it economical to digitally control even more devices and processes. Mixed signal microcontrollers are common, integrating analog components needed to control non-digital electronic systems. In the context of the internet of things, microcontrollers are an economical and popular means of data collection, sensing and actuating the physical world as edge devices. Some microcontrollers may use four-bit words and operate at frequencies as low as 4 kHz for low power consumption (single-digit milliwatts or microwatts). They generally have the ability to retain functionality while waiting for an event such as a button press or other interrupt; power consumption while sleeping (CPU clock and most peripherals off) may be just nanowatts, making many of them well suited for long lasting battery applications[8]. Other microcontrollers may serve performance-critical roles, where they may need to act more like a digital signal processor (DSP), with higher clock speeds and power consumption.

HISTORY

The origins of both the microprocessor and the microcontroller can be traced back to the invention of the MOSFET (metal-oxide-semiconductor field-effect transistor), also known as the MOS transistor. It was invented by Mohamed M. Atalla and Dawon Kahng at Bell Labs in 1959, and first demonstrated in 1960.9 The same year, Atalla proposed the concept of the MOS integrated circuit, which was an integrated circuit chip fabricated from MOSFETs. By 1964, MOS chips had reached higher transistor density and lower manufacturing costs than bipolar chips[2]. MOS chips further increased in complexity at a rate predicted by Moore's law, leading to large-scale integration (LSI) with hundreds of transistors on a single MOS chip by the late 1960s. The application of MOS LSI chips to computing was the basis for the first microprocessors, as engineers began recognizing that a complete computer processor could be contained on a single MOS LSI chip.

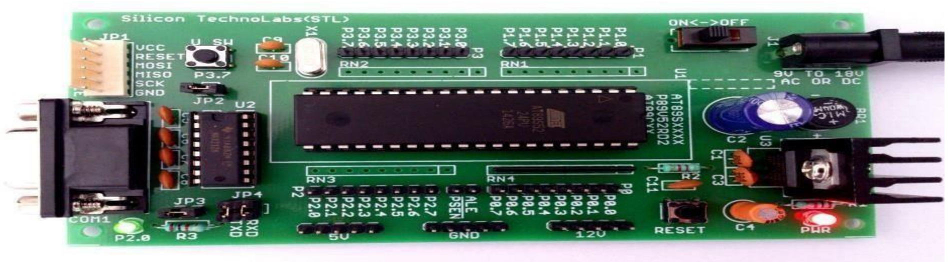

Fig.1.3.2: 8051 Microcontroller Board

Most microcontrollers at this time had concurrent variants. One had EPROM program memory, with a transparent quartz window in the lid of the package to allow it to be erased by exposure to ultraviolet light. These erasable chips were often used for prototyping. The other variant was either a mask programmed ROM or a PROM variant which was only programmable once. For the latter, sometimes the designation OTP was used, standing for "one-time programmable". In an OTP microcontroller, the PROM was usually of identical type as the EPROM, but the chip package had no quartz window; because there was no way to expose the EPROM to ultraviolet light, it could not be erased. Because the erasable versions required ceramic packages with quartz windows, they were significantly more expensive than the OTP versions, which could be made in lower-cost opaque plastic packages. For the erasable variants, quartz was required, instead of less expensive glass, for its transparency to ultraviolet light— to which glass is largely opaque—but the main cost differentiator was the ceramic package itself .

In 1993, the introduction of EEPROM memory allowed microcontrollers (beginning with the Microchip PIC16C84) to be electrically erased quickly without an expensive package as required for EPROM, allowing both rapid prototyping, and in-system programming. (EEPROM technology had been available prior to this time, but the earlier EEPROM was more expensive and less durable, making it unsuitable for low-cost mass-produced microcontrollers.) The same year, Atmel introduced the first microcontroller using Flash memory, a special type of EEPROM. Other companies rapidly followed suit, with both memory types. Nowadays microcontrollers are cheap and readily available for hobbyists, with large online communities around certain processors.

INTRODUCTION TO INTERNET OF THINGS

The Internet of things (IoT) describes the network of physical objects—a.k.a. "things"—that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the Internet.Things have evolved due to the convergence of multiple technologies, real-time analytics, machine learning, ubiquitous computing, commodity sensors, and embedded systems.[1] Traditional fields of embedded systems, wireless sensor networks, control systems, automation (including home and building automation), and others all contribute to enabling the Internet of things. In the consumer market, IoT technology is most synonymous with products pertaining to the concept of the "smart home", including devices and appliances (such as lighting fixtures, thermostats, home security systems and cameras, and other home appliances) that support one or more common ecosystems, and can be controlled via devices associated with that ecosystem, such as smartphones and smart speakers. The IoT can also be used in healthcare systems.

Internet of Things (IOT) is a network of devices that connect directly with each other to capture and share data through a secure service layer that connects to a central command and control server in the cloud. The closure\look suggest that the way people collect, record and analyze data—not just in health care but in every industry today. The idea of devices connecting directly with each other is basically called Internet of Things.

The Internet of Things also a called the Internet of Objects, refers to a wireless network between objects, usually the network will be wireless and self-configuring. Internet of Things (IOT) is one of the major component advances in present time that links the internet with everyday sensor and working devices. Smart objects play an important role in the Internet of Things vision, since embedded communication and information technology would have the potential to change the utility of these objects. Using sensors they are able to recognize their condition, and via built-in connecting power they would be able to interact with each other.

Benefits of IOT

Ubiquitous networks -: Personal Wi-Fi on your smart phones and on many of the other devices. Everyone (and everything) wants as well as needs to be connected.

Connected computing -:We want all of the devices, smart phones, televisions(colored or black and white), dvd players, vehicles etc. to keep record of what we are doing, seeing, reading, and/or listening to as we sway through the day, from one place to another – the handoffs from device to device is happening already.

Analytics-as-a-Service-: The API and App economies are already wide and growing which enables to "do something interesting" as long as it can be connected to an API or can invoke an App that carries out a network-based service. The thing is a data generator as well as collector that learns from, makes forecast, and maybe even takes data-driven actions in response to the data that are collected too.

Marketing automation-: Smart phone customer engagement, geological-location, Apple's iBeacon etc. are all developing a network of knowledge and information regarding customers' locations, intentions, preferences, as well as buying patterns. Obviously, the degree of geological location-based knowledge needs to maintain the right balance between user privacy as well as the timely delivery of important and significant products and services to the particular user.

Supply Chain Analytics-: Delivering the just-in-time products at the time of need (inclusive of the use of RFID-based tracking). Significantly, everything is a customer (inclusive of machines, automobiles, manufacturing plants, ATM machines, etc.), as well as the IOT is monitoring, watching, as well as waiting for the product needs to arise.

MOTIVATION OF THE PROJECT

In this era of modernization, technologies are advancing rapidly. Every day we realize some new technology coming in market to simplify our lives more than ever. Here this system is created to make one more system in the fulfillment of the goal of smart city. Here this system used to monitor the air and noise pollution without human intervention and helps in taking measures to control the pollution if it exceeds the normal range to better quality of life.

CHAPTER 2

LITERATURE SURVEY AND EXISTING MODELS

LITERATURE REVIEW ON RESEARCH AREA:

1. IOT based Air and Sound Pollution Monitoring System : The air pollution monitoring system contains sensors to monitor the interested pollution parameter in environment. They simulated the three air pollutants gases including carbon monoxide, carbon dioxide &sulphur dioxide in air because these gases decide the degree of pollution level. They also applied the approach in various applications like leaking cooking gas in our homes, to alert the workers in oil &gas industry to detect the leakage etc.

2. Implementation of an Efficient Noise and Air Pollution Monitoring System Using Internet of Things (IoT) A Smart City is one with at least one initiative addressing one or more of the following six characteristics: Smart Governance, Smart People, Smart Living, Smart Mobility, Smart Economy and Smart Environment. In this simulation, these three gases are successfully tested in four areas. Then extended the simulated results to update in web.

3. An IoT Based Automated Noise and Air Pollution Monitoring System: The proposed embedded device for monitoring noise and air levels in atmosphere to make the environment intelligent or interactive with object. The proposed model is adaptable and distributive in nature to monitor the environmental parameters. The architecture is developed for noise and air pollution monitoring.

4. Implementation of an Efficient Noise and Air Pollution Monitoring System Using Internet of Things (IoT) : In the present era, air and noise pollution is the growing hazardous issue. It is necessary to monitor air quality and keep it under control for a better future and healthy living for all. Here we propose an air quality as well as sound pollution monitoring system that allows us to monitor and check live air quality as well as sound pollution in a particular areas through IOT.

5. A System For Monitoring Air And Sound Pollution Using Ardunio Controller With IOT Technology : Some of the research works carried out for monitoring the pollution parameters in a

particular area of interest for making the environment smart in that area, different techniques and methods which were used in the past discussed in this section

6. Industrial Air Pollution Monitoring and Analysis System: An embedded system for hazardous gas detection has been implemented; here only two gases (LPG and Propane) have been detected for demo purpose. The gas sensors and the critical level of the respective gas should be known, and then this system can be implemented for detecting various gases either in domestic area such as places of educational institutions, residential and industrial areas which avoids endangering of human lives. This system provides quick response rate and the diffusion of the critical situation can be made faster than the manual methods

REVIEW OF RELATED LITERATURE:

The purpose of this project is to identify the harm caused by the air and sound pollution to the environment. Pollution in simple words can be explained by, the presence of an foreign object in the environment which has harmful effect, we as a society have to ensure that all the pollution levels are maintained to the minimum, In today's world, pollution is the biggest concern, pollution has a lot of harmful effects on the wellbeing of the people. Our project is a small step to this big initiative to ensure that pollution stays under control. This project helps in detecting the major gases in air and the decibel levels in the surrounding environment. Our project will be a boon to the society as our project will be making sure that every individual will be able to keep a track of the pollution from the website . It is the need of the hour to monitor air quality and keep it under control for a better future and healthy living for all.

The motive of making a smart city can be fulfilled by using technology, thus making the life better and also enhancing the quality of services, therefore meeting every individual's needs. With modern technology in fields of information and communication, it has become easy to interact with the authorized people of city to tell the where abouts of the area or city, how well the city is developing and how to make it possible to achieve a better life quality. In this system, an application was created to make one more step in the fulfillment of the goal. An area is analyzed for evaluating how much pollution is affecting the area. The components of gases and sound intensity their amounts are calculated and checked. If the amount is higher than normal then the officials are reported about it. After that the people are made to clear the area and taken to a safe place.

CONCLUSION ON REVIEWS:

Hence as the technology is advancing day by day and we have to follow the new technologies so in the proposed system we used internet of things for makings things smarter. Here in the proposed system it consists of two units – in the first unit , we connect all the sensors to the Arduino uno that the sensors sense the concentration of harmful gases and sound intensity and sends to Arduino uno. In the second unit ,this transmitted information is displayed on the lcd and simultaneously sends to the online server.

CHAPTER 3

PROJECT DESIGN

BLOCK DIAGRAM:

The system is used for measuring air and noise pollution in the environment .The system consists of gas sensor to measure the concentration of harmful gases in the environment and sound sensor for measuring intensity of sound .These sensed information is transmitted to the Arduino and it process the information and continuously displays these values on the lcd display which is connected to it, simultaneously this information is transmitted to the online server by the wi-fi module .By using the website thingspeak we can monitor the level of air and noise pollution in the environment. This allows authorities to monitor air pollution in different areas and take action against it.

1. Arduino UNO

Arduino is open source software. Arduino Uno is a microcontroller, ATmega328Pcontain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2. MQ2 gas sensor

Gas sensors main aim is to sense hazardous gases that evolve its surroundings. It detects the concentrations of combustible gas in the air and outputs its reading as an analog voltage. The sensor can measure concentrations of flammable gas of 300 to 10,000 ppm. The sensor can operate at temperatures from -20 to 50°C and consumes less than 150 mA at 5 V. This sensor is connected to LCD and when there is a leakage of gas this sensor senses and a message is displayed on the LCD indicating the leakage of gas. This sensor is also connected to a buzzer and the buzzer sounds whenever the gas leakage is detected.

3. Sound sensor

The sound sensor is a small board that combines a microphone (50Hz-10kHz) and some processing circuitry to convert sound waves into electrical signals.This electrical signal is fed to on-board LM393 High Precision Comparator to digitize it and is made available at OUT pin. The module has a built-in potentiometer for sensitivity adjustment of the OUT signal. We can set a threshold by using a potentiometer; So that when the amplitude of the sound exceeds the threshold value, the module will output LOW otherwise HIGH.

4. LCD

The LCD is used to display when ever there is a gas leakage or fire detected in the area. When ever there is a gas leakage the Arduino that is connected to the sensor and LCD sends a message to LCD to display ‘Gas leakage’. When there is fire outbreak the Arduino again sends a message to LCD to display ‘Fire Detected’ notifying us if there is a gas leakage or fire detected in the vicinity.

5.ESP8266 Wi-Fi Module

The ESP8266 WiFi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

6. Power Supply Unit

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage 31 stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

Schematic Diagram

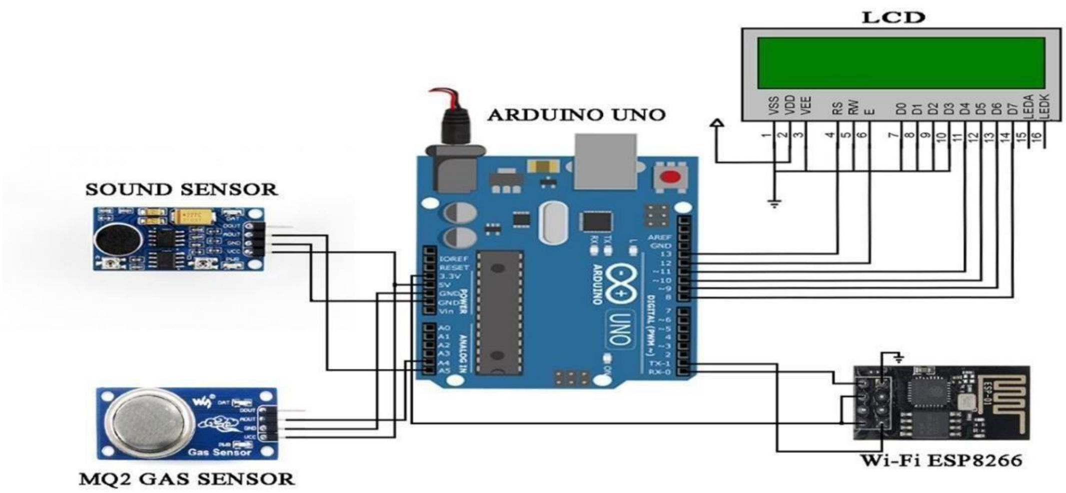

Fig.3.2.1: Schematic Diagram

Schematic Explanation

Arduino UNO has 6 analog pins from A0 to A6 which are generally input pins. It also has 14 digital pins from 0-13 which are the output pins. The analog pin A4 is connected to the output pin of the mq2 gas sensor and analog pin A5 is connected to the output pin of the sound sensor. The digital pins 8-13 is connected to the lcd to display the output values. Here pin 0 is the receiver pin and pin 1 is the transmitter pin. These pins are used for the esp8266 wi-fi module to transmit the information to the online server.

CHAPTER 4

HARDWARE AND SOFTWARE DESCRIPTION

HARDWARE COMPONENTS

The hardware components used for the implementation of Air And Noise Pollution Monitoring System Over An IOT are

1. Arduino Uno
2. MQ2 gas sensor
3. Sound sensor
4. LCD
5. ESP8266 Wi-Fi module
6. Power supply

ARDUINO UNO

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message and turn it into an output activating a motor, turning on an led, publishing as it reached a wider community, the Arduino board started something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based Wiring), the Arduino Software (IDE), based on Processing. Arduino was born at the area Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming wearable, 3dprinting, and embedded environments. All Arduino boards are completely open-source, empowering from everyday objects to complex scientific instruments. Professional gathered around open-source plat form, the software too is opensource, it is growing through the contributions of users worldwide, the Arduino board is shown in below figure.

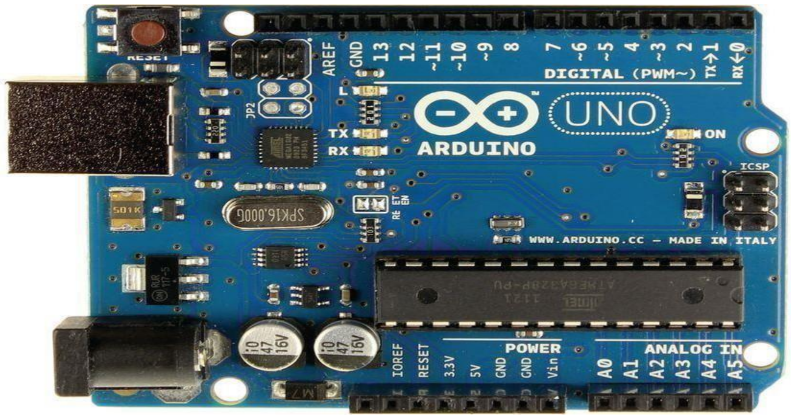

Fig.4.1.1: Arduino uno board

Why Arduino?

Arduino Uno is inexpensive. Arduino is cross platform, its IDE can run on multiple Operating Systems such as Windows, Macintosh, Linux and many more. It has simple and clear programming environment. Its software and hardware are open-source and extensible, that is, Arduino programming can be expanded through C++ libraries and can also leap to AVR ‘C’ language programming. It is simple and accessible to user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove the chemistry and physics principles or to get started with programming and robotics. Designers and the architects build interactive prototypes, musicians, artists use it for installations and to experiment with new musical instruments. Makers of course use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers can start tinkering just following the step by step I constructions of a kit or sharing ideas online with other members of the Arduino community. There are many other microcontrollers platforms available for physical computing. Parallax Basic Stamp, Netmedia's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-touse package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems. • Inexpensive

Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50 • Cross-platform The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. • Simple, clear programming environment The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works. • Open source and extensible software The Arduino software is published as opensource tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to. • Open source and extensible hardware The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money and the parts of Arduino board is shown below

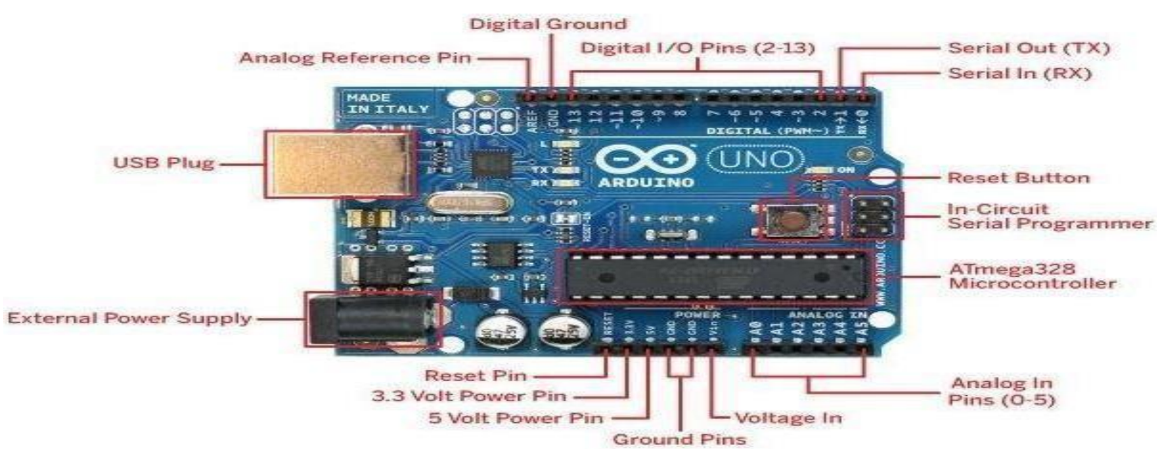

Fig.4.1.2: Arduino board description

Features of Arduino

Microcontroller	ATmega328
Operating Voltage	5V
Input Voltage	7-9V
Input Voltage (limits)	6-20V
Digital I/O Pins	14 (6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 mA
DC Current for 3.3V Pin	50 mA
Flash Memory	32 KB (ATmega328) (0.5 KB used by bootloader)
SRAM	2 KB (ATmega328)
EEPROM	1 KB (ATmega328)
Clock Speed	16 MHz

Table 4.1.1: Features of Arduino uno

Programming

The Arduino Uno can be programmed with the Arduino Software (IDE). Select Arduino Uno from the Tools Board After your code is compiled using Arduino IDE, it should be uploaded to the main microcontroller of the Arduino UNO using a USB connection. Because the main microcontroller doesn't have a USB transceiver, you need a bridge to convert signals between the serial interface (UART interface) of the microcontroller and the host USB signals. The ATmega328 on the Arduino Uno comes pre-programmed with a boot loader that allows you to upload new code to it without the use of an external hardware programmer. It communicates using the original STK500 protocol. You can also bypass the bootloader and program the microcontroller through the ICSP (In Circuit Serial Programming) header using Arduino are similar. The ATmega16U2 (or 8U2 in the rev1&rev2 boards) firmware source code is available in the Arduino repository. The ATmega16U2 or 8U2 is loaded with a DFU bootloader, which can be activated by On Rev1 boards connecting the solder jumper on the back of the board and then resetting the 8U2. You can then use Atmel's FLIP software (Windows) or the DFU programmer (Mac OS X and Linux) to load a new firmware. Or you can use the ISP header with an external programmer (overwriting the DFU bootloader). Arduino is an opensource hardware platform that is being used by people around the globe for building electronics projects. It is an integrated platform which contains both the physical and programmable circuit otherwise known as microcontroller and a software (or IDE) that you can run on your computer to write and upload the code onto the physical board. Arduino Board is quite popular among many people who want to get started with electronics, and unlike other embedded system boards Arduino does not require any additional hardware to upload the code (generally known as programmer). The Arduino Program can be written and uploaded using the Arduino IDE that needs just an USB cable to connect. Since the interface is simple and complicacies are less Arduino is preferred by most of the aspiring engineers. Here we will try to understand about the Arduino Architecture and its functionalities. The processor of the Arduino Board uses Harvard Architecture for which the program code and program data have separate memory. The memory of it is divided into two namely program memory and data memory. The data will be stored in the data memory whereas the program code will be stored in the flash program memory. For ex: The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM, 1kb of EPROM and operates at 16MHz clock speed. Some of the other basic functions of Arduino are:

- Digital write pin is used to write the digital value of the given pin.
- Pin mode pin is used to set the pin to I/O mode.
- Analog read pin reads and returns the value.
- Analog write pin writes the value of the pin
- Serial. Begins pin sets the beginning of serial communication by setting the rate of bit
- Digital read pin reads the digital value of given pin.

Advantages

Inexpensive -Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50.

1. Cross-platform - The Arduino software runs on Windows, Macintosh OSX, and the Linux operating systems. Most microcontroller systems are limited to Windows.

2. Simple programming environment- Here the Arduino programming environment is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with the look and feel of Arduino.

3. Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to

4. Open source and extensible hardware - The Arduino is based on Atmel's ATmega8 and ATmega168 microcontrollers. The plans for the modules are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even 19 relatively inexperienced users that can build the breadboard version of the module in order to understand how it works and save money.

Applications

• It is an easy USB interface. This allows interface with USB as this is like a serial device.

• The chip on the board plugs straight into your USB port and supports on your computer as a virtual serial port. The benefit of this setup is that serial communication is an extremely easy protocol which is time-tested and USB makes connection with modern computers and makes it comfortable.

• It is easy-to-find the microcontroller brain which is the ATmega328 chip. It has more number of hardware features like timers, external and internal interrupts, PWM pins and multiple sleep modes.

• It is an open source design and there is an advantage of being open source is that it has a large community of people using and troubleshooting it. This makes easy to help in debugging projects

. • It is 16MHz clock which is fast enough for most applications and does not speeds up the microcontroller.

• It is very convenient to manage power inside it and it had a feature of built-in voltage regulation. This also be powered directly off a USB port without any external power. You can connect an external power source of up to 12v and this regulates it to both 5v and 3.3v.

• 13 digital pins and 6 analog pins. This sort of pins allows you to connect hardware to your Arduino Uno board externally. These pins are used as a key for extending the computing capability of the Arduino Uno into the real world. This has an ICSP connector for bypassing the USB port and interfacing the Arduino directly as a serial device. This port is necessary to re-boot load your chip if it corrupts and can no longer used to your computer.

• It has a 32 KB of flash memory for storing your code.

• An on-board led is attached to digital pin 13 to make fast the debugging of code and to make the debug process easy finally it has the button to reset.

Power

The Arduino Uno can be powered via through USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter (wall-wart) or battery. The adapter can be connected by plugging a 2.1mm centre-positive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and Vin pin headers of the POWER connector. The board can operate on an external supply of 6 to 20 volts. If supplied with less than 7V, however, the 5V pin may supply less than five volts and the board may be unstable. If using more than 12V, the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. the power pins are as follows.

• VIN. The input voltage to the Arduino board when it's using an external power source (as opposed to 5 volts from the USB connection or other regulated power source). You can supply voltage through this pin, or, if supplying voltage via the power jack, access it through this pin. • 5V. The regulated power supply used to power the microcontroller and other components on the board. This can come either from VIN via an on-board regulator, or be supplied by USB or another regulated 5V supply.

• 3.3V. A 3.3volt supply generated by the on-board regulator. Maximum current draw is 50 mA.

• GND. Ground pins.

Introduction to Atmega328

ATmega328 is an eight (8) bit Microcontroller. It can handle the data sized of up to eight (8) bits. It is an AVR based micro-controller. Its built-in internal memory is around 32KB. It operates ranging from 3.3V to 5V. It has an ability to store the data even when the electrical supply is removed from its biasing terminals. it is the excellent features include the cost efficiency and low power dissipation, programming lock for security purposes, real timer counter with the separate oscillator and It is generally or normally used in Embedded Systems applications. ATmega-328 is shown in the figure given below.

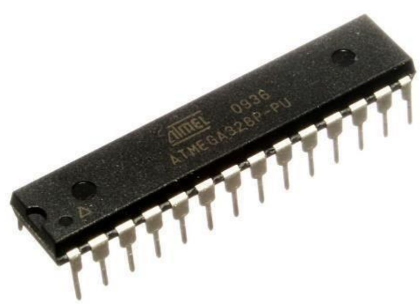

Fig.4.1.3: ATMega328 Microcontroller

Arduino UNO Atmega328

The Arduino UNO is a micro controller board based on the ATmega. UNP means one in Italian and is named to mark the upcoming release of the given Arduino 1.0 it has 14 digital input/output pins, 6 analog inputs, 16MHz ceramic resonator. A USB connection. A power jack, An ICSP header and a reset button.it contains information everything needed to support the microcontroller. simply connect it to a computer with a USB cable or power it with a ac-to-dc adapter or battery to get started. The UNO differs from all preceding boards in that it does not use the FTDI USBto serial driver chip. Instead it features the ATMega 16U2ATMega 8U2 up to version instead R2) programmed as a USB to-serial converter.

Architecture and Working of Arduino Uno

The Arduino UNO can be also powered via the USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter or battery. The adapter can connected by plugging a 2.1mm centre positive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and vin pin headers of the power connector. The board can operate on an external supply of 6to 20 volts. If supplied with less than 7v however, the 5v pin may supply less than five volts and the board may be unstable. If using more than 12v.the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. The processor of the Arduino board uses the Harvard architecture where the program code and program data have separate memory. It consists of two memories such as program memory and data memory. Where in the data is stored in data memory and the code is stored in the flash program memory. The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM 1kb of EPROM and operates with a 16MHz clock speed. Architecture of Atmega328 is shown below.

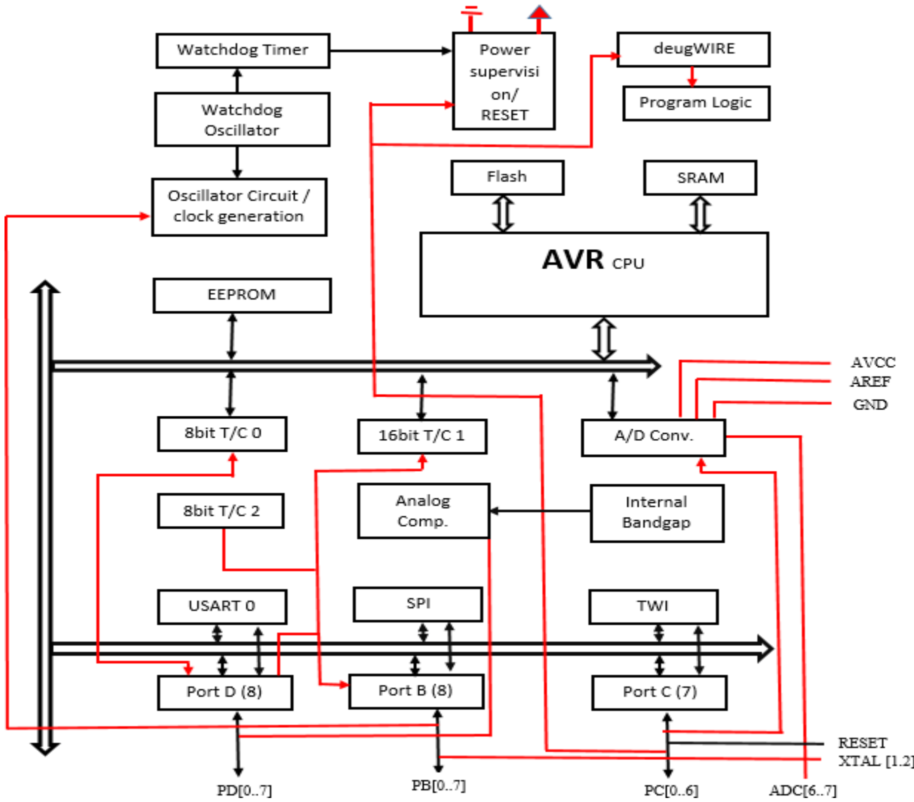

Fig.4.1.4: ATmega328P Architecture

Atmega328 Pins Description

Functions associated with the pins must be known in order to use the device appropriately. ATmega-328 pins are divided into different ports which are given in detail below.

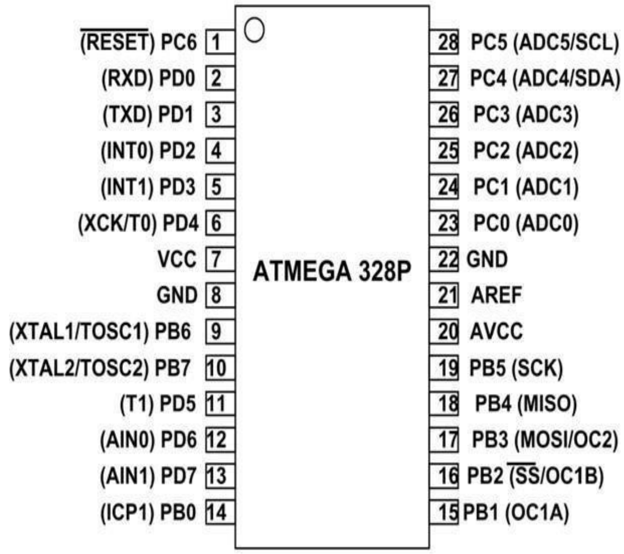

Fig.4.1.5: ATmega328P Ports

AVCC is a supply voltage pin for analog to digital converter.

VCC is a digital voltage supply GND denotes Ground and it has a 0V.

Port A consists of the pins from PA0 to PA7. These pins serve as analog input to analog to digital converters. If analog to digital converter is not used, port A acts as an eight (8) bit bidirectional input/output port.

Port B consists of the pins from PB0 to PB7. This port is an 8 bit bidirectional port having an internal pull-up resistor.

Port C consists of the pins from PC0 to PC7. The output buffers of port C

Port D consists of the pins from PD0 to PD7. It is also an 8bit input/output port having an internal pull-up resistor. All of the AVR ports are shown in figure given below.

GAS SENSOR

• Gas sensors main aim is to sense hazardous gases that evolve its surroundings

• Gas sensor detects the concentrations of combustible gas in the air and ouputs its reading as an analog voltage. The sensor can measure concentrations of flammable gas of 300 to 10,000 ppm. The sensor can operate at temperatures from -20 to 50°C and consumes less than 150 mA at 5 V.

• High sensitivity to LPG, Propane and Hydrogen.

Fig 4.1.6: MQ2 Gas Sensor

Gas sensing technologies

▪ Metal Oxide Based Gas Sensors

▪ Capacitance Based Gas Sensors

▪ Acoustic Wave Based Gas Sensors

▪ Calorimetric Gas Sensors

▪ Optical gas sensors

▪ Electrochemical gas sensors

Types

1. Metal Oxide Based Gas Sensors

▪ Metal oxide sensors are also known as chemiresistors

▪ The detection principle of resistive sensors is based on change of the resistance of a thin film upon adsorption of the gas molecules on the surface of a semiconductor.

▪ The gas-solid interactions affect the resistance of the film because of the density of electronic species in the film.

2. Capacitance Based Gas Sensors

▪ They measure the change in dielectric constant of films between the electrodes as a function of the gas concentration.

▪ The capacitive sensor relies on inter-digitated electrode structures, which correspond to the two plates of a standard capacitor, to monitor changes of the dielectric coefficient of the film. ▪ The simple theory behind it is if the dielectric constant of the film is lower than that of the analyte, the capacitance will increase and vice versa.

3. Acoustic Wave Based Gas Sensors

▪ Sound based gas sensors are known as acoustic wave based gas sensors.

▪ To launch the acoustic waves, this type of sensor uses piezoelectric material either in the thin film form or in bulk form which has one or more transducers on its surface.

4. Carbon monoxide gas sensor

▪ It can either be battery-operated or AC powered.

▪ Mostly the sensor will not sound an alarm at lower concentrations (e.g. 100 ppm). The alarm will sound within a few minutes at 400 ppm. So the function is specific to concentration-time. It shows simple carbon monoxide sensor. Carbon monoxide sensor can be of different types such as:

▪ Semiconductor sensor

▪ Electrochemical sensor

▪ Digital sensor

▪ Biomimetic sensor (chem-optical or gel cell sensor)

Power Supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

LCD (Liquid Crystal Display)

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other. A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0) For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Pin No	Symbol	Level	Description
1	Vss	0 V	Ground
2	V_{DD}	5.0V	Supply voltage for logic
3	V o	variable	Operating voltagefor LCD
4	RS	H/L	H data/L instruction code
5	R/W	H/L	H/Read (MPU-module) L/write (MPU-module)
6	E	H, H-L	Chip enable signal
7	DB0	H/L	Data bit 0
8	DB1	H/L	Data bit 1
9	DB2	H/L	Data bit 2
10	DB3	H/L	Data bit 3
11	DB4	H/L	Data bit 4
12	DB5	H/L	Data bit 5
13	DB6	H/L	Data bit 6
14	DB 7	H/L	Data bit 7
15	A		Power supply for LED backlight (+)
16	K		Power supply for LED backlight (-)

Table 4.1.2: Pin description

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

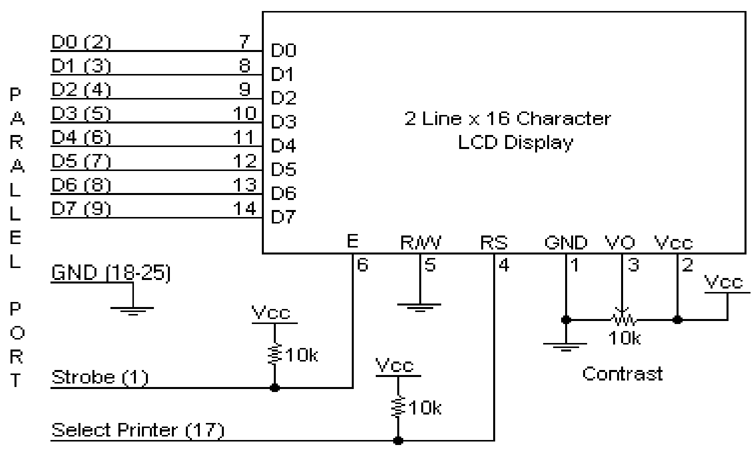

Fig.4.1.7: Schematic Diagram of LCD

• Above is the quite simple schematic. The LCD panel's Enable and register select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pullup resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

• We make no effort to place the Data bus into reverse direction. Therefore we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

• The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table 4.1.3: LCD commands

SOUND SENSOR

A sound sensor is defined as a module that detects sound waves through its intensity and converting it to electrical signals. Sound detection sensor works similarly to our Ears, having diaphragm which converts vibration into signals. However, what’s different as that a sound sensor consists of an in-built capacitive microphone, peak detector and an amplifier (LM386, LM393, etc.) that’s highly sensitive to sound.

With these components, it allows for the sensor to work:

1. Sound waves propagate through air molecules

2. Such sound waves cause the diaphragm in the microphone to vibrate, resulting in capacitance change

3. Capacitance change is then amplified and digitalized for processing of sound intensity

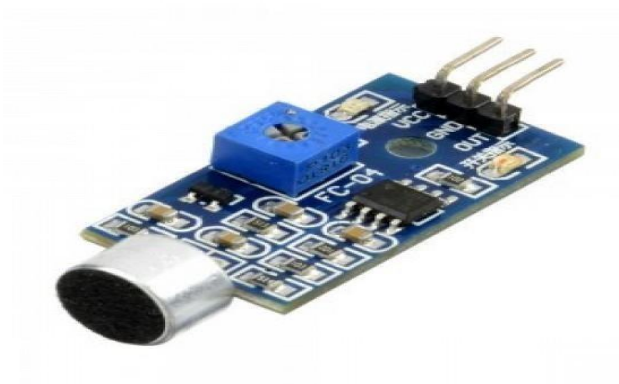

Fig 4.1.8: Sound Sensor

Applications

Apart from building various electronic projects with Arduino (covered in the later section) and more, sound sensors are used in many other day to day applications including:

- Consumer electronics such as phones, computers, music systems
- Security and Monitoring systems such as burglar alarms, door alarm, etc.
- Home automation such as lighting your house by detecting whistle/clap instead of physically turning the light switch
- Ambient sound recognition and sound level recognition

features :

- Grove compatible interface
- Seeed's own plug and play system, no soldering or jumper wires needed for pairing as compared to other sound sensor breakout boards
- Analog output signal
- Wide supply voltage range: 4V-12V
- Low quiescent current drain: 4mA
- 2.0cm x 2.0cm twig module
- Minimum external parts

WIFI ESP8266 MODULE:

- The ESP8266 WiFi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.
- This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

- There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transforming this module into an IoT (Internet of Things) solution!

- Note: The ESP8266 Module is not capable of 5-3V logic shifting and will require an external Logic Level Converter. Please do not power it directly from your 5V dev board. This ESP8266 WiFi Module Adaptor comes with on-board logic level converter and 3.3V LDO regulator for easy interfacing to Arduino boards.

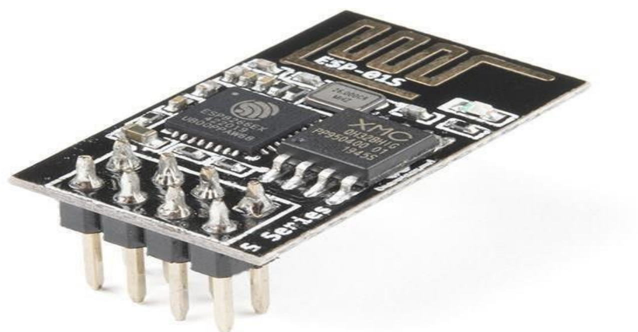

Fig 4.1.9: ESP8266 Wi-Fi Module

Features:

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval

- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)
- Default baudrate: 115200

Software Requirement

- Arduino software
- Programming language

Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino 44 software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

• Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

• Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

• Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

• Open source and extensible software - The Arduino software is published as opensource tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products.
- Install the Arduino Software (IDE) on Windows PCs-
- This document explains how to install the Arduino Software (IDE) on Windows machines.
- Download the Arduino Software (IDE)
- Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually. When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.2.1: USB Cable A plug to B plug

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.4.2.2: USB Cable A plug to Mini-B plug

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, 47 which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

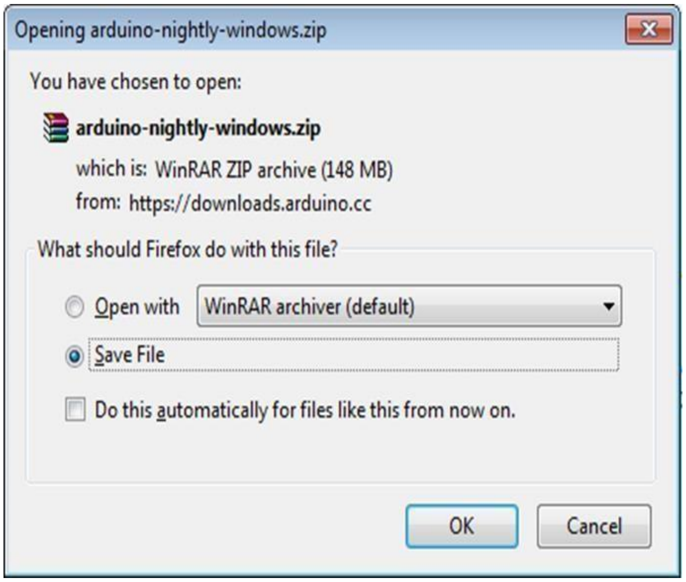

Fig.4.2.3: Unzip of Arduino IDE software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

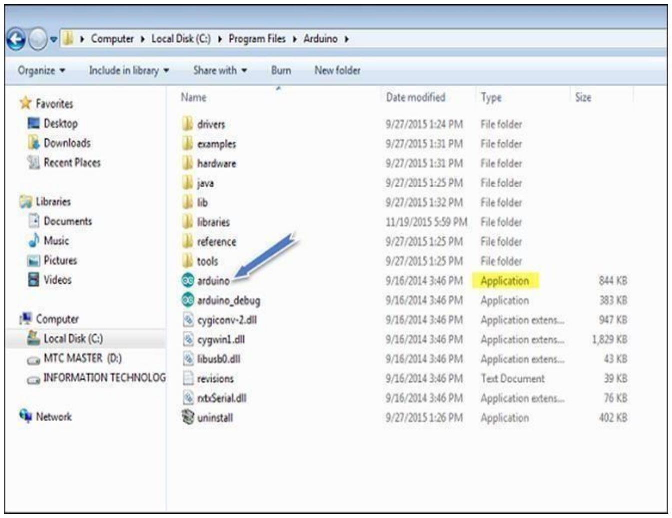

Fig.4.2.4: Open IDE software

Step 5 − Open your first project.

Once the software starts, you have two options:

• Create a new project

. • Open an existing project example.

To create a new project, select File → New.

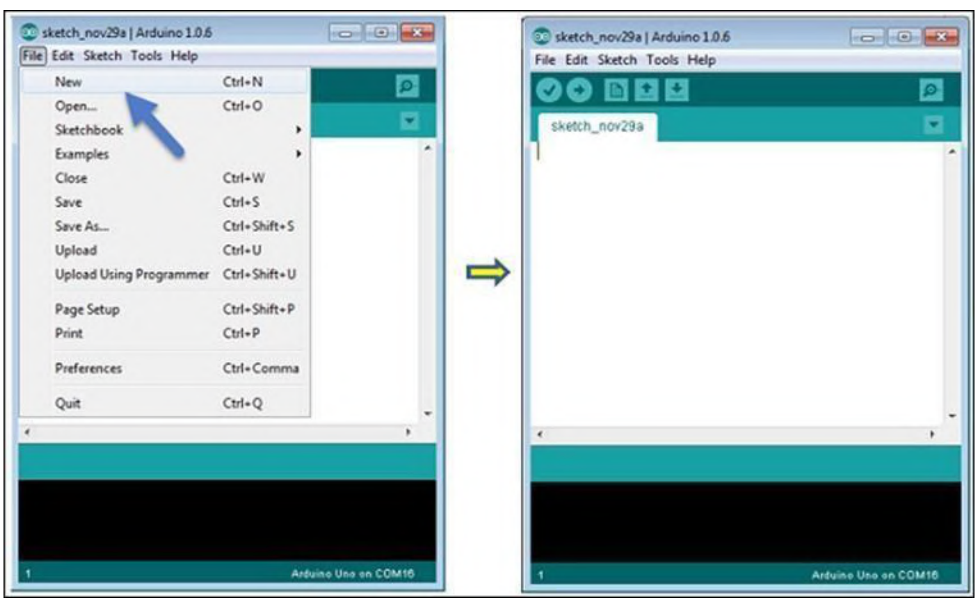

Fig.4.2.5: Open First Project

To open an existing project example, select File → Example → Basics → Blink.

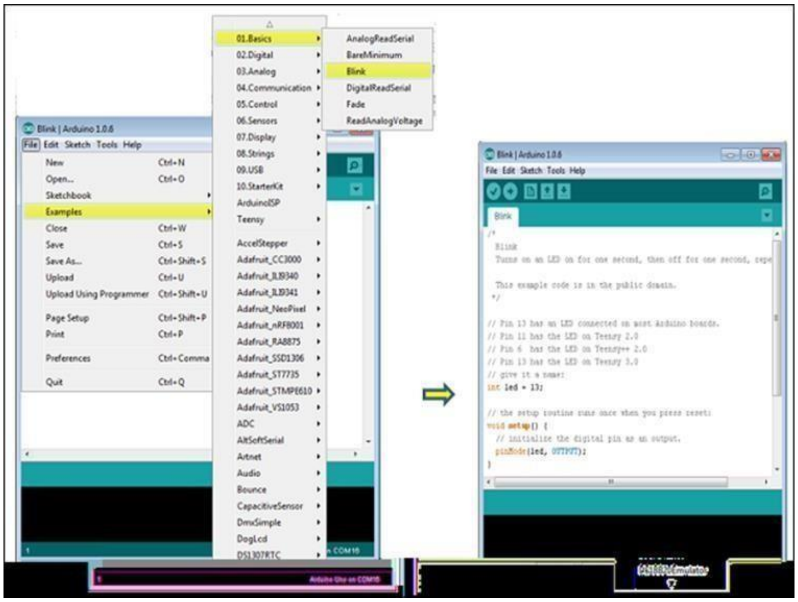

Fig.4.2.6: Open existing Project

Here, we are selecting just one of the examples with the name Blink. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board. To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer. Go to Tools → Board and select your board.

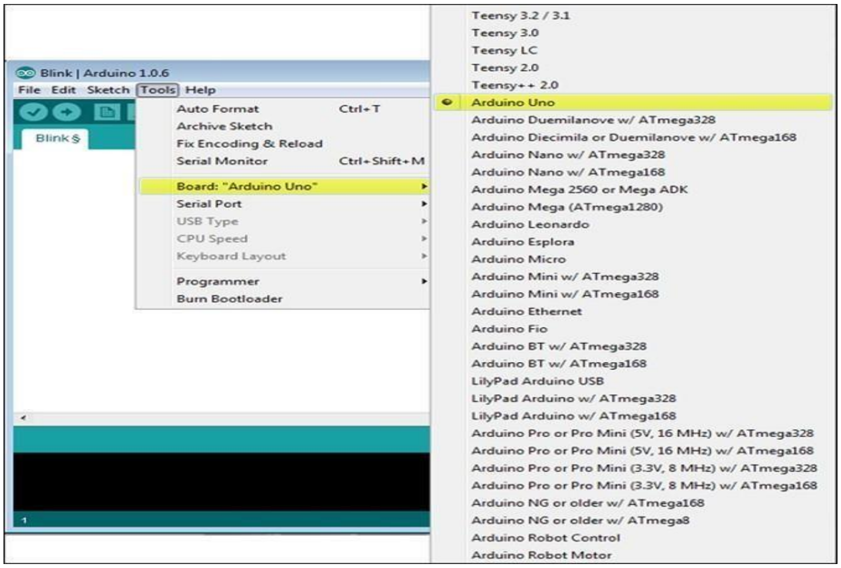

Fig.4.2.7: Selection of Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port. Select the serial device of the Arduino board. Go to Tools → Serial Port menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

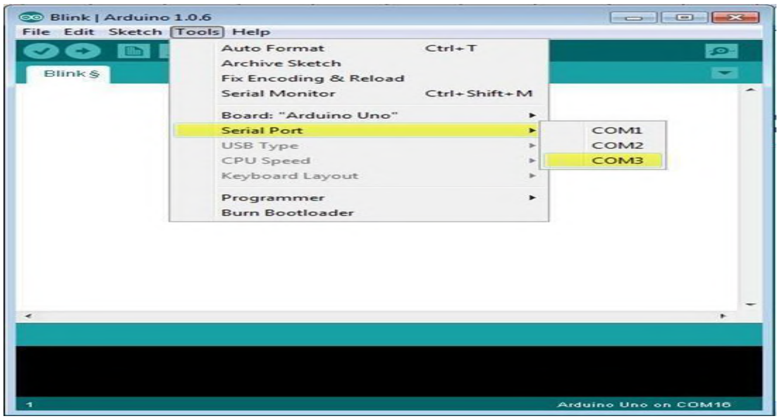

Fig.4.2.8: Selection of Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

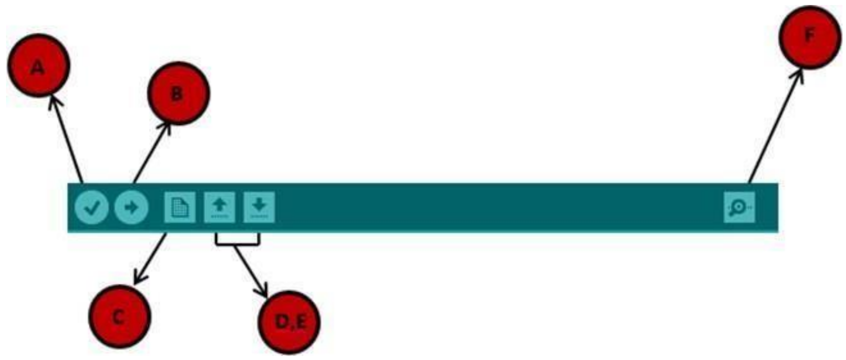

Fig.4.2.9: Uploading the program to board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Proteus

Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also has 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc. ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

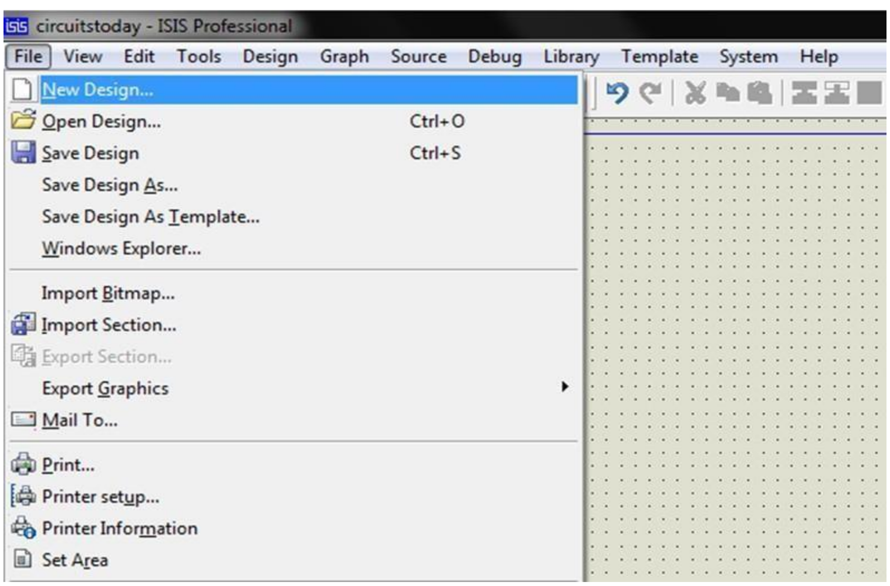

Fig.4.2.10: Proteus file menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No 57 depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

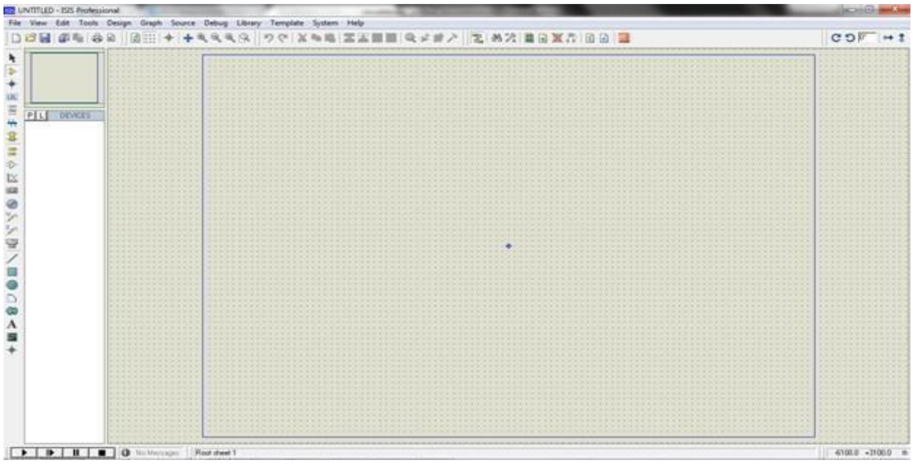

Fig.4.2.11: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

Step 6: Select the components from categories or type the part name in Keywords text box.

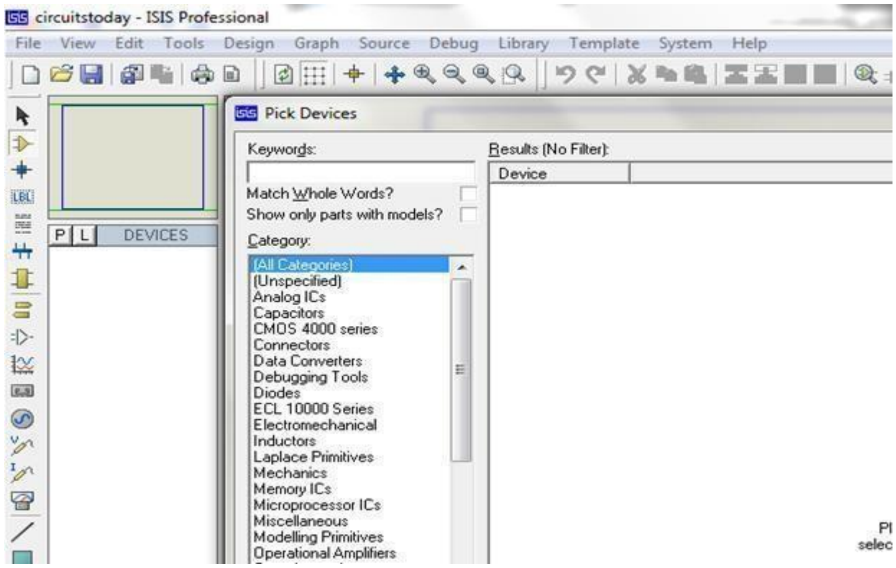

Fig.4.2.12: Key Textbox

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click. Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

Step 8: After connecting the circuit, click on the play button to run the simulation.

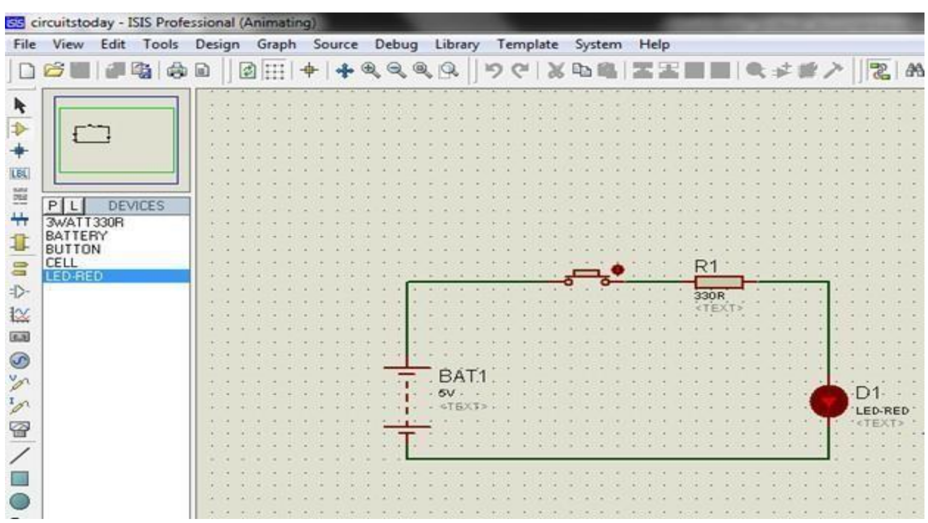

Fig.4.2.13: Stimulation Software

CHAPTER 5

SOFTWARE TESTING AND CODE IMPLEMENTATION

SOFTWARE TESTING

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

TESTING LEVELS

There are various testing levels based on the specificity of test.

- Unit testing: Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.
- Integration Testing: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.
- System Testing: System testing tests a completely integrated system to verify that the system meets its requirements.
- Acceptance testing: Acceptance testing tests the readiness of application, satisfying all requirements.

• Performance testing: Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

CODE IMPLEMENTATION

PROJECT

CODE #include

CHAPTER 6

RESULTS ANALYSIS

RESULTS:

This hardware setup gives a brief idea as to how the project “Air And Noise Pollution Monitoring System Over An IOT” works. The below figure shows the hardware setup of the proposed system and constitutes of gas sensor and sound sensor for the detection of concentration of harmful gases in the environment and level of intensity of sound in the surroundings respectively. It also constitutes of lcd display for display the information i.e., the values detected by the two sensors and a esp8266 wi-fi module for transmitting this values continuously to the online server.

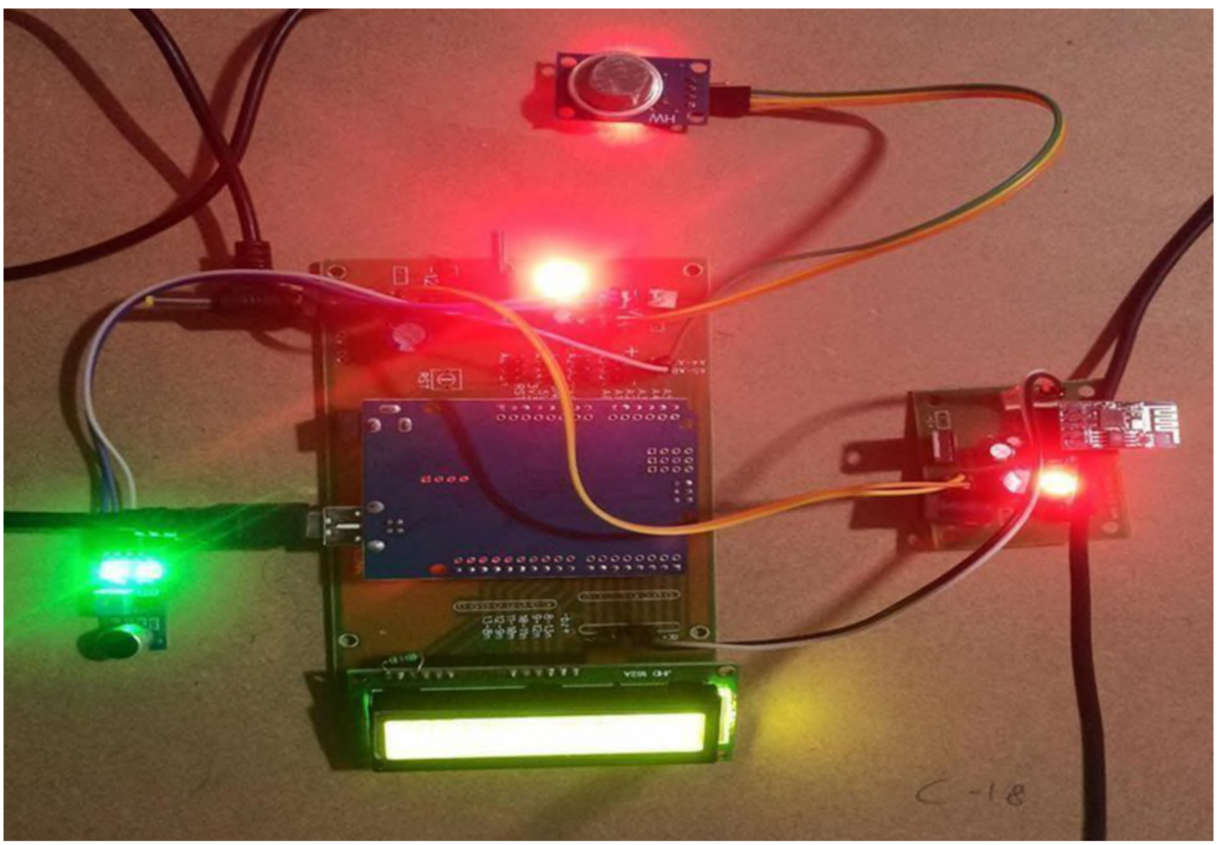

Fig 6.1:The Hardware setup of the proposed system

Displaying normal reading values on the lcd

Gas sensor and sound sensor sense the concentration of harmful gases and level of intensity of sound in the environment continuously and sends that information continuously to the Arduino uno. Now the Arduino uno which is brain of this project takes the information from the sensors and transmits that values to the lcd for displaying them. The below figure represents lcd display that displaying normal readings of the sensors and this values are normal range of concentration of harmful gases and intensity of sound that doesn't cause any harm to the living beings.

Fig 6.2: LCD display that displaying normal range values

Displaying of warning messages

Here the two sensors i.e., gas sensor and sound sensor consists of potentiometer using this we can set the threshold .When the readings from the gas sensor and sound sensor exceeds the set threshold it will display warning messages on the lcd. If the concentration of harmful gases exceeds the set threshold it will display “Danger gas” as warning message on the lcd and if the level of sound intensity exceeds the set threshold it will display “ Danger sound” warning message on the lcd.

Fig 6.3 : Displaying of warning message “Danger gas”

Fig 6.4: Displaying of warning message “Danger sound”

Monitoring readings of the sensor in the online server

Here the readings from the two sensors are continuously transmitted to the online server by the esp8266 wi-fi module and we can monitor those readings by using an open IOT platform thingspeak website .Here in this website all the readings can be viewed in graphical manner.

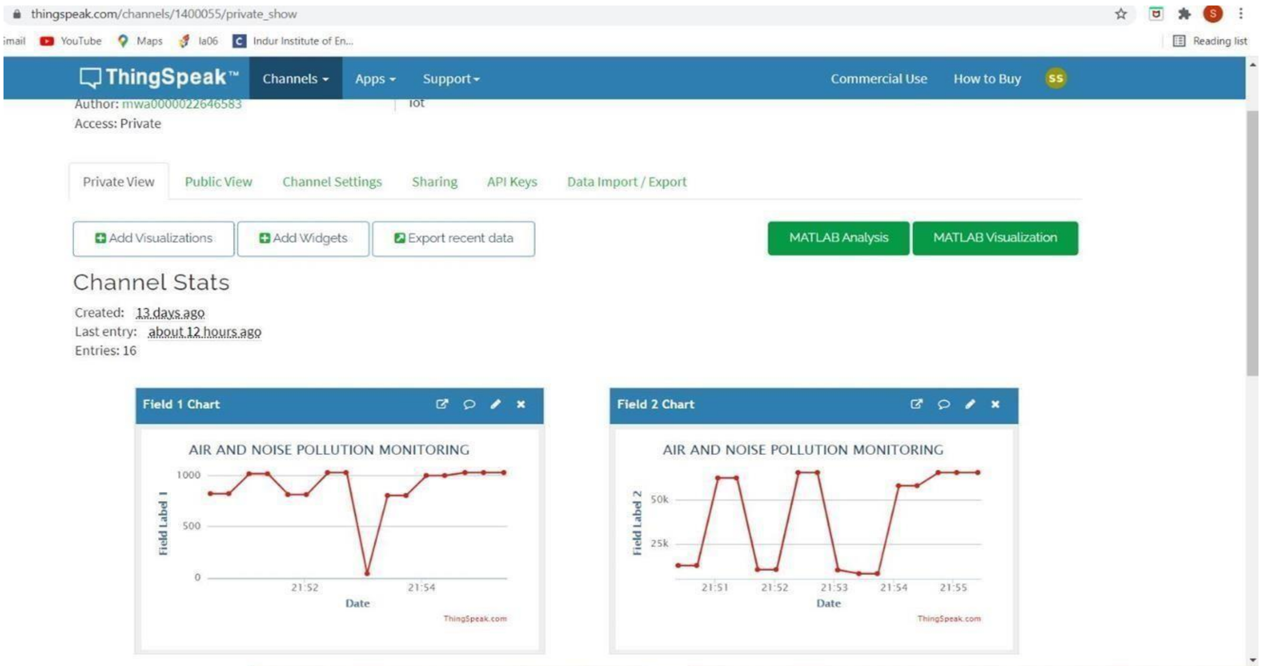

Fig 6.5 : Thingspeak website

For displaying graphical output on the website we need to create a channel in that website and we have add a particular API key to our project code. This API key unique for every project. The API key of this proposed system is given below

Fig 6.6: API key

CHAPTER 7

APPLICATIONS AND ADVANTAGES

APPLICATIONS OF THE PROJECT:

- Industrial pollution monitoring
- Public areas
- School area
- Environmental Section
- Installed in Vehicles

ADVANTAGES OF THE PROJECT:

- Remotely we can monitor pollution
- Cheap in Cost
- Data can be used to control pollution
- Small in size
- Data is useful to government Health Departments

CHAPTER-8

CONCLUSION AND FUTURE ENHANCEMENT

CONCLUSION:

The **air** & **sound monitoring system** overcomes the problem of the highly-polluted areas which is a major issue. It supports the new technology and effectively supports the healthy life concept. The Automatic Air & Sound management system is a step forward to contribute a solution to the biggest threat. The air & sound monitoring system overcomes the problem of the highly-polluted areas which is a major issue. It supports the new technology and effectively supports the healthy life concept.

This system has features for the people to monitor the amount of pollution on their mobile phones using the application. So, it becomes very reliable and efficient for the Municipal officials along with the Civilians to monitor environment. Letting civilians also involved in this process adds an extra value to it. As civilians are now equally aware and curious about their environment, this concept of IOT is beneficial for the welfare of the society. And it is implemented using the latest technology

FUTURE SCOPE:

The project is intended victimization structured modeling and is ready to supply the required results. It is with success enforced as a true Time system with bound modifications. Science is discovering or making major breakthrough in varied fields, and thus technology keeps dynamic from time to time. Going more, most of the units is fictional on one in conjunction with microcontroller so creating the system compact thereby creating the present system simpler.33 To make the system applicable for real time functions parts with larger vary must be enforced. This model is any enlarged to observe the developing cities and industrial zones for pollution monitoring. To safeguard the general public health from pollution, this model provides associate economical and low price resolution for continuous observance of atmosphere.

ACKNOWLEDGEMENT

We sincerely thank the management of our college **St. MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work. We derive our great pleasure in expressing our sincere gratitude to our principal **Dr. P. Santosh Kumar Patra** for his timely suggestions, which helped us to complete the project work successfully. It is the very auspicious moment to express our gratitude to **Dr. B. Hari Krishna**, Head of the Department, ECE for his consistent encouragement during the progress of this project. We take it as a privilege to thank our project coordinator **Mr. K. Karthik** Professor, department of ECE for the ideas that led to complete the project work and we also thank them for their continuous guidance, support and unfailing patience, throughout the course of this work. We sincerely thank our project Internal guide **Mr. G. Ramesh Reddy**, Assistant Professor, Department of ECE for guidance and encouragement in carrying out this project work.

DECLARATION

We, the students of **'Bachelor of Technology in Department of Electronics and Communication Engineering'**, session: 2017 – 2021, St. Martin's Engineering College, dullapally, kompally, secunderabad hereby declare that the project work entitled '**Super Resolution By Image enhancement Using Textual Transfer**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

P. Bharath Chandra Reddy	**(17K81A04A2)**
G. R Srawan kumar Reddy	**(17K81A0478)**

Abstract

Recent deep learning approaches in single image super resolution (SISR) can generate high-definition textures for super-resolved (SR) images. However, they tend to hallucinate fake textures and even produce artifacts. An alternative to SISR, reference-based SR (Ref SR) approaches use high resolution (HR) reference (Ref) images to provide HR details that are missing in the low-resolution (LR) input image. We propose a novel framework that leverages existing SISR approaches and enhances them with Ref SR. Specifically, we refine the output of SISR methods using neural texture transfer, where HR features are queried from the Ref images. The query is conducted by computing the similarity of textural and semantic features between the input image and the Ref images. The most similar HR features, patch-wise, to the LR image is used to augment the SR image through an augmentation network. In the case of dissimilar Ref images from the LR input image, we prevent performance degradation by including the similarity scores in the input features of the network. Furthermore, we use random texture patches during the training to condition our augmentation network to not always trust the queried texture features. Different from past Ref SR approaches, our method can use arbitrary Ref images and its lower-bound performance is based on the SR image. We showcase that our method drastically improves the performance of the base SISR approach

CHAPTER 1

INTRODUCTION

Introduction to the Project

The earth is associate aquatic planet and the maximum amount as eightieth of its surface is roofed by water. Moreover, there is a strong interest in knowing what lies in underwater. Present days, an image of deep waters has a scope to large investigation to explore the underwater for sea floor expedition and navigation. Enthusiasm of underwater imaging includes the inspection of plants, seabed exploration, the search for wrecks up and to the exploration of natural resources. There were several issues faced by the human in the underwater, if he dives deep into the ocean and stay there for a long time to perform experimentation. Due to the above reasons, unmanned remote vehicles are used to sea floor exploration.

Historical Development

Underwater image quality improvement approaches present a path to magnify the object recognition in underwater surrounding. A heap of research started for the upgradation of image visual quality, but a little amount of work has been carried out in this area. In the deep waters, image quality is degrading due to poor illumination conditions and the light properties differ in water compared to air.[2]. There were several parameters which decreases the quality of an image in underground waters. So, in order to remove all these effects

there are several techniques has been implemented and practiced.

Need for Pre process

Initially processing is necessary for deep water images due to their poor-quality during acquisition. Necessity for pre-processing of deep-water images is discussed below:

(i) Quality of images taken from deep water is deteriorated due to light ray attributes like scattering and absorption of light.

(ii) Specificity of surroundings such as lighting inequalities, water torridness, and blue complexion is more or less influential when vehicles move.
(iii) Video or image captured from deep waters like unknown rigid scene, and the depth of the scene and low light sensitivity due to Marine snow etc.

TRADITIONAL TECHNIQUES FOR IMAGE ENHANCEMENT

There are several techniques which are used very frequently for processing the image to improve the visual quality. Some of them are as follows:
(i) Contrast Stretching

(ii) Adaptive Histogram Equalization

Contrast stretching

The contrast stretching is a method to transform high intense region of image into brighter and less intense region into darker by using a predefined transformation function T(r) [2]. Generally, the underwater images will have fewer grey values. There are 256 grey values. ‘0’ indicates black and ‘255’ indicates white. In this method the current grey value of the image is stretched towards 255 i.e., from black to white, pixel by pixel. That means the contrast of the image is stretched, so that the quality of the image is improved for better vision.
For example:

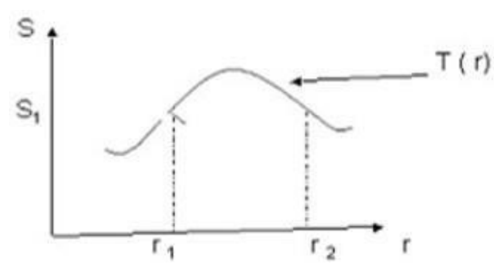

Fig.1.1 Two different gray levels look same

Here two different thresholds are considered for the entire image and the values between them are stretched to the maximum extent, so that the contrast increases. And more over by this method the entire global image contrast is enhanced.

Fig.1.2 (a) Raw image (b) Enhanced image

But the disadvantage here is that the transformation function is not unique. Depending on the application the suitable transformation function is chosen.

Adaptive histogram equalization

Adaptive histogram equalization is a PC based image processing technique which is used to improve the quality of image properties like contrast. It is similar to contrast stretching method but with a slight difference. It computes several intensities of specific gray value, each corresponding to a distinct portion of an image, and with the help of them intensities are rearranged by applying a suitable transformation function. For example, a simple transformation function such as each pixel transformed based on the histogram of a square surrounding the pixel [3]. Existing values will be mapped to new values keeping actual number of intensities in the resulting image equal or less than the original number of intensities. The transformation function applied on the histogram is proportional to the cumulative distributive function (CDF) of pixel values in the neighbourhood. Therefore it suits for enhancing the local details and enhancing the edge information of each region of an image.

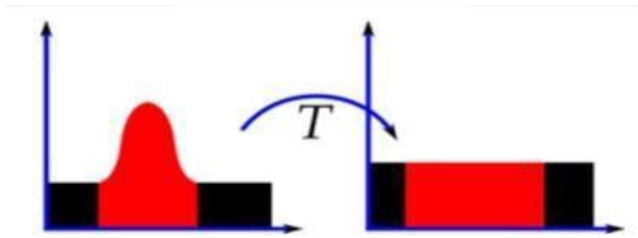

Fig 1.3. Histograms of an image before and after histogram equalization

Histogram equalization is a technique for changing the overall pixel intensities based on transformation function and contrast of an image. Histogram equalization is an effective technique which will benefit for the images with extreme contrast values. The limitation of this technique highlights the unwanted noise present in the background of an image and lead to loss in the information signal. It results in undesired effects in the resultant images.

Fig.1.4. (a) Raw image **(b) Enhanced image**

Here the noise in relatively homogeneous regions of the image is amplified which results in poor SNR. And also, only the local objects of the image are enhanced and the background is left unenhanced.

Introduction to Image Processing

1.3.1. Image:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.5 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

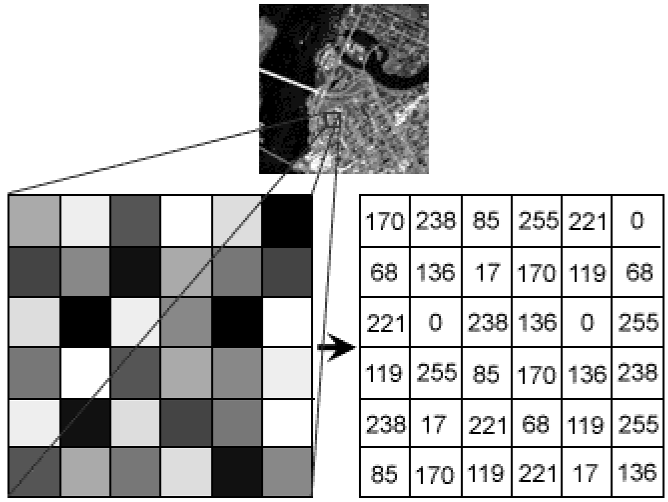

Fig 1.6 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

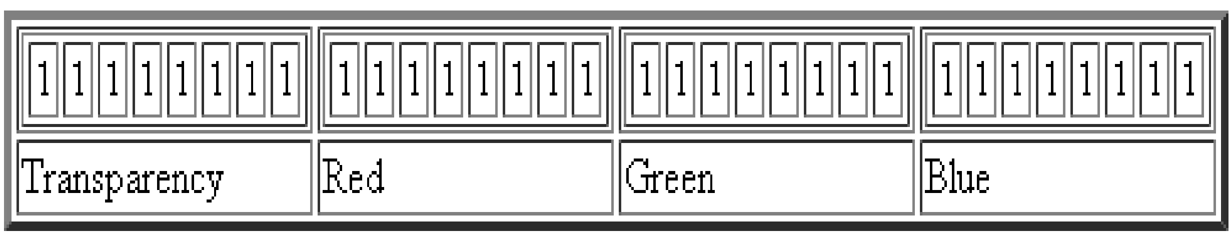

Fig 1.7 Transparency image

IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12-megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

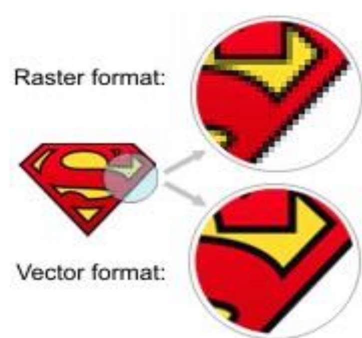

Fig 1.8 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobes PDF files.

EXIF:

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

TIFF:

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

PNG:

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

GIF:

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

BMP:

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man’s ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factors combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low-cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

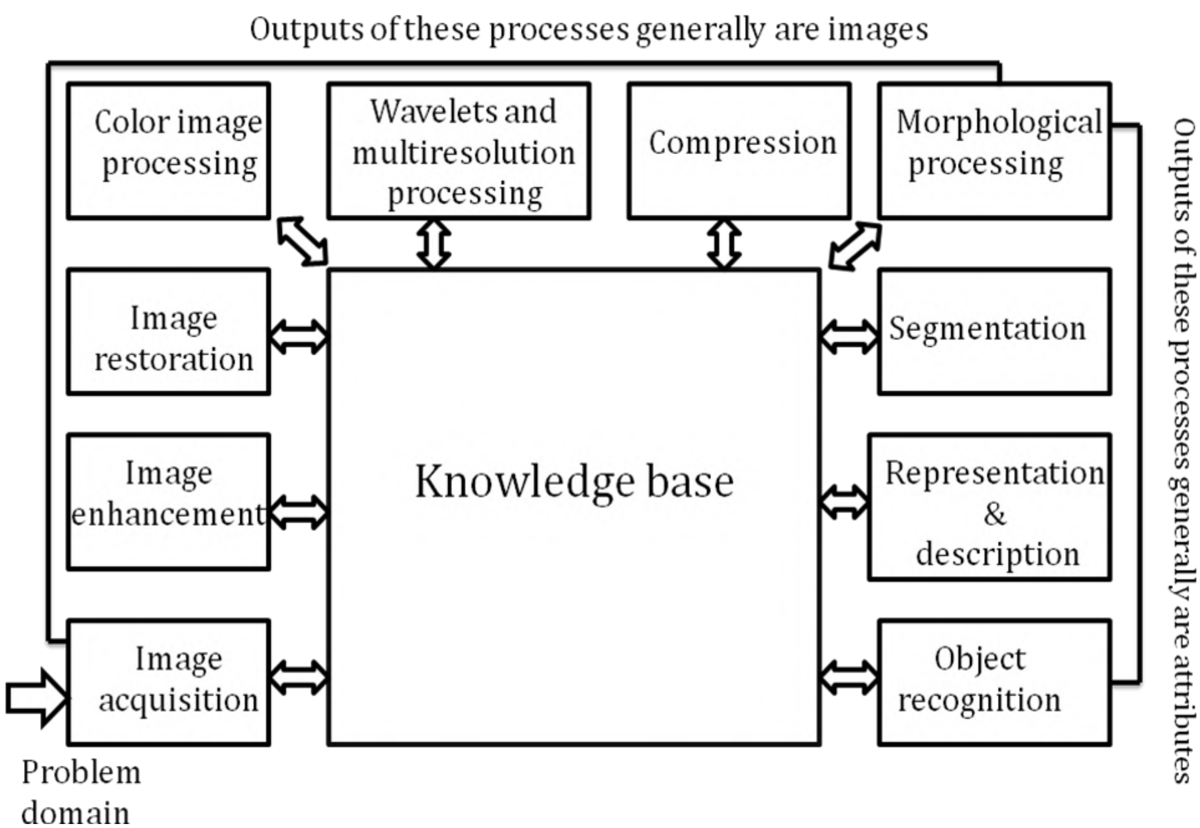

Fig 1.9 Image fundamental

Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.10 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.11 digital camera cell

Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.12 Image enhancement

Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.13 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.14 Color & Gray scale image

Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform-based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

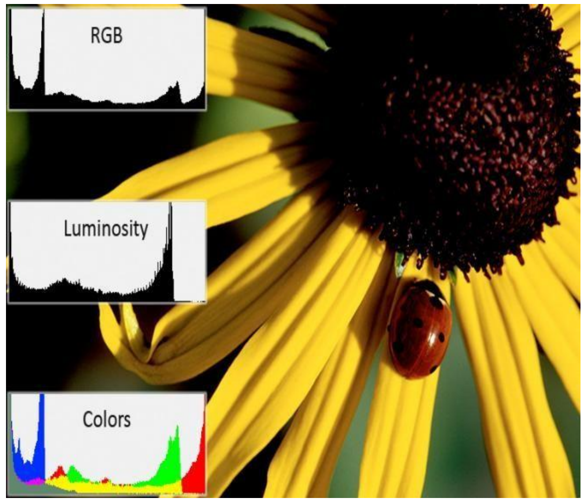

Fig 1.15 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.16 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black (or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

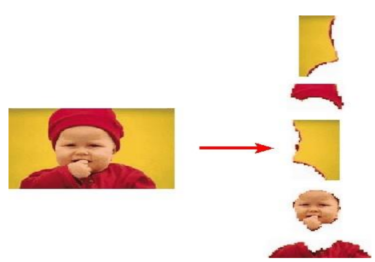

Fig 1.18 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

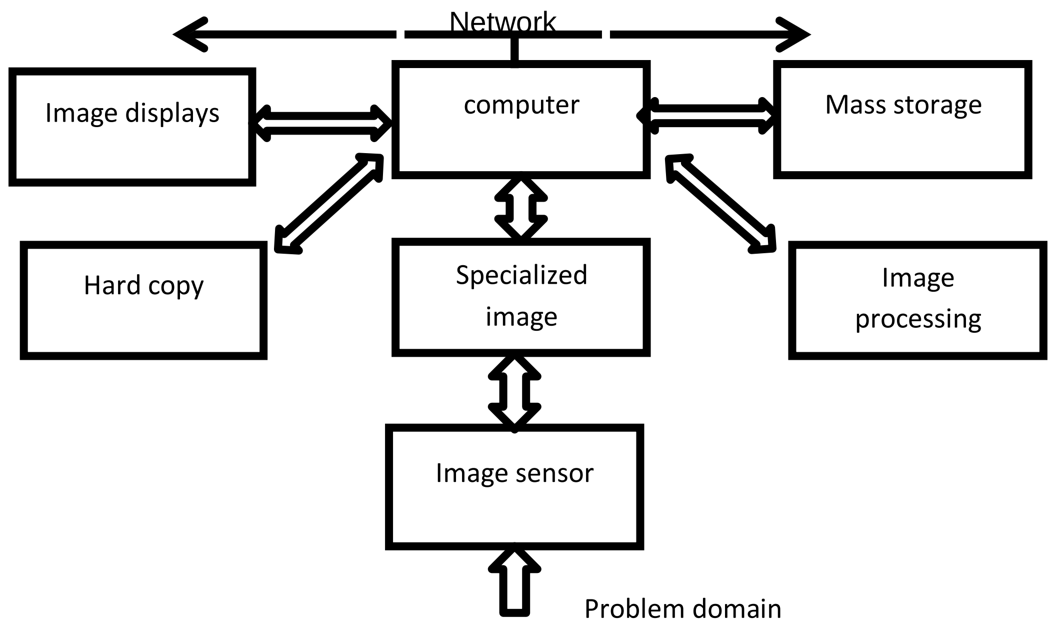

Fig 1.19 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Bytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

  Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are their requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

  Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

  Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl ∈{0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \mathrm{Pr}((\mathrm{gl}_{\ } \ \mathrm{gl}$$

g-cm (i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three-dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD; CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights. One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi-channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this project, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix

(ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically, there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Tertiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal number of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the tertiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drop just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON-INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 & if \quad h \in [316,20] \\ 1 & if \quad h \in [21,40] \\ 2 & if \quad h \in [41,75] \\ 3 & if \quad h \in [76,155] \\ 4 & if \quad h \in [156,190] \\ 5 & if \quad h \in [191,270] \\ 6 & if \quad h \in [271,295] \\ 7 & if \quad h \in [296,315] \end{cases}$$

$$S = \begin{cases} 0 & if \quad s \in [0,0.2) \\ 1 & if \quad s \in [0.2,0.7) \\ 2 & if \quad s \in [0.7,1) \end{cases}$$

$$V = \begin{cases} 0 & if \quad v \in [0,0.2) \\ 1 & if \quad v \in [0.2,0.7) \\ 2 & if \quad v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc.,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real-world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:

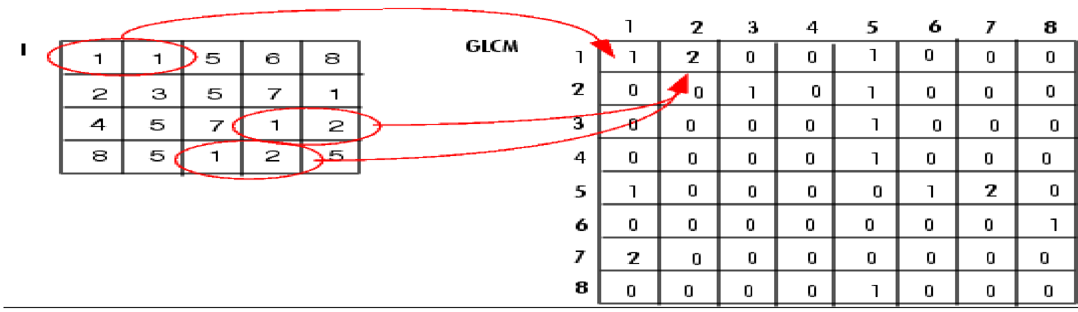

Fig 3.7 Texture enhancement

Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

$$f\,(xylem)= \begin{matrix} f(0,0) & f(0,1) & \ldots\ldots\ldots.. & f(0,N-1) \\ f(1,0) & f(1,1) & \ldots\ldots\ldots\ldots & f(1,N-1) \\ . & . & & . \\ . & . & & . \\ f(M-1,0) & f(M-1,1) & \ldots\ldots\ldots\ldots\ldots & f(M-1,N-1) \end{matrix}$$

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

$$
f = \begin{matrix} f(1,1) & f(1,2) \ldots\ldots & f(1,N) \\ f(2,1) & f(2,2)\ldots\ldots\ldots & f(2,N) \\ . & . & . \\ . & . & . \\ f(M,1) & f(M,2)\ldots\ldots\ldots & f(M,N) \end{matrix}
$$

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax Imread (‘filename’)

Format name	Description	recognized extension
BMP	Windows Bitmap	.bmp
GIF	Graphics Interchange Format	.gif
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
PNG	Portable Network Graphics	.png
TIFF	Tagged Image File Format	.tif, .tiff
XWD	X Window Dump	.xwd

Table 1.1 Syntax for Imread

Here filename is a spring containing the complete of the image file (including any applicable extension).For example the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chest ray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name **Description**

Double Double _ precision, floating_ point numbers the Approximate.

Uint8 unsigned 8_bit integers in the range [0,255] (1byte per Element).

Uint16 unsigned 16_bit integers in the range [0, 65535] (2byte per element).

Uint 32 unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element). Int8 signed 8_bit integers in the range [-128,127] 1 byte per element)

Int 16 signed 16_byte integers in the range [32768, 32767] (2 bytes per element).

Int 32 Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1. Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB. A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: is logical(c).

If c is a logical array, this function returns a 1. Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1]. The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double, then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly, the range of values is [0,255] or [0, 65535]. For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible colors in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER 2

LITERATURE SURVEY

2.1 Literature survey

Image generation tasks such as deblurring, DE mosaicking, and super-resolution are difficult tasks because there are multiple viable image outputs. In super resolution, recent advancements allow the domain of possible outputs to be constricted using perceptual loss and adversarial loss. State-of-the-art methods use these losses to generate realistic high-resolution (HR) images. These methods are single-image super resolution (SISR) approaches that attempts to recover a high-resolution (HR) image from its low-resolution (LR) observation. However, using single images for super-resolution is not practical for recovering textural details when using large upscaling factors due to the extreme information loss. For example, take an image patch of a green cloth with grid patterns, after image down sampling image, the image patch will become a blob of green and the information about the grid patterns is lost. Different from SISR, reference-based super-resolution (Ref SR) solutions utilize HR reference images to compensate lost details in LR images. Previous works in Ref SR have good performance by using image statistics of the reference (Ref) images to enhance the LR input image. However, these approaches assume the Ref images have similar content and/or have good alignment with the LR image; otherwise, their performance would degrade and even become worse than SISR methods. Recent works also use texture transfer; however, the Ref images are assumed to be homogeneous texture images and there is still performance reduction if the Ref images are different from the LR input. Ideally, a robust Ref SR algorithm should outperform SISR when good Ref images are given, and achieve comparable performance as SISR when Ref images are not provided or do not possess relevant texture at all.

CHAPTER 3

PROPOSED METHOD

Block Diagram

Introduction

Our proposed method, Aug TT (Augmented Texture Transfer), is a robust Ref SR approach that improves upon existing SISR algorithms. Aug TT leverages the performance of existing SISR approaches by refining their super-resolved (SR) outputs rather than building an SR image from ground up. We enhance the SISR output by performing neural texture transfer, where we query the Ref images for the best matching texture features then use the queried features to augment the SR image. The query is performed by computing the similarity of the texture and semantic features between the patches of the LR image and LR counterpart of the Ref Image. The most similar features are used to enhance the SR output of the SISR baselines through an augmentation network. Previous Ref SR approaches have performance degradation when Ref images have dissimilar content with the LR image. To prevent this problem, we use the similarity scores, which was computed in the texture query, as supplementary input to our network. Furthermore, during network training, we randomly select patch features from the Ref image to condition our augmentation network to not immediately trust the queried texture features. This ensures that our method has at least comparable results with the SISR methods and the lower-bound performance is based on the SISR method.

We proposed a Ref SR method that enhances image out-puts of existing SISR methods using neural texture transfer. We implemented a texture query method that takes account of texture and semantic details. We ensured that our method is robust even if using dissimilar Ref images by utilizing similarity scores in the input features and performing random feature queries during the training. We present that our method drastically improves existing SISR approaches.

The proposed method, Aug TT, is a Ref SR approach that attempts to reconstruct the HR image IHR given the input LR image ILR with the help of Ref images IRef . Different from other Ref SR approaches that attempts to generate IHR by itself, Aug TT leverages existing SISR approaches. Specifically, the SISR method SISR(·), will attempt to generate an SR image ˆISR given ILR. In this paper, we use 4 × magnification factor for the ILR.

$$\hat{I}_{SR} = SISR(I_{LR}) \qquad (1)$$

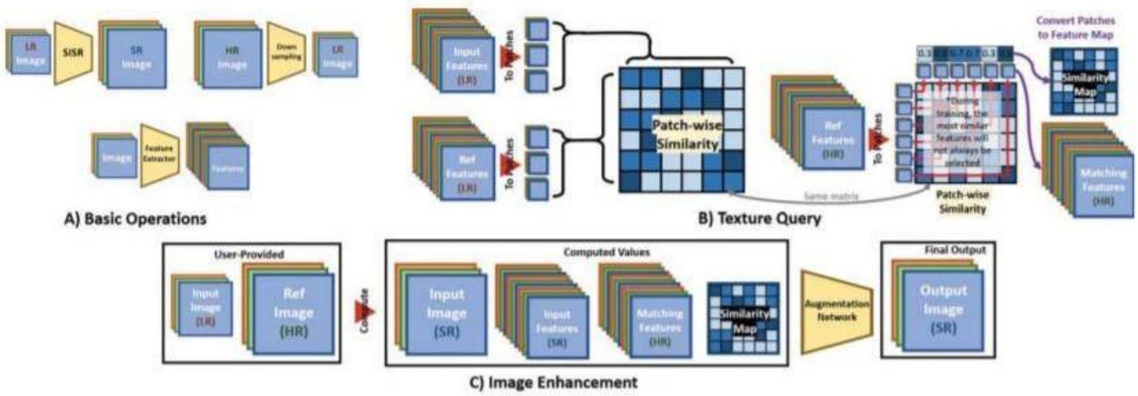

Fig 3.1 Block diagram

Our method, Aug TT, attempts to refine ˆISR using Ref images IRef. Note that there could be more than one Ref images but for simplicity's sake IRef is represented as if it is a single

$$I_{SR} = AugTT(\hat{I}_{SR}, I_{Ref}) \qquad (2)$$

entity

Aug TT stands for Augmented Texture Transfer, where the Augmented keyword represents its refinement of existing SISR methods, while the Texture Transfer is the refinement methodology. In the following subsections we will explain

Texture Query

To enhance the SR image ˆISR, we query the Ref images IRef for relevant texture features. The query is performed by finding the most similar patches to the input image from the Ref image. However, the input and Ref images are in different domains, as such, we match them. The Ref image is in the natural HR domain while the input image could be in the LR domain (ILR) or SR domain (ˆISR). We do not have access to the natural HR domain while computing in the SR domain is too memory-intensive. Therefore, we down sample the Ref image to the LR domain using bicubic interpolation producing I↓ Ref . We extract the texture and semantic features of both ILR and I↓ Ref using a pre-trained VGG19 network [17]. The intermediate outputs of the layers in a VGG network can extract different levels of details [19], with shallow layers extracting low-level features (e.g., textures, edges) and deeper layers extracting high-level features (e.g., shapes, objects). The texture and semantic features of ILR and I↓ Ref are from the intermediate outputs of the VGG network, specifically, we use the layers relu1 1, relu2 1, and relu3 1. Then, we convert the features into patches, with stride = 1 and patch size = 3. The patches are acquired in a sliding window fashion similar to the convolution operation. Since we view the features as patches, we could use arbitrary number of Ref images, with each additional Ref image appending more patches in the patch list.

For each intermediate features (e.g., relu1 1), we compute a similarity matrix between the two sets of patches using cosine distance. The final similarity matrix S is the weighted sum of the similarity matrix for each intermediate features. We set the shallow layers (i.e., relu1 1) of VGG [17] to have the highest weights. We will use S for querying the HR Ref features for the best matching patches

We extract the features from the original Ref image IRef, specifically, relu1 1. We selected only this layer since it has sufficient information to reconstruct the entire image [19]. Then we convert the features into patches and use matrix S to query the best matching patches. The patches are converted into feature map in a reverse sliding window fashion. The feature maps has cell overlaps so we divide each cell with its corresponding number of overlaps.

In case of Ref images that has dissimilar content with the input image, we include the similarity score in the input of our augmentation network. The similarity scores of the best patches is converted into a feature map using the similar method performed on the feature patches.

Image Enhancement

We will use the queried texture features to enhance the SR image through an augmentation network defined in Figure 2. The network has four input maps that will be concatenated channel-wise. The (1) similarity map and (2) matching feature map from the texture query. The (3) SR image from the SISR method, and (4) its features. The SR features and the matching features are generated from the same layer, so that processing the queried features will be easier. The augmentation network is a feed-forward network with stacks of CNN but there is a residual connection from the SR image and before the refined SR output. We want the network to learn the modifications on the input SR to generate the refined SR, rather than build the final output from ground up.

Training Details

During training, the best matching features is not always selected for image enhancements. This is to ensure that the network can still function despite the sub-optimal texture guidance. Furthermore, the augmentation network is initially trained with Bicubic interpolation as the SISR method. The network is optimized for different SISR approaches after the initial training. To train our augmentation network, we use the following loss functions. Reconstruction loss is computed using mean -norm in the pixel space (i.e. RGB) between ISR and IHR. Perceptual loss is computed with MSE in the feature space using a VGG network [17] to extract the features. Adversarial loss is computed using the formula provided by WGANGP [20] and it is, basically, a loss function that could learn the image statistics of real HR images. The dataset we used for training our augmentation network is CUFED5 [16], which contains HR target image, Ref image, and LR input image with sizes 160×160, 160×160, and 40×40, respectively.

CHAPTER 4

SOFTWARE INTRODUCTION:

Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension. fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

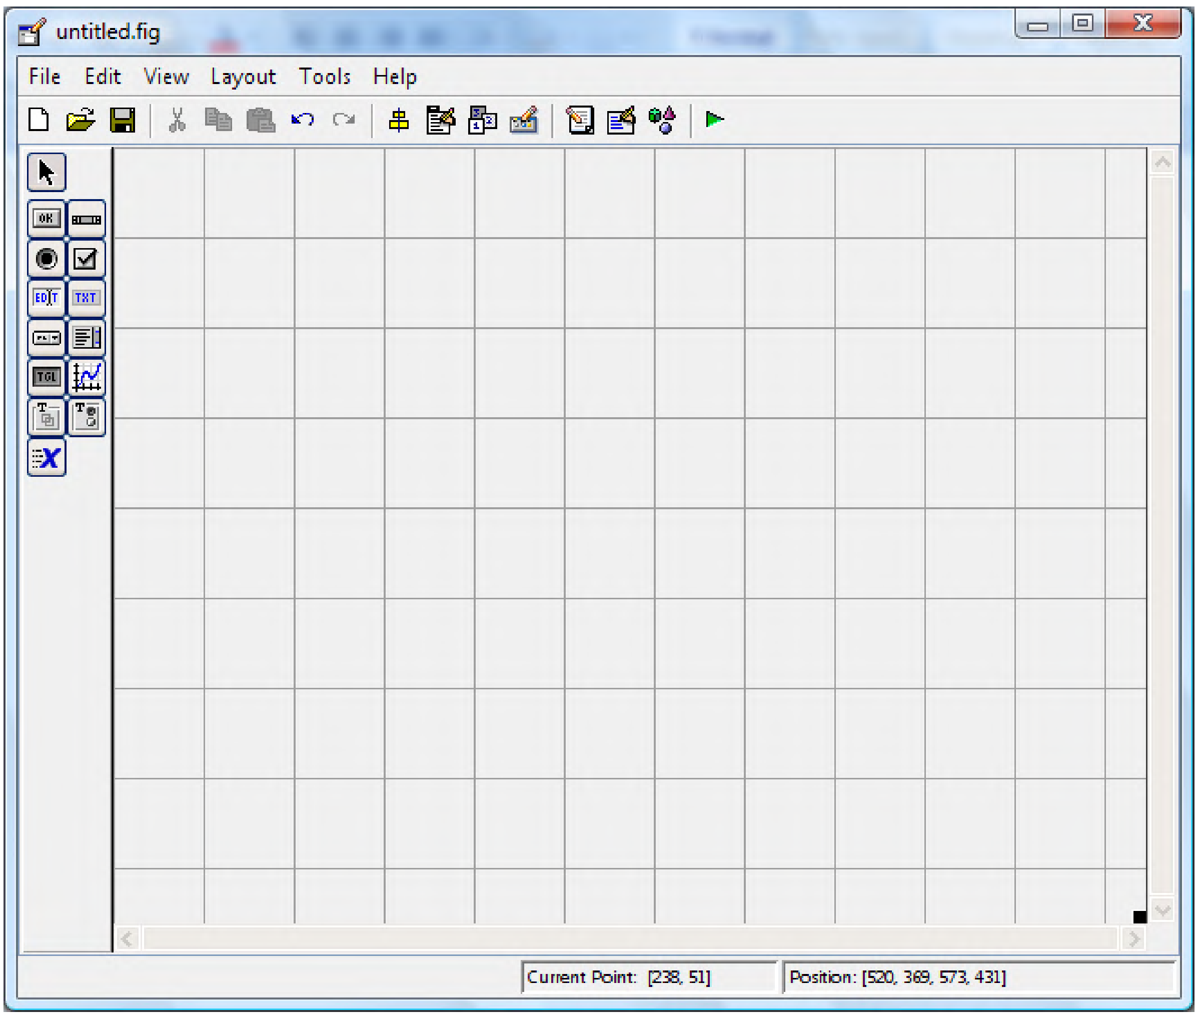

Fig 4.1 Graphical user interface

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

DEVELOPMENT ENVIRONMENT

4.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with

MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example, emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Content’s tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorite's tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace as from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a. mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

MANIPULATING MATRICES

Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Durer’s matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Durer’s matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

   16    3    2   13
```

5	10	11	8
9	6	7	12
4	15	14	1

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3 -99 0.0001

9.6397238 1.60210e-20 6.02252e23

1i -3.14159j 3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power

'	Complex conjugate transpose
( )	Specify evaluation order

Table: 4.1 Operators

Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2- \varepsilon)2^{1023}$
Inf	Infinity

NaN	Not-a-number

Table 4.2 Constants

GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

GUI Development Environment

The process of implementing a GUI involves two basic tasks.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uncontrol's and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

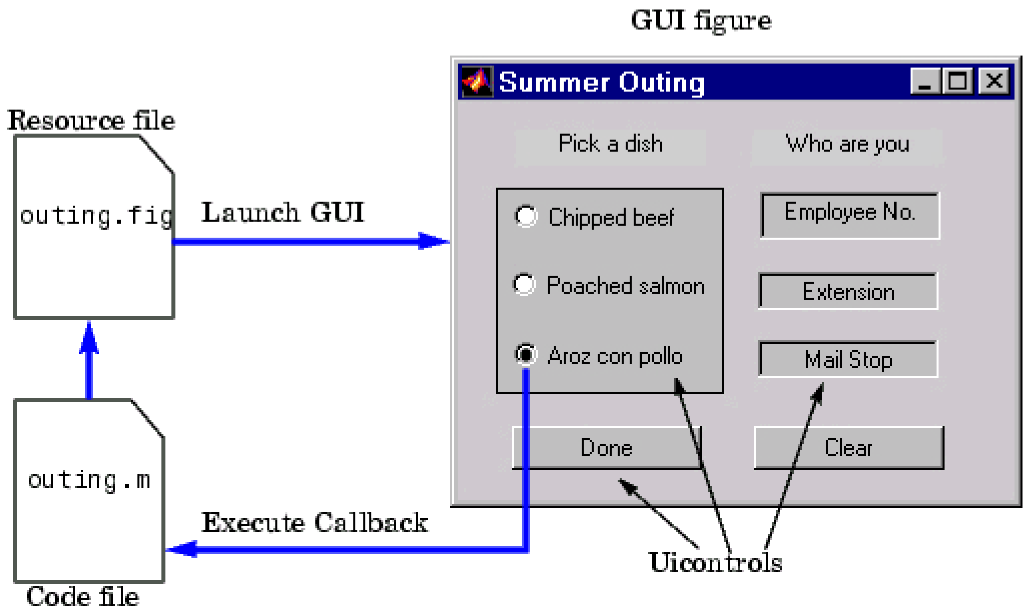

FIG 4.2 Graphical user blocks

Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uncontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uncontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % Toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 true color image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand (16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

 .

 .

 .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

   % then checkbox is checked-take approriate action

else

   % checkbox is not checked-take approriate action

end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uncontrol's can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non integer values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

List boxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's Button-down callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uncontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button-down property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes(handles. axes1)

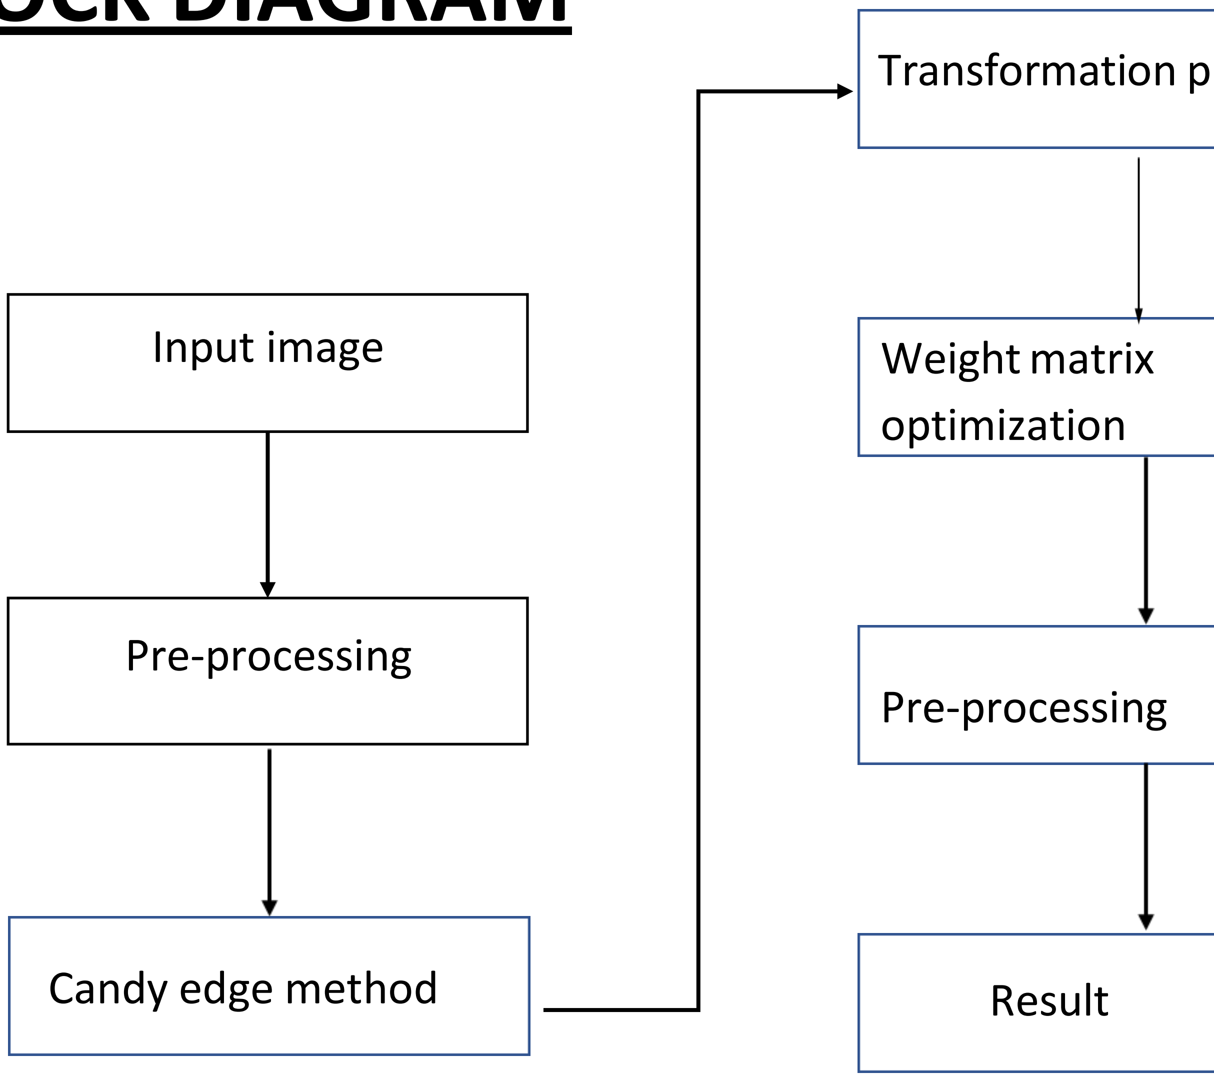
makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axis. See GUI with Multiple Axes for an example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 5:

BLOCK DIAGRAM



Recent deep learning approaches in single image super resolution (SISR) can generate high-definition textures for super-resolved (SR) images. However, they tend to hallucinate fake textures and even produce artifacts. An alternative to SISR, reference-based SR (Ref SR) approaches use high resolution (HR) reference (Ref) images to provide HR details that are missing in the low-resolution (LR) input image. We propose a novel framework that leverages existing SISR approaches and enhances them with Ref SR. Specifically, we refine the output of SISR methods using neural texture transfer, where HR features are queried from the Ref images. The query is conducted by computing the similarity of textural and semantic features between the input image and the Ref images. The most similar HR features, patch-wise, to the LR image is used to augment the SR image through an augmentation network. In the case of dissimilar Ref images from the LR input image, we prevent performance degradation by including the similarity scores in the input features of the network. Furthermore, we use random texture patches during the training to condition our augmentation network to not always trust the queried texture features. Different from past Ref SR approaches, our method can use arbitrary Ref images and its lower-bound performance is based on the SR image. We showcase that our method drastically improves the performance of the base SISR approach

CHAPTER 8

CONCLUSIONS AND FUTURE ENCHANCEMENT

Conclusion

In this paper, we proposed the RefSR method AugTT, which augments the output of existing SISR methods using Ref images. The Ref images provide the missing texture details that cannot be retrieved from the LR image due to extreme down sampling scale (e.g. 4 ×). We query the Ref images for the best matching texture using textural and semantic features extracted using a pre-trained VGG [17] network. The best matching texture features is used to enhance the image output of the SISR baselines. To prevent degradation due to Ref-LR content dissimilarity, we use the similarity scores in the input features of our augmentation network. Furthermore, during training, we don't always use the best matching features so that we condition our network to not always trust the provided features. Our method sets the SR input image for its lower-bound performance. We showcase that AugTT could drastically enhance the SR image and our method is robust even when the Ref images does not provide relevant textures.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our college management** for their kind support and permission to use the facilities available in the institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, our **beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna, Head & professor,** the **Dept. of Electronics and Communication Engineering** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Dept. Project Coordinator** Dr. **A. Anand, Assistant Professor, Dept.of ECE** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project guide, **Mr.K.Karthik, Assistant Professor,** Department of ECE and our class project coordinator **Mr. K. Karthik, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level project coordinators **Dr.Malayadri, Professor in IT & Dr.R.Santhosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

ABSTRACT

Least Significant Bit (LSB) is a very popular method in the spatial domain of steganographic images. This method is widely used and continues to be developed to date, because of its advantages in steganographic image quality. However, the traditional LSB method is very simple and predictable. It needs a way to improve the security of hidden messages in this way. This research proposes a simple and safe way to hide messages in LSB techniques. Three times the XOR operation is done to encrypt the message before it is embedded on the LSB. To facilitate the process of encryption and decryption of messages, three MSB bits are used as keys in XOR operations. The results of this study prove that this method provides security to messages with very simple operation. The imperceptibility quality of the stego image is also excellentwith a PSNR value above 50 dB.

CHAPTER-1

INTRODUCTION

Introduction to the project

Data hiding is of importance in many applications. For hobbyists, secretive data transmission, for privacy of users etc. the basic methods are: Steganography and Cryptography. Steganography is a simple security method. Generally there are three different methods used for hiding information: steganography, cryptography, watermarking. In cryptography, the information to be hidden is encoded using certain techniques; this information is generally understood to be coded as the data appears nonsensical. Steganography is hiding information; this generally cannot be identified because the coded information doesn't appear to be abnormal i.e. its presence is undetectable by sight. Detection of steganography is called Steganalysis.

IMAGE STEGANOGRAPHY

Image compression is a technique which is widely used in Steganography. It is of two types- lossy compression and lossless compression. Lossy compression may not preserve the integrity of original image where as Lossless compression preserves the original image data correctly. Hence lossless compression is chosen. Examples of Lossless compression formats are GIF [84], BMP and PNG formats. JPEG format is the example for Lossy compression format.

Types of Steganography

1. Text steganography
2. Image steganography
3. Audio steganography
4. Video steganography

In all of these methods, the basic principle of steganography is that a secret message is to be

embedded in another cover object which may not be of any significance in such a way that the encrypted data would finally display only the cover data. So it cannot be detected easily to be containing hidden information unless proper decryption is used.

Cryptography, where the goal is to secure communications from an eaves- dropper, steganographic techniques strive to hide the very presence of the message itself from an observer. The general idea of hiding some information in digital content has a wider class of applications that go beyond steganography, The techniques involved in such applications are collectively referred to as information hiding. For example, an image printed on a document could be annotated by metadata that could lead a user to its high resolution version.

In general, metadata provides additional information about an image. Although metadata can also be stored in the file header of a digital image, this approach has many limitations. Usually, when a file is transformed to another format (e.g., from TIFF to JPEG or to BMP), the metadata is lost. Similarly, cropping or any other form of image manipulation destroys the metadata. Finally, metadata can only be attached to an image as long as the image exists in the digital form and is lost once the image is printed. Information hiding allows the metadata to travel with the image regardless of the file format and image state (digital or analog).

A special case of information hiding is digital watermarking. Digital watermarking is the process of embedding information into digital multimedia content such that the information (the watermark) can later be extracted or detected for a variety of purposes including copy prevention and control. Digital watermarking has become an active and important area of research, and development and commercialization of watermarking techniques is being deemed essential to help address some of the challenges faced by the rapid proliferation of digital content.

The key difference between information hiding and watermarking is the absence of an active adversary. In watermarking applications like copyright protection and authentication, there is an active adversary that would attempt to remove, invalidate or forge watermarks. In information hiding there is no such active adversary as there is no value associated with the act of removing the information hidden in the content. Nevertheless, information hiding techniques need to be robust against accidental distortions. Unlike information hiding and digital watermarking, the main goal of steganography is to communicate securely in a completely undetectable manner. Although steganography is an ancient art, first used against the persian by the romans, it has evolved much through the years.

Image Steganography has many applications, especially in today's modern, hightech world. Privacy and anonymity is a concern for most people on the internet. Image Steganography allows for two parties to communicate secretly and covertly. It allows for some morally-conscious people to safely whistle blow on internal actions; it allows for copyright protection on digital files using the message as a digital watermark. One of the other main uses for Image Steganography is for the transportation of high-level or top-secret documents between international governments. While Image Steganography has many legitimate uses, it can also be quite nefarious. It can be used by hackers to send viruses and trojans to compromise machines, and also by terrorists and other organizations that rely on covert operations to communicate secretly and safely.

Types of Steganography messages in text

Secret messages can be hidden in text format by reframing the text of the carrier file, while maintaining the context. On e form of steganography is a program called Spam Mimic. Based on a set of rules called a mimic engine by Peter Wayner, it encodes your message into what looks like your typical, quickly deleted Spam message. However, hiding a message in plain text is a thing of past, as people are suspicious of irrelevant text. MESSAGES IN STILL IMAGES most popular tool is outguess. MESSAGES IN AUDIO data is hidden in layer III of encoding process of MP3 file. Messages in audio are always sent along with ambient noise. The data is hidden in the heart of the layer III encoding process of MP3 file, namely the inner loop during compression.

The inner loop limits the input data and increases the step size until the data can be coded with the available number of bits. The data is compressed, encrypted and then hidden in MP3 bit stream. MESSAGES IN VIDEO embedding information into multimedia data has gained increasing attention lately. The method of encryption is the same as in audio steganography. Video files are generally very good carrier files since they have a lot of irrelevant bits. AN EXAMPLE Fishing freshwater bends and saltwater coasts rewards anyone feeling stressed. Resourceful anglers usually find masterful leapers fun and admit swordfish rank overwhelming any day. “Send lawyers guns and money” Steganography is closely related to the problem of "hidden channels" in secure operating system design, a term which refers to all communication paths that can not easily be restricted by access control mechanisms (e.g. two processes that communicate by modulating and measuring the CPU load).

Steganography is also closely related to spread spectrum radio transmission, a technique that allows to receive radio signals that are over 100 times weaker than the atmospheric background noise, as well as TEMPEST, techniques which analyze RF transmissions of computer and communication equipment in order to get access to secret information handled by these systems. Most communication channels like telephone lines and radio broadcasts transmit signals which are always accompanied by some kind of noise. This noise can be replaced by a secret signal that has been transformed into a form that is indistinguishable from noise without knowledge of a secret key and this way, the secret signal can be transmitted.

Implementation:

There are currently three effective methods in applying Image Steganography: LSB Substitution, Blocking, and Palette Modification. LSB (Least Significant Bit) Substitution is the process of modifying the least significant bit of the pixels of the carrier image. Blocking works by breaking up an image into “blocks” and using Discrete Cosine Transforms (DCT). Each block is broken into 64 DCT coefficients that approximate luminance and color—the values of which are modified for hiding messages. Palette Modification replaces the unused colors within an image’s color palette with colors that represent the hidden message. With LSB Substitution I could easily change from Image Steganography to Audio Steganography and hide a zip archive instead of a text message. LSB Substitution lends itself to become a very powerful Steganographic method with few limitations. LSB Substitution works by iterating through the pixels of an image and extracting the ARGB values. It then separates the color channels and gets the least significant bit. Meanwhile, it also iterates through the characters of the message setting .

Steganography can be viewed as akin to cryptography. Both have been used throughout recorded history as means to protect information. At times these two technologies seem to converge while the objectives of the two differ. Cryptographic techniques "scramble" messages so if intercepted, the messages cannot be understood. Steganography, an essence, "camouflages" a message to hide its existence and make it seem "invisible" thus concealing the fact that a message is being sent altogether. An encrypted message may draw suspicion while an invisible message will not. In an ideal world we would all be able to openly send encrypted email or files to each other with no fear of reprisals. However there are often cases when this is not possible, either because you are working for a company that does not allow encrypted email or perhaps the local government does not approve of encrypted communication (a reality in some parts of the world). This is where steganography can come into play.

A good steganography system should fulfill the same requirements posed by the "Kirchhoff principle" in cryptography. This means that the security of the system has to be based on the assumption that the "enemy" has full knowledge of the design and implementation details of the steganographic system. The only missing information for the "enemy" is a short easily exchangeable random number sequence, the secret key, and without the secret key, the "enemy" should not have the slightest chance of even becoming suspicious that on an observed communication channel hidden communication might take place. Steganography cannot be detected. Therefore, it is used when encryption is not permitted. Or, more commonly, steganography is used to supplement encryption. An encrypted file may still hide information using steganography, so even if the encrypted file is deciphered, the hidden message is not seen.

Evolution of Steganography Code Breakers :

David Kahn's The Code breakers and Bruce Norman’s Secret Warfare: The Battle of Codes and Ciphers recounts numerous tales of steganography. INVISIBLE INK : An innocent letter may contain a very different message written between the lines with invisible ink. Common sources for invisible inks are milk, vinegar, fruit juices and urine. All of these darken when heated. Later on, more sophisticated inks were developed which react to various chemicals. MICRODOTS: The Germans developed microdot technology.

Microdots are photographs the size of a printed period having the clarity of standard-sized typewritten pages. The first microdots were discovered masquerading as a period on a typed envelope carried by a German agent in 1941. Besides being so small, microdots permitted the transmission of large amounts of data including drawings and photographs.

DISSECTING STEGANOGRAPHY

Steganography is a term used for hiding messages within an image. Any colour pixel is made of a combination of red –green-blue mode (RGB) wherein each RGB component consist of 8 bits. If letters in ASCII are to be represented within the colour pixels, the rightmost digit, called the least significant bit (LSB), can be altered. Any variation in the value of this bit leads to very minimal variation in colour. If we have to hide the word ‘digit’ in the image, we take the LSB of every colour and hide each bit of the word in its RGB combination. To insert the letter ‘D’ we modify three colour pixels with three bits in each colour pixel.

Steps for hiding an image using Steganography

1. Start s-tool and window explorer using the later as drag and drop interface for the software. 2. Drag and drop the image to be used as the carrier file from the explorer onto the actions window in s-tool.

3. Drag and drop the data file on the carrier file.

4. Give pass phrase and encryption algorithm when prompted. Pass these to receiver too.

5. The hidden file is ready. Receiver has to click on the “reveal” button to extract the data.

Steganography simply takes one piece of information and hides it within another. Computer files (images, sounds recordings, even disks) contain unused or insignificant areas of data. Steganography takes advantage of these areas, replacing them with information (encrypted mail, for instance). The files can then be exchanged without anyone knowing what really lies inside of them. An image of the space shuttle landing might contain a private letter to a friend. A recording of a short sentence might contain your company's plans for a secret new product. Steganography can also be used to place a hidden "trademark" in images, music, and software, a technique referred to as watermarking

There are two different methods for image steganography:

1. Spatial methods
2. Transform methods

In spatial method, the most common method used is LSB substitution method. Least significant bit (LSB) method is a common, simple approach to embedding information
in a cover file. In steganography, LSB substitution method is used. i.e. since every image has three components (RGB). This pixel information is stored in encoded format in one byte. The first bits containing this information for every pixel can be modified to store the hidden text. For this, the preliminary condition is that the text to be stored has to be smaller or of equal size to the image used to hide the text.

LSB based method is a spatial domain method. But this is vulnerable to cropping and noise. In this method, the MSB (most significant bits) of the message image to be hidden are stored in the LSB (least significant bits) of the image used as the cover image. It is known that the pixels in an image are stored in the form of bits.

In a grayscale image, the intensity of each pixel is stored in 8 bits (1byte). Similarly for a colour (RGB-red, green, blue) image, each pixel requires 24 bits (8bits for each layer). The Human visual system (HVS) cannot detect changes in the colour or intensity of a pixel when the LSB bit is modified. This is psycho-visual redundancy since this can be used as an advantage to store information in these bits and yet notice no major difference in the image.

Steps used in LSB steganography:

a. Steps for hiding message image:

1. Read the image to be used as cover image. Noise is added to make it easier to disguise
changes due to embedding the message image.
2. Read the image to be sued as message image.
3. Separate the bit planes of each image.

As it is known that the LSB (least significant bit) plane contains the least information associated with any image, and the MSB (most significant bit) plane contains most of the shape, colour information of an image. It is generally ideal to replace up to 4 least bitplanes of the cover image, with the upper 4 bit-planes without revealing changes in the resultant image. Lesser number of bit-planes from the message image could be used, but the retrieved image would become distorted and loses information.

4. Replace the least 4 bit-planes of cover image with the 4 most significant bit- planes from
message image.

5. Get the resultant Steganographic image by recombining these bit-planes.

b. Retrieving message image:

1. Read the Steganographic image.
2. Extract the required number of bit-planes of the image.
3. Recombining the lower four bit-planes would give the retrieved message image.

Steganographic Security:

In steganography, unlike other forms of communications, one's awareness of the underlying communication between the sender and receiver defeats the whole purpose. Therefore, the first requirement of a steganographic system is its undetectability. In other words, a steganographic system is considered to be insecure, if the warden Wendy is able to differentiate between cover objects and stego-objects. There have been various approaches in defining and evaluating the security of a steganographic system. Zollner et al. were among the first to address the undetectability aspect of stegano graphical systems.

They provide an analysis to show that information theoretically secure steganography is possible if embedding operation has a random nature and the embedded message is independent from both the cover-object and stego-object. These conditions, however, ensure undetectability against an attacker who knows the stego- object but has no information available about the indeterministic embedding operation. That is, Wendy has no access to the statistics, distribution, or conditional distribution of the cover-object. On the other hand, approached steganographic security from a complexity theoretic point of view. Based on cryptographic principles, they propose the design of encryption-decryption functions for steganographic embedding and detection.

In this setting, the underlying distribution of the cover-objects is known by the attacker, and undetectability is defined in a conditional sense as the inability of a polynomial-time attacker (Wendy) to distinguish the stego-object from a cover-object. This model assumes that stego-object is a distorted version of the cover-object, however, it does not attempt to probabilistically characterize the stego object. Cachin defined the first steganographic security measure that quantifies the information theoretic security of a stegosystem. His model assigns probability distributions to cover-object and stego-object under which they are produced. Then, the task of Wendy is to decide whether the observed object is produced according to known cover-object distribution or not. In the best case scenario, Wendy also knows the distribution of stego-object and makes a decision by performing a binary hypothesis test. Consequently, the detectability of a stegosystem is based on relative entropy between the probability distributions of the cover-object and stego-object, denoted by Pc and Ps, respectively, i.e., D(Pc||Ps) = Z Pc log Pc Ps . (1)

From this equation, we note that D(Pc||Ps) increases with the ratio P c P s which in turn means that the reliability of steganalysis detector will also increase. Accordingly, a stego technique is said to be perfectly secure if D(Pc||Ps) = 0 (Pc and Ps are equal), and ²-secure if the relative entropy between Pc and Ps is at most ², D(Pc||Ps) ≤ ². Perfectly secure algorithms are shown to exist, although they are impractical.

However, it should be noted that this definition of security is based on the assumption that the cover-object and stego-object are independent, identically distributed (i.i.d.) vectors of random variables. Since Wendy uses hypothesis testing in distinguishing between stegoobjects and cover-objects, she will make two types of errors, namely, typeI and type-II errors.

A type-I error, with probability α occurs, when a cover-object is mistaken for a stego-object (false alarm rate), and a typeII error, with probability β, occurs when a stego-object is mistaken for a cover-object (miss rate). Thus bounds on these error probabilities can be computed using relative entropy, thereby relating steganographic security to detection error probabilities. Cachin obtains these bounds utilizing the facts that deterministic processing can not increase the relative entropy between two distributions, say, Pc and Ps, and hypothesis testing is a form of processing by a binary function that yields α (P(detect message present | message absent)) and β (P(detect message absent | message present)). Then, the relative entropy between distributions Pc and Ps and binary relative entropy of two distributions with parameters $(\alpha, 1 - \alpha)$ and $(\beta, 1 - \beta)$ need to satisfy $d(\alpha, \beta) \leq D(Pc||Ps)$, (2) where $d(\alpha, \beta)$ is expressed as $d(\alpha, \beta) = \alpha \log \alpha\ 1 - \beta + (1 - \alpha) \log 1 - \alpha\ \beta$. (3) Then, for an ²- secure stegosystem we have $d(\alpha, \beta) \leq$ ². (4) Consequently, when the false alarm rate is set to zero ($\alpha = 0$), the miss rate is lower bounded as $\beta \geq 2$ −² . It should be noted that the probability of detection error for . If we approximate the probability distribution functions using histograms, then, examples such a Wendy is defined as Pe = αP(message absent) + βP(message present). (5) Based on above equations, for a perfectly secure stegosystem, $\alpha + \beta = 1$, and when a cover-object is equally likely to undergo embedding operation, then Pe = 1 2 . Hence, Wendy's decisions are unreliable. As one can observe, there are several shortcomings in the above definition of security.

This is because, real life cover-objects have a rich statistical structure in terms of correlation, higher-order dependence, etc. By exploiting these structures, it is possible to design good steganalysis detectors even if the first order probability distribution is preserved (i.e., ² = 0) during the embedding process. If we approximate the probability distribution functions using histograms, then, examples such as show that it is possible to design good steganalysis detectors even if the histograms of the cover image is and the stego image are the same.

Techniques for Image Steganography :

Given the proliferation of digital images, and given the high degree of redundancy present in a digital representation of an image (despite compression), there has been an increased interest in using digital images as cover-objects for the purpose of steganography. Therefore we have limited our discussion to the case of images for the rest of this tutorial. We should also note that there have been much more work on embedding techniques which make use of the transform domain or more specifically JPEG images due to their wide popularity. Thus to an attacker the fact that an image other that that of JPEG format is being transferred between two entities could hint of suspicious activity. There have been a number of image steganography algorithm proposed, these algorithm could be categorized in a number of ways:

• Spatial or Transform, depending on redundancies used from either domain for the embedding process.

• Model based or ad-hoc, if the algorithm models statistical properties before embedding and preserves them, or otherwise.

• Active or Passive Warden, based on whether the design of embedder- detector pair takes into account the presence of an active attacker.

Another category for embedding techniques for which a number of algorithms have been proposed is the transform domain embedding category. Most of the work in this category has been concentrated on making use of redundancies in the DCT (discrete cosine transform) domain, which is used in JPEG compression. But there has been other algorithms which make use of other transform domains such as the frequency domain [30]. Embedding in DCT domain is simply done by altering the DCT coefficients, for example by changing the least significant bit of each coefficient. One of the constraints of embedding in DCT domain is that many of the 64 coefficients are equal to zero, and changing two many zeros to non-zeros values will have an effect on the compression rate. That is why the number of bit one could embed in DCT domain, is less that the number of bits one could embed by the LSB method. Also the embedding capacity becomes dependent on the image type used in the case of DCT embedding, since depending on the texture of image the number of non-zero DCT coefficients will vary. Although changing the DCT coefficients will cause unnoticeable visual artifices, they do cause detectable statistical changes.

As mentioned before, another transform domain which has been used for embedding is the frequency domain. Alturki et al. propose quantizing the coefficients in the frequency domain in order to embed messages. They first decorrelate the image by scrambling the pixels randomly, which in effect whitens the frequency domain of the image and increases the number of transform coefficients in the frequency domain thus increasing the embedding capacity. The frequency coefficients are then quantized to even or odd multiples of the quantization step size to embed zeros or ones. Then the inverse FFT of the signal is taken and descrambled. The resulting image would be visually incomparable to the original image. But statistically the image changes and as the authors show in their work, the result of the embedding operation is the addition of a gaussian noise to the image.

Nowadays and because of unsecure networks and internet that can be accessed by anyone it became very risky to send important messages and files without any security measures. Before sending an important message we have to make sure that it will arrive to the destination in a secure way without being seen or modified by an intruder. Because of the threats mentioned before, steganography was discovered. Steganography in brief is the art of hiding information by other information. Usually we need to hide a text beneath any type of media. The most type of media used in hiding text is image. Steganography can be considered a new technology that still needs work and improvements. We are interesting in image steganography base type because it is very good idea according to a security method to send an image that doesn‟t draw any attention or suspicions about containing an important message.

Another important reason for our choice was the use of this type of security by terrorists to hide their plans so everyone should read and be aware of such subjects. Steganography is one of the newest technologies in sending secure data between sender and receiver. After the large spread of cryptography a new concept was added in order to add a new security level that prevents the detection of hidden information under a cover of any digital media. Nowadays, the internet became a robust and enormous world that offers a diversity of facilities and needs, because of these different functionalities it became easier to find diversity of ways to send messages to people without anyone noticing or even knowing that the message exist. Steganography is the procedure in which one type of communication (text, sound or image beneath another type.

Steganography is described by Neil F. Johnson and Sushil Jajodia in their paper „Steganalysis: The Investigation of Hidden Information" as „The goal of Steganography is to avoid drawing suspicion to the transmission of a hidden message. If suspicion is raised, then this goal is defeated." This technology is used widely nowadays, and a lot of people started hiding data, images video and audio by using it. For this reason even if a message seems normal and innocent it might be holding within it a secret message with high important data. The source of the word Steganography comes from the Greek word steganos which means covered or secret and the word graphy which means writing or drawing. So the whole meaning is secret writing .

To clarify the idea of steganography, the three famous characters named Alice, Bob and Ward are used. Alice (A) wants to send a secret message (M) to Bob (B). Bob must receive it safely without raising suspicion. To do that, Alice changes the message (M) into a steganography object (stego-object, i.e. new file carrying the embedded-object) (S). Stego-object is created by covering the message (M) with another random harmless message to produce a cover (C, i.e. data file that will hold the secret message). Covering the massage (M) with message (C) happens by using a secret key (stego-key) (K). Now Alice should be able to send the stego-object (S) to Bob without being detected by Ward. When Bob receives (S) he will use the stego- key (K) which he already knows to reproduce secret message (M) from the cover message (C) and be able to read it. Steganography have to guarantee these requirements :

Robustness: information is robust when it is embedded inside an image and although it disappeared behind it but it is not destroyed, it is present, but is only detected with reliability after modifying the image.

Undetectability: the data hidden under an image cannot be detected as long as the cover image is not doubtable or suspicious and looks unchanged.

Perceptual transparency: this requirement depends on human visual andaudio system. If the hidden data didn't raise the attention of human systems and no one could distinguish whether the cover contains secret data then this requirement is guaranteed.

Security: as long as no one other than the legal receiver can remove theembedded data from behind cover, the embedding algorithm is said to be secure. This requirement assures that no targeted attacks can detect or view the hidden message unless they have a full knowledge of the embedding algorithm.

There may be different approaches for steganography methods classification. They may be grouped according to the type of cover file or according to the different modifications each method may apply during embedding process. Our proposed technique belongs to the second classification type. We can find more than six different methods concerning the second classification, noting that in some cases it is very difficult to classify a specific method one clear category. Here are the six most used methods: Substitution, Injection (or insertion), Distortion, Generation, Transform domain techniques, Statistical steganography.

Internet technology provides many benefits for humans, especially in getting or exchanging information, learning, working, and others. One of the problems on the internet is security and data privacy. Many methods have been applied in providing security such as cryptography, steganography, watermarking, and digital signatures . Steganography and watermarking are branches of the science of hiding data on other media called cover . The difference is in its function, where steganography is used to hide messages while watermarking is used to preserve copyright. Data hiding in the image is divided into two domains, namely spatial domain and frequency domain. In the frequency domain, the message is hidden by first transforming the cover image. Transformations that have been widely used are, DCT, DWT, and SVD .

This chapter applies LSB Steganography technique for various lossless file formats such as BMP, GIF and PNG. The science which deals with the hidden communication is called Steganography. There are different kinds of steganographic techniques which are complex and which have strong and weak points in hiding the invisible information in various file formats. The innocent carriers are the possible cover carriers which will hold the hidden communication.

A Steganography method is admirably secure only when the statistics of the cover information and the stego information are similar with each other.

In other words it conveys the meaning that the relative entropy between the cover information and the stego information is zero. The LSB embedding technique suggests that data can be hidden in such a way that even the naked eye is unable to identify the hidden information in the LSBs of the cover file.

An encryption and decryption technique on the data to be hidden into the image file is performed to provide additional security to the data. 47 Steganography is an alternative method for privacy and security. Instead of encrypting, we can hide the messages in other innocuous looking medium (carrier) so that their existence is not revealed. Among the several advantages for employing the Steganography, secretly transmitting the secret information from source to destination is one. In this chapter, different approaches towards implementation of image Steganography have been thoroughly and clearly discussed. Among several techniques, Masking and Filtering, Algorithms and Transformations and LSB insertion are some of the methods to achieve Steganography. Among these techniques, LSB insertion is a very simple and commonly applied technique for embedding data in a cover file.

CHARCTERIZING DATA HIDING TECHNIQUES

An image is a picture that has been created or copied and stored in electronic form. An image can be described in terms of vector graphics or raster graphics. An image stored in raster form is sometimes called a bitmap. An image map is a file containing information that associates different locations on a specified image with hypertext links. An image is a collection of numbers that constitute different light intensities in different areas of the image.

This numeric representation forms a grid and the individual points are referred to as pixels (picture element).Greyscale images use 8 bits for each pixel and are able to display 256 different colours or shades of grey. Digital colour images are typically stored in 24-bit files and use the RGB colour model, also known as true colour. All colour variations for the pixels of a 24-bit image are derived from three primary colours: red, green and blue, and each primary colour is represented by 8 bits. Thus in one given pixel, there can be 256 different quantities of red, green and blue.

Steganography is a kind of technique which can embed a message inside a cover object. There are a number of features that characterizes the merits and demerits of the embedding techniques. The way they are applied decides the importance of each and every feature. A set of criteria are proposed to define the invisibility of an algorithm. The criterias are as follows: Invisibility The imperceptibility of a Steganography technique is the most important necessity, since the quality of Steganography lies in its capacity to be unseen by the naked eyes.

Payload Capacity Steganography techniques used aim at hiding the embedded secret data and also maximize the amount of information embedded. The amount of information that is hidden is called payload capacity. Hiding Capacity Concealing capacity is nothing but the size of data that could be concealed with respect to the size of the cover object. A vast concealing capacity permits the use of smaller cover images and thus decreases the data transmission needed to broadcast the stego image. Perceptual Transparency The inability of an eavesdropper to detect hidden data is referred by Perceptual transparency.

BINARY REPRESENTATION OF AN RGB COLOR IMAGE

For a 24-bit RGB image, every RGB component requires 8 bits of memory. The range of every RGB component value is in between 0 to 255 where 255 represent brightest shade of the color and 0 represents darkest shade of the color. All different colors could be produced with the combination of these ranges. Subsequently, the test image is represented by integer matrix. Every pixel is a mix of RGB values.

CHAPTER 2
LITERATURE SURVEY

Discrete Cosine Transform (DCT) method:

When information is embedded in spatial domain, losses can occur such as when the image is cropped etc. To overcome this problem the information is embedded in frequency domain in such a way that we embed the secret information in the significant frequency values and omit the higher frequency part. First the required transformations are applied and then accordingly to hide the secret message, the transform coefficients are changed. Like in other transforms, de-correlation of the image data is required after applying discrete cosine transform (DCT). And encoding can be then done independently for each coefficient. Hence, compression efficiency is not lost.

In blocking method, blocks of the image are considered and DCT (discrete cosine transform) is done in order to break them. Each block is then subdivided into

64 parts (DCT coefficients). These coefficients are modified i.e. the colour gets modified a little by storing some text or another image in it. Embedding the secret data in the carrier image is generally done for the DCT coefficients that are lower than the chosen threshold value. But embedding information in DCT coefficient value 0 is avoided as this may lead to visual distortion of the cover image.

Palette modification:

In palette modification, the unused colours in an image’s colour palette are replaced with colours to represent hidden message. Palette Modification replaces the unused colours within an image’s colour palette with colours that represent the hidden message. For example, we have an image containing 6shades of blue and 5 shades of brown. By modifying the bits, it is possible to generate a completely new palette of colours that were
originally absent in the previous image. This changed colour palette may not be detected easily by human eye (HVS) and hence can be used to store other data or information.

CHAPTER 3

PROPOSED SYSTEM

ALGORITHMS USED IN PROPOSED METHOD

In the proposed method, Steganography is combined with Cryptography. It changes the meaning of the information as well as it hides the presence of information from the hacker. The LZ algorithm for compression and RSA algorithm for encryption and decryption are used in this chapter.

LSB The easiest way to embed secret information within the cover file is called LSB insertion. In this technique, the binary representations of the secret data have been taken and the LSB of each byte is overwritten within the image. If 24-bit color images are used, then the quantity of modification will be small. As an example, supposing that we have three neighbouring pixels (nine bytes) with the following RGB encoding:

50 01101010

11110010 00110110

01101001 11110000

00110101 01100000

11101111 00110100

Now if we wish to embed the following 9 bits of compressed secret information: 010010011. If we insert these 9 bits over the LSB of the 9 bytes above, we get the following sequence of bits (where bits in red color have been modified):

01101010 11110011

00110110 01101000

11110001 00110100

01100000 11101111

00110101

Note that we have successfully hidden 9 bits but at a cost of only modifying 5, or roughly 50% of the LSB bits. 3.4.2 LZ Compression Algorithm:

Step-1: Read the original file.

Step-2: Count the total number of words, alphabets, special characters and digits.

Step-3: Find out the repeated words in the file.

Step-4: Prepare the word dictionary for the original file context.

Step-5: Create compressed file. In the compressed file place the word's number instead of actual words.

Step-6: Add dictionary to compressed file.

Step-7: Save the compressed file along with the dictionary.

RSA Algorithm

In Cryptography, RSA is an algorithm for public-key Cryptography. The RSA algorithm involves three steps: Key generation, encryption and decryption. Key Generation: The keys for the RSA algorithm are generated in the following way:

Step-1: Choose two different random prime numbers p and q.

Step-2: Compute n = p*q. n is used as the modulus for both the private and public Keys.

Step-3: Compute φ (n) = (p-1) (q-1). (φ is Euler's totient function).

Step-4: Choose an integer e such that 1 < e < φ (pq), and gcd (e, φ(n))=1 Step-5: Compute d =e-1 mod [φ (n)]

Step-6: Publish the public encryption key: (e; n)

Step-7: Keep secret private decryption key: (d; n) 53

Encryption: The steps required to encrypt information at sender are as follows: Step-1: Obtain public key of recipient (e; n)

Step-2: Represent the information as an integer m in [0, n-1] Step-3: Compute c = me mod n Decryption:

The steps required to decrypt information at receiver side are as follows: Step-1: use private key (d; n)

Step-2: compute m = cd mod n

IMPLEMENTATION LSB :

Insertion is the easiest way to embed secret data in an image. By replacing the LSB of each sampling bit with a binary information, LSB insertion permits for a huge amount of secret information to be embedded. During hiding and unhiding procedure, the content of the secret information should not be modified.

LSB Encoding Algorithm First the original image, and the compressed encrypted secret message are taken. Then the encrypted secret data has to be converted into binary format. Binary conversion is done by taking the American Standard Code of Information Interchange (ASCII) values of the character and converting them into binary format and generating stream of bits. Similarly, in cover image, bytes representing the pixels are taken in single array and byte stream is generated. Message bits are taken sequentially and then are placed in LSB bit of image byte.

Same procedure is followed till all the message bits are placed in image bytes. Image generated is called 'Stego-Image'. It is ready for transmission through the Internet. Algorithm for hiding secret data in Cover image:

Step-1: Read the cover image and secret text information which is to be embedded in to the cover image.

Step-2: Compress the secret information.

Step-3: Convert the compressed secret information into cipher text by using secret key shared by receiver and sender.

Step-4: Convert compressed encrypted text message into binary form.

Step-5: Find LSBs of each RGB pixels of the cover image.

Step-6: Embed the bits of the secret information into bits of LSB of RGB pixels of the cover image.

Step-7: Continue the procedure until the secret information is fully hidden into cover file.

LSB Decoding Algorithm First, 'Stego-Image' is taken and single array of bytes are generated as it was done at the time of encoding. The total number of bits of encrypted secret information and the bytes representing the pixels of stego-image are taken. Counter is initially set to 1, which in turn gives the index number of the pixel byte where secret message bit is available in LSB.

The process is continued till final count of secret message bit is reached. After this, the bit stream of the message shall be generated. Available bits are grouped to form bytes such that each byte represents single ASCII character. Characters are stored in text file which represents the encrypted embedded message. After that the decryption and decompression are to be performed.

Algorithm for un hiding secret data from Stego image:

Step-1: Read the stego image.

Step-2: Find LSBs of each RGB pixel of the stego image.

Step-3: Find and retrieve the LSBs of each RGB pixel of the stego image.

Step-4: Continue the process until the message is fully extracted from stego image.

Step-5: Decompress the extracted secret data.

Step-6: Using shared key, decrypt secret information to get original information.

Step-7: Reconstruct the secret information.

Comparing cover image with stego image needs an image quality measure. Commonly used measures are MSE, PSNR, Correlation and Histogram.

MSE In statistics, MSE is quantifying the difference between values implied by an estimator and the true values of the quantity being estimated. MSE measures the average of the squares of the "errors.

PSNR scales the MSE according to the image range. The PSNR between cover image and stego image. A higher PSNR indicates that the quality of the stego image is similar to the cover image.

Correlation, a best-known method, not only evaluates the degree of closeness between two functions but also determines the extent to which the cover image and the stego image are close to each other even after embedding data.

The MSE, PSNR and Correlation values for various image file formats. Quality Metrics for various Image File Formats Cover Image Name Stego Image Name MSE PSNR (dB) Correlation Cover_Leena.bmp Stego_Leena.bmp 3.6791
46.19 0.9984 Cover_Barbara.bmp Stego_Barbara.bmp 4.0184 49.42 0.9986 Cover_Baboon.gif Stego_Baboon.gif 2.1883 44.72 0.9993 Cover_House.gif Stego_House.gif 3.8426 47.49.0. The results show that MSE, PSNR and correlation are in comparison with already existing results. The MSE obtained for different file formats varies from 2.6 to 4.0 and PSNR varies from 42.15 to 49.42 dB and 99.98% of correlation is obtained with the proposed technique.

According to Steganography, the secret message which is hidden may result in a distortion less image. At the same time this distortion will be perceptible to the naked eye. The quantity of information invisibly hidden in the image resulting in a distortion less image plays a pivotal role and this is decided by algorithm. The required characteristics are assessed while chosing a specific file format for Steganography.

In the process of Steganography, the message which is hidden is invisible. An attempt has been made to implement encryption and decryption techniques on the data to be hidden into the carrier files, so that this will provide additional security to the data. The sender and receiver only know how to hide and 61 unhide the data into the carrier files. No other intermediate person will even know that there is a second the carrier file. The sender and receiver only know the commands to hide and unhide. Since BMP utilizes lossless compression, LSB makes utilization of BMP image.

To have the capacity to conceal secret information within a BMP image, one requires a substantial cover medium. The advantage of LSB hiding is its simplicity. LSB embedding technique also allows high perceptual transparency. The data hiding capacity of LSB technique is high and more secure. Embedding secret information with Steganography technique decreases the probability of secret information being detected. LSB insertion method to image Steganography works effectively for 24 BMP, GIF and PNG image file formats. Using this embedding and extracting algorithms, one can extract the secret message exactly as original message without changing the cover image.

Hiding information into a medium requires following elements

1. The cover medium(C) that will hold the secrat message.
2. The secret message (M), may be plain text, digital image file or any type of data.
3. The stegonographic techniques
4. A stego-key (K) may be used to hide and unhide the message.

In modern approach, depending on the cover medium, steganography can be divided into five types:

1. Text Steganography
2. Image Steganography
3. Audio Steganography
4. Video Steganography
5. Protocol Steganography

• **Text steganography** Hiding information in text file is the most common method of steganography. The method was to hide a secret message into a text message. After coming of Internet and different type of digital file formats it has decreased in importance. Text stenography using digital files is not used very often because the text files have a very small amount of excess data.

• **Image steganography** Images are used as the popular cover medium for steganography. A message is embedded in a digital image using an embedding algorithm, using the secret key. The resulting stego-image is send to the receiver. On the other side, it is processed by the extraction algorithm Contents using the same key. During the transmission of stego- image unauthenticated persons can only notice the transmission of an image but cant see the existence of the hidden message.

• **Audio steganography** Audio steganography is concerned with embedding information in an innocuous cover speech in a secure and robust manner.

Communication andtransmission security and robustness are essential for transmitting vital information to intended sources while denying access to unauthorized persons. An audible, sound can be inaudible in the presence of another louder audible sound

.This property allows to select the channel in which to hide information . Existing audio steganography software can embed messages in WAV and MP3 sound files.

The list of methods that are commonly used for audio steganography are listed and discussed below.

• LSB coding
• Parity coding
• Phase coding
• Spread spectrum
• Echo hiding
• Video steganography

Video Steganography is a technique to hide any kind of files in any extension into a carrrying Video file.

• Protocol steganography The term protocol steganography is to embedding information within network protocols such as TCP/IP. We hide information in the header of a TCP/IP packet in some fields that can be either optional or are never used.

Applications of

Steganography

(i)Secret

Communications

The use steganography does not advertise secret communication and therefore avoids scrutiny of the sender, message, Contents and recipient. A trade secret, blueprint, or other sensitive information can be transmitted without alerting potential attackers.

(ii) Feature Tagging Elements can be embedded inside an image, such as the names of individuals in a photo or locations in a map. Copying the stego-image also copies all of the embedded features and only parties who possess the decoding stego- key will be able to extract and view the features.

(iii) Copyright Protection Copy protection mechanisms that prevent data, usually digital data, from being copied.

IMAGE STEGNOGRAPHY TECHNIQUES

There are several Steganographic techniques for image file format which are as follows:

Spatial Domain Technique:

There are many versions of spatial steganography, all directly change some bits in the image pixel values in hiding data.

Least significant bit (LSB) based steganography is one of the simplest techniques that hides a secret message in the LSBs of pixel values without perceptible distortions. To our human eye, changes in the value of the LSB are imperceptible. Least Significant Bit (LSB) replacement technique, Matrix embedding, are some of the spatial domain techniques. Advantages of spatial domain LSB technique are:

1. Degradation of the original image is not easy.
2. Hiding capacity is more i.e. more information can be stored in an image.

Disadvantages of LSB technique are:

i. Robustness is low

ii. Hidden data can be destroyed by simple attacks.

Masking and Filtering Masking and Filtering:

It is a steganography technique which can be used on gray-scale images. Masking and filtering is similar to placing watermarks on a printed image. These techniques embed the information in the more significant areas than just hiding it into the noise level. Watermarking techniques can be applied without the fear of image destruction due to lossy compression as they are more integrated into the image.

Advantages of Masking and filtering Techniques: This method is much more robust than LSB replacement with respect to compression. Disadvantages: Techniques can be applied only to gray scale images and restricted to 24 bits.

Transform Domain Technique:

The Frequency domain the message is inserted into transformed coefficients of image giving more information hiding capacity and more robustness against attacks. Transform domain embedding can be termed as a domain of embedding techniques for which a number of algorithms have been suggested . Most of the strong steganographic systems today operate within the transform domain Transform domain techniques have an advantage over LSB techniques as they hide information in areas of the image that are less exposed to compression, cropping, and image processing.

Some transform domain techniques do not seem dependent on the image format and they may outrun lossless and lossy format conversions. Transform domain techniques are of different types[3]:

1. Discrete Fourier transformation technique (DFT).
2. Discrete cosine transformation technique (DCT).
3. Discrete Wavelet transformation technique (DWT).

Distortion Techniques:

In this technique, store information by signal distortion and measure the deviation from the original cover in the decoding process. Distortion techniques need knowledge of the original cover image during the decoding process where the decoder functions to check for differences between the original cover image and the distorted cover image in order to restore the secret message. In this technique, a stego-image is created by applying a sequence of modifications to the cover image.

This sequence of modifications is use to match the secret message required to transmit. The message is encoded at pseudo-randomly chosen pixels. If the stego image is different from the cover image at the given message pixel, the message bit is a 1. Otherwise, the message bit is a 0. The encoder can modify the 1 value pixels in such a manner that the statistical properties of the image are not affected. If an attacker interfere with the stego-image by cropping, scaling or rotating, the receiver can easily detect it.

Characteristics feature of Data Hiding Techniques:

Perceptibility does embedding message distort cover medium to a visually unacceptable level.

Capacity how much information can be hidden with relative to the change in perceptibility.

Robustness to attacks can embedded data exist manipulation of the stego medium in an effort to destroy, or change the embedded data.

Tamper Resistance Beyond robustness to destruction, tamper-resistance refers to the difficulty for an attacker to alter a message once it has been embedded in a stego- image.

Image Steganalysis :

Steganalysis is the breaking of steganography and is the science of detecting hidden information . The main objective of steganalysis is to break steganography and the detection of stego image. Almost all steganalysis algorithms depend on steganographic algorithms introducing statistical differences between cover and stego image. Steganalysis are of three different types:

Visual attacks it discovered the hidden information, which helps to separate the image into bit planes for further more analysis.

Statistical attack:

Statistical attacks may be passive or active. Passive attacks involves with identifying presence or absence of a secret message or embedding algorithm used. Active attacks is used to investigate embedded message length or hidden message location or secret key used in embedding.

Structural attacks The format of the data files changes as the data to be hidden is embedded, identifying this characteristic structure changes can help us to find the presence of image/text file.

Steganalytic tools :

There are several steganalytic tools available in market like PhotoTitle, 2Mosaic and StirMark Benchmark etc. These three steganalytic tools can remove steganographic content from any image. This is achieved by destroying secret message by two techniques: break apart and resample.

Least-Significant Bit (LSB) Technique

The least significant bit (in other words, the 8th bit) of some or all of the bytes inside an image is changed to a bit of the secret message. Digital images are mainly of two types

(i) 24 bit images and

(ii) 8 bit images.

In 24 bit images we can embed three bits of information in each pixel, one in each LSB position of the three eight bit values. Increasing or decreasing the value by changing the LSB does not change the appearance of the image; much so the resultant stego image looks almost same as the cover image.

Cover and Hidden Images:

The hidden image is extracted from the stego-image by applying the reverse process. If the LSB of the pixel value of cover image C(i,j) is equal to the message bit m of secret massage to be embedded, C(i,j) remain unchanged; if not, set the LSB of C(i, j) to m. The message embedding procedure is given below

S(i,j) = C(i,j) - 1, if LSB(C(i,j)) = 1 and m = 0

S(i.j) = C(i,j), if LSB(C(i,j)) = m

S(i,j) = C(i,j) + 1, if LSB(C(i,j)) = 0 and m = 1 where LSB(C(i, j)) stands for the LSB of cover image C(i,j) and m is the next message bit to be embedded. S(i,j) is the stego image As we already know each pixel is made up of three bytes consisting of either a 1 or a 0. For example, suppose one can hide a message in three pixels of an image (24-bit colors). Suppose the original 3 pixels are:

(11101010 11101000 11001011)

(01100110 11001010 11101000)

(11001001 00100101 11101001)

A steganographic program could hide the letter ”J” which has a position 74 into ASCII character set and have a binary representation ”01001010”, by altering the channel bits of pixels.

(11101010 11101001 11001010)

(01100110 11001011 11101000)

(11001001 00100100 11101001)

In this case, only four bits needed to be changed to insert the character successfully. The resulting changes that are made to the least significant bits are too small to be recognised by the human eye, so the message is effectively hidden. The advantage of LSB embedding is its simplicity and many techniques use these methods

. LSB embedding also allows high perceptual transparency.

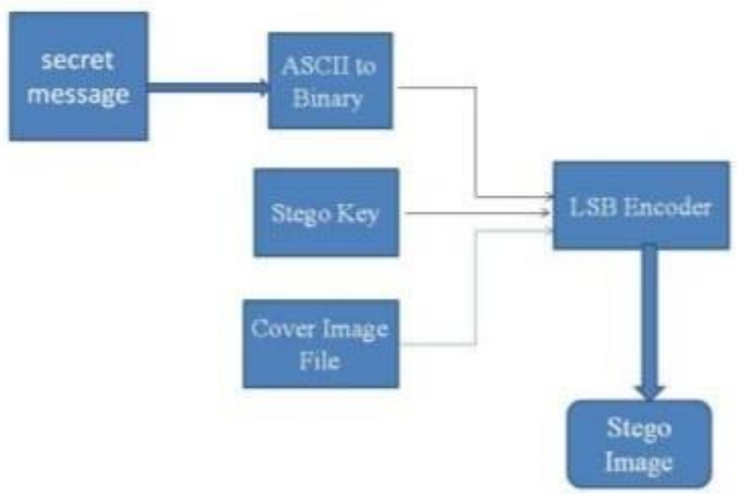

Fig3.2 LSB insertion technique

Data Embedding :

The embedding process is as follows.

Inputs Cover image, stego-key and the

text file Output stego image Procedure

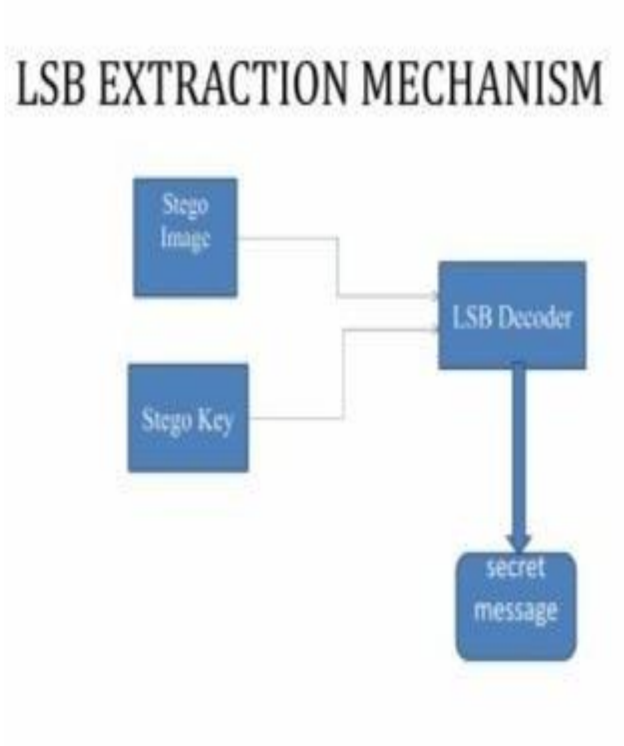

Fig3.3 LSB extraction

mechanism Step 1: Extract the pixels of the cover image.

Step 2: Extract the characters of the text file. Step 3: Extract the characters from the Stego key.

Step 4: Choose first pixel and pick characters of the Stego key and place it in first component of pixel.

Step 5: Place some terminating symbol to indicate end of the key. 0 has been used as a terminating symbol in this algorithm.

Step 6: Insert characters of text file in each first component of next pixels by replacing it.

Step 7: Repeat step 6 till all the characters has been embedded.

Step 8: Again place some terminating symbol to indicate end of data. Step 9: Obtained stego image.

Data Extraction

The extraction process is as follows. Inputs Stego-image file, stego-key Output Secret text message. Procedure:

Step 1: Extract the pixels of the stego image.

Step 2: Now, start from first pixel and extract stego key characters from first component of the pixels. Follow

Step3: up to terminating symbol, otherwise follow step 4.

Step 4: If this extracted key matches with the key entered by the receiver, then follow Step 5, otherwise terminate the program.

Step 5: If the key is correct, then go to next pixels and extract secret message characters from first component of next pixels. Follow Step 5 till up to terminating symbol, otherwise follow step 6.

Step 6: Extract secret message.

Image Encoding Algorithm

Inputs Image file, stego key and image file Output Stego image.

1. The cover and secret images are read and converted into the unit8 type.
2. The numbers in secret image matrix are conveyed to 8-bit binary. Then the matrix is reshaped to a new matrix a.
3. The matrix of the cover image is also reshaped to matrix b
4. Perform the LSB technique described above
5. The stego-image, which is very similar to the original cover image, is achieved by reshaping matrix b.
6. While extracting the data, the LSB of the stego image is collected and they are reconstructed into the decimal numbers. The decimal numbers are reshaped to the secret image.

Pseudo-Random Encoding Technique

In this technique, A random key is used to choose the pixels randomly and embed the message. This will make the message bits more difficult to find and hopefully reduce the realization of patterns. Data can be hidden in the LSB of a particular colour plane (Red plane) of the randomly selected pixel in the RGB colour space. This will make the message bits more difficult to find and hopefully reduce the realization of patterns.

Embedding Algorithm

In this process of encoding method, a random key is used to randomised the cover image and then hide the bits of a secret message into the least significant bit of the pixels within a cover image. The transmitting and receiving end share the stego key and random-key. The random-key is usually used to seed a pseudo-random number generator to select pixel locations in an image for embedding the secret message.

Inputs Cover image, stego-key and the message Output stego image

1) Read character from text file that is to be hidden and convert the ASCII value of the character into equivalent binary value into an 8 bit integer array.

2) Read the RGB colour image(cover image) into which the message is to be embedded.

3) Read the last bit of red pixel.

4) Initialize the random key and Randomly permute the pixels of cover image and reshape into a matrix.

5) Initialize the stego-key and XOR with text file to be hidden and give message. 6) Insert the bits of the secret message to the LSB of the Red plane's pixels. 7) Write the above pixel to Stego Image File.

Extraction of Hidden Message:

In this process of extraction, the process first takes the key and then random- key. These keys takes out the points of the LSB where the secret message is randomly distributed . Decoding process searches the hidden bits of a secret message into the least significant bit of the pixels within a cover image using the random key. In decoding algorithm the random-key must match i.e. the random-key which was used in encoding should match because the random key sets the hiding points of the message in case of encoding. Then receiver can extract the embedded messages exactly using only the stego-key.

Message extraction algorithm:

Inputs Stego-image file, stego-key, random key. Output Secret message.

1) Open the Stego image file in read mode and from the Image file, read the RGB colour of each pixel.

2) Extract the red component of the host image.

3) Read the last bit of each pixel.

4) Initialize the random-key that gives the position of the message bits in the red pixel that are embedded randomnly.

5) For decoding, select the pixels and Extract the LSB value of red pixels.

6) Read each of pixels then content of the array converts into decimal value that is actually ASCII value of hidden character.

7) ASCII values got from above is XOR with stego-key and gives message file, which we hide inside the cover image.

GRAY SCALE

The following chart displays all 256 Gray-scale colours. The gray-scale colour naming scheme uses a two digit hex value to define up to 256 shades of gray. In photography and computing, a gray scale digital image is an image in which the value of each pixel is a single sample, that is, it carries only intensity information. Images of this sort, also known as black-and-white, are composed exclusively of shades of gray, varying from black at the weakest intensity to white at the strongest.

Gray scale images are distinct from one-bit bi-tonal black-and-white images, which in the context of computer imaging are images with only the two colours, black (also called bi-level or binary images). Gray scale images have many shades of gray in between. Gray scale images are often the result of measuring the intensity of light at each pixel in a single band of the electromagnetic spectrum (e.g. infrared, visible light, ultraviolet, etc.), and in such cases they are monochromatic proper when only a given frequency is captured. Gray scale Shading Strengths (0=no colour; 15=full colour.

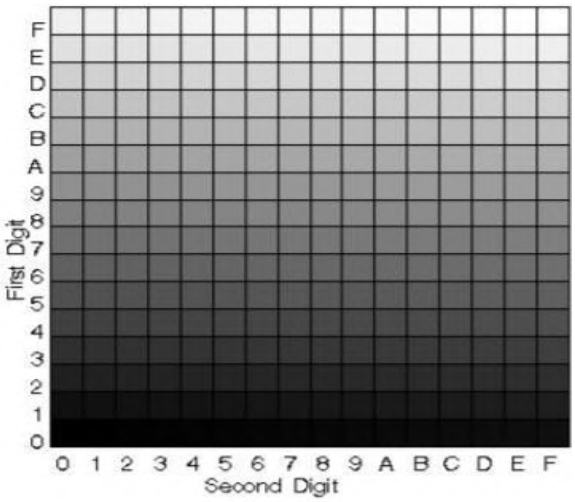

Figure 1: Gray Scale color

A message is embedded into the image by the stego system encoder via a secret key or password. This password or secret key should be kept secret. The resulting stego image is transmitted over a channel to the receiver. The stego system at the decoder end, using the same key or password, will decode the stego image.

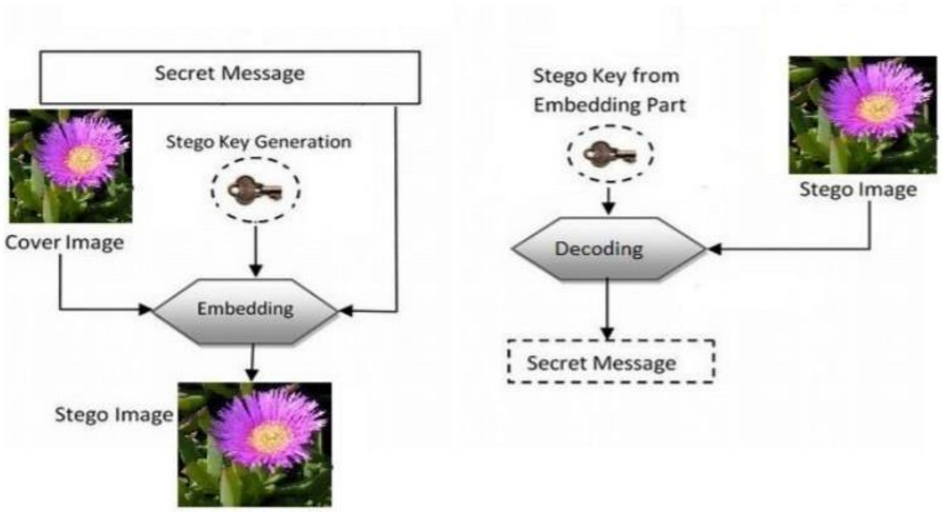

Fig 3.4 stegnography block diagram

There are two important components, cover image and hiding data, in data hiding technique. The cover image I is an 8-bit gray scale image. The size of cover image is m×n. The hiding data H embedded in I is g-bits bit stream. We use the equation below to express image C, data D and each pixel separately.I= { } H= One of the simplest systems for embedding digital data into a digital cover is the Least Significant Bit method.

Consider an N×M image in which each pixel value is represented by a decimal number in the range determined by the number of bits used. In a gray-scale image, with 8 bit precision per pixel, each pixel assumes a value between [0, 255] and each positive number P can be represented by: P= + = This property allows the decomposition of an image into a collection of binary images by separating the into n bit planes.

In the classical LSB embedding methods, the secret message is inserted into the least-significant bit plane of the cover image either by directly replacing those bits. The amount of data to be embedded may also be fixed or variable in size depending on the number of pixels selected. The main advantage of such a technique is that the modification of the LSB plane does not affect the human perception of the overall image quality as the amplitude variation of the pixel values is bounded by ±1. The masking properties of the Human Visual System allow significant amounts of embedded information to be unnoticed by imperceptible by the average observer under normal viewing conditions. “Masking” refers to the phenomenon where a signal can be imperceptible to an observer in the presence of another signal. A detailed review of these techniques is given in. Other advantages of LSB data hiding included high embedding capacity and low computational complexity. The main disadvantages are the weaknesses with respect to robustness, tampering, geometric attacks, filtering, and compression.

In LSB steganography, the least significant bits of the cover media’s digital data are used to conceal the message. The simplest of the LSB steganography techniques is LSB replacement. LSB replacement steganography changes the last bit of each of the pixel values to reflect the message that needs to be hidden. Consider an 8- bit gray scale bitmap image where each pixel is stored as a byte representing a gray scale color value. Suppose the first eight pixels of the original image have the following gray color values:

01010010

01001010

10010111

11001100

11010101

01010111

00100110

01000011

To hide the letter Z whose binary value of ASCII [11] code is 10110101, we would replace the LSBs of these pixels to have the following new values:

01010011

01001010

10010111

11001101

Note that, on average, only half the LSBs need to change. The difference between the cover (i.e. original) image and the stego image will be hardly noticeable to the human eye. However, one of its major limitations is small size of data which can be embedded in such type of images using only LSB. LSB is extremely vulnerable to attacks. LSB techniques implemented to 24 bit formats for the color image are difficult to detect contrary to 8 bit format.

LEAST SIGNIFICANT BIT TECHNIQUE

Least significant bit (LSB) insertion is a common and simple approach to embed information in an image file. In this method the LSB of a byte is replaced with an M"s bit. This technique works good for image steganography. To the human eye the stego image will look identical to the carrier image. For hiding information inside the images, the LSB (Least Significant Byte) method is usually used. To a computer an image file is simply a file that shows different colors and intensities of light on different areas of an image.

The best type of image file to hide information inside is a 24 Bit BMP (Bitmap) image. When an image is of high quality and resolution it is a easier to hide information inside image. Although 24 Bit images are best for hiding information due to their size. Some people may choose 8 Bit BMP"s or possibly another image format such as GIF. The reason being is that posting of large images on the internet may arouse suspicion. The least significant bit i.e. the eighth bit is used to change to a bit of the secret message. When using a 24-bit image, one can store 3 bits in each pixel by changing a bit of each of the red, green and blue color components.

Suppose that we have three adjacent pixels (9 bytes) with the RGB encoding

[3] [3]

10010101

00001101

11001001

10010110

00001111

11001011

10011111

00010000

When the number 300, can be which binary representation is 100101100 embedded into the least significant bits of this part of the image. If we overlay these 9 bits over the LSB of the 9 bytes above we get the following (where bits in bold have been changed) 10010101 00001100 11001000
10010111 00001110
11001011 10011111
00010000 11001010

Here the number 300 was embedded into the grid, only the 5 bits needed to be changed according to the embedded message. On average, only half of the bits in an image will need to be modified to hide a secret message using the maximum cover size.

1. Select a cover image of size M*N as an input.
2. The message to be hidden is embedded in RGB component only of an image.
3. Use a pixel selection filter to obtain the best areas to hide information in the cover image to obtain a better rate. The filter is applied to Least Significant Bit (LSB) of every pixel to hide information, leaving most significant bits (MSB).
4. After that Message is hidden using Bit Replacement method.

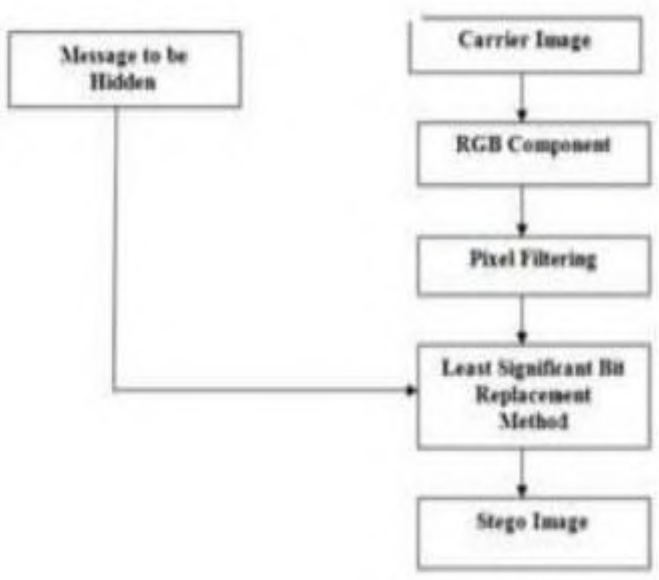

Fig 3.5 Algorithm of Least Significant Bit

CHAPTER-4

SOFTWARE REQUIREMENTS

Introduction to MATLAB

What is MATLAB?

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modelling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building.

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for *matrix laboratory*. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called *toolboxes*. Very important to most users of MATLAB, toolboxes allow you to *learn* and *apply* specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M-files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

LOCAL ENVIRONMENT SET UP :

Setting up MATLAB environment is a matter of few clicks. The installer can be downloaded from http://in.mathworks.com/downloads/web_downloads: MathWorks provides the licensed product, a trial version and a student version as well. You need to log into the site and wait a little for their approval. After downloading the installer the software can be installed through few clicks.

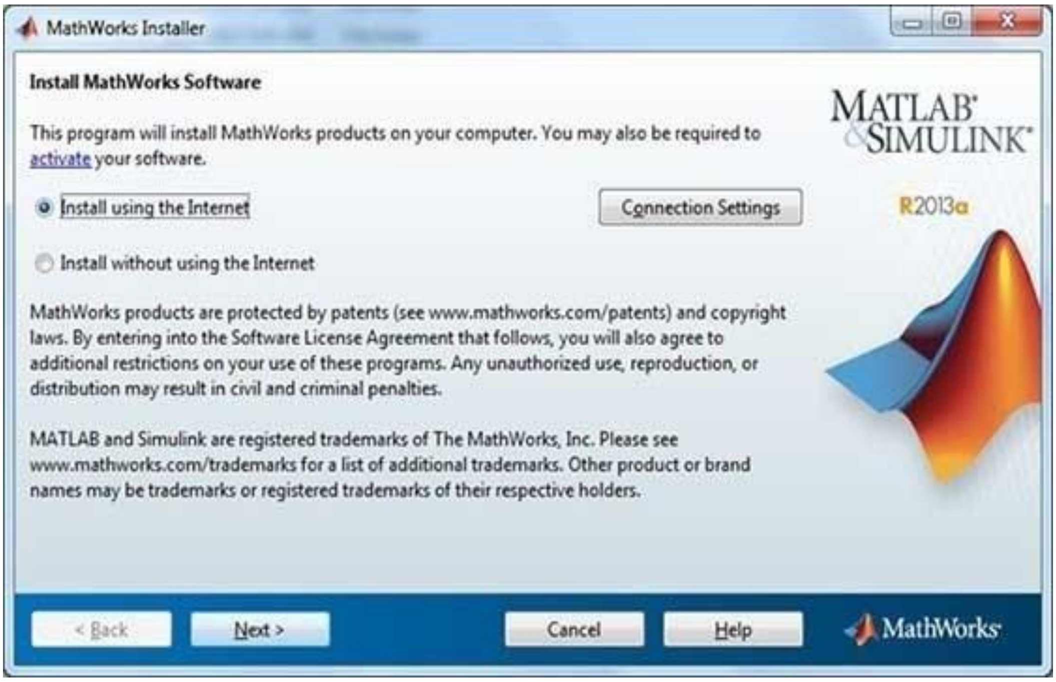

Figure 4.1: local environment setup

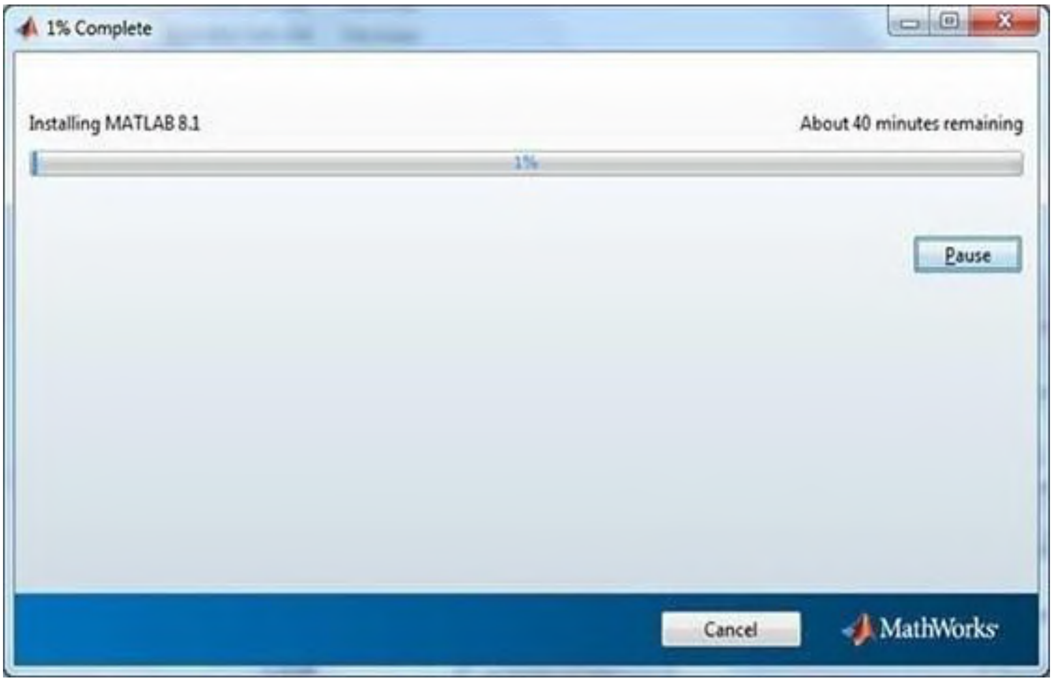

Figure4.2: Installing matlab software

THE MATLAB SYSTEM :

The MATLAB system consists of five main parts:

Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and Command Window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

MATLAB Mathematical Function:

This is a vast collection of computational algorithms ranging from elementary functions like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigen values, Bessel functions, and fast Fourier transforms.

MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create complete large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

MATLAB Application Program Interface (API):

This is a library that allows you to write C and Fortran programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

MATLAB WORKING ENVIRONMENT:

Matlab desktop :

Matlab Desktop is the main Matlab application window. The desktop contains five sub windows, the command window, the workspace browser, the current directory window, the command history window, and one or more figure windows, which are shown only when the user displays a graphic.

The command window is where the user types MATLAB commands and expressions at the prompt (>>) and where the output of those commands is displayed. MATLAB defines the workspace as the set of variables that the use session. The workspace browser shows these variables and some information about them. Double clicking on a variable in the workspace browser launches the Array Editor, which can be used to obtain information and income instances edit certain properties of the variable.

The current Directory tab above the workspace tab shows the contents of the current directory, whose path is shown in the current directory window. For example, in the windows operating system the path might be as follows: C:\MATLAB\Work, indicating that directory “work” is a subdirectory of the main directory “MATLAB”; WHICH IS INSTALLED IN DRIVE C. clicking on the arrow in the current directory window shows a list of recently used paths. Clicking on the button to the right of the window allows the user to change the current directory.

MATLAB uses a search path to find M-files and other MATLAB related files, which are organize in directories in the computer file system. Any file run in MATLAB must reside in the current directory or in a directory that is on search path. By default, the files supplied with MATLAB and math works toolboxes are included in the search path. The easiest way to see which directories are on the search path. The easiest way to see which directories are soon the search path, or to add or modify a search path, is to select set path from the File menu the desktop, and then use the set path dialog box. It is good practice to add any commonly used directories to the search path to avoid repeatedly having the change the current directory.

The Command History Window contains a record of the commands a user has entered in the command window, including both current and previous MATLAB sessions. Previously entered MATLAB commands can be selected and re-executed from the command history window by right clicking on a command or sequence of commands. This action launches a menu from which to select various options in addition to executing the commands. This is useful to select various options in addition to executing the commands. This is a useful feature when experimenting with various commands in a work session. The Command History Window contains a record of the commands a user.

Using the MATLAB Editor to create M-Files:

The MATLAB editor is both a text editor specialized for creating M-files and a graphical MATLAB debugger. The editor can appear in a window by itself, or it can be a sub window in the desktop. M-files are denoted by the extension .m, as in pixel up.m. The MATLAB editor window has numerous pull-down menus for tasks such as saving, viewing, and debugging files. Because it performs some simple checks and also uses color to differentiate between various elements of code, this text editor is recommended as the tool of choice for writing and editing M-functions. To open the editor , type edit at the prompt opens the M-file filename.m in an editor window, ready for editing. As noted earlier, the file must be in the current directory, or in a directory in the search path.

Getting Help:

The principal way to get help online is to use the MATLAB help browser, opened as a separate window either by clicking on the question mark symbol on the desktop toolbar, or by typing help browser at the prompt in the command window. The help Browser is a web browser integrated into the MATLAB desktop that displays a Hypertext Markup Language(HTML) documents. The Help Browser consists of two panes, the help navigator pane, used to find information, and the display pane, used to view the information. Self-explanatory tabs other than navigator pane are used to perform a search.

HISTORY:

Origins

MATLAB was invented by mathematician and computer programmer Cleve Moler. The idea for MATLAB was based on his 1960s PhD thesis. Moler became a math professor at the University of New Mexico and started developing MATLAB for his students as a hobby. He developed MATLAB's initial linear algebra programming in with his one-time thesis advisor , George Forsythe . This was followed by Fortan code for linear equations in 1971.

The first early version of MATLAB was completed in the late 1970s. The software was disclosed to the public for the first time in February 1979 at the Naval Postgraduate school in California. Early versions of MATLAB were simple matrix calculators with 71 pre-built functions. At the time, MATLAB was distributed for free to universities. Moler would leave copies at the universities he visited and the software developed a strong following in the math departments of university campuses.

In the 1980s, Cleve Moler met John N. Little. They decided to reprogram MATLAB in C and market it for the IBM desktops that were replacing mainframe computers at the time. John Little and programmer Steve Bangert re-programmed MATLAB in C, created the MATLAB programming language , and developed features for toolboxes.

Commercial Development

MATLAB was first released as a commercial product in 1984 at the Automatic Control Conference in Las Vegas. MathWorks, Inc. was founded to develop the software and the MATLAB programming language was released. The first MATLAB sale was the following year, when Nick Trefethen from the Massachusetts Institute of Technology bought ten copies.

By the end of the 1980s, several hundred copies of MATLAB had been sold to universities for student use. The software was popularized largely thanks to toolboxes created by experts in various fields for performing specialized mathematical tasks. Many of the toolboxes were developed as a result of standard students that used MATLAB in academia, then brought the software with them to the private sector.

Over time, MATLAB was re-written for early operating systems created by Digital Equipment corporation, VAX, Sun Microsystems and for Unix PCs.Version 3 was released in 1987. The first MATLAB compiler was developed by Stephen c. Jhonson in the 1990s.

In 2000, MathWorks added a Fortran-based library for linear algebra in MATLAB 6, replacing the software's original LINPACK and EISPACK subroutines that were in C. MATLAB's Parallel Computing Toolbox was released at the 2004 Supercomputing Conference and support for graphics processing units (GPUs) was added to it in 2010.

Recent history

Some especially large changes to the software were made with version 8 in 2012.The user interface was reworked:517 and simulink's functionality was expanded. By 2016, MATLAB had introduced several technical and user interface improvements, including the MATLAB Live Editor notebook, and other feature.

4.1 **Table: Operators**

Syntax

The MATLAB application is built around the MATLAB programming language. Common usage of the MATLAB application involves using the "Command Window" as an interactive mathematical shell or executing text files containing MATLAB code.

Variables

Variables are defined using the assignment operator, =. MATLAB is a weakly function language because variables can be assigned without declaring their type, except if they are to be treated as symbolic objects, and that their type can change.

Values can come from constants from computation involving values of other variables, or from the output of a function.

Structures

MATLAB supports structure data types. Since all variables in MATLAB are arrays, a more adequate name is "structure array", where each element of the array has the same field names. In addition, MATLAB supports dynamic field names (field look-ups by name, field manipulations, etc.)

Functions

MATLAB supports elements of lambda function by introducing function handles, or function references, which are implemented either in .m files or anonymous nested functions.

Classes and object-oriented programming

MATLAB supports object oriented programming including classes, inheritance, virtual dispatch, packages, pass-by-value semantics, and pass-by-reference semantics. However, the syntax and calling conventions are significantly different from other languages. MATLAB has value classes and reference classes, depending on whether the class has *handle* as a super-class (for reference classes) or not (for value classes).

Method call behaviour is different between value and reference classes. For example, a call to a method:

object.method();

can alter any member of *object* only if *object* is an instance of a reference class, otherwise value class methods must return a new instance if it needs to modify the object.

Interfacing with other languages

MATLAB can call functions and subroutines written in the programming languages C or Fortron. A wrapper function is created allowing MATLAB data types to be passed and returned. Mex files (MATLAB executables) are the dynamically loadable object files created by compiling such functions. Since 2014 increasing two- way interfacing with was python being added.

Libraries written in perl, Java, ActiveX or .Net can be directly called from MATLAB, and many MATLAB libraries (for example XML or SQL support) are implemented as wrappers around Java or ActiveX libraries. Calling MATLAB from Java is more complicated, but can be done with a MATLAB toolbox which is sold separately by Mathworks, or using an undocumented mechanism called JMI (Java-to- MATLAB Interface), (which should not be confused with the unrelated Java meta interface that is also called JMI). Official MATLAB API for Java was added in 2016.

As alternatives to the MuPAD based Symbolic Math Toolbox available from MathWorks, MATLAB can be connected to Maple or Mathematica.

Libraries also exist to import and export MathML.

MATLAB Windows

The MATLAB **Command Window** is the main window where you type commands directly to the MATLAB interpreter. The MATLAB **Editor Window** is a simple text editor where you can load, edit and save complete MATLAB programs. The Editor window also has a menu command (Debug/Run) which allows you to submit the program to the command window. The MATLAB **Help Window** gives you access to a great deal of useful information about the MATLAB language and MATLAB computing environment. It also has a number of example programs and tutorials.

COMMAND WINDOW:

This is the main area where commands can be entered at the command line. It is indicated by the command prompt (>>).

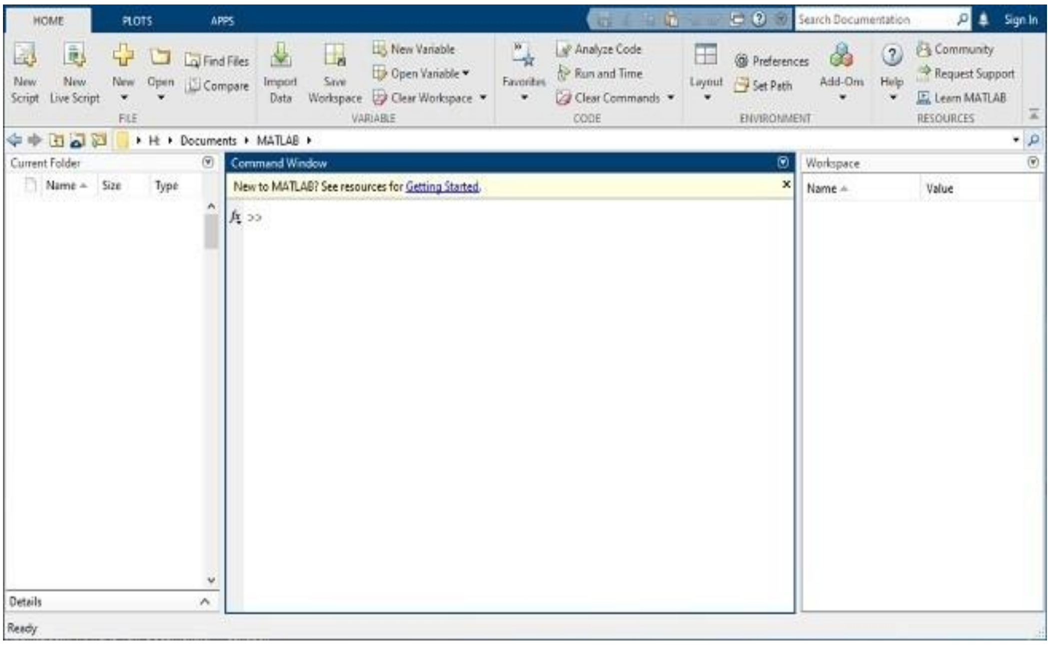

Figure 4.3: Command window

MATLAB Workspace

The workspace contains variables that you create or import into MATLAB from data files or other programs. You can view and edit the contents of the workspace in the Workspace browser or in the Command Window. For more information, see [Create and Edit Variables](#).

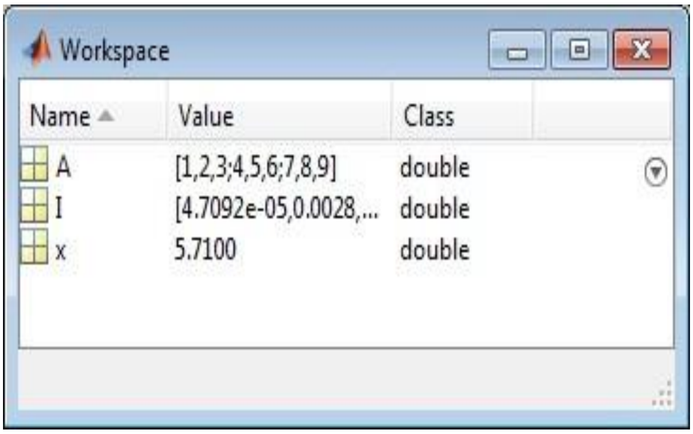

Figure 4.4: MATLAB workspace

Figure Window

Figure creates figure graphics objects. figure objects are the individual windows on the screen in which MATLAB displays graphical output.

`Figure ('PropertyName', PropertyValue,...)` creates a new figure object using the values of the properties specified. MATLAB uses default values for any properties that you do not explicitly define as arguments.

figure(h) does one of two things, depending on whether or not a figure with handle h
exists. but is an integer, figure(h) creates a figure, and assigns it the handle h. figure(h) where h is not the handle to a figure, and is not an integer, is an error.

h = figure(...) returns the handle to the figure object.

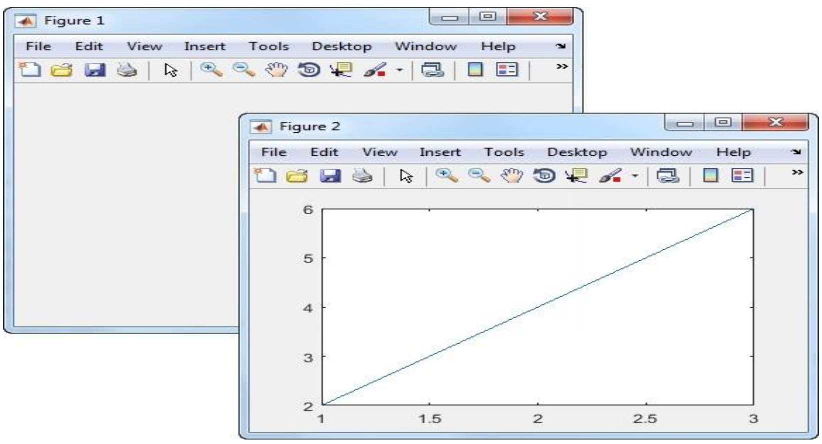

Figure 4.5: Matlab figure window

CURRENT FOLDER:

This panel allows you to access the project folders and files.

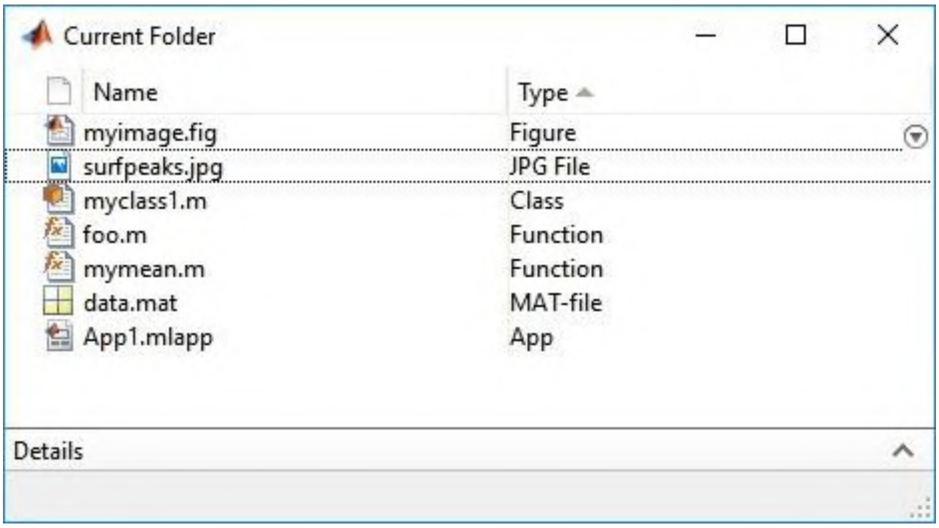

Figure4.6: Current folder

COMMAND HISTORY:

This panel shows or rerun commands that are entered at the command line.

Figure 4.7: Command history

FUNCTIONS:

Reading images

Images are read in MATLAB environment using the function ‘imread.’ Syntax of imread is: imread(‘filename’); where ‘filename’ is a string having the complete name of the image, including its extension. For example,

F=imread(‘Penguins_grey.jpg’);

Please note that when no path information is included in ‘filename,’ ‘imread’ reads the file from the current directory. When an image from another directory has to be read, the path of the image has to be specified.

Semicolon (;) at the end of a statement is used to suppress the output. If it is not included, MATLAB displays on the screen the result of the operation specified in that line.

‘>>’ indicates the beginning of a command line as it appears in the MATLAB command window. imread, imshow and imwrite functions in MATLAB are used to read images in MATLAB environment, display them on MATLAB desktop and write them to the current directory, respectively.

Figure 4.8: Grayscale image of penguins

In case of grayscale images, the resultant matrix of the imread statement comprises 256×256 or 65,536 elements. The first statement takes grey values of all the pixels in the grayscale image and puts them into a matrix F(256×256 elements), which is now a MATLAB variable on which various matrix operations can be performed.

Image display

Images are displayed on the MATLAB desktop using the function imshow, which has the basic syntax: imshow(f);

where ‘f’ is an image array of data type ‘uint8’ or double. Data type ‘uint8’ restricts the values of integers between 0 and 255.

It should be remembered that for a matrix of type ‘double,’ the imshow function expects the values to be between 0 and 1, where 0 is displayed as black and 1 as white., and a value less than zero is displayed as black. To get the values within this range, a division factor can be used. The larger the division factor, the darker will be the image.

As an example, if you give the command imshow(F), the image shown on the desktop is given in Fig. 5.3 ‘imshow(f, [low high])’ displays as black all values less than or equal to ‘low’ and as white all values equal to or greater than ‘high.’ The values in between are displayed as intermediate intensity values.

Figure 4.9: Image obtained with imshow(F) command

‘imshow(f, [ ])’ sets variable low to the minimum value of array ‘f’ and high to its maximum value. This helps in improving the contrast of images having a low dynamic range.

Multiple images can be displayed within one figure using the subplot function. This function has three parameters within the brackets, where the first two parameters specify the number of rows and columns to divide the figure. The third parameter specifies which subdivision to use. For example, subplot(3,2,3) tells MATLAB to divide the figure into three rows and two columns and set the third cell as active. To display the images Penguins_RGB.jpg and Penguins_grey.jpg together in a single figure, you need to give the following commands:

A=imread(‘Penguin_grayscal

e.jpg’);

B=imread(‘Penguin_RGB.jp

g’):

Figure

subplot(1,2,1),imsh

ow(A);

subplot(1,2,2),imshow(B);

MEDIAN FILTER:

2dimentional median filter is represented as

medfilt2 Syntax:

J=medfilt2(I)

J=medfilt2(I,[

m,n])

J=medfilt2(,

padopt)

Description:
J = medfilt2(I) performs median filtering of the image I in two dimensions. Each output pixel contains the median value in a 3-by-3 neighborhood around the corresponding pixel in the input image.

J = medfilt2(I,[m n]) performs median filtering, where each output pixel contains the median value in the m-by-n neighborhood around the corresponding pixel in the input image.

J = medfilt2(___,padopt) controls how medfilt2 pads the image boundaries.

UIGETFILE:

Uigetfile command is used to open file selection dialog box.

Syntax:

file =
uigetfile
[file,path] =
uigetfile
[file,path,indx] = uigetfile
___= uigetfile(filter)
___= uigetfilter(filter,title)
___= uigetfile(filter ,title, defname)
___= uigetfile(,'multiselect',mode)

Description ***:***

file = uigetfile opens a modal dialog box that lists files in the current folder. It enables a user to select or enter the name of a file. If the file exists and is

valid, uigetfile returns the file name when the user clicks **Open**. If the user clicks **Cancel** or the window close button (X), uigetfile returns 0.

[file,path] = uigetfile returns the file name and path to the file when the user clicks **Open**. If the user clicks **Cancel** or the window close button (X),
then uigetfile returns 0 for both of the output arguments.

[file,path,indx] = uigetfile returns the index of the filter selected in the dialog box when the user clicks **Open.**

____= uigetfile(filter) specifies a file extension by which files displayed in the dialog box are filtered. Use this syntax with any of the output argument combinations in the previous syntaxes.

Typically, only files with a matching file extension are displayed. On some platforms, uigetfile displays files that do not match the filter, but dims those file names. If the filter is missing or empty, uigetfile uses the default list of file types .

____= uigetfile(filter,title) specifies a dialog box title. To filter using the default file filter, but specify a custom title, use empty quotes for the filter value. For example:

file = uigetfile('','Select a File')

____= uigetfile(filter,title,defname) specifies a default file name for the **File name** field.

____= uigetfile(_,'MultiSelect',mode) specifies whether a user can select multiple files. Set the mode to 'on' to enable multifile selection. By default it is set to 'off'.

Windows® libraries can span multiple folders.

CORRELATION COEFFICIENT:

2Dimentional correlation coefficient is represented as corr2.

Syntax:

R = corr2(A, B)

Description:

R = corr2(A,B) returns the 2-D correlation coefficient R between arrays A and B.

MATRIX TO GRAYSCALE IMAGE:

2Dimensional matrix to grayscale command is represented as mat2gray. Syntax:

I=mat2gray(A,[amin, amax]) I=mat2gray(A)

Description:

`I = mat2gray(A,[amin amax])` converts the matrix `A` to a grayscale image `I` that contains values in the range 0 (black) to 1 (white). `amin` and `amax` are the values in `A` that correspond to 0 and 1 in `I`. Values less than `amin` are clipped to 0, and values greater than `amax` are clipped to 1.

`I = mat2gray(A)` sets the values of `amin` and `amax` to the minimum and maximum values in `A`.

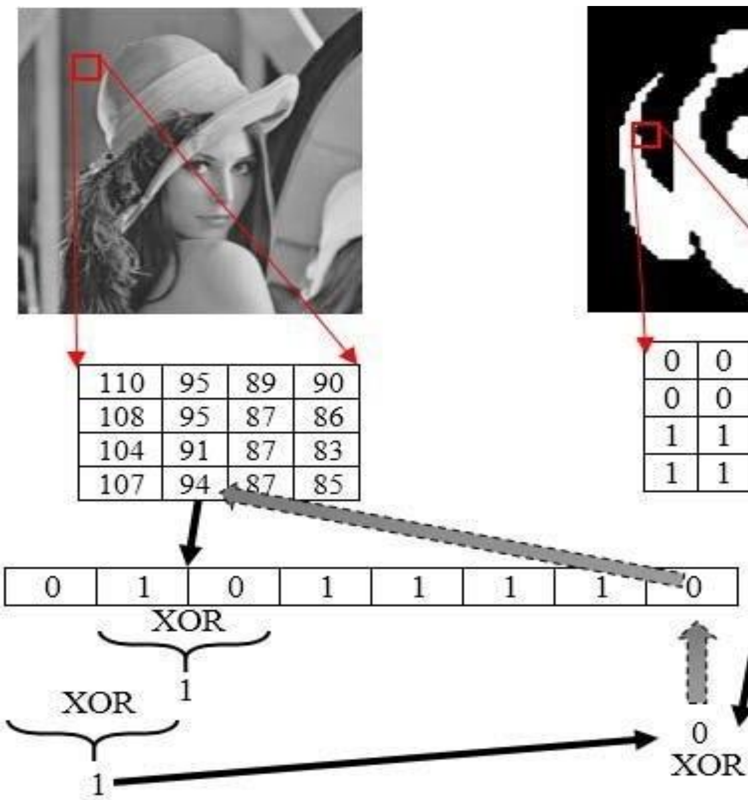
CHAPTER -5

DESIGN AND IMPLEMENTATION

In the method we propose, there are two main schemes, namely message embedding and message extraction. For more details can be seen in the sub-section below.

5.1. Embedding Scheme

In the embedding, scheme required input in the form of gray-scale cover image and image of the message in the form of a binary image with the exact same size. While the output obtained is a stego image. For more details can see the visualization in Figure below



.

Fig 5.1 embedded scheme

Here are the steps for the embedding process:

Step 1: Read the cover image (A) and message

image (B). Step 2: Change the pixel value to binary.

Step 3: Perform XOR operations on the 7th and on the 6th bit.

Step 4: Perform XOR operation on bit 8th with XOR operation result on the 7th and on the 6th bits

Step 5: Perform XOR operations on message bits with three MSB bits (8th, 7th, and 6th bits).

Step 6: Save the XOR operation result in the message bit, then convert again to uint8, the result of this conversion being the stego image pixel value.

Extraction Scheme

In the extraction scheme only required input in the form of stego image. While the output of the recovered message in the form of a binary image.

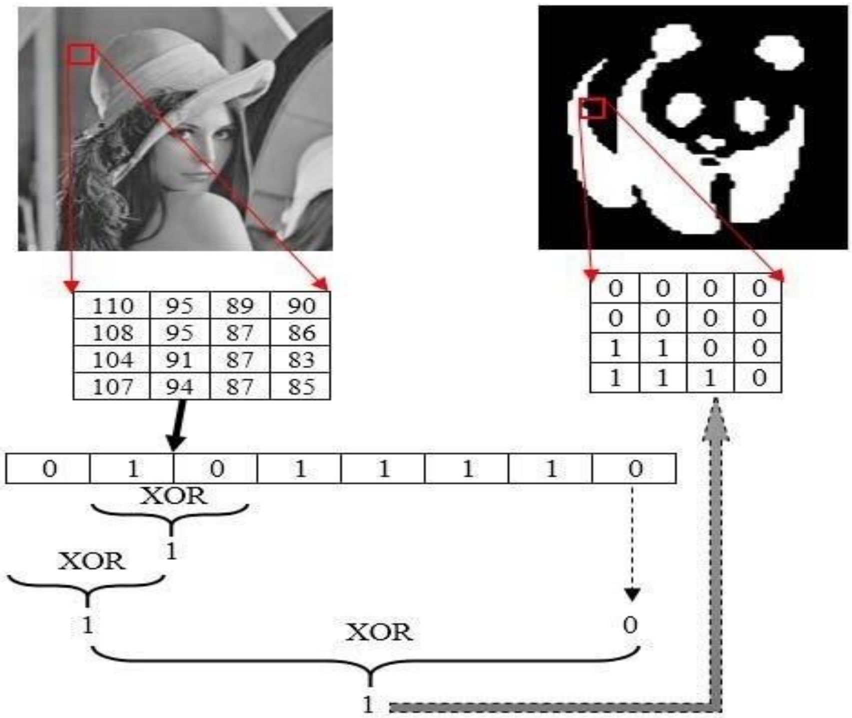


Fig 5.2 Extraction Scheme

Figure 2 shows the visualization of the extraction process, in detail, the steps in the extraction process are as follows:

Step 1: Read the stego image (S).

Step 2: Change the pixel value to binary.

Step 3: Perform XOR operations on the 7th and 6th bits.

Step 4: Perform XOR operation on the 8th bit with XOR operation result on the 7th and on the 6th bit.

Step 5: do the XOR operation on the LSB with three bits MSB (bits 8th, 7th, and 6th). Step 6: Save and collect the results of the XOR operation on the LSB, then convert again to uint8, the result of this conversion being a recovery .

FLOW CHART

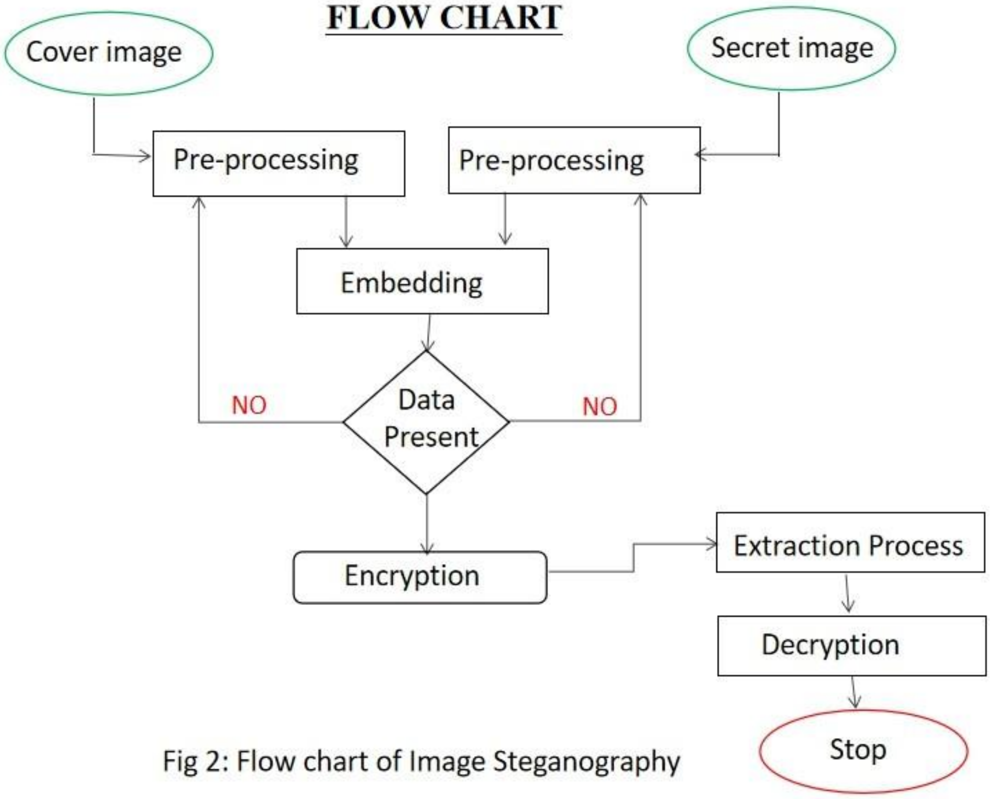

Fig 2: Flow chart of Image Steganography

Applications

1) In Military applications.

2) To communicate between two international governments.

3) Database managements.

CHAPTER-6
EXPERIMENT AND RESULTS

Experiments conducted in this research using two images, one as the cover image and another image as a secret image. The cover image and message image have the same size, 256 * 256 in size. Here is a cover image used in this study:

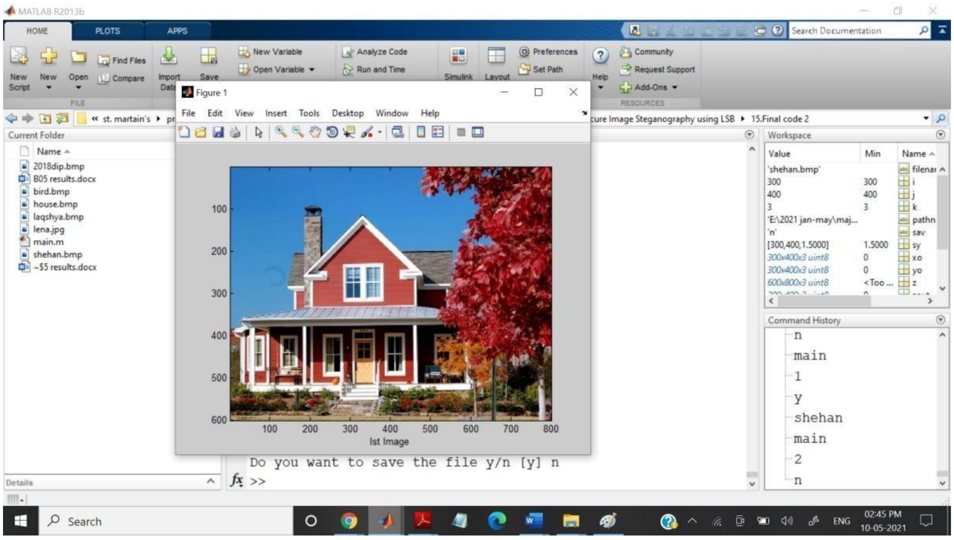

Fig 6.1: Cover Image used in the project

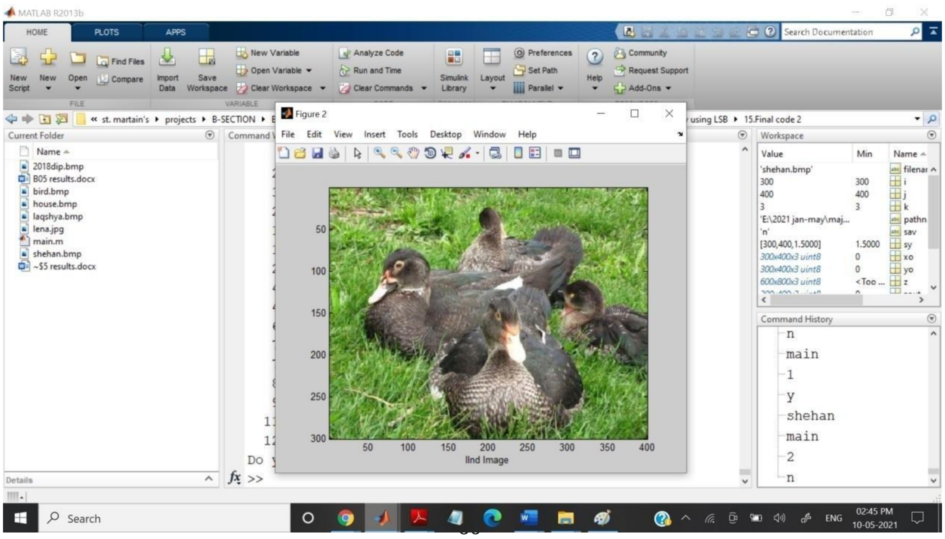

Fig 6.2: Secret Image used in the project

cover image and the message image have same pixel size. Then one pixel of message image embedded on one cover image pixel. The number of message bits embedded in the cover image is 65536 bits. Furthermore, an experiment of embedding the message using the method proposed above.

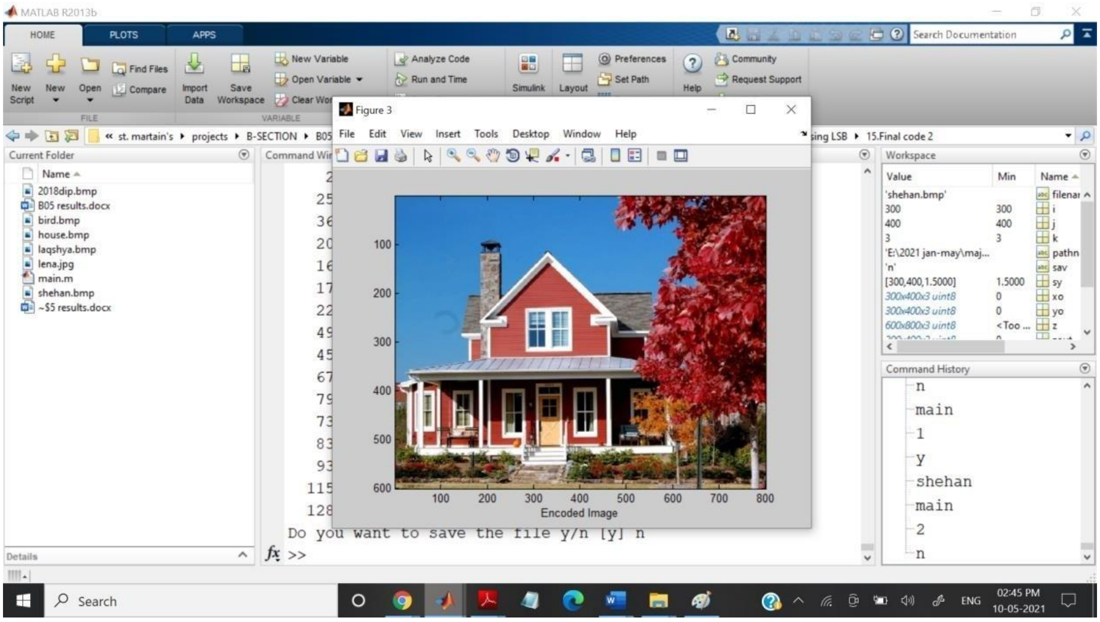

Fig 6.3: Embedded Image

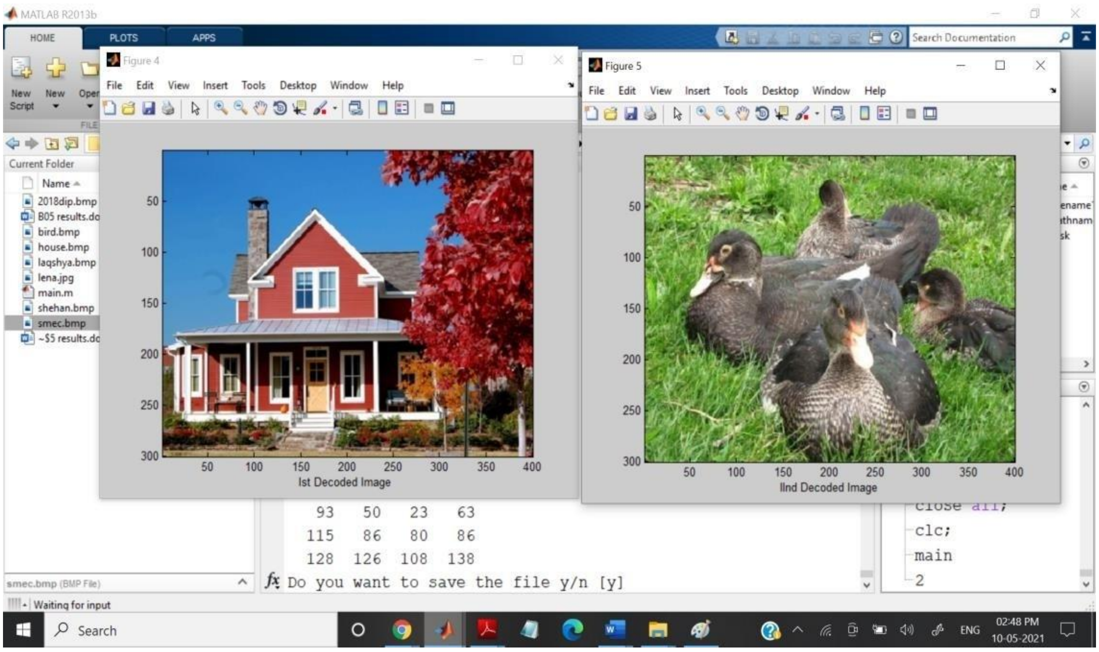

Fig 6.4: Extracted Image(Decoded Image)

In plain view, humans cannot distinguish the difference between the stego image and the cover image. Then, does this mean the stego image is good? Obviously needed a tool to measure the quality of stego image above. In this study used PSNR, MSE and image histogram to measure stego image quality. The measurement is done by comparing the cover image with stego image. To calculate MSE used Formula 1 and to calculate PSNR used Formula

$$MSE = \sum_{h=1}^{H-1}\sum_{g=1}^{G-1}\left\|A_f(h,g) - S_f(h,g)\right\| \quad (1)$$

$$PSNR = 10log_{10}\left(\frac{256-1}{MSE}\right) \quad (2)$$

Furthermore, histogram measurement is done by using the 'imhist' function in MATLAB.

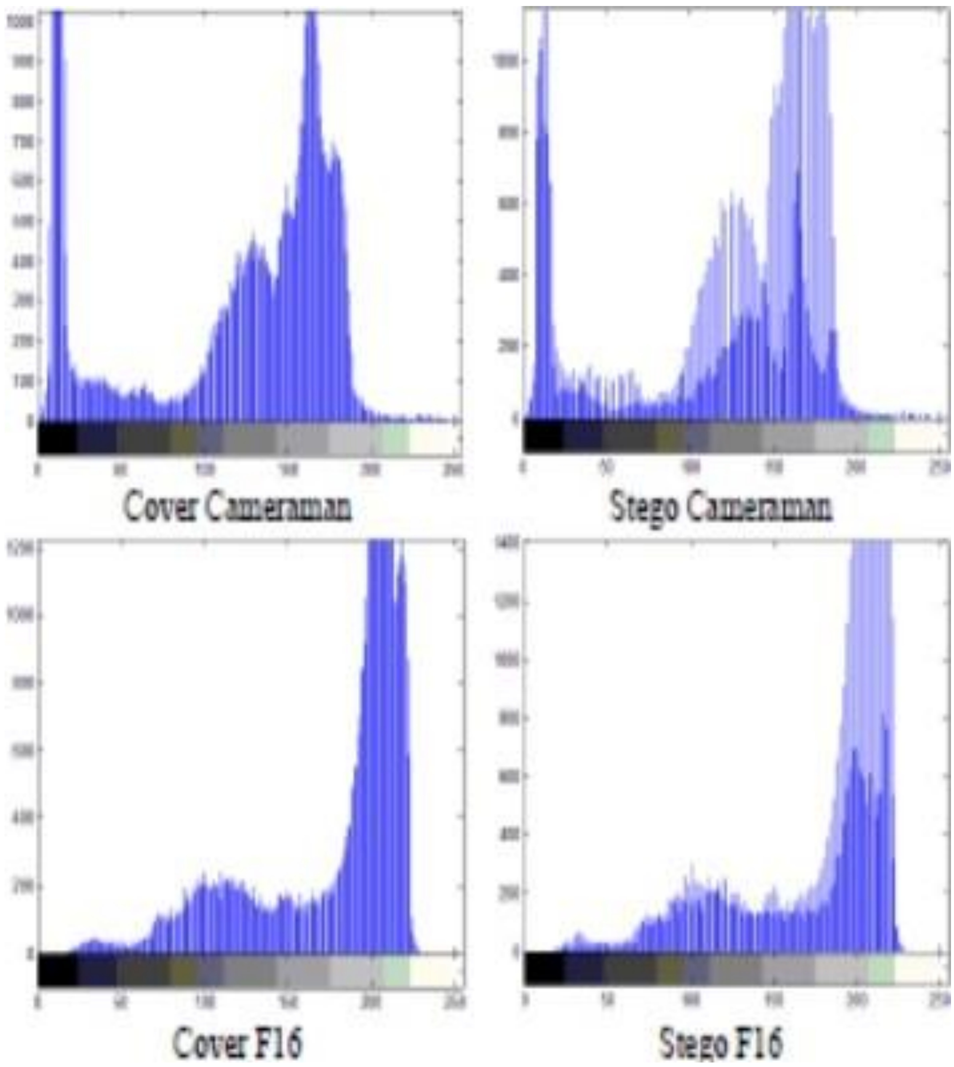

Fig. 6.5: The histogram of the cover image (left) and the stego image (right)

If Figure 6.5 observed carefully there is a difference between histogram image cover and stego image. The histogram on the stego image has a more split pattern than the cover image. As for the measurement of PSNR and

MSE values measurements are shown in Table .

TABLE I. PSNR AND MSE RESULTS

Image	PSNR	MSE
Lena	54.616	0.225
Barbara	54.037	0.257
cameraman	54.665	0.222
F16	56.035	0.162
Pentagon	53.714	0.277
peppers	54.307	0.241

To know the performance of extraction results. Recover message image is also measured using correlation coefficient (CC). A CC value equal to 1 indicates that the extraction processcan be done perfectly. If the value of cc between 0 to 1 then there are bits of messages that can not be extracted properly. To compute CC used Formula 3.

$$cc = \frac{\sum_h \sum_g (I_o - \bar{I}_o)(I_r - \bar{I}_r)}{\sqrt{\sum_h \sum_g (I_o - \bar{I}_o) \sum_h \sum_g (I_r - \bar{I}_r)}} \qquad (3)$$

CHAPTER 7
CONCLUSION AND FUTURE ENHANCEMENT

Conclusion

The method proposed in this study has an advantage in the aspect of imperceptibility as evidenced by the excellent value of PSNR and MSE. Where all PSNR values are more than 50dB, so does the MSE value not more than 0.3. This method is also very simple and safe because with XOR operation steganography process can be done quickly and easily. With the XOR operator, the embedded bits cannot be directly guessed. Moreover, there are three keys used, with three times the XOR operation. The use of an integrated key in the cover image also keeps the stego file the same size, and no key delivery is required to the receiver so it can speed up the messaging process as the file size is maintained. However, based on histogram analysis there is a distinct pattern difference between the cover image and stego image.

Future Enhancement

This model can be further implemented to send multiple objects at a time and can also be used to send videos and document files.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to our College Management for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Aboveall, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, andthe vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **dept. Project coordinator Dr. A. Anand** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our project internal guide, **Ms. E.parvathi, Assistant professor**, department of ECE and our class project coordinator, **Mr. K.Karthik, Assistant professor**, department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Guide **Dr. Maalyadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

3. D. Jyothi

ABSTRACT

Wireless communication systems rely on antennas for signal reception. Proper positioning of antennas is necessary according to satellites/transmitters to achieve effective wireless communication. Manual antenna changes are often risky in a way that usually results in unexpected accidents and can lead to death.

So here, we propose an IOT based antenna positioning system that allows for remotely positioning of antennas based over IOT. To determine its position, the sensors are mounted on the antenna, and the motors change their position. Here, sensor-based system with motor on each antenna using antenna to check its facing direction that is transmitted and its direction will be changed by motors using IOT. If the direction of a satellite or transmitting station changes over time, the antenna direction must also be changed accordingly.

The receiving antennas may be placed far apart from each other across the globe. So, our system allows for antenna positioning over very long distances. The antenna positions are visible over internet to controlling operator on the IOT GUI. We here use IOT Gecko to develop the antenna monitoring GUI system. Our system allows for monitoring antenna direction as well as transmitting new coordinates to position the antenna and motor appropriately positions the antenna accordingly.

CHAPTER-1

INTRODUCTION

Objective of the project

There are many commercial communications satellites in the geosynchronous orbit. Geostationary satellites are located in orbit directly above the equator and stay in the same place in the sky since they go around the earth at the same angular speed as that of the earth as it rotates. Satellite locations may thus be defined by longitude only. Geo Orbit position is the longitude position around the geostationary orbit. The most common issue anyone will come across when aligning the dish is aiming at the correct satellite for the broadcasts and receiving, they require. Satellite receivers do have details on them regarding the satellites to which they are communicating. They cannot determine whether you are aligned to the correct satellite and rely on the user to align the dish in the correct direction. The alignment of satellite dishes is currently performed manually wasting many hours to perform this process. Basically, for the manual, we use a spectrum analyser to monitor the signal during movement of the antenna until the desired satellite is found. Also, to look for the location of a satellite in order to achieve the best reception is an exhaustive process. Due to manual installation of the system, there is possibility of human errors i.e., misalignment of the antenna. Since each antenna is dedicated to a satellite, it is difficult to point it. So, it is necessary for an automated system in order to achieve the optimum positioning for reception of the signal.

IOT is one of the latest and emerging technology with the ability to transform the beautiful world like industries with smart machines, smarter cities etc. However, the importance of technology like IOT in communication systems has very great impact. In wireless communication concept antennas important for receiving signals. For very effective results of wireless communication the proper direction of antennas matters. So, we proposed a model for antenna positioning based on IOT technology. Sensors will be mounted on the antenna to detect the proper direction and the interesting thing is the motors using IOT concept will change the direction from anywhere across the world. The direction of transmitting stations changes with time means when the transmitting station changes over time the antenna direction need to be automatically changes accordingly. In simple words this model will help us in monitoring the direction of antennas and transmitting new coordinates to properly position the antennas. In IoT (Internet of things), “things” refer to a wide range of devices such as heart monitoring implants, remotely handling home appliances, biochip transponders used on farm animals, cameras that are streaming live feeds of wild animals in coastal waters etc.

Thus, we can say that “things” are a “mixture of hardware, software, data and services”. System engineering of a satellite-based data communication baseline concept is presented to achieve terabit per second throughput if sensors and actuators are augmented, the technology becomes as more general class of cyber physical systems which can also encompass the technologies.

Project overview

Embedded systems

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer. An embedded system is a dedicated computer system designed for one or two specific functions. This system is embedded as a part of a complete device system that includes, such as electrical and mechanical components [1].

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory [4].

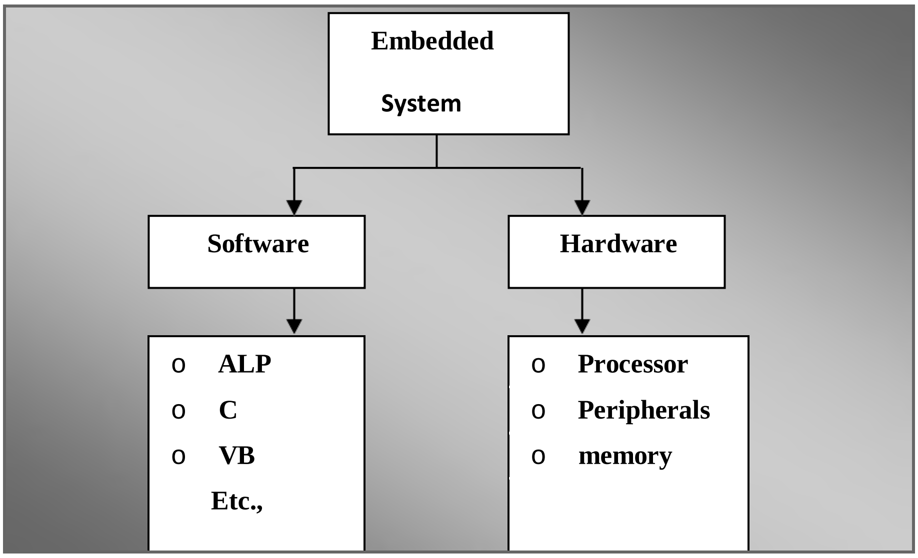

Figure 1.1: embedded system

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor [6].

Three basic characteristics differentiate microprocessors:

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. The Control Unit provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

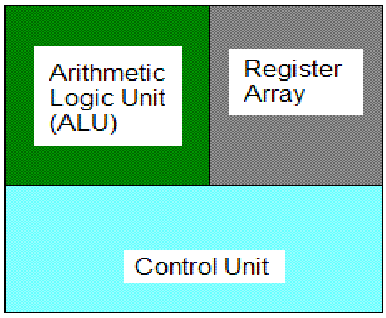

Figure 1.2: elements of microprocessor

Micro Controller (μc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.

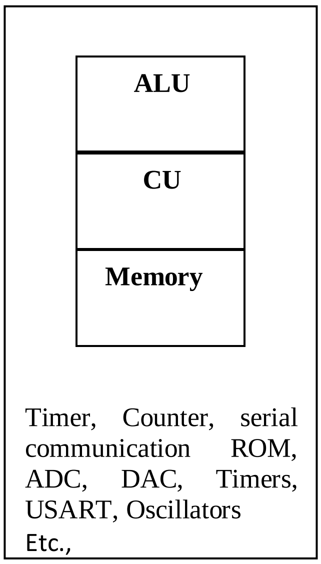

Figure 1.3: block diagram of micro controller

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function. Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine [3].

ASIC typically contains

- CPU cores for computation and control.
- Peripherals to control timing critical functions.
- Memories to store data and program.
- Analog circuits to provide clocks and interface to the real world which is analog in nature.
- I/O's to connect to external components like LEDs, memories, monitors etc.

Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

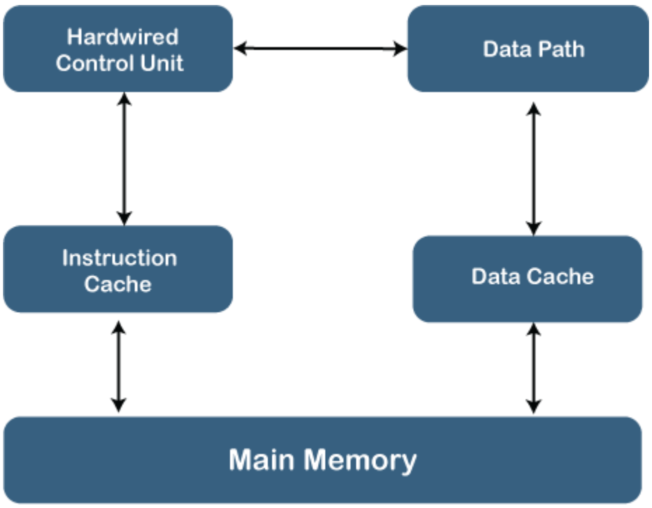

Figure 1.4(a): RISC architecture

RISC characteristics

- **Simple instruction set:** In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.
- **Same length instructions:** Each instruction is the same length, so that it may be fetched in a single operation.
- **1machine-cycleinstructions:** Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

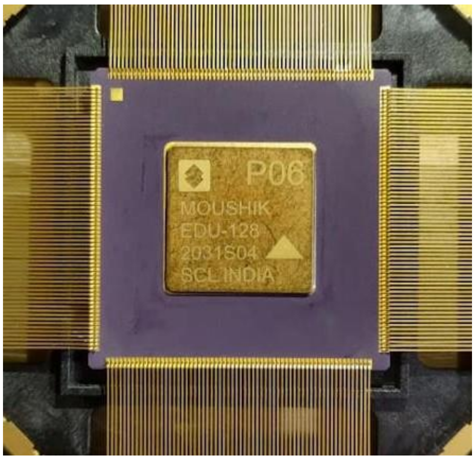

Figure 1.4(b): RISC-V of India

Complex Instruction Set Computer (CISC)

CISC, which stands for Complex Instruction Set Computer**,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

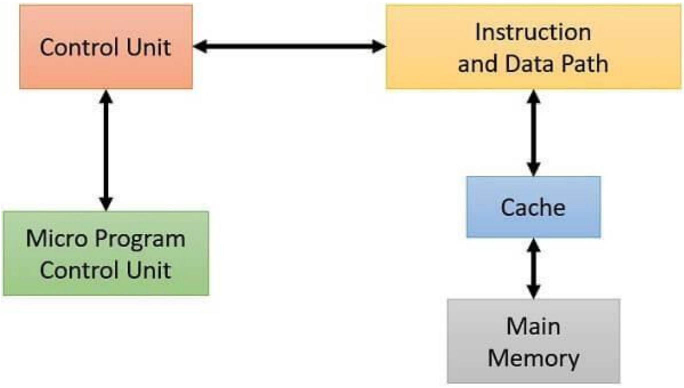

Figure 1.5(a): CISC architecture

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

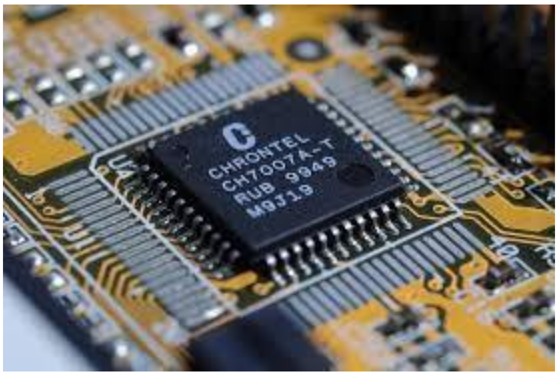

Figure 1.5(b): CISC chip

Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

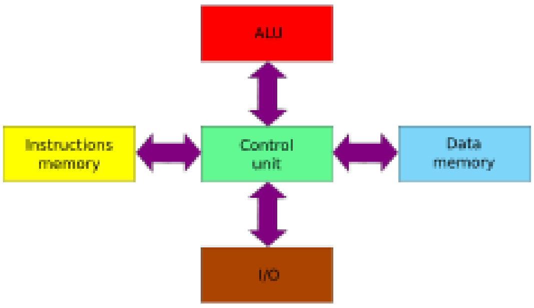

Figure 1.6: Harvard architecture

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture. The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

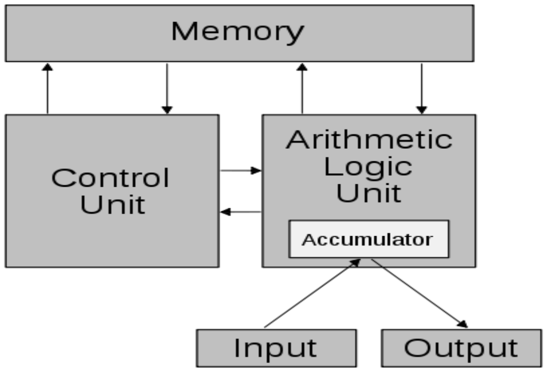

Figure 1.7: Von-Neumann Architecture

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

Types of Embedded System

1. Real Time Systems

Real-time systems are those which give a quick response to critical situations. They are used in military, medical and industrial applications. Engineers working in these systems have high demand is current days. To develop the Realtime embedded system we require timing analysis, multitasking design, debugging, cross platform testing and architecture design. In these systems, quick response is very important.

2. Standalone Embedded System

This type of embedded system works for itself as a device without needing any interconnected computer. It can take data in the form of Analog or digital signals. This system first process data and then outputs data by displaying on the screen.

3. Networked Embedded System

Networked embedded systems are those systems which are connected to the network to give output to the attached resources. The devices in the networked embedded system are connected to the network with network interfaces. The network can be either a local area network (LAN) or a wide area network (WAN).

4. Mobile Embedded System

Mobile embedded systems are limited in resources including memory. Examples of mobile embedded systems include • Personal digital assistants (PDA) • Cellular phones • Mp3 players 6 • Digital cameras.

5. Small-Scale Embedded System

Small-scale embedded systems consist of 8–16-bit microcontroller. This system can perform tasks at a small level. They have on-chip ROM and RAM. Small scale systems can be even activated by the battery. The tools used to develop small scale embedded systems are an editor, cross assembler, assembler and integrated development environment (IDE). The purpose of this system is not computation but to control as a computer embedded inside it. It behaves as a component of a computer and its function is not to compute. The small-scale system is dedicated to some specific tasks.

6. Medium Scale Embedded System

This embedded system has 16–32-bit microprocessor or microcontroller with external RAM and ROM They can perform medium to complex level works. The integration between hardware and software is complex in these embedded systems. Programming languages used to develop medium scale embedded systems include Java, C, Visual C++, debugger, C++, RTOS, simulator, source code engineering tool and IDE.

7. Sophisticated Embedded System

The embedded system which can do large-scale works with multiple 32-64 bit chips is known as sophisticated embedded systems. They can perform distributed work on a large scale. The complexity of hardware and software is very high in these systems. In sophisticated embedded systems, hardware and software are assembled together on large scale and designing of hardware products is also included in these systems.

Power supply

Block diagram

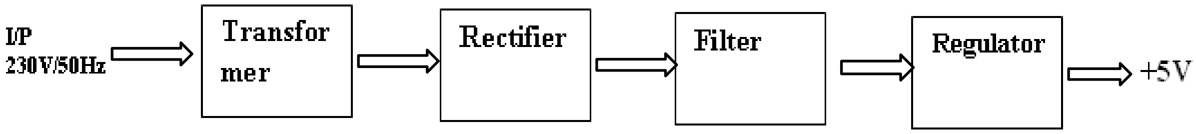

Figure 1.8: Block diagram of the power supply unit

Description

1.2.4.2(a) Transformer

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

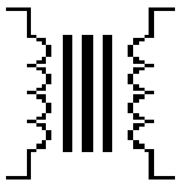

Figure 1.9: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

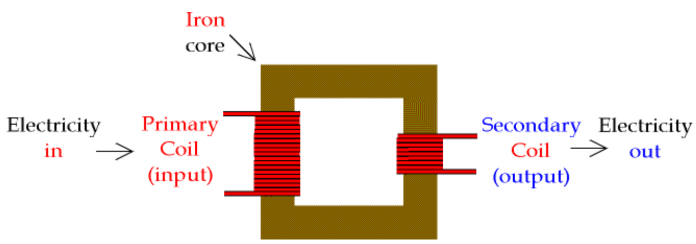

Figure 1.10: Transformer

Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

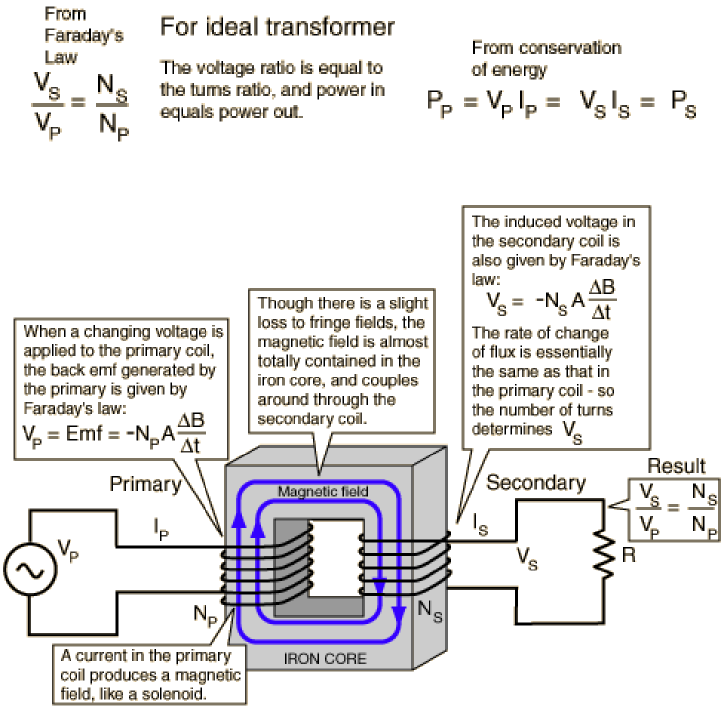

Figure 1.11: Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

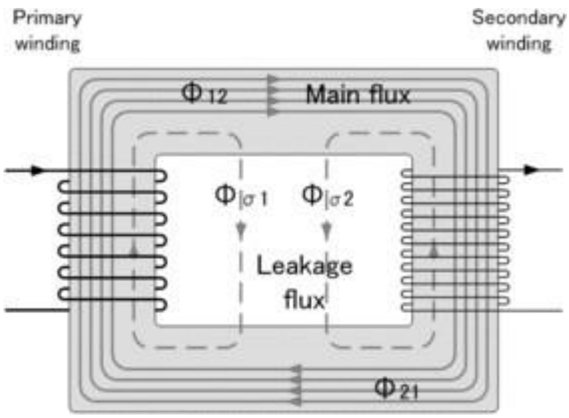

Figure 1.12: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers is designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step-down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers is made up of two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

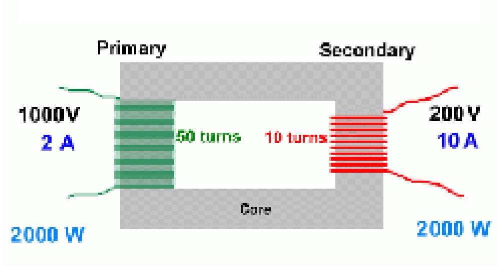

Figure 1.13: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step-up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it.

A step-up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So, a step-up transformer increases the voltage and a step-down transformer decreases the voltage.

The primary components for voltage transformation are the step-up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground.

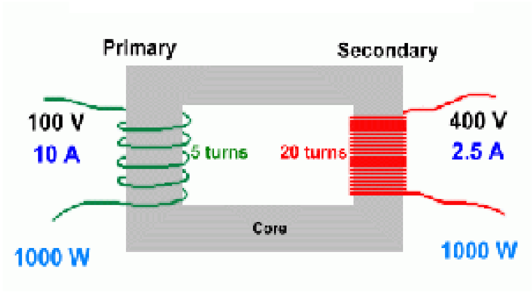

Figure 1.14: Step-Up Transformer

1.2.4.2(b) Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

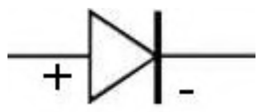

Figure 1.15: Diode Symbol

A diode is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

1.2.4.2(c) Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as 'half-wave' and 'full-wave' rectifiers. Both use components called diodes to convert AC into DC.

THE HALF-WAVE RECTIFIER

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

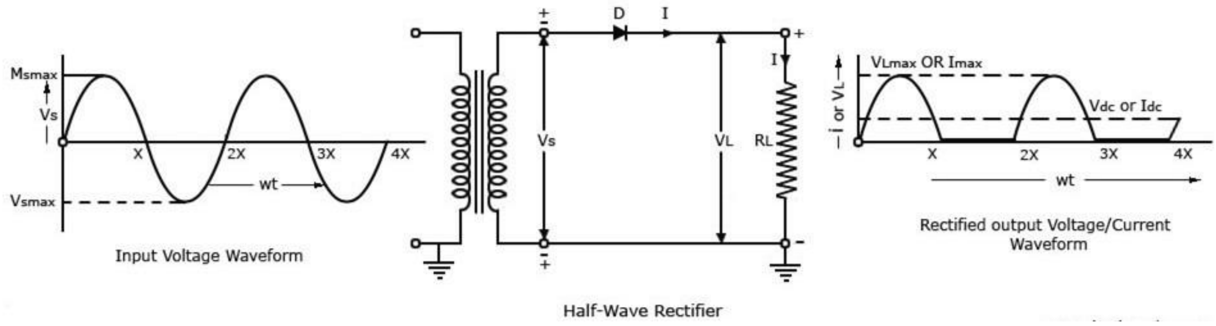

Figure 1.16: Half Wave Rectifier

Figure shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

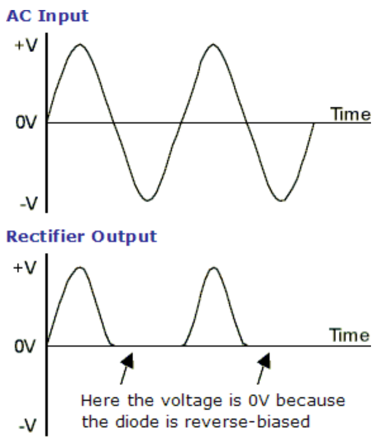

Figure 1.17: Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

THE FULL-WAVE RECTIFIER

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

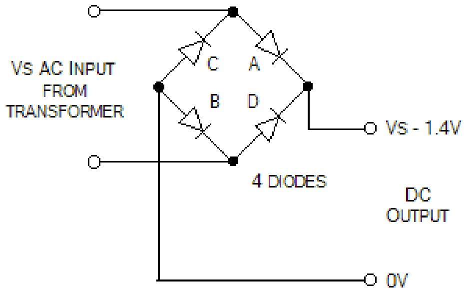

Figure 1.18: Full-Wave Rectifier

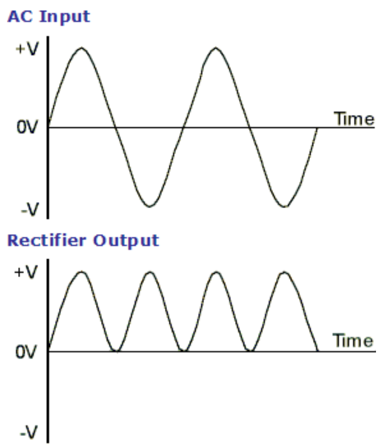

Figure 1.19: Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

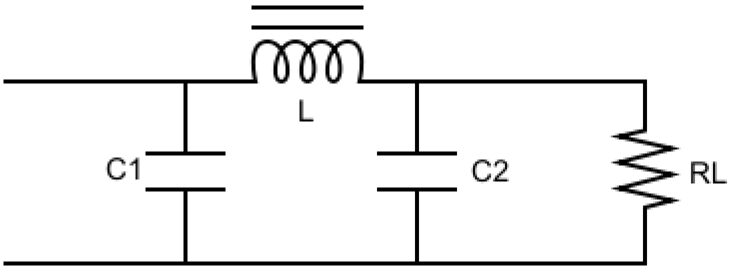

Figure 1.20: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

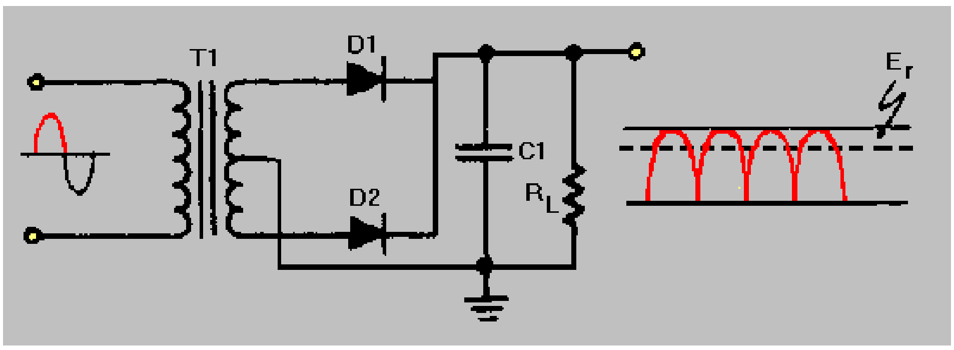

Figure 1.21: Centred Tapped Full-Wave Rectifier with a Capacitor Filter

1.2.4.2(d)Voltage Regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulators are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

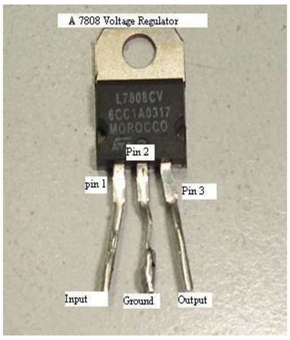

Figure 1.22: Regulator

Circuit diagram

CHAPTER-2

LITERATURE SURVEY

[1] IEEE paper of "Design of miniature antennas for IoT applications", by L. Lizzi, F. Ferrero, P. Monin, C. Danchesi, S. Boudaud, Published in: 2016 IEEE Sixth International Conference on Communications and Electronics (ICCE). PIC microcontroller was designed to develop a satellite dish positioning system which can be operated by using a Bluetooth control. This project helps n adjusting the position of the dish through a remote Control which acts as a transmitter whose data is received by a Bluetooth receiver which is interfaced to a Microcontroller of PIC 16F877A.

[2] "Antenna Positioning Based on IOT", by Khalid Makhdoomi, published by International Journal of Trends in Scientific Research and Development (IJTSRD), Volume 2, Issue 5, July-August 2018.This system uses sensors and mounts motors on each antenna to verify its facing direction transmitted over IoT. In case the direction of satellite or station changes with time the direction of antenna also changes accordingly. The antenna positions are visible to operator on the IoT GUI through the internet. The IoT Gecko is used to develop the GUI system for antenna monitoring. Our model allows for monitoring antenna direction as well as transmitting new coordinates to position the antenna and motor appropriately positions the antenna accordingly.

[3] "Design of Advanced Antenna Positioning System", by Rahane Suraj Dildar, Mhaske Shital Arun, Shingate Sujata Rajendra and Prof. S. B. Mandlik, published by International Journal of Research in Advent Technology, Vol.6, No.3, March 2018. Design of advanced antenna positioning system consists of various transmitters, a delay circuit & a receiver which is placed at the centre of antenna. When a signal is received at receiver, it provides adequate strength and gets transferred to an Analog to Digital Converter and the converted data is sent to a microcontroller. The microcontroller analyzes data and gives output accordingly to the motor driver which is connected to servomotor. In this way servomotor gets the adequate data or information required for correct positioning of receiving antenna.

[4] "Implementing an IOT based Antenna Positioning System", by Pooja Revane, Shradha Salaskar, KomalShelke, Priyanka Tawar, Akshata Raut, published in International Journal for Research in Applied Science & Engineering Technology (IJRASET), Volume 6 Issue IV, April 2018. In this system sensors will be mounted on the antenna to detect its direction and its direction will be changed by motors using IoT. When the direction of a transmitting station changes over time, the antenna direction must also be changed accordingly.

[5] “Automatic Dish Antenna Positioning System”, by Jadhav Seema, Shejwalkar Rakshanda, Andhale Jyoti, published by JournalNX - A Multidisciplinary Peer Reviewed Journal, ISSN No: 2581-4230, 21st - 22nd February, 2018. Dish antenna positioning is used to get broadcast signals from the satellite. The aim of this project is to control the dish automatically, which will be capable of receiving the broadcast signals from the satellite. It will rotate horizontally and vertically. The position of the dish is adjusted by an android application or Bluetooth. Power meter is used to measure the maximum signal strength. This system uses two stepper motors which helps it top move horizontally and vertically.

[6] “Microcontroller Based Wireless Automatic Antenna Positioning System” by Surya deo choudhary, Pankanj Rai, Arvind kumar, Irshad Alam used to design automatic Antenna Positioning system primarily functions to identify the source of signal. The signal may be of any type and any kind, it automatically identifies the presence of a particular signal and the antenna will remain stationary as long as the signal link is established.

[7] “Automated Antenna Positioning for Wireless Networks” by Amit Dvir, Yehuda Ben Shimol, Yoav Ben-Yehezkel, Michael Segal. This article addresses a real-life problem which is obtaining communication links between multiple base stations sites. This is done by positioning a minimal set of fixed-access relay antenna sites on a given terrain. To minimize the number of relay antenna sites is considered difficult due to substantial installation and maintenance costs. Despite the potential significant cost saving by eliminating even a single antenna site, a hardly optimal manual approach is employed due to the computation complexity of the problem.

[8] “Remote Alignment of Dish Positioning By Android Application” by Prajwal Basnet, Pranjal Grover Preeti Pannu. The project is designed to develop a dish positioning system which can be operated by using an Android application. The main application of using a dish is to receive signal from satellites and other broadcasting sources. In order to position the dish to the exact angle to receive the maximum signal of a particular frequency, it needs to be adjusted manually.

CHAPTER-3

ILLUSTRATION

Introduction to antennas

An Antenna is a transducer, which converts electrical power into electromagnetic waves and vice versa.

An Antenna can be used either as a transmitting antenna or a receiving antenna.

- A transmitting antenna is one, which converts electrical signals into electromagnetic waves and radiates them.
- A receiving antenna is one, which converts electromagnetic waves from the received beam into electrical signals.
- In two-way communication, the same antenna can be used for both transmission and reception.

Antenna can also be termed as an Aerial. Plural of it is, antennae or antennas. Now-adays, antennas have undergone many changes, in accordance with their size and shape. There are many types of antennas depending upon their wide variety of applications [2].

Figure 3.1: Satellite antenna

NEED OF ANTENNA

In the field of communication systems, whenever the need for wireless communication arises, there occurs the necessity of an antenna. Antenna has the capability of sending or receiving the electromagnetic waves for the sake of communication, where you cannot expect to lay down a wiring system. The following scenario explains this.

Radiation Mechanism

The sole functionality of an antenna is power radiation or reception. Antenna (whether it transmits or receives or does both) can be connected to the circuitry at the station through a transmission line. The functioning of an antenna depends upon the radiation mechanism of a transmission line.

A conductor, which is designed to carry current over large distances with minimum losses, is termed as a transmission line. For example, a wire, which is connected to an antenna. A transmission line conducting current with uniform velocity, and the line being a straight one with infinite extent, radiates no power.

For a transmission line, to become a waveguide or to radiate power, has to be processed as such.

- If the power has to be radiated, though the current conduction is with uniform velocity, the wire or transmission line should be bent, truncated or terminated.
- If this transmission line has current, which accelerates or decelerates with a time varying constant, then it radiates the power even though the wire is straight.
- The device or tube, if bent or terminated to radiate energy, then it is called as waveguide. These are especially used for the microwave transmission or reception.

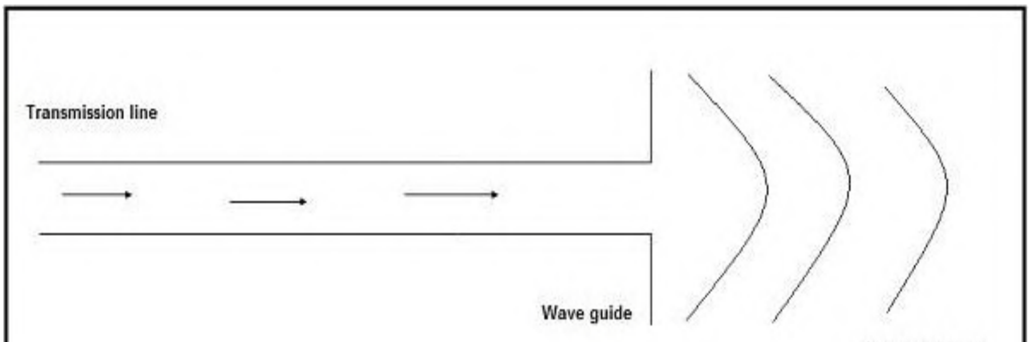

Figure 3.2: Radiation

The above diagram represents a waveguide, which acts as an antenna. The power from the transmission line travels through the waveguide which has an aperture, to radiate the energy.

TYPES OF ANTENNAS

Antennas may be divided into various types depending upon −

- The physical structure of the antenna.
- The frequency ranges of operation.
- The mode of applications etc.

Physical structure

Following are the types of antennas according to the physical structure. You will learn about these antennas in later chapters.

- Wire antennas
- Aperture antennas
- Reflector antennas
- Lens antennas
- Micro strip antennas
- Array antennas

Frequency of operation

Following are the types of antennas according to the frequency of operatio:.

- Very Low Frequency (VLF)
- Low Frequency (LF)
- Medium Frequency (MF)
- High Frequency (HF)
- Very High Frequency (VHF)
- Ultra-High Frequency (UHF)
- Super High Frequency (SHF)
- Micro wave
- Radio wave

Mode of Applications

Following are the types of antennas according to the modes of applications:

- Point-to-point communications
- Broadcasting applications

- Radar communications
- Satellite communications

Introduction to IOT

The internet of things, or IoT, is a system of interrelated computing devices, mechanical and digital machines, objects, animals or people that are provided with unique identifiers (UIDs) and the ability to transfer data over a network without requiring human-to-human or human-to-computer interaction. It may also refer to the billions of physical devices around the world that are now connected to the internet, all collecting and sharing data.

A ***thing*** in the internet of things can be a person with a heart monitor implant, a farm animal with a biochip transponder, an automobile that has built-in sensors to alert the driver when tire pressure is low or any other natural or man-made object that can be assigned an Internet Protocol (IP) address and is able to transfer data over a network.

Increasingly, organizations in a variety of industries are using IoT to operate more efficiently, better understand customers to deliver enhanced customer service, improve decision-making and increase the value of the business.

How IOT works?

An IoT ecosystem consists of web-enabled smart devices that use embedded systems, such as processors, sensors and communication hardware, to collect, send and act on data they acquire from their environments. IoT devices share the sensor data they collect by connecting to an IoT gateway or other edge device where data is either sent to the cloud to be analyzed or analyzed locally. Sometimes, these devices communicate with other related devices and act on the information they get from one another. The devices do most of the work without human intervention, although people can interact with the devices -- for instance, to set them up, give them instructions or access the data.

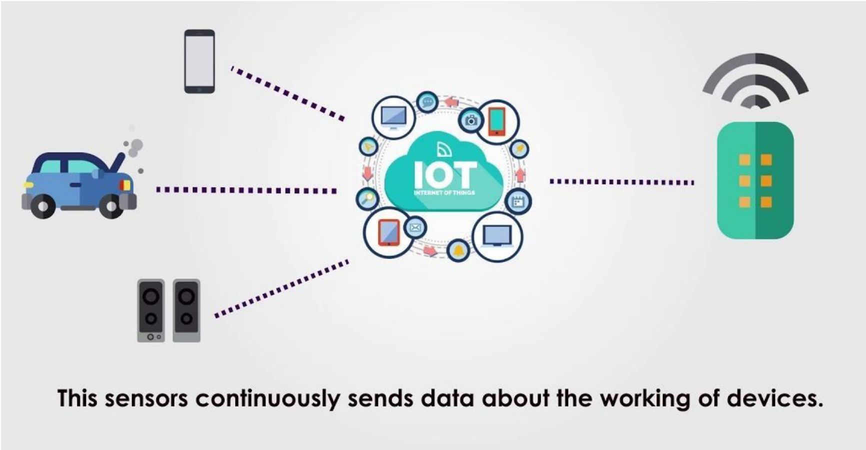

Figure 3.3: Working of IOT

Existing system

In existing system, tracking capability of a control system is critical. Antenna are controlled manually which is time consuming and accuracy was less. Place the antenna to the exact angle to obtain the full signal of a given frequency and it requires manual adjustment. Antennas are stationary and are not allowed to receive the signals which have gone the particular degree beyond the antenna is capable to receive the signal.

Disadvantages:

- Since the antennas are set manually, it is time consuming and less accurate.
- Number of antennae required is more.
- High cost and man labour is required.
- Antennas are inflexible and failed to receive the signals from all the direction.

Proposed system

Hence, we propose an antenna positioning system which enables antennas to be placed remotely over IoT. Because the position of the transmitting station changes over time even the position of the antenna should be changed accordingly. The signal received by antennas is affected by the direction of transmitting stations those changes over time so there is a need of system that Automatically changes the antenna positioning if there is any change in transmitting station over time [9]. This is used by measuring the degree of command from remote and input to drive the motor at the desired degree.

Advantages:

- Use of an IOT application to control the positioning of antenna around the globe.
- The device can receive signals from all directions.
- Increase in the range of detection.
- Decrease in man power and less time consuming.
- Increase in accuracy of the signal.
- Decrease in the number of antennas.

Block diagram of the project

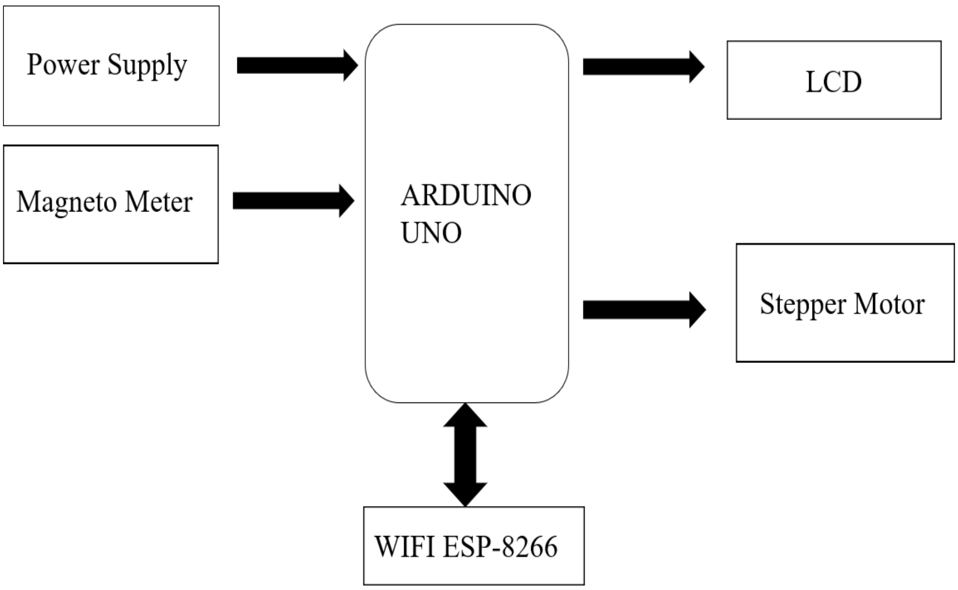

Figure 3.4: Block diagram of the project

Explanation

The power supply is given to the system, the magnetometer is considered for the direction of the antenna. When the magnetometer is moved in a certain angle the Arduino which is being programmed acts as the medium, sends the information to the stepper motor, LCD and the wi-fi module. The various acts that take place after receiving the signal from the Arduino, (1) there a rotation of the stepper motor in the desired axis with a considerable amount of change in angle (2) the LCD displays the amount to angle change and the direction of the shift (3) the wi-fi module receives the signal and notifies the user with the amount of change in angle and axis in the form of message into the mobile application.

There is another way to access the rotation of antenna with the help of mobile application. A command is given through the application for rotation. A "*" is given for the rotation of clockwise direction & "#" is given for the rotation of anti-clockwise direction.

CHAPTER-4

SOFTWARE DESCRIPTION

Introduction to proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting a new design

Step 1: Open ISIS software and select new design in File menu

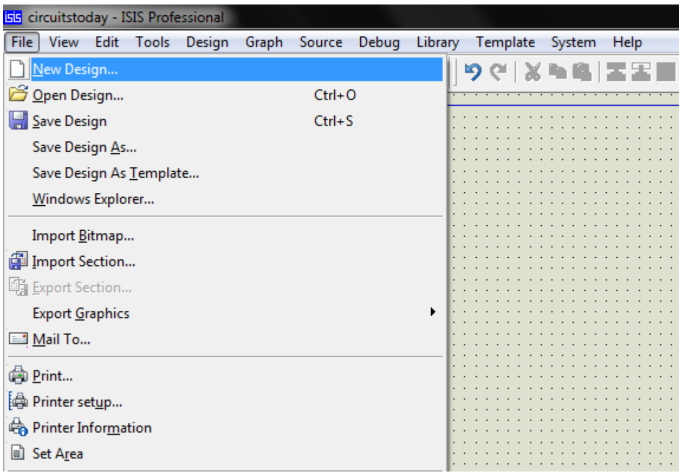

Figure 4.1: Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

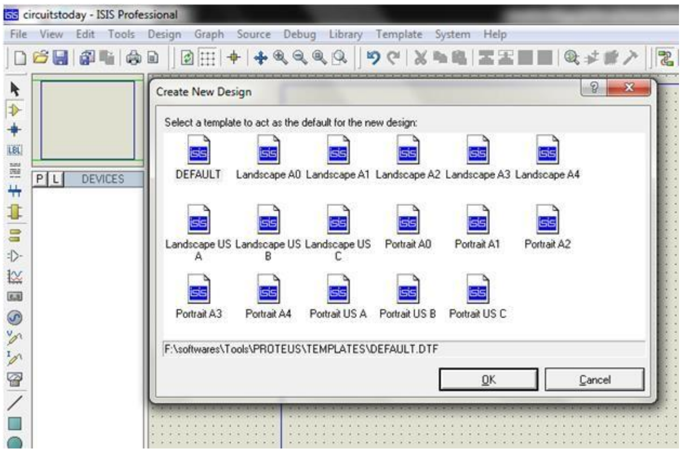

Figure 4.2: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

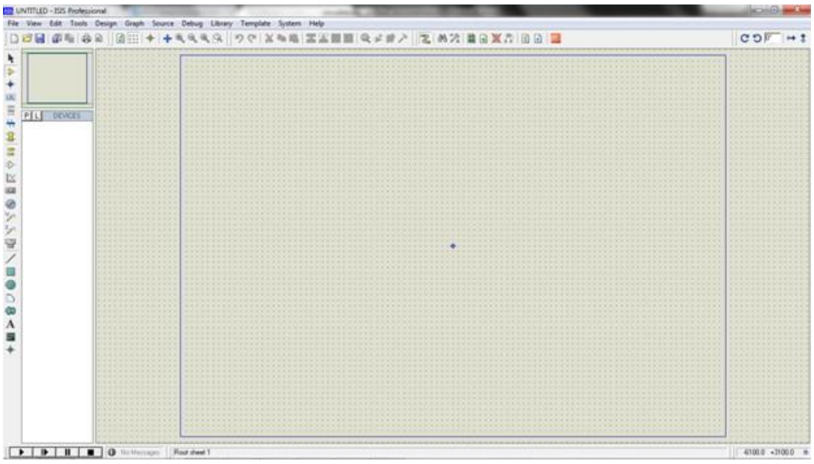

Figure 4.3: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

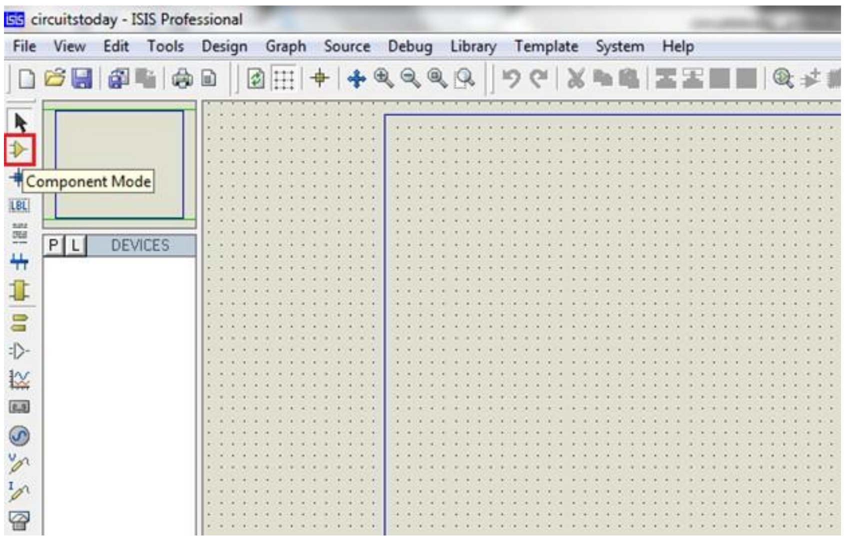

Figure 4.4: Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

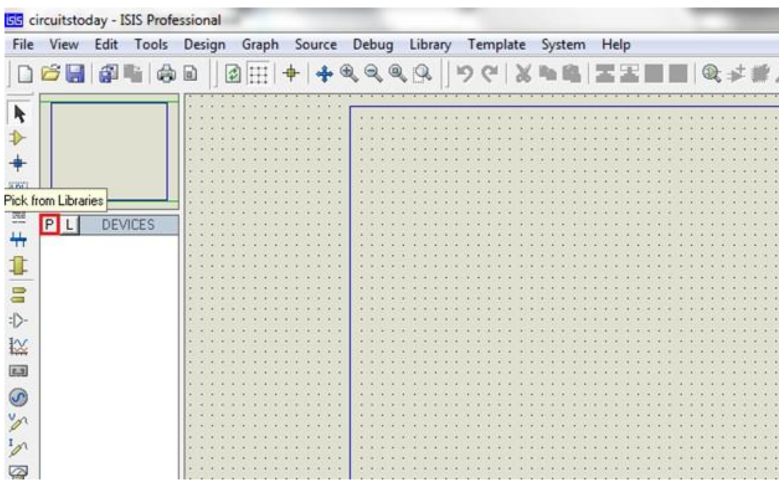

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

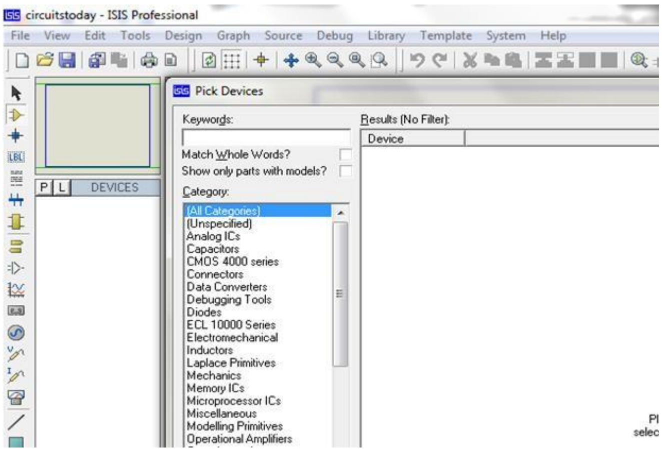

Figure 4.6: Keywords Textbox

Example shows selection of push button. Select the components accordingly.

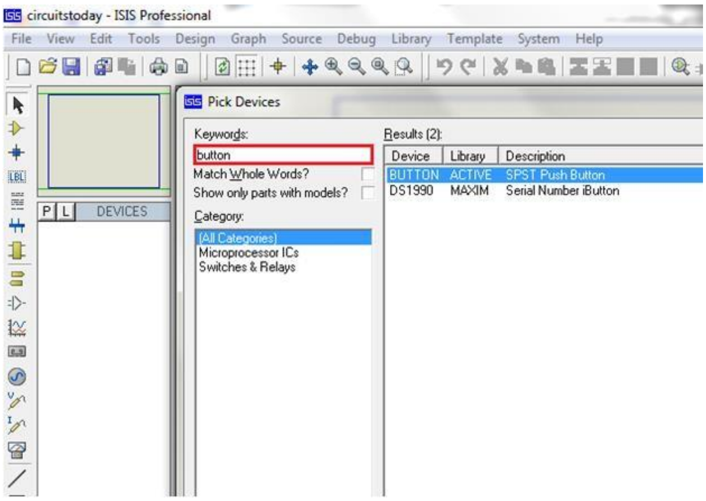

Figure 4.7: Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

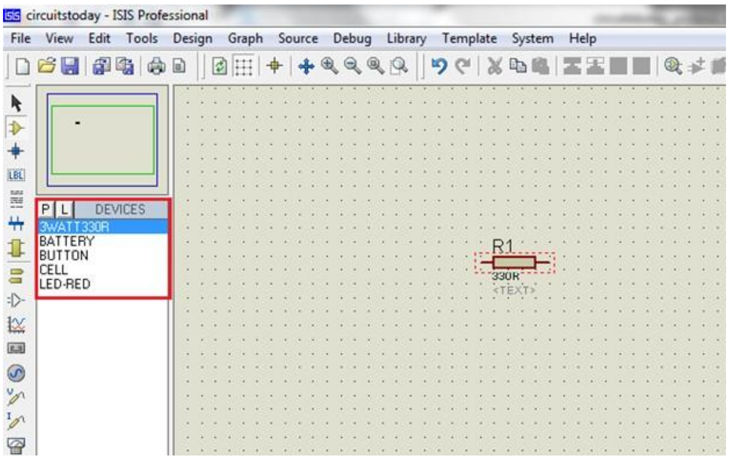

Figure 4.8: Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

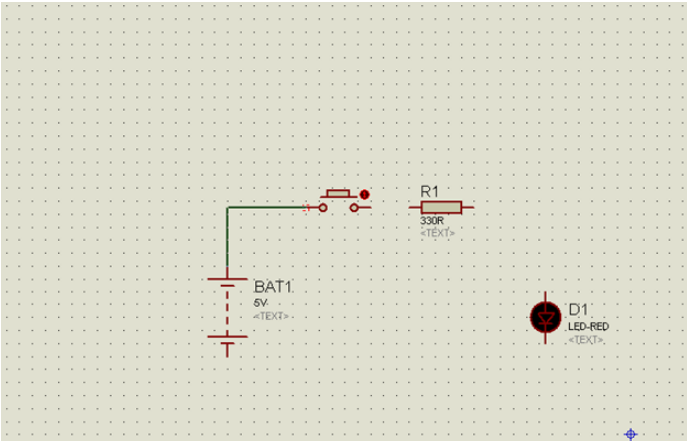

Figure 4.9: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

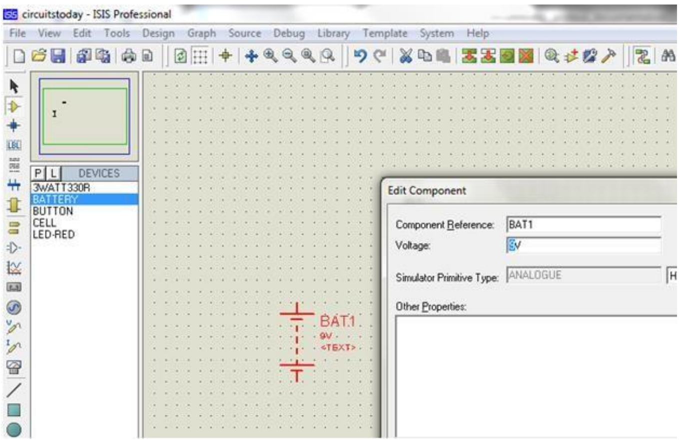

Figure 4.10: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

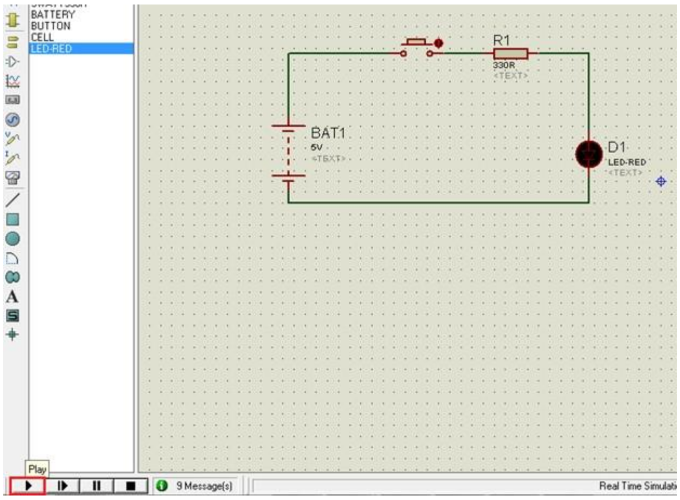

Figure 4.11: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

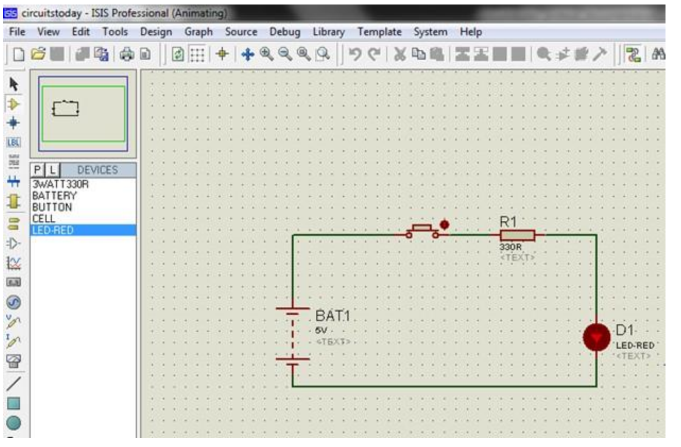

Figure 4.12: Simulation Animating

Simulation can be stepped, paused or stopped at any time.

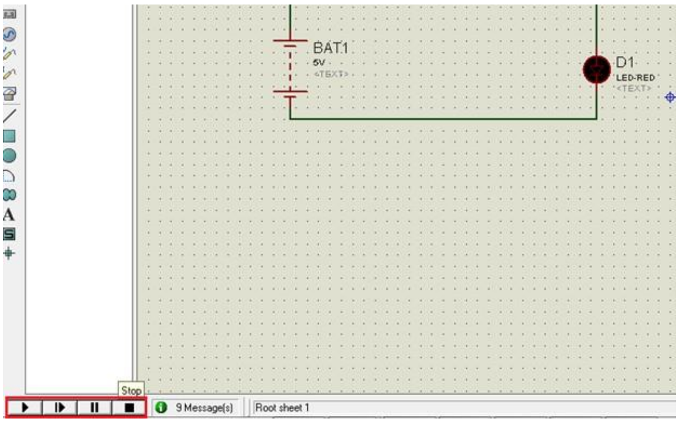

Figure 4.13: Simulation Step-Pause-Stop Buttons

Arduino IDE

The Arduino Integrated Development Environment (IDE) is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago
Repository	github.com/Arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux

Table 4.1: Arduino IDE description

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

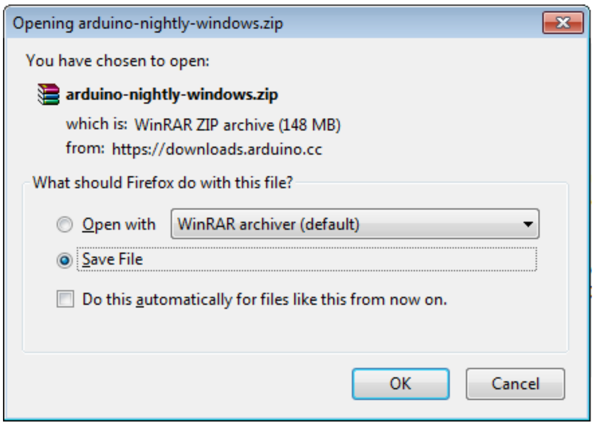
Figure 4.14: USB cable B plug

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Figure 4.15: USB cable A plug

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



Opening arduino-nightly-windows.zip

You have chosen to open:

arduino-nightly-windows.zip

which is: WinRAR ZIP archive (148 MB)

from: https://downloads.arduino.cc

What should Firefox do with this file?

Open with WinRAR archiver (default)

Save File

Do this automatically for files like this from now on.

OK Cancel

Figure 4.16: Downloading program

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

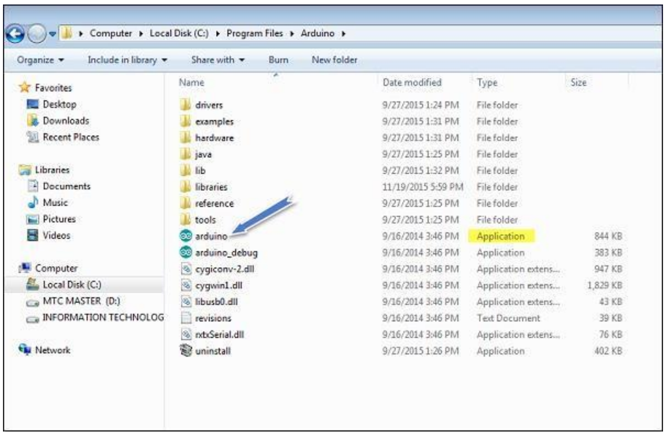


Figure 4.17: Launching the software

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

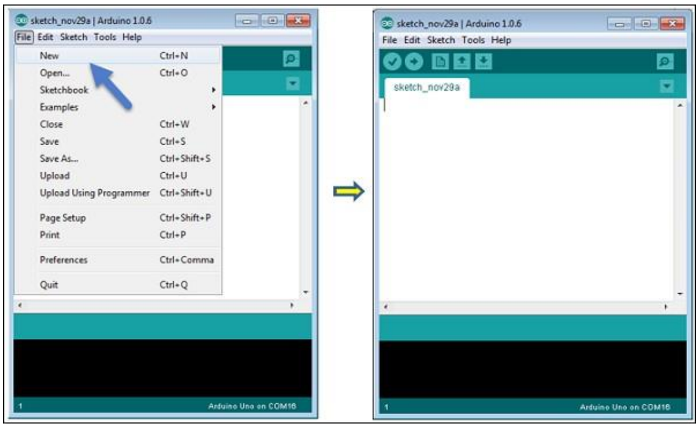

Figure 4.18: open new project

To open an existing project example, select File → Example → Basics → Blink.

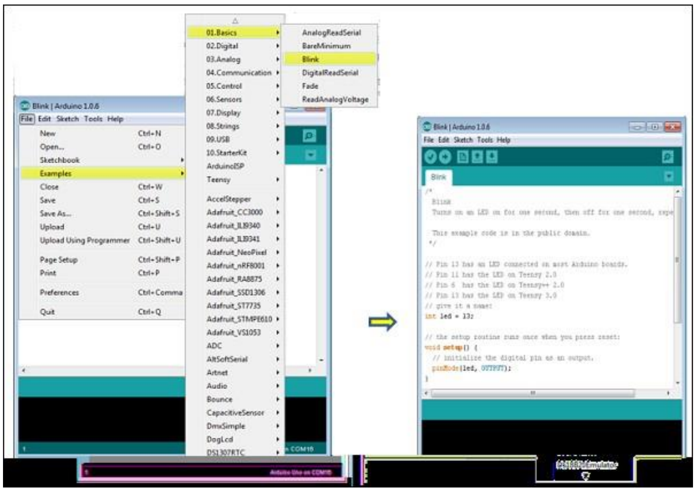

Figure 4.19: open new project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

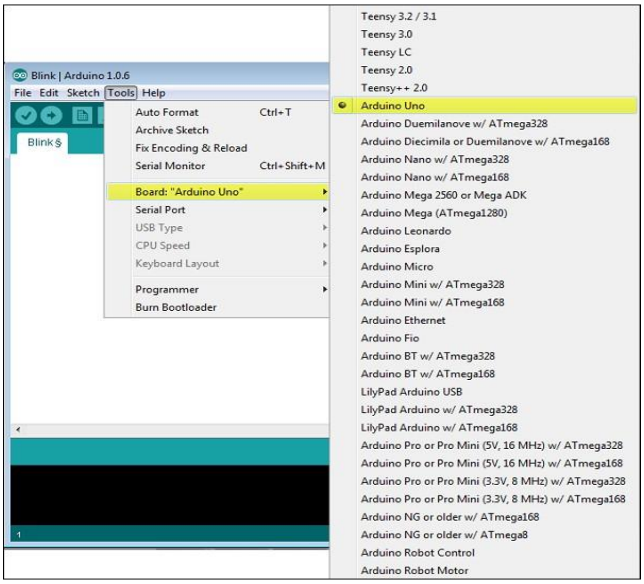

Figure 4.20: selecting board type

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

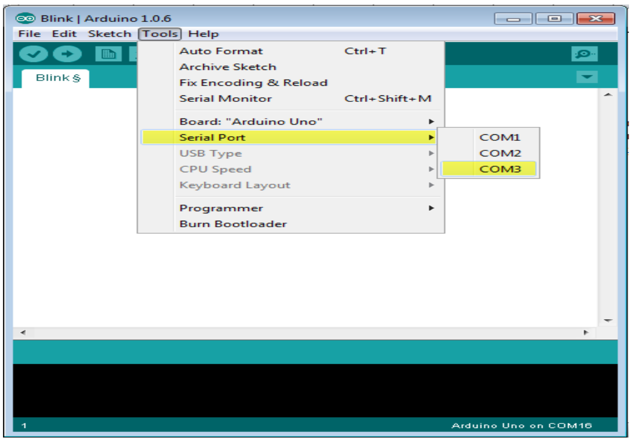

Figure 4.21: selection of port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

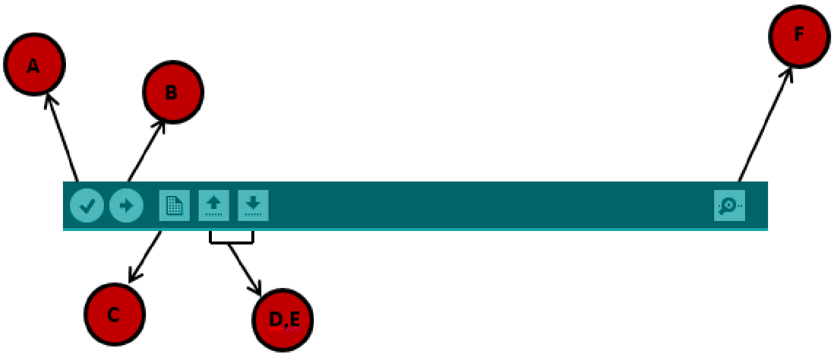

Figure 4.22: uploading the program

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

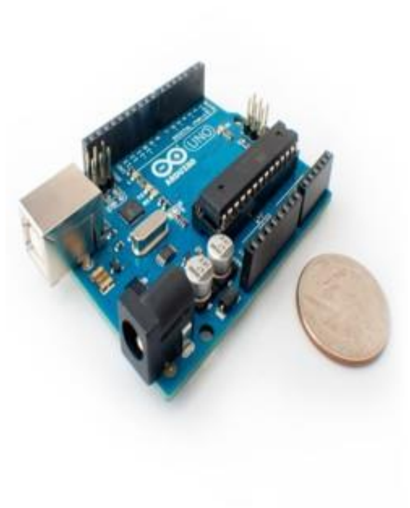
CHAPTER-5

HARDWARE DESCRIPTION

Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board. The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.



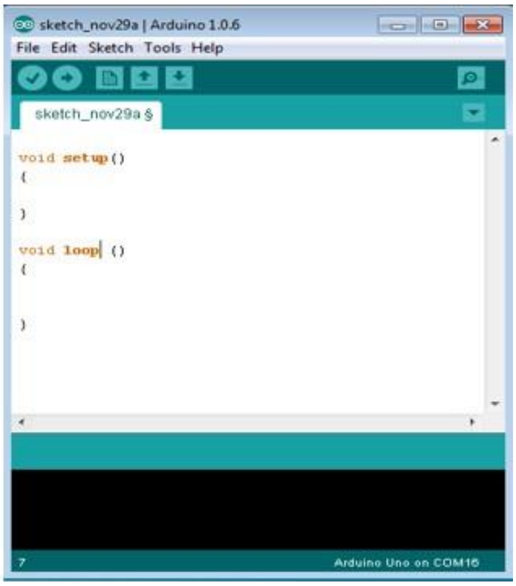


Figure 5.1: Arduino board and program page

Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE. The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

Board Description

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

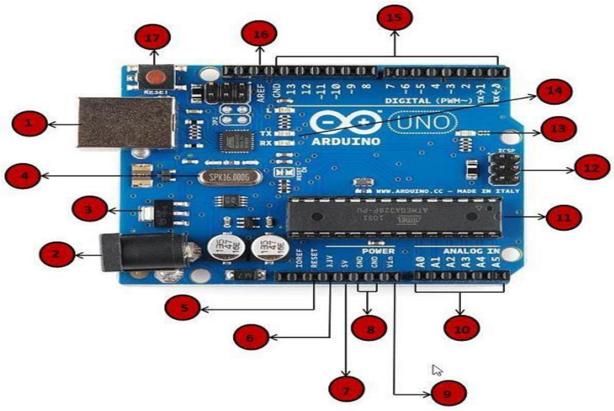

Figure 5.2: Arduino UNO

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed

	on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.

13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 5.5: pin configuration and description

Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

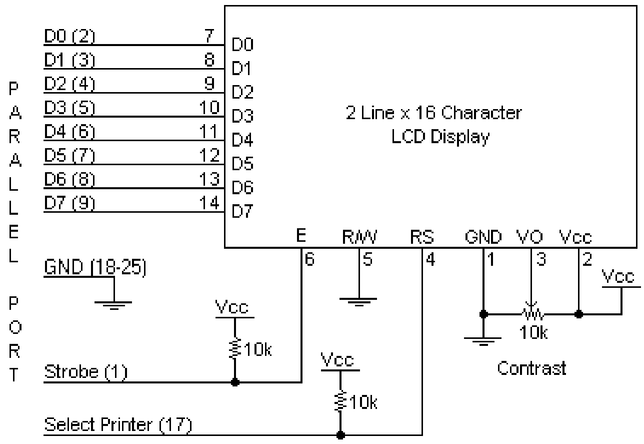

Figure 5.3: Schematic diagram of LCD

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

SPECIFICATIONS:

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table 5.6: Specification of LCD

Pin Description:

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers has 16 Pins (two pins are extra in both for back-light LED connections).

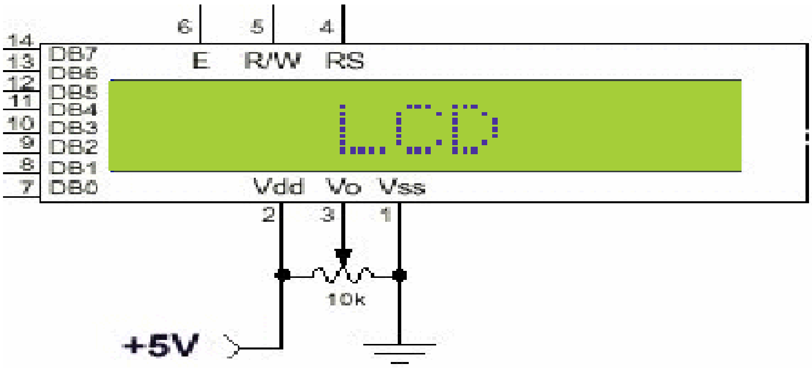

Figure 5.4: Pin diagram of 1x16 lines LCD

Control lines

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are writing commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF

C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table 5.7: Commands

Stepper Motor

Stepper motors are DC motors that move in discrete steps. They have multiple coils that are organized in groups called "phases". By energizing each phase in sequence, the motor will rotate, one step at a time.

With a computer controlled stepping you can achieve very precise positioning and/or speed control. For this reason, stepper motors are the motor of choice for many precision motion control applications. Stepper motors come in many different sizes and styles and electrical characteristics.

How Stepper Motor Works?

Stepper motors are very different from a regular DC motor. Instead of spinning like DC motors do, stepper motor steps at a specific resolution for each pulse. The motor that we are using needs 48 steps / pulses just to complete a single revolution! That should be enough to talk about its precision.

Another advantage of stepper motors is the fact that their speed of rotation can be achieved almost instantly even if you change the spinning direction. Stepper motor consists of a **rotor** - the permanent magnet that rotates inside, and **stator** - four coils (north, east, south, west) that are part of the case, and which **don't move**. Rotor can be moved by sequentially applying a pulsed DC voltage to one or two coils at a time.

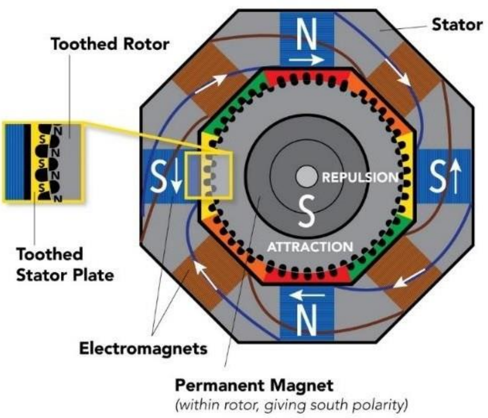

Figure 5.5: Working of stepper motor

Stepper Motor Connections

Unipolar motor should have five or six connections depending on the model. If the motor has six connections like the one pictured above, you have to join pins 1 and 2 (red) together and connect them to a (+) 12-24V voltage supply. The remaining pins; a1 (yellow), b1 (black), a2 (orange), b2 (brown) should be connected to a driver (ULN2003) as shown on the schematic.

Working

Frame 1: The top electromagnet (1) is turned on, attracting the nearest tooth of a gear-shaped iron rotor. With the teeth aligned to electromagnet 1, they will be slightly offset from electromagnet 2. **Frame 2:** The top electromagnet (1) is turned off, and the right electromagnet (2) is energized, pulling the nearest teeth slightly to the right. This results in a rotation of 3.6° in this example. **Frame 3:** The bottom electromagnet (3) is energized; another 3.6° rotation occurs. **Frame 4:** The left electromagnet (4) is enabled, rotating again by 3.6°. When the top electromagnet (1) is again enabled, the teeth in the sprocket will have rotated by one tooth position; since there are 25 teeth, it will take 100 steps to make a full rotation in this example.

A stepper motor (or step motor) is a brushless, synchronous electric motor that can divide a full rotation into a large number of steps. The motor's position can be controlled precisely without any feedback mechanism (see Open-loop controller), as long as the motor is carefully sized to the application. Stepper motors are similar to switched reluctance motors (which are very large stepping motors with a reduced pole count, and generally are closed-loop commutated.)

TYPES

There are three main types of stepper motors:

1. Permanent Magnet Stepper
2. Hybrid Synchronous Stepper
3. Variable Reluctance Stepper

Permanent magnet motors use a permanent magnet (PM) in the rotor and operate on the attraction or repulsion between the rotor PM and the stator electromagnets. Variable reluctance (VR) motors have a plain iron rotor and operate based on the principle of that minimum reluctance occurs with minimum gap, hence the rotor points are attracted toward the stator magnet poles. Hybrid stepper motors are named because they use a combination of PM and VR techniques to achieve maximum power in a small package size.

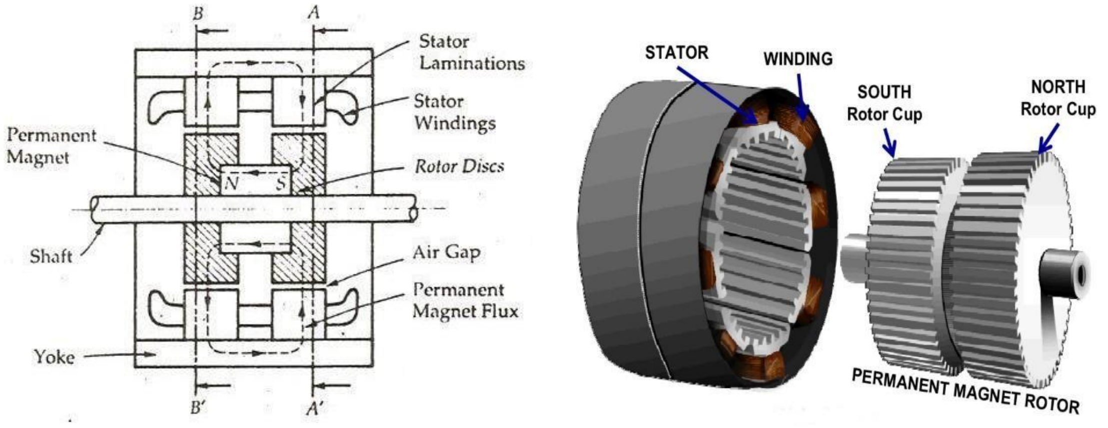

Figure 5.6: Permanent Magnet Stepper Hybrid Synchronous Stepper

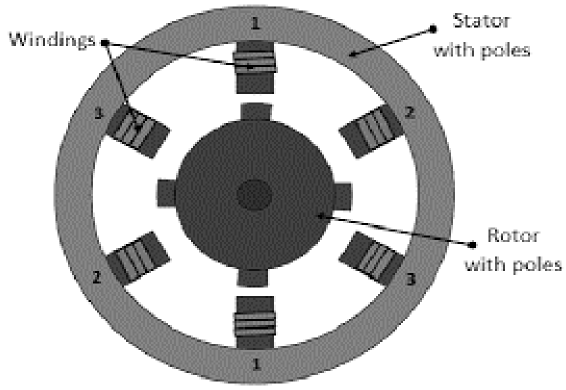

Figure 5.7: Variable reluctance stepper

►Connecting Stepper Motor

There are actually many ways you can interface a stepper motor to your controller, out of them the most used interfaces are:

1. Interface using L293D - H-Bridge Motor Driver
2. Interface using ULN2003/2004 - Darlington Arrays

We will discuss both connection techniques one by one. The above-mentioned methods need 4 controller pins for interface.

► Connecting stepper using L293D

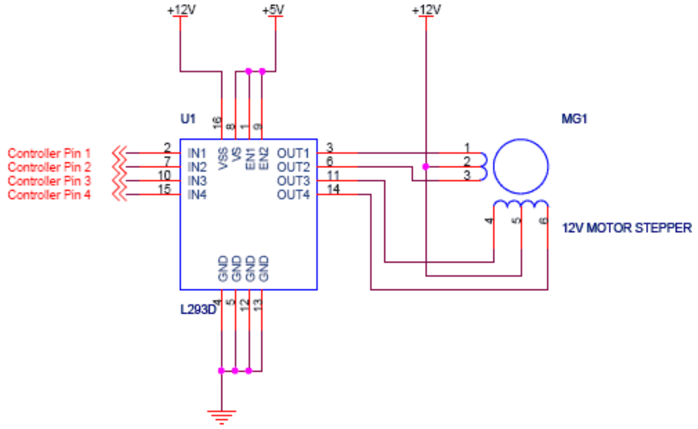

Figure 5.8: Connecting unipolar stepper using L293D

As you see in the circuit above the four pins "Controller pin 1",2,3 and 4 will control the motion and direction of the stepper motor according to the step sequence programmed in the controller.

➢ Connecting stepper using ULN2003/2004 - Darlington Arrays

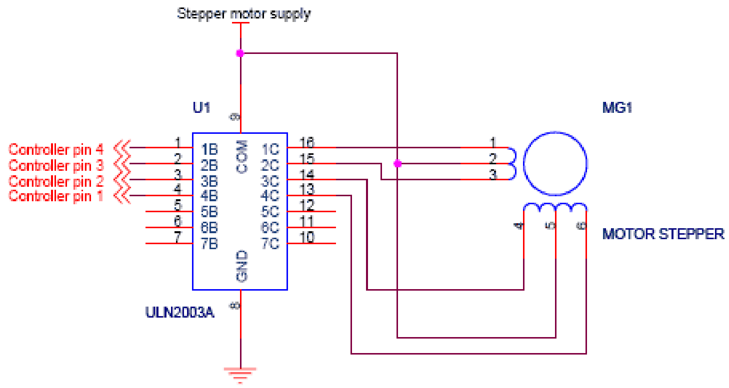

Figure 5.9: Connecting unipolar stepper using ULN2003/2004

here in this circuit too the four pins "Controller pin 1", 2, 3 and 4 will control the motion and direction of the stepper motor according to the step sequence sent by the controller. 8051 Microcontroller receives the decoded data through the input port of 8255 and process the data according to the control software to generate the control signal for the stepper motor to rotate at the desired angular position. The control signal goes to motor driver ULN 2003 to drive the stepper motor. [5]

Magneto Metre

A magnetometer is a device that measures magnetic field or magnetic dipole moment. Some magnetometers measure the direction, strength, or relative change of a magnetic field at a particular location. A compass is one such device, one that measures the direction of an ambient magnetic field, in this case, the Earth's magnetic field. Other magnetometers measure the magnetic dipole moment of a magnetic material such as a ferromagnet.

The first magnetometer capable of measuring the absolute magnetic intensity at a point in space was invented by Carl Friedrich Gauss in 1833 and notable developments in the 19th century included the Hall effect, which is still widely used.

Magnetometers are widely used for measuring the Earth's magnetic field, in geophysical surveys, to detect magnetic anomalies of various types, and to determine the dipole moment of magnetic materials. In an aircraft's attitude and heading reference system, they are commonly used as a heading reference. Magnetometers are also used by the military in magnetic mines to detect submarines.

Magnetometers can be used as metal detectors: they can detect only magnetic (ferrous) metals, but can detect such metals at a much larger depth than conventional metal detectors; they are capable of detecting large objects, such as cars, at tens of metres, while a metal detector's range is rarely more than 2 metres.

In recent years, magnetometers have been miniaturized to the extent that they can be incorporated in integrated circuits at very low cost and are finding increasing use as miniaturized compasses (MEMS magnetic field sensor).

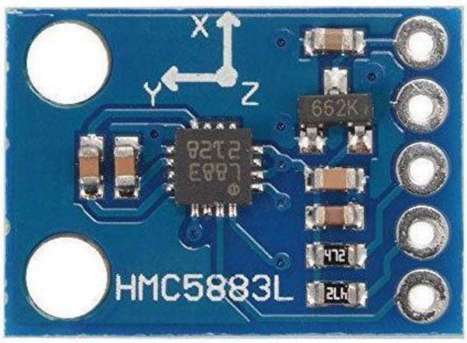

Figure 5.10: Magnetometer

Types of magnetometers

The Magnetometer experiment for the Juno orbiter for Juno can be seen here on the end of a boom. The spacecraft uses two fluxgate magnetometers. (See, also Magnetometer (Juno))

There are two basic types of magnetometer measurement. Vector magnetometers measure the vector components of a magnetic field. Total field magnetometers or scalar magnetometers measure the magnitude of the vector magnetic field. Magnetometers used to study the Earth's magnetic field may express the vector components of the field in terms of declination (the angle between the horizontal component of the field vector and magnetic north) and the inclination (the angle between the field vector and the horizontal surface).

Absolute magnetometers measure the absolute magnitude or vector magnetic field, using an internal calibration or known physical constants of the magnetic sensor. Relative magnetometers measure magnitude or vector magnetic field relative to a fixed but uncalibrated baseline. Also called variometers, relative magnetometers are used to measure variations in magnetic field.

Magnetometers may also be classified by their situation or intended use. Stationary magnetometers are installed to a fixed position and measurements are taken while the magnetometer is stationary. Portable or mobile magnetometers are meant to be used while in motion and may be manually carried or transported in a moving vehicle. Laboratory magnetometers are used to measure the magnetic field of materials placed within them and are typically stationary. Survey magnetometers are used to measure magnetic fields in geomagnetic surveys; they may be fixed base stations, as in the INTERMAGNET network, or mobile magnetometers used to scan a geographic region.

Performance and capabilities

The performance and capabilities of magnetometers are described through their technical specifications. Major specifications include

- Sample rate is the number of readings given per second. The inverse is the cycle time in seconds per reading. Sample rate is important in mobile magnetometers; the sample rate and the vehicle speed determine the distance between measurements.
- Bandwidth or bandpass characterizes how well a magnetometer tracks rapid changes in magnetic field. For magnetometers with no onboard signal processing, bandwidth is determined by the Nyquist limit set by sample rate. Modern magnetometers may perform smoothing or averaging over sequential samples, achieving a lower noise in exchange for lower bandwidth.

- Resolution is the smallest change in a magnetic field the magnetometer can resolve. A magnetometer should have a resolution a good deal smaller than the smallest change one wishes to observe.
- Quantization error is caused by recording roundoff and truncation of digital expressions of the data.
- Absolute error is the difference between the readings of a magnetometer true magnetic field.
- Drift is the change in absolute error over time.
- Thermal stability is the dependence of the measurement on temperature. It is given as a temperature coefficient in units of nT per degree Celsius.
- Noise is the random fluctuations generated by the magnetometer sensor or electronics.
- Sensitivity is the larger of the noise or the resolution.
- Heading error is the change in the measurement due to a change in orientation of the instrument in a constant magnetic field.
- The dead zone is the angular region of magnetometer orientation in which the instrument produces poor or no measurements. All optically pumped, proton-free precession, and Over Hauser magnetometers experience some dead zone effects.
- Gradient tolerance is the ability of a magnetometer to obtain a reliable measurement in the presence of a magnetic field gradient. In surveys of unexploded ordnance or landfills, gradients can be large.

WIFI ESP8266:

Description

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers. The ESP8266 module is an extremely cost-effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existence interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

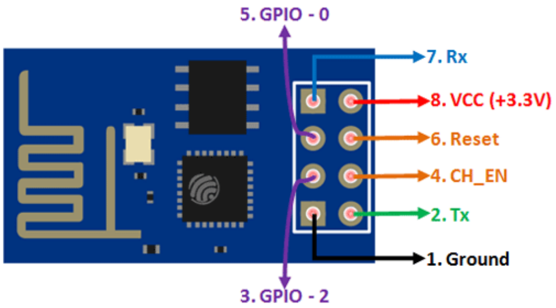

Figure 5.11: Pin configuration of the wi-fi module

Features

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)
- Default baud rate: 115200

CHAPTER-6

PROJECT DESCRIPTION

Schematic diagram of the project

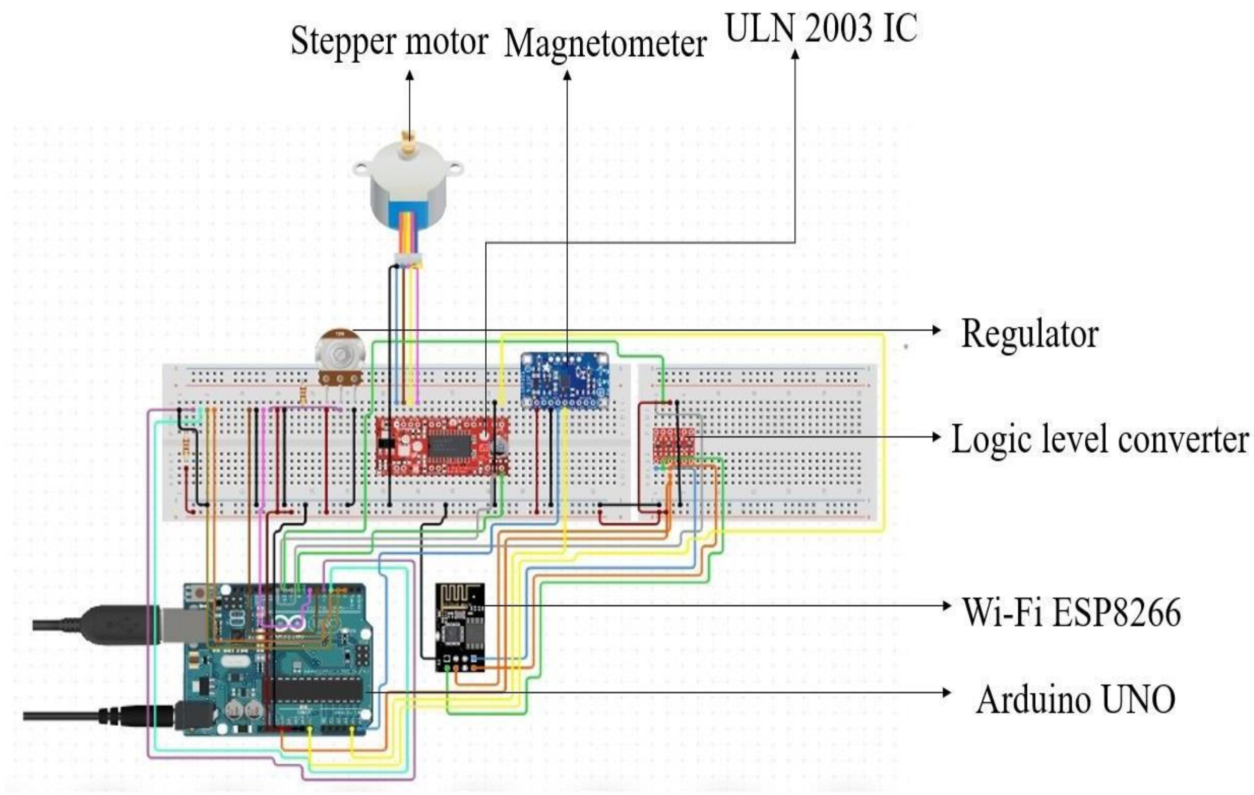

Figure 6.1: Schematic diagram of the project

The Arduino UNO is dumped with a desired code and is connected to the circuit with the help of the USB cable type B. The Arduino is now connected to the logic level converter to converter the user understandable(dumped), into the system understandable code to be executed. The A3, A4, A5 pins are considered as the connection of input and output of the X-axis, Y-axis and the Z-axis respectively. Now the logic level converter is connected to the wi-fi module and takes the input from it, which acts as a two-way wi-fi connection. The wi-fi is turned ON and the Arduino output pins are connected to the input port of the ULN2003IC, which performs the electrical form to the mechanical form of energy to be provided to the stepper motor and vice-verse from the stepper motor to the system. The regulator and capacitor are used for the stepping down of the voltage. The magnetometer is handled as the moving object to determine the direction of the antenna movement, as it moves the signal is sent to the Arduino, where it decides the angle of the change in the rotation and varies accordingly. The output pins of the ULN2003IC are connected to the stepper motor and give the appropriate angle of rotation to the stepper motor to rotate.

Flow chart and description

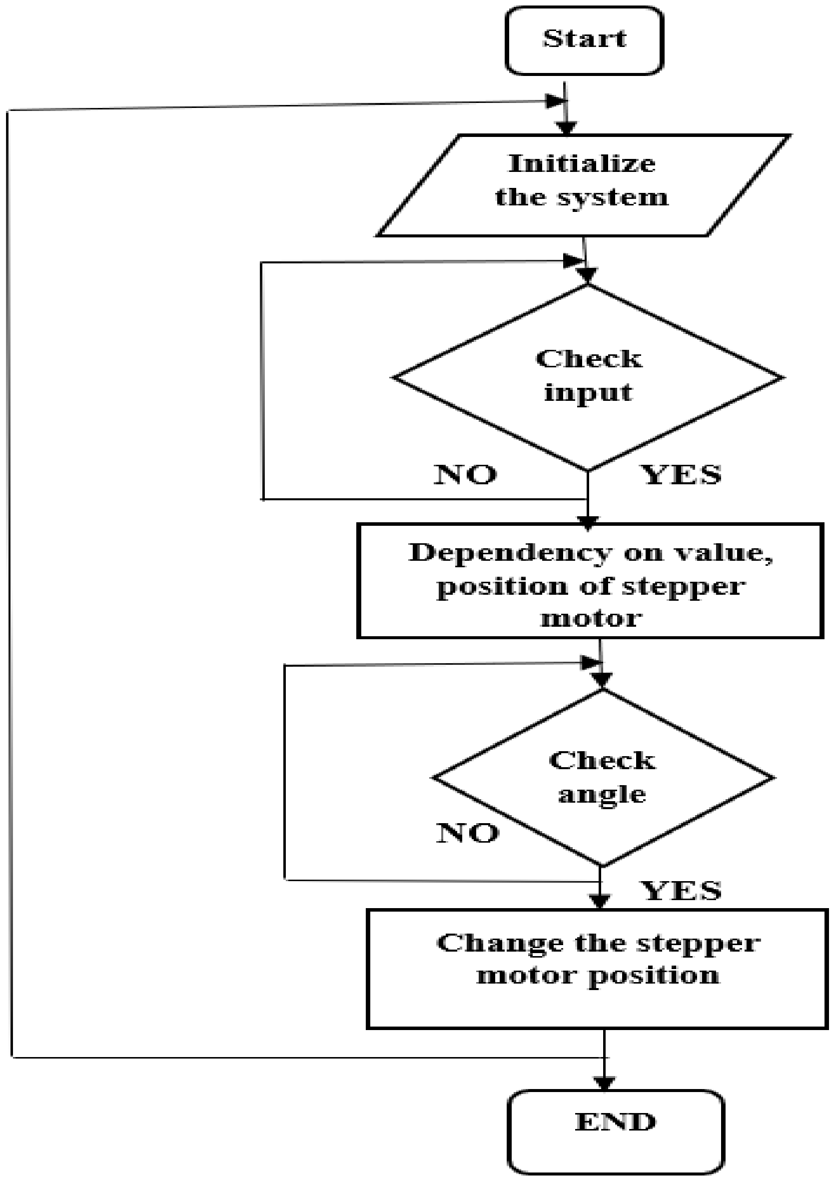

Figure 6.2: Flow chart of the code

- STEP-1: The system is turned ON and initialised.
- STEP-2: The input is checked given either from the magnetometer or the mobile application (Telnet). If No input, it returns back to the initialised stage. If YES input, then it moves to the next stage.
- STEP-3: Moving on to the next step, depending on the value of the input the system verifies the position of the stepper motor, whether to rotate or not.
- STEP-4: The angle of input is checked with the angle of stepper motor. If NO input change, the system returns to the step-3. If YES input change, it moves on to the step-5

- STEP-5: The stepper motor changes the amount of angle given as the input buy the user.
- STEP-6: The system then ends the program of execution and returns to the initialised position of the system simultaneously.

Output

There are 2 ways of varying the antenna position with an angle as the output:

1. From the magnetometer
2. From the mobile application

1. From the magnetometer

The magnetometer is kept in a constant position considering it as the Z-axis and when it is moved, there 2 cases occurring:

- When the magnetometer is moved in the forward direction (X-axis direction), the stepper motor moves in the clockwise direction.
- When the magnetometer is moved in the backward direction (Y-axis direction), the stepper motor moves in the anti- clockwise direction.

2. From the mobile application

There mobile TELNET application, the user can operate and rotate the antenna in 2 cases:

- When the user gives * <degree of angle change> then the antenna is rotated in the clockwise direction.

  Example: *16, the antenna is moved with 16 degrees in clockwise direction.
- When the user gives #<degree of angle change> then the antenna is rotate in the anti-clockwise direction.

  Example: #32, the antenna is moved with 32 degrees in anti-clockwise direction.

CHAPTER-7

RESULTS

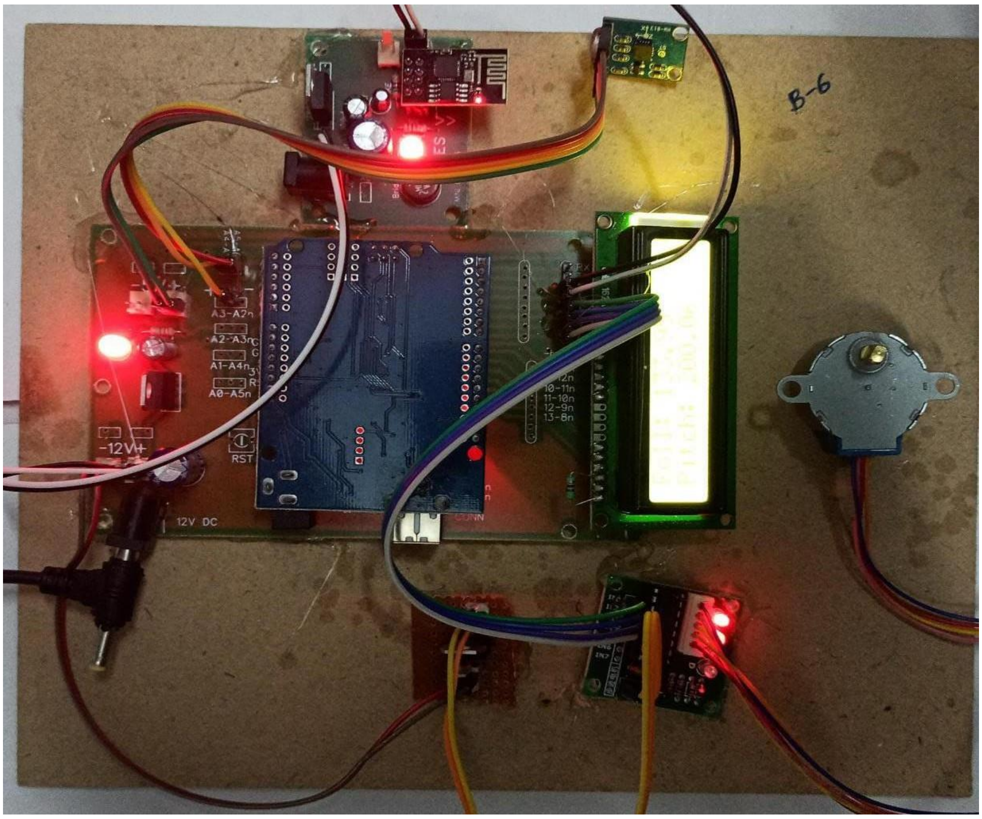

Figure 7.1: The circuit kit of the project

The Arduino UNO is connected to the system with a required code dumped in it. The LCD is displaying the variation of the angle and the direction of the movement. The stepper motor is rotated accordingly. The wi-fi module is providing the system with the wireless communication task like the mobile hotspot in our daily life.

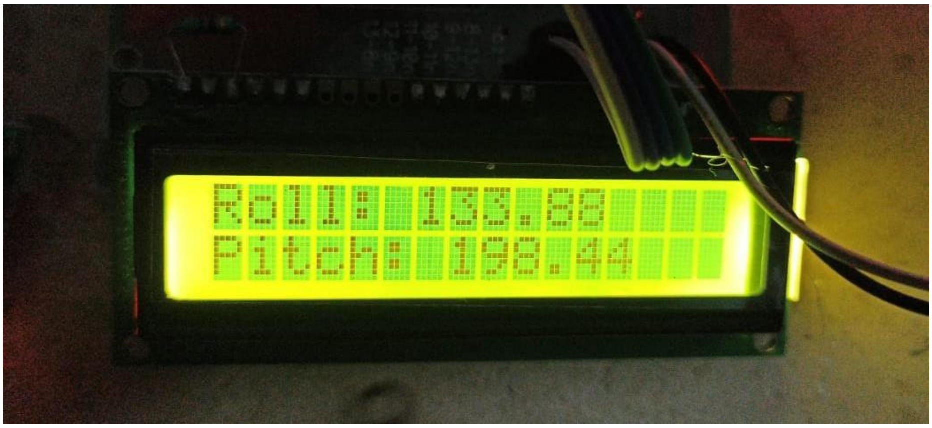

Figure 7.2: LCD displaying the angle

Here, the roll refers to the angle after the rotation in a particular direction with the reference being the Z-axis and the pitch refers to the total angle of rotation of the Z-axis when moved in other direction.

Figure 7.3: LCD displaying the direction of rotation

The position of the antenna after rotation being stable is being determined and displayed on the LCD and the direction of the antenna facing is also being shown up on the LCD for a brief report of the user understanding.

CHAPTER-8

CONCLUSION

Conclusion

The IOT is a latest and emerging technology with great significance in every domain of life. The proposed system describes the implementation of latest technologies in antenna positioning. This model allows for monitoring antenna direction as well as transmitting new coordinates to position the antenna and motor appropriately positions the antenna accordingly. IoT and microcontrollers are the most common and important technical concepts in every field of life. IoT based antenna positioning system can be beneficial in remote areas.

The Automatic Antenna Positioning System primarily functions to spot the presence of any signal. The automatic antenna positioning system is also used to position the antenna without any human interface it automatically positions itself depending upon the received signal strength. The antenna position mainly depends upon the precision of the motor. So as to beat the problem of adjusting manually, this planned system helps in adjusting the position of the antenna.

Future enhancements

- AI can be a big player here in this field. Moreover, new self-defence mechanisms will securitise IoT as well. All these connected devices will make IoT robust. Also, confirming some standard communication protocols will help in betterment of IoT security.
- The future of IoT has the potential to be limitless. Advances to the industrial internet will be accelerated through increased network agility, and the capacity to deploy, automate, orchestrate and secure diverse use cases at hyperscale.
- This may increase the need of the big data into play. Where every small detail of the IOT devices and usage is stored.
- Modification in the motors and the sensor to grasp maximum amount of the signal from every end.
- The maximum providence of the signal in a higher rate to meet the user’s need.
- The increase in the new variant of the element in the rotation of the antenna.

Code of execution

```
#include<SoftwareSerial.h>

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our Beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna, Head &Professor**, the Dept. of Electronics and Communication Engineering for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to Our Department **Project Coordinator Mr. K. Karthik** for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

Finally, we are highly grateful and obliged to our college level **Project Guide Ms. B. Shiny Sucharitha, Assistant Professor** in ECE for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

3. M. Ratnakar Reddy
4. Md. Azam Ali

ABSTRACT

Now a days due to easy availability of all the information on the internet, students are less motivated to attend the classes, due to which most of the students are unable to maintain minimum attendance. This work is to simplify the attendance recording system by using Radio Frequency Identification (RFID) technology. RFID based Attendance system with SMS notification System is developed to overcome the above stated problem.

The system will be developed by using GSM (Global System for Mobile communication) technology and google firebase database and android application support. The information from RFID Database handling System will be used for taking attendance and for sending SMS alerts also.

This System interacts with parents by sending messages. Therefore, the system functionality not only records the student attendance, but also sends alert SMS to their parents when the student is absent.

Data will be automatically sent to the Google Firestore Database Server by the ESP8266-01 Wi-Fi module which is connected to IP. when a proper connection is established with server, Android Application which will allow us to monitor and control the system. The Android Application gives the information about past and current Attendance.

Keywords- Internet of Things (IoT), Smart Attendance, RFID, GSM, Arduino Software, ESP8266-01 12E, Android Studio, Android Application and Google Firebase Database.

CHAPTER – 1

INTRODUCTION

OVERVIEW OF THE PROJECT

The goal of this project is to simplify attendance recording system by using Radio Frequency Identification technology. In the system, RFID Based Attendance System has ability to uniquely identify and take attendance of the students, in this user having RFID card which is an IC chip that has unique code contained in it and only need to place their RFID tag on the RFID reader to take attendance, and RFID reader is interfacing with Arduino Uno

Hence, it is a very time efficient system. Attendance will be taken if the RFID card ID matches the tagged ID which is predefined in memory. Otherwise, an error message will be displayed on LCD. And this attendance will send to the authorised contact which already predefined in memory via GSM module

The main aim of this paper is to design and implement an efficient Attendance system through which the required parameters are monitored remotely using internet and the data gathered ais stored in the google cloud database (Firebase) and to project the estimated trend on the Android application. A solution to simplify attendance recording system using wireless embedded computing system is proposed in this paper. This data is live updated to be viewed on the online server system.

Fig. 1.1: Overview of the project

OBJECTIVES OF THE PROJECT

The main objective of the RFID-based Attendance System project is to take the attendance of students or employees. The microcontroller does the task of storing the attendance of the respective person in the microcontroller memory. To demolish the flaws associated with the manual attendance system.

The immense potential of RFID based systems has been identified and explained in literature earlier. It will open the door to applications which were unthought of a few years ago. Also, the evolution of the technology and role of individual components has been explained in detail

The use of Wi-Fi module in RFID based systems has also been shown. Such a system significantly improves the current manual process of taking attendance in the University Environment. It also promotes a fully automated approach in monitoring the students in the Campus

SCOPE OF THE PROJECT

Main objective of RFID based Attendance System project is to take the attendance of students or employees. Microcontroller does the task of storing the attendance of the respective person in the Microcontroller memory. The existing attendance system is manual, and it is taken on paper, and it consumes lot of time.

Overcome the old attendance system which the attendance has to be taken manually. Design a database that supports such a system that has been mentioned earlier. Develop a smart attendance system that be implemented in classes, laboratory etc. by combining the software with the proposed hardware.

MATERIAL REQUIREMENT

HARDWARE REQUIREMENT

1. Arduino UNO R3
2. RC522 RFID Reader Module
3. SIM800L GSM Module
4. ESP8266-01 Wi-Fi Module
5. 16X2 I2C LCD Module
6. Power Adapter

SOFTWARE REQUIREMENT

1. Arduino IDE
2. Android Studio
3. Google Firebase Database CLI

INTRODUCTION TO EMBEDDED SYSTEMS

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor, or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

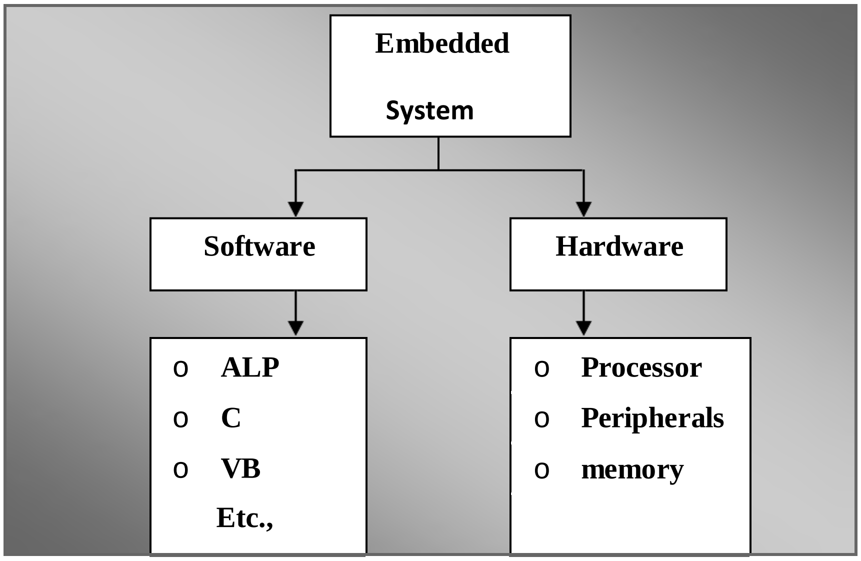

Fig 1.5 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types like:

- Micro Processor (μp)
- Micro controller (μc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

Micro Processor (μp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

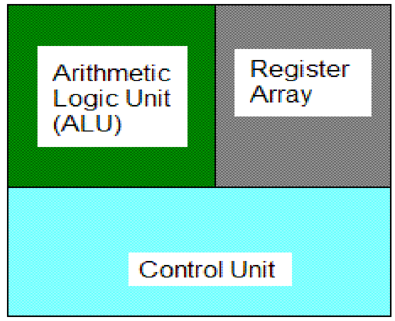

Figure 1.5.1 Three Basic Elements of a Microprocessor

Micro Controller (µc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the Microprocessors used in Personal computers or other general purpose applications.

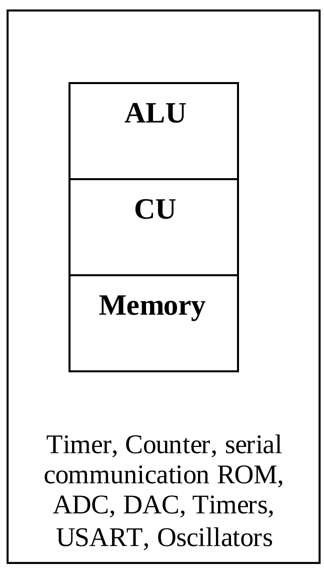

Figure 1.5.2 Block Diagram of Micro Controller (µc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program
- Analog circuits to provide clocks and interface to the real world
- I/Os to connect to external components like LEDs, memories, etc.

Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.
- The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

RISC characteristics

- **Simple instruction set:**

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- **Same length instructions.**

  Each instruction is the same length, so that it may be fetched in a single operation.

- **1machine-cycle instructions.**

  Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The Advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The Disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.
- CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

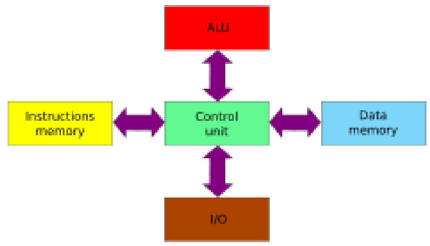

Figure 1.5.8 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where trade-offs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by

Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

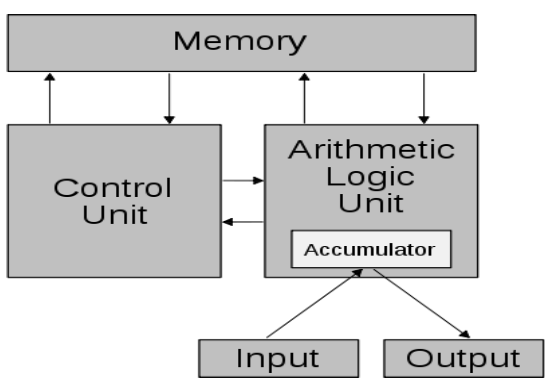

Figure 1.5.9 Schematic of the Von-Neumann Architecture

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER - 2

LITERATURE SURVEY

LITERATURE REVIEW ON RESEARCH AREA

Title : 1 RFID Attendance Monitoring System

RFID Attendance Monitoring System (2013), this system is an electronic device which is use in attendance management system by faculty members. It provides robust, secure and automatic attendance administration in faculties.

Radio-Frequency Identification Attendance Monitoring has programmed RFID software specially for optimizing attendance tracking. Thus, combined RFID hardware with this software, it automates the whole system.

Title :2 RFID Technology Based Attendance Management System

According to Sumita Nainan and et.al (2013), the primary aim of the research is to uniquely identify individual students based on their unique tag identifiers. The research should shower light on how scalable and efficient the system is. A systematic and serialised approach is required to solve this conundrum. The key characteristics of the application include; Perform automated attendance, Generate report of attendees for a particular course, Error free tag identifier detection, Easy scalability to incorporate more records, Integrity and security in data storage.

This paper concentrates on the principal purpose to overcome the human errors while recording student attendance and the creation of a data centric student attendance database system with an improved overall efficiency.

Title : 3 School of Information Technology Faculty Monitoring using Radio Frequency Identification (RFID)

According to Justin Lee and et.al (2013), this study was to improve the faculty monitoring of University of Baguio in School of Information Technology Department. This helps the Student Assistant to easily locate the Faculty Members if needed and can generate a summary report. This may also lessen the tardiness of Faculty Members. RFID systems also provide good personal security access to confidential data's.

REVIEW OF RELATED WORKS

A number of related works exist in literature, application of RFID Technology to different areas and specifically to the area of academic attendance monitoring problem. In [6], authors designed and implemented a model of a secured and portable embedded reader system to read the biometric data from the electronic passport. The authors attempted to solve problems of reliability, security and privacy in E-passports by authenticating holder online using Global System of Mobile Communications (GSM) network.

The GSM network is the main interface between identification centre and the e- passport reader. The communication data is protected between server and e-passport reader by using AES to encrypt data for protection while transferring through GSM network. Author in [5] reviewed the current research application of RFID to different areas with emphasis on application for supply chain management and developed a taxonomic framework to classify literature which enables swift and easy content analysis to help identify areas for future research. Authors in [9] reviewed the use of RFID in an integrated- circuit(IC) packaging house to resolve inventory transaction issues. His study suggests that RFID contributes significant improvements to the water receiving process and the inventory transaction process that reduce labour cost and man-made errors. In [10], an automated attendance management system was implemented both in electronic and mobile platform using stationary matrix AR 400 RFID reader with four circulatory polarized antennae and Symbol MC9000-G handheld RFID reader respectively. In the electronic platform, the attendance management system

DISADVANTAGES OF EXISTING SYSTEM

- Need to enter attendance data manually.
- Replication of attendance data may be a tedious work.
- There is always a risk of human error.
- Need spend a lot of time correcting these errors
- Can be easily manipulated.

PROPOSED SYSTEM

The proposed system uses the Radio Frequency Identification Technology (RFID) and interacts with the objects through wireless communication. The proposed model is further adaptable and distributive in nature to simplify attendance system. The implemented system consists of an Arduino UNO R3 as a main processing unit for the entire system and all the Sensing Modules and communication devices are connected with the microcontroller. The Sensing modules can be operated by the microcontroller to retrieve the data from them and analyse the data with data in memory.

RFID card which is an IC chip that has unique code contained in it and only need to place their RFID tag on the RFID reader. After sensing the data from RFID module devices, Microcontroller compares the data and identifies the user with the Associated user data such as Name, ID, Phone Number and Class Details. An alert will be sent to the authorized contact which already predefined in memory via GSM module.

The data will be automatically sent to the Google Firestore Database Server by the ESP8266-01 Wi-Fi module which is connected to IP. when a proper connection is established with server, Android Application which will allow us to monitor and control the system. The Android Application gives the information about past and current Attendance.

ADVANTAGES OF THE PROPOSED SYSTEM

- Fully Automated.
- No Human Error Occurs.
- Error Free Data and can be used for different purposes without duplication.
- Fast and Reliable.
- Low Power Consumption, Even works with Battery Supply.

HARDWARE DESCRIPTION

ARDUINO UNO R3

Fig 4.1 Arduino UNO R3

The Arduino Uno is a microcontroller board based on the ATmega328 . It has 14 digital input/output pins, 6 analog inputs, a 16 MHz crystal oscillator, a USB connection, a power jack, an ICSP header, and a reset button. It contains everything needed to support the microcontroller; simply connect it to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. The Uno differs from all preceding boards in that it does not use the FTDI USB-to-serial driver chip. Instead, it features the Atmega8U2 programmed as a USB-to-serial converter.

Technical Specifications

- Microcontroller ATmega328
- Operating Voltage 5V
- Input Voltage 7-12V
- Input Voltage 6-20V
- Digital I/O Pins 14 (of which 6 provide PWM output)
- Analog Input Pins 6
- DC Current per I/O Pin 40 mA

- DC Current for 3.3V Pin 50 mA
- Flash Memory 32 KB of which 0.5 KB used by bootloader
- SRAM 2 KB EEPROM 1 KB Clock Speed 16 MH

Features

- High Performance, Low Power AVR® 8-Bit Microcontroller Family
- Advanced RISC Architecture
  - 131 Powerful Instructions
  - Most Single Clock Cycle Execution
  - 32 x 8 General Purpose Working Registers
  - Fully Static Operation─Up to 20 MIPS Throughput at 20MHz
  - On-chip 2-cycle Multiplier

- High Endurance Non-volatile Memory Segments
  - 4/8/16/32KBytes of In-System Self-Programmable Flash program memory
  - 256/512/512/1KBytes EEPROM─512/1K/1K/2KBytes Internal SRAM
  - Write/Erase Cycles: 10,000 Flash/100,000 EEPROM
  - Data retention: 20 years at 85°C/100 years at 25°C(1)
  - Optional Boot Code Section with Independent Lock Bits
    - In-System Programming by On-chip Boot Program
    - True Read While-Write Operation

o Programming Lock for Software Security

- QTouch® library support
  - Capacitive touch buttons, sliders and wheels
  - QTouch and QMatrix™ acquisition
  - Up to 64 sense channels

- Peripheral Features
  - Two 8-bit Timer/Counters with Separate Prescaler and Compare Mode
  - One 16-bit Timer/Counter with Separate Prescaler, Compare Mode, and Capture Mode

- Real Time Counter with Separate Oscillator
- Six PWM Channels

- 8-channel 10-bit ADC in TQFP and QFN/MLF package λ
  - Temperature Measurement
- 6-channel 10-bit ADC in PDIP Package
  - Temperature Measurement
- Programmable Serial USART
- Master/Slave SPI Serial Interface
- Byte-oriented 2-wire Serial Interface (Philips I2C compatible)
- Programmable Watchdog Timer with Separate On-chip Oscillator
- On-chip Analog Comparator
- Interrupt and Wake-up on Pin Change
- I/O and Packages
- Operating Voltage: 1.8 - 5.5V
- Temperature Range: -40°C to 85°C
- Speed Grade:
  - 0 - 4MHz @ 1.8 - 5.5V
  - 0 - 10MHz @ 2.7 - 5.5.V
  - 0 - 20MHz @ 4.5 - 5.5V
- Power Consumption at 1MHz, 1.8V, 25°C
- Active Mode: 0.2mA
- Power-down Mode: 0.1µA
- Power-save Mode: 0.75µA (Including 32kHz RTC)

PIN DESCRIPTION

For pin description of Arduino UNO, let us assume some basic numbering. Let the numbering begin with the RX Pin (D0). So, RX is Pin 1, TX is Pin 2, D2 is Pin 3 and so on. On the other side, NC is Pin 19, IOREF is Pin 20 etc. Overall, there are 32 pins on the Arduino UNO Board.

With this information, let us now see the pin description of Arduino UNO.

Pin Number	Pin Name	Description	Alternative Functions
1	RX / D0	Digital IO Pin 0 Serial RX Pin	Generally used as RX
2	TX / D1	Digital IO Pin 1 Serial TX Pin	Generally used as TX
3	D2	Digital IO Pin 2	
4	D3	Digital IO Pin 3	Timer (OC2B)
5	D4	Digital IO Pin 4	Timer (T0/XCK)
6	D5	Digital IO Pin 5	Timer (OC0B/T1)
7	D6	Digital IO Pin 6	
8	D7	Digital IO Pin 7	
9	D8	Digital IO Pin 8	Timer (CLK0/ICP1)
10	D9	Digital IO Pin 9	Timer (OC1A)
11	D10	Digital IO Pin 10	Timer (OC1B)

12	D11	Digital IO Pin 11	SPI (MOSI) Timer (OC2A)
13	D12	Digital IO Pin 12	SPI (MISO)
14	D13	Digital IO Pin 13	SPI (SCK)
15	GND	Ground	
16	AREF	Analog Reference	
17	SDA / D18	Digital IO Pin 18	I2C Data Pin
18	SCL / D19	Digital IO Pin 19	I2C Clock Pin
19	NC	Not Connected	
20	IOREF	Voltage Reference	
21	RESET	Reset (Active LOW)	
22	3V3	Power	
23	5V	+5V Output from regulator or +5V regulated Input	
24	GND	Ground	
25	GND	Ground	
26	VIN	Unregulated Supply	
27	A0	Analog Input 0	Digital IO Pin 14

28	A1	Analog Input 1	Digital IO Pin 15
29	A2	Analog Input 2	Digital IO Pin 16
30	A3	Analog Input 3	Digital IO Pin 17
31	A4	Analog Input 4	Digital IO Pin 18 I2C (SDA)
32	A5	Analog Input 5	Digital IO Pin 19 I2C (SCL)

Table 4.1.3 Arduino Uno Pinout

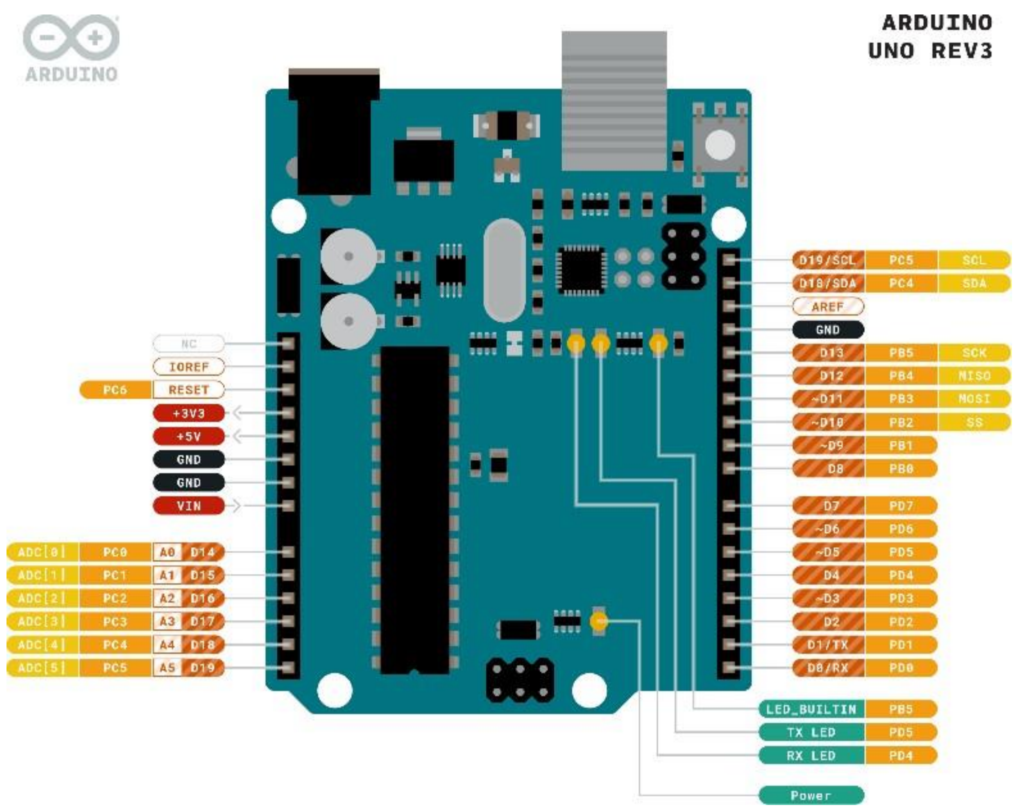

Fig 4.1.3 Arduino Uno PinOut Diagram

RC522 RFID Reader Module

The RC522 is a 13.56MHz RFID module that is based on the MFRC522 controller from NXP semiconductors. The module can supports I2C, SPI and UART and normally is shipped with a RFID card and key fob. It is commonly used in attendance systems and other person/object identification applications.

Fig 4.2: RC522 RFID Reader Module

The reader can communicate with a microcontroller over a 4-pin Serial Peripheral Interface (SPI) with a maximum data rate of 10Mbps. It also supports communication over I2C and UART protocols.The module comes with an interrupt pin. It is handy because instead of constantly asking the RFID module “is there a card in view yet? “, the module will alert us when a tag comes into its vicinity.

The operating voltage of the module is from 2.5 to 3.3V, but the good news is that the logic pins are 5-volt tolerant, so we can easily connect it to an Arduino or any 5V logic microcontroller without using any logic level converter.

RC522 Pinout Configuration

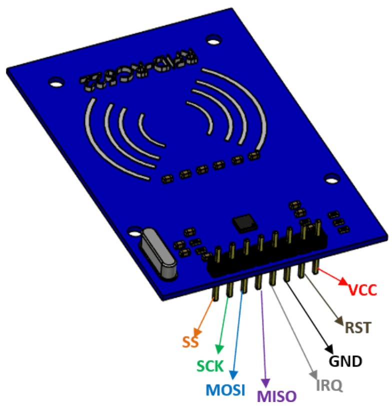

Fig 4.2.1: RC522 Pinout Configuration

Pin Number	**Pin Name**	**Description**
1	Vcc	Used to Power the module, typically 3.3V is used
2	RST	Reset pin – used to reset or power down the module
3	Ground	Connected to Ground of system
4	IRQ	Interrupt pin – used to wake up the module when a device comes into range
5	MISO/SCL/Tx	MISO pin when used for SPI communication, acts as SCL for I2c and Tx for UART.
6	MOSI	Master out slave in pin for SPI communication
7	SCK	Serial Clock pin – used to provide clock source
8	SS/SDA/Rx	Acts as Serial input (SS) for SPI communication, SDA for IIC and Rx during UART

RC522 Features

- Highly integrated analog circuitry to demodulate and decode responses
- Buffered output drivers to connect an antenna with minimum number of external components
- Supports ISO/IEC 14443A / MIFARE®
- Typical operating distance in Reader/Writer mode for communication to a ISO/IEC 14443A MIFARE® up to 50 mm depending on the antenna size and tuning
- Supports MIFARE® Classic encryption in Reader/Writer mode
- Supports ISO/IEC 14443A higher transfer speed communication up to 848 kbit/s
- Support of the MFIN / MFOUT
- Additional power supply to directly supply the smart card IC connected via MFIN / MFOUT
- Supported host interfaces
- SPI interface up to 10 Mbit/s
- I2C interface up to 400 kbit/s in Fast mode, up to 3400 kbit/s in High-speed mode
- serial UART in different transfer speeds up to 1228.8 kbit/s, framing according to the RS232 interface with voltage levels according pad voltage supply
- Comfortable 64 byte send and receive FIFO-buffer
- Flexible interrupt modes
- Hard reset with low power function
- Power-down mode per software
- Programmable timer
- Internal oscillator to connect 27.12 MHz quartz
- 2.5 - 3.3 V power supply
- CRC Co-processor
- Free programmable I/O pins
- Internal self-test

RC522 Specifications

- 13.56MHz RFID module
- Operating voltage: 2.5V to 3.3V
- Communication : SPI, I2C protocol, UART
- Maximum Data Rate: 10Mbps
- Read Range: 5cm
- Current Consumption: 13-26mA
- Power down mode consumption: 10uA (min)

Applications of RC522 Module

- Automatic billing systems
- Attendance systems
- Verification/Identification system
- Access control systems

SIM800L GSM Module

SIM800L is a miniature cellular module which allows for GPRS transmission, sending and receiving SMS and making and receiving voice calls. Low cost and small footprint and quad band frequency support make this module perfect solution for any project that require long range connectivity. After connecting power module boots up, searches for cellular network and login automatically. On board LED displays connection state (no network coverage - fast blinking, logged in - slow blinking).

Fig. 4.3 SIM800L GSM Module

SIM800 is a quad-band GSM/GPRS module that works on frequencies 850MHz GSM, 900MHz EGSM, 1800MHz DCS, and 1900MHz PCS.It also features GPRS multi-slot class 12/class 10 (optional), and supports CS-1, CS-2, CS-3, and CS-4 GPRS coding schemes.

It has one UART port. It also has one USB port that can be used for updating firmware and for debugging. Audio channels are also there, which include a microphone input and a receiver output.SIM800 has one SIM card interface.It integrates TCP/IP protocol.

SIM800 can be controlled/configured using simple AT commands. A host microcontroller can send AT commands over the UART interface and control the SIM800. It is operated on a supply in the range of 3.4 to 4.4V.

It can be used for sending/receiving messages, making calls, sending/receiving data over the internet, etc. This makes it useful for applications such as home automation, agriculture automation, etc.

An antenna is required to use the module for any kind of voice or data communications as well as some SIM commands. So, selecting an antenna could be a crucial thing. There are two ways you can add an antenna to your SIM800L module.

Fig. 4.3a SIM800L GSM Module with Helical Antenna

The first one is a Helical GSM antenna which usually comes with the module and solders directly to NET pin on PCB. This antenna is very useful for projects that need to save space but struggles in getting connectivity especially if your project is indoors.

Fig. 4.3b SIM800L GSM Module with 3dBi Antenna

The second one is any 3dBi GSM antenna along with a U.FL to SMA adapter which can be obtained online for less than $3. You can snap-fit this antenna to small u.fl connector located on the top-left corner of the module. This type of antenna has a better performance and allows putting your module inside a metal case – as long the antenna is outside

One of the most important parts of getting the SIM800L module working is supplying it with enough power.

Depending on which state it is in, the SIM800L can be a relatively power-hungry device. The maximum current draw of the module is around 2A during transmission burst. It usually will not pull that much, but may require around 216mA during phone calls or 80mA during network transmissions

SIM800L Specifications

- Quad-band 850/900/1800/1900MHz
- GPRS multi-slot class12 connectivity: max. 85.6kbps(down-load/up-load)
- GPRS mobile station class B
- Controlled by AT Command (3GPP TS 27.007, 27.005 and SIMCOM enhanced AT Commands)
- Supports Real Time Clock
- Supply voltage range 3.4V ~ 4.4V
- Supports A-GPS
- Supports 3.0V to 5.0V logic level
- Low power consumption, 1mA in sleep mode
- Compact size 23mm x 35mm x 5.6mm
- Micro SIM Card

SIM800L Pinout Configuration

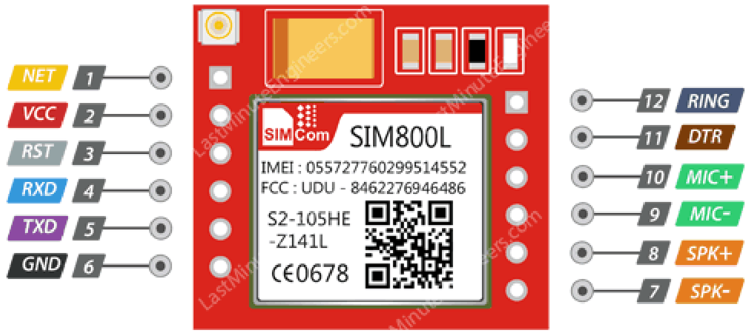

Fig. 4.3.2 SIM800L Pinout

- **NET** is a pin where you can solder Helical Antenna provided along with the module.
- **VCC** supplies power for the module. This can be anywhere from 3.4V to 4.4 volts. An external power source like Li-Po battery or DC-DC buck converters rated 3.7V 2A would work.
- **RST** (Reset) is a hard reset pin. If you absolutely got the module in a bad space, pull this pin low for 100ms to perform a hard reset.
- **RxD** (Receiver) pin is used for serial communication.
- **TxD** (Transmitter) pin is used for serial communication.
- **GND** is the Ground Pin and needs to be connected to GND pin on the Arduino.
- **RING** pin acts as a Ring Indicator. It is basically the 'interrupt' out pin from the module. It is by default high and will pulse low for 120ms when a call is received. It can also be configured to pulse when an SMS is received.
- **DTR** pin activates/deactivates sleep mode. Pulling it HIGH will put module in sleep mode, disabling serial communication. Pulling it LOW will wake the module up.
- **MIC±** is a differential microphone input. The two microphone pins can be connected directly to these pins.
- **SPK±** is a differential speaker interface. The two pins of a speaker can be tied directly to these two pins.

SIM800L Features

- Network support: Quad-Band 850/900/1800/1900 MHz – works on GSM networks in all countries across the world.
- TTL serial interface compatible with 3.3V and 5V MCU
- The small size is suitable for all kinds of sleeve belt type and embedded.
- Playing card slot, convenient change mobile phone card. Can side reserve replacement cell phone bayonet into the box.
- Using the IPX interface can arbitrarily change the antenna. The default PCB antenna greatly reduces & use the space.
- The board with gold plated board, more stable performance.
- When wiring neat guarantee board running more stable.
- This module adds a protection device, which can realize the prevention, high pressure, reduce the loss of the board, suitable for the project and learn

AT Commands of SIM800L Module

To send or read SMS from the module we need to set the module to SMS mode and then use the AT Commands for SMS.

- To set the GSM Module in SMS mode, use the following code.

  AT+CMGF=1

- Once it returns OK, then use the second command to read the SMS.

  AT+CMGR=1

- To Send an SMS, set the GSM Modem to SMS mode using 'AT+CMGF=1' and then use the following command.

  AT+CMGS="+91XXXXXXXX"

- The modem will return an arrow to enter the message (>). Type the message and hit enter.
- To exit from SMS Mode, we need to send 'CTRL' in ASCII Form.
  The '26' is the ASCII Character for 'CTRL'.

  println((char)26)

ESP8266-01 WI-FI MODULE

The ESP-01 ESP8266 Serial WIFI Wireless Transceiver Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a Wi-Fi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost-effective board with a huge, and ever growing, community.

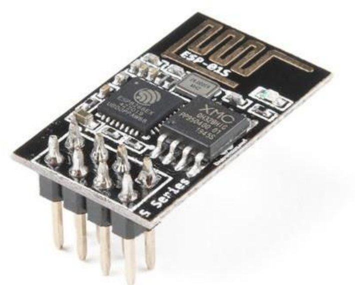

Fig. 4.4 ESP8266-01 Wi-Fi Mofule

This module has a powerful enough onboard processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existing interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution!

Note: The ESP8266 Module is not capable of 5-3V logic shifting and will require an external Logic Level Converter. Please do not power it directly from your 5V dev board.

ESP-01 Wi-Fi module is developed by Ai-thinker Team. core processor ESP8266 in smaller sizes of the module encapsulates Tensilica L106 integrates industry-leading ultra-low power 32-bit MCU micro, with the 16-bit short mode, Clock speed support 80 MHz, 160 MHz, supports the RTOS, integrated Wi-Fi MAC/BB/RF/PA/LNA, on-board antenna.

The module supports standard IEEE802.11 b/g/n agreement, complete TCP/IP protocol stack. Users can use the add modules to an existing device networking or building a separate network controller.

ESP8266 is high integration wireless SOCs, designed for space and power constrained mobile platform designers.

It provides unsurpassed ability to embed Wi-Fi capabilities within other systems, or to function as a standalone application, with the lowest cost, and minimal space requirement.

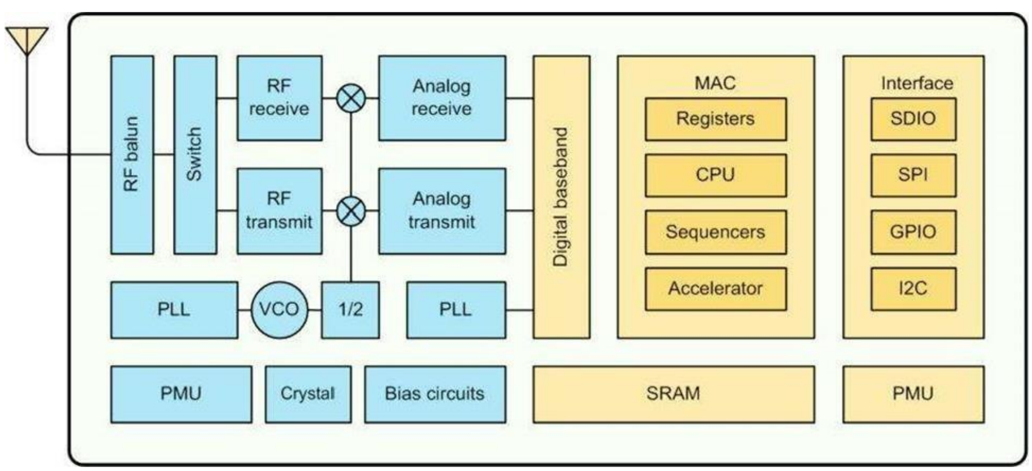

Fig. 4.4a ESP8266 Architecture

ESP8266EX offers a complete and self-contained Wi-Fi networking solution; it can be used to host the application or to offload Wi-Fi networking functions from another application processor.

When ESP8266EX hosts the application, it boots up directly from an external flash. In has integrated cache to improve the performance of the system in such applications.

Alternately, serving as a Wi-Fi adapter, wireless internet access can be added to any micro controller based design with simple connectivity (SPI/SDIO or 12C/UART interface).

ESP8266-01 Specifications

- 802.11 b/g/n
- Integrated low power 32-bit MCLI
- Integrated 10-bit ADC
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, INA, power amplifier and matching network
- Integrated PLL, regulators, and power management units
- Supports antenna diversity
- Wi-Fi 2.4 GHz, support WPA,WPA2
- Support STA/AP/STA+AP operation modes
- Support Smart Link Function for both Android and iOS devices
- Support Smart Link Function for both Android and iOS devices
- SDIO 2.0, (H) SPI, UART, 12C, 12S, IRDA, PWM, GPIO
- STBC, IXI MIMO, 2x1 MIMO
- A-MPDU & A-MSDIJ aggregation and 0.4s guard interval
- Deep sleep power <10uA, Power down leakage current < 5uA
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)
- +20dBm output power in 802.11b mode
- Operating temperature range -40C 125C

ESP8266-01 Parameters

Categories	Items	Values
Wi-Fi Parameters	Wi-Fi Protocols	802.11 b/g/n
	Frequency Range	2.4GHz-2SGHz (2400M-2483SM)
Hardware Parameters	Peripheral Bus	UART/HSPI/12C/12S/ir Remote Control
		GPIO/PWM
	Operating Voltage	
	Operating Current	Average value.' 80mA
	Operating Temperature Range	-aom2s•
	Ambient Temperature Range	Normal temperature
	Package Size	14.3mrn*24.8mm *3mm
	External Interface	N/A
Software Parameters	Wi-Fi mode	station/softAP/SoftAP+station
	Security	WPA/WPA2
	Encryption	WEP/TKIP/AES
	Firmware Upgrade	IJART Download / OTA (via network) / download and write firmware via host
	Software Development	Supports Cloud Server Development / SDK for custom firmware development
	Network Protocols	IPv4» TCP/IJDP/HTTP/FTP
	User Configuration	AT Instruction Set* Cloud Server* Android/iOS App

Table 4.4.2 ESP8266-01 Parameters

ESP8266-01 Module Pin Description

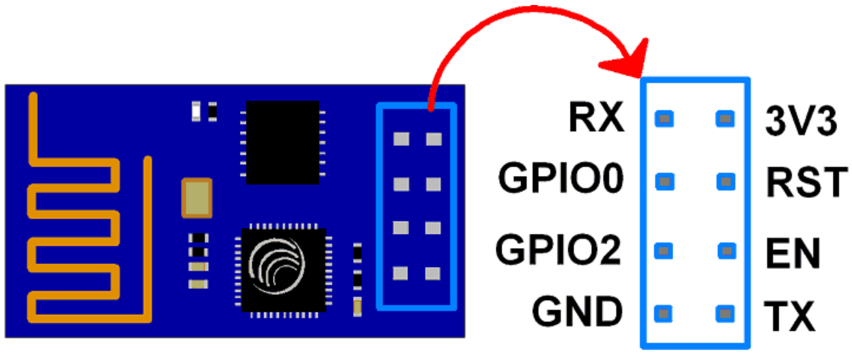

Fig. 4.4.3 ESP8266-01 Pinout

- **3V3**: - 3.3 V Power Pin.
- **GND**: - Ground Pin.
- **RST**: - Active Low Reset Pin.
- **EN**: - Active High Enable Pin.
- **TX**: - Serial Transmit Pin of UART.
- **RX**: - Serial Receive Pin of UART.
- **GPIO0 & GPIO2**: - General Purpose I/O Pins. These pins decide what mode (boot or normal) the module starts up in. It also decides whether the TX/RX pins are used for Programming the module or for serial I/O purpose.
- To program the module using UART, Connect GPIO0 to ground and GPIO2 to VCC or leave it open. To use UART for normal Serial I/O leave both the pins open (neither VCC nor Ground).

ESP8266-01 Functional Description

ESP8266EX is embedded with Tensilica L106 32-bit micro controller (MCU), which features extra low power consumption and 16-bit RSIC. The CPU clock speed is 80MHz. It can also reach a maximum value of 160MHz. ESP8266EX is often integrated with external sensors and other specific devices through its GPIOs; codes for such applications are provided in examples in the SDK.

Internal SRAM and ROM

ESP8266EX Wi-Fi SOC is embedded with memory controller, including SRAM and ROM. MCU can visit the memory units through iBus, dBus, and ABB interfaces. All memory units can be Visited upon request, while a memory arbiter Will decide the running sequence according to the time When these requests are received by the processor.

According to our current version of SDK provided, SRAM space that is available to users is assigned as below:

- RAM size < 36kB when ESP8266EX is working under the station mode and is connected to the router, programmable space accessible to user in heap and data section is around 36kB.)
- There is no programmable ROM in the SOC, therefore, user program must be stored in an external SPI flash.

External SPI Flash

This module is mounted with an 1 MB external SPI flash to store user programs. If larger definable storage space is required, a SPI flash with larger memory size is preferred. Theoretically speaking, up to 16 MB memory capacity can be supported.

Suggested SPI Flash memory capacity:

OTA is disabled: the minimum flash memory that can be supported is 512 kB; OTA is enabled: the minimum flash memory that can be supported is 1 MB.

Several SPI modes can be supported, including Standard SPI, Dual SPI, and Quad SPI.

Therefore, please choose the correct SPI mode When you are downloading into the flash, otherwise firmware/programs that you downloaded may not work in the right way.

Crystal

Currently, the frequency of crystal oscillators supported include 40MHz, 26MHz and 24MHz. The accuracy of crystal oscillators applied should be ±IOPPM, and the operating temperature range should be between -200C and 85 0C.

When using the downloading tools, please remember to select the right crystal oscillator type. In circuit design, capacitors CI and C2, which are connected to the earth, are added to the input and output terminals of the crystal oscillator, respectively. The values of the two capacitors can be flexible, ranging from 6pF to 22pF, however, the specific capacitive values of Cl and C2 depend on further testing and adjustment on the overall performance of the whole circuit. Normally, the capacitive values of Cl and C2 are within 10pF if the crystal oscillator frequency is 26MHz, while the values of Cl and C2 are 10pF<C1, C2<22pF if the crystal oscillator frequency is 40MHz.

Interfaces

Interface	Pin Name	Description
HSPI	MISO MOSI CLK CS	SPI Flash 2, display Screen, and MCIJ can be connected using HSPI interface.
PWM	R G B	Currently the PWM interface has four channels. PWM interface can be used to control LED lights, buzzers & so on.
IR Remote Control	IR-T IR-R	The functionality of Infrared remote-control interface can be implemented via software programming.

ADC	TOUT	ESP8266EX integrates a 1 0-bit analog ADC. It can be used to test the power supply voltage of VDD3P3 (Pin3 and Pin4) and the input power voltage of TOUT (Pin 6).
12C	SCL SDA	12C interface can be used to connect external sensor products and display screens, etc.

Interface	**Pin Name**	**Description**
UART	TXD RXD RTS UART TXD	Devices with UART interfaces can be connected with the module.
		UART will output some printed information when the device is powered On and is booting up, if this issue exerts influence on some specific applications, users can exchange the inner pins of UART when initializing exchange UTXD, URXD with URTS, UCTS.
I2S	12S Input: (12Sl_DATA) ; (12Sl_BCK) (12Sl_WS); 12S Output: (12SO_BCK) (12SO_DATA); (12SO_WS)	I2S interface is mainly used for collecting, processing, and transmission of audio data.

ESP8266-01 Schematic Circuit

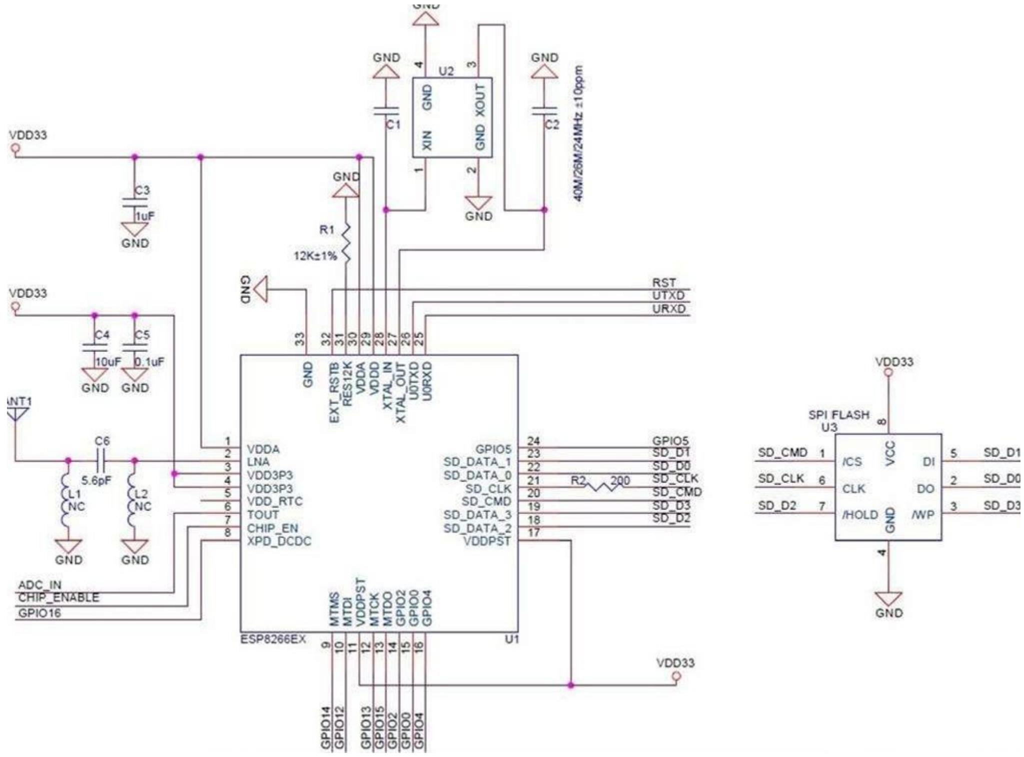

Fig. 4.4.6 ESP8266-01 Schematic Circuit

Advantages of ESP8266-01 Module

- Low cost
- Integrated support for WIFI network
- Reduced size of the board
- Low energy consumption

Disadvantages

- Need to learn a new language and IDE
- Reduced pinout
- Scarce documentation

Applications

- Home appliances
- Home automation
- Smart plugs and lights
- Industrial wireless control
- Baby monitors
- IP cameras
- Sensor networks
- Wearable electronics
- Wi-Fi location-aware devices
- Security ID tags
- Wi-Fi position system beacons

16X2 LIQUID CRYSTAL DISPLAY

An LCD is an electronic display module which uses liquid crystal to produce a visible image. The 16×2 LCD display is a very basic module commonly used in DIYs and circuits. The 16×2 translates to a display 16 characters per line in 2 such lines. In this LCD each character is displayed in a 5×7-pixel matrix.

Fig. 4.5a: JHD 16x2 LCD

To connect an LCD display with an Arduino, you may have noticed that it consumes a lot of pins on the Arduino. Even in 4-bit mode, the Arduino still requires a total of seven connections – which is half of Arduino's available digital I/O pins.

The solution is to use an I2C LCD Display. It consumes only two I/O pins that are not even part of a set of digital I/O pins and can also be shared with other I2C devices.
A typical I2C LCD display consists of a HD44780 based character LCD display and an I2C LCD adapter.

Fig. 4.5b: JHD 16x2 LCD with I2C Module

16x2 LCD with I2C Module Pin Configuration

Fig 4.5.1 16x2 LCD with I2C Module Pinout

- **GND**
  - GND is a ground pin and should be connected to the ground of MCU.
- **VCC**
  - VCC supplies power to the module and the LCD. Connect it to the 5V output of the MCU or a separate power supply.
- **SDA**
  - Serial Data pin. This line is used for both transmit and receive. Connect to the SDA pin on the MCU.
- **SCL**
  - Serial Clock pin. This is a timing signal supplied by the Bus Master device. Connect to the SCL pin on the MCU.

Power Supply Adapter

12V power supplies are one of the most common power supplies in use today. In general, a 12VDC output is obtained from a 50VAC or 240VAC input using a combination of transformers, diodes and transistors. 12V power supplies can be of two types: 5V regulated power supplies, and 12V unregulated power supplies. 12V regulated power supplies come in three styles: Switching regulated AC to DC, Linear regulated AC to DC, and Switching regulated DC to DC.

Fig. 4.6: 12V Power Supply Adapter

Regulated 12VDC power supplies regulate the 12VDC output voltage using a complex high frequency switching technique that employs pulse width modulation and feedback. regulated power supplies also employ extensive EMI filtering and shielding to attenuate both common and differential mode noise conducted to the line and load. Galvanic isolation is standard in our 12 VDC switchers, affording our users input to output and output to ground isolation for maximum versatility. Regulated power supplies are highly efficient, small and lightweight, and are available in both AC-DC single and wide-adjust output and DC-DC configurations. Our Low Profile wide adjust output switchers can be voltage or current regulated and are externally programmable.

CHAPTER - 5

SOFTWARE DESCRIPTION

ARDUINO IDE 1.8.13

The Arduino Integrated Development Environment (IDE) is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of third-party cores, other vendor development boards.

Fig. 5.1: Arduino IDE 1.8.13

The source code for the IDE is released under the GNU General Public License, version The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures.

User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution.

The Arduino IDE employs the program avrdude to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

By default, avrdude is used as the uploading tool to flash the user code onto official Arduino boards.

With the rising popularity of Arduino as a software platform, other vendors started to implement custom open source compilers and tools (cores) that can build and upload sketches to other microcontrollers that are not supported by Arduino's official line of microcontrollers.

Arduino IDE Features

- **Inexpensive** - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

- **Cross-platform** - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

- **Simple, clear programming environment** - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well.

- For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- **Open source and extensible software** - The Arduino software is published as open source tools, available for extension by experienced programmers.

  - The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based.

  - Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

- **Open source and extensible hardware** - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version

- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

Installing Arduino IDE

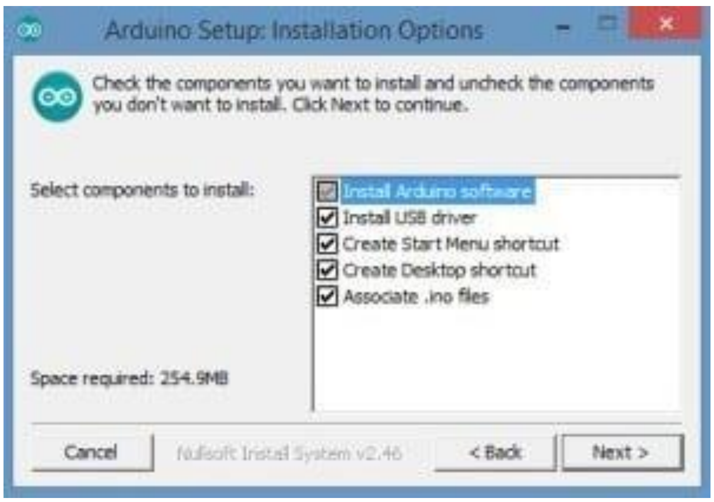
1. Visit http://www.arduino.cc/en/main/software to download the latest Arduino IDE version for your computer's operating system. There are versions for Windows, Mac, and Linux systems. At the download page, click on the "Windows Installer" option for the easiest installation.

2. Save the .exe file to your hard drive.

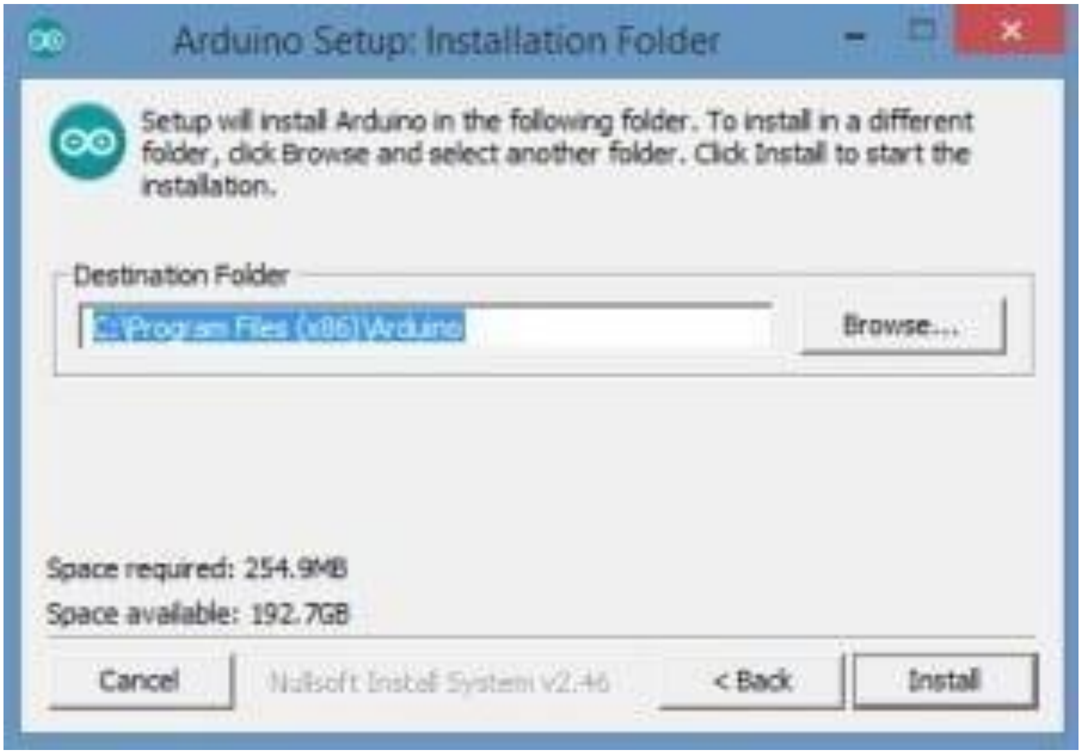
3. Open the .exe file.

4. Click the button to agree to the licensing agreement:

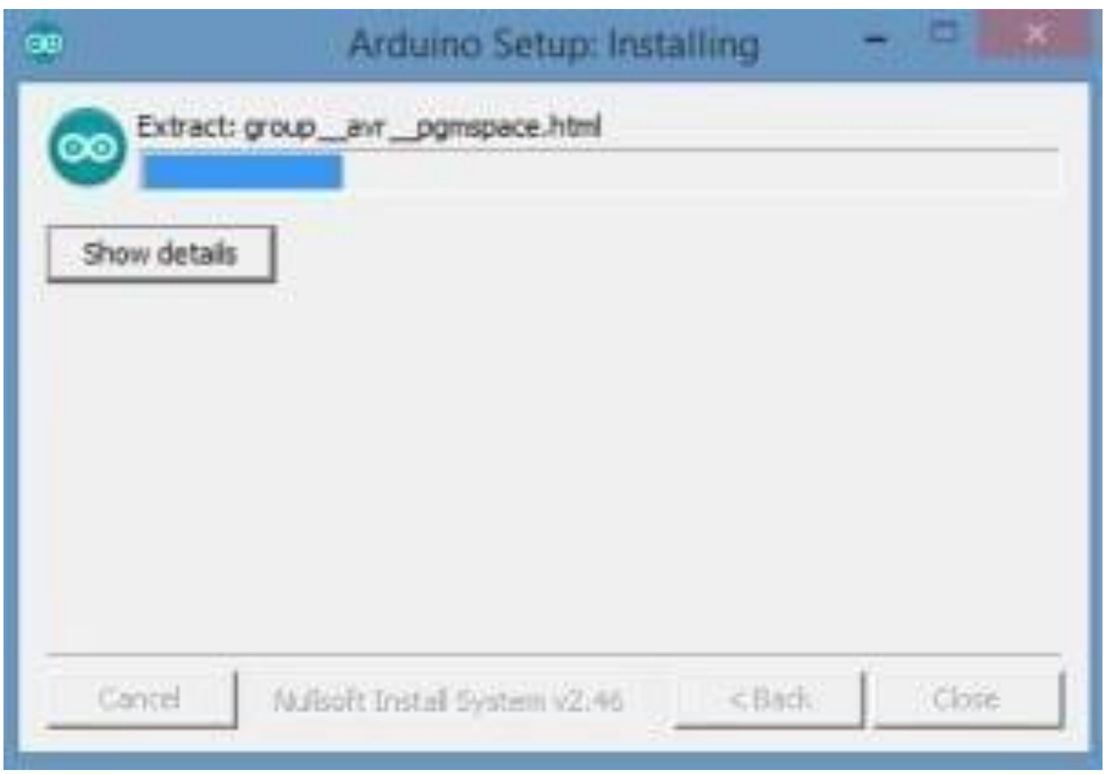
5. Decide which components to install, then click "Next":



6. Select which folder to install the program to, then click “Install”:



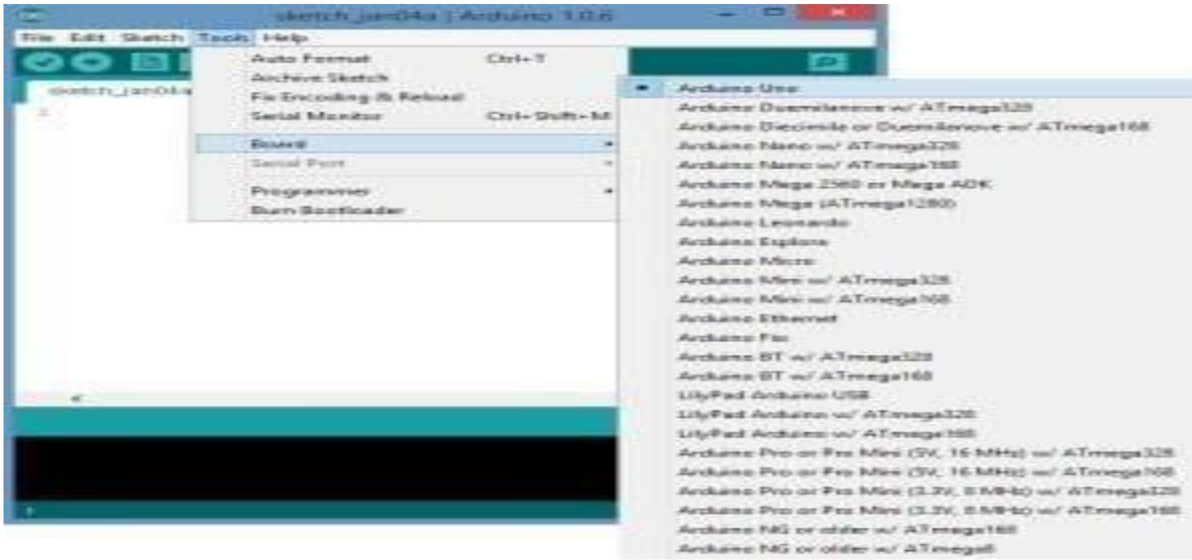
7. Wait for the program to finish installing, then click “Close”:



8. Now find the Arduino shortcut on your Desktop and click on it. The IDE will open up and you’ll see the code editor:

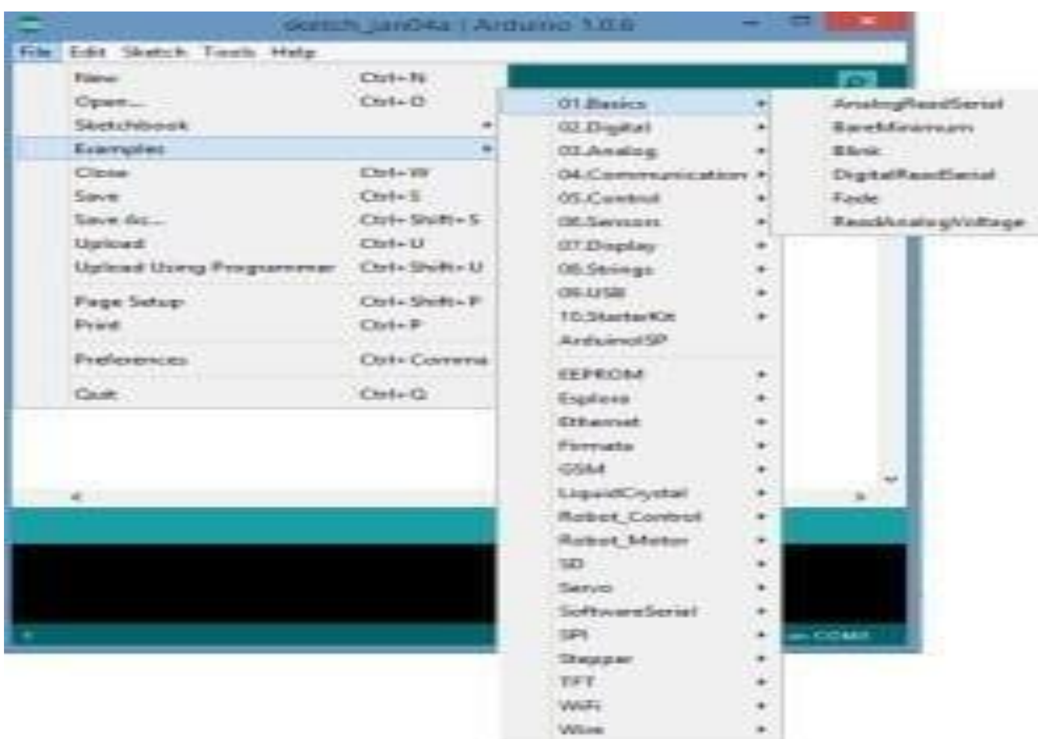
- **CONFIGURING THE ARDUINO IDE**

The next thing to do is to make sure the software is set up for your particular Arduino board. Go to the “Tools” drop-down menu, and find “Board”. Another menu will appear, where you can select from a list of Arduino models. I have the Arduino Uno R3, so I chose “Arduino Uno”.



- **EXPLORING THE ARDUINO IDE**

If you want, take a minute to browse through the different menus in the IDE. There is a good variety of example programs that come with the IDE in the “Examples” menu. These will help you get started with your Arduino right away without having to do lots of research:



Android Studio

Android Studio is the official integrated development environment (IDE) for Google's Android operating system, built on JetBrains' IntelliJ IDEA software and designed specifically for Android development. It is available for download on Windows, macOS and Linux based operating systems or as a subscription-based service in 2020. It is a replacement for the Eclipse Android Development Tools (E-ADT) as the primary IDE for native Android application development.

Android Studio was announced on May 16, 2013 at the Google I/O conference. It was in early access preview stage starting from version 0.1 in May 2013, then entered beta stage starting from version 0.8 which was released in June 2014. The first stable build was released in December 2014, starting from version 1.0.

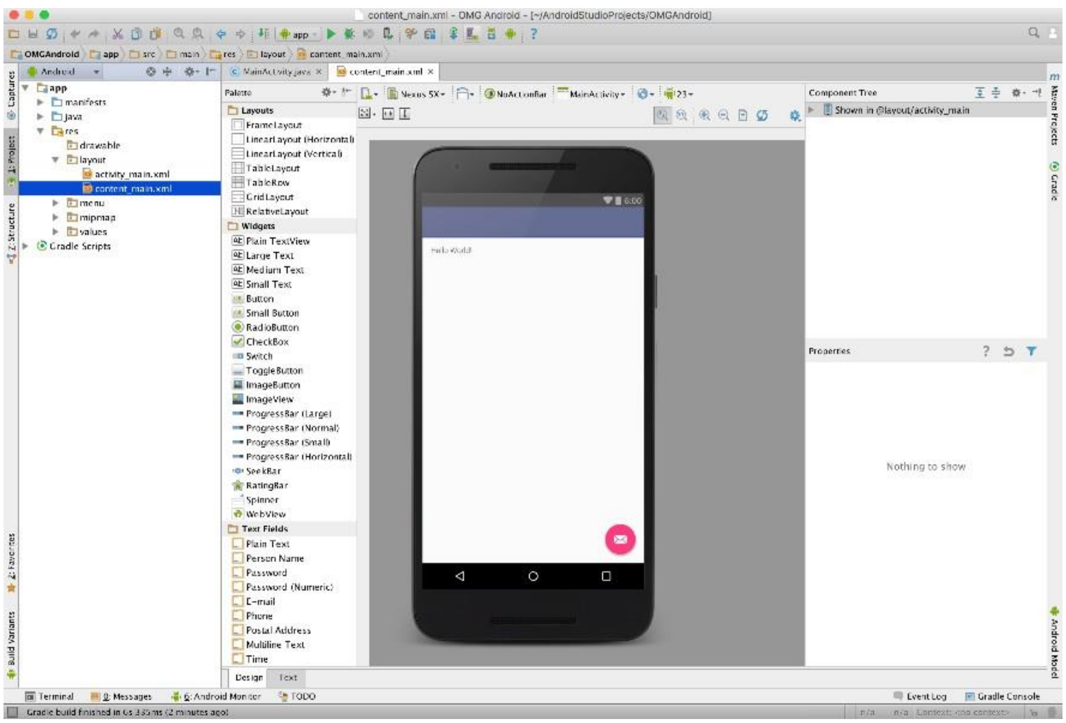


Fig. 5.2 Android Studio IDE

Android Studio Features

- Gradle-based build support
- Android-specific refactoring and quick fixes
- Lint tools to catch performance, usability, version compatibility and other problems
- ProGuard integration and app-signing capabilities
- Template-based wizards to create common Android designs and components
- A rich layout editor that allows users to drag-and-drop UI components, option to preview layouts on multiple screen configurations.
- Support for building Android Wear apps
- Built-in support for Google Cloud Platform, enabling integration with Firebase Cloud Messaging (Earlier 'Google Cloud Messaging') and Google App Engine.

Android Virtual Device (Emulator) to run and debug apps in the Android studio. Android Studio supports all the same programming languages of IntelliJ e.g. Java, C++, and more with extensions, such as Go and Android Studio 3.0 or later supports Kotlin and all Java 7 language features and a subset of Java 8 language features that vary by platform version. External projects backport some Java 9 features. While IntelliJ states that Android Studio supports all released Java versions, and Java 12, it's not clear to what level Android Studio supports Java versions up to Java 12. At least some new language features up to Java 12 are usable in Android.

Once an app has been compiled with Android Studio, it can be published on the Google Play Store. The application has to be in line with the Google Play Store developer content policy

System Requirements

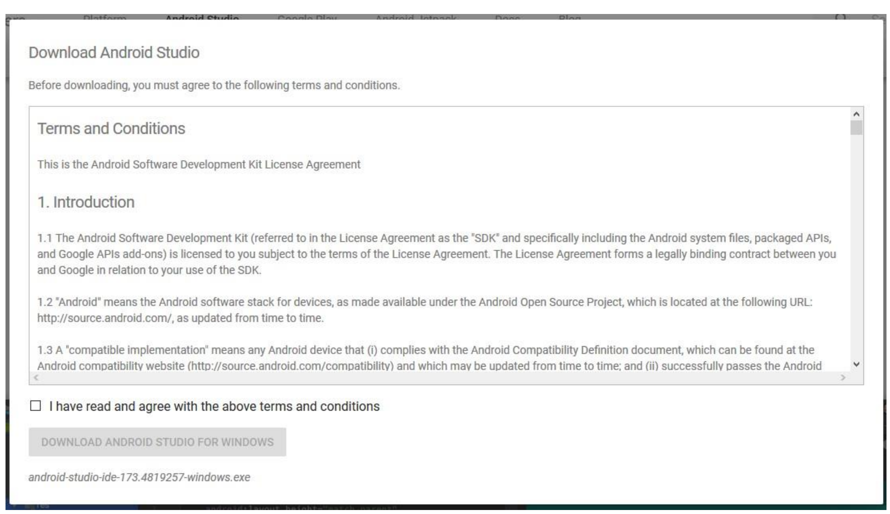
Operating System	Microsoft Windows	Mac	Linux
Operating System Version	Microsoft® Windows® 7/8/10 (32- or 64-bit) *The Android Emulator only supports 64-bit Windows.*	Mac® OS X® 10.10 (Yosemite) or higher, up to 10.14 (macOS Mojave)	GNOME or KDE desktop *Tested on Linux based on Debian (4.19.67-2rodete2).*
Random Access Memory (RAM)	4 GB RAM minimum; 8 GB RAM recommended.		
Free disk space	2 GB of available disk space minimum, 4 GB Recommended (500 MB for IDE + 1.5 GB for Android SDK and emulator system image).		
Minimum required JDK version	Java Development Kit 8		
Minimum screen resolution	1280 x 800		

Installation of Android Studio

To install Android Studio on Windows, proceed as follows:

- If you downloaded an .exe file (recommended), double-click to launch it.
- If you downloaded a .zip file, unpack the ZIP, copy the android-studio folder into your Program Files folder, and then open the android-studio > bin folder and launch studio64.exe (for 64-bit machines) or studio.exe (for 32-bit machines).
- Follow the setup wizard in Android Studio and install any SDK packages that it recommends.
- Head over to this link to get the Android Studio executable or zip file .
- Click on the download android studio button .

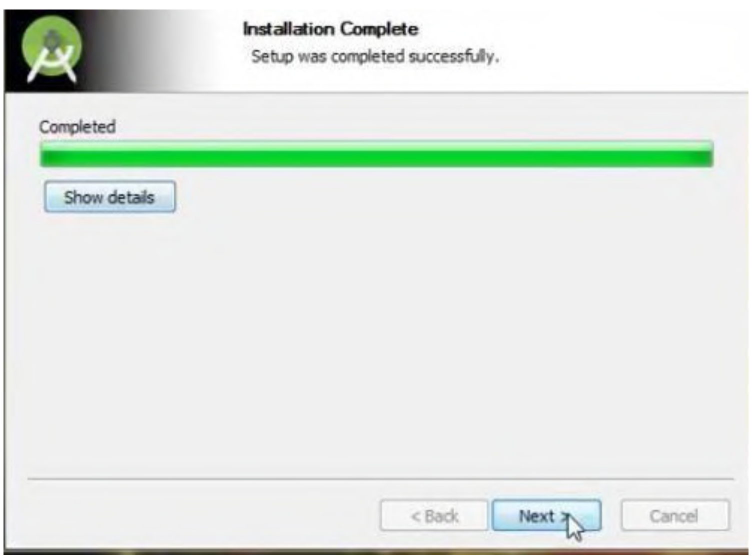
- Click on the “I have read and agree with the above terms and conditions” checkbox followed by the download button.



- Click on Save file button in the appeared prompt box and the file will start downloading .

- After the downloading has finished, open the file from downloads and run it . It will prompt the following dialogue box .

- Click on next .
- In the next prompt it'll ask for a path for installation. Choose a path and hit next.
- Note :The installation path should have the required minimum space.
- It will start the installation, and once it is completed, it will be like the image shown below .



- Click on next .

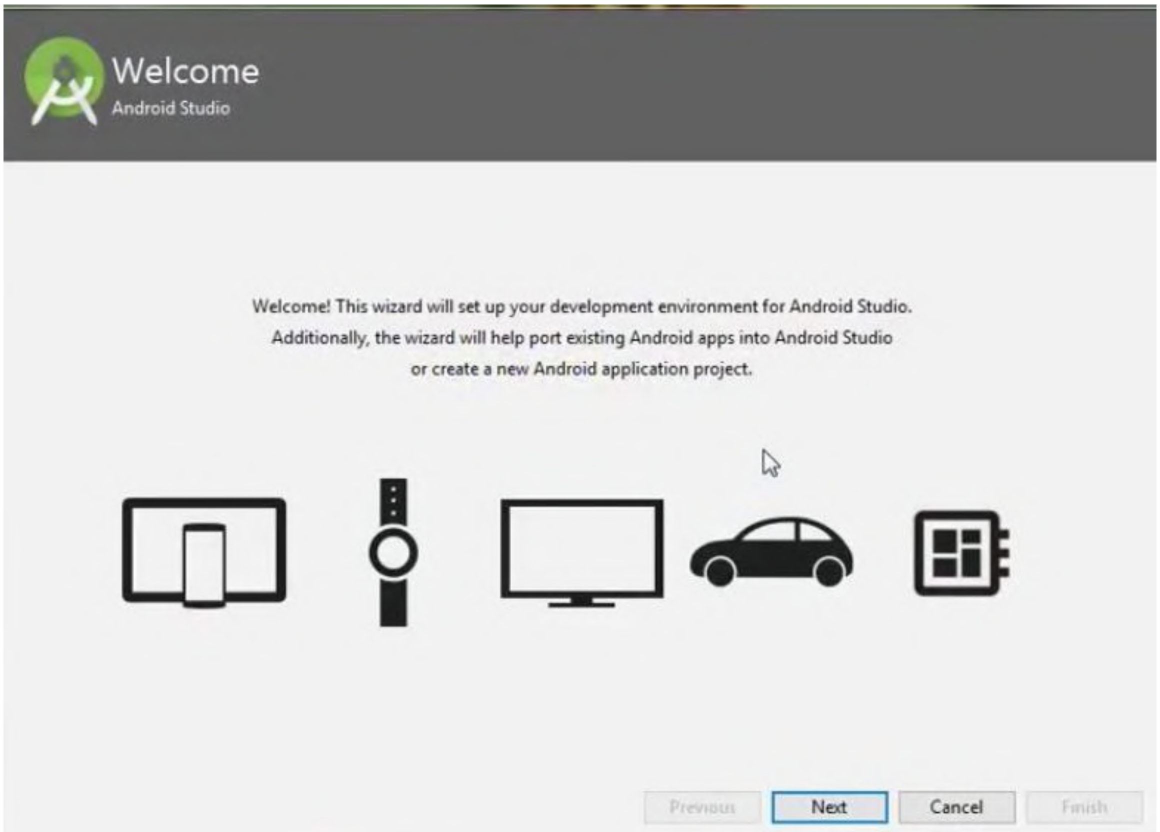
- Once “Finish” is clicked, it will ask whether the previous settings needs to be imported [if android studio had been installed earlier], or not.

  It is better to choose the ‘Don’t import Settings option’ .

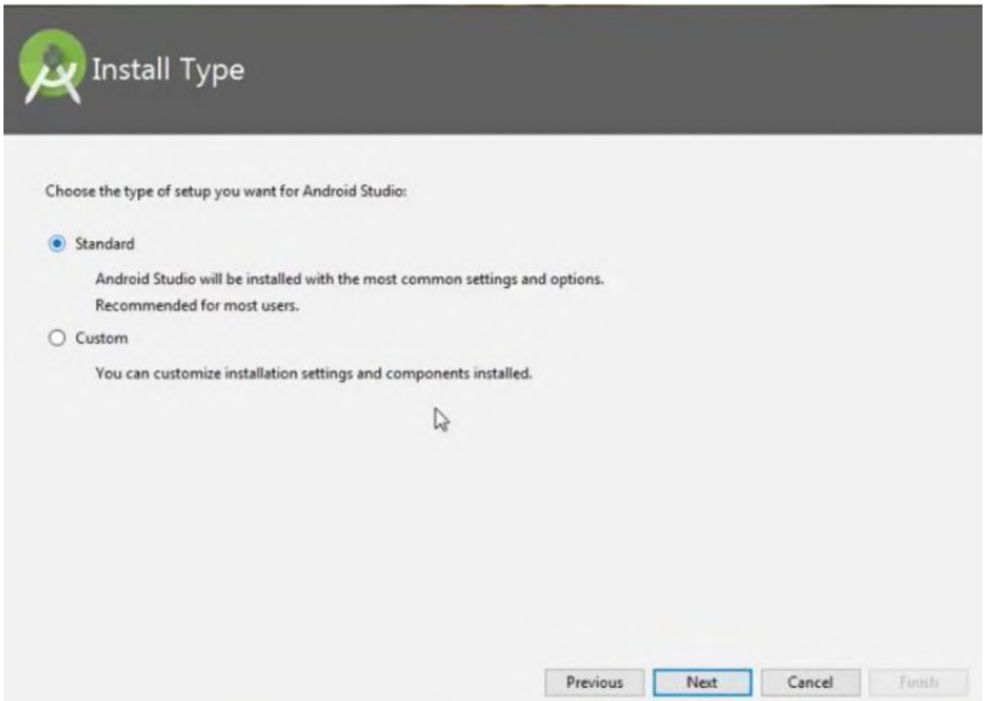
- Click the OK button.
- This will start the Android Studio.

- Meanwhile it will be finding the available SDK components .

- After it has found the SDK components, it will redirect to the Welcome dialog box .



- Click on next .

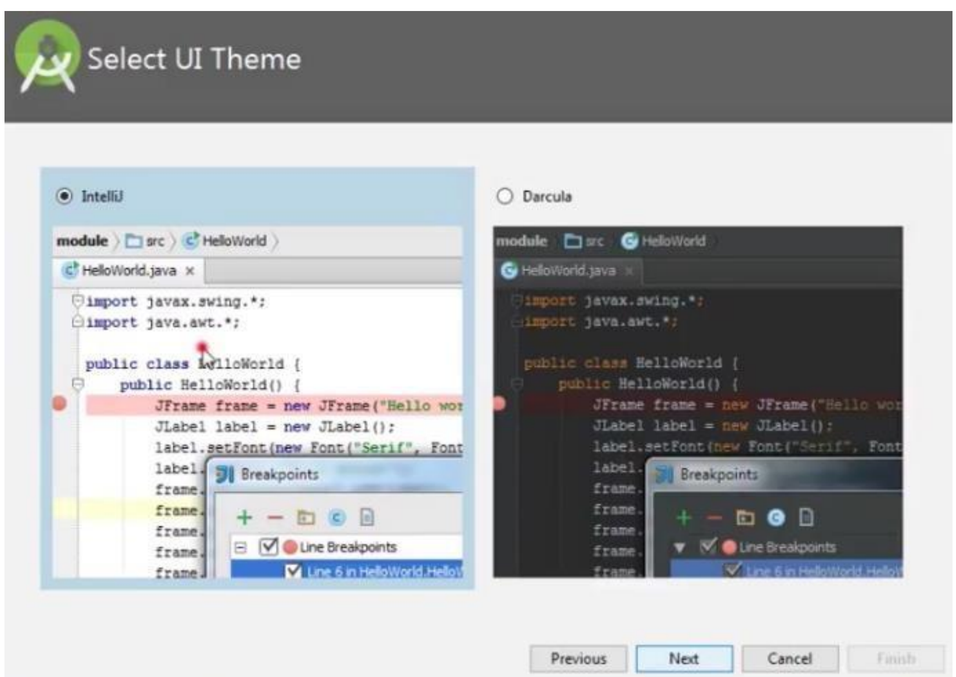


- Choose Standard and click on Next.

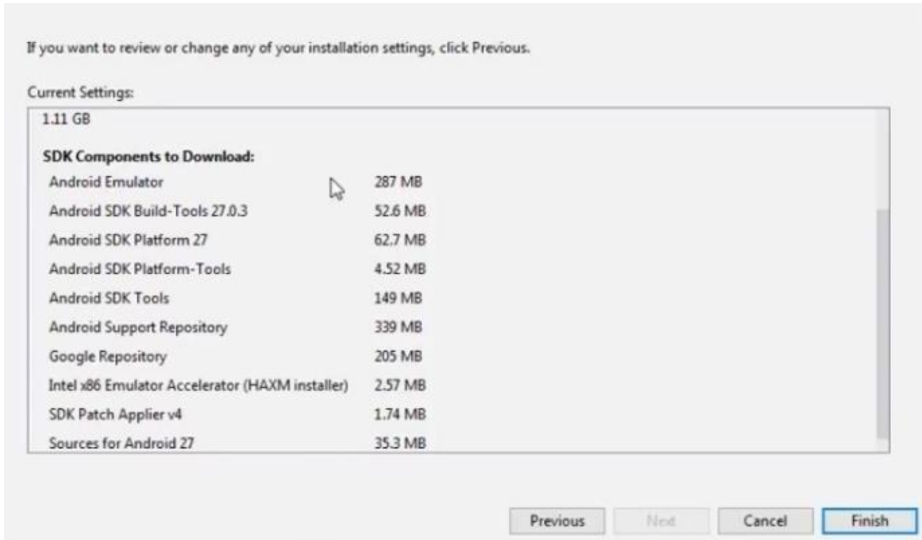
  Now choose the theme, whether Light theme or the Dark one .

  The light one is called the IntelliJ theme whereas the dark theme is called Darcula

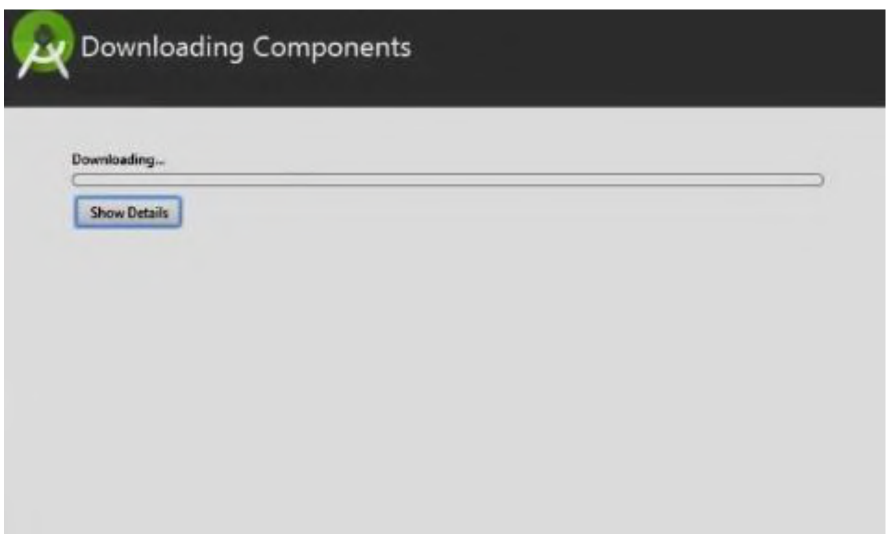
- Choose as required.



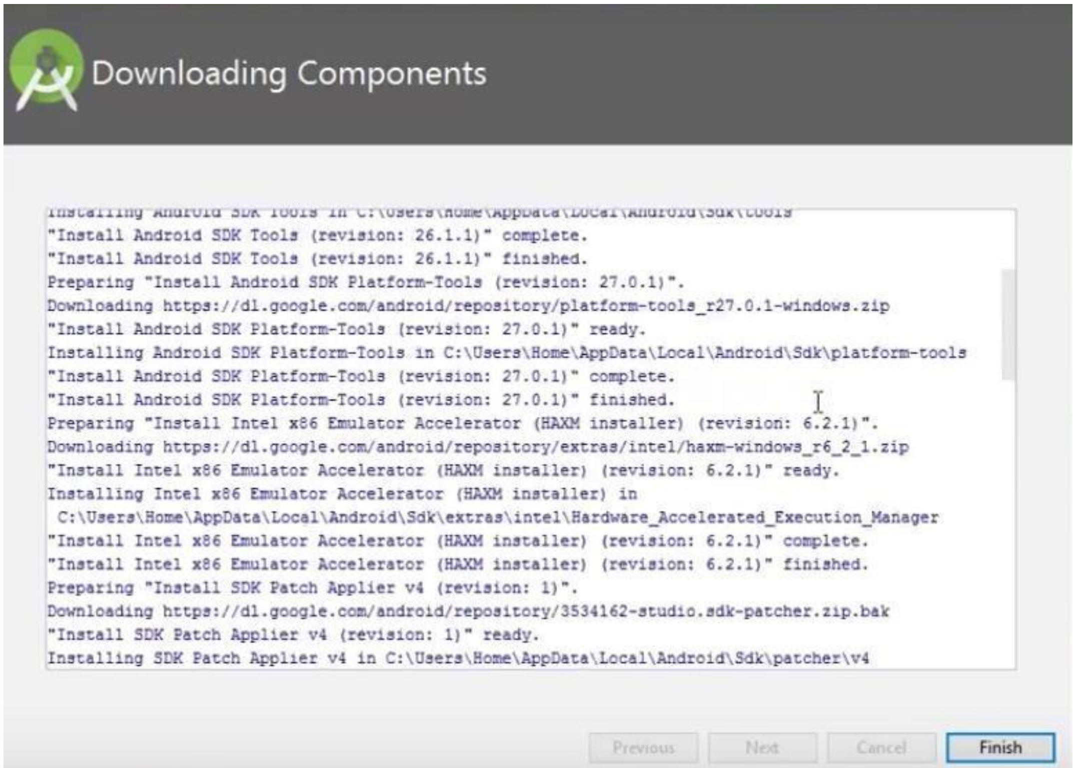
- Click on the Next button
- Now it is time to download the SDK components .



- Click on Finish .



- It has started downloading the components



- The Android Studio has been successfully configured.
  Now it’s time to launch and build apps.
- Click on the Finish button to launch it.

- Click on ‘Start new android project’ to build a new app.

CHAPTER - 7

PROJECT TESTING

TESTING THE RFID TAG, RFID READER AND LCD DISPLAY

This has to do with powering and testing the RFID Card of each student, the RFID reader and the LCD segment. When the system is powered, it displays “Swipe your RFID CARD”, meaning that the system is ready to scan card as shown below in Fig 6.1.

Fig 7.1a: LCD powered ON

When the card is swiped across the RFID reader, the reader will sense it, decode the embedded code on it and sends the decoded signal to the central microcontroller to process, if found valid, details will be display on the LCD screen as shown below in Fig 2

Fig 7.1b: Access Granted

TESTING THE SIM800L GSM MODULE.

As the central microcontroller is sending the decoded information from RFID reader to LCD and computer screen for display, it also sends SMS notification through the Sim800LGSM module to a particular programmed student phone number as back up means. The SMS notification will send “Attendance, Student name, Registration number” as shown below in Fig 6.2 and Fig 6.3

Fig 7.2: Sending SMS to Parent

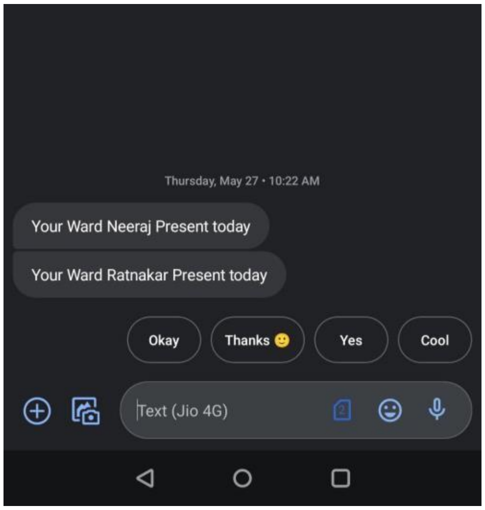

Fig 7.3: SMS Received by Parent

CHAPTER - 8

ADVANTAGES AND APPLICATIONS

Advantages of The Project

- Fully Automated.
- No Human Error Occurs.
- Error Free Data and can be used for different purposes without duplication.
- Fast and Reliable.
- Low Power Consumption, Even works with Battery Supply.

Applications of The Project

- Can be used to take attendance for student in school, college, and university.
- It also can be used to take attendance for workers in working places
- Used for Library Access and Books Management token

CHAPTER - 9

CONCLUSION AND FUTURE SCOPE

CONCLUSION

- We have developed an RFID based student attendance system with SMS notification and Database integration which is helpful in saving valuable time of both students and lecturers and helps to generate accurate reports when required.

- The SMS feature serves as a backup if data or connection loss occurs on the PC.

- Every Information is updated to College Portals and Android Applications in Real-time

FUTURE SCOPE

- We can extend this project by implement UHF RFID Reader module. So that attendance can be taken without placing the card on the reader.
- We can use Raspberry pi for fully Automating the Circuit with AI and ML Concepts.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Mrs. V. Sreeja, Associate Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mr. K. Karthik,** Department of ECE and our project **Internal guide, Mrs. V. Sreeja, Associate Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

User Based Device control using fingerprint sensing. We come across areas where we need to switch no device for a particular user as soon as he enters. The device could be his Pc, fan, lights etc. For this purpose we suggest a fingerprint based device switcher project. The system switches on device for a particular user automatically on sensing him through his fingerprint scan. For this we use a fingerprint scanner interfaced to a microcontroller based circuit. As soon as a person enters he/she is allowed to scan his/her finger on the scanner. On scanning the data is sent to the microcontroller, based on this data the scanned copy is now verified for authentication. If the user is verified the microcontroller switches on a device (light) to indicate as the users verification.

CHAPTER 1
INTRODUCTION

OBJECTIVE OF THE PROJECT

The system switches on device for a particular user automatically on sensing him through his fingerprint scan. For this we use a fingerprint scanner interfaced to a microcontroller based circuit. As soon as a person enters he/she is allowed to scan his/her finger on the scanner.

On scanning the data is sent to the microcontroller, based on this data the scanned copy is now verified for authentication. If the user is verified the microcontroller switches on a device (light) to indicate as the users verification.

Introduction of Embedded System

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

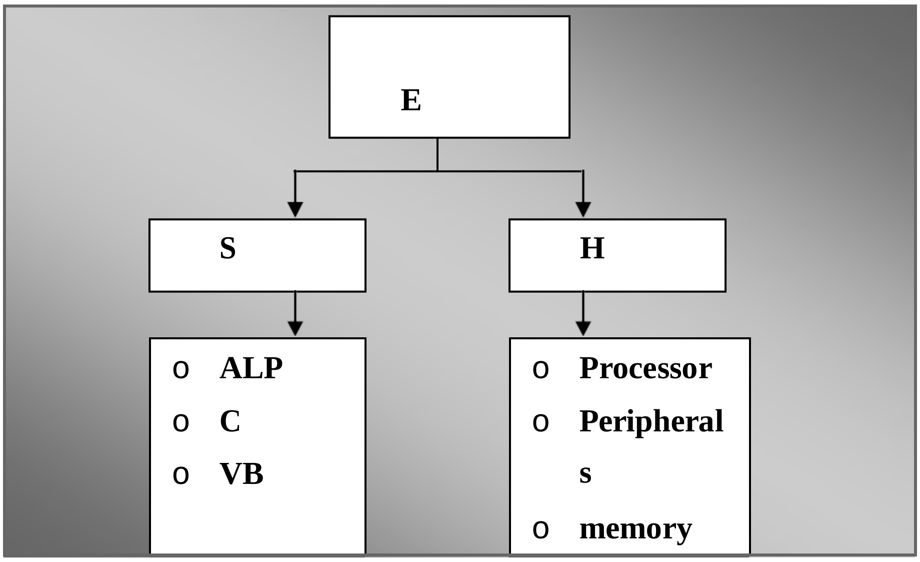

Figure 1.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors types

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)

Application Specific Integrated Circuits (ASIC)

- Micro Processor (μp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

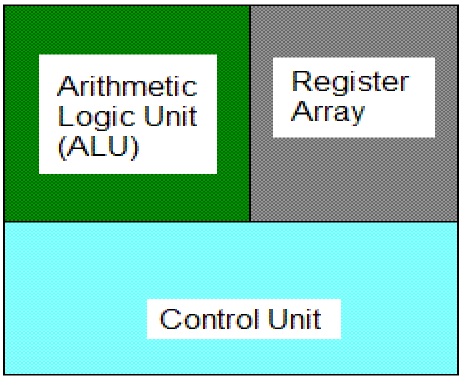

Fig1.2 basic elements of microprocessor

Three Basic Elements of a Microprocessor

Micro Controller (µc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.

Digital Signal Processors (DSPs)

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

CPU cores for computation and control

Peripherals to control timing critical functions

Memories to store data and program

Analog circuits to provide clocks and interface to the real world which is analog in nature

Os to connect to external components like LEDs, memories, monitors etc.

Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and

2. CISC (Complex Instruction Set computer)

Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.

Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.

The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

RISC characteristics

Simple instruction set:

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

Same length instructions.

Each instruction is the same length, so that it may be fetched in a single operation.

1machine-cycleinstructions.

Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

Complex Instruction Set Computer (CISC)

CISC, which stands for Complex Instruction Set Computer**,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC:

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.

The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.

As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.

Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.

So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.

Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.

CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

Memory Architecture

There two different type's memory architectures there are:

Harvard Architecture

Von-Neumann Architecture

Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The **Harvard architecture** is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

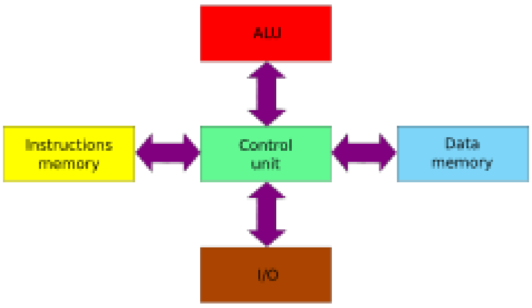

Figure 1.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

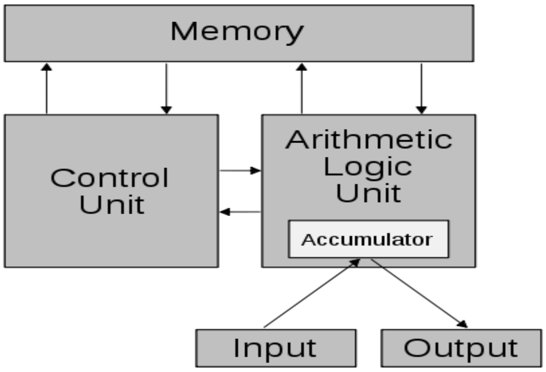

Figure 1.4 Schematic of the Von-Neumann Architecture.

Difference between Harvard and Von-Neumann Architecture

The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.

Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.

In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.

In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.

Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER 2

LITERATURE SURVEY

Fingerprint matching has been successfully used by law enforcement for more than a century. The technology is now finding lot of other applications such as identity management and access control. In this context, an automated fingerprint recognition system and identification of key challenges are described along with the switching opportunities. The description is like a product design in this report implementing RTOS (Real time operating system) under the domain of embedded system. Fingerprint Recognition is a widely popular but complex pattern recognition Problem. In this paper, we have come with a novel approach to solve the existing problems with a proper Embedded System Design. In this project as well the fingerprint detection makes it coherent with the application involved within. The solutions viable are never ending but the switching mechanisms are to be sought after

From earlier times, security was and also till now is an issue of concern in our households and also in office, shops, etc. Everyone has a fear of unauthorized person entering to their home or office without their knowledge. The normal door can be fitted with locks which are capable of breaking with the use of an alternate key. Alternatives to this system can be found like the password or pattern system in the locks which again has the possibility of getting exposed and opening the lock. So, a solution to such problems can be by combining door lock with biometrics. Biometric verification is any means by which a person can be uniquely identified by evaluating one or more distinguishing biological traits. Unique identifiers include fingerprints, hand geometry, earlobe geometry, retina and iris patterns, voice waves, DNA, and signatures. Here we will use fingerprint for biometric verification as it is one such thing which is unique to every individual and the use of fingerprint as the key to door locks can overcome the security problem of unauthorized people trespassing to our homes, shops, offices, etc to a great extent as duplicacy in such key is not possible. Also, this system will not lead to problems like losing keys because we do not require carrying keys if this system is used instead of traditional locks. So, using arduino we will try to implement the system with features which will increase the security level.

Current biometric recognition systems for website authentication are mostly web server based, needing server support and infrastructure, and sometimes dedicated external hardware, for online authentication. Not many web servers support this kind of infrastructure for authentication. On the other hand, pure device based authentication systems are of the `all or none' type, serving to authenticate users for every action when using the device, or having authentication once and then keeping the device free to use. In this paper we propose a hybrid model, where fingerprint authentication is used in combination with the auto complete function on the browser for logging in to certain types of websites, or accessing only certain kind of information on the browser. In this method, the fingerprint module, inbuilt on certain mobile devices like Samsung Galaxy, is triggered automatically when certain pre-configured rules are met, such as the user visiting certain categories of websites. Also, based on the identity of the person swiping their fingerprint, the device has the ability to switch between one of a number of preconfigured security modes. Such a model can enable enhanced authentication for logging in to websites on mobile devices. We present the results of tests on a browser enabled with this system to study average response times, accuracy and effect on browser performance.

Network security has always had an issue with secure authentication and identification. In the current mixed device network of today, the number of nodes on a network has expanded but these nodes are often unmanaged from a network security perspective. The solution proposed requires a paradigm shift, recognition of what has already happened, identity is for sale across the internet. That identity is the users' network ID, their behaviour, and even their behaviour in using the networks. Secondly a majority of the devices on the Internet have been fingerprinted. Use of device fingerprinting can help secure a network if properly understood and properly executed. The research into this area suggests a solution. Which is the use of device fingerprints including clock skews to identify the devices and a dual- authentication process targeted at authenticating the device and the user? Not only authenticating the identity presented but also combining them into a unified entity so failure to authenticate part of the entity means the whole is denied access to the network and its resources.

CHAPTER 3

BLOCK DIAGRAM

Block Diagram Of Project:

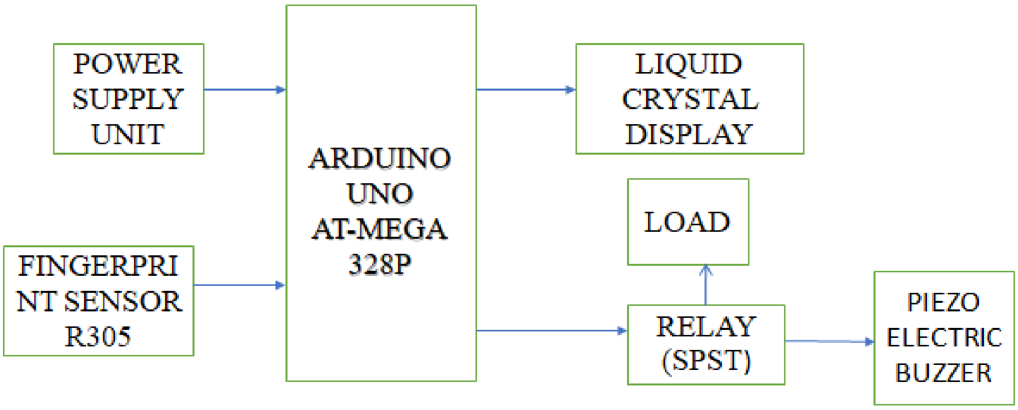

Fig 3.1 Block diagram of finger print based device switcher

The block diagram of finger print based device switcher is

The Proposed system finger print device switcher used for the authentication of any switching device. it means when user will be easily switch on his device and the wrong person will be switched on then the buzzer will be ringed otherwise correct person will accessed then the device will be on. Here we will connected the Lcd display used for it will display the information about to the project we will see in the display.

COMPONENT DESCRIPTION

ARDUINO UNO

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

Arduino is used as a controlling device .It comes comes with an open supply hardware feature that permits users to develop their own kit.

3.2.1LIQUID CRISTAL DISPLAY

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

3.2.3 Fingerprint Recognition Sensor

The sensor is a solid-state fingerprint sensor that reliably captures fingerprint information. It is designed to integrate into devices for improved security and convenience. The sensor provides a reliable, quick and user-friendly alternative to passwords, PIN's and other forms of user authentication.

This fingerprint scanner is capable of gathering and storing unique finger prints. Simply hold your finger on the optical scanner, query the device over serial, and you will be issued a unique ID. Use that ID within your embedded system to determine access levels, time clocks, door locks, etc. Unit includes 4 pin connector cable to connect and read to controller. The outputs is TTL level serial data.

CHAPTER 4

HARDWARE AND SOFTWARE COMPONENTS

POWER SUPPLY

Block Diagram

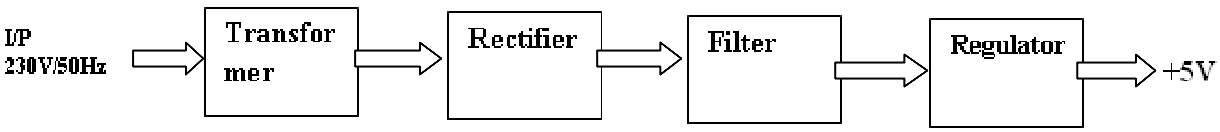

Figure 4.1 Block diagram Power Supply

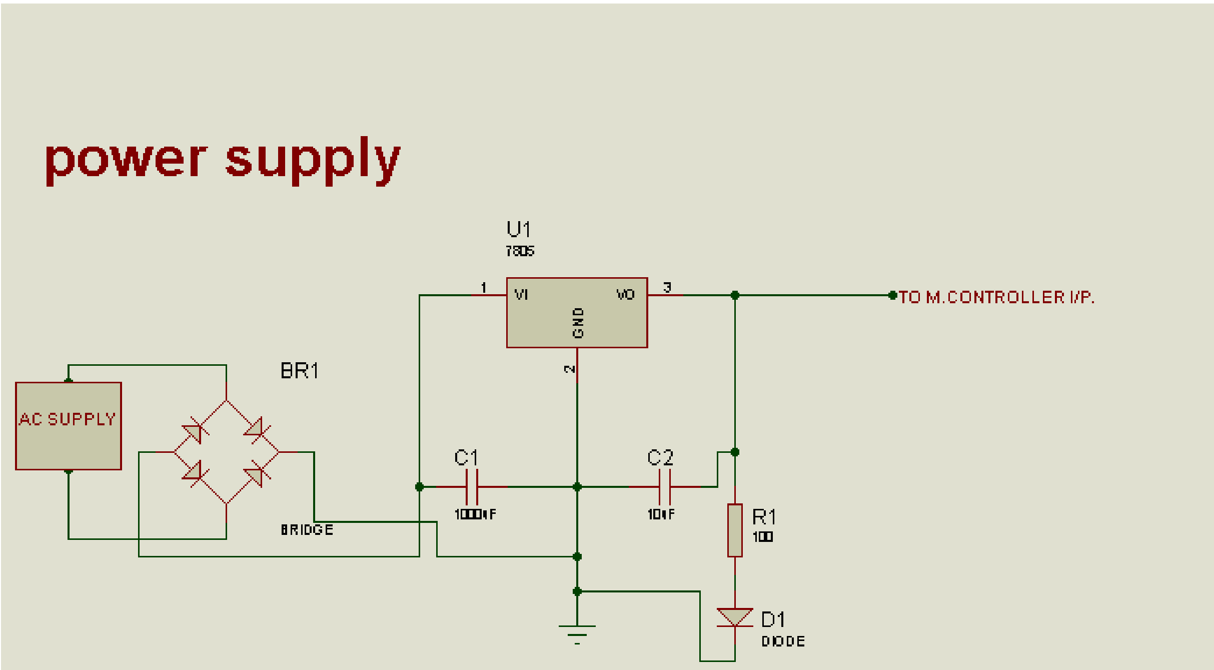
Circuit Diagram



circuit diagram of power supply

Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors the transformer's coils. A varying current in the first or primary winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

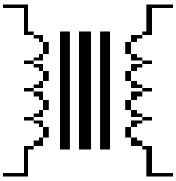


Figure: 4.3 Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

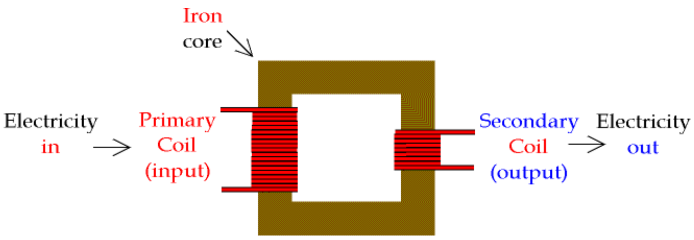

Figure 4.4 Transformer

Principle of trans former:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

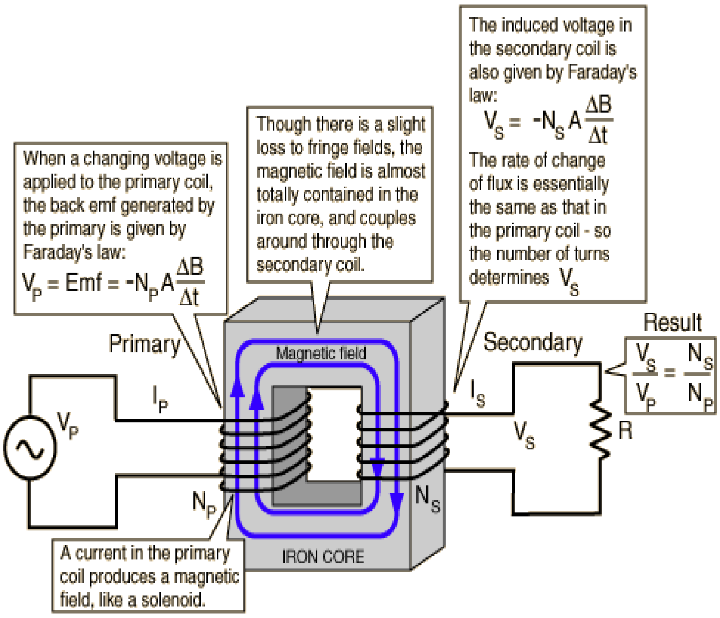

Figure: 4.5Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

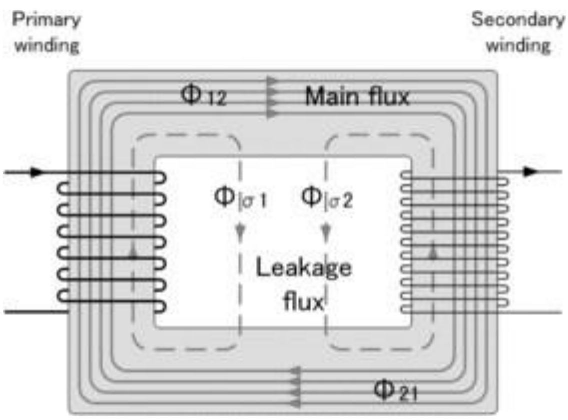

Figure: 4.6Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

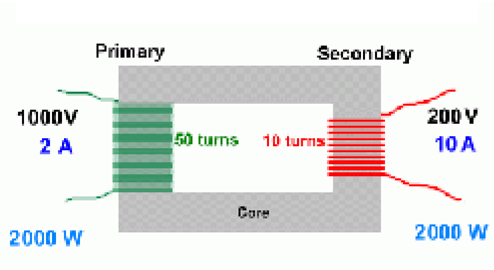

Figure: 4.7 Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

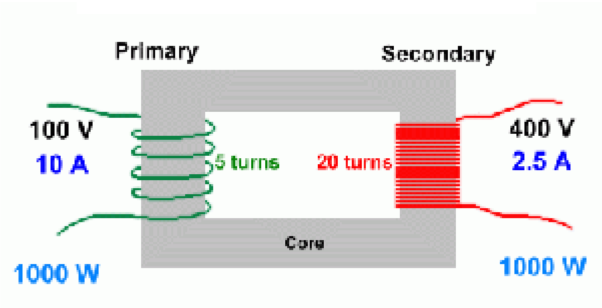

Figure: 4.8Step-Up Transformer

Applications

Generally these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

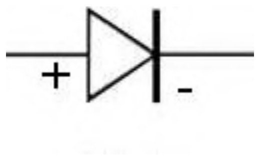

Figure 4.9 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-wave Rectifier

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure .

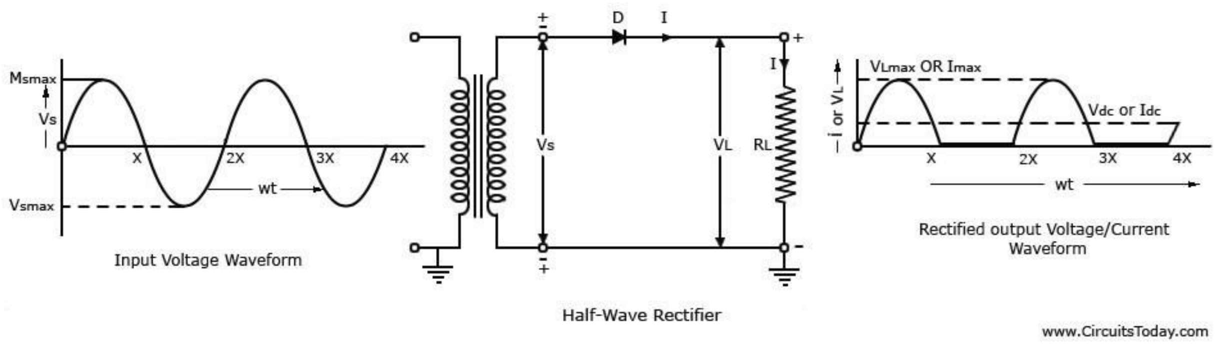

Figure 4.10 Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

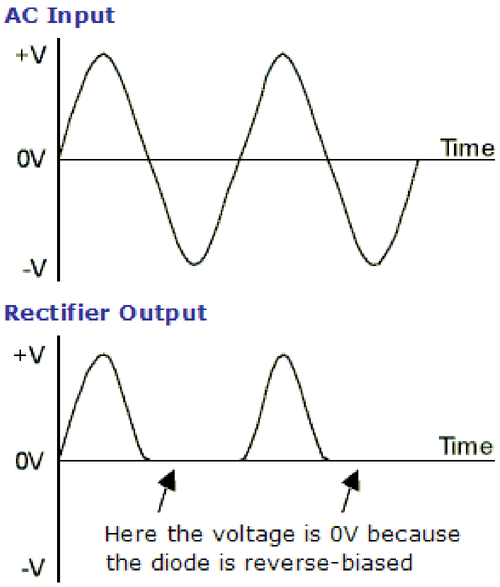

Figure 4.11 Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 4.

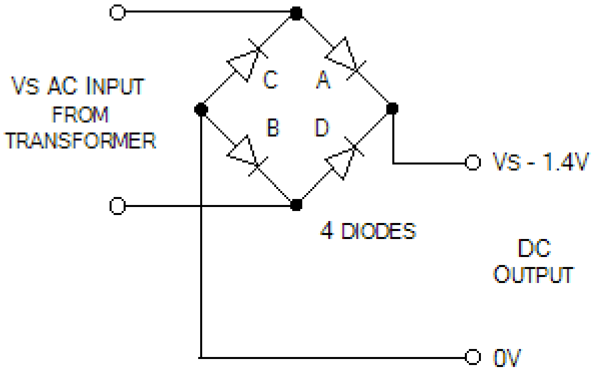

Figure:4.12 Full-Wave Rectifier

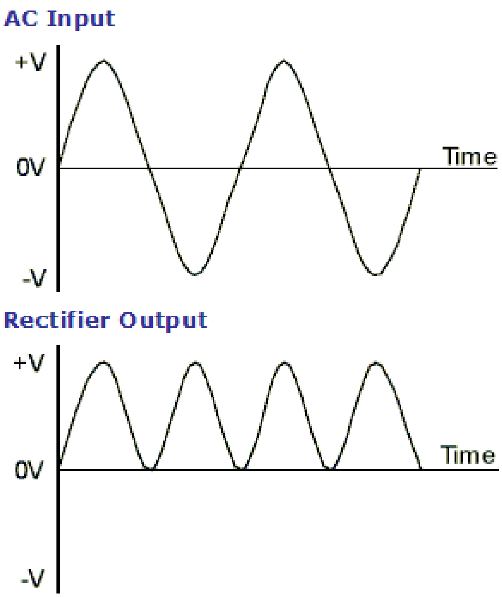

Figure :4.13Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

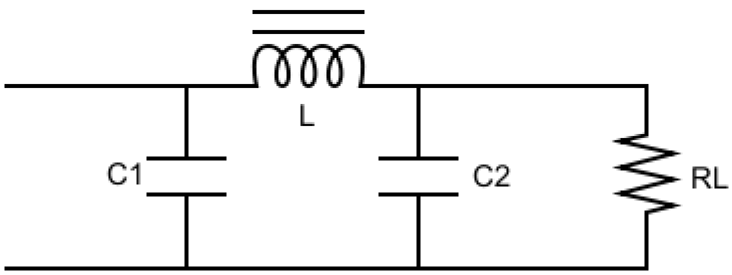

Figure: 4.14Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

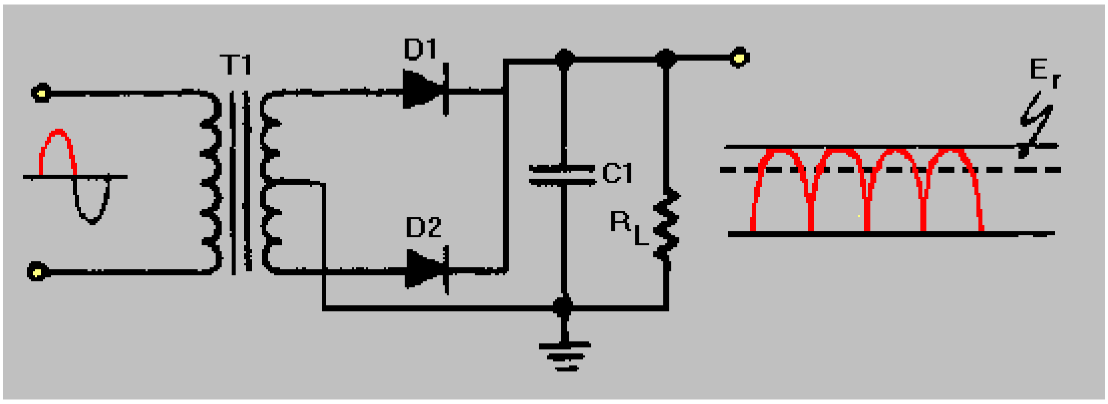

Figure: 4.15Centered Tapped Full-Wave Rectifier with a Capacitor Filter

Voltage Regulator

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

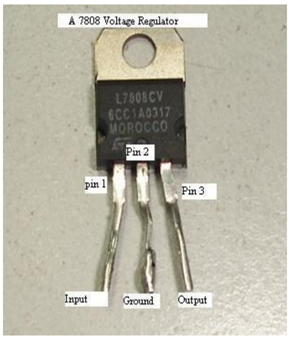

Figure 4.16 Regulator

Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

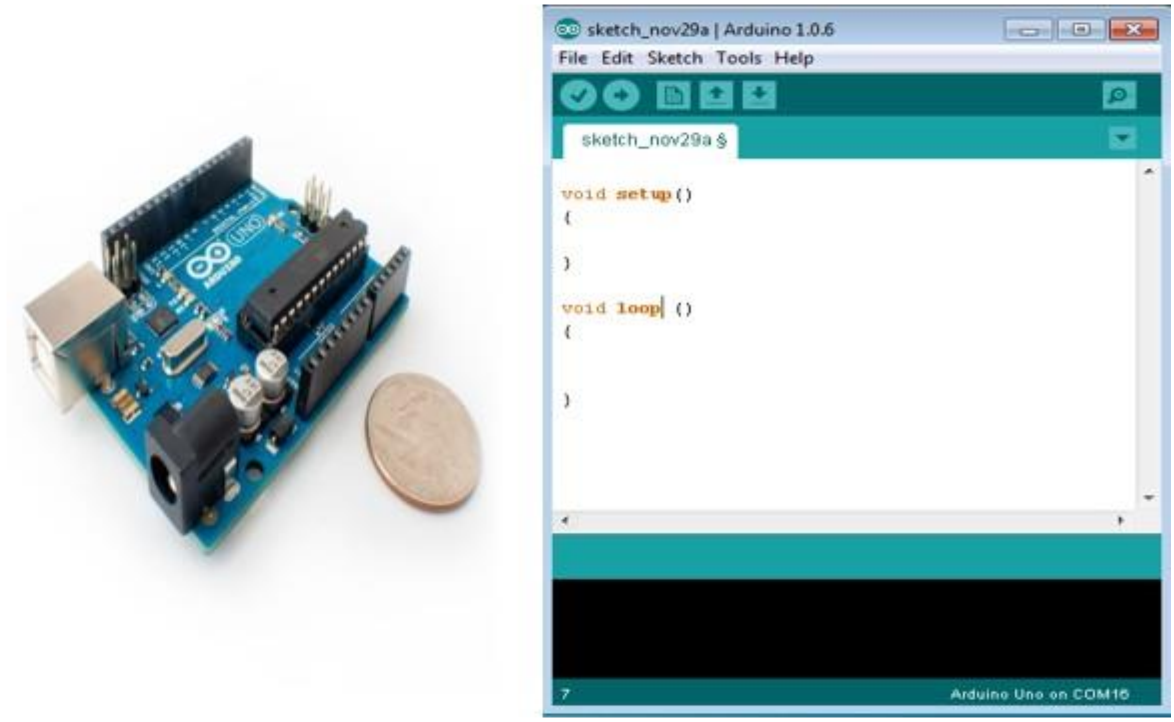

FIG:4.17 ARDUINO PLATFORM

Ardunio Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 4.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Voltage	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U 2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mh z	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

4.2.2Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

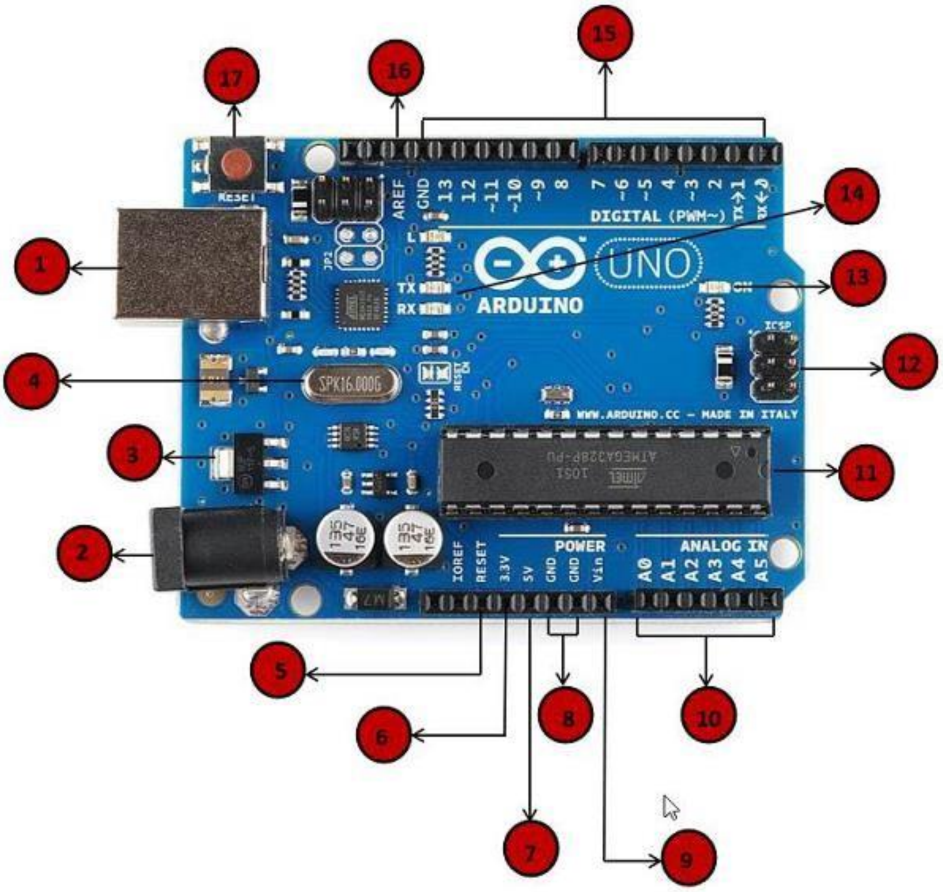

FIGURE:4.18 PIN DISCRIPTION OF ARDUINO UNO

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital

	value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1)

	or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Description Of 16x2

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic diagram

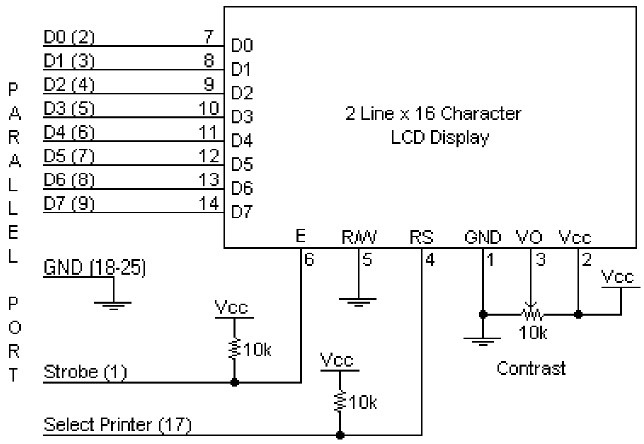

FIGURE:4.19 Schamatic diagram of lcd

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of w
- hich may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if

the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

TABLE:4.5 16 x 2 Alphanumeric LCD Module Specifications

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input

5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

FEATURES

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure :4.20 Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

PIN DESCRIPTION

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

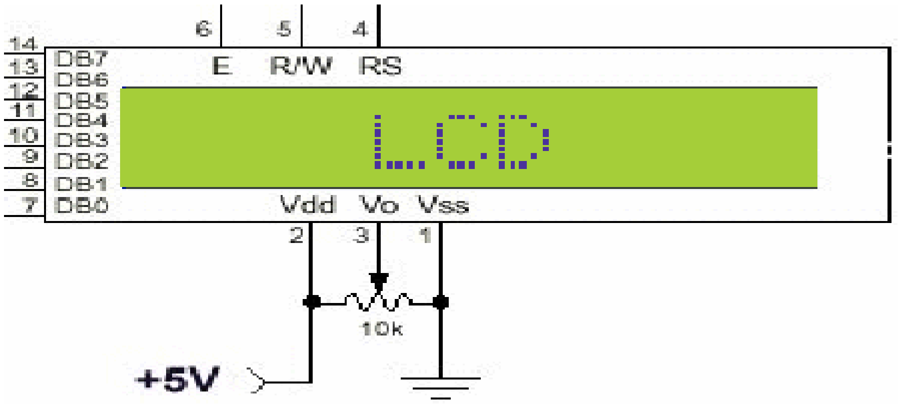

Figure 4.21 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 4.22 Pin specifications

CONTROL LINE

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or

8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines

- E - 0 Access to LCD disabled
- 1 Access to LCD enabled
- R/W - 0 Writing data to LCD
- 1 Reading data from LCD
- RS - 0 Instructions
- 1 Character

Writing data to the LCD

1) Set R/W bit to low
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Read data from data lines (if it is reading) on LCD

1) Set R/W bit to high
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Entering Text

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 4.6 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Fingerprint Sensor

The fingerprint sensor can read different fingerprints and store in its own flash memory. The sensor can perform three functions namely Add(Enroll) , Empty Database or search database and return the ID of stored fingerprint. Any of three functions can be called simply by making the pin low of the sensor or pressing onboard three switches. The response is either error or ok which is indicated by onboard LED. The response is also returned as single serial data byte.

The return byte is a valid ID or error code. The response byte is a single byte at 9600 bps thus making whole sensor very easy to use. We have provided indicating LEDs and function switch already so it's ready to use when you receive it. Just give power and start using the sensor using onboard switches. Then you can move on making external application using these functions.

Inputs and Outputs of Sensor

Input: Two ways to trigger the function of fingerprint sensor

1) Onboard switch: Add, Empty or Search.

2) Make pin low from external microcontroller for 5ms as per function required to be executed.

Outputs(Response): Two ways to monitor output response after a function is executed

1) Onboard LEDs: ERROR or OK

2) Read byte after executing function

Types of function

There are namely three functions you can call for the fingerprint sensor. We will see each in brief.

Add(Enroll) Function: Adds a fingerprint to database and return a byte of newly added ID. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function

Search Function: When a finger is put and search funtion is called, it returns a matching ID if found in its existing memory. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function.

Empty Function: When you wish to empty all fingerprint data stored on sensor you can use thisfunction. After executing this function, you will get 0xCC as OK or 0xFF in case of error.

About Fingerprint Recognition Sensor Module

The sensor is a solid-state fingerprint sensor that reliably captures fingerprint information. It is designed to integrate into devices for improved security and convenience. The sensor provides a reliable, quick and user-friendly alternative to passwords, PIN's and other forms of user authentication.

This fingerprint scanner is capable of gathering and storing unique finger prints. Simply hold your finger on the optical scanner, query the device over serial, and you will be issued a unique ID. Use that ID within your embedded system to determine access levels, time clocks, door locks, etc. Unit includes 4 pin connector cable to connect and read to controller. The outputs is TTL level serial data.

A biometric sensor, fingerprint sensor to be specific, also known as the fingerprint reader, is a fingerprint image capture device, the very front end of the biometric fingerprint identification/verification module. The fingerprint sensor captures the fingerprint images, matches the uniqueness of each print read by the sensor and compares it to the one stored in its module or local system database.

It consists of optical fingerprint sensor, high performance DSP processor and Flash. It boasts of functions such as fingerprint enrollment, fingerprint deletion, fingerprint verification, fingerprint upload, fingerprint download, etc.

3.3.4.2 Applications

- Computer peripherals – improves security and convenience
- Transportation systems – validation of operators, drivers and inspectors
- Medical equipment – authorization of operator or technician
- Physical access systems – approval for entry
- Kiosks and vending machines – confirmation of person receiving the selection
- Point of Sale terminals – authentication of tellers and cashiers

Specification

- Fingerprint enrollment time <250ms
- Fingerprint search time <1s（100 fingerprint, average value in test）
- Resolutions 500 DPI
- Security level 5, Adjustable
- Capacity 768 Templates
- FAR <0.0001%
- FRR <0.01%

- Power Supply 4.3V to 6V
- Working Current <80mA
- Peak Current <90mA
- Communication Interface TTL
- Communication Baud Rate 57600 bps
- Working Temperature -10 deg C to +40 deg C
- Working Humidity 40% RH to 85% TH (no dew)
- Module Dimensions 60x21x25 mm (LxWxH)

Electrical Interface

Module is connected to HOST via 4 PIN cable(provided with module).

Pin Number Pin Name Details

1 +Ve Positive power pin(+), Apply proper filtered DC regulated power (Typical 5V)

2 TXD Module Serial Transmit Output, Open-drain output, need to use pull-up resistance to supply in application

(Typical value: 10KΩ)

3 RXD Module Serial Receive Input, Wide voltage input up to 7V (TTL level)

4 GND Power supply ground

Note: The PIN close to the edge of circuit board is PIN4: Ground

Relays

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.

basics on relay handling

- To maintain initial performance, care should be taken to avoid dropping or hitting the relay.
- Under normal use, the relay is designed so that the case will not detach. To maintain initial performance, the case should not be removed. Relay characteristics cannot be guaranteed if the case is removed.
- Use of the relay in an atmosphere at standard temperature and humidity with minimal amounts of dust, SO 2, H 2 S, or organic gases is recommended.
- Please avoid the use of silicon-based resins near the relay, because doing so may result in contact failure. (This applies to plastic sealed type relays, too.)
- Care should be taken to observe correct coil polarity (+, –) for polarized relays.
- Proper usage requires that the rated voltage be impressed on the coil. Use rectangular waves for DC coils and sine waves for AC coils.
- Be sure the coil impressed voltage does not continuously exceed the maximum allowable voltage.
- Absolutely avoid using switching voltages and currents that exceed the designated values.
- The rated switching power and life are given only as guides. The physical phenomena at the contacts and contact life greatly vary depending on the type of load and the operating conditions. Therefore, be sure to carefully check the
- type of load and operating conditions before use.
- Do not exceed the usable ambient temperature values listed in the catalog.
- Use the flux-resistant type or sealed type if automatic soldering is to be used.
- Use alcohol based cleaning solvents when cleaning is to be performed using a sealed relay
- Avoid ultrasonic cleaning of all types of relays.
- Avoid bending terminals, because it may cause malfunction.
- As a guide, use a Faston mounting pressure of 40 to 70N {4 to 7kgf}for relays with tab terminals.

A relay is used to isolate one electrical circuit from another. It allows a low current control circuit to make or break an electrically isolated high current circuit path. The basic relay consists of a coil and a set of contacts. The most common relay coil is a length of magnet wire wrapped around a metal core. When voltage is applied to the coil, current passes through the wire and creates a magnetic field. This magnetic field pulls the contacts together and holds them there until the current flow in the coil has stopped. The diagram below shows the parts of a simple relay.

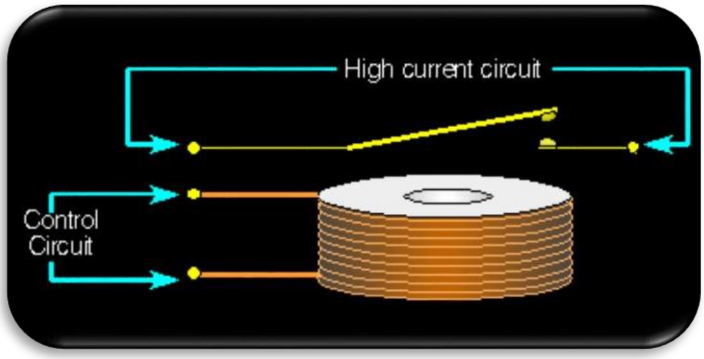

Figure:4.23 Relay

Operation

When a current flows through the coil, the resulting magnetic field attracts an armature that is mechanically linked to a moving contact. The movement either makes or breaks a connection with a fixed contact. When the current is switched off, the armature is usually returned by a spring to its resting position shown in figure 6.6(b). Latching relays exist that require operation of a second coil to reset the contact position.

By analogy with the functions of the original electromagnetic device, a solid-state relay operates a thyristor or other solid-state switching device with a transformer or light-emitting diode to trigger it.

Pole and throw

Since relays are switches the terminology applied to switches is also applied to relays. A relay will switch one or more *poles*, each of whose contacts can be thrown by energizing the coil in one of three ways

- Normally-open (**NO**) contacts connect the circuit when the relay is activated; the circuit is disconnected when the relay is inactive. It is also called a **Form A** contact or "make" contact.

- Normally-closed (**NC**) contacts disconnect the circuit when the relay is activated; the circuit is connected when the relay is inactive. It is also called a **Form B** contact or "break" contact.
- Change-over (**CO**), or double-throw (**DT**), contacts control two circuits: one normally-open contact and one normally-closed contact with a common terminal. It is also called a **Form C** contact or "transfer" contact ("break before make"). If this type of contact utilizes a "make before break" functionality, then it is called a **Form D** contact.

SPST RELAY

SPST relay stands for Single Pole Single Throw relay. Current will only flow through the contacts when the relay coil is energized.

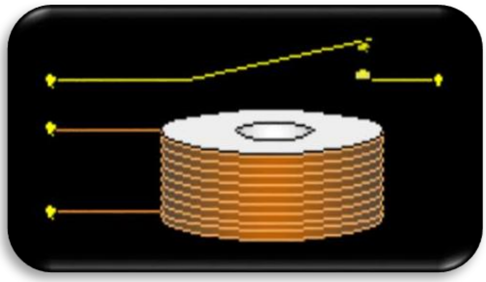

Figure:4.24 SPST Relay

SPDT Relay

SPDT Relay stands for Single Pole Double Throw relay. Current will flow between the movable contact and one fixed contact when the coil is De-energized and between the movable contact and the alternate fixed contact when the relay coil is energized. The most commonly used relay in car audio, the Bosch relay, is a SPDT relay.

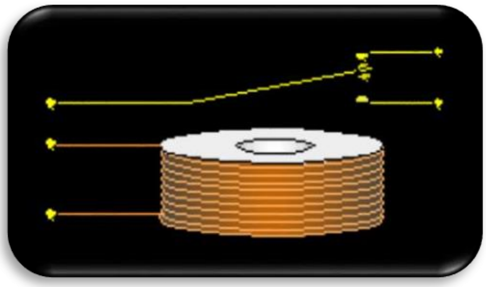

Figure:4.25 SPDT Relay

DPST Relay

DPST relay stands for Double Pole Single Throw relay. When the relay coil is energized, two separate and electrically isolated sets of contacts are pulled down to make contact with their stationary counterparts. There is no complete circuit path when the relay is De-energized.

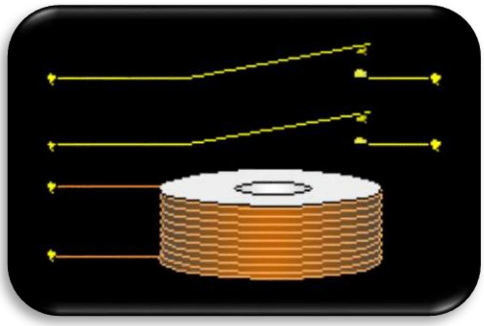

Figure:4.26 DPST Relay

DPDT Relay

DPDT relay stands for Double Pole Double Throw relay. It operates like the SPDT relay but has twice as many contacts. There are two completely isolated sets of contacts.

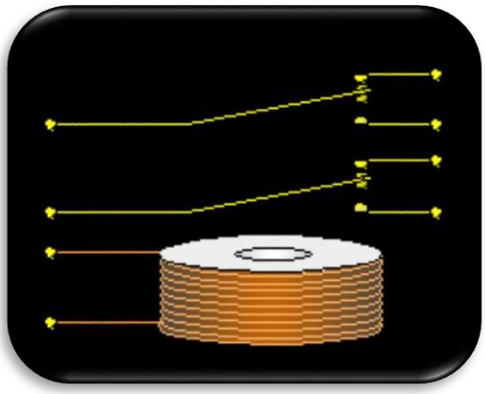

Figure:4.27 DPDT Relay

This is a 4 Pole Double Throw relay. It operates like the SPDT relay but it has 4 sets of isolated contacts.

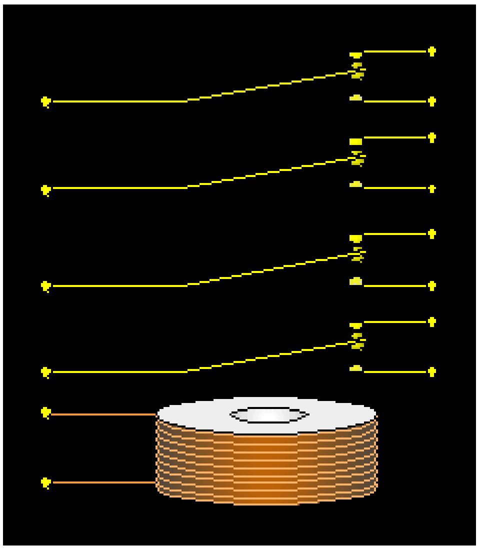

Figure: 4.28 4 Pole Double Throw relay

Types of relay:

1. Latching Relay
2. Reed Relay
3. Mercury Wetted Relay
4. Machine Tool Relay
5. Solid State Relay (SSR)

Latching relay

Latching relay, dust cover removed, showing pawl and ratchet mechanism. The ratchet operates a cam, which raises and lowers the moving contact arm, seen edge-on just below it. The moving and fixed contacts are visible at the left side of the image.

A **latching relay** has two relaxed states (bi-stable). These are also called "impulse", "keep", or "stay" relays. When the current is switched off, the relay remains in its last state. This is achieved with a solenoid operating a ratchet and cam mechanism, or by having two opposing coils with an over-center spring or permanent magnet to hold the armature and contacts in position while the coil is relaxed, or with a remanent core. In the ratchet and cam example, the first pulse to the coil turns the relay on and the second pulse turns it off. In the two coil example, a pulse to one coil turns the relay on and a pulse to the opposite coil turns the relay off. This type of relay has the advantage that it consumes power only for an instant, while it is being switched, and it retains its last setting across a power outage. A remanent core latching relay requires a current pulse of opposite polarity to make it change state.

Figure:4.29 Latching relay

Reed relay

A reed relay has a set of contacts inside a vacuum or inert gas filled glass tube, which protects the contacts against atmospheric corrosion. The contacts are closed by a magnetic field generated when current passes through a coil around the glass tube. Reed relays are capable of faster switching speeds than larger types of relays, but have low switch current and voltage ratings.

Mercury-wetted relay

A **mercury-wetted reed relay** is a form of reed relay in which the contacts are wetted with mercury. Such relays are used to switch low-voltage signals (one volt or less) because of their low contact resistance, or for high-speed counting and timing applications where the mercury eliminates contact bounce. Mercury wetted relays are position-sensitive and must be mounted vertically to work properly. Because of the toxicity and expense of liquid mercury, these relays are rarely specified for new equipment. See also mercury switch.

Machine tool relay

A **machine tool relay** is a type standardized for industrial control of machine tools, transfer machines, and other sequential control. They are characterized by a large number of contacts (sometimes extendable in the field) which are easily converted from normally-open to normally-closed status, easily replaceable coils, and a form factor that allows compactly installing many relays in a control panel. Although such relays once were the backbone of automation in such industries as automobile assembly, the programmable logic controller (PLC) mostly displaced the machine tool relay from sequential control applications.

Solid-state relay

A solid state relay (SSR) is a solid state electronic component that provides a similar function to an electromechanical relay but does not have any moving components, increasing long-term reliability. With early SSR's, the tradeoff came from the fact that every transistor has a small voltage drop across it. This voltage drop limited the amount of current a given SSR could handle. As transistors improved, higher current SSR's, able to handle 100 to 1,200 Amperes, have become commercially available. Compared to electromagnetic relays, they may be falsely triggered by transients.

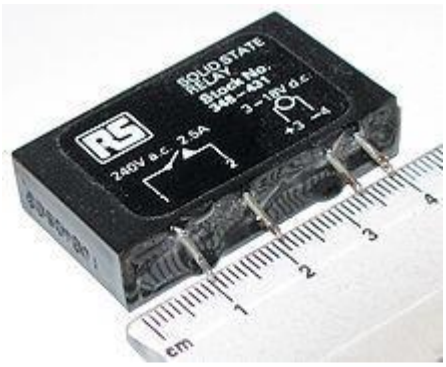

Figure: 4.30 Solid relay, which has no moving parts

Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current

- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

Applications:

Relays are used:

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems,
- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.

➢ To perform time delay functions. Relays can be used to act as an mechanical time delay device by controlling the release time by using the effect of residual magnetism by means of a inserting copper disk between the armature and moving blade assembly.

Switches

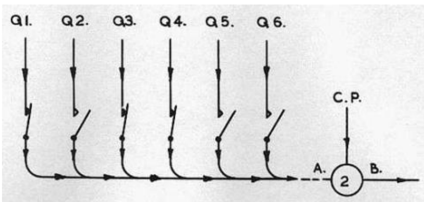
Introduction

A switch is an electrical component that can break an electrical circuit, interrupting the current or diverting it from one conductor to another. The most familiar form of switch is a manually operated electromechanical device with one or more sets of electrical contacts. Each set of contacts can be in one of two states: either 'closed' meaning the contacts are touching and electricity can flow between them, or 'open', meaning the contacts are separated and non-conducting.

Figure:4.31 switches

CONSTRUCTION

Keys are placed for giving instructions to the particular part. For example if need to operate a robot .keys are placed and each key is giving an instruction through which the robot moves. If we need to operate the



Switches with larger numbers of poles or throws can be described by replacing the "S" or "D" with a number or in some cases the letter "T" (for "triple"). In the rest of this article the terms SPST, SPDT and intermediate will be used to avoid the ambiguity in the use of the word "way".

WORKING

A pair of contacts is said to be "closed" when current can flow from one to the other. When the contacts are separated by an insulating air gap, an air space, they are said to be "open", and no current can flow at typical voltages.

Switches are classified according to the arrangement of their contacts in electronics. Electricians installing building wiring use different nomenclature, such as "one-way", "two-way", "three-way" and "four-way" switches

In a push-button type switch, in which the contacts remain in one state unless actuated, the contacts can either be normally open (abbreviated "n.o." or "no") until closed by operation of the switch, or normally closed ("n.c. or "nc") and opened by the switch action. A switch with both types of contact is called a changeover switch. These may be "make-before-break" which momentarily connect both circuits, or may be "break-before-make" which interrupts one circuit before closing the other

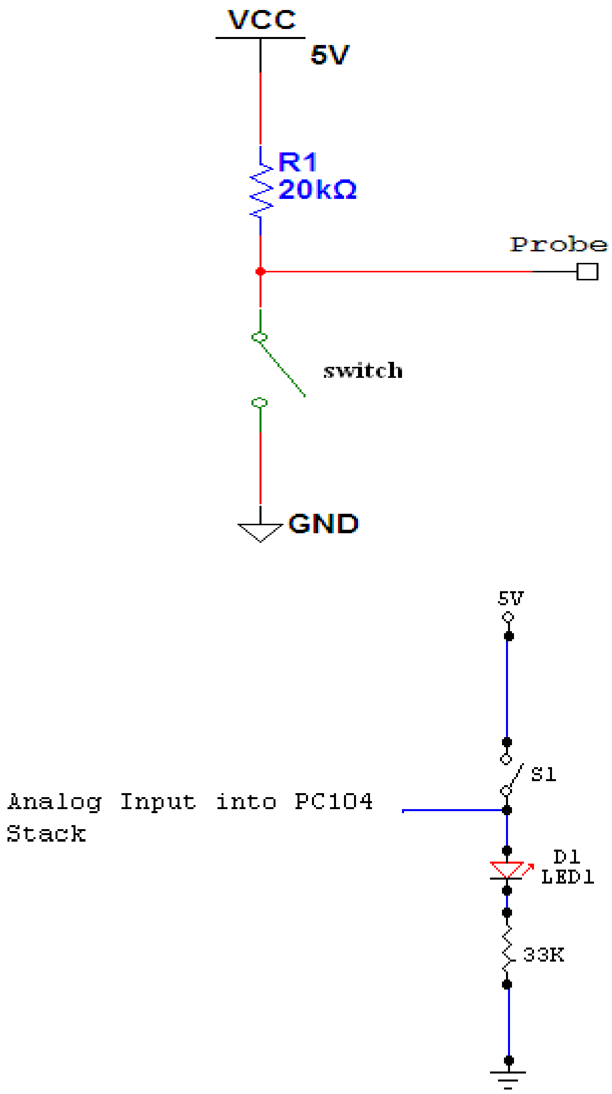


Figure:4.32 circuits of the switch

From the above circuit it explains the working of the switch when supply is given to the circuit the resistor take the current and oppose to the certain extend until the switch is pressed. These switches can be connected parallel or serial in required manner.

We can have resistor, capacitor, light resistor diode etc as the combination of the switch. For example w the reset circuit in which we the resistor and capacitor as the combination.

APPLICATIONS

- They are used for the given instructions to the required device like robot, driving the motor, etc.
- Switches can arrange in the matrix from or in the required from according to the application.
- Reset circuit of the controller, motor also has the switches for its particular functioning.

SOFTWARE REQUIERMENTS

Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

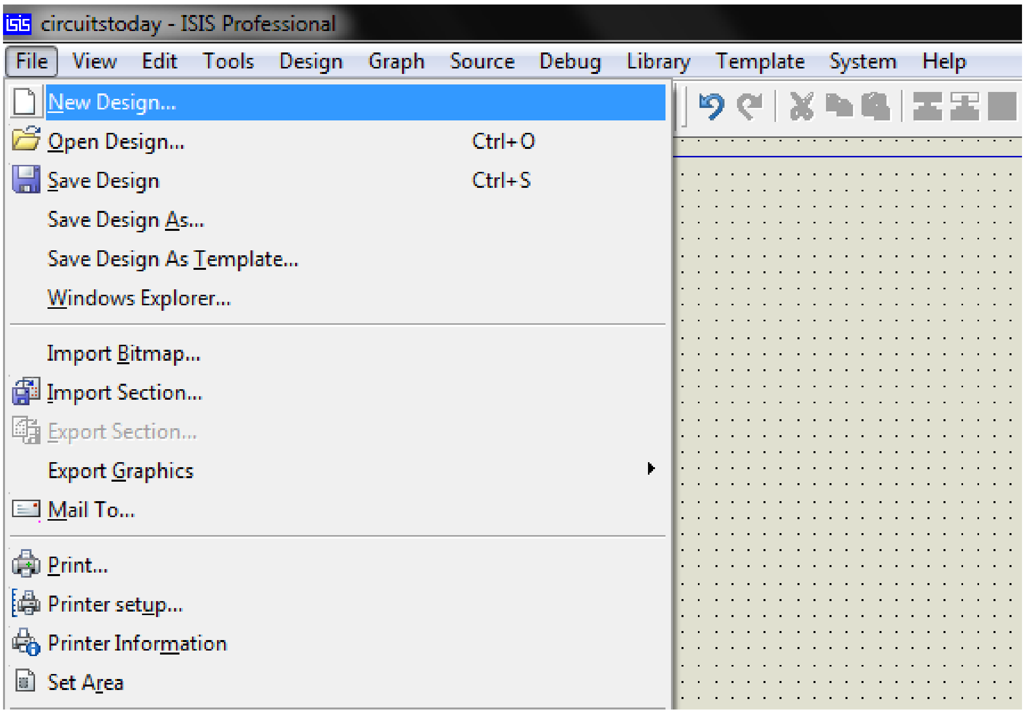

Figure 4.33 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

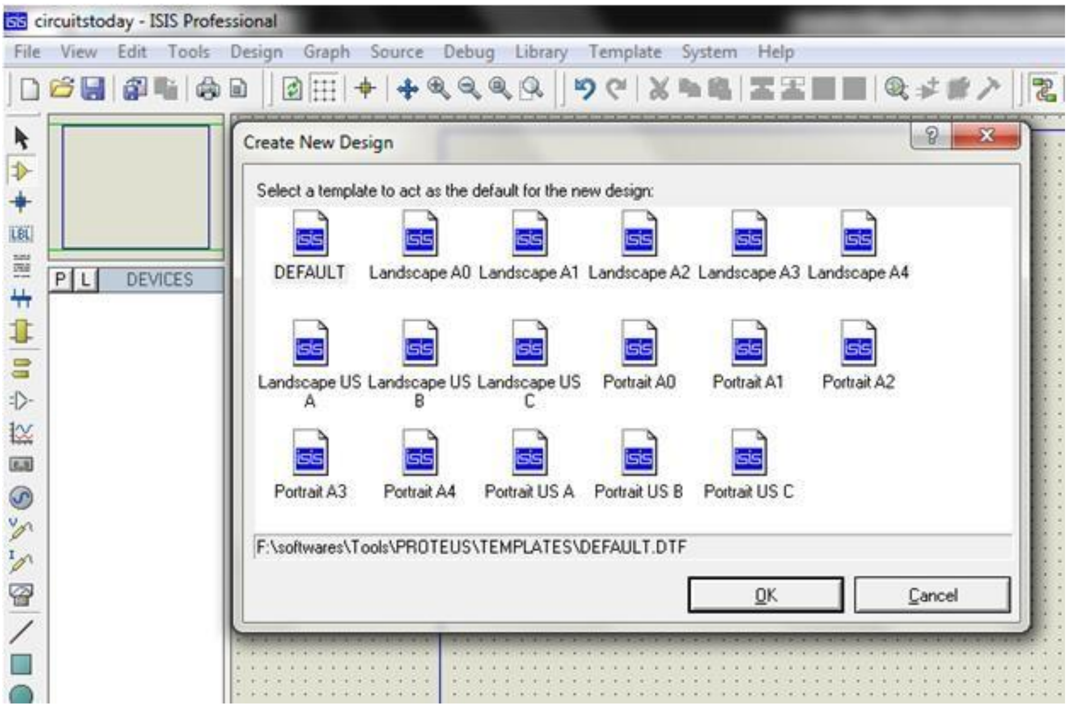

Figure:4.34 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

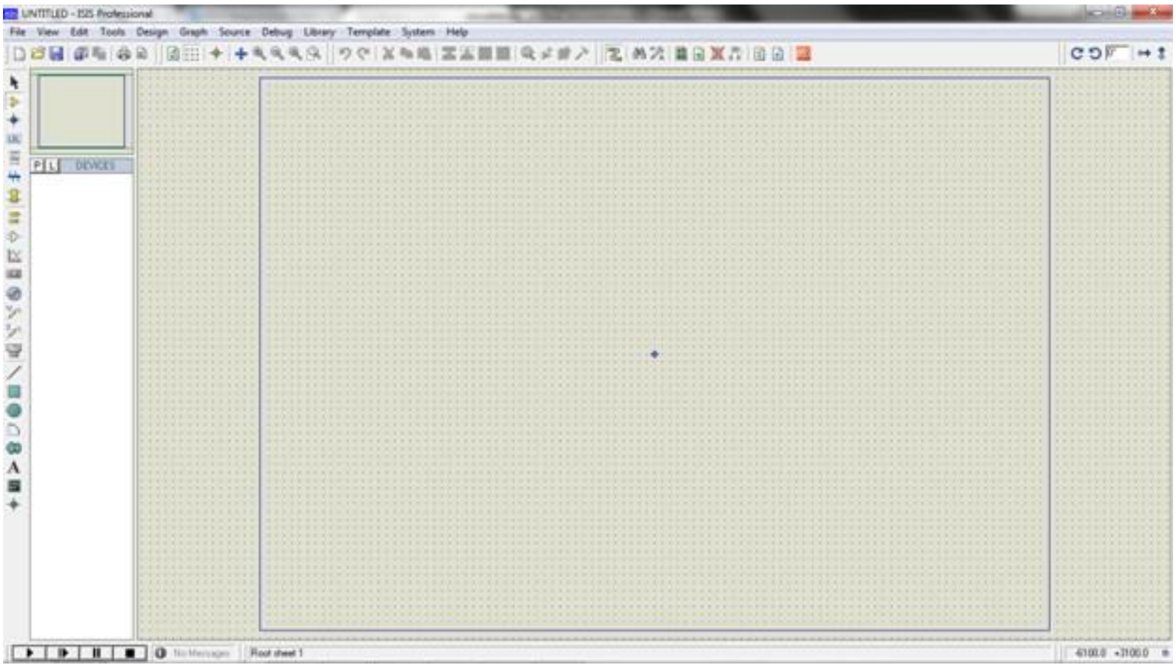

Figure: 4.35 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

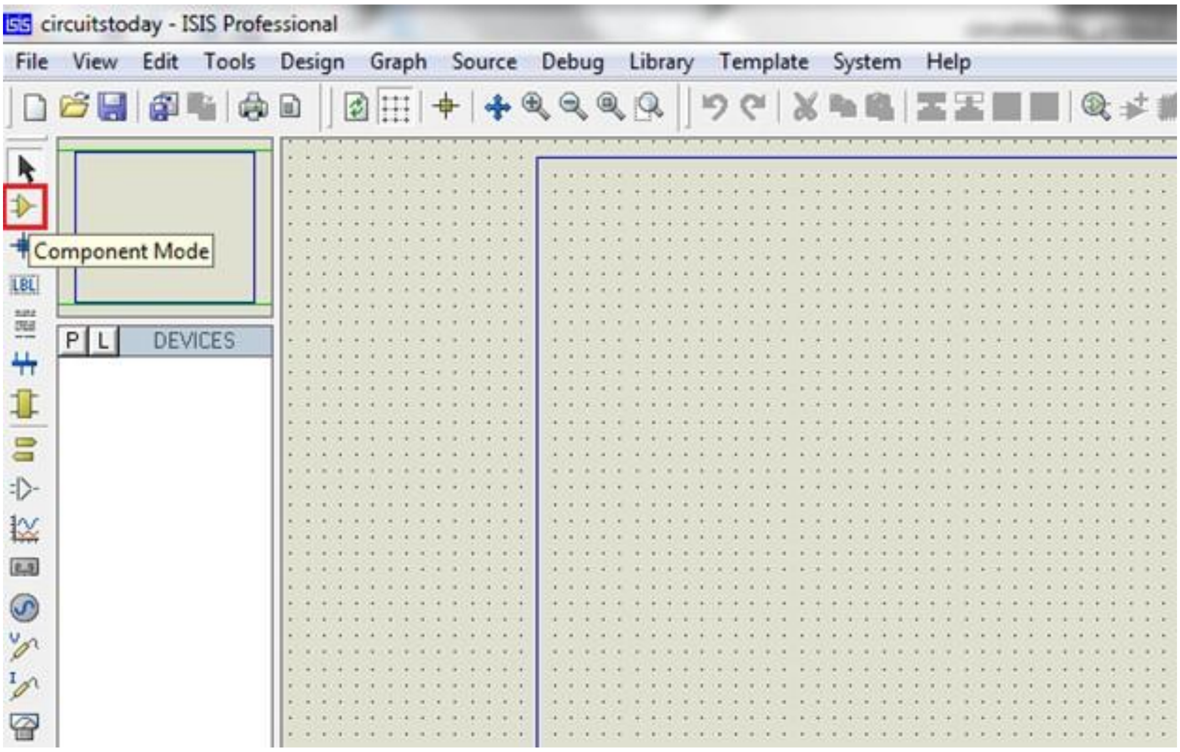

Figure: 4.36 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

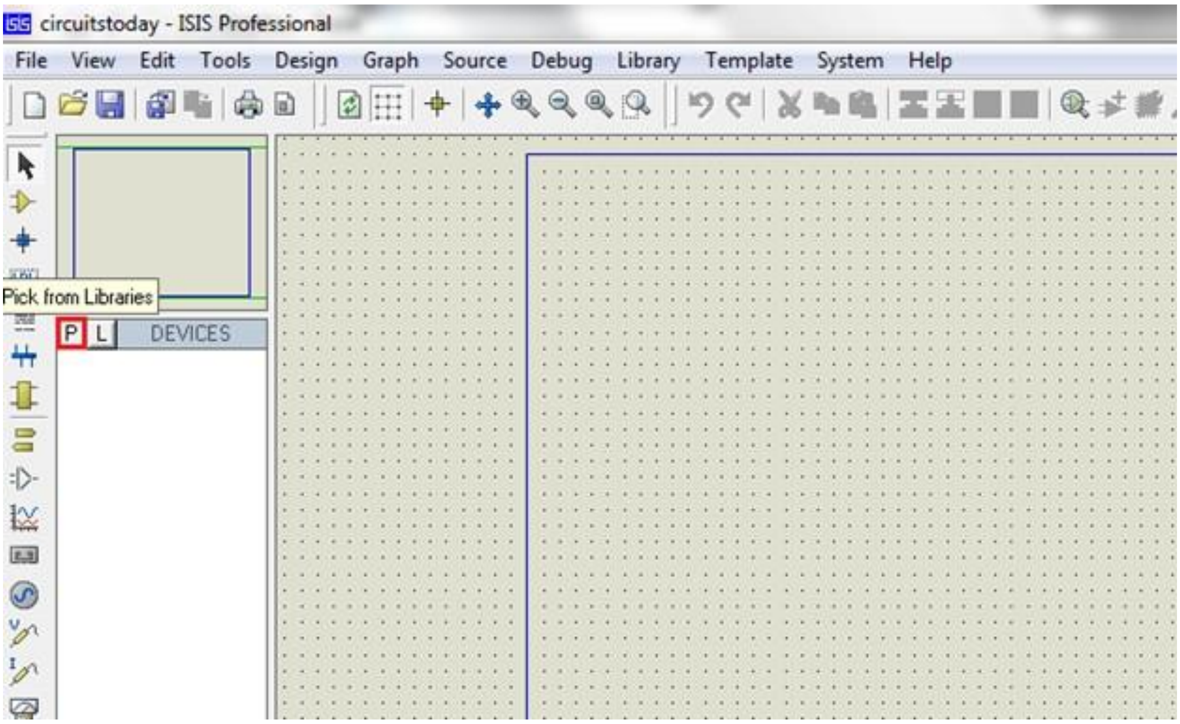

Figure: 4.37 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

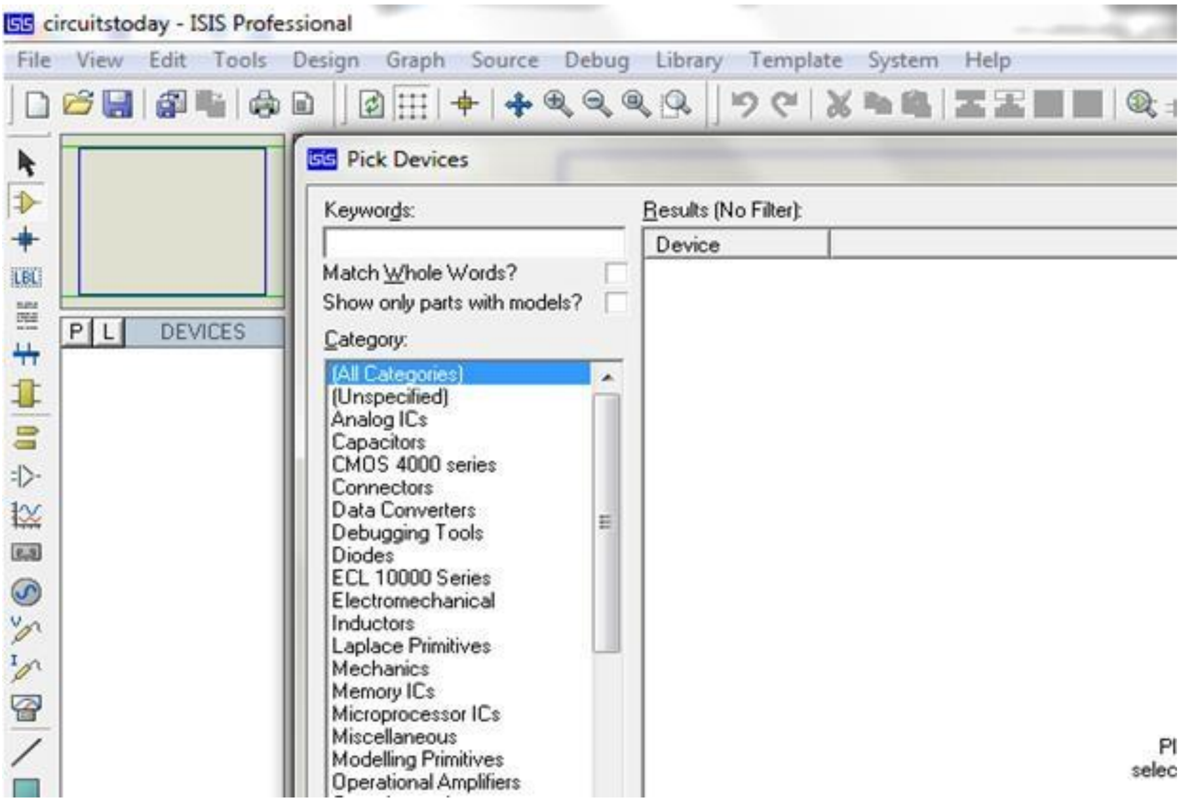

Figure:4.38 Keywords Textbox

Example shows below selection of push button. Select the components accordingly.

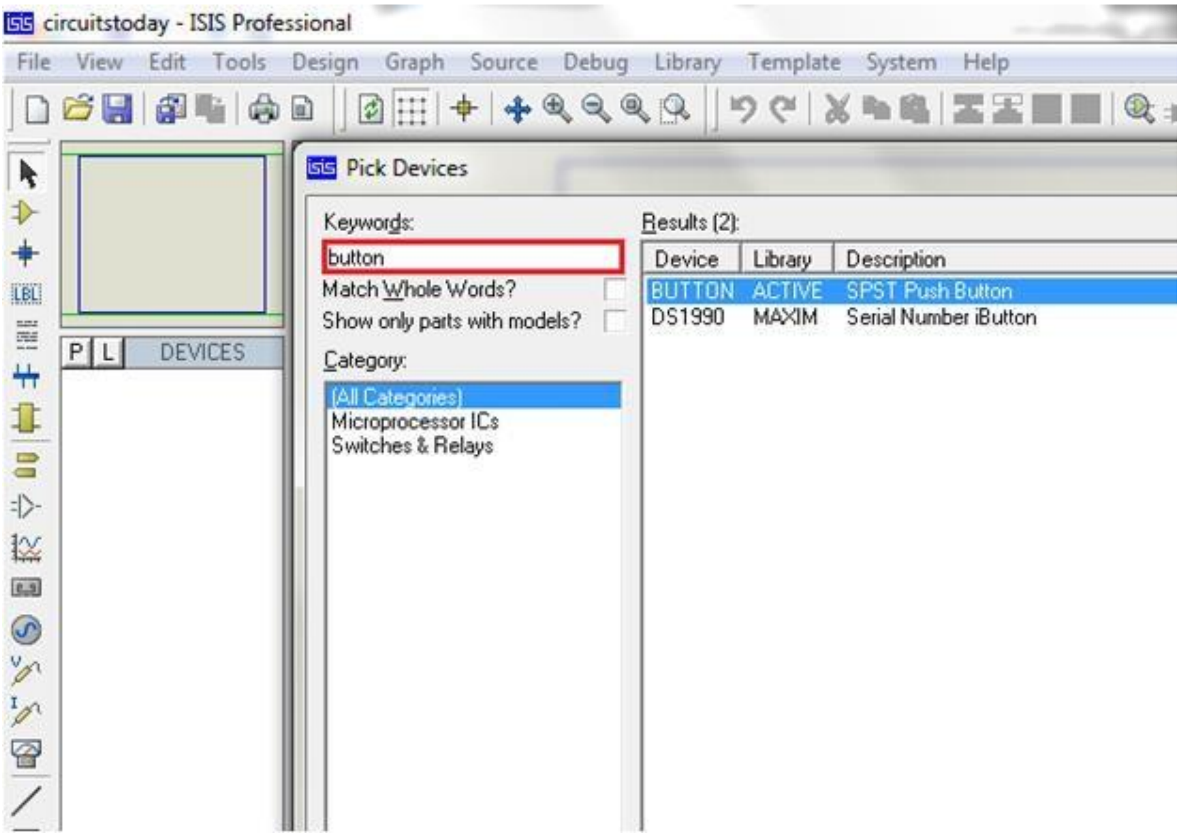

Figure:3.34 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

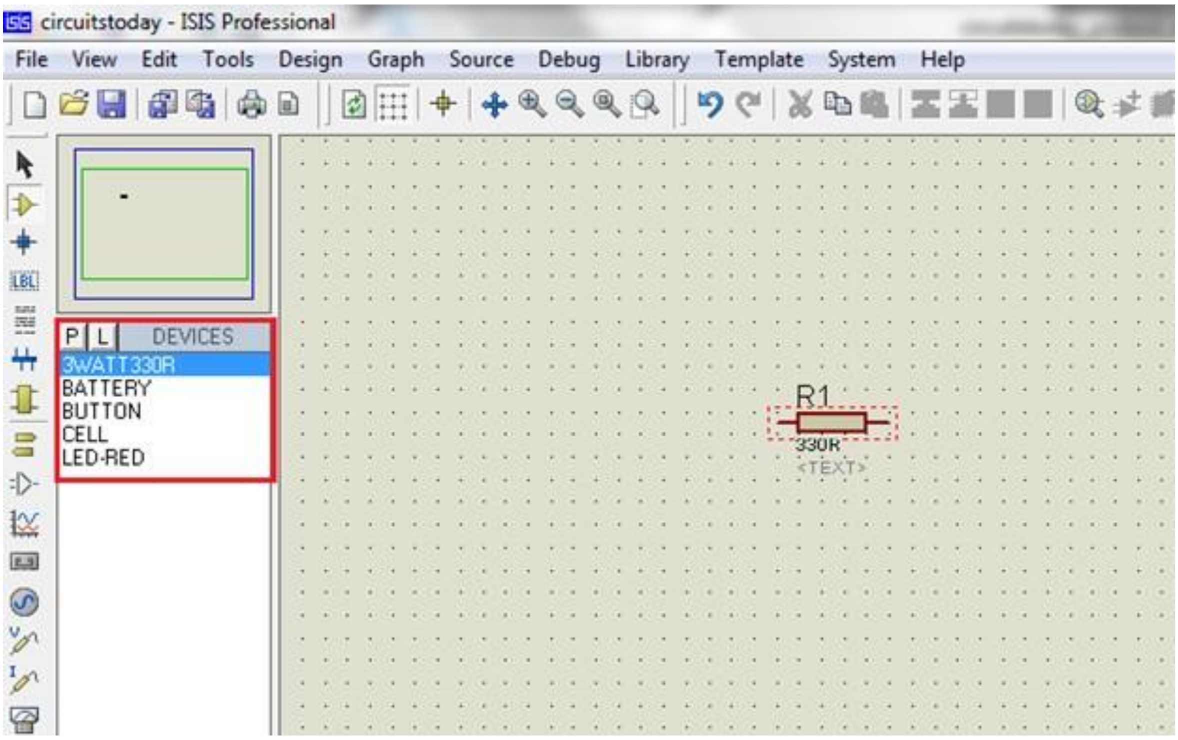

Figure:4.40 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

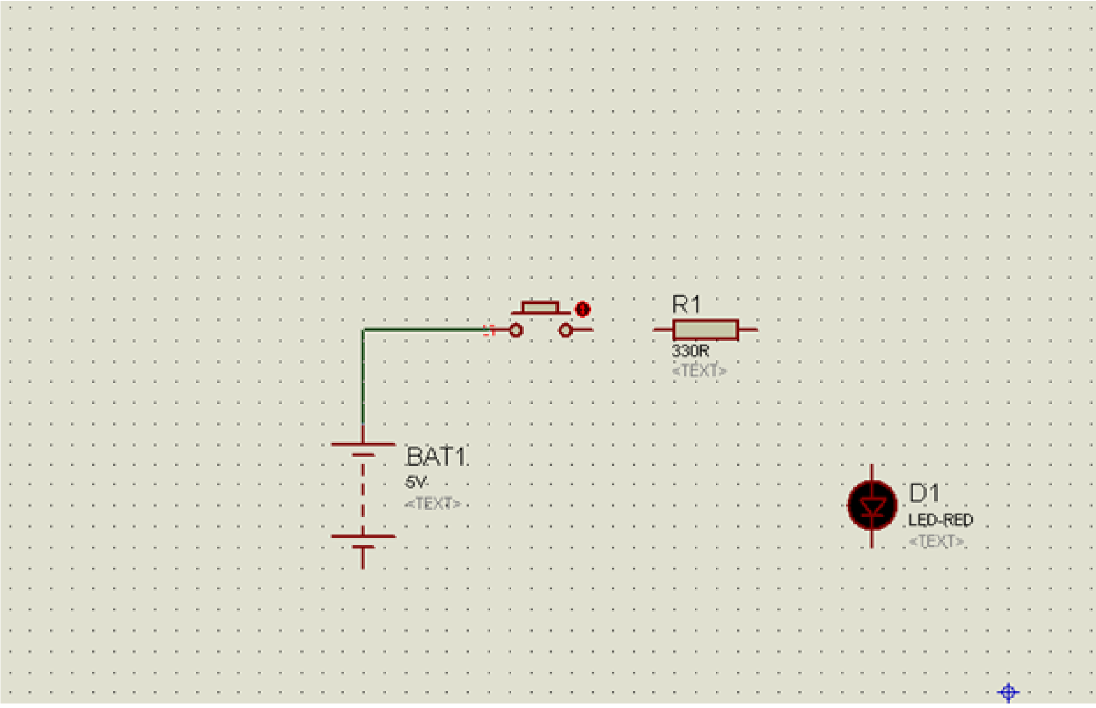

Figure:4.41 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

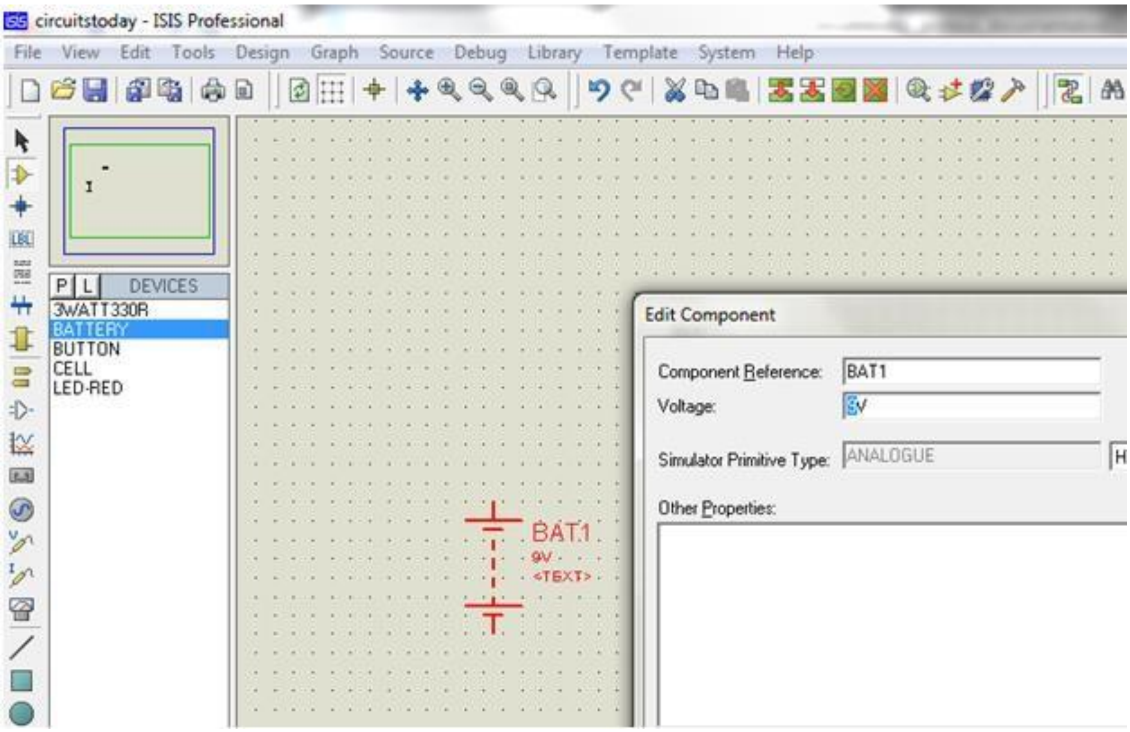

Figure: 4.42 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

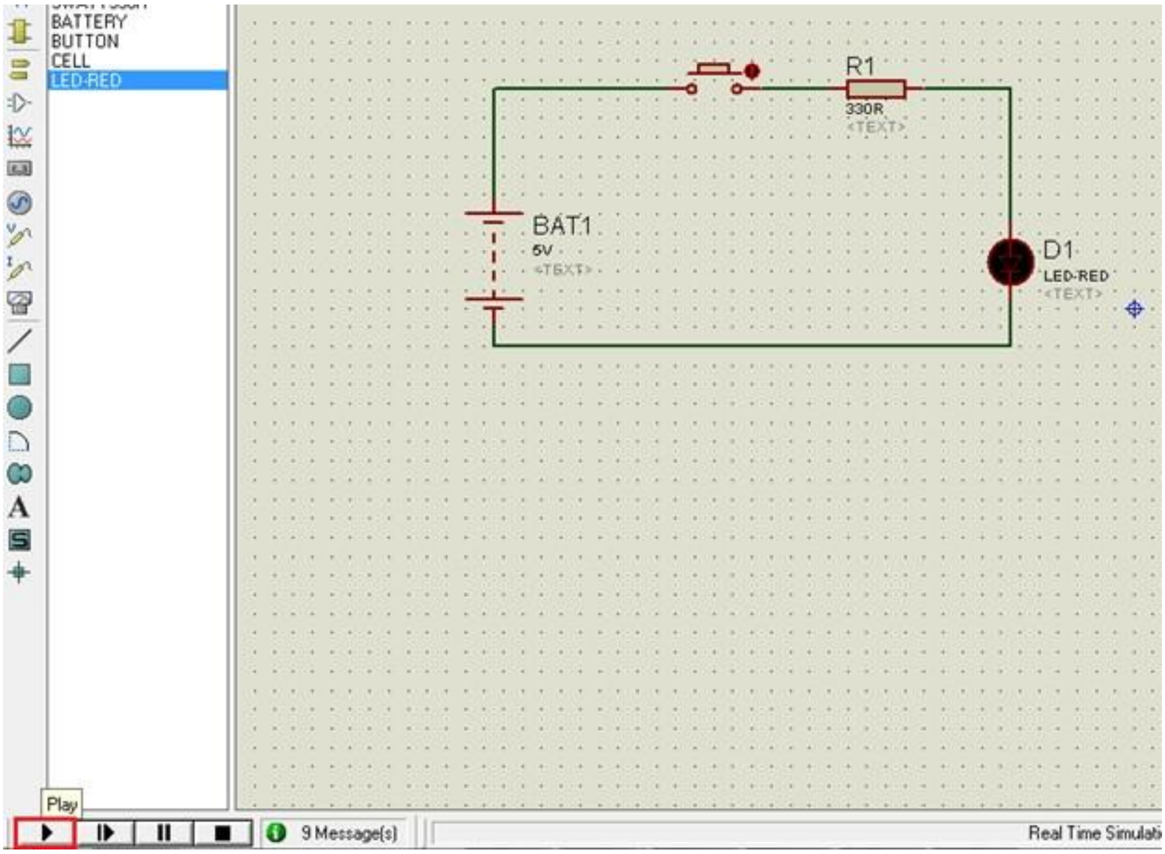

Figure:4.43 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

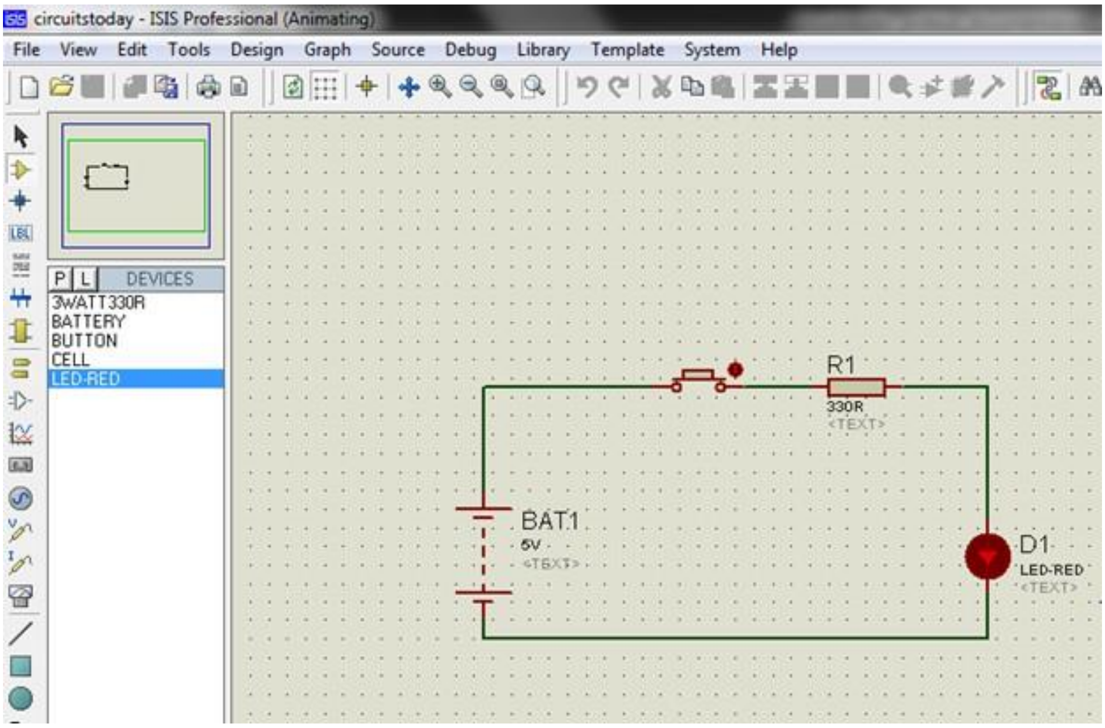

Figure:4.44 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

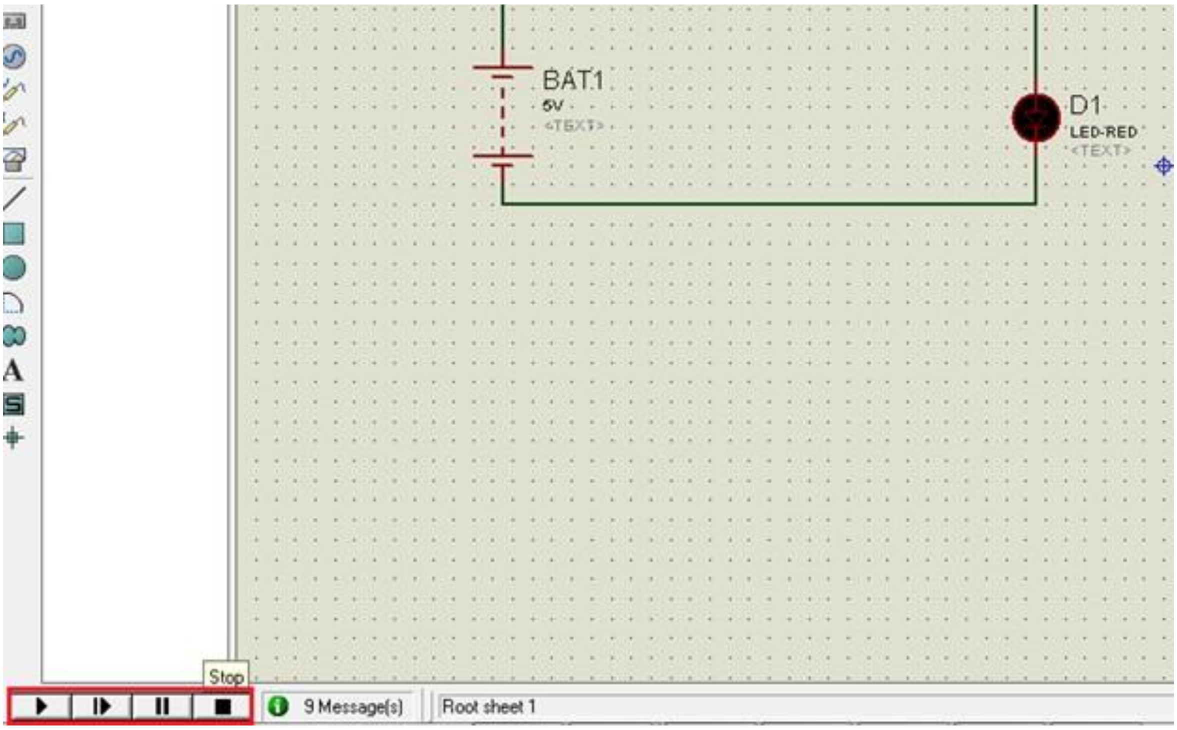

Figure:4.45 Simulation Step-Pause-Stop Buttons

Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]
Repository	github.com/arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux
Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig:4.46 usb cable

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

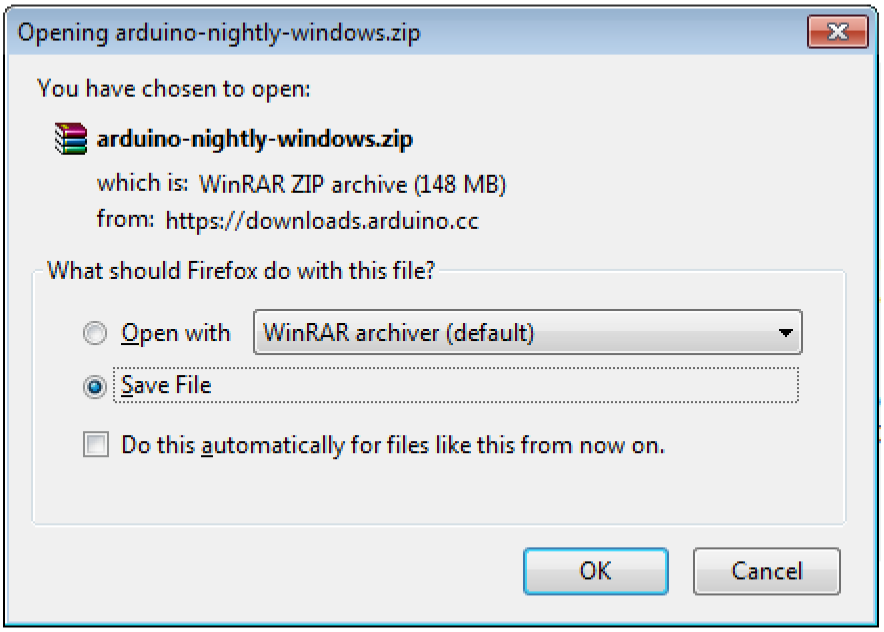

Fig:4.47 down load aurdino ide

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

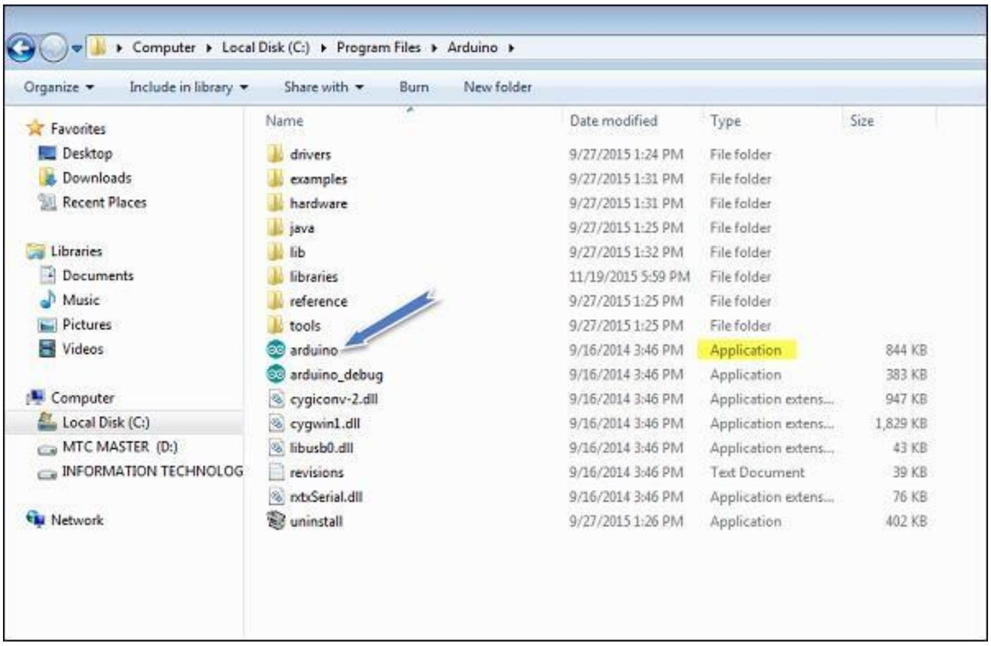

Fig:4.48launching aurdino ide

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

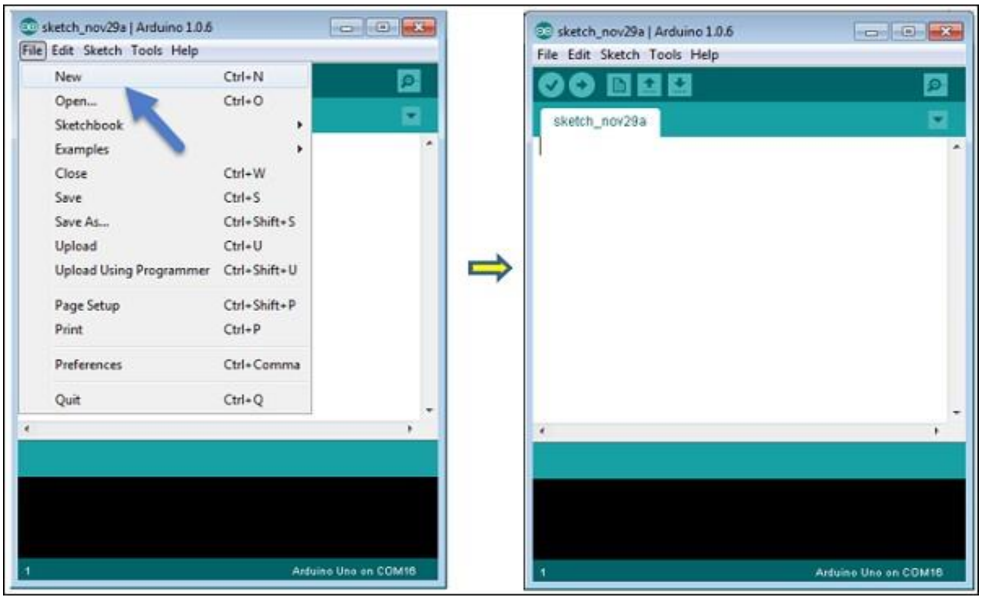

Fig:4.49 opeaning first project

To open an existing project example, select File → Example → Basics → Blink.

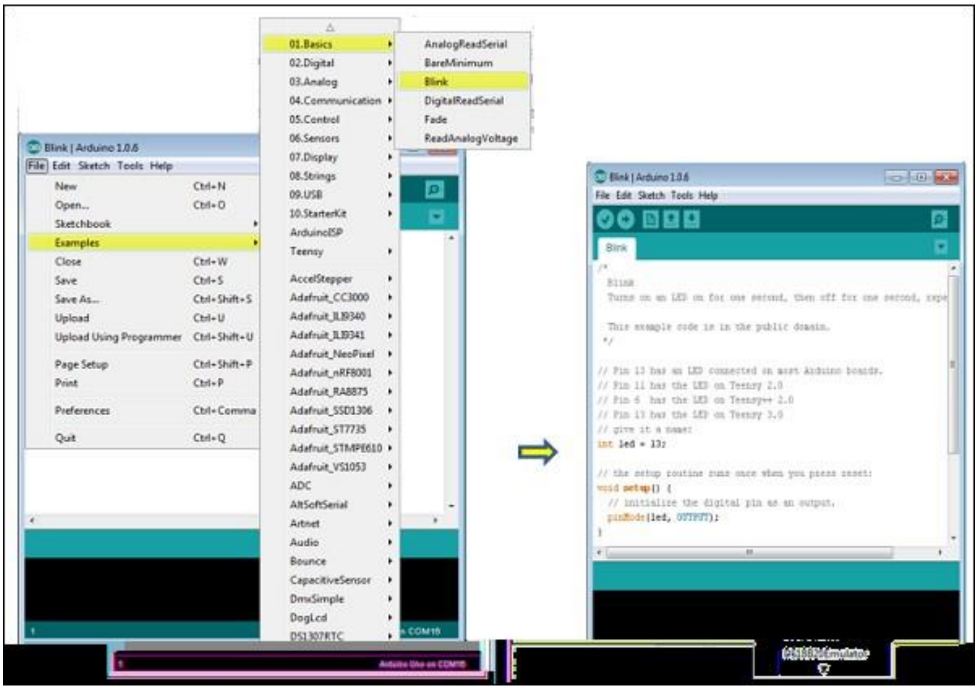

Fig:4.50selecting aurdino board

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

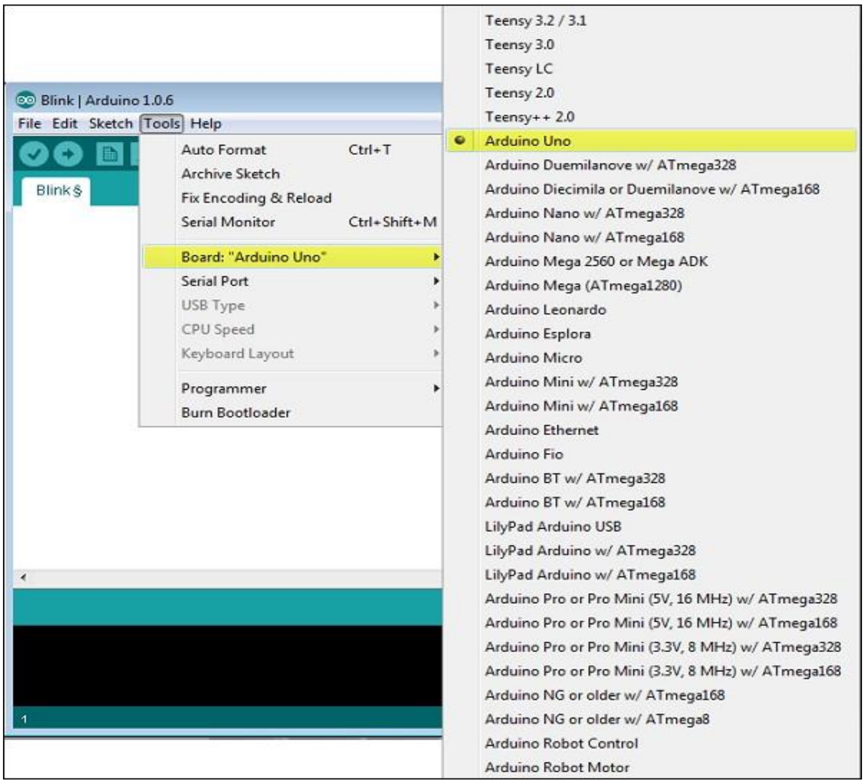

Fig:4.50 selecting aurdino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

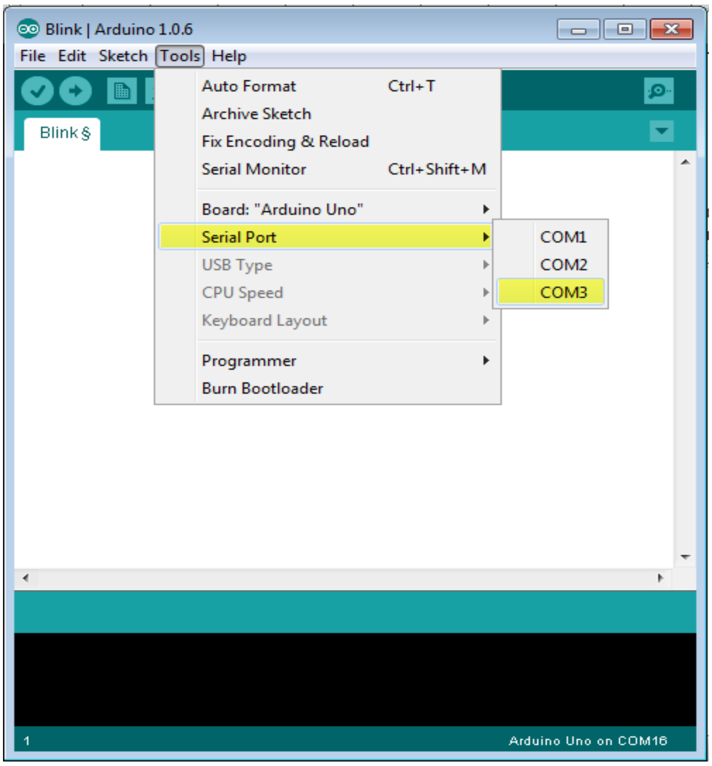

Fig:4.51 selecting serial poart

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

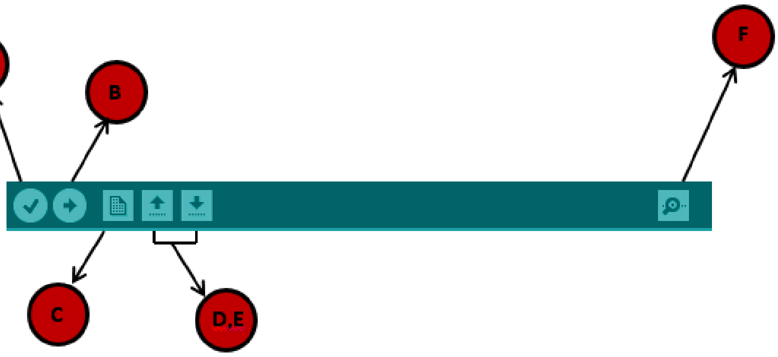

Fig:4.52 upload the program on board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

WORKING

The first we will give the 5v dc supply to give the kit .then switch on the device, then the finger print module will ask to enrolled the finger print . After enrolled the finger print is enrolled will display in LCD display board. Then automatically it will store the finger print. Then we switch on the device then the LCD display will asks the put your finger. After that if the correct person will authenticate the device will be switched The door lock will be opened. After that the unauthorized person will try to switch on the kit the device will not opened .the door will be locked .the buzzer will ringing

CHAPTER 5

RESULTS

RESULTS

The Finger print based device switcher project prototype as shown in below figure below

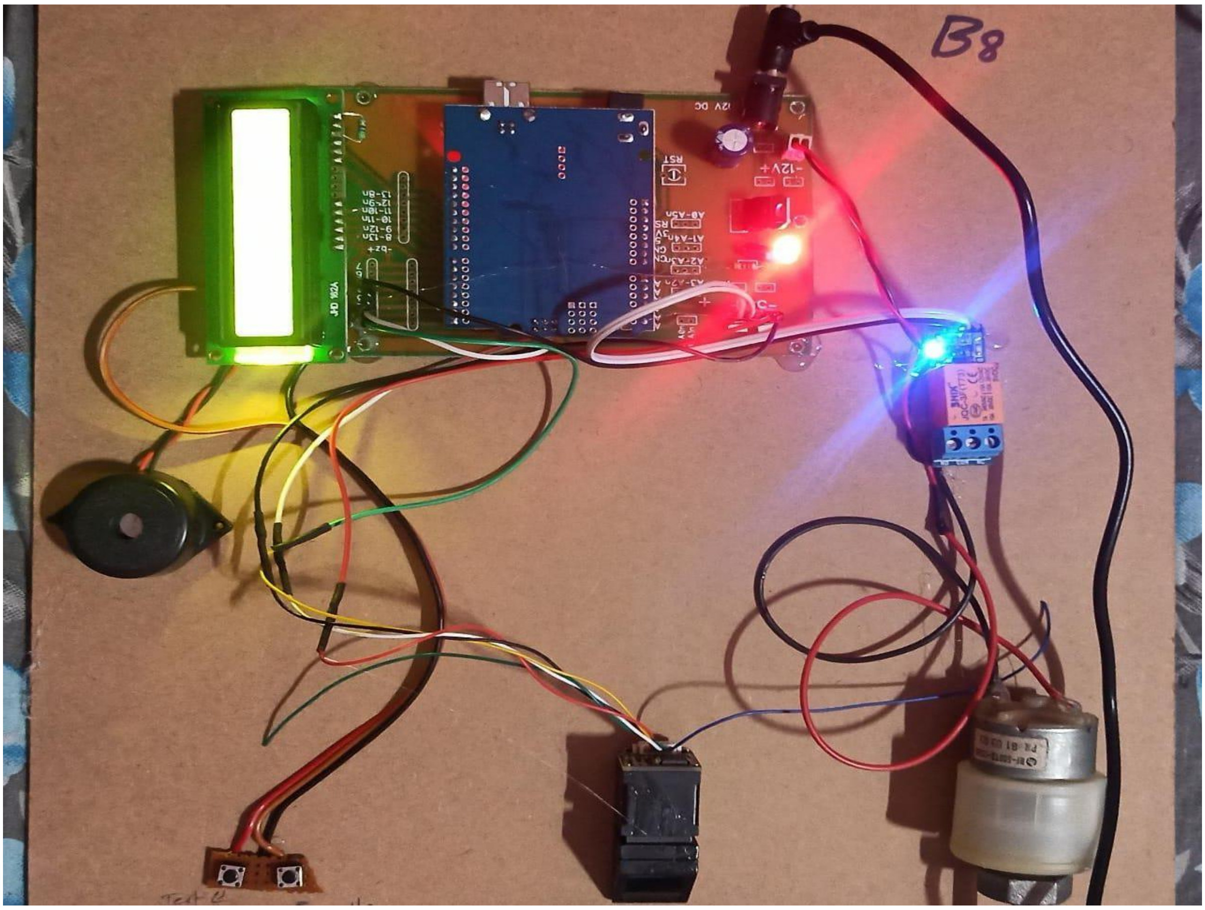

Fig:5.1 Finger print base device switcher proto type

RESULTS

RESULT 1

When the person to store the finger print first he was enrolled the finger print the stored the finger print

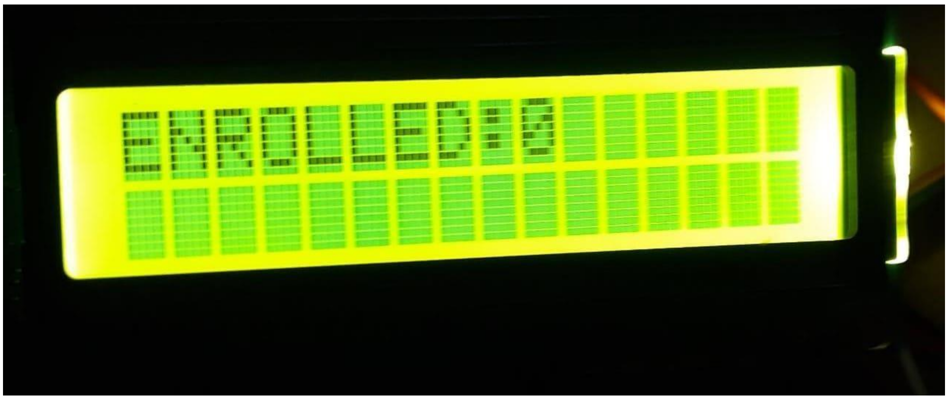

Fig:5.2 Enrolled the finger print

RESULT 2

Here the correct person eill authenticated the finger print then the device will be switched on

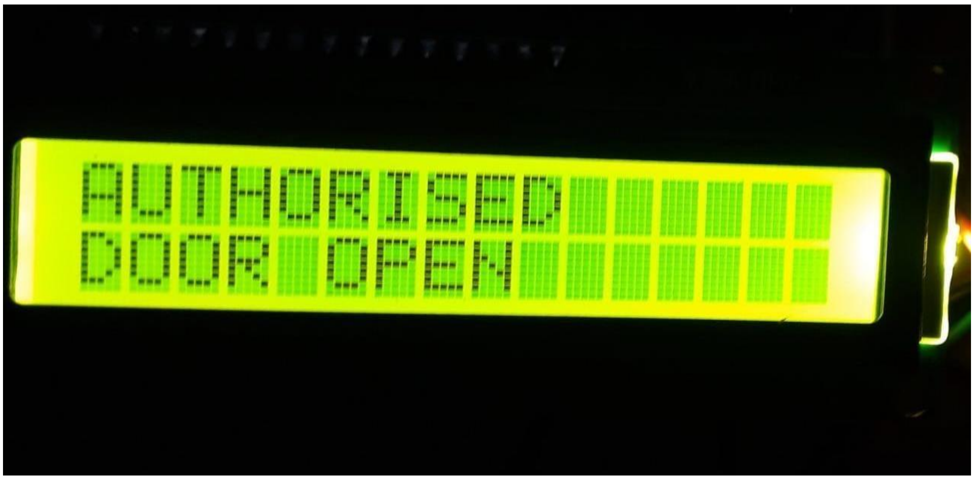

Fig:5.3 the door will opeaned

RESULT 3

When the un authorized person will try to switch on the device then it will automatically turned off and and the door will be locked

Fig:5.4 Door will locked

CHAPTER 6

ADVANTAGES AND DIS ADVANTAGES

Advantages:

- easy to construct
- less cost
- easy to transport
- specified persons to unlock the device
- 3 rd party will not allowed

Disadvantages:

- It will use to unlock fixed places
- It has a low bit rate

Applications

- It is used industrial applications
- Used in home and personal locker systems
- Used to switch any missionary and devices
- Used in automobiles

CHAPTER 7

CONCLUSION AND FUTURE ENHANCE MENT

Future scope:

New fingerprint sensing technologies are constantly being explored and developed. For example, Multispectral Fingerprint Imaging and this finger print of Msi technology more accurate to the conventional optical sensors

Conclusion

This project uses very popular finger print sensing technology for the purpose of electrical switching for security and various other switching purposes. The technology is mainly used for the identification and access control of various switches for identifying individuals that need surveillance or automation.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics and Communication Engineering, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled Zigbee Based Secure Wireless Communication using AES is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Angirekula Subash	Bodhanapu Archeshma	Vallamshetty Shravya Guptha
(17K81A0464)	(17K81A0467)	(17K81A04B7)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. Project coordinator Mr. K. Karthik** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Guide **Mr. Venkanna Mood**, **Associate Professor in ECE** advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1. Angirekula Subash
2. Bodhanapu Archeshma
3. Vallamshetty Shravya Guptha

ABSTRACT

The Zigbee based secured wireless communication using AES encryption allows us to communicate wirelessly with security feature. The data transfer during communication between two system is encrypted using 128-bit AES encryption which is highly secure. The data can be decrypted with correct key only, otherwise it returns some garbage value. This is two-way communication system where we can transmit as well as receive at both ends. We used ATMega microcontroller interfaced with xbee along with LCD display to send message and key, also have USB keyboards connected to each system and powered by 12V supply. After starting system, we will able to enter message on system. The maximum limit of message is 32 characters. After that system asks for key, the key limit is 16character it can be number or alphabet. Entering key will send the encrypted message to other system. Then the other system ask key to view the message. If the users enter correct key the message gets decrypted otherwise it will show garbage value thus securing the wireless communication.

INTRODUCTION

Overview of the Project

Nowadays communication plays a vital role in almost all industries. Be it sports, banks, armed forces, shopping malls etc., our project Zigbee based secure wireless communication using AES helps us to communicate i.e., transfer or receive data and since were using aes our data will be encrypted that means when an external person tries to hack or get access to our information, they'll need to enter a predefined key which is password in order to access the information. And since were using Zigbee we don't need to connect the transmitter and receiver on a daily basis this connection lasts for a longer duration to be approx. for a couple of months. The technology defined by the Zigbee specification is intended to be simpler and less expensive than other wireless personal area networks such as Bluetooth or more general wireless networking such as WIFI. Applications include wireless light switches, home energy monitors, traffic management systems, and other consumer and industrial equipment that requires short-range low-rate wireless data transfer. Its low power consumption limits transmission distances to 10-100 meters line of sight, depending on power output and environmental characteristics. ZigBee devices can transmit data over long distances by passing data through a mesh network of intermediate devices to reach more distant ones. As one of its defining features, ZigBee provides facilities for carrying out secure communications protecting establishment and transport of cryptographic keys.

Objective of the Project

Wireless technology is being developed rapidly nowadays advancement in microelectromechanical systems brings integration of sensing signal processing and RF capability on very small devices all kind of portable applications tend to be able to communicate without the use of any wires. Aim of wireless communication is to gather information or perform certain task in the environment a typical sensor node contains 3 C's are collection, competition and communication units. Based on the request of the sink, gathered information will be transmitted wirelessly. The collection unit has series of sensors, completion unit contains microcontroller and memory. Finally, the communication unit contains transceiver to transmit and receive. Zigbee is one of the most widely utilised wireless sensor network standards with low power, low data rate, low cost and short time delay characteristics, simple to develop and deploy and provides robust security and high data reliability. Name of the Zigbee came from zigzagging patterns of honey bees between flowers, represents the communication between nodes in a mesh network.

Scope of the Project

Zigbee has a very promising future in front of it. By rapid rise in home networking, Zigbee would provide revolutionizing statistics in the upcoming years which would entirely change to the wireless world. Various types of areas such as defence, national security, monitoring and control etc., can be facilitated by devices based on Zigbee standards. It leads to the cheap wireless technology, so that it can be widely used for low-rate data transfer. Zigbee aims to achieve greater efficiency. Range of the system can be increased by building a mesh wireless network. Using flexible PCB or SCB will further reduce size and weight of the sensor. Different wireless protocol such as ANT or Wibree will be investigated to further reduce power consumption since the amount of data transmission is very small. To simplify the device, the wireless link can be replaced with 1 or 2 GB mini/SD card.

Material Requirement

Hardware Requirements

- Arduino UNO
- Liquid Crystal Display.
- Zigbee
- USB-TTL
- Power supply.

Software Requirements

- Ardunio IDE
- Proteus software.

- X-CTU Software

Procurement Of Equipment’s

We brought all the required hardware components in a electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software. Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way. We calculated and got all health vital information of coma patient’s and displayed on LCD and also updated on Server. So, doctor can check and track the patient’s health status from any- where in the world.

Introduction to Embedded System

An embedded system is a combination of computer hardware and software, either fixed in capability or programmable, designed for a specific function or functions within a larger system. Industrial machines, agricultural and process industry devices, automobiles, medical equipment, cameras, household appliances, airplanes, vending machines and toys, as well as mobile devices, are possible locations for an embedded system. An embedded system is a dedicated computer system designed for one or two specific functions. This system is embedded as a part of a complete device system that includes, such as electrical and mechanical components [1]. The embedded system is unlike the general-purpose computer, which is engineered to manage a wide range of processing tasks. Because an embedded system is engineered to perform certain tasks only, design engineers may optimize size, cost, power consumption, reliability and performance. Embedded systems are typically produced on broad scales and share across a variety of environments and applications. An embedded system is one that has computer hardware with software embedded in it as one of its most important components. It is a dedicated computer-based system for an application or product. An embedded system has three main components.

- It has hardware
- It has main application software.
- It has a real time operating system (RTOS)

An embedded system has software designed to keep in view three constraints:

(i) Available system memory.

(ii) Available processor speed.

(iii) The need to limit power dissipation when running the system.

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious. Some of these computers are however very simple systems as compared with a personal computer. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware. The simplest devices consist of a single microprocessor (often called a chip) which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine [3]. As the embedded system is the combination of both software and hardware.

History of Embedded Systems

Embedded systems date back to the 1960s. Charles Stark Draper developed an integrated circuit (IC) in 1961 to reduce the size and weight of the Apollo Guidance Computer, the digital system installed on the Apollo Command Module and Lunar Module. The first computer to use ICs, it helped astronauts collect real-time flight data. In 1965, Auto now a part of Boeing, developed the D-17B, the computer used in the Minuteman I missile guidance system.

Block Diagram of Embedded System

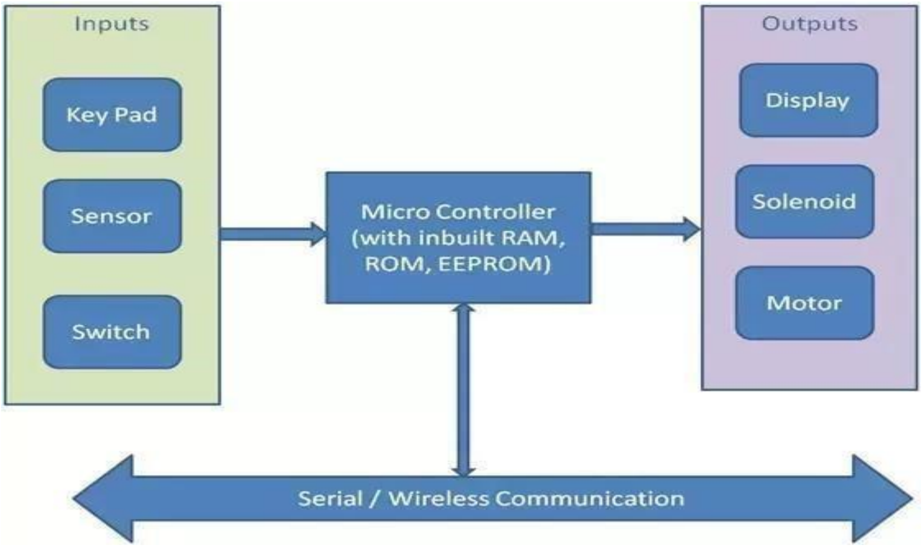

Figure.1.6.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Embedded System Hardware

Embedded system hardware can be microprocessor- or microcontroller-based. In either case, an integrated circuit is at the heart of the product that is generally designed to carry out computation for real-time operations[4]. Microprocessors are visually indistinguishable from microcontrollers, but while the microprocessor only implements a central processing unit (CPU) and, thus, requires the addition of other components such as memory chips, microcontrollers are designed as self-contained systems.

Embedded System Software

A typical industrial microcontroller is unsophisticated compared to the typical enterprise desktop computer and generally depends on a simpler, less-memory intensive program environment. The simplest devices run on bare metal and are programmed directly using the chip CPU's machine code language. Often, embedded systems use operating systems or language platforms tailored to embedded use, particularly where real-time operating environments must be served. At higher levels of chip capability, such as those found in SoCs designers have increasingly decided the systems are generally fast enough and the tasks tolerant of slight variations in reaction time that near-real-time approaches are suitable.

Examples of Embedded System

Some examples of embedded systems are below

- ATM
- Digital Cameras
- Microwave ovens
- Factory controllers
- Washing machine
- Calculator
- TV remote
- Traffic lights
- Digital watches
- Mp3 player
- Video games consoles

• Printers

• GPS receivers

• Dishwashers

• Thermostats

• Anti-lock banking system

Types of Embedded System

1. Real Time Systems

Real-time systems are those which give a quick response to critical situations. They are used in military, medical and industrial applications. Engineers working in these systems have high demand is current days. To develop the Realtime embedded system we require timing analysis, multitasking design, debugging, cross platform testing and architecture design. In these systems, quick response is very important.

2. Standalone Embedded System

This type of embedded system works for itself as a device without needing any interconnected computer. It can take data in the form of Analog or digital signals. This system first process data and then outputs data by displaying on the screen.

3. Networked Embedded System

Networked embedded systems are those systems which are connected to the network to give output to the attached resources. The devices in the networked embedded system are connected to the network with network interfaces. The network can be either a local area network (LAN) or a wide area network (WAN).

4. Mobile Embedded System

Mobile embedded systems are limited in resources including memory. Examples of mobile embedded systems include

• Personal digital assistants (PDA)

• Cellular phones

• Mp3 players

• Digital cameras

5. Small-Scale Embedded System

Small-scale embedded systems consist of 8–16-bit microcontroller. This system can perform tasks at a small level. They have on-chip ROM and RAM. Small scale systems can be even activated by the battery. The tools used to develop small scale embedded systems are an editor, cross assembler, assembler and integrated development environment (IDE). The purpose of this system is not computation but to control as a computer embedded inside it. It behaves as a component of a computer and its function is not to compute. The small-scale system is dedicated to some specific tasks.

6. Medium Scale Embedded System

This embedded system has 16–32-bit microprocessor or microcontroller with external RAM and ROM They can perform medium to complex level works. The integration between hardware and software is complex in these embedded systems. Programming languages used to develop medium scale embedded systems include Java, C, Visual C++, debugger, C++, RTOS, simulator, source code engineering tool and IDE.

7. Sophisticated Embedded System

The embedded system which can do large-scale works with multiple 32-64 bit chips is known as sophisticated embedded systems. They can perform distributed work on a large scale. The complexity of hardware and software is very high in these systems. In sophisticated embedded systems, hardware and software are assembled together on large scale and designing of hardware products is also included in these systems.

Applications of Embedded Systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment

- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Microcontroller

A microcontroller is a small computer on a single metal oxide semiconductor (MOS) integrated circuit (IC) chip. A microcontroller contains one or more CPUs along with memory and programmable input/output peripherals. Program memory in the form of ferroelectric RAM, NOR flash or OTP ROM is also often included on chip, as well as a small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications consisting of various discrete chips[7]. In modern terminology, a microcontroller is similar to, but less sophisticated than, a system on a chip (SoC). SoC may include a microcontroller as one of its components, but usually integrates it with advanced peripherals like graphics processing unit (GPU), Wi-Fi module, or one or more coprocessors.

Figure.1.7.1: Microcontroller

Microcontrollers are used in automatically controlled products and devices, such as automobile engine control systems, implantable medical devices, remote controls, office machines, appliances, power tools, toys and other embedded systems. By reducing the size and cost compared to a design that uses a separate microprocessor, memory, and input/output devices, microcontrollers make it economical to digitally control even more devices and processes. Mixed signal microcontrollers are common, integrating analog components needed to control nondigital electronic systems. In the context of the internet of things, microcontrollers are an economical and popular means of data collection, sensing and actuating the physical world as edge devices.

Some microcontrollers may use four-bit words and operate at frequencies as low as 4 kHz for low power consumption (single-digit milliwatts or microwatts). They generally have the ability to retain functionality while waiting for an event such as a button press or other interrupt; power consumption while sleeping (CPU clock and most peripherals off) may be just nanowatts, making many of them well suited for long lasting battery applications[8]. Other microcontrollers may serve performance-critical roles, where they may need to act more like a digital signal processor (DSP), with higher clock speeds and power consumption.

Microprocessor	Microcontroller
CPU is stand alone, RAM,ROM, I/O & timer are separate.	CPU, RAM,ROM, I/O & timer all are on single chip.
Designer can decide amount of RAM,ROM, & I/O ports.	Fixed amount of on-chip RAM,ROM, & I/O ports.
High processing power	Low processing power
High power consumption	Low power consumption
Typically 32/64 bit	8/16 bit
General purpose	Single purpose(control oriented)
Less reliable	Highly reliable
Eg.- 8086,8085	8051

Table 1.7.1: Difference between microprocessor and microcontroller

History

The origins of both the microprocessor and the microcontroller can be traced back to the invention of the MOSFET (metal-oxide-semiconductor field-effect transistor), also known as the MOS transistor. It was invented by Mohamed M. Atalla and Dawon Kahng at Bell Labs in 1959, and first demonstrated in 1960.

The same year, Atalla proposed the concept of the MOS integrated circuit, which was an integrated circuit chip fabricated from MOSFETs. By 1964, MOS chips had reached higher transistor density and lower manufacturing costs than bipolar chips[2]. MOS chips further increased in complexity at a rate predicted by Moore's law, leading to large-scale integration (LSI) with hundreds of transistors on a single MOS chip by the late 1960s. The application of MOS LSI chips to computing was the basis for the first microprocessors, as engineers began recognizing that a complete computer processor could be contained on a single MOS LSI chip.

Figure.1.7.2: 8051 Microcontroller Board

Most microcontrollers at this time had concurrent variants. One had EPROM program memory, with a transparent quartz window in the lid of the package to allow it to be erased by exposure to ultraviolet light. These erasable chips were often used for prototyping. The other variant was either a mask programmed ROM or a PROM variant which was only programmable once. For the latter, sometimes the designation OTP was used, standing for "one-time programmable. For the erasable variants, quartz was required, instead of less expensive glass, for its transparency to ultraviolet light— to which glass is largely opaque—but the main cost differentiator was the ceramic package itself. In 1993, the introduction of EEPROM memory allowed microcontrollers (beginning with the Microchip PIC16C84) to be electrically erased quickly without an expensive package as required for EPROM, allowing both rapid prototyping, and in-system programming. (EEPROM technology had been available prior to this time, but the earlier EEPROM was more expensive and less durable, making it unsuitable for low-cost mass-produced microcontrollers.)

Zigbee Technology

So, where does Zigbee Technology fit into the existing pool of Wireless Technologies? The Zigbee Wireless Technology fits into a market that is not completely filled by other technologies. For example, other wireless technologies like WiFi and Bluetooth are striving to go faster, add more features, provide streaming of high-definition content and run for hours. In contrast, the Zigbee Technology is designed for low data rates, fit into a tiny stack, controlling simple devices like LEDs or Thermostats and run for years. Although Zigbee Technology has many applications like Home Automation and Military, the main category that the Zigbee Technology has been aimed for is called as Wireless Sensor Network or WSN.

Wireless Sensor Network (WSN) is a collection (network) of wireless sensors that collect, store and process environmental information and also communicate with neighboring networks. More about WSN later. WSN has few unique requirements like low power and low cost and Zigbee Technology achieves these requirements with the help of a constraint: Low Data Rate.

Wireless Sensor Network (WSN) is a technology that being warmly used both for research and to help human activities. System security is one of the important things that must be considered both in wireless and wire line network. Wireless sensor networks are expanding which are vulnerable and therefore require an effective security mechanism. Wireless sensor networks have several constraints such as limited memory, energy and computational capabilities that create constraints when coupled with security at sensor nodes. To solve the problem, this final project will implement and analyze security system in wireless sensor network refers to ZigBee standard. ZigBee schemes can be synchronized with new protocols targeted at low rates, small power devices, and sensor nodes. ZigBee requires cryptography that is expected to save power, computing power, and storage resources. To that end, the chosen security system is using AES encryption algorithm (Advanced Encryption Standard) which is implemented directly on ZigBee. In this research successfully apply AES128 decryption and encryption algorithm on wireless sensor network. The test used is a passive attack that can only see and capture the package only. In a security performance analysis, the confidentiality parameter is not fulfilled if it does not use security. Integrity parameters are fulfilled using or without security. The largest throughput value is 1122 bytes / s at a distance of 21 meters. And the last delay at a distance of 49.5 meters with a value of 4.1483 s.

Wireless Sensor Network (WSN) is a technology used for research as well and to facilitate daily life. WSN is a network infrastructure that can detect, calculate and have communication elements that can transmit data to the administrator to measure, observe, and give orders if there are certain conditions. The security system is one of the important things that must be considered both wireless and wired networks. WSN users should believe that the information they receive from the network is reliable, accurate, and not damaged by irresponsible parties. Wireless sensor networks have several constraints such as memory limitations, energy and computational capabilities that create constraints when added to the security of the node sensor. To send information that has been read by the node ZigBee needed to send the information to the user WSN. To solve the problem, this research applies and analyzes system security on wireless sensor network refers to ZigBee standard. ZigBee is an emerging standard for low power, low level wireless communications with the goal of both systems being able to work together and can include all devices within the scope of power despite low WSN node sensors. ZigBee requires cryptography which is expected to save power, computing power, and storage resources. In the end, the security system is chosen using AES encryption algorithm (Advanced Encryption Standard) which is implemented directly on ZigBee.

What is ZigBee Technology

Zigbee Technology is a Wireless Communication Standard that defines a set of protocols for use in low data rate, short to medium range wireless networking devices like sensors and control networks. The target of Zigbee Technology is low cost, low power, battery operated wireless sensors that do not need to constantly update its status and also allows sleep mode or low power mode for its electronics and radio.

Zigbee Technology is based on IEEE 802.15.4 Standard and the Zigbee devices operate in the unlicensed 2.4 GHz ISM Band (ISM – Industrial, Scientific and Medical). Although 2.4 GHz band is commonly used worldwide for commercial Zigbee devices, there are devices that use a different set of frequency bands like 784 MHz, 868 MHz and 915 MHz in China, Europe and USA (and Australia) respectively.

Since we are talking about low data rates of Zigbee Technology from the beginning, let us see the data rates supported by Zigbee. The data rates in Zigbee Technology are dependent on the frequency band. For example, the 868 MHz band supports a data transfer rate of 20 kbps while the more common 2.4 GHz band supports data rates up to 250 kbps. Before digging deep in to Zigbee Technology, let us take a look at two applications, where Zigbee can be used. One application is the in-home patient monitoring, where a patient wears a Zigbee device, which periodically collects the information like blood pressure and heart rate.

This data is then wirelessly transmitted to a local server in the patient's home (local server – like a PC). The local server performs basic analysis and the vital information is sent to the Doctor over the internet. Another application of Zigbee is the building's structural health monitoring. This application is very useful in earthquake prone areas. Several Zigbee based wireless sensors like accelerometers are installed throughout the build. These sensors, which form a wireless sensor network, collect information that can be used to detect signs of damage and evaluate whether the building is safe for public or not.

Why Low Data Rates in Zigbee?

When other wireless technologies like WiFi and Bluetooth are aiming to provide high speed data transfers, why the data rates are low in Zigbee standard? The answer is very simple. The intention behind the development of Zigbee Technology is to use it in wireless monitor and control. The amount of information and the frequency of communication in such applications is very less.

Even though it is possible for an IEEE 802.15.4 network to achieve higher data rates, the Zigbee Technology, which is based on IEEE 802.15.4, is not designed to do so.

Zigbee Alliance

The Zigbee Alliance works to simplify wireless product integration to help product manufacturers introduce energy-efficient wireless control into their products faster and more cost-effectively. Alliance members create standards that offer reliable, secure, low-power and easy-to-use wireless communication, using an open standards development process to guide their work. The alliance is organized by committees, work groups, study groups, task forces and special interest groups.

Figure.1.8.1: Zigbee Alliance

There are three types of membership with different rights and benefits:

- An **adopter** offers access to final, approved specifications, participation in interoperability events and access to standard work/task group documents and development activities.
- A **participant** offers voting rights in work groups and has early access to all Zigbee Alliance standards and specifications in development.
- A **promoter** offers automatic voting rights in all work groups, final approval rights on all standards and a seat on the alliance's board of directors.

Zigbee Network Topologies

The Zigbee Network Layer in the Zigbee Stack is responsible for formation of the network. There are three Zigbee Network Topologies: Star, Cluster Tree and

Mesh. These three Zigbee Topologies come under one of the two network topologies mentioned in the IEEE 802.15.4 i.e., Star and Peer-to-Peer.

Star Topology

In a Star Network Configuration, there is one Coordinator and any number of End Devices. All the End Devices are connected to the coordinator and the individual End Devices are isolated, both physically and electrically i.e. no direct communication between end devices.

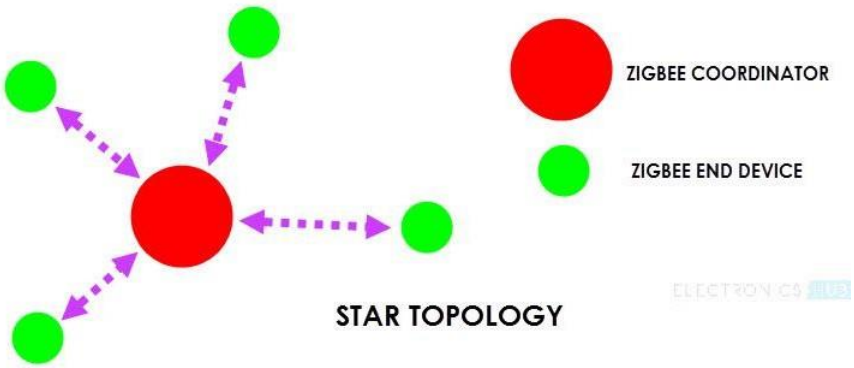

Figure.1.8.2: Star Topology

All the information must pass through the coordinator, even the information from one End Device to another.

Cluster Tree Topology

The Cluster Tree Topology is a type of Peer-to-Peer Topology. In Zigbee Cluster Tree Topology, the End Devices join the network via the Coordinator or the Router. As the Zigbee Router extends the range of the Zigbee Network, the End Device need not be in the range of the coordinator.

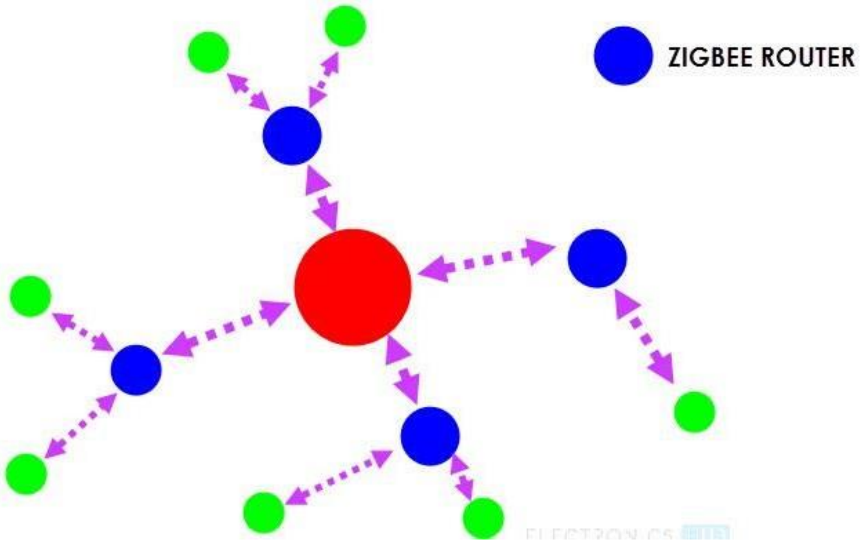

Figure.1.8.3: Cluster Tree Topology

Even in Tree Topology, the End Devices cannot communicate with each other directly but the Router can communicate with other Routers and the Coordinator.

Mesh Topology

The Zigbee Mesh Topology is also a Peer-to-Peer Topology and is an extension to the Cluster Tree Topology. The End Devices that are configured as FFD can directly communicate with other FFD Devices (either Routers or End Devices). But End Devices configured as RFD, still need to communicate through Routers or Coordinators.

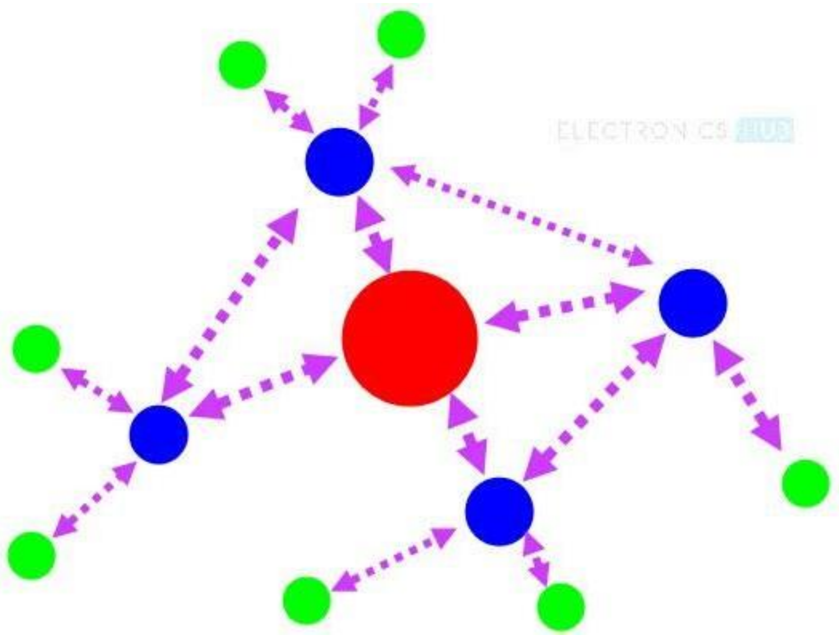

Figure.1.8.4: Mesh Topology

Applications of Zigbee Technology

Zigbee Networking and Zigbee Technology has a wide range of application like Home Automation, Healthcare and Material Tracking. Let us see few Applications of Zigbee Technology, where Zigbee Devices can increase efficiency and reduce cost.

- Home Automation
    - Security Systems
    - Meter Reading Systems
    - Light Control Systems
    - HVAC Systems
- Consumer Electronics
    - Gaming Consoles
    - Wireless Mouse
    - Wireless Remote Controls
- Industrial Automation
    - Asset Management
    - Personnel Tracking
    - Livestock Tracking
- Healthcare
- Hotel Room Access
- Fire Extinguishers

Motivation of the Project

The main reason for preferring this project is to make sure that the data communication is done securely from transmitter to receiver. The system, primarily intended for the benefit of the locations where the data communication is low, can be used and implemented by various other types of individuals as well. For example, a hospital, library, working office, hotel, restaurant etc use data transfer protocols on a day-to-day basis and this can be securely done using secure ZigBee communication which is encrypted using advanced encryption standards.

CHAPTER-2

LITERATURE SURVEY

Literature Survey

As per the exploration paper of Amar Abana [1] explains that Named Data Networking (NDN) is a new architecture which allows communications using data's natural names rather than hosts' logical addresses. In recent years, several research projects have demonstrated the ability of NDN to support emerging IoT applications like home automation, smart cities and smart farming applications. This work aims to integrate NDN with ZigBee to give NDN a better support for INTERNATIONAL JOURNAL OF CURRENT ENGINEERING AND SCIENTIFIC RESEARCH applications that are known to require wireless sensing/actuating abilities, mobility support and low power consumption. For this purpose, we present our NDN-overZigBee design and we show through experiments conducted with three different scenarios the suitability and the ease of use of NDN in IoT context. The choice of ZigBee is motivated by the fact that it is a network specification for low power Wireless Personal Area Networks (WPANs) and supports a large number of nodes.

Jiasong Mu Liang Han [2] said that The ZigBee network is widely studied and deployed recently because of its low cost and simplicity features. However, the power consumption issue needs a further improvement since the application requirements are not fully satisfied. The emerging 5G communication technology is characterized by the smarter devices and the native support for the M2M communication. On that basis, the 5G terminals are capable of joining the existing ZigBee networks and have the potential to improve the data transmission. In this paper, we investigate the performance of the ZigBee networks in the 5G environment for different scenarios. Then a Nearest Access Routing (NAR) algorithm based on the physical depth is proposed for different communication types. To reduce the loads in ZigBee networks, the data flow in the neighbourhood of 5G terminals is gathered and transmitted via the IP networks. The simulation results showed that NAR effectively share the communication in ZigBee networks. It leads to better performances with higher packet delivery ratio, less hop counts from ZigBee devices, lower latency, fewer packets sent by ZigBee nodes and zero routing overheads.

Jiangsu [3] proposes that a modified AODV Junior routing protocol is adopted as part of the combined routing strategy in the ZigBee networks. However, its routing overhead caused by the routing discovery and the routing table maintenance needs to be further reduced. Considering the deploying environment, the emerging 5G technology tends to be ubiquitous in the near future. Due to its native support to the smart devices and the M2M communication, the 5G terminals may be used as gateways for the ZigBee networks to improve the existing routing method. The ZigBee coordinator and the 5G terminals, which both have the accessibility to the internet, are defined as Associated Gateways (AG). Aiming to the higher efficiency and the shorter path, an improved ZigBee AODV (ZAODV) routing protocol using associated gateways for the heterogeneous networks in the 5G environment is proposed in this paper. Besides the regular ZigBee function, by sharing the neighbour and routing information via IP network, the AGs are also responsible for collaboratively finding the optimum path and transmitting the packets to reduce the consumption for ZigBee devices. Moreover, an additional routing information collecting method is developed to further improve the routing performance. The proposed algorithm is evaluated based on simulation results. It is shown that our routing method outperforms the existing ones by higher picketer deliver ratio, shorter path length, lower latency, fewer packets sent per ZigBee node and lower routing overhead.

Chia-HsinCheng [4] proposes a multichannel ZigBee Wireless Sensor Network (WSN) for robust data transmission. This study sought to increase the Packet Delivery Ratio (PDR) through the application of multi-channel technology. Based on a cluster-tree construction protocol, we implemented a multi-channel time division multiple-access scheme using hardware devices. Furthermore, ZigBee and Wireless LAN (WLAN) both operate on the 2.4 GHz band, referred to as the industrial, scientific, and medical unlicensed band. As a result, ZigBee faces severe interference problems in the presence of WLAN. In this study, we developed an interference avoidance method to improve conditions for the coexistence of ZigBee and WLAN and then conducted experiments using a practical network implementation to evaluate the resulting performance. Our experiment results demonstrate considerable improvements in the PDR of ZigBee transmission in an environment with interference from WLAN.

Jacek Stępień [5] conversed that an implementation of mobile nodes tracking system based on ZigBee and Wi-Fi wireless networks is presented. On the base of known algorithmic as well as circuit solutions a simple yet universal system, applied in prototype application dedicated for person's localization in museum premises has been developed. Since system INTERNATIONAL JOURNAL OF CURRENT ENGINEERING AND SCIENTIFIC RESEARCH utilizes entirely wireless communication, it can be applied in any closed objects. The system has been preliminarily verified in real in-situ environment.

Rob Toulson [6] e states introduce concepts and applications relating to wireless data communication. It starts with a review of the principles, including the electromagnetic spectrum, radio transceivers, protocols and antennae. The background to short distance, personal area network protocols is introduced, through reference to IEEE Working Groups. Bluetooth is introduced, and trialled using the RN-41 Bluetooth module. The RN-41 is used to develop key Bluetooth concepts. Simple PC-tombed and mbed-to-mbed Bluetooth links are demonstrated. The Zigbee protocol, its typical networks and applications are introduced. XBee radio modules are used to illustrate simple Zigbee links, in transparent mode. Use of the XBee in its more flexible API mode is then introduced, which opens the door to more advanced Zigbee applications.

Jia Jia [7] said that the physical layer of ZigBee communication systems was defined by IEEE 802.15.4 and has good external white noise resistance due to its spread spectrum characteristic and error correction of the baseband coding process. However, previous research has shown the performance of ZigBee to degrade in the presence of impulsive noise. In this regard, an improvement of the ZigBee receiver is warranted in order to improve the decoding process. A novel Error-Balanced Wavelet filtering approach utilizing the multiresolution property is proposed to suppress the impact of impulsive noise prior to symbol detection and thus improve the Bit Error Rate (BER) performance of the ZigBee demodulation process. This assessment is based on computer simulations and verifies that the overall transmission performance is improved by our proposed approach. The results obtained are also compared with existing impulsive noise suppression approaches and it is shown that our waveletbased method outperforms other methods in improving the system.

BER. L.K. Wadhwa [8] et.al. proposes that Energy efficiency and network lifetime are main concerns in WSN. In order to improve these factors ZigBee plays an important role. Low cost, low data rate features of ZigBee results in low power consumption and makes it useful in wireless sensor networks, increasing life of small batteries of nodes in the network. Since tree routing in ZigBee does not require any routing tables to send the packet to the destination, it can be used in ZigBee end devices that have limited resources. Routing protocols such as AODV (Ad-hoc On Demand distance Vector routing), ZTR (ZigBee Tree Routing), and STR (Shortcut Tree Routing) are compared on the basis of different performance metrics (End to end delay, routing overload, throughput, packet delivery ratio). The performance evaluation shows that STR achieves better performance as compared to other two routing protocols. But there are some limitations of the STR method. Performance of packet delivery ratio of STR is less as compared to AODV. Performance of end-toend delay of STR is poor as compared to AODV. Hence ESTR is proposed. The main aim of proposed ESTR [Extended STR] is to present new ZigBee network routing protocol with goal of improving the performance of ESTR in terms of PDR and delay against STR and AODV.

Shashwat Pathak. [9] explains an energy efficient wireless telemonitoring scenario of cardiac patients through ZigBee, based on variable duty cycle being rendered to sensors. In an intra-hospital telemedicine scenario, Electro Cardio Gram (ECG) signals of patients are acquired through ECG sensor nodes having transmission capability and these ECG signals are received by Personal Digital Assistant (PDA) kept at nursing station through ZigBee network. ECG signals are further transmitted to Doctor's PDA. If the duty cycle is varied as per the load or number of active sensors, total energy consumed in idle mode can be avoided and total energy consumed by sensors is reduced hence increasing total network lifetime. This paper, comparatively analyses the energy efficiency of ZigBee sensors with different percentage of duty cycle on the basis of energy consumption parameter under variable load conditions. The matrices used in performance evaluation are energy consumption in transmit mode, energy consumption in received mode and energy consumption in idle mode.

Existing Methods

The previously existing method of this project was using keyboards i.e., the data transfer would be possible with AES through a lcd using a keyboard. Which was not efficient, and would consume more power comparatively to our proposed system and in order to receive the transferred information the receiver had to enter the predefined password every time they wanted to access the transferred information. And this wasn't as secure as compared to our proposed system cause of the risk of someone else getting access to our information.

Proposed Methods

In our proposed method we use ZigBee as a transfer protocol to transfer the data and that too from a system to system. In this we will have a better efficiency and since the transfer of data is from system to system, we don't need to enter the predefined password at the receiver every time we want to access the received information. Since the ZigBee is designed in pairs at the time of manufacturing.

CHAPTER-3

PROJECT DESCRIPTION

BLOCK DIAGRAM OF THE PROJECT:

The Zigbee based secured wireless communication using AES encryption allows us to communicate wirelessly with security feature. The data transfer during communication between two system is encrypted using 128-bit AES encryption which is highly secure. The data can be decrypted with correct key only, otherwise it returns some garbage value. This is two-way communication system where we can transmit as well as receive at both ends. We used ATMega microcontroller interfaced with x-bee along with LCD display to send message and key, also have USB keyboards connected to each system and powered by 12V supply. After starting system, we will able to enter message on system. The maximum limit of message is 32 characters. After that system asks for key, the key limit is 16character it can be number or alphabet. Entering key will send the encrypted message to other system. Then the other system ask key to view the message. If the users enter correct key the message gets decrypted otherwise it will show garbage value thus securing the wireless communication.

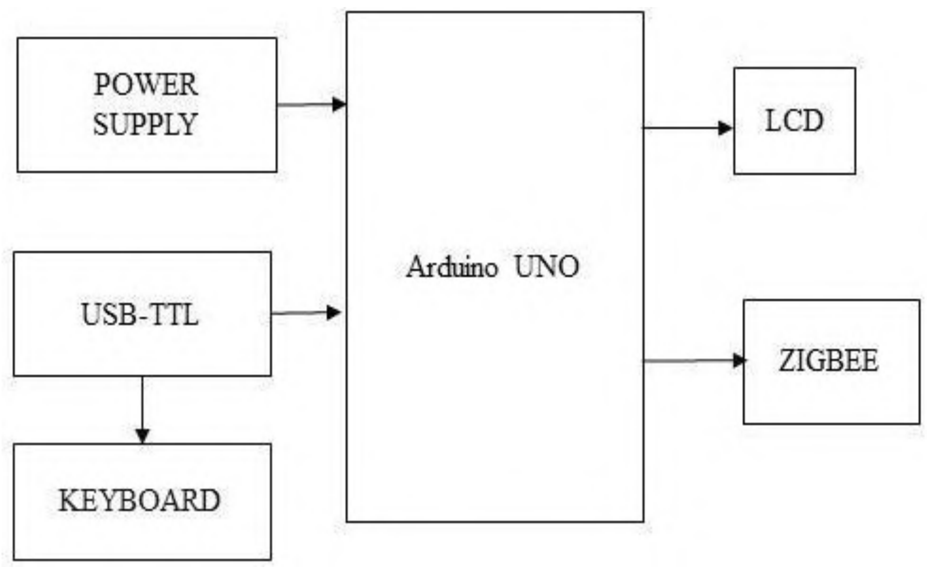

Figure 3.1.1: Block Diagram of Transmitter

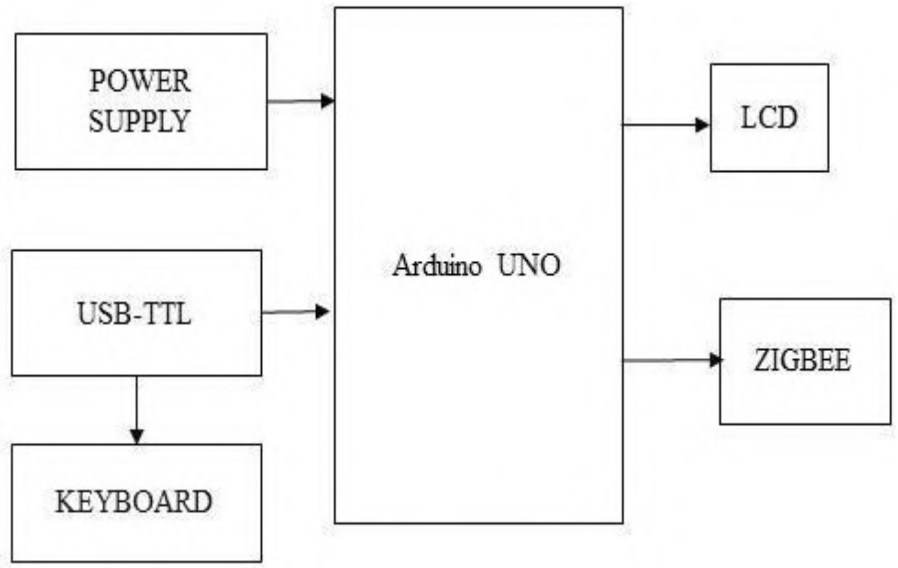

Figure 3.1.2: Block Diagram of Receiver

The Block of Circuits are

1) Arduino UNO
2) Power Supply Unit
3) Zigbee
4) USB-TTL
5) LCD
6) Keyboard

1. Arduino UNO

Arduino is open-source software. Arduino Uno is a microcontroller, ATmega328Pcontain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2. Power Supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices.

3. Zigbee

Zigbee is a standards-based wireless technology developed to enable low-cost, low-power wireless machine-to-machine (M2M) . Zigbee is for low-data rate, low-power applications and is an open standard. This, theoretically, enables the mixing of implementations from different manufacturers, but in practice, Zigbee products have been extended and customized by vendors and, thus, plagued by interoperability issues.

4. USB-TTL

This is an USB2.0 to TTL UART converter module which is based on CP2102 bridge by silabs. This module can be used with laptop's which don't have standard serial port. This module creates a virtual com port using usb on your computer which can support various standard baud rates for serial communication.

5. LCD

The LCD here is used to display us the information. Here we use two LCD’s one at Transmitter, one at Receiver. When we send the information from transmitter to receiver. The information which we have sent is displayed on the LCD. The information is display on both the LCD’s i.e., on transmitter side and receiver side.

6. Keyboard

In this project we use two keyboard’s one at transmitter side and the other one at receiver side. To type the information which we want to send. we use keyboards to type the information.

SCHEMATIC DESCRIPTION:

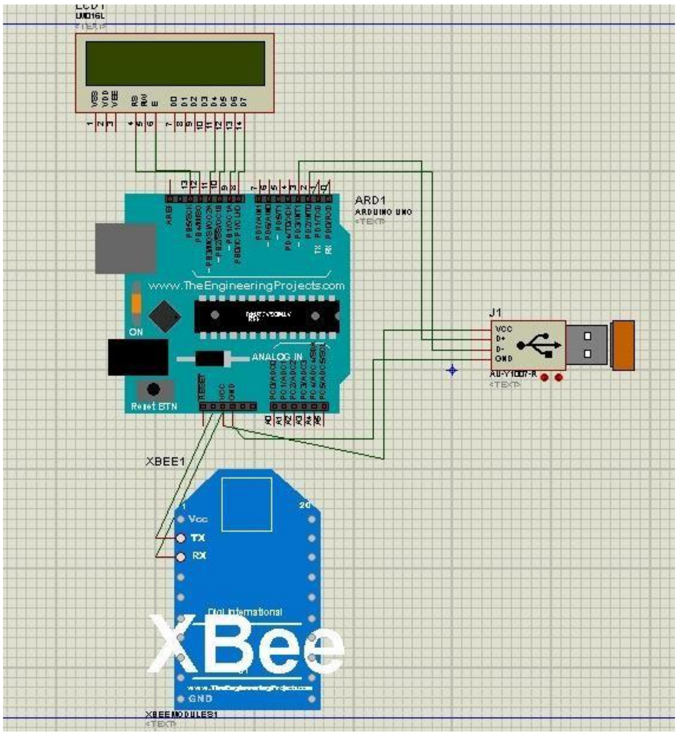

Figure 3.2.1: Schematic Diagram of Transmitter

- Here we can see the schematic diagram of the transmitter side where 2 Zigbee's are connected to ports 2 and 3 of Arduino and the ports 13,12,11,10,9 and 8 are connected to Arduino.
- The lcd we use is a 16,2 lcd i.e., 16 characters per line and 2 such lines.
- We will be having 2 possibilities of sending the information either through a Zigbee or from serial ports.
- We give a delay to make things stable and we transmit the information.
- Then we will read the information received through the X-CTU software.

HARDWARE AND SOFTWARE DESCRIPTION

Hardware Components

The hardware components used for the implementation of “Zigbee Based Secure Wireless Communications using AES” are

1. Arduino UNO
2. Power Supply Unit
3. Zigbee
4. LCD’S
5. USB TTLS-2
6. Keyboard

Arduino UNO

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message and turn it into an output activating a motor, turning on an led, publishing as it reached a wider community, the Arduino board started something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board.

To do so you use the Arduino programming language (based Wiring), the Arduino Software (IDE), based on Processing. Arduino was born at the area Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming wearable, 3dprinting, and embedded environments. All Arduino boards are completely open-source, empowering from everyday objects to complex scientific instruments.

Professional gathered around open-source plat form, the software too is open-source, it is growing through the contributions of users worldwide, the Arduino board is shown in below figure.

Figure.4.1.1: Arduino uno board

Why Arduino?

Arduino Uno is inexpensive. Arduino is cross platform, its IDE can run on multiple Operating Systems such as Windows, Macintosh, Linux and many more. It has simple and clear programming environment. Its software and hardware are open-source and extensible, that is, Arduino programming can be expanded through C++ libraries and can also leap to AVR ‘C’ language programming.

It is simple and accessible to user experience; Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux.

There are many other microcontrollers platforms available for physical computing. Parallax Basic Stamp, Netmedia's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems.

- **Inexpensive**
  Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50
- **Cross-platform**
  The Arduino Software (IDE) runs on Windows, Macintosh OSX, and

Linux operating systems. Most microcontroller systems are limited to Windows.

- **Simple, clear programming environment**
  The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- **Open source and extensible software**
  The Arduino software is published as opensource tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- **Open source and extensible hardware**
  The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money and the parts of Arduino board is shown below.

Figure.4.1.2: Arduino board description

Features of Arduino

Micro controller	Atmega328
Operating voltage	5V
Input Voltage(recommended)	7-12V
Input Voltage	6-20V
Digital I/O	14(of which 6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 Ma
DC Current for 3.3V Pin	50 Ma
Flash Memory	32 KB (Atmega328 of which 0.5 KB used by bootloader)
SRAM	2 KB (ATmega32)
EEPROM	1 KB(ATmeha328)
Clock Speed	16 MHz

Table 4.1.1: Features of Arduino uno

- It is an easy USB interface. This allows interface with USB as this is like a serial device.
- The chip on the board plugs straight into your USB port and supports on your computer as a virtual serial port. The benefit of this setup is that serial communication is an extremely easy protocol which is time-tested and USB makes connection with modern computers and makes it comfortable.
- It is easy-to-find the microcontroller brain which is the ATmega328 chip. It has more number of hardware features like timers, external and internal interrupts, PWM pins and multiple sleep modes.
- It is an open-source design and there is an advantage of being open source is that it has a large community of people using and troubleshooting it. This makes easy to help in debugging projects.
- It is 16MHz clock which is fast enough for most applications and does not speeds up the microcontroller.
- It is very convenient to manage power inside it and it had a feature of built- in voltage regulation. This also be powered directly off a USB port without any

external power. You can connect an external power source of up to 12v and this regulates it to both 5v and 3.3v.

- 14 digital pins and 6 analog pins. This sort of pins allows you to connect hardware to your Arduino Uno board externally. These pins are used as a key for extending the computing capability of the Arduino Uno into the real world. This has an ICSP connector for bypassing the USB port and interfacing the Arduino directly as a serial device. This port is necessary to re-boot load your chip if it corrupts and can no longer used to your computer.
- It has a 32 KB of flash memory for storing your code.
- An on-board led is attached to digital pin 13 to make fast the debugging of code and to make the debug process easy finally it has the button to reset.

Pin Configuration on Arduino UNO

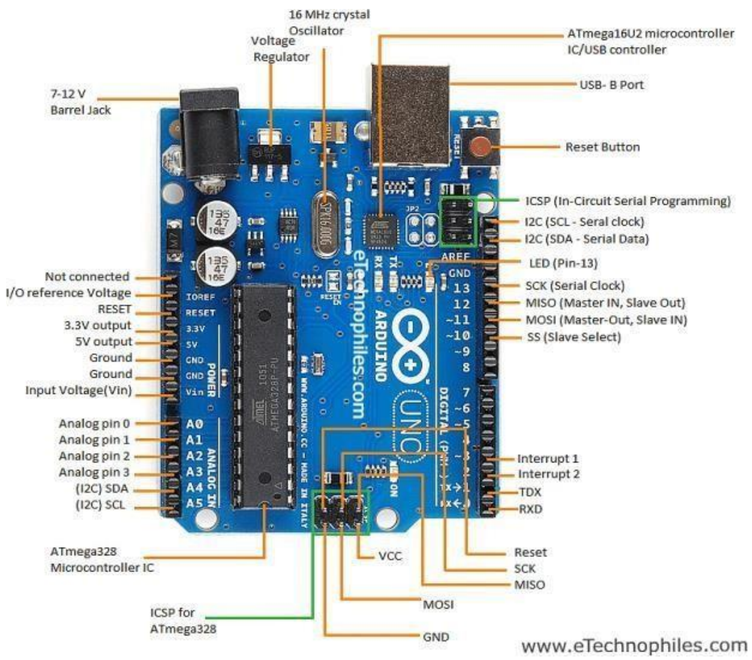

Figure.4.1.3: Pin configuration

- **Reset Pin:** resets the microcontroller.
- **GND :** used to connect the circuit to Ground
- **A0-A5:** used to provide analog input in the range of 0-5V.
- **Digital pins(0-13) :** can be used as input or output pins.
- **0(RX),1(TX) :** used to receive and transmit TTL serial data.
- **AREF :** To provide reference voltage for input voltage.
- **SPI :** used for SPI communication.

Working of Arduino

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The 14 digital input/output pins can be used as input or output pins by using pinMode(), digitalRead() and digitalWrite() functions in arduino
programming. Each pin operate at 5V and can provide or receive a maximum of 40mA current, and has an internal pull-up resistor of 20-50 KOhms which are disconnected by default. Out of these 14 pins, some pins have specific functions as listed below:

- **Serial Pins 0 (Rx) and 1 (Tx):** Rx and Tx pins are used to receive and transmit TTL serial data. They are connected with the corresponding ATmega328P USB to TTL serial chip.
- **External Interrupt Pins 2 and 3:** These pins can be configured to trigger an interrupt on a low value, a rising or falling edge, or a change in value.
- **PWM Pins 3, 5, 6, 9 and 11:** These pins provide an 8-bit PWM output by using analogWrite() function.
- **SPI Pins 10 (SS), 11 (MOSI), 12 (MISO) and 13 (SCK):** These pins are used for SPI communication.
- **In-built LED Pin 13:** This pin is connected with an built-in LED, when pin 13 is HIGH – LED is on and when pin 13 is LOW, its off.
- **Analog pins (A0-A5) :** used to provide analog inputs in the range of 0-5V.

- Analog pin 4 (SDA) and pin 5 (SCA) also used for TWI communication using Wire library.

Arduino Uno has a couple of other pins as explained below:

- **AREF:** Used to provide reference voltage for analog inputs with analogReference () function.
- **Reset Pin:** resets the microcontroller.

Advantages

Inexpensive -Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50.

- Cross-platform

The Arduino software runs on Windows, Macintosh OSX, and the Linux operating systems. Most microcontroller systems are limited to Windows.

- Simple programming environment

Here the Arduino programming environment is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with the look and feel of Arduino.

- Open source and extensible software

The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

- Open source and extensible hardware

The Arduino is based on Atmel's ATmega8 and ATmega168 microcontrollers. The plans for the modules are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even 19 relatively inexperienced users that can build the breadboard version of the module in order to understand how it works and save money.

Power Supply

The Arduino Uno can be powered via through USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter (wallwart) or battery. The adapter can be connected by plugging a 2.1mm centre positive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and Vin pin headers of the POWER connector.

The board can operate on an external supply of 6 to 20 volts. If supplied with less than 7V, however, the 5V pin may supply less than five volts and the board may be unstable. If using more than 12V, the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. the power pins are as follows.

- **VIN.** The input voltage to the Arduino board when it's using an external power source (as opposed to 5 volts from the USB connection or other regulated power source). You can supply voltage through this pin, or, if supplying voltage via the power jack, access it through this pin.
- **5V.** The regulated power supply used to power the microcontroller and other components on the board. This can come either from VIN via an on-board regulator, or be supplied by USB or another regulated 5V supply.
- **3.3V.** A 3.3volt supply generated by the on-board regulator. Maximum current draw is 50 mA.
- GND. Ground pins.

Programming

The Arduino Uno can be programmed with the Arduino Software (IDE). Select Arduino Uno from the Tools Board After your code is compiled using Arduino IDE, it should be uploaded to the main microcontroller of the Arduino UNO using a USB connection. Because the main microcontroller doesn’t have a USB transceiver, you need a bridge to convert signals between the serial interface (UART interface) of the microcontroller and the host USB signals. The ATmega328 on the Arduino Uno comes pre-programmed with a boot loader that allows you to upload new code to it without the use of an external hardware programmer. It communicates using the original STK500 protocol. You can also bypass the bootloader and program the microcontroller through the ICSP (In-Circuit Serial Programming) header using Arduino are similar. The ATmega16U2 (or 8U2 in the rev1&rev2 boards) firmware source code is available in the Arduino repository. The ATmega16U2 or 8U2 is loaded with a DFU bootloader, which can be activated by On Rev1 boards connecting the solder jumper on the back of the board and then resetting the 8U2.

You can then use Atmel's FLIP software (Windows) or the DFU programmer (Mac OS X and Linux) to load a new firmware. Or you can use the ISP header with an external programmer (overwriting the DFU bootloader). Arduino is an open-source hardware platform that is being used by people around the globe for building electronics projects. It is an integrated platform which contains
both the physical and programmable circuit otherwise known as microcontroller and a software (or IDE) that you can run on your computer to write and upload the code onto the physical board.

Arduino Board is quite popular among many people who want to get started with electronics, and unlike other embedded system boards Arduino does not require any additional hardware to upload the code (generally known as programmer).
Here we will try to understand about the Arduino Architecture and its functionalities. The processor of the Arduino Board uses Harvard Architecture for which the program code and program data have separate memory. The memory of it is divided into two namely program memory and data memory. The data will be stored in the data memory whereas the program code will be stored in the flash program memory. For ex: The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM, 1kb of EPROM and operates at 16MHz clock speed. Some of the other basic functions of Arduino are:

- **Digital write pin** is used to write the digital value of the given pin.
- **Pin mode pin** is used to set the pin to I/O mode.
- **Analog read pin** Reads the value from the specified Analog pin.
- **Analog write pin** writes the value from the specified Analog pin
- **Serial. Begins pin** sets the beginning of serial communication by setting the rate of bit
- **Digital read pin** reads the digital value of given pin.

Introduction to ATMega328

ATmega328 is an eight (8) bit Microcontroller. It can handle the data sized of up to eight (8) bits. It is an AVR based micro-controller. Its built-in internal memory is around 32KB. It operates ranging from 3.3V to 5V. It has an ability to store the data even when the electrical supply is removed from its biasing terminals. it is the excellent features include the cost efficiency and low power dissipation, programming lock for security purposes, real timer counter with the separate oscillator and It is generally or normally used in Embedded Systems applications. ATmega-328 is shown in the figure given below.

Figure.4.1.4: ATMega328 Microcontroller

Arduino UNO Atmega328

The Arduino UNO is a micro controller board based on the ATmega. UNP means one in Italian and is named to mark the upcoming release of the given Arduino 1.0 it has 14 digital input/output pins, 6 analog inputs, 16MHz ceramic resonator. A USB connection. A power jack, An ICSP header and a reset button.it contains information everything needed to support the microcontroller. simply connect it to a computer with a USB cable or power it with an ac-to-dc adapter or battery to get started.

The UNO differs from all preceding boards in that it does not use the FTDI USB-to serial driver chip. Instead, it features the ATMega 16U2ATMega 8U2 up to version instead R2) programmed as a USB to-serial converter.

Architecture and Working of Arduino Uno

The Arduino UNO can be also powered via the USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter or battery. The adapter can connect by plugging a 2.1mm centre positive plug into the board’s power jack. Leads from a battery can be inserted in the Gnd and vin pin headers of the power connector. The board can operate on an external supply of 6to 20 volts. If supplied with less than 7v however, the 5v pin may supply less than five volts and the board may be unstable. If using more than 12v.the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. The processor of the Arduino board uses the Harvard architecture where the program code and program data have separate memory. It consists of two memories such as program memory and data memory. Where in the data is stored in data memory and the code is stored in the flash program memory. The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM 1kb of EPROM and operates with a 16MHz clock speed. Architecture of Atmega328 is shown below.

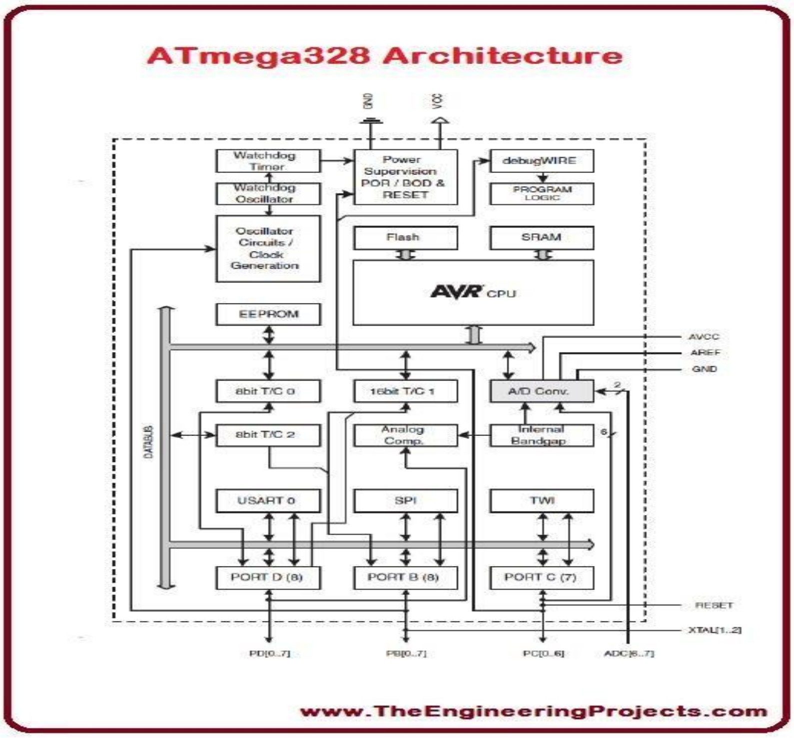

Figure.4.1.5: ATmega328P Architecture

Atmega328 Pins Description

Functions associated with the pins must be known in order to use the device appropriately. ATmega-328 pins are divided into different ports which are given in detail below.

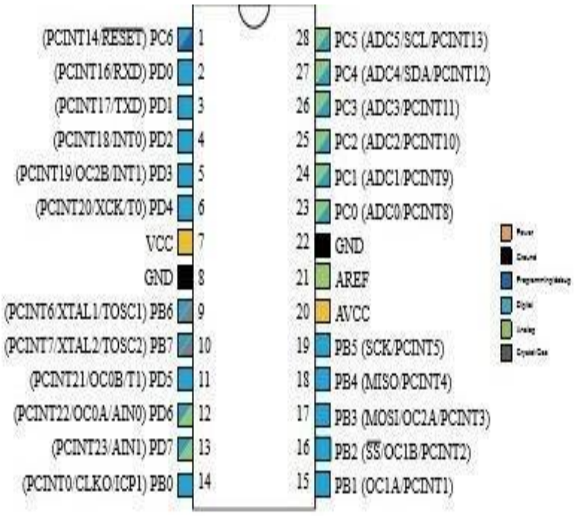

Figure.4.1.6: ATmega328P Ports

AVCC is a supply voltage pin for analog to digital converter.

VCC is a digital voltage supply

GND denotes Ground and it has a 0V.

Port A consists of the pins from PA0 to PA7. These pins serve as analog input to analog to digital converters. If analog to digital converter is not used, port A acts as an eight (8) bit bidirectional input/output port.

Port B consists of the pins from PB0 to PB7. This port is an 8 bit bidirectional port having an internal pull-up resistor.

Port C consists of the pins from PC0 to PC7. The output buffers of port C **Port D** consists of the pins from PD0 to PD7. It is also an 8bit input/output port having an internal pull-up resistor. All of the AVR ports are shown in figure given below.

Power Supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices.

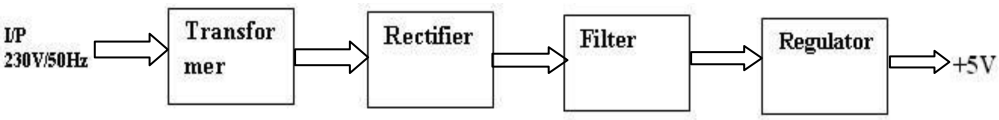

Figure.4.1.7: Block Diagram of Power supply

There are various types of power electronic converters such as step-down converter, step-up converter, voltage stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems-based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

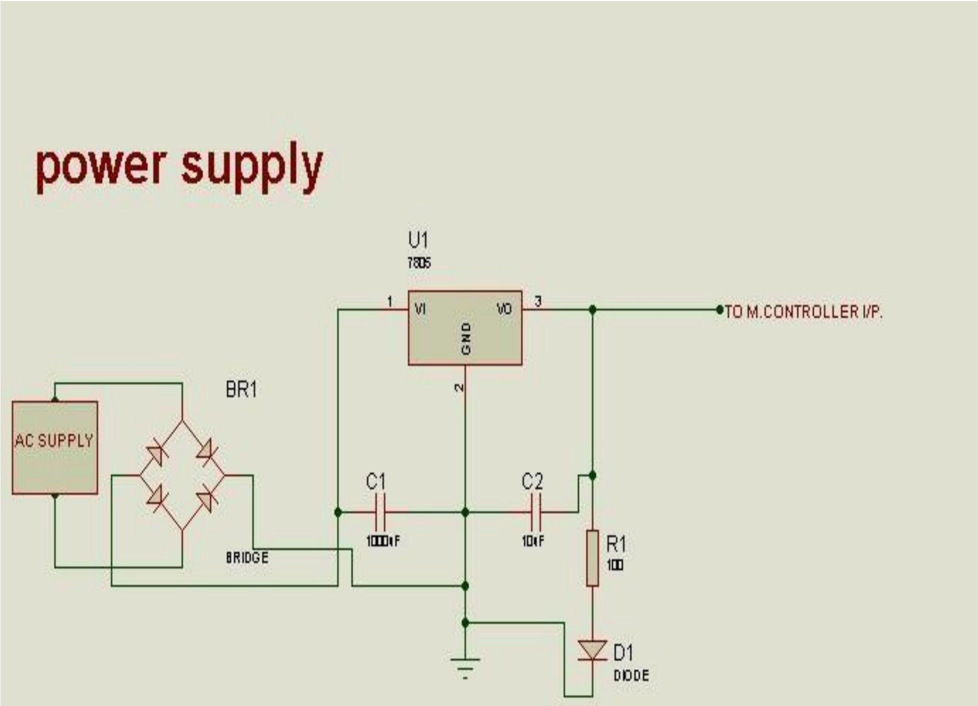

Figure. 4.1.8: Circuit diagram of Power supply

ZIGBEE

Xbee is the module using Zigbee protocol. Zigbee is a wireless communication protocol like Wi-Fi and Bluetooth. ZigBee defines a network layer above the 802.15.4 layers to support advanced mesh routing capabilities. Xbee can be used for wireless communication with low power consumption. A 3.6V 600mA Lithium battery may last 6 - 12 months for powering up an Xbee while the wireless range can up to 1 mile. It talks with well-known UART interface and makes it easy to use. It is simple and straight forward if you only use 2 Xbee for communication. People use this for their own electronics projects for wireless communication.

The Xbee Wireless Communication Starter Kit provides everything you need to harness the powerful and versatile technology of Zigbee 802.15.4 wireless communication. Do you want to free your robot of wires? Send sensory data back to your PC? Control your robot from up to 300 feet away without having to worry about interference issues inherit in most 2.4ghz technology? Zigbee technology is the answer. From simply 'cutting' your serial cable, to creating a wireless mesh network perfect for swarm robotics, you can take your robotics projects to the next level with Zigbee!

Figure.4.1.9: X-bee Module

This is the very popular 2.4GHz XBee module from Digi (formally Maxstream). These modules take the 802.15.4 stack (the basis for Zigbee) and wrap it into a simple to use serial command set. These modules allow a very reliable and simple communication between microcontrollers, computers, systems, really anything with a serial port! Point to point and multi-point networks supported.

ZigBee is a specification for a suite of high-level communication protocols using small, low-power digital radios based on the IEEE 802.15.4-2003 standard for wireless personal area networks (WPANs), such as wireless headphones connecting with cell phones via short-range radio. The technology defined by the ZigBee specification is intended to be simpler and less expensive than other WPANs, such as Bluetooth. ZigBee is targeted at radio-frequency (RF) applications that require a low data rate, long battery life, and secure networking.

History of Zigbee Technology

In the year 1990, the digital radio networks with self-organizing ad hoc were implemented. The Zigbee specification like IEEE 802.15.4-2003 was approved in the year 2004, on December 14. The Specification 1.0 was announced by Zigbee Alliance in the year 2005, on June 13, called the Specification of ZigBee 2004.

Overview

ZigBee is a low-cost, low-power, wireless mesh networking proprietary standard. The low cost allows the technology to be widely deployed in wireless control and monitoring applications, the low power-usage allows longer life with smaller batteries, and the mesh networking provides high reliability and larger range. The ZigBee Alliance, the standards body that defines ZigBee, also publishes application profiles that allow multiple OEM vendors to create interoperable products.

ZigBee operates in the industrial, scientific and medical (ISM) radio bands; 868 MHz in Europe, 915 MHz in the USA and Australia, and 2.4 GHz in most jurisdictions worldwide. Because ZigBee can activate (go from sleep to active mode) in 15 msec or less, the latency can be very low and devices can be very responsive — particularly compared to Bluetooth wake-up delays, which are typically around three seconds. Because ZigBee's can sleep most of the time, average power consumption can be very low, resulting in long battery life.

Protocol

The protocols build on recent algorithmic research (Ad-hoc On-demand Distance Vector, neuRFon) to automatically construct a low-speed ad-hoc network of nodes. In most large network instances, the network will be a cluster of clusters. It can also form a mesh or a single cluster. The current profiles derived from the ZigBee protocols support beacon and non-beacon enabled networks.

Zigbee specification

ZigBee is the specification of a low-cost, low-power wireless communications solution, meant to be integrated as the main building block of ubiquitous networks.

It is maintained by the ZigBee Alliance, which develops the specification and certifies its proper implementation. As of 2007, the latest publicly available revision is the 2006 version.

Zigbee Architecture

Zigbee system structure consists of three different types of devices as Zigbee Coordinator, Router, and End device. Every Zigbee network must consist of at least one coordinator which acts as a root and bridge of the network. The coordinator is responsible for handling and storing the information while performing receiving and transmitting data operations.

Zigbee routers act as intermediary devices that permit data to pass to and for through them to other devices. End devices have limited functionality to communicate with the parent nodes such that the battery power. The number of routers, coordinators, and end devices depends on the type of networks such as star, tree, and mesh networks. Zigbee protocol architecture consists of a stack of various layers where IEEE 802.15.4 is defined by physical and MAC layers while this protocol is completed by accumulating Zigbee's own network and application layers.

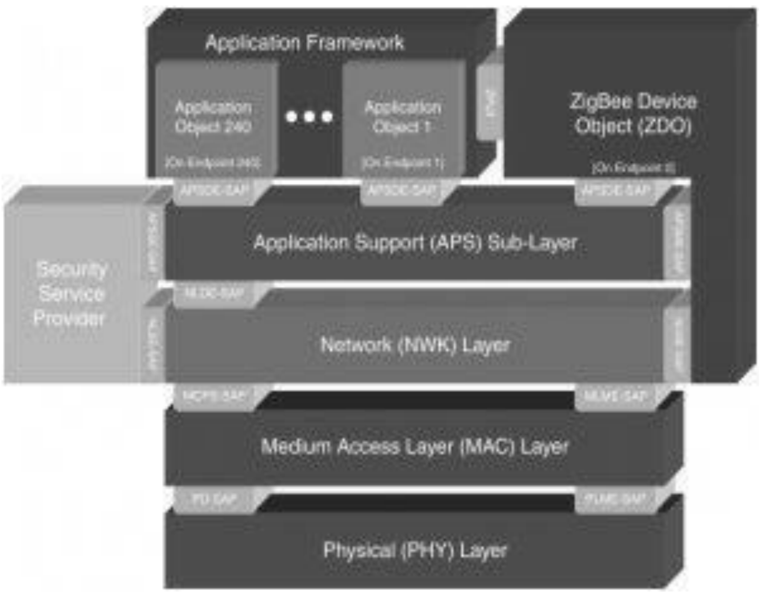

Figure.4.1.10: Zigbee Architecture

- **Physical Layer**: This layer does modulation and demodulation operations upon transmitting and receiving signals respectively. This layer's frequency, data rate, and a number of channels are given below.
- **MAC Layer**: This layer is responsible for reliable transmission of data by accessing different networks with the carrier sense multiple access collision avoidances (CSMA). This also transmits the beacon frames for synchronizing communication.
- **Network Layer**: This layer takes care of all network-related operations such as network setup, end device connection, and disconnection to network, routing, device configurations, etc.
- **Application Support Sub-Layer**: This layer enables the services necessary for Zigbee device objects and application objects to interface with the network layers for data managing services. This layer is responsible for matching two devices according to their services and needs.
- **Application Framework**: It provides two types of data services as key-value pair and generic message services. The generic message is a developer-defined structure, whereas the key-value pair is used for getting attributes within the application objects. ZDO provides an interface between application objects and the APS layer in Zigbee devices. It is responsible for detecting, initiating, and binding other devices to the network.

Zigbee Operating Modes

Zigbee two-way data is transferred in two modes: Non-beacon mode and Beacon mode. In a beacon mode, the coordinators and routers continuously monitor the active state of incoming data hence more power is consumed. In this mode, the routers and coordinators do not sleep because at any time any node can wake up and communicate.

These beacon networks are work for time slots which means, they operate when the communication needed results in lower duty cycles and longer battery usage. These beacon and non-beacon modes of Zigbee can manage periodic (sensors data), intermittent (Light switches), and repetitive data types.

Zigbee Topologies

Zigbee supports several network topologies; however, the most commonly used configurations are star, mesh, and cluster tree topologies. Any topology consists of one or more coordinators. In a star topology, the network consists of one coordinator which is responsible for initiating and managing the devices over the network. All other devices are called end devices that directly communicate with the coordinator. This is used in industries where all the endpoint devices are needed to communicate with the central controller, and this topology is simple and easy to deploy. In mesh and tree topologies, the Zigbee network is extended with several routers where the coordinator is responsible for staring them.

If any node fails, the information is routed automatically to other devices by these topologies. As redundancy is the main factor in industries, hence mesh topology is mostly used. In a cluster-tree network, each cluster consists of a coordinator with leaf nodes, and these coordinators are connected to the parent coordinator which initiates the entire network.

Zigbee Devices

The specification of IEEE 802.15.4 Zigbee mainly includes two devices like Full-Function Devices (FFD) as well as Reduced-Function Devices (RFD). An FFD Device performs different tasks which are explained within the specification & it can adopt any task within the network.

In an IEEE 802.15.4 n/w, the Zigbee devices play three different roles like Coordinator, PAN Coordinator & Device. Here, FFD devices are Coordinator as well as PAN Coordinator whereas the Device is either an RFD/ FFD Device.

Basic Security Model

The basic mechanism to ensure confidentiality is the adequate protection of all keying material. Trust must be assumed in the initial installation of the keys, as well as in the processing of security information. In order for an implementation to globally work, its general correctness (e.g., conformance to specified behaviours) is assumed.

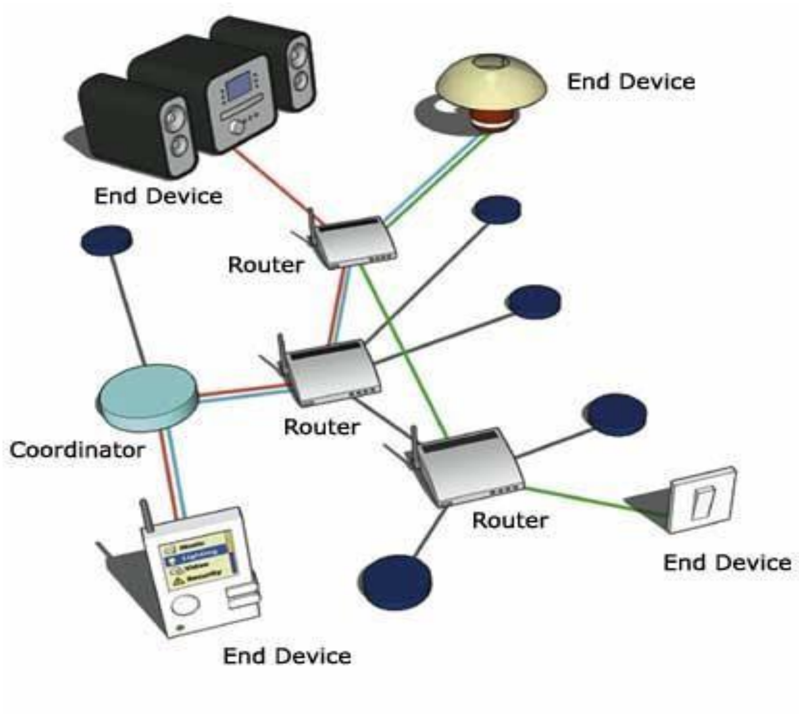

Figure.4.1.11: Basic Security Model

Why Zigbee is Better than Wi-Fi?

In Zigbee, the data transfer speed is less as compared with WiFi, so it's the highest speed is simply 250kbps. It is very less as compared with the less speed of WiFi. One of the most best quality of Zigbee is the rate of power utilization as well as the life of the battery. Its protocol lasts for several months because once it is assembled then we can forget.

What Devices use Zigbee?

The following list of devices supports the ZigBee protocol.

- Belkin WeMo
- Samsung SmartThings
- Yale smart locks
- Philips Hue

- Thermostats from Honeywell
- Ikea Tradfri
- Security Systems from Bosch
- Comcast Xfinity Box from Samsung
- Hive Active Heating & accessories
- Amazon Echo Plus
- Amazon Echo Show

Instead of connecting every Zigbee device separately, a central hub is required for controlling all the devices. The central hub will scan the network for all the supported devices and provides you simple control of the above devices with a central app.

Zigbee Advantages

The advantages of Zigbee include the following.

- This network has a flexible network structure
- Battery life is good.
- Power consumption is less
- Very simple to fix.
- It supports approximately 6500 nodes.
- Less cost.
- It is self-healing as well as more reliable.
- Network setting is very easy as well as simple.
- Loads are evenly distributed across the network because it doesn’t include a central controller
- Home appliances monitoring as well controlling is extremely simple using remote
- The network is scalable and it is easy to add/remote ZigBee end device to the network.

Applications of Zigbee

The applications of ZigBee technology include the following.

- **Industrial Automation:** In manufacturing and production industries, a communication link continually monitors various parameters and critical equipment. Hence Zigbee considerably reduces this communication cost as well as optimizes the control process for greater reliability.
- **Home Automation:** Zigbee is perfectly suited for controlling home appliances remotely as a lighting system control, appliance control, heating, and cooling system control, safety equipment operations and control, surveillance, and so on.
- **Smart Metering:** Zigbee remote operations in smart metering include energy consumption response, pricing support, security over power theft, etc.
- **Smart Grid monitoring:** Zigbee operations in this smart grid involve remote temperature monitoring, fault locating, reactive power management, and so on.

LCD (Liquid Crystal Display)

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Pin	Symbol	I/O	Description
1	GND	-	Ground
2	Vcc	-	+5V power supply
3	VEE	-	Contrast control
4	RS	I	command/data register selection
5	R/W	I	write/read selection
6	E	I/O	Enable
7	DB0	I/O	The 8-bit data bus
8	DB1	I/O	The 8-bit data bus
9	DB2	I/O	The 8-bit data bus
10	DB3	I/O	The 8-bit data bus
11	DB4	I/O	The 8-bit data bus
12	DB5	I/O	The 8-bit data bus
13	DB6	I/O	The 8-bit data bus
14	DB7	I/O	The 8-bit data bus

Table.4.1.2: LCD Pin Description

Description of 16X2

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board. 16×2 LCD is named so because; it has 16 Columns and 2 Rows.

Schematic Diagram

The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

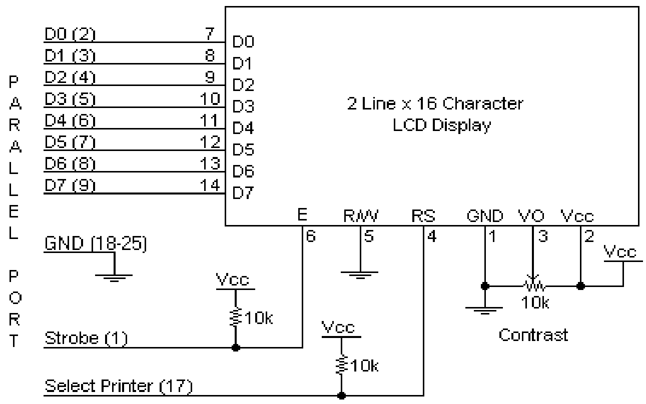

Figure.4.1.12: Schematic Diagram of LCD

Code (hex)	Command to LCD Instruction Register
1	Clear display screen
2	Return home
4	Shift cursor to left
5	Shift display right
6	Shift cursor to right
7	Shift display left
8	Display off, Cursor off
A	Display off, Cursor on

Table 4.1.3: LCD commands

Pin Description

- Pin1 (Ground/Source Pin): This is a GND pin of display, used to connect the GND terminal of the microcontroller unit or power source.

- Pin2 (VCC/Source Pin): This is the voltage supply pin of the display, used to connect the supply pin of the power source.
- Pin3 (V0/VEE/Control Pin): This pin regulates the difference of the display, used to connect a changeable POT that can supply 0 to 5V.
- Pin4 (Register Select/Control Pin): This pin toggles among command or data register, used to connect a microcontroller unit pin and obtains either 0 or 1(0 = data mode, and 1 = command mode).
- Pin5 (Read/Write/Control Pin): This pin toggles the display among the read or writes operation, and it is connected to a microcontroller unit pin to get either 0 or 1 (0 = Write Operation, and 1 = Read Operation).
- Pin 6 (Enable/Control Pin): This pin should be held high to execute Read/Write process, and it is connected to the microcontroller unit & constantly held high.
- Pins 7-14 (Data Pins): These pins are used to send data to the display. These pins are connected in two-wire modes like 4-wire mode and 8-wire mode. In 4-wire mode, only four pins are connected to the microcontroller unit like 0 to 3, whereas in 8-wire mode, 8-pins are connected to microcontroller unit like 0 to 7.
- Pin15 (+ve pin of the LED): This pin is connected to +5V
- Pin 16 (-ve pin of the LED): This pin is connected to GND.

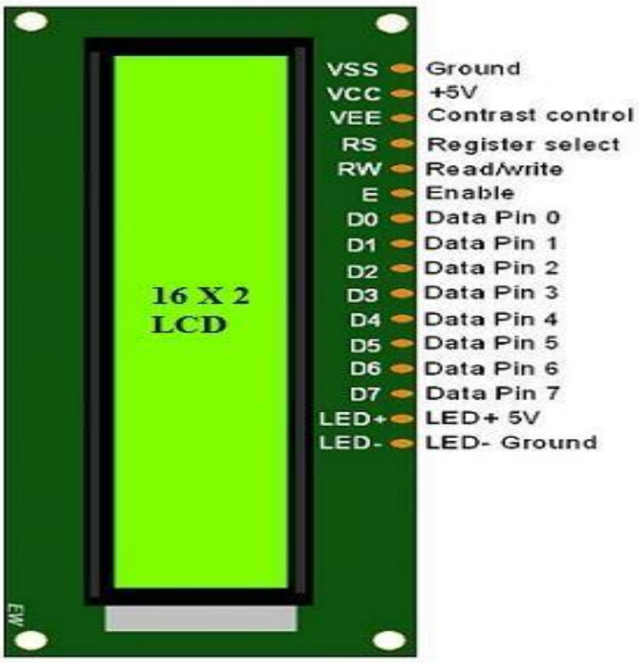

Figure.4.1.13: LCD-16X2 Pin Diagram

Features of LCD16X2

The features of this LCD mainly include the following.

- The operating voltage of this LCD is 4.7V-5.3V
- It includes two rows where each row can produce 16-characters.
- The utilization of current is 1mA with no backlight
- Every character can be built with a 5×8-pixel box
- The alphanumeric LCDs alphabets & numbers
- Is display can work on two modes like 4-bit & 8-bit
- These are obtainable in Blue & Green Backlight.
- It displays a few custom generated characters

Registers of LCD

A 16×2 LCD has two registers like data register and command register. The RS (register select) is mainly used to change from one register to another. When the register set is ‘0’, then it is known as command register. Similarly, when the register set is ‘1’, then it is known as data register.

(i) Command Register

The main function of the command register is to store the instructions of command which are given to the display. So those predefined tasks can be performed such as clearing the display, initializing, set the cursor place, and display control. Here commands processing can occur within the register.

(ii) Data Register

The main function of the data register is to store the information which is to be exhibited on the LCD screen. Here, the ASCII value of the character is the information which is to be exhibited on the screen of LCD. Whenever we send the information to LCD, it transmits to the data register, and then the process will be starting there. When register set =1, then the data register will be selected.

LCD Interfacing with the Arduino Module

The following circuit diagram shows the liquid crystal display with the Arduino module. From the circuit diagram, we can observe that the RS pin of the

LCD is connected to the pin 12 of the Arduino. The LCD of R/W pin is connected to the ground. The pin 11 of the Arduino is connected to the enable signal pin of LCD module. The LCD module & Arduino module are interfaced with the 4-bit mode in this project. Hence there are four input lines which are DB4 to DB7 of the LCD. This process very simple, it requires fewer connection cables and also, we can utilize the most potential of the LCD module.

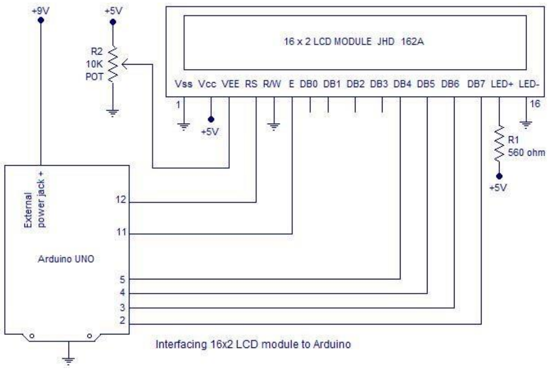

Figure.4.1.14: LCD Interfacing with the Arduino.

The digital input lines (DB4-DB7) are interfaced with the Arduino pins from 5-2. To adjust the contrast of the display here we are using a 10K potentiometer. The current through the back LED light is from the 560-ohm resistor. The external power jack is provided by the board to the Arduino. Using the PC through the USB port the Arduino can power. Some parts of the circuit can require the +5V power supply it is taken from the 5V source on the Arduino board.

Applications

- In most of the applications that's have only small values to show, uses the LCD.
- Most of the commercial meters use this module to represent the data output.
- In the toys and developing projects, it is still vastly in use.
- In black and white printers, it helps to show the printer settings and status.

USB-TTL

This USB-TTL converter is a port-powered bi-directional USB to TTL/CMOS 5V converter, which can be used to convert any standard full-duplex

USB port into a full-duplex TTL port and vice versa. The unit is powered from the USB port and it supports data auto-sensing & self-adjusting, and therefore, no baud rate setting is required. USB to TTL /stc microcontroller programmer / pl2303 in nine upgrades plate with a transparent cover compatible with Arduino, raspberry pi, avr, pic, 8051, etc. The USB to rs232 module based TTL provides the best and convenient way to connect your rs232 TTL devices or demo board to your pc via the USB port.

The purpose of this device to connect your PC to a serial (TTL level) device. The CP2102 is a highly-integrated USB-to-UART Bridge Controller providing a simple solution for updating RS-232 designs to USB using a minimum of components and PCB space. The CP2102 includes a USB 2.0 full-speed function controller, USB transceiver, oscillator, EEPROM, and asynchronous serial data bus (UART) with full modem control signals in a compact 5 x 5 mm QFN-28 package. No other external USB components are required.

Working

The CP2102 is a highly-integrated USB-to-UART Bridge Controller providing a simple solution for updating RS-232 design to USB using a minimum of components and PCB space. Cp2102 Based boards are better, reliable and faster than Cheap PL2303 based boards. This board can be easily used in conjunction with Arduino Pro/ Arduino Por Mini Boards for Programming.

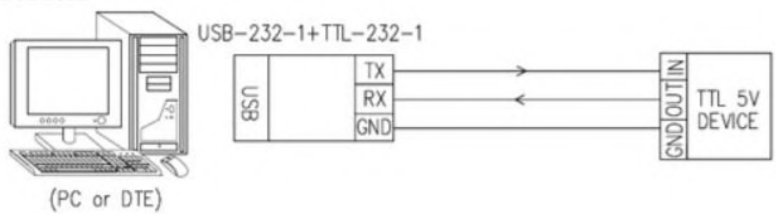

Figure.4.1.15: USB-TTL Converter Connection to PC

Features

- Stable and reliable chipset CP2102
- USB specification 2.0 compliant with full-speed 12Mbps
- Standard USB type A male and TTL 6pin connector.

- 6pins for 3.3V, RST, TXD, RXD, GND & 5V
- All handshaking and modem interface signals
- Baud rates: 300 bps to 1.5 Mbps
- Byte receive buffer; 640 byte transmit buffer
- Hardware or X-On/X-Off handshaking supported
- Event character support Line break transmission
- USB suspend states supported via SUSPEND pins
- Temperature Range: -40 to +85
- Supports Windows 98SE, 2000, XP, Window7, Mac OS 9 & Linux 2.4

Pin Description

- TX = Connect to Transmit Pin (TXD) of Micro controller. This pin is RX pin of CP2102 on board.
- RX = Connect to Receive Pin (RXD) of Micro controller. This pin is TX pin of CP2102 on board.
- RST = Normally Unconnected. Reset Pin for CP2102. Initiate a system reset by driving this pin low for atleast 15 µs.
- GND = Should be common to microcontroller ground.
- 3V3 = Optional output to power external circuit upto 50mA.
- 5V = Optional output to power external circuit upto 100mA

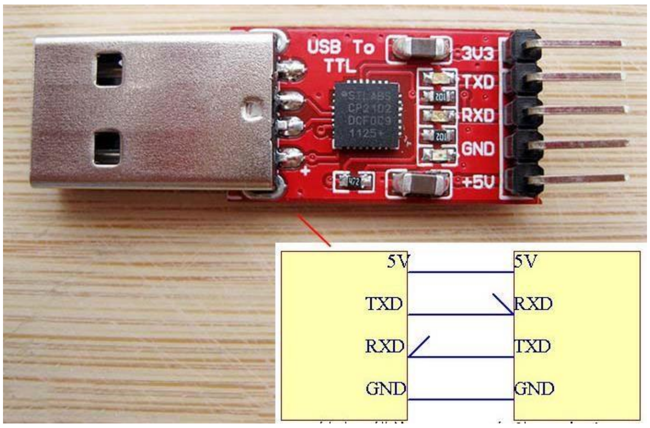

Figure.4.1.16: USB-TTL Converter

Troubleshooting

- Make sure that the USB-TTL converter is connected to your USB port, and the driver is installed correctly (as shown below); otherwise, please reinstall the driver.

- Perform a loopback test by using CommFront's 232Analyzer software: Connect a USB-TTL converter to your USB port, short pin TX (TTL Out) to RX (TTL in) on the termination board, and then send commands from the 232Analyzer software. You should receive an echo of the commands sent. By performing a simple loopback test like this, you can test both the transmitter and receiver of the USB-TTL converter. This is very helpful when you are in doubt about the performance of your converter.

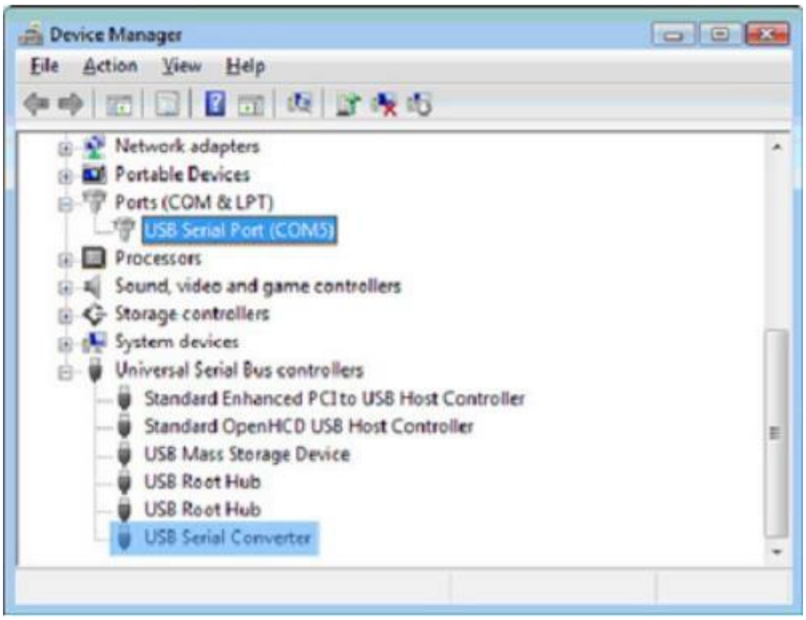

Figure.4.1.17: USB-TTL driver connected to PC

KEYBOARD

A keyboard is one of the primary input devices that allows users to input text into a computer or any other electronic machinery. It is a peripheral device that is the most basic way for the user to communicate with a computer. It consists of multiple buttons, which create numbers, symbols, and letters, and special keys like the Windows and Alt key, including performing other functions. The design of the keyboard comes from the typewriter keyboards, and numbers and letters are arranged on the keyboard in that way, which helps to type quickly.

Keyboards are divided into two main categories based on input method. These categories are:

- **Wired Keyboards**

A wired keyboard means there is a wire connecting your keyboard to your computer. At the end of the wire is a USB plug that goes into a USB port on your computer. Wired keyboards are extremely reliable—there is little that could go wrong with this direct connection. The one drawback to having a wired keyboard is that your distance is limited between the keyboard and your computer; you can only have your keyboard as far from your desktop or laptop as the wire length.

- **Wireless Keyboards**

A wireless keyboard works just like a wireless mouse; you plug a receiver into one of the USB ports on your computer. The receiver then sends a signal to your battery-powered keyboard. Keep in mind, wireless USB keyboards do have a limited range and some must be within the line of sight of your receiver, depending on the type of signal it uses. Also, if your cordless keyboard starts acting sluggish, it probably requires new batteries.

Figure.4.1.18: Keyboard

How it Works

A keyboard consists of two parts: a set of keys that are pushed in sequence by the typist and an encoder that identifies each pressed key and generates a code that uniquely identifies that key. The key set includes the standard alphanumeric keys found on old typewriters and additional keys, such as cursor keys, navigation and function keys, Apple or Windows keys, and a numeric keypad. Keyboards for laptop computers have the minimum number of keys.

The encoder is a microprocessor located in the keyboard that detects each key as it is pressed and released. When the typist presses a key, a connection is made on the grid. If, for example, the connection is in the first row and the third column, the encoder immediately identifies the pressed key and sends a special signal, called a "scanning code," to the computer. The computer translates the scanning code into the appropriate binary code and displays the character on the monitor so that the typist can verify that the correct key was pushed.

The lights on the keyboard (for Caps Lock, Num Lock, Scroll Lock, and so on) are controlled by the computer, not the keyboard. For example, when the typist presses the Caps Lock key, the keyboard encoder sends the code for the Caps Lock key to the computer, and the computer turns on the keyboard's Caps Lock light.

Software Requirements

- Arduino IDE software
- Proteus
- X-CTU

Arduino IDE

The Arduino integrated development atmosphere (IDE) may be a cross-platform application (for Windows, macOS, Linux) that's written within the artificial language Java. it's wont to write and transfer programs to Arduino compatible boards, but also, with the assistance of third-party cores, different trafficker development boards. The ASCII text file for the IDE is free beneath the wildebeest General Public License, version 2. The Arduino IDE supports the languages C and C++ victimisation special rules of code structuring. The Arduino IDE provides a software package library from the Wiring project, that provides several common input and output procedures. User-written code solely needs 2 basic functions, for beginning the sketch and also the main program loop, that are compiled associated connected with a program stub main () into an feasible cyclic programme with the wildebeest tool chain, additionally enclosed with the IDE distribution. The Arduino IDE employs the program argued to convert the feasible code into a document in positional representation system secret writing that's loaded into the Arduino board by a loader program within the board's computer code.

The key highlights are:

- Arduino sheets can understand simple or computerized information signals from various sensors and transform it into a yield, for example, actuating an engine, turning LED on/off, associate with the cloud and numerous different activities.
- You can control your board capacities by sending a lot of guidelines to the microcontroller on the board by means of Arduino IDE (alluded to as transferring programming).
- Dissimilar to most past programmable circuit sheets, Arduino needn't bother with an additional bit of equipment (called a developer) so as to stack another code onto the board. You can basically utilize a USB link.
- Moreover, the Arduino IDE utilizes a rearranged rendition of C++, making it simpler to figure out how to program.
- At long last, Arduino gives a standard structure factor that breaks the elements of the smaller scale controller into an increasingly available bundle.

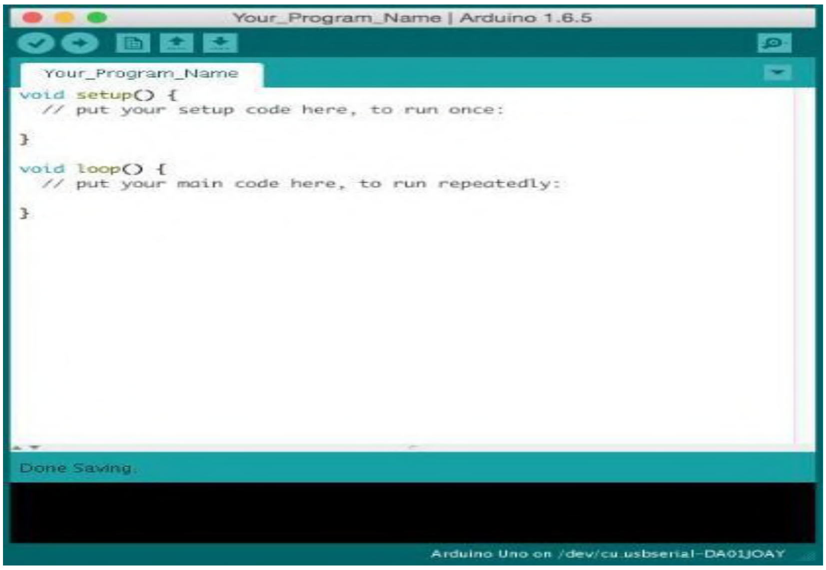

Figure.4.2.1:Program Page

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually. When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.2.2: USB Cable A plug to B plug

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.4.2.3: USB Cable A plug to Mini-B plug

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

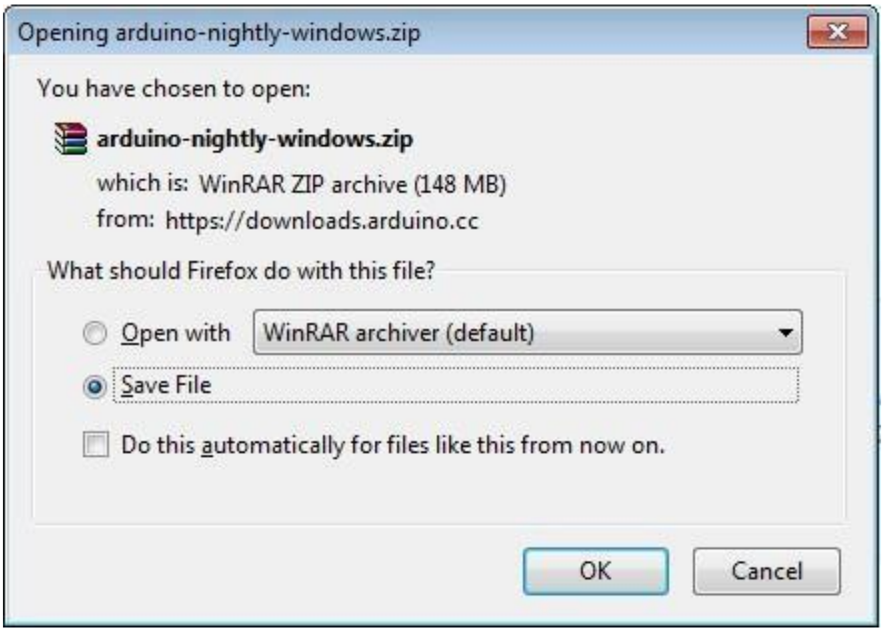

Figure.4.2.4: Unzip of Arduino IDE software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port. Connect the Arduino board to your computer using the USB cable. The green power LED (labelled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder.

Inside the folder, you can find the application icon with an infinity label. Double-click the icon to start the IDE.

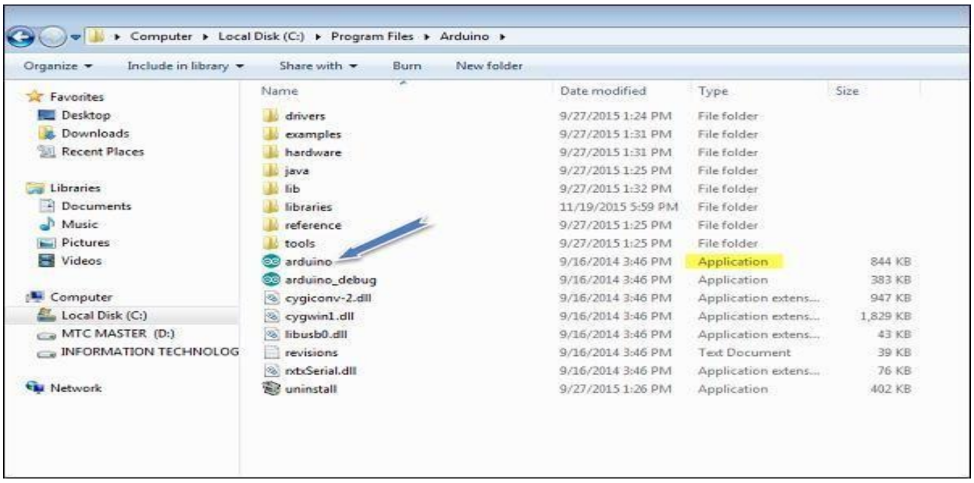

Figure.4.2.5: Open IDE software

Step 5 − Open your first project.

Once the software starts, you have two options:

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

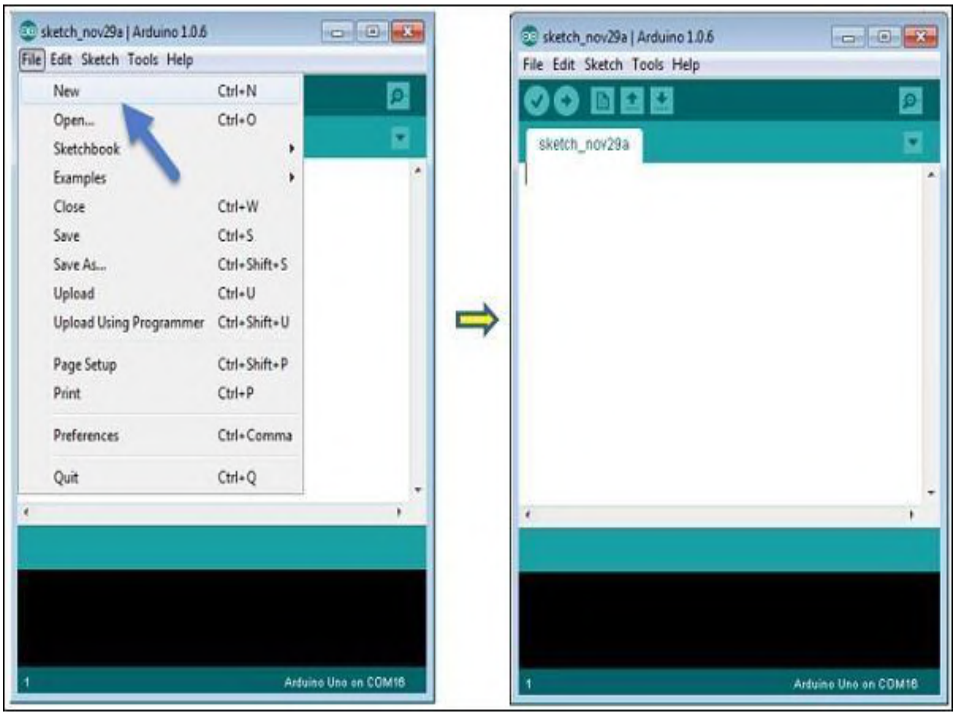

Figure.4.2.6: Open First Project

To open an existing project example, select File → Example → Basics → Blink.

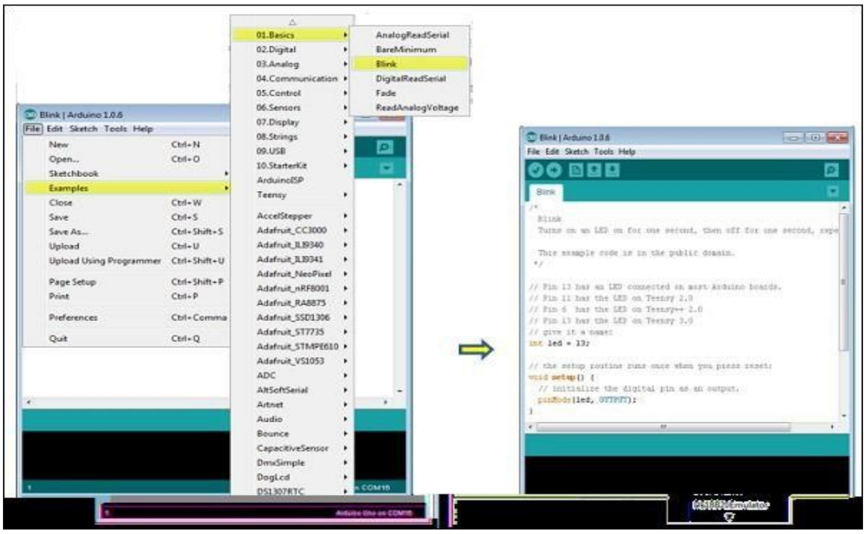

Figure.4.2.7: Open existing Project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

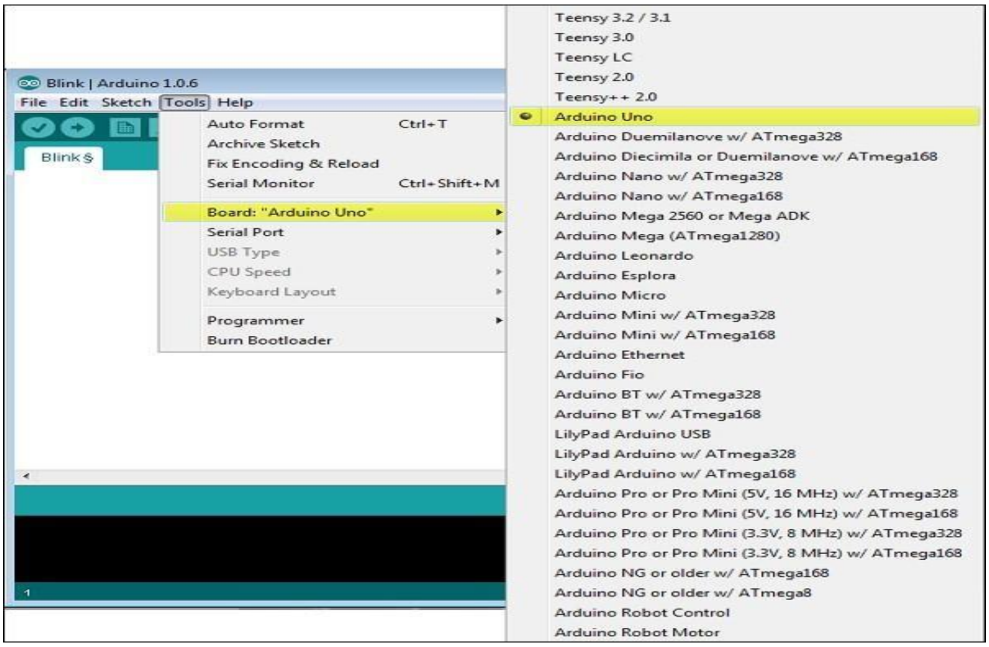

Figure.4.2.8: Selection of Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

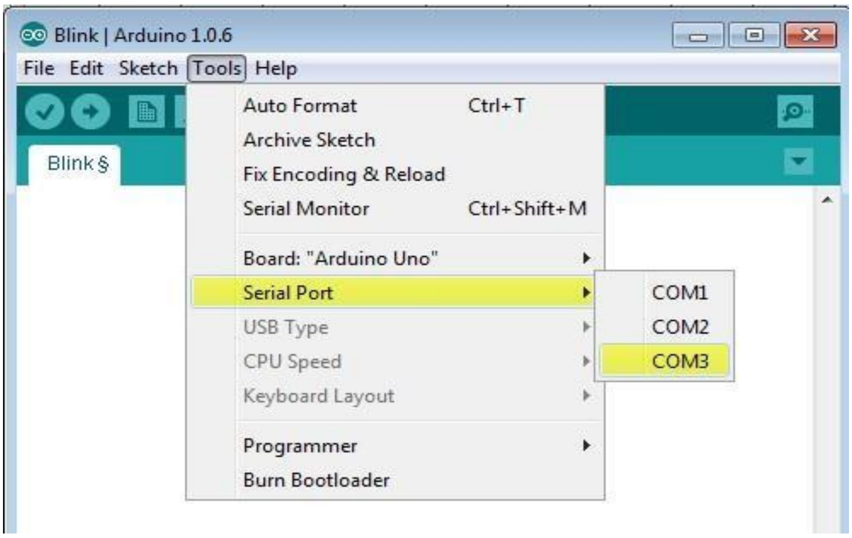

Figure.4.2.9: Selection of Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

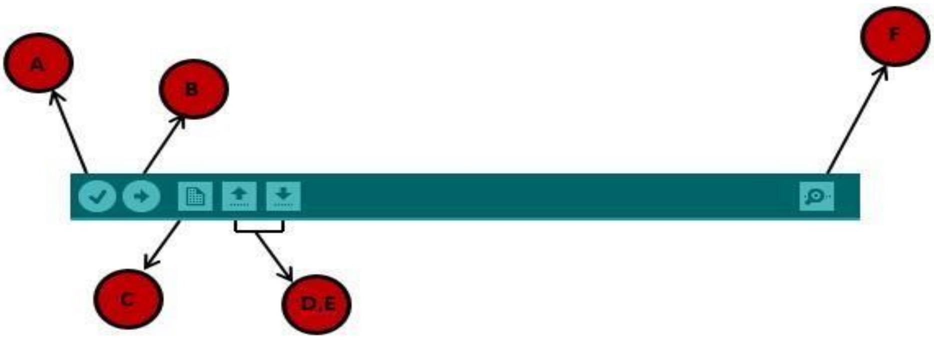

Figure.4.2.10: Uploading the program to board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F – Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Moving on

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Figure.4.2.11: Program in Arduino-speak.

Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc. ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

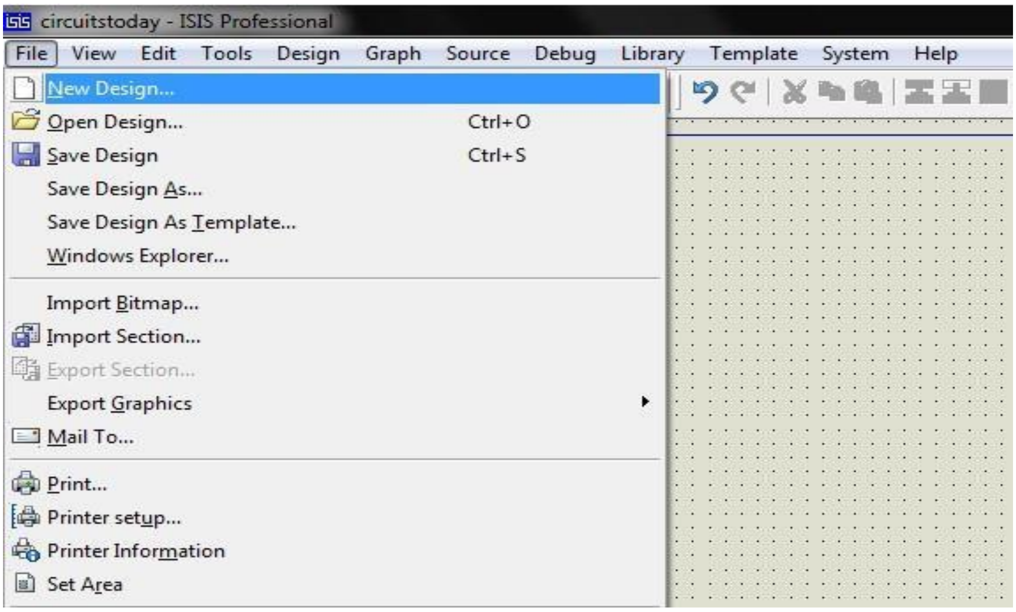

Figure.4.2.12: Proteus file menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

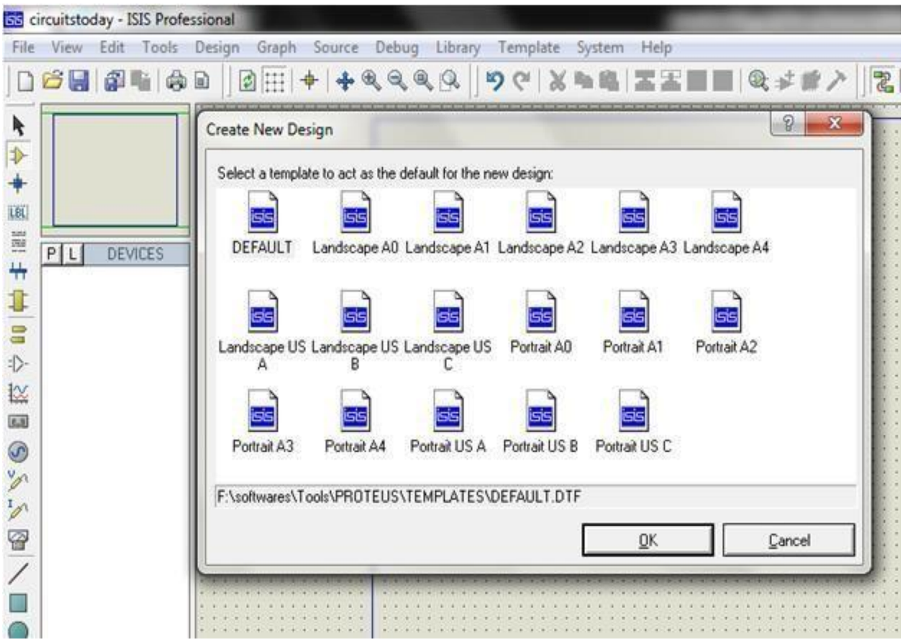

Figure. 4.2.13: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

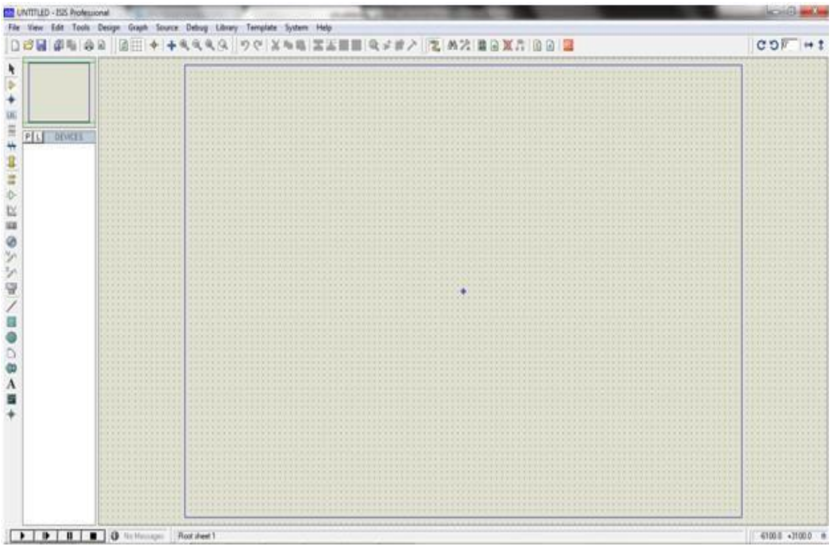

Figure. 4.2.14: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

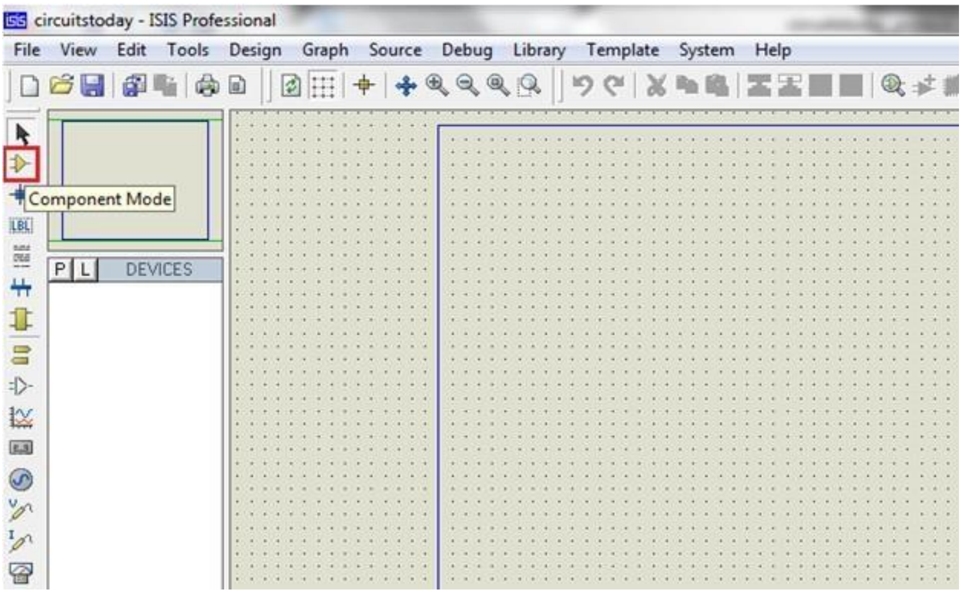

Figure. 4.2.15: Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

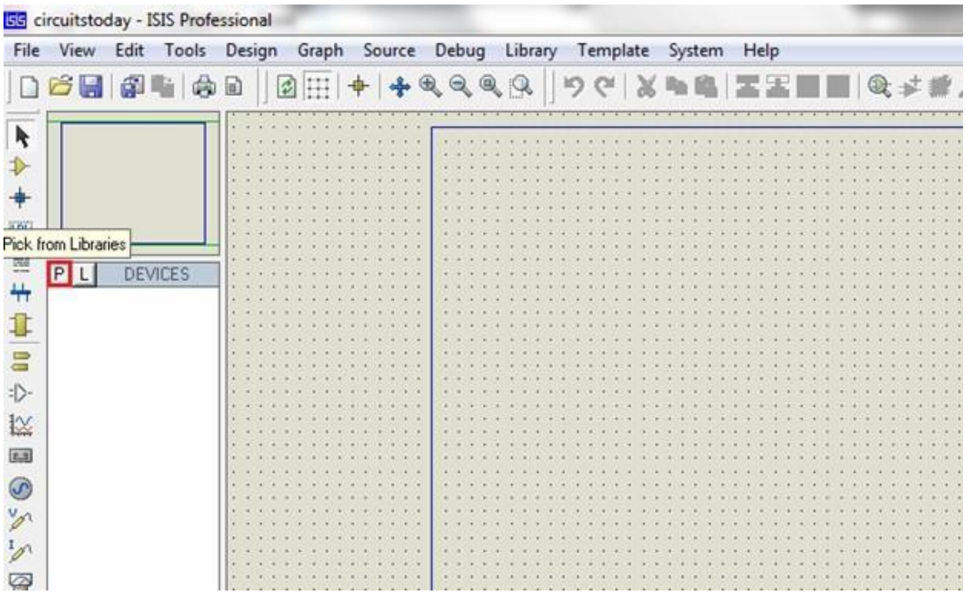

Figure. 4.2.16: Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

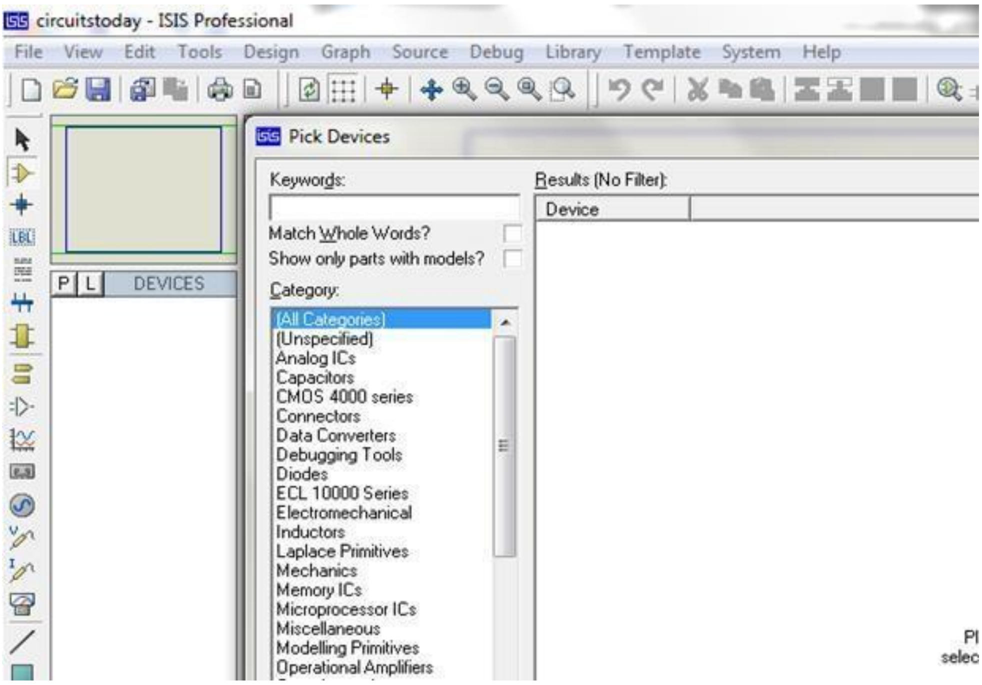

Figure.4.2.17: Keywords Textbox

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

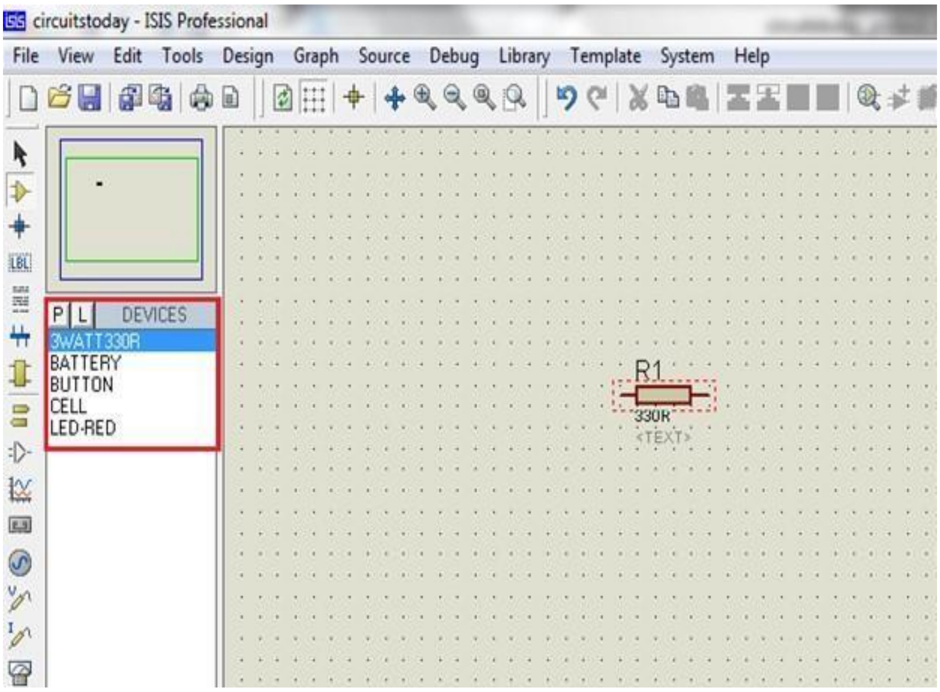

Figure. 4.2.18: Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

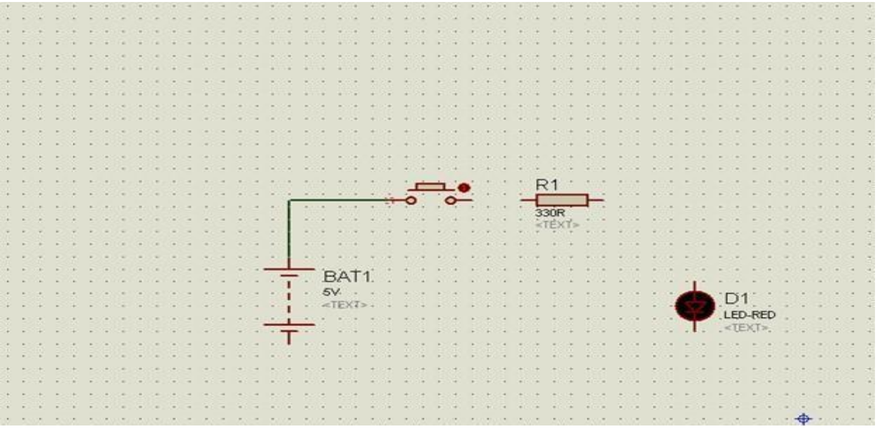

Figure.4.2.19: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

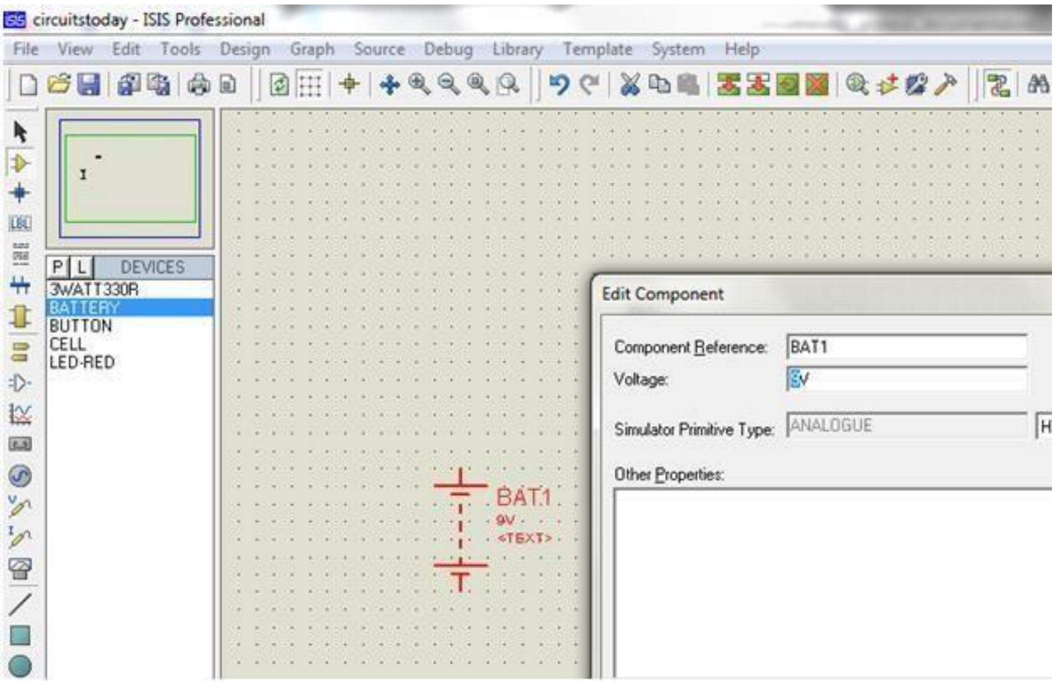

Figure.4.2.20: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

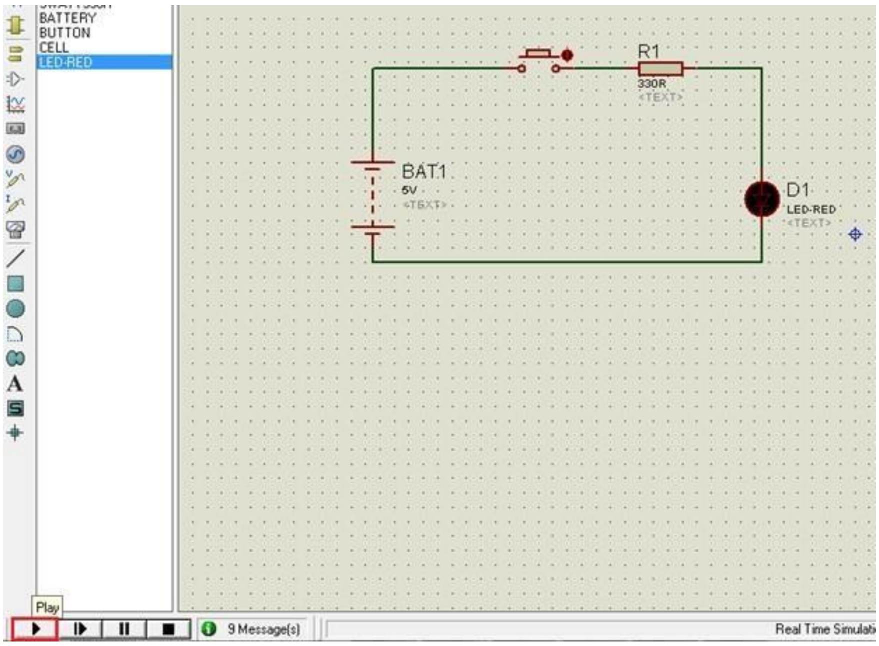

Figure.4.2.21: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

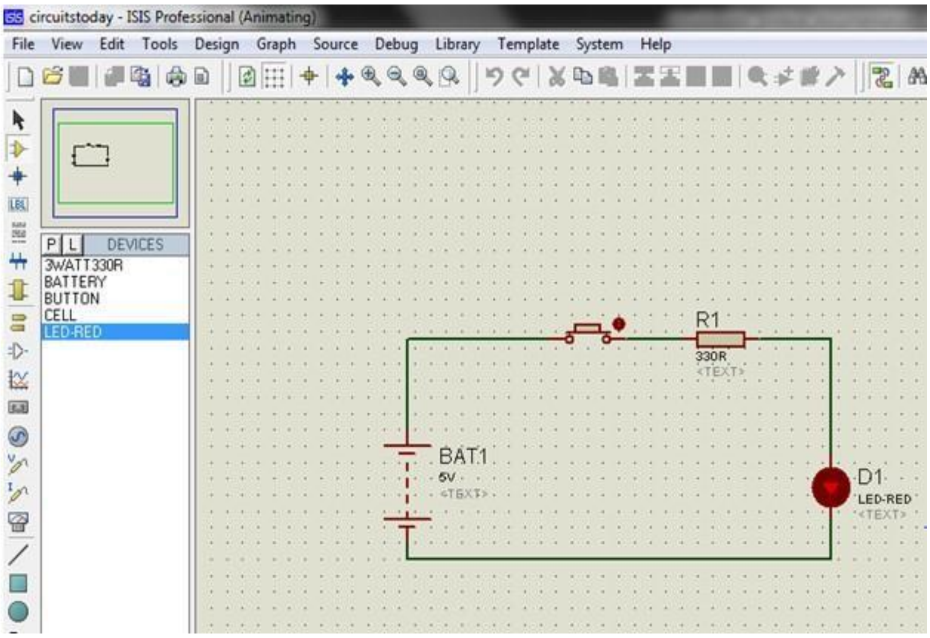

Figure.4.2.22: Simulation Animating

Simulation can be steppe Simulation can be stepped, paused or stopped at any time

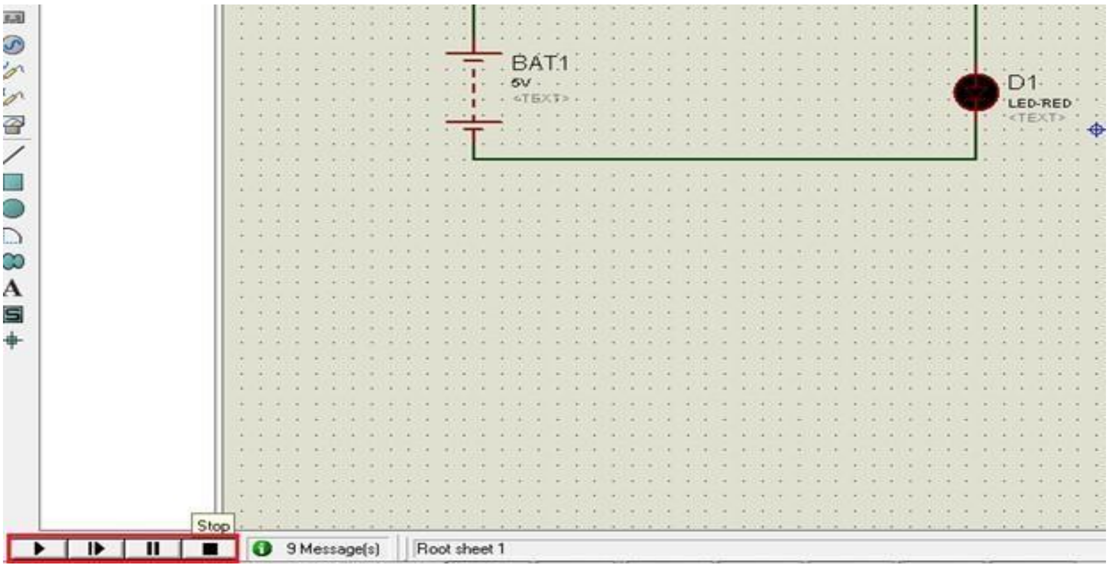

Figure.4.2.23: Simulation Step-Pause-Stop Buttons

X-CTU Software

- XCTU is a free, multi-platform application compatible with Windows, MacOS and Linux
- Graphical Network View for simple wireless network configuration and architecture
- API Frame Builder is a simple development tool for quickly building XBee API frames
- Firmware Release Notes Viewer allows users to explore and read firmware release notes

What is XCTU?

XCTU is a free multi-platform application designed to enable developers to interact with Digi RF modules through a simple-to-use graphical interface. It includes new tools that make it easy to set-up, configure and test XBee® RF modules.

XCTU includes all of the tools a developer needs to quickly get up and running with XBee. Unique features like graphical network view, which graphically represents the XBee network along with the signal strength of each connection, and the XBee API frame builder, which intuitively helps to build and interpret API frames for XBees being used in API mode, combine to make development on the XBee platform easier than ever.

Other highlights of XCTU include the following features:

- You can manage and configure multiple RF devices, even remotely (over-the-air) connected devices.
- The firmware update process seamlessly restores your module settings, automatically handling mode and baud rate changes.
- Two specific API and AT consoles, have been designed from scratch to communicate with your radio devices.
- You can now save your console sessions and load them in a different PC running XCTU.
- XCTU includes a set of embedded tools that can be executed without having any RF module connected:

- Frame’s generator: Easily generate any kind of API frame to save its value.
- **Frame’s interpreter**: Decode an API frame and see its specific frame values.
- **Recovery**: Recover radio modules which have damaged firmware or are in programming mode.
- **Load console session**: Load a console session saved in any PC running XCTU.
- **Range test**: Perform a range test between 2 radio modules of the same network.
- **Firmware explorer**: Navigate through XCTU's firmware library.

- An update process allows you to automatically update the application itself and the radio firmware library without needing to download any extra files.
- XCTU contains complete and comprehensive documentation which can be accessed at any time.

Installation of X-CTU

1. Download X-CTU at www.digi.com/xctu.
2. Browse to the folder to which you saved the above install file.
3. Double-click on the installer file and follow the X-CTU Setup Wizard.
4. When asked if you would like to check Digi's web site for firmware updates, click Yes.
5. After the firmware updates are complete, click Close. Updates may take few minutes, please be patient.
6. Start X-CTU by double-clicking on the X-CTU icon on your desktop, or by selecting Start > Programs Digi > X-CTU.
7. The X-CTU software is now ready to be used.

Zigbee wireless communication Set up

Step 1: Download X-CTU Software.

The X-CTU software is free to download and provides a simple interface to configure and update your XBee transceivers. With this software firmware updates are a breeze and configuration is simple.

Step 2: Configure 1st XBee as a coordinator

When opening the X-CTU software you should see a window like that shown. After selecting the proper COM port click the Test/Query button.

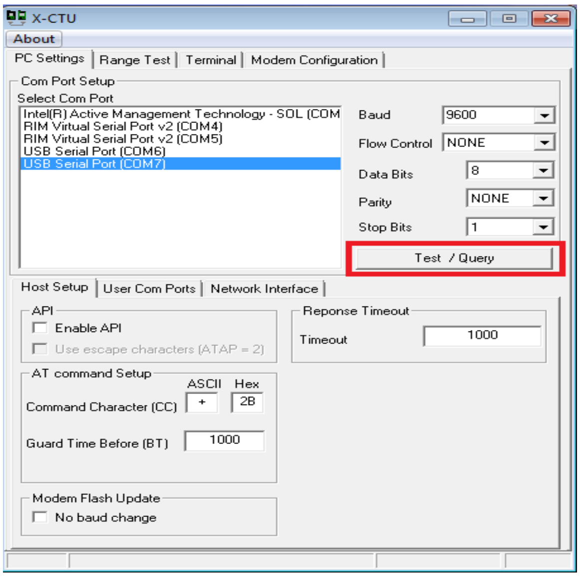

Figure.4.2.24: Configure of 1st Xbee as a transmitter

After selecting the Test/Query button, you should see a dialogue box like the one below. You will want to record the serial number shown as you will need it in a couple minutes.

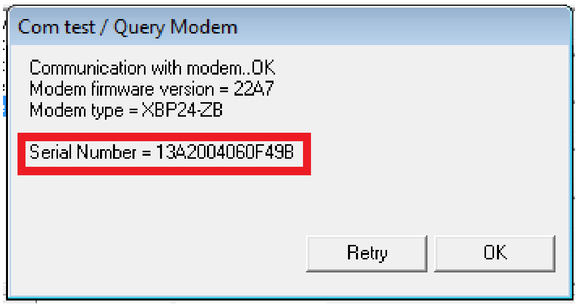

Figure.4.2.25: Com test / query modem

After recording the serial number, you can click OK. Next, select the Modem Configuration tab at the top of the window. Once here, select the read button. This will bring up the current configuration for the connected XBee and will be similar to the following:

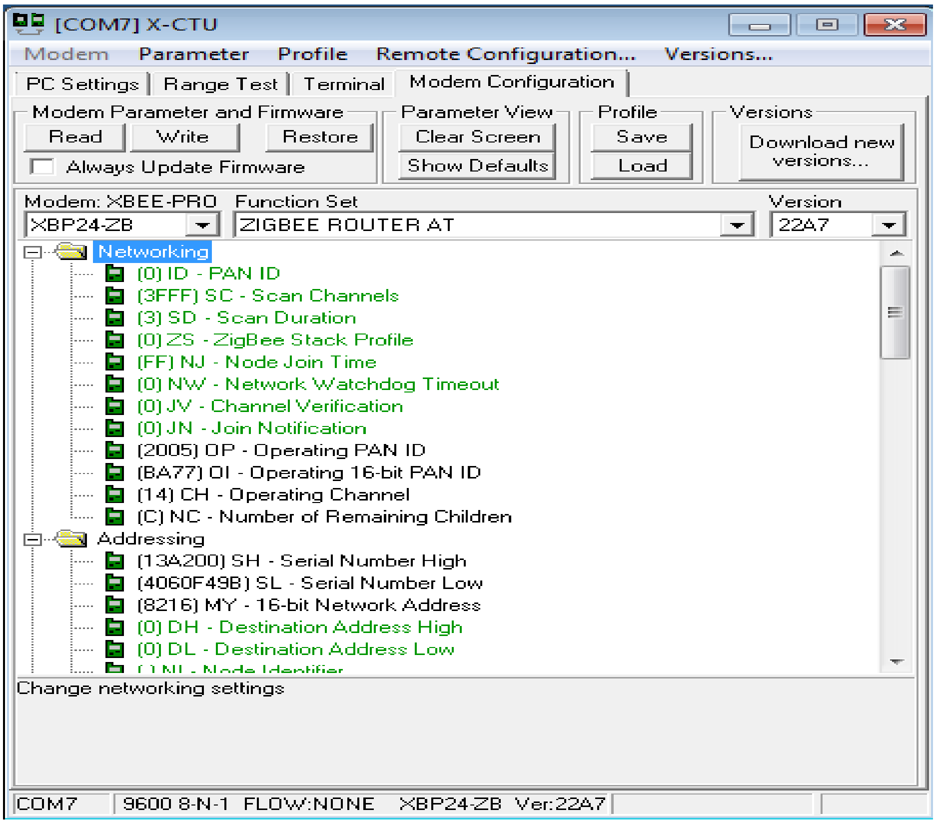

Figure.4.2.26:X-CTU networking

Once here, you want to select Zigbee Coordinator AT in the function set drop down menu.

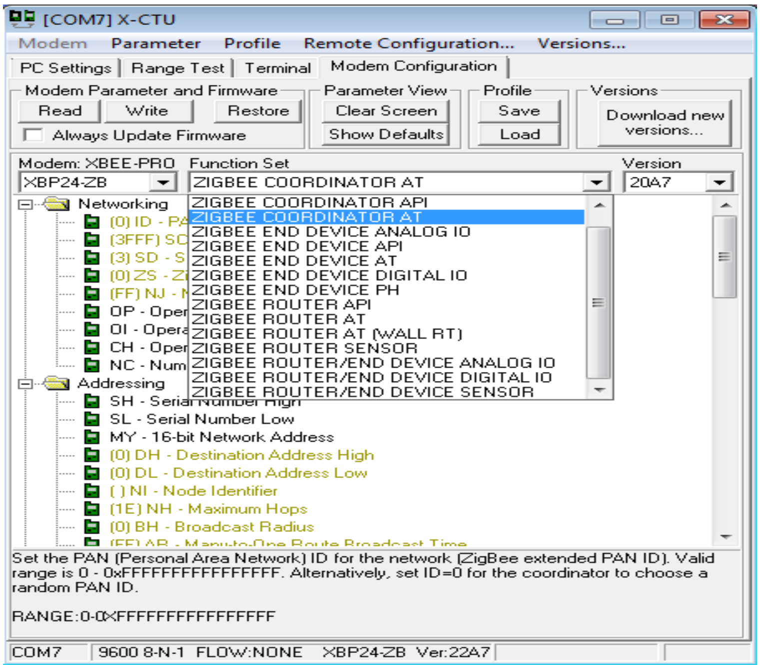

Figure.4.2.27: Zigbee Transmitter

Step 3: Configure 2nd XBee as Router

To configure the 2nd XBee, you will follow the same process as for the coordinator with one difference. In the PC settings tab, again, click the “Test/Query” button and record the serial number. Then in the Modem configuration tab, click the read button to load the current configuration of the XBee and set the PAN ID to the same ID used for the coordinator. The only change will be the function set you choose. For the second XBee we will set this as Zigbee Receiver AT.

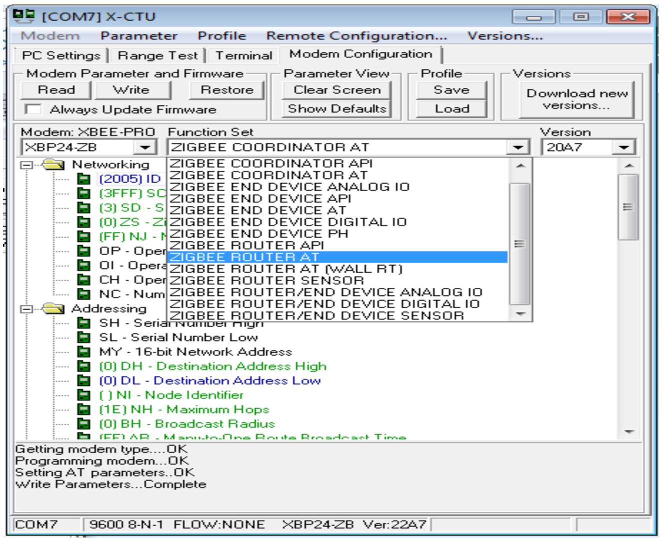

Figure.4.2.28: Zigbee Receiver

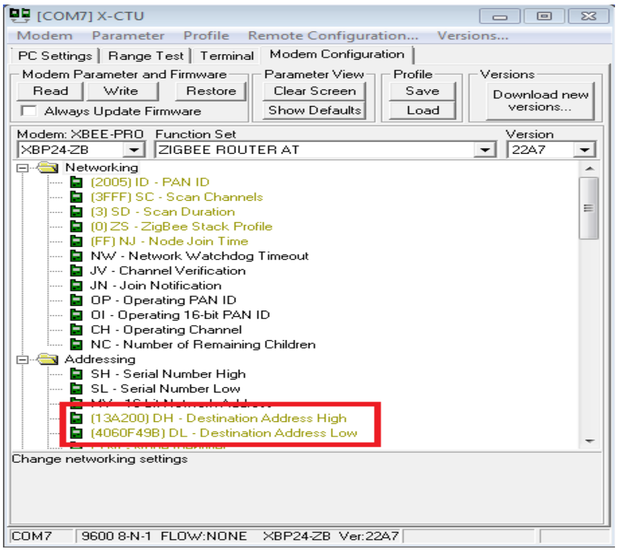

Figure.4.2.29 :X-CTU Receiver

Step 5: Test the configuration

A simple test can be done to be sure the two XBees are communicating properly. You can connect either one of the XBees to the computer. Then, connect the second XBee to 3.3V power and connect the Dout and Din pins together. This will cause the XBee to automatically retransmit any data it receives. When you have both XBees connected go to the Terminal tab in the X-CTU window. Whatever you type in the terminal window will appear in blue font and whatever is received will appear in red font. If the XBees are configured correctly every character you type should be mirrored in red.

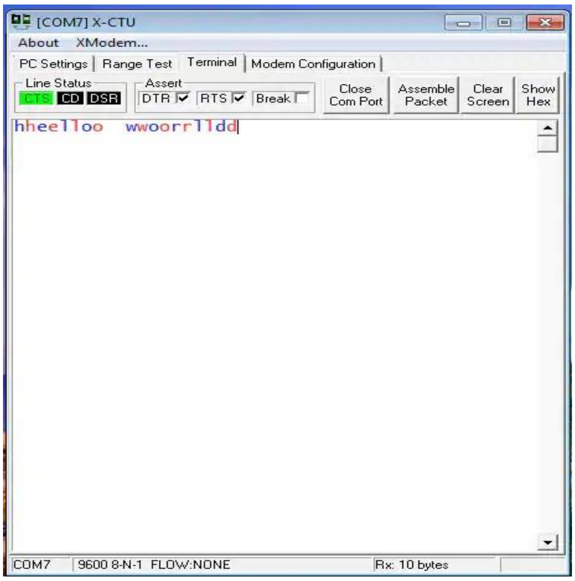

Figure.4.2.30: X-CTU sending information.

When typing single characters, you should see a screen similar to the one above. To send strings of data you can assemble a data packet. To do this click the "Assemble Packet" button and type the wanted string into the box then click send data. This will send the entire packet before receiving the same packet back.

If everything you type is being reflected back in red, you are successfully transmitting and receiving with your XBees!! You are now ready to use them however you wish. You can connect them to any microcontroller and transmit data through the UART peripheral or you can connect each XBee to a different computer and have a chat application. There are many more possibilities that are now at your fingertips with your working XBees.

Figure.4.2.31:Result of information sent.

CHAPTER-5

SOFTWARE TESTING AND CODE IMPLEMENTATION

Software Testing

Software Testing is a process of executing the application with an intent to find any software bugs.It is used to check whether the application met its expectations and all the functionalities of the applicationis working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncoveredand corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

Testing Levels

There are various testing levels based on the specificity of test.

- **Unit testing**: Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.

- **Integration Testing**: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.

- **System Testing**: System testing tests a completely integrated system to verify that the system meets its requirements.

- **Acceptance testing**: Acceptance testing tests the readiness of application, satisfying all requirements.

- **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions ofinstructions per second etc.

System Test Cases

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

Code Implementation

Project Code- Transmitter End

```
#include <SoftwareSerial.h>

SoftwareSerial ZIGBEE(2, 3); //TX, RX respetively

#include <LiquidCrystal.h>

LiquidCrystal lcd(13,12,11,10,9,8);

String readvoice;

void setup() {

ZIGBEE.begin(9600);

Serial.begin(9600);

lcd.begin(16,2);

lcd.clear();
```

```
 lcd.setCursor(0,0);
 lcd.print("***WELCOME***");
 ZIGBEE.println("***WELCOME***");
 Serial.println("***WELCOME***");
 delay(3000);
}

void loop() {

  while (Serial.available()){  //Check if there is an available byte to read
  delay(10); //Delay added to make thing stable
 // readvoice +=Serial.read();
  char c = Serial.read(); //Conduct a serial read
  readvoice += c; //build the string- "forward", "reverse", "left" and "right"
         }

 while (ZIGBEE.available()){  //Check if there is an available byte to read
delay(10); //Delay added to make thing stable
 // readvoice +=ZIGBEE.read();
char c = ZIGBEE.read(); //Conduct a serial read
  readvoice += c; //build the string- "forward", "reverse", "left" and "right"
         }
   /* lcd.clear();
   lcd.setCursor(0, 0);
```

```
lcd.print(readvoice);

Serial.println(readvoice); delay(4000);

ZIGBEE.print(readvoice);

delay(4000);*/

if(readvoice.length() > 0) {

 lcd.clear();

 lcd.setCursor(0,1);

 lcd.print(readvoice);

 Serial.println(readvoice); delay(1000);

 ZIGBEE.print(readvoice);

 delay(1000);

readvoice="";

        }

      } //Reset the variable
```

Project Code- Receiver End

```
#include <SoftwareSerial.h>
SoftwareSerial ZIGBEE(2, 3); //TX, RX respetively
#include <LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);
```

```
String readvoice;

 void setup() {
 ZIGBEE.begin(9600);
 Serial.begin(9600);

  lcd.begin(16,2);
  lcd.clear();
  lcd.setCursor(0,0);
  lcd.print("***WELCOME***");
  ZIGBEE.println("***WELCOME***");
  Serial.println("***WELCOME***");
  delay(3000);

}

void loop() {

  if (ZIGBEE.available()){ //Check if there is an available byte to read
  delay(10); //Delay added to make thing stable
  char c = ZIGBEE.read(); //Conduct a serial read
  readvoice += c; //build the string- "forward", "reverse", "left" and "right"
          }

if (Serial.available()){ //Check if there is an available byte to read
delay(10); //Delay added to make thing stable
char c = Serial.read(); //Conduct a serial read
readvoice += c; //build the string- "forward", "reverse", "left" and "right"
          }

   /* lcd.clear();
 lcd.setCursor(0, 0);
```

```
  lcd.print(readvoice);
  Serial.println(readvoice); delay(4000);
  ZIGBEE.print(readvoice);
  delay(4000);*/

   if(readvoice.length() > 0) {

   lcd.clear();
   lcd.setCursor(0,1);
   lcd.print(readvoice);
   Serial.println(readvoice); delay(1000);
   ZIGBEE.print(readvoice);
   delay(1000);

 readvoice="";
}

} //Reset the variable
```

CHAPTER-6

RESULT ANALYSIS

Case 1: LCD displaying at Transmitter Side

Figure.5.1.1: lcd displaying the message that is getting transmitted

- Here we can see the lcd displaying the message that we are going to transmit i.e., 8 bytes of information.
- The maximum possibility of transmission of information is 32 bytes of information. And we will be getting the same image at the receiver side respectively.

Case 2: LCD Displaying at Receiver Side

Figure.5.2.1 : lcd displaying the message that is getting received

- Here we can see the lcd displaying the message that we received i.e., 8 bytes of information.
- The maximum possibility of receiving of information is 32 bytes of information. And we can see the information is the same as the transmitted information.

Case 3: Transmission and Receiving in X-CTU Software

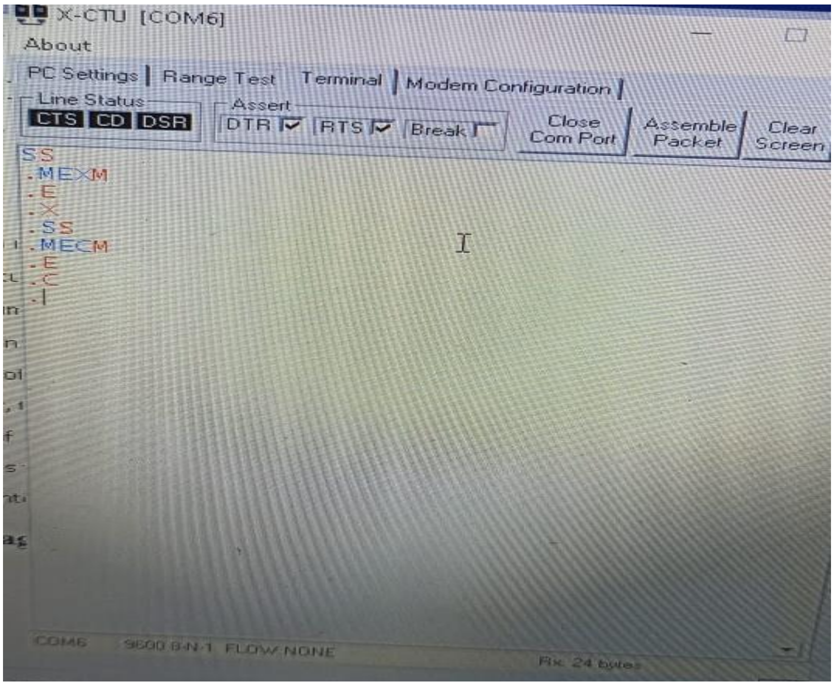

Figure.5.3.1: Transmission and Receiving the Information in X-CTU Software.

- In our project we use X-CTU software for transmission and receiving from a system to system.
- Here blue coloured information is the transmitted information and the orange-coloured information is the received information.
- since were using X-CTU there is no limit for the message size for transmission or receiving.

Case 4: Transmission and Receiving from System to System

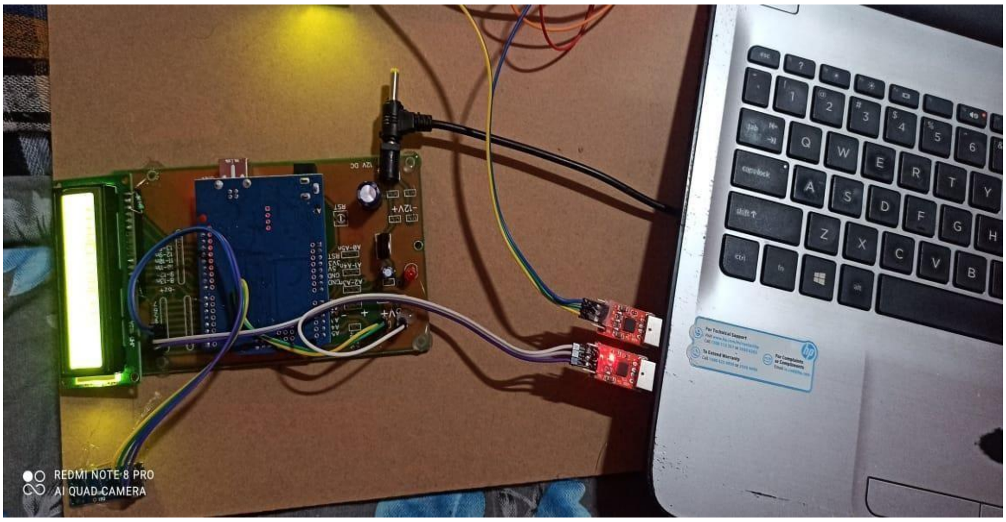

Figure.5.4.1: transmitting and receiving Zigbee’s connected to systems.

- Here we can see the clear connections of our project i.e., the ZigBee is connected to the Arduino along with the lcd.
- Now the Arduino is connected to the system using USB-TTL.
- And now the transmission and receiving of information happens from a system to system through a Zigbee using X-CTU software.

CHAPTER-7

LIMITATIONS AND ADVANTAGES

Limitations

- It is so highly risky to be used for official private information.
- The zigbee has low transmission rate.
- Replacement with zigbee compliant appliances can be costly.
- It does not have many end devices available yet.
- It cannot be used as outdoor wireless communication system dur to it has short coverage limited.
- It is not secure like wifi based secured system.

Advantages

- The Zigbee has flexible network structure.
- It has a very long battery life.
- It is low power consumption.
- It is easy to install.
- It can be easily implemented.
- It supports large number of nodes i.e., 6500 nodes approximately.
- It has a very low cost.
- It is more reliable and self-healing.
- Setting up the network is very simple and easy.

CHAPTER-8

CONCLUSION AND FUTURE WORK

Conclusion

- We can conclude this project by telling that is a ZigBee based wireless communication in order to transmit and receive the message in a secure manner by pairing the devices so that only authorized devices can have the access to the message.
- Zigbee has its own benefits i.e., the communication can happen to long distances when compared to WIFI module and Bluetooth module.
- Also, once you pair the device, the connection is established for longer duration i.e., we don't have to pair the device again and again.

Future Work

- Zigbee has a promising future in front of it. By rapid rise in home networking Zigbee would provide revolutionizing statistics in the upcoming years.
- And we don't need to connect it on a daily basis cause a ZigBee's connection lasts for a lot of time up to a couple of months to be specific.
- Various types of areas such as defense, national security, monitoring and control etc. can be facilitated by devices based on ZigBee standard. Some of its future applications can be:
- Wireless home security.
- Call button for elderly and disabled.
- Wireless smoke detectors.

Industrial automation:

- In manufacturing and production industries a communication link continuously monitors various parameters and critical equipment.

Home automation:

- Lighting system control and appliance control, heating and cooling system control in our home can be controlled using a ZigBee because we have a hub in it and the hub acts as the heart of the appliance automation.

Electronics and Communication Engineering

CERTIFICATE

This is to certify that the project entitled **Alcohol sensing display with alarm** is being submitted by**1. Ms. L Harshasri (18K85A0419), 2. Ms. G Srilekha Reddy (17K81A0477) 3. Mr. K Venkateswar Reddy (18K85A0420)** in partial fulfillment of the requirement for the award of the degree of **BACHELOR OF TECHNOLOGY IN ELECTRONICS AND COMMUNICATION ENGINEERING** is recorded of bonafide work carried out by them. The results embodied in this report have been verified and found satisfactory.

	Head of the Department
Mr. Santhosh Singireddy	Mr. B Hari Krishna
Department of ECE	Department of ECE

Internal Examiner	External Examiner

Place:

Date:

TUESDAY, 15 JUNE 2021

INTERNSHIP CERTIFICATE

THIS IS TO CERTIFY THAT **G. SRILEKA** WITH ROLL NO.**17K81A0477, K. VENKATESHWAR** WITH ROLL NO.**18K85A0420**, **L. HARSHA SRI** WITH ROLL NO.**18K85A0419**, OF B.TECH – IV YEAR, **ELECTRONICS AND COMMUNICATIONS ENGINEERING DEPARTMENT** OF **ST. MARTIN'S ENGINEERING COLLEGE**, KOMPALLY, SECUNDERABAD HAVE COMPLETED ONE MONTH INTERNSHIP PROGRAM AT **LASYA IT SOLUTION PVT. LTD, KOMPALLY.**

DURING THE PERIOD, THEY HAVE SUCCESSFULLY COMPLETED MAJOR PROJECT TITLED "**ALCOHOL SENSING DISPLAY WITH ALARAM**" AT OUR DEVELOPMENT CENTER, KOMPALLY.

WE WISH THEM SUCCESS IN THEIR FUTURE ENDEVOUR.

Lasya IT Solutions Pvt. Ltd. Kompally-500014.

ORUGANTI VENKAT
DIRECTOR
TRAININGS & PLACEMENTS
LASYA IT SOLUTIONS PVT LTD.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics and Communication Engineering, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **Alcohol sensing display with alarm** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

L Harshasri (18K85A0419)
G Srilekha Reddy (17K81A0477)
K Venkateswar Reddy (18K85A0420)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to Dr. B Hari Krishna, **Head &Professor**, the Dept. of Electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr. A. Anand kumar, the Dept. of ECE** for his advice, supervision and for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr. Santhosh Singireddy, Assistant professor, Department of ECE** and our class project coordinator **Mr. K Karthik, Assistant professor, Department of ECE** for guidance and encouragement in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Mr. Santhosh Singireddy, Assistant Professor in ECE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. L Harshasri
2. G Srilekha Reddy
3. K Venkateshwar Reddy

ABSTRACT

This is an important IoT and sensor-based project implemented using microcontrollers. In this project, we have interfaced the MQ series gas sensor with 8051 microcontrollers. We cannot interface the alcohol sensor directly to the 8051 microcontrollers because the output of the gas sensor is in analog format. The 8051 microcontroller recognizes only digital input. The best and the low-cost solution for this is to connect a comparator between the gas sensor and Microcontroller. Comparator contains an operational amplifier comparator has two inputs. One input is from the sensor and another is from the Potentiometer. Whenever the sensor value crosses the threshold limit then the comparator output goes high. In this way the microcontroller comes to know that the alcohol percentage is more than the threshold limit. Potentiometer can be used to vary the trigger level or the threshold limit.

We have provided a piezoelectric buzzer in this project. This Buzzer will be turned on whenever this project detects the alcohol. This Buzzer helps to alert the people that the person undergoing the test for alcohol detection has consumed alcohol. This buzzer is driven through a transistor.

We have also provided an LCD display in this alcohol detector mini project. The LCD display shows two messages. Whenever you turn on the project, the LCD shows the project title. And whenever alcohol is detected, system shows a message as Alcohol sensor crossed limit.

TABLE OF CONTENTS

LIST OF ABBREVIATIONS

• AC	Alternating current
• LCD	Liquid crystal display
• DC	Direct current
• Op-amp	Operational amplifier
• BAC	Blood alcohol concentration
• GSM	Global system for mobile communication
• IoT	Internet of things
• DUI	Driving under influence
• PCB	Printed circuit board
• CDS	Computerized documentation service
• ISIS	Integrated set of information systems
• LED	Light emitting diode
• IDE	Integrated development environment

CHAPTER 1
INTRODUCTION

Introduction of the project

Drunk driving is a very dangerous behaviour because excessive consumption of alcohol causes distortion in the thought pattern of drivers. The investigation conducted by the World Health Organization in 2008 shows that about 50%–60% of traffic accidents are related to drunk driving. In present times, the cases of traffic accidents caused by drunk driving have increased rapidly. It has, therefore, become evident that drunk driving does great harm to public security. Different technologies and techniques have been adopted to reduce the incidence of road accidents due to drunk driving by motorists. The alcohol detector is made up of the alcohol sensor, Alternating Current (AC) power supply, LM 393 Operational Amplifier (Op-Amp), and Liquid Crystal Display (LCD) circuitry. This device displays the results of the alcohol sensor as it senses the alcohol molecules in air present around it, and displays when alcohol is detected when it crosses the fixed threshold set by the LM393 Op Amp. The drawback of this system was that it required whosoever to be tested to be close to the AC power outlet due to the system running on AC power. Also, the LM393 op amp which was acting as a comparator in the circuit and came with a preset value 600 for the threshold upon crossing, had no response such as an alarm to warn that the threshold had been crossed. This system required two participants i.e., one person to carry out the testing and note when the threshold is crossed and the other as the person being tested. This system was nowhere close to proving a means of inhibiting a driver if he/she were drunk, not to mention real time implementation.

James and John proposed an alcohol detection system that alerts the driver through his/her cell phone. The major components of this system were the GSM module and the LM358 module. This system was a huge advancement from breath analysers as it was based on GSM technology using the GSM module and dumped the use of an alarm circuit but still employed the LM358 Op-Amp. The system alerted via text messages using a GSM module and had a unique ringtone for such text messages set on the cell phone.

Its major demerit was the lack of an LCD unit and an alarm circuit which could be useful in cases where the driver is not in possession of his/her phone. Another drawback is the presence of the LM358 Op-Amp as a comparator instead of using a microcontroller to allow for flexibility in changing the blood alcohol concentration (BAC) threshold due to probability in changes of body chemistry of the driver. The issue of cell phone batteries running down also comes up implying that the system would be inactive in the state that a cell phone battery is dead. Also, with most drivers in the habit of keeping their cell phones in the vibration or silent mode while driving, this inhibited the alerting property of the work.

Another alcohol detection system was developed based on the PIC16F877A microcontroller. The presence of the microcontroller allowed for ease of manipulation of the threshold depending on body chemistry. The presence of the microcontroller gave room for addition of other features in the future. The only major drawback was the system's inability for a direct real time implementation due to it being powered by an AC power supply, as the alcohol sensor wouldn't have the opportunity to have at least 3 h full run-in time it would get if on DC supply (vehicle battery) to give the sensor the degree of accuracy it requires for its operation. Implementation of our proposed embedded alcohol trigger device enclosed in cars that there might be no accident caused by drunk driving.

The aim of this project is to reduce road accidents related to drunk driving to the barest minimum by using Internet of Things (IoT) technology. With the help of this system, drivers under the influence of alcohol can be detected, monitored, and tracked by relevant law enforcement agencies in the smart city. The Internet of Things (IoT) is the most recent communication display in which the objects of regular day to day existence will be outfitted with microcontrollers, transceivers for digital communication, and appropriate convention stacks that will make them ready to speak with each other and with the clients, turning into a fundamental piece of the Internet.

This system is a very innovative system which will help to keep the roads free from drunk driving related accidents by not only shutting down the vehicle engine upon sensing the drunken state of the driver but would also help road traffic officials to be able to track down the vehicle inhabiting the drunk driver before the vehicle is shut down and allow for quick evacuation of the vehicle and the driver by the authorities so as to prevent traffic on such road.

The system is divided into sections; the interlock section and the monitoring section. The interlock section is made up of the MQ-3 Sensor (alcohol sensor) which senses the alcohol molecules in the air breathed by the driver, an ATMEGA328P microcontroller, a buzzer, an LCD screen, Wireless Fidelity (Wi-Fi) module and mobile cell phone. The monitoring system is a web application built to view the BAC concentration levels of the driver. The system is powered by a 12-V DC source. The system has a threshold value, 600, for communicating the BAC level and coordinates of the vehicle to the monitoring system.

We here propose an alcohol sensing system that measures alcohol intake, displays percentage of alcohol and also sounds an alarm if it is above a particular threshold. Here we use an alcohol sensor circuit along with an LCD display and a buzzer alarm. Our system first uses the alcohol sensor in order to detect alcohol. The sensor provides analog output.

This analog output is now provided to the microcontroller for further processing. Based on the input the microcontroller calculates the percentage of alcohol and displays the same on an LCD display. It also sounds an alarm if the amount of alcohol exceeds a particular amount. Our system thus allows measuring the amount of alcohol and then displaying the percentage of alcohol measured. Also, an alarm is sounded that indicates that measured alcohol is above a particular percentage.

Outcomes of the project

The outcomes of the project are it will measure concentration of alcohol gas taken by the driver when he blows out, when the sensor brought near to him and detects whether the level of alcohol taken was more normal and display it on the lcd.

Gives the result to the mobile user who is connected with the WIFI module’s hotspot and displays the result detected by the WIFI module through a software application called mobile telnet application.

Description of the project

This project is about monitoring the consumption of alcohol by using the technology of the internet of things.

Here this project contains a gas sensor that is used to measure the level of concentration of alcohol that is taken by the automobile driver.

The WIFI module is responsible for transmitting continuous measured results to the online server.

Introduction to embedded systems

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as a combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems include computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware.

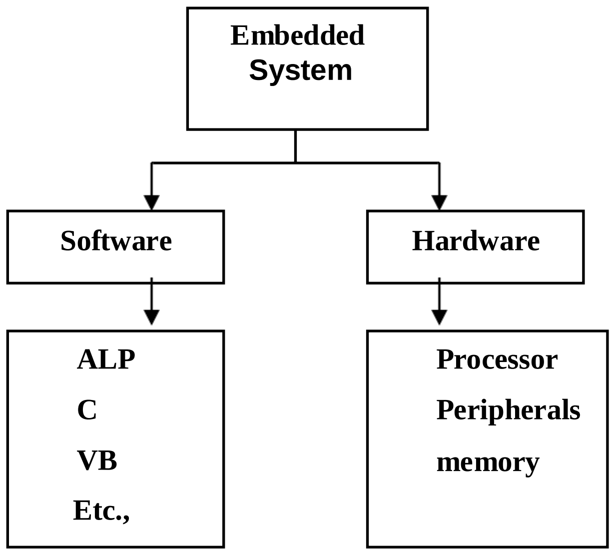

Figure 1.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types like:

- ➢ Microprocessor (µp)
- ➢ Micro controller (µc)
- ➢ Digital Signal Processor (DSP)
- ➢ Application Specific Integrated Circuits (ASIC)

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

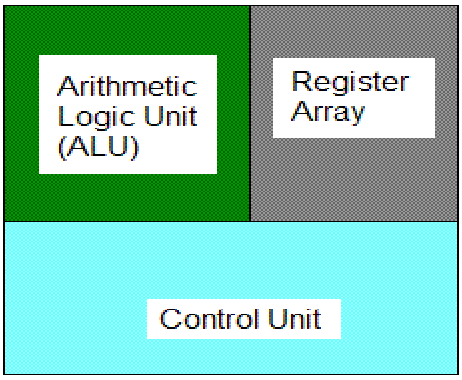
➢ **Instruction set**: The set of instructions that the microprocessor can execute.

➢ **Bandwidth :** The number of bits processed in a single instruction.

➢ **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).



Three Basic Elements of a Microprocessor

Micro Controller (μc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.

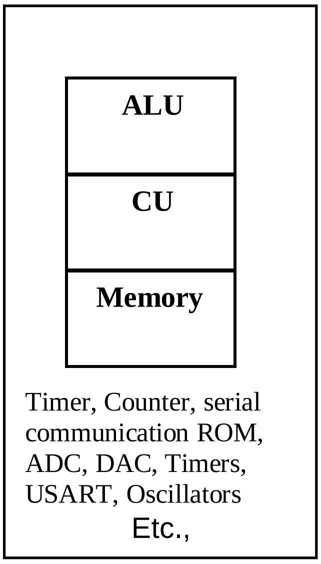


Figure 1.2 Block Diagram of Microcontroller (μc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operations. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating-point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program
- Analog circuits to provide clocks and interface to the real world which is analog in nature
- I/Os to connect to external components like LEDs, memories, monitors etc.

Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.
- The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

RISC characteristics

- **Simple instruction set:**

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- **Same length instructions.**

Each instruction is the same length, so that it may be fetched in a single operation.

- **1machine-cycleinstructions.**

Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because microprogram instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.

➢ Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.

➢ CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

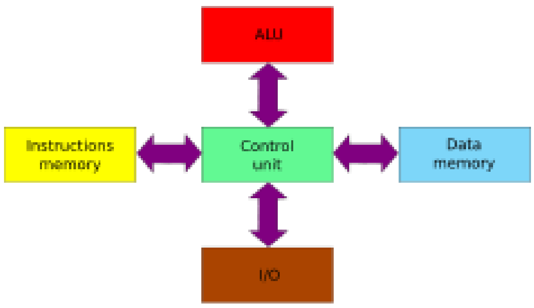

Figure 1.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction prefetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were an advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

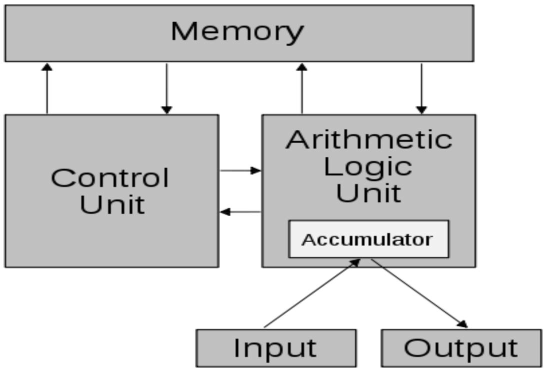

Figure 1.4 Schematic of the Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading an instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit

complexity because data access and instruction fetches do not contend for use of a single memory pathway.

➢ Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

IoT Technology

The Internet of things (IoT) describes the network of physical objects—a.k.a. "Things"—that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the Internet of Things have evolved due to the convergence of multiple technologies, Realtime analytics, machine learning, ubiquitous computing, commodity sensors, and embedded systems. Traditional fields of embedded systems, wireless sensor networks, control systems, automation (including home and building automation), and others all contribute to enabling the Internet of things. In the consumer market, IoT technology is most synonymous with products pertaining to the concept of the "smart home", including devices and appliances (such as lighting fixtures, thermostats, home security systems and cameras, and other home appliances) that support one or more common ecosystems, and can be controlled via devices associated with that ecosystem, such as smartphones and smart speakers. The IoT can also be used in healthcare systems.

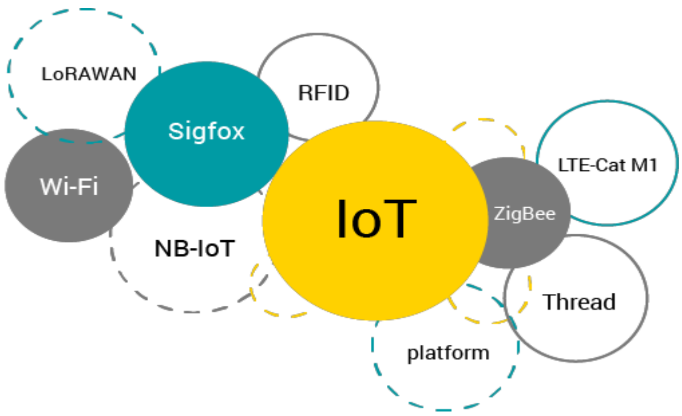

Fig 1.5: IoT Technology

There are a number of serious concerns about dangers in the growth of the IoT, especially in the areas of privacy and security, and consequently industry and governmental moves to address these concerns have begun including the development of international standards.

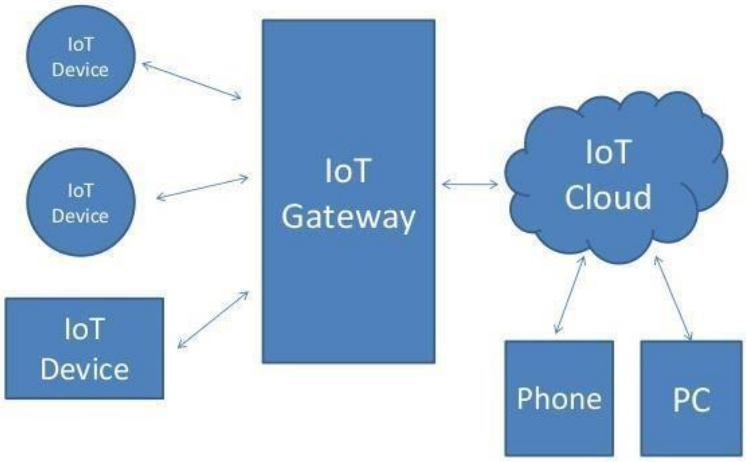

Fig 1.6: IoT Block diagram

History

The main concept of a network of smart devices was discussed as early as 1982, with a modified Coca-Cola vending machine at Carnegie Mellon University becoming the first ARPANET-connected appliance, able to report its inventory and whether newly loaded drinks were cold or not. Mark Weiser's 1991 paper on ubiquitous computing, "The Computer of the 21st Century", as well as academic venues such as UbiComp and PerCom produced the contemporary vision of the IOT. In 1994, Reza Raji described the concept in IEEE Spectrum as "[moving] small packets of data to a large set of nodes, so as to integrate and automate everything from home appliances to entire factories". Between 1993 and 1997, several companies proposed solutions like Microsoft's at Work or Novell's NEST. The field gained momentum when Bill Joy envisioned device-to-device communication as a part of his "Six Webs" framework, presented at the World Economic Forum at Davos in 1999. The concept of the "Internet of Things" and the term itself, first appeared in a speech by Peter T. Lewis, to the Congressional Black Caucus Foundation 15th Annual Legislative Weekend in Washington, D.C, published in September 1985[25]. According to Lewis, "The Internet of Things, or IoT, is the integration of people, processes and technology with connectable devices and sensors to enable remote monitoring, status, manipulation and evaluation of trends of such devices."

The term "Internet of things" was coined independently by Kevin Ashton of Procter & Gamble, later MIT's Auto-ID Centre, in 1999, though he prefers the phrase "Internet for things' '. At that point, he viewed radio frequency identification (RFID) as essential to the Internet of things, which would allow computers to manage all individual things. The main theme of the Internet of Things is to embed short range mobile transceivers in various gadgets and daily necessities to enable new forms of communication between people and things, and between things themselves. Defining the Internet of things as "simply the point in time when more 'things or objects were connected to the Internet than people", Cisco Systems estimated that the IoT was "born" between 2008 and 2009, with the things/people ratio growing from 0.08 in 2003 to 1.84 in 2010.

The IoT technology stack and its Connectivity Solutions

It can prove a hard task if you'd like to find your way through the IoT technological maze given the diversity and sheer numerousness of the technology solutions that surround it. However, for matters of simplicity, we could break down the IoT technology stack into four basic technology layers involved in making the Internet of Things work. These are the following:

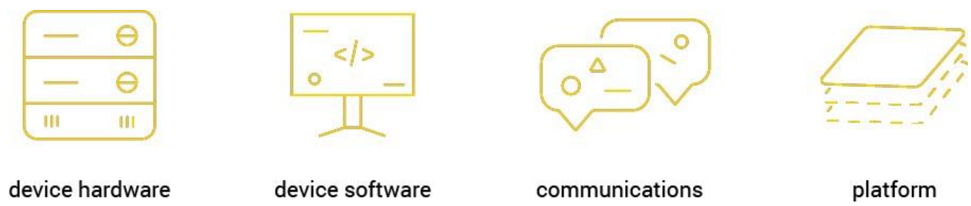

Fig 1.7: IoT technology stack

1. Device Hardware

Devices are objects which actually constitute the 'things' within the Internet of Things. Acting as an interface between the real and the digital worlds, they may take different sizes, shapes and levels of technological complexity depending on the task they are required to perform within the specific IoT deployment. Whether pinhead sized microphones or heavy construction machines, practically every material object (even the animate ones, like animals or humans) can be turned into a connected device by the addition of necessary instrumentation (by adding sensors or actuators along with the appropriate software) to measure and collect the necessary data. Obviously, sensors, actuators or other telemetry gear can also constitute standalone smart devices by themselves. The only limitation to be encountered here is the actual IoT use case and its hardware requirements (size, ease of deployment and management, reliability, useful lifetime, cost-effectiveness)

2. Device Software

This is what actually makes the connected devices 'smart'. Software is responsible for implementing the communication with the Cloud, collecting data, integrating devices as well as performing real-time data analysis within the IoT network. What is more, it is device software that also caters for application-level capabilities for users to visualize data and interact with the IoT system.

3. Communications

Having the device hardware and software in place, there must be another layer which will provide the smart objects with ways and means of exchanging information with the rest of the IoT world. While it is true that communications mechanisms are strongly tied to device hardware and software, it is vital to consider them as a separate layer. Communication layer includes both physical connectivity solutions (cellular, satellite, LAN) and specific protocols used in varying IoT environments (ZigBee, Thread, Z-Wave, MQTT, LwM2M). Choosing the relevant communications solution is one of the vital parts in constructing every IoT technology stack. The technology chosen will determine not only the ways in which data is sent to/received from the Cloud, but also how the devices are managed and how they communicate with third party devices. For the purpose of the present article, we will go into the details of some of the present-day communications solutions later in the text.

4. Platform

As mentioned earlier, thanks to the 'smart' hardware and the software installed the device is able to 'sense' what is going on around it and communicate that to the user via a specific communications channel. An IoT platform is the place where all of this data is gathered, managed, processed, analysed and presented in a user-friendly way. Thus, what makes such a solution especially valuable is not merely its data collection and IoT device management capabilities, but rather its ability to analyse and find useful insights from the portions of data provided by the devices via the communications layer. Again, there are quite a number of IoT platforms on the market, with choice depending on the requirements of the specific IoT project and such factors as architecture and IoT technology stack, reliability, customization properties, protocols used, hardware agnosticism, security and cost-effectiveness. It is also worth mentioning that platforms can be either installed on-premise or cloud-based.

Coiote IoT Device Management platform is a good example of such a platform as it can be deployed on-site as well as in the cloud. The same applies to another IoT platform by AV System — Coiote IoT Data Orchestration.

Connectivity solutions

As many as there are possible real-life applications of the IoT technologies, there is no shortage of connectivity solutions behind them. Depending on the specifications of a given IoT use case, each communications option may offer different service enablement scenarios while having trade-offs between power consumption, range and bandwidth. With this multiplicity and diversity of communication standards and protocols in mind, one may raise a question about the actual need for developing new solutions while there are some well-proven Internet protocols that have been in use already for decades. The reason for this is that existing Internet protocols, such as Transmission Control Protocol Internet Protocol (TCP/IP), are often not effective enough and too power-consuming to be able to work efficiently within the emerging IoT technology applications. This section will present a short overview of the major alternative Internet protocols specially dedicated for use by IoT systems. The overview concerns the most popular IoT radio technologies broken down by radio-frequency range achieved by each of the solutions: short range IoT radio solutions, medium range solutions, and long-range Wide Area Networks solutions.

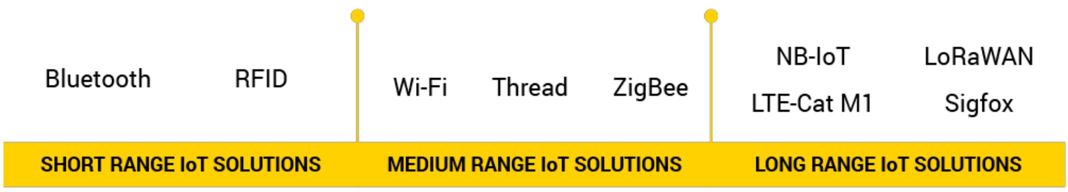

Fig 1.8: Connectivity Solutions

Short range IoT radio solutions

1. Bluetooth

As a well-established short-range connectivity technology, Bluetooth is considered to be the key solution particularly for the future of the wearable electronics market such as wireless headphones or geolocation sensors, especially given its widespread integration with smartphones. Designed with cost-effectiveness and reduced power consumption in mind, the Bluetooth Low-Energy (BLE) protocol requires very little power from the device. Yet, this comes with a compromise: when transferring frequently higher amounts of data, BLE may not be the most effective solution.

2. RFID

Being among the first IoT applications ever implemented, Radio-frequency identification (RFID) offers positioning solutions for IoT applications, especially in supply chain management and logistics, which require the ability of determining the object position inside buildings. The future of RFID technology clearly goes far beyond the simple localisation services, with possible applications ranging from tracking hospital patients to improving efficiency in healthcare to providing real-time merchandise location data to minimize out-of-stock situations for retail stores.

Medium Range Solutions

1. Wi-Fi

Developed based on IEEE 802.11, it remains the most widespread and generally known wireless communications protocol. Its broad usage across the IoT world is mainly limited by higher-than-average power consumption resulting from the need of retaining high signal strength and fast data transfer for better connectivity and reliability. As a key technology in the development of IoT, WiFi provides a wide-ranging ground to a staggering number of IoT solutions, yet it also needs to be managed and used in terms of marketing to yield profits to service providers and users alike. A fine example of a WiFi management platform that offers a value-added service empowering public WiFi access points is Linkify. As one of AVSystem's cutting edge solutions, Linkify allows for practically limitless guest WiFi customization and marketing options.

2.Zigbee

This popular wireless mesh networking standard finds its most frequent applications in traffic management systems, household electronics, and machine industry. Built on top of the IEEE 802.15.4 standard, Zigbee supports low data exchange rates, low power operation, security, and reliability.

Long Range Wide Area Networks (WAN) solutions:

1. NB-IOT

A product of existing 3GPP technologies, Narrowband IoT is a brand-new radio technology standard that ensures extremely low power consumption (10 years of battery power operation) and provides connectivity with signal strength approx. 23 dB lower than in the case of 2G. What is more, it uses existing network infrastructure, which ensures not only global coverage in LTE networks, but also guaranteed signal quality. In many cases, this fact allows for implementing NB-IoT instead of solutions that required the construction of local networks, such as LoRa or Sigfox.

2. Lora WAN

Lora WAN is a low-power Long Range Wide-Area Networking protocol optimized for low-power consumption and supporting large networks with millions of devices. Aiming at wide-area network (WAN) applications, Lora WAN is designed to furnish low-power WANs with features required to support low-cost, mobile and secure bi directional communication within IoT, M2M, smart city, and industrial applications.

3. Sigfox

The concept behind Sigfox is to provide an effective connectivity solution for low power M2M applications requiring low levels of data transfer for which the WiFi range is too short, and cellular range is too expensive and too power-hungry. Sigfox employs UNB, a technology that enables it to handle low data-transfer speeds of 10 to 1,000 bits per second. Consuming up to 100 times less energy compared to cellular communication solutions, it delivers a typical stand-by time of 20 years for a 2.5Ah battery. Offering a robust, energy-efficient and scalable network able to support communication between thousands of thousands of battery-operated devices across areas of several square kilometres, Sigfox proves suitable for various M2M applications, including smart street lighting, intelligent meters, patient monitors, security devices, and environmental sensors

4. LTE-Cat M1

LTE-Cat M1 is a low-power wide-area (LPWA) connectivity standard that connects IoT and M2M devices with medium data rate requirements. It supports longer battery lifecycles and offers enhanced in-building range as compared to cellular technologies such as 2G, 3G, or LTE-Cat 1. Being compatible with the existing LTE network, CAT M1 doesn’t require the carriers to build new infrastructure to implement it. As compared to NB-IoT, LTE Cat M1 proves to be perfect for mobile use cases, as its handling of hand-over between cell sites is significantly better and is very similar to high speed LTE.

IoT vs Embedded Systems

	IoT	Embedded System
Definition	Things that contain computer, software and networking capabilities’	Things that contain computers and software.
Example	A talking doll that accepts voice commands and regularly learns new words.	A talking doll that never learns but that isn’t a privacy concern because it transmits no data.

Table 1.1: IoT vs Embedded system

IoT Technology in Transportation

The IoT can assist in the integration of communications, control, and information processing across various transportation systems. Application of the IoT extends to all aspects of transportation systems (i.e. the vehicle, the infrastructure, and the driver or user). Dynamic interaction between these components of a transport system enables inter- and intra-vehicular communication, smart traffic control, smart parking, electronic toll collection systems, logistics and fleet management, vehicle control, safety, and road assistance.

Motivation of the Project

Vehicles are considered to be the key element in this era. They are being developed on a regular basis to make them more and more safe. But, the one thing that makes people feel afraid of sitting in the vehicle is accidents. These accidents mostly take place under the influence of alcohol, and there is no technology to minimize the chances of accidents happening. To avoid this problem, the Vehicle accident and alcohol sensing alert with engine locking system is introduced.

CHAPTER 2
LITERATURE SURVEY

Literature survey

In many civilized cultures, the use of alcohol is taken as a tradition. The habit is also connected with traditions, used in festivities and different personal parties. A small level of alcohol will change the way humans behave where its bodily behaviour, its actions are diminished. This type of body's inability to control itself can be highly dangerous and can involve car accidents which will risk the persons sitting inside the car also on the persons on the road. The legislation has brought in a number of laws like fines, cancellation of driving licenses etc. so that this can be minimized. The above-mentioned causes show the necessity of a simple, accurate and precise instrument to be used by the automobile manufacturers and vehicle modifiers so that the vehicle will not start due to alcohol content in the air inside the vehicle. The consumption of alcohol is more common in young groups where they drink and cause accidents due to rash driving. The person consuming alcohol changes the blood alcohol concentration in the body thus affects the body's actions. There is a direct connection between blood alcohol and breath alcohol concentration. For the blood alcohol content measurement blood samples have to be taken but for breath alcohol concentration measurement there are sensors available which detect breath. The first method of taking blood samples can be possible by taking on the spot samples by the traffic police which is also a good method. In the second method breath analyzers are used to sense the breath but this itself is not enough, this method can be integrated with the car system. so that any smell of alcohol in the car will force the car to start. The system proposed is developed on embedded applications on Arduino family of boards.

In the modern arena, most of the accidents are caused by drunken driving and driving under the influence (DUI). Drunk driving is the only one reason behind most of the unnatural deaths in the world. In this project, a Novel based IOT (Internet of Things) module is proposed to protect the people from unnecessary deaths caused by road accidents due to drunken driving. The Proposed system makes use of the Internet of things (IOT) device as Raspberry Pi 3 model B as a core. It mainly includes Touch sensor, alcohol concentration detection sensor, Facial recognition, Heart beat rate, to safeguard the drowsy driver. We use different types of safeguarding things such as GPS modules, Triggering an alarm and Automatic ignition off etc.

We here propose an alcohol sensing system that measures alcohol intake, displays percentage of alcohol and also sounds an alarm if it is above a particular threshold. Here we use an alcohol sensor circuit along with an LCD display and a buzzer alarm. Our system first uses the alcohol sensor in order to detect alcohol. The sensor provides analog output. This analog output is now provided to the microcontroller for further processing. Based on the input the microcontroller calculates the percentage of alcohol and displays the same on an LCD display. It also sounds an alarm if the amount of alcohol exceeds a particular amount. Our system thus allows us to measure the amount of alcohol and then display the percentage of alcohol measured. Also an alarm is sounded that indicates that measured alcohol is above a particular percentage.

Problem statement

Previously, there was no technology to lock the engine of the vehicle after sensing the alcohol consumption by the driver, which was considered to be the main cause of the accidents. There was manual checking after a particular distance on the roads or the highways but still these checks were not sufficient to stop the mishaps. So, to avoid these problems, this project vehicle detection and alcohol sensing alert with engine locking system is developed.

CHAPTER 3

PROJECT DESCRIPTION

Block Diagram

In the present day's scenario, with growing technologies and adverse development in the metropolitan cities. This is an important sensor-based project implemented using a microcontroller. In this project, we have interfaced the MQ series gas sensor with 8051 microcontrollers. We cannot interface the alcohol sensor directly to the 8051 microcontrollers because the output of the gas sensor is in analog format. The 8051 microcontroller recognizes only digital input. The best and the low-cost solution for this is to connect a comparator between the gas sensor and Microcontroller. Comparator contains an operational amplifier comparator has two inputs. One input is from the sensor and another is from the Potentiometer. Whenever the sensor value crosses the threshold limit then the comparator output goes high. In this way the microcontroller knows that the alcohol percentage is more than the threshold limit. Potentiometer can be used to vary the trigger level or the threshold limit.

We have provided a piezoelectric buzzer in this project. This Buzzer will be turned on whenever this project detects the alcohol. This Buzzer helps to alert the people that the person undergoing the test for alcohol detection has consumed alcohol. This buzzer is driven through a transistor.

We have also provided an LCD display in this alcohol detector mini project. The LCD display shows two messages. Whenever you turn on the project, the LCD shows the project title. And whenever alcohol is detected, the system shows a message as the Alcohol sensor crosses the limit.

Block Diagram

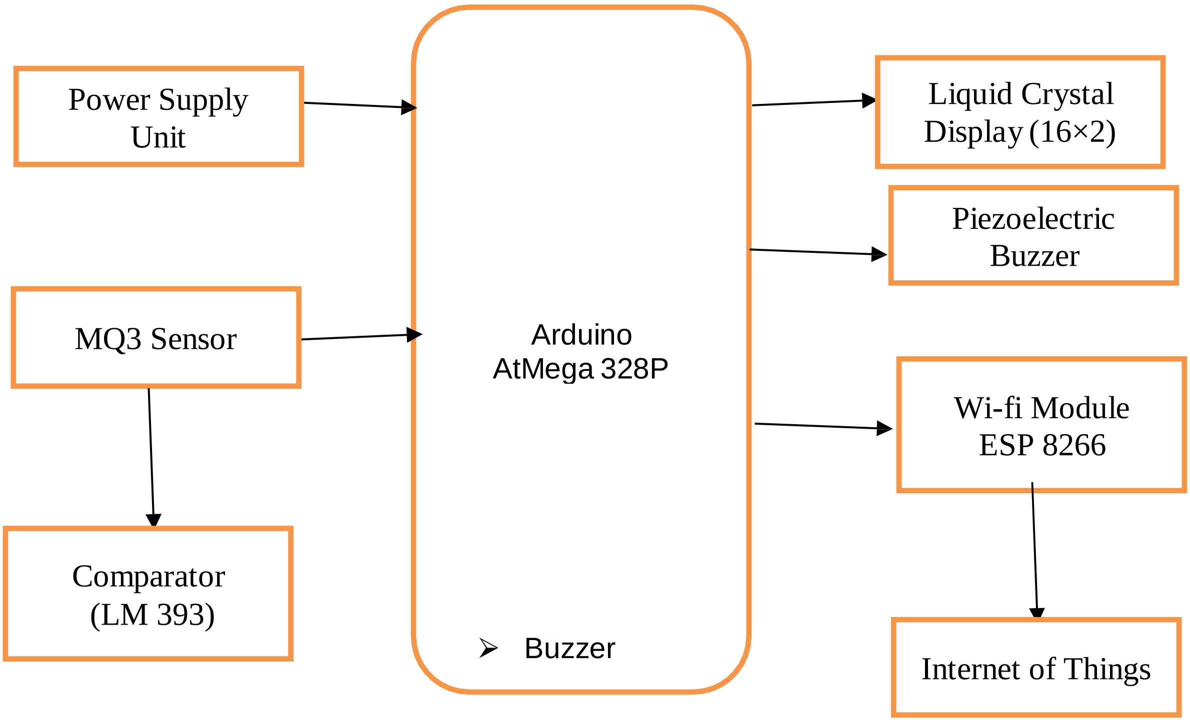

Fig 3.1 Block diagram

The blocks of the circuit are:

1.Arduino UNO

2.Power supply unit

3.MQ3 sensor

4.Comparator

5.Liquid crystal display

6.WIFI module

7.Piezoelectric buzzer

1. Arduino UNO

Arduino is an open-source platform based on easy-to-use hardware and software. Arduino Uno is a microcontroller board, which has an ATmega328P microcontroller in it. It has 14 digital i/o pins and 6 analog input pins, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2. Power Supply unit

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices.

3. MQ3 Sensor

MQ-3 module is suitable for detecting Alcohol, Benzine, CH_4, Hexane, LPG, CO. Sensitive material of the MQ-3 gas sensor is SnO_2, which has lower conductivity in clean air. When the target alcohol gas exists, the sensor's conductivity is higher along with the gas concentration rising. MQ-3 gas sensor has high sensitivity to Alcohol, and has good resistance to disturbance of gasoline, smoke and vapor.

This sensor provides an analog resistive output based on alcohol concentration. When the alcohol gas exists, the sensor's conductivity gets higher along with the gas concentration rising. There is a resistance across an A and B inside the sensor which varies on detection of alcohol. More the alcohol, the lower the resistance. The alcohol is measured by measuring this resistance. The sensor and load resistor form a voltage divider, and the lower the sensor resistance, the higher the voltage.

4. Comparator

The IC LM393 has two internally inbuilt operational amplifiers which are internally compensated with frequency. These ICs are specially designed for performing their different tasks using a single power supply. It can also execute its functions properly with a split power supply. The supply of current-drain does not rely on the amount of the power supply. One of the most important features of this IC is, it includes ground in its common-mode input voltage. The applications of this IC mainly include various fields in real life, and also industrial, ADC (analog to digital converters), electrical systems powered by the battery, time-delay generators limit comparators, etc. This article discusses an overview of the LM393 IC and its working.

5. Liquid Crystal Display

The LCD here is used to display the reading. When the sensor is placed near the Automobile driver then it displays either the driver drunk exceeds the input value or the normal value.

6. Wi-Fi Module

The ESP8266 Wi-Fi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes preprogrammed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much Wi-Fi-ability.

7. Piezoelectric Buzzer

In simplest terms, a piezo buzzer is a type of electronic device that's used to produce a tone, alarm or sound. It's lightweight with a simple construction, and it's typically a low-cost product. Yet at the same time, depending on the piezo ceramic buzzer specifications, it's also reliable and can be constructed in a wide range of sizes that work across varying frequencies to produce different sound outputs.

Schematic Diagram

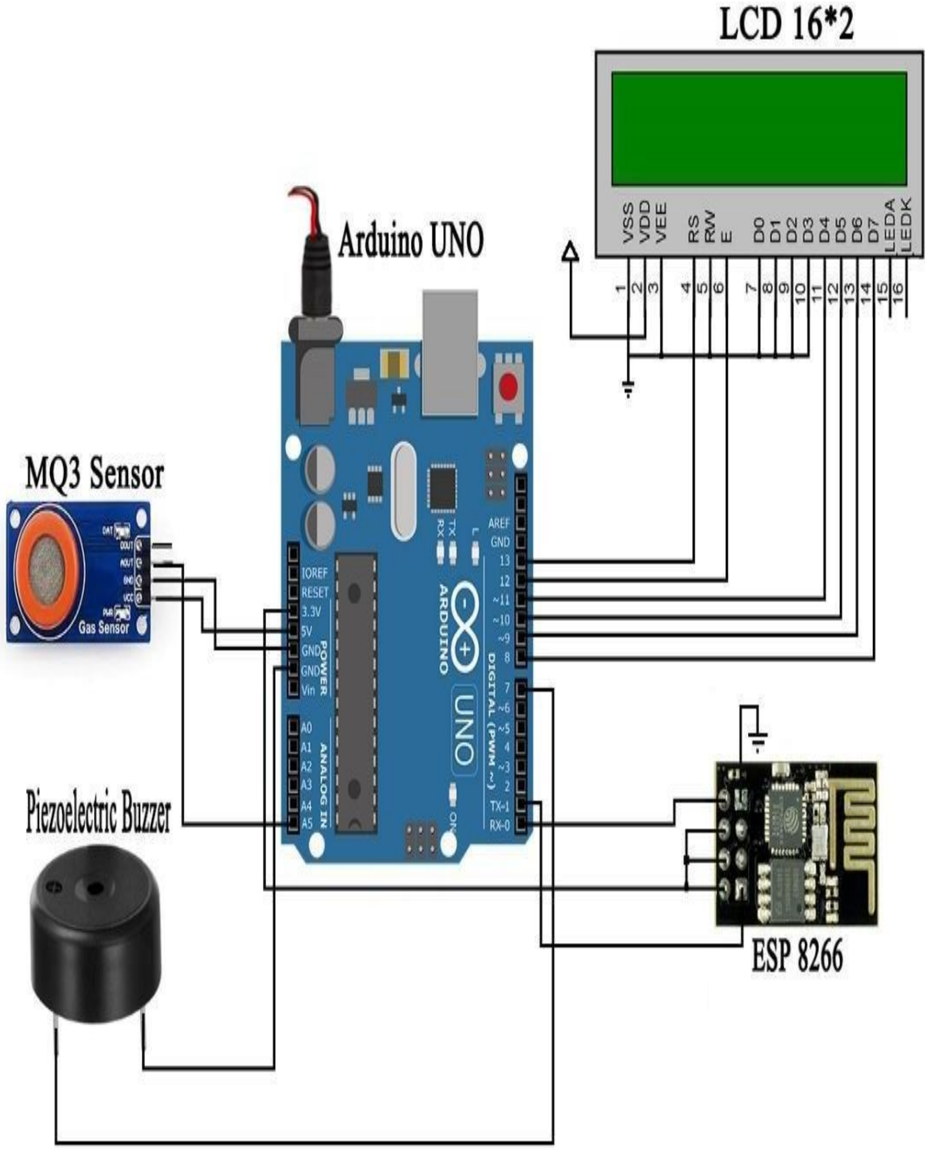

Fig 3.2: Schematic Diagram

Schematic Description

Arduino UNO has 28 pins among which we have 6 analog pins i.e.; A0-A5 to which we connect the input and 14 digital pins i.e.; D0-D15 where the output devices are connected. A MQ3 sensor which is popularly known as an alcohol sensor, is our input device with 4 pins i.e., VCC, D-Out, A-Out and Gnd pins respectively. The VCC pin is connected to the 5V pin of Arduino, Gnd pin to the common Gnd of Arduino Uno and the A-out pin is connected to one of the analog input pins(A0-A5) of Arduino. The D-Out pin of the Alcohol sensor is kept connectionless. The output of the alcohol sensor is given to an analog input pin of Arduino A5.We use two physical output devices i.e.; a piezoelectric buzzer, to give an alert as to whether the alcohol is detected or not. And the other device is a 16×2 Alphanumeric Liquid Crystal Display to show whether the alcohol consumption is detected or normal. We employed an LCD whose 4,6,11,12,13,14 pins are connected to 13,12,11,10,9,8 pins of Arduino Uno. We use a wi-fi module (ESP 8266) which consists of 8 pins, where the tx and rx pins are connected to rx, tx pins of Arduino and gnd pin to gnd, reset and VCC pins to 3.3V pin of Arduino. Internet of Things technology is used for a portable and connectionless interaction to the automobile driver and to the police, in order to generate a friendly interaction and display messages of alcohol content in the mobile, a software application is used through a WIFI module called mobile Telnet application making the user install the application.

CHAPTER 4

SOFTWARE AND HARDWARE DESCRIPTION

A- SOFTWARE

Proteus

Proteus is a simulation and design software tool developed by Lab center Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has a wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semiconductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the footprints of different categories of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in ISIS can be directly transferred to ARES.

Starting New Design

Step 1: Open ISIS software and select new design in File menu

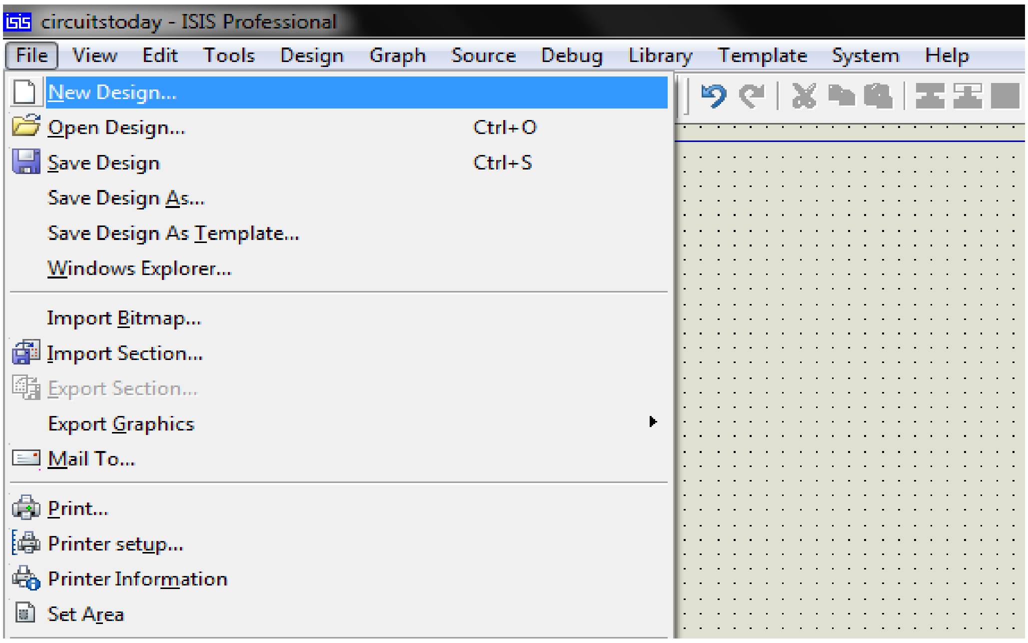

Figure 4.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

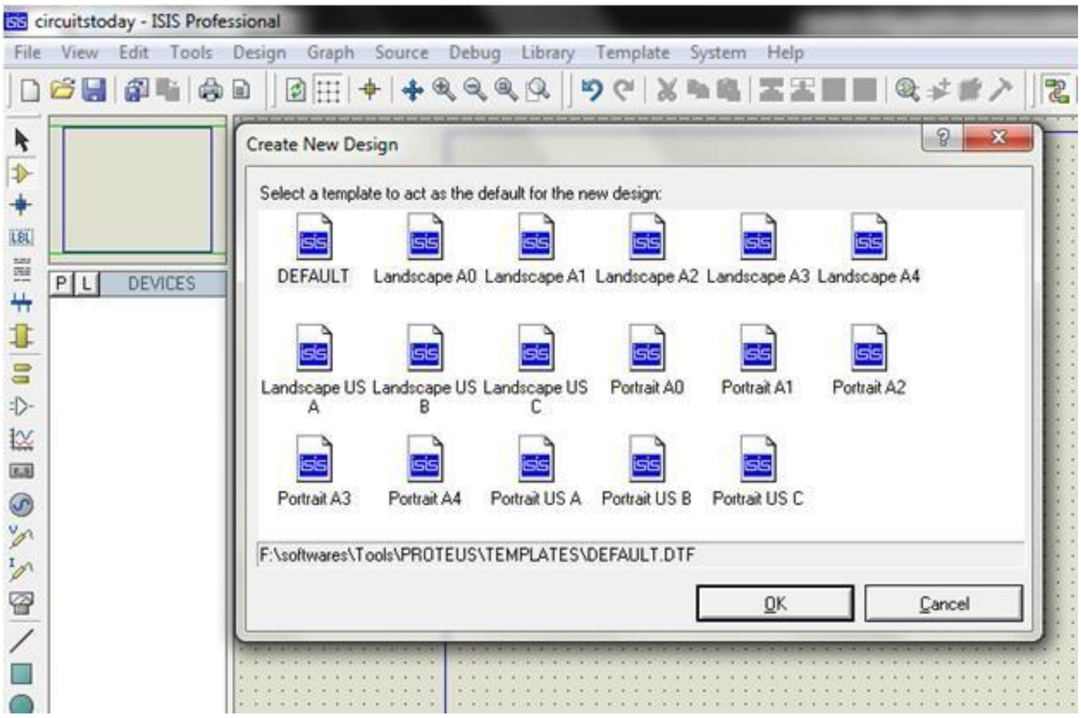

Figure 4.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

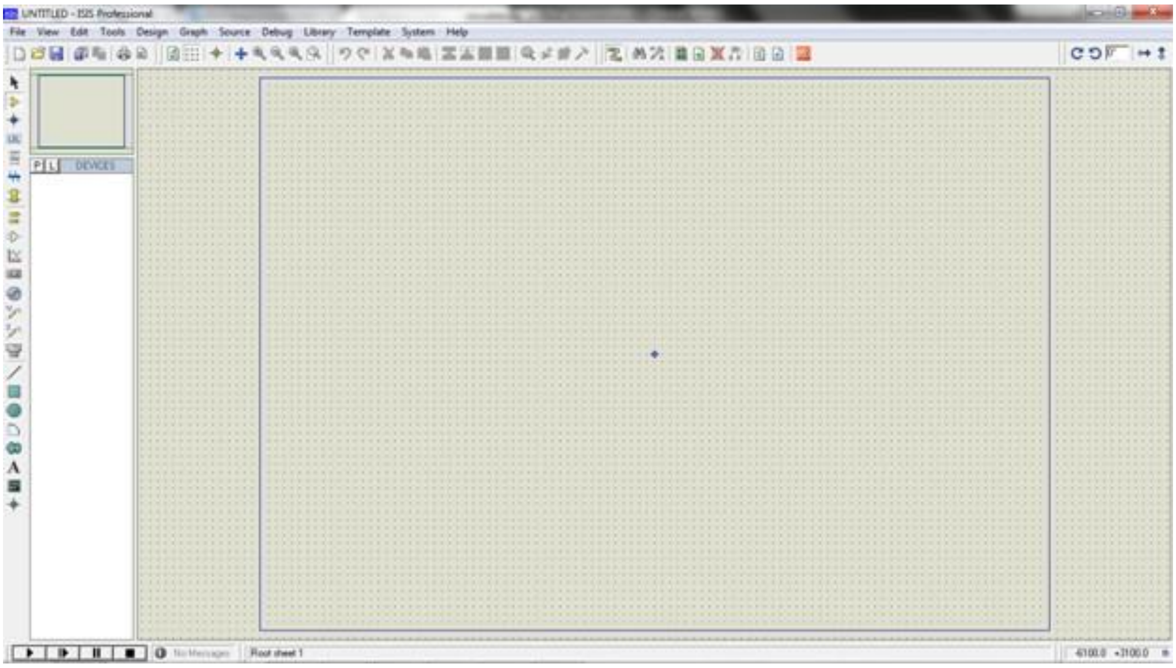

Figure 4.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

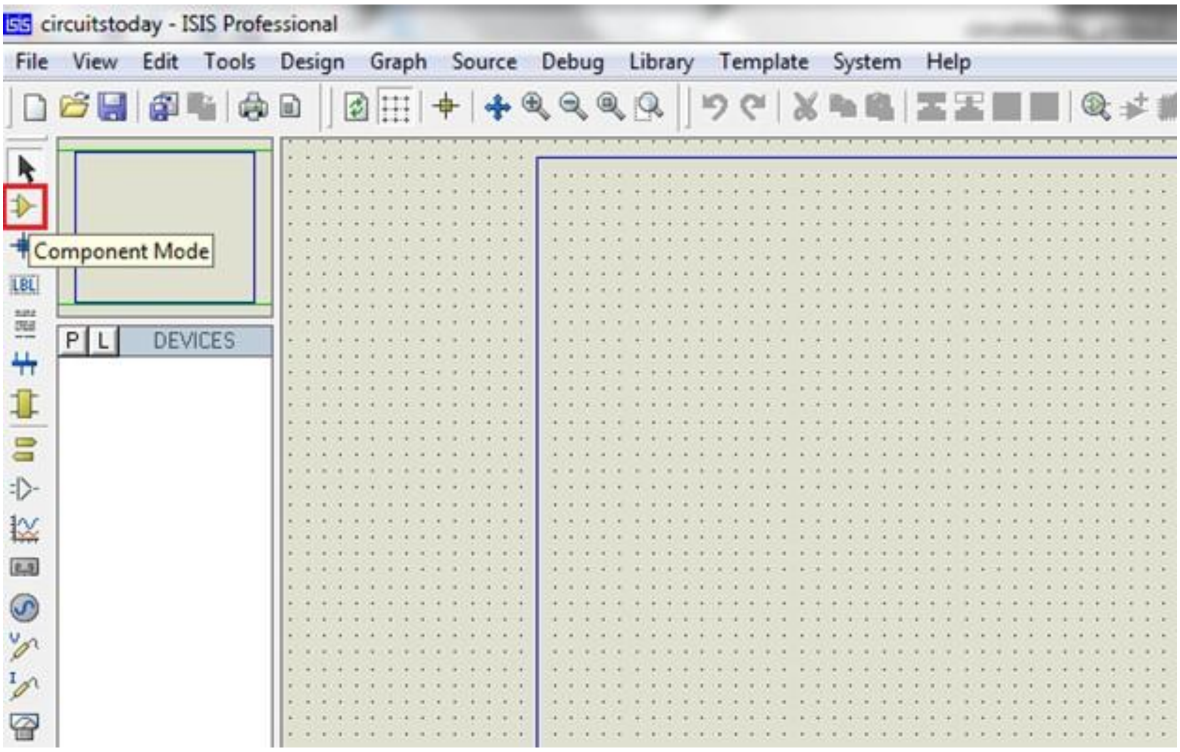

Figure 4.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

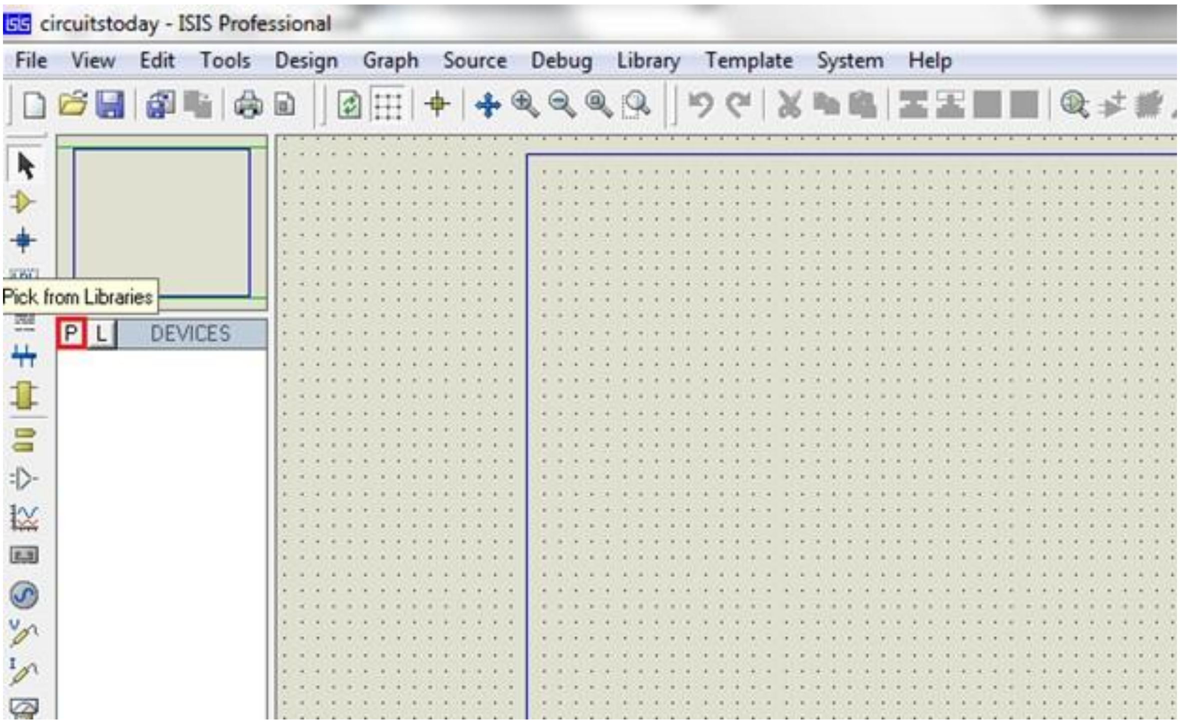

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

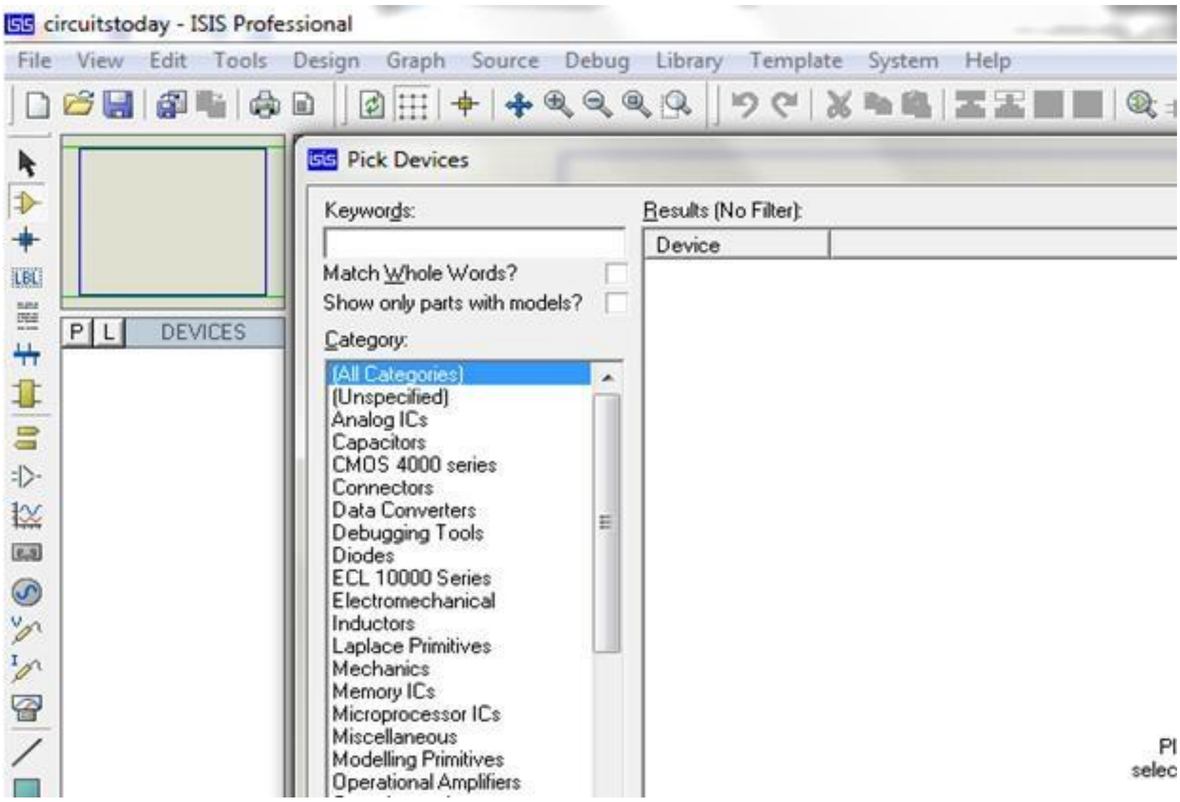

Figure 4.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

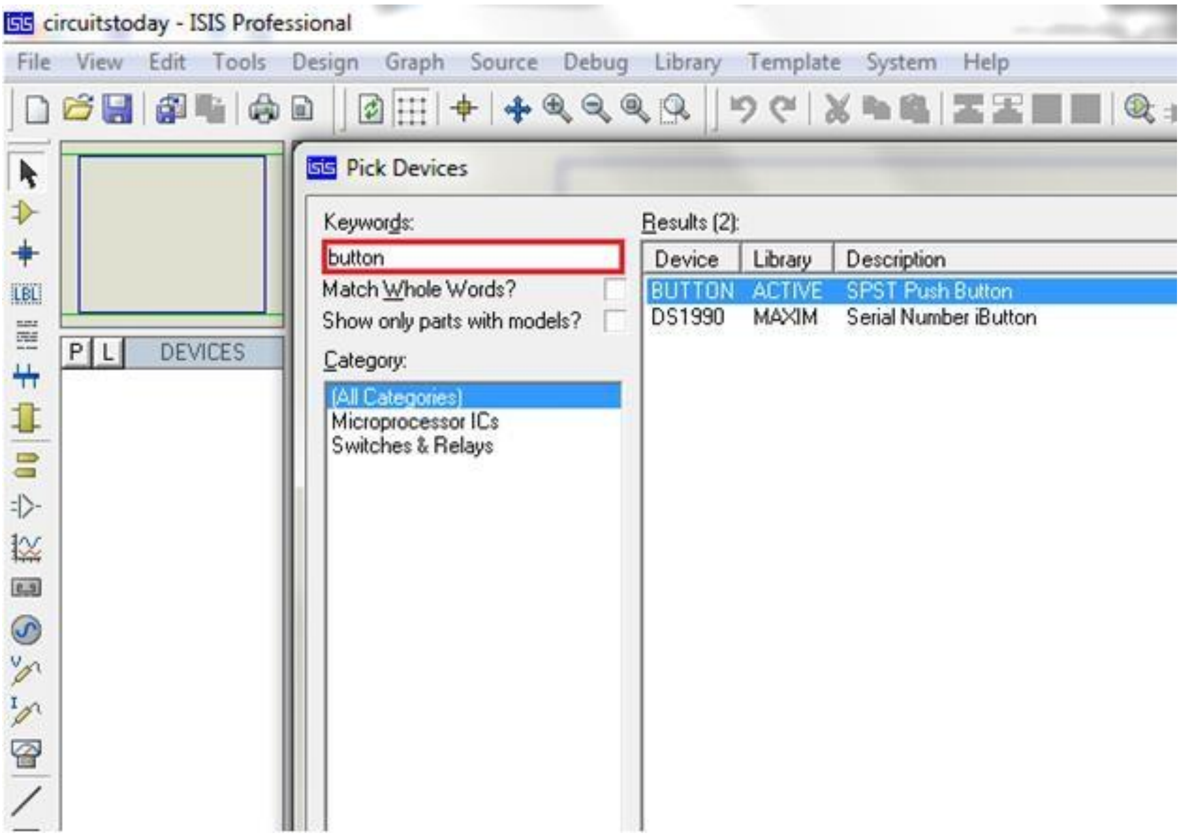

Figure 4.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

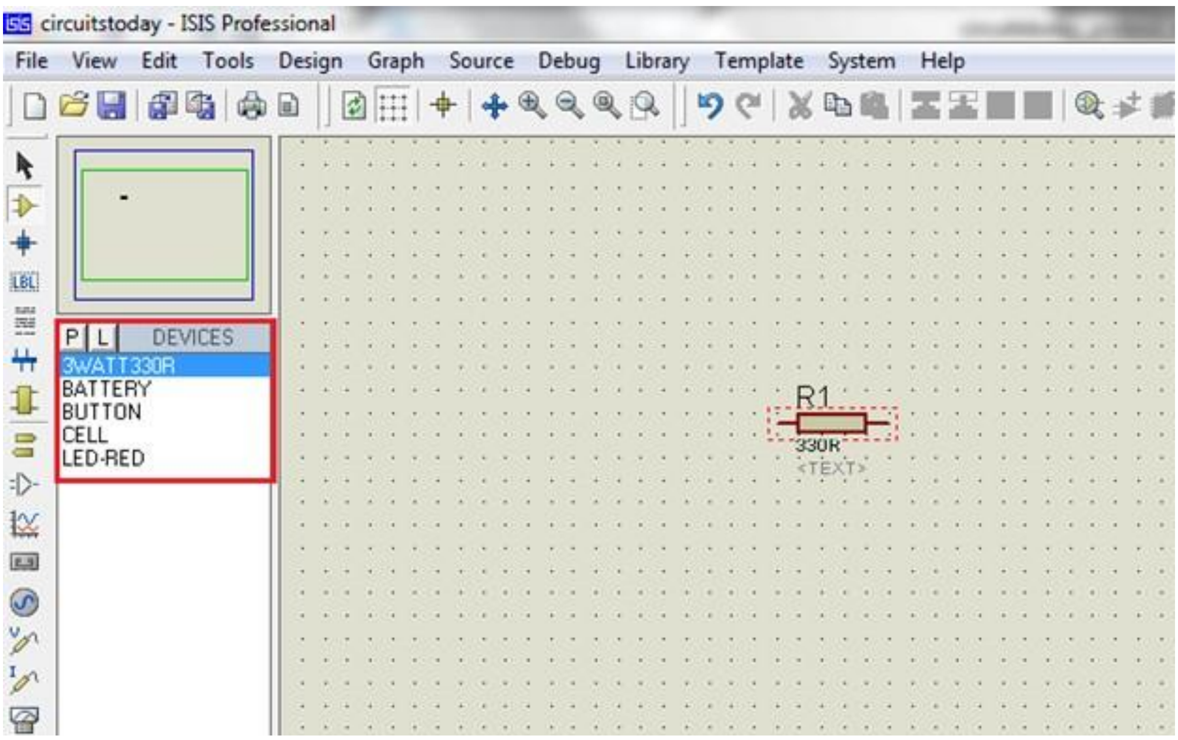

Figure 4.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows it to connect through wires. Left click from one terminal to another to make a connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

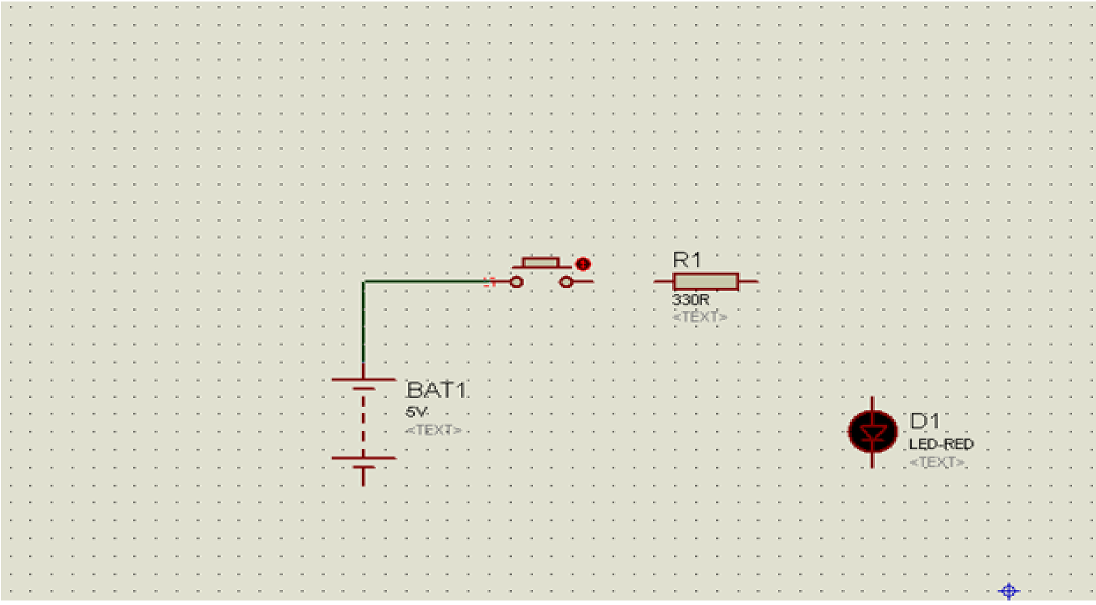

Figure 4.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

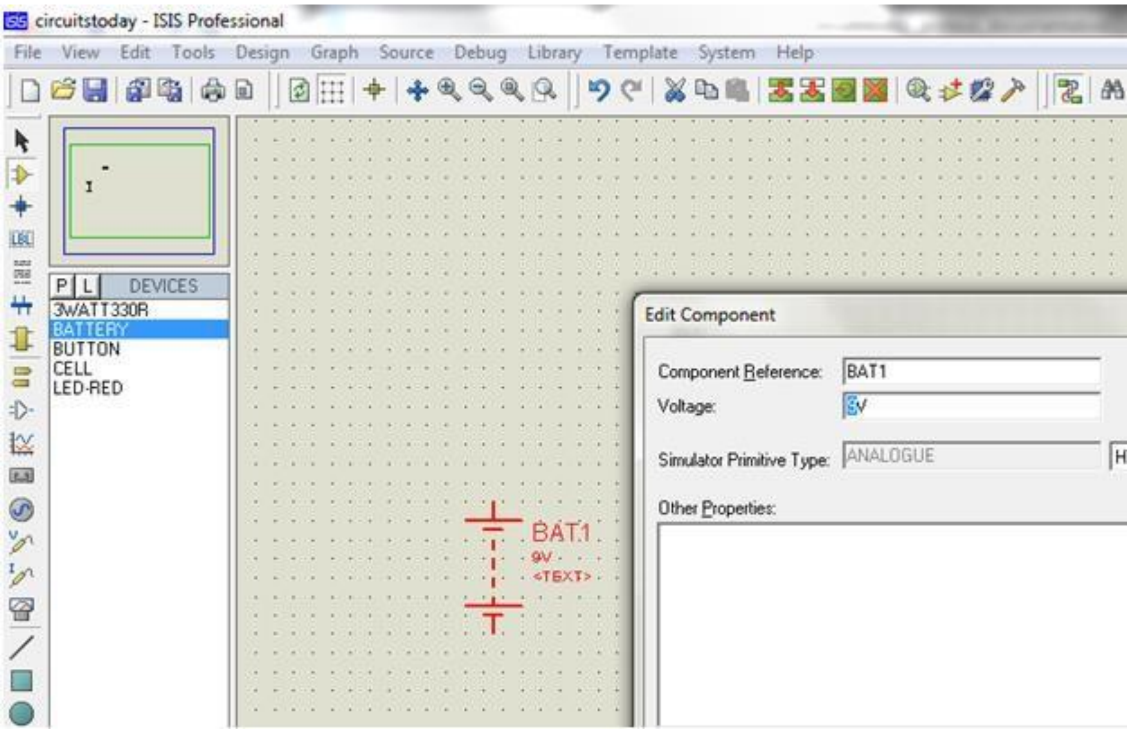

Figure 4.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

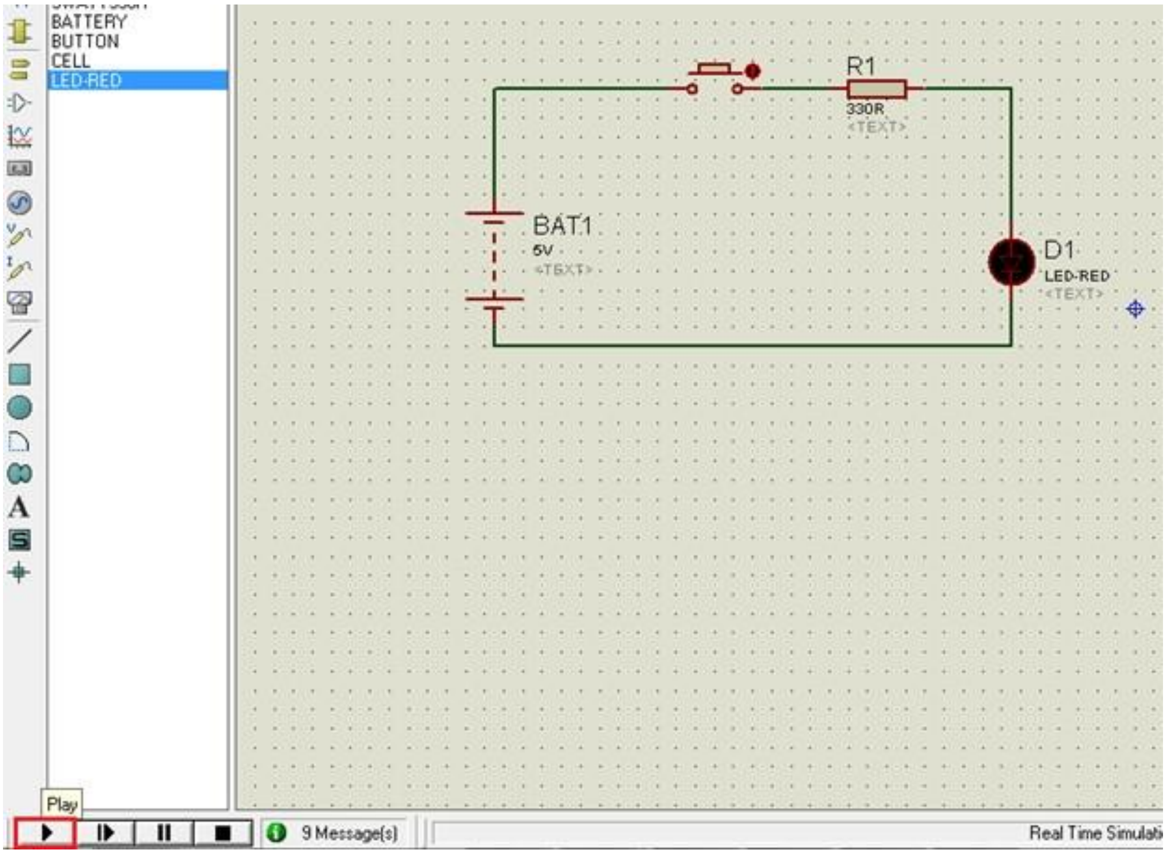

Figure 4.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make the LED glow.

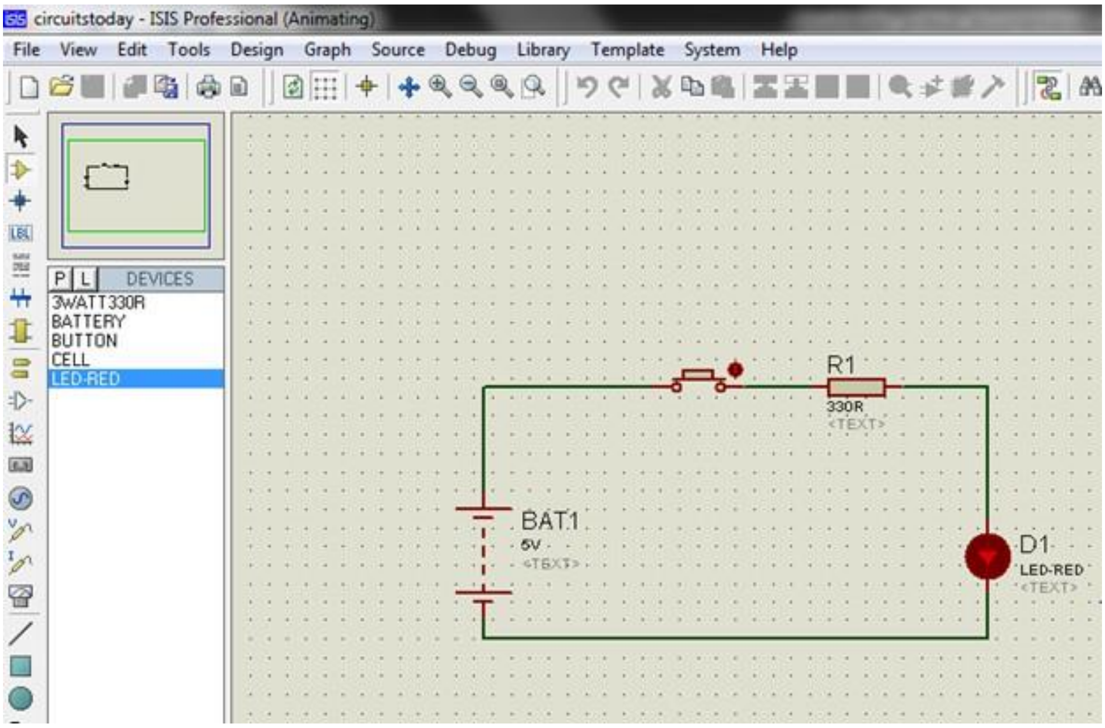

Figure 4.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

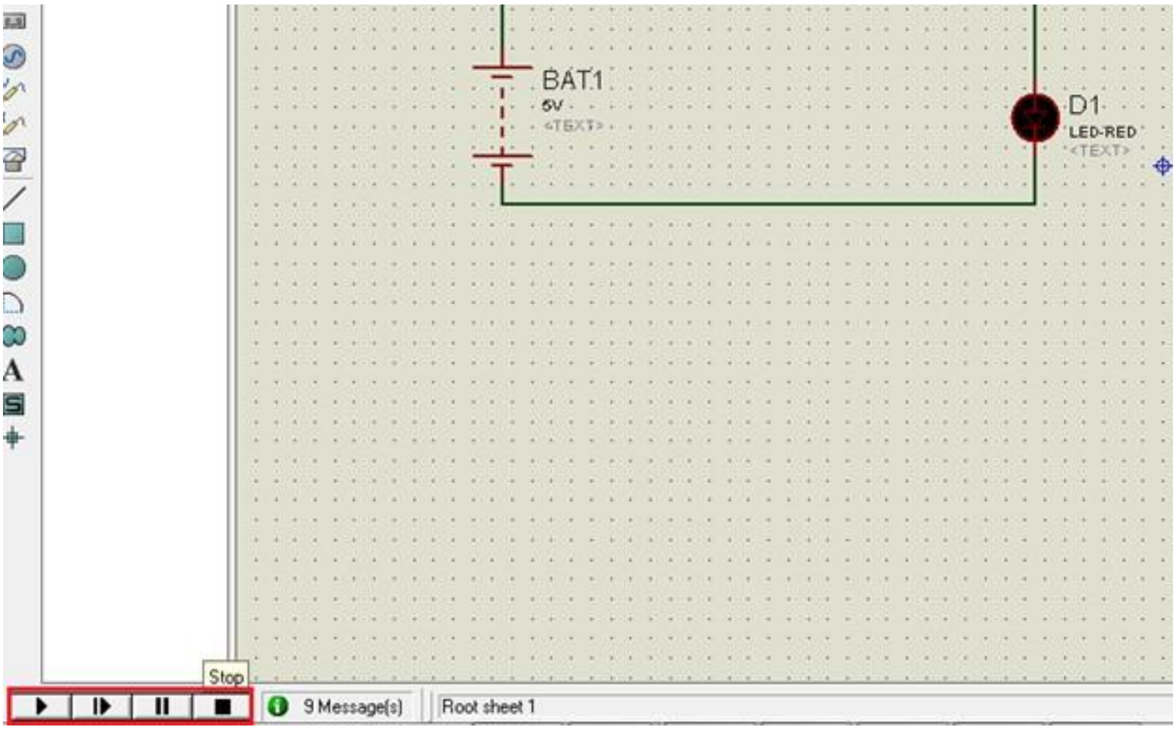

Figure 4.13 Simulation Step-Pause-Stop Buttons

Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program argued to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE

Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago
Repository	github.com/Arduino/Arduino
Written in	C, C++

Table 4.1 Arduino pro IDE

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

Installation

In this section, we will learn in easy steps how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Figure 4.14 USB cable (B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Figure 4.15 USB Cable (mini-B plug)

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

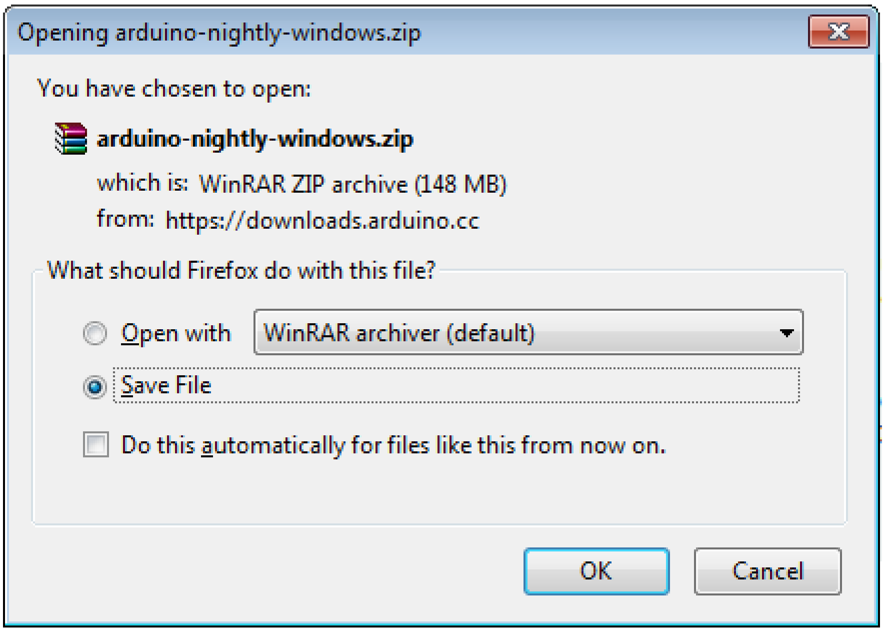

Figure 4.16 downloading Arduino IDE software

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labelled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

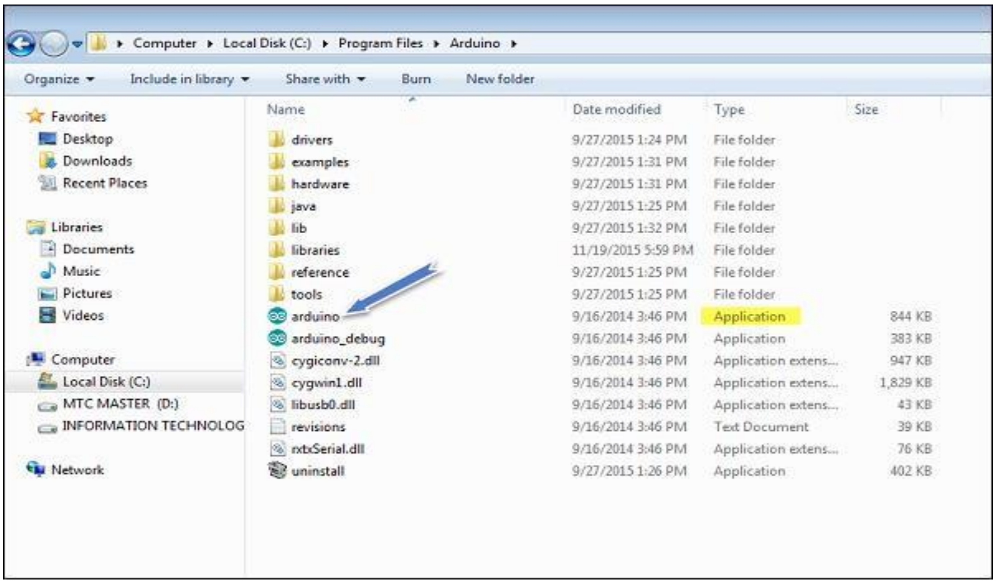

Figure 4.17 launching Arduino

Step 5 – Open your first project.

Once the software starts, you have two options –

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

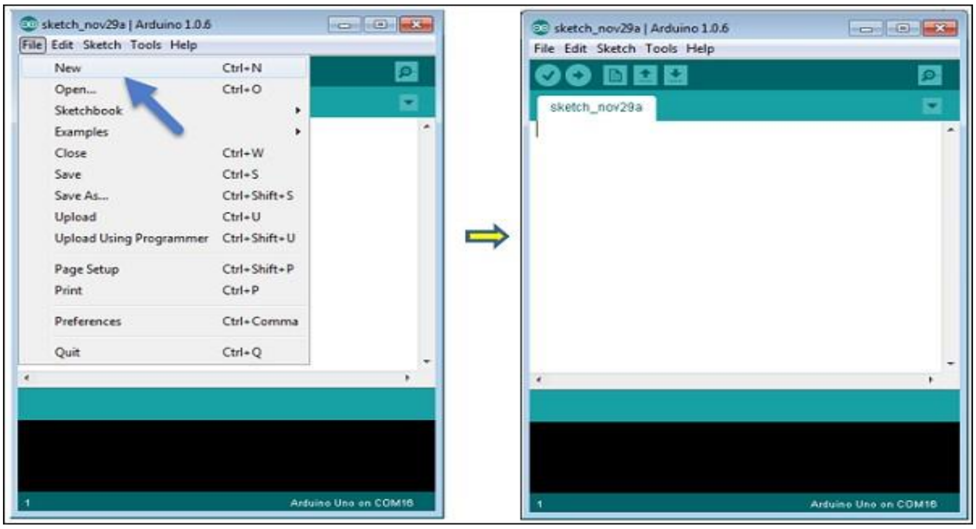

Figure 3.18(a) open new file

To open an existing project example, select File → Example → Basics → Blink.

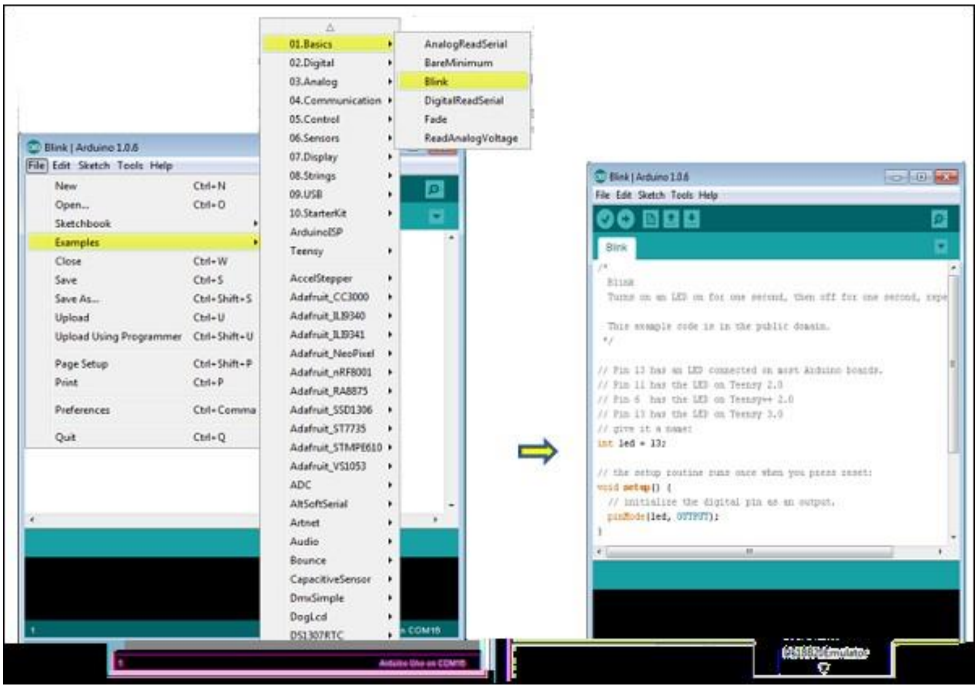

Figure 4.18(b) open existing project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 – Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

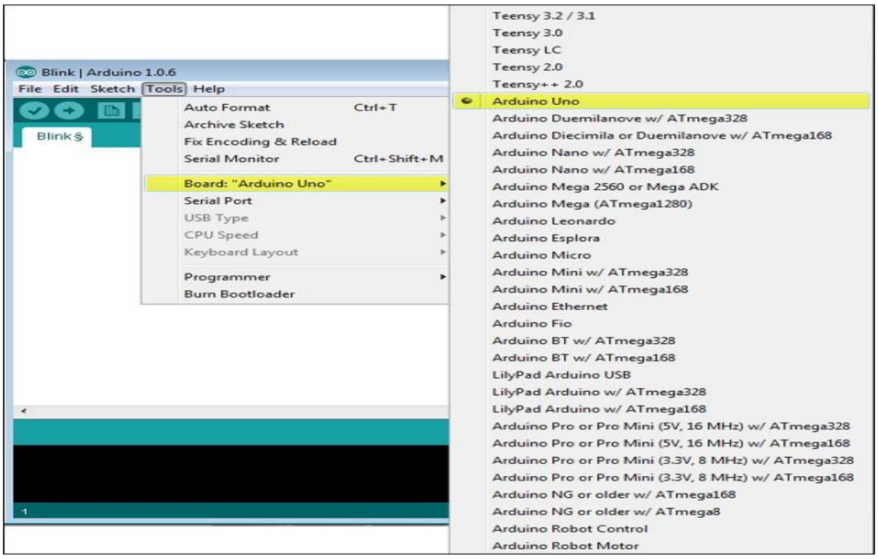

Figure 4.19 Selection of Arduino board

Here, we have selected the Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

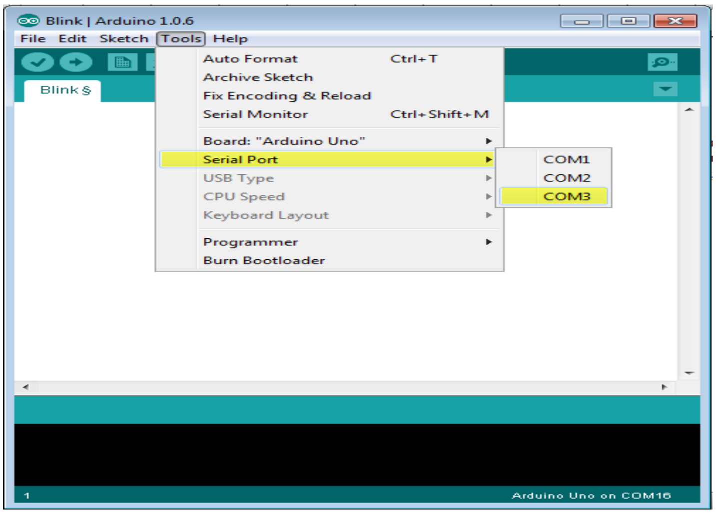

Figure 4.20 selection of serial port

Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

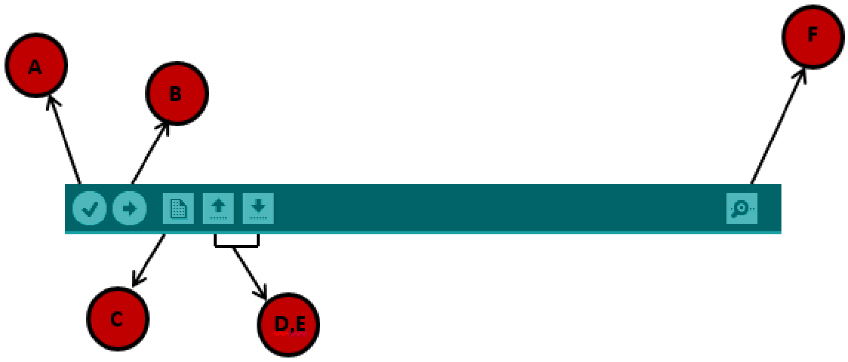

Figure 4.21 upload program

A – Used to check if there is any compilation error.

B – Used to upload a program to the Arduino board.

C – Shortcut used to create a new sketch.

D – Used to directly open one of the example sketch.

E – Used to save your sketch.

F – Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note – If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

B- HARDWARE

Arduino UNO

Arduino is a prototype platform (open-source) based on easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated

Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connecting to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

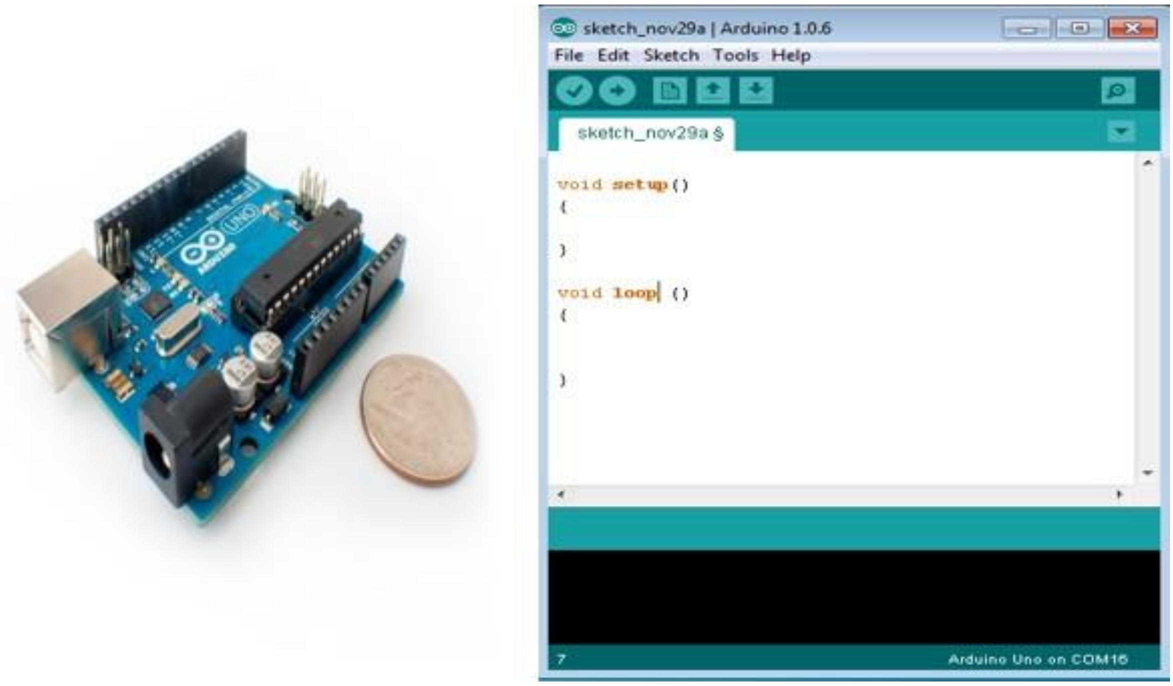

Figure 4.22 Arduino board

Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini-05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini-3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

Table 4.5 Arduino boards based on AT91SAM3X8E microcontroller

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have the majority of these components in common.

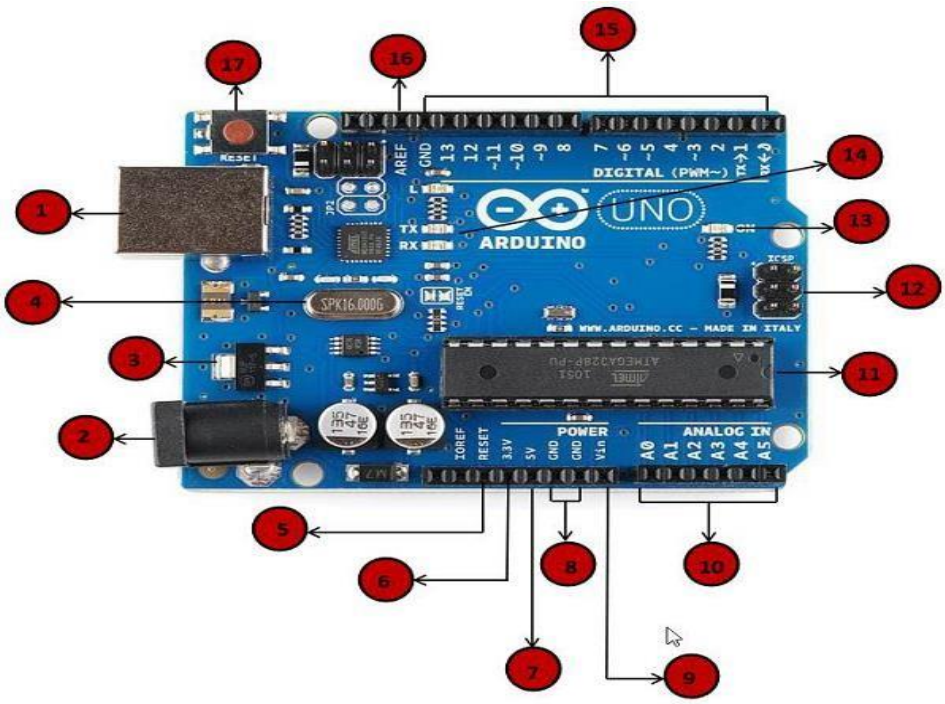

Figure 4.23 Arduino board description

1	**Power USB** An Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) – Supply 3.3 output volt • 5V (7) – Supply 5 output volt • Most of the components used with Arduino boards work fine with 3.3 volts and 5 volts. • GND (8) (Ground) – There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) – This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.

11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speeds while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labelled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 4.6 Arduino pins description

Liquid Crystal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Shapes and S

available. Line lengths of 8, 16, 20, 24, 32 and 40 characters are all standard, in one, two

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around the LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if not all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

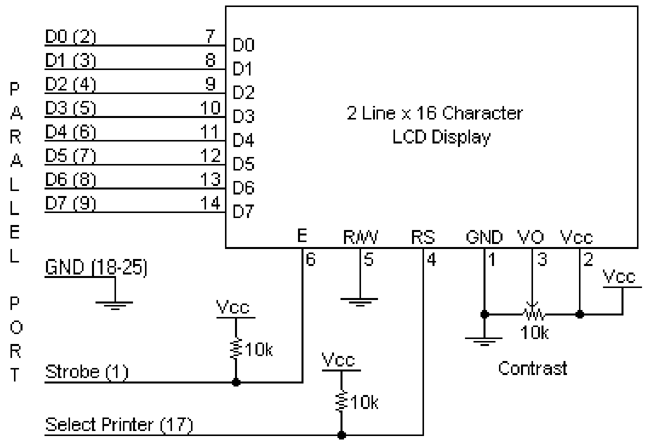

Figure 4.24 Schematic diagram.

- Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus in the reverse direction. Therefore, we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use an onboard +5 regulator. Remember a few decoupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 Alphanumeric LCD Module Specifications:

PIN	**Symbol**	**Level**	**Function**
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H, H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

Table 4.7: 16 x 2 Alphanumeric LCD Module Specifications.

FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×2 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure 4.25 Address locations for a 16×2-line LCD

Even limited to character-based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four-line versions.

Several different LC technologies exist. “Supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

PIN DESCRIPTION:

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers have 16 Pins (two pins are extra in both for back-light LED connections).

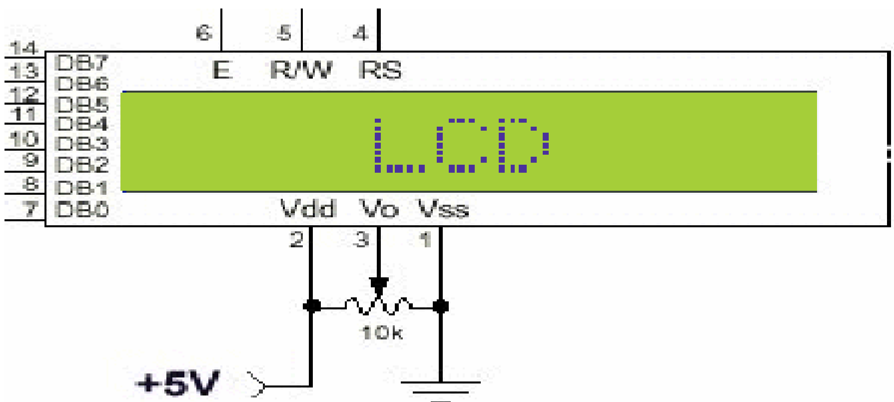

Figure 4.26 Pin diagram of 16x2 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table 4.8 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RDW is low (0), the information on the data bus is being written to the LCD. When RDW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are written commands, so RW will almost always be low.

Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. a switch pack with a re-wiring is necessary.

LCD Commands:

There are some present command instructions in the LCD, which we need to send to the LCD through some microcontroller. Some important command instructions are given below:

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)

06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table 4.9 Commands

ALCOHOL SENSOR

MQ3 is one of the most commonly used sensors in the MQ sensor series. It is a Metal Oxide Semiconductor (MOS) type of sensor. Metal oxide sensors are also known as **Chemiresistors**, because sensing is based on the change of resistance of the sensing material when exposed to alcohol. So, by placing it in a simple voltage divider network, alcohol concentrations can be detected.

Figure 4.27 MQ3 Alcohol sensor

The MQ3 alcohol sensor works on 5V DC and draws around 800mW. It can detect Alcohol concentrations anywhere from 25 to 500 ppm.

Here are the complete specifications

Operating voltage	5V
Load resistance	200KΩ
Heater resistance	33Ω± 5%
Heating consumption	<800mw
Sensing resistance	1 MΩ – 8 MΩ
Concentration scope	25 – 500 ppm
Preheat time	Over 24 hours

Table 4.9 Alcohol sensor specifications

Internal structure of MQ3 Alcohol Sensor

MQ3 is a heater-driven sensor. That's why it is enclosed in two layers of fine stainless-steel mesh called an **Anti-explosion network**. It ensures that the heater element inside the sensor will not cause an explosion, as we are sensing flammable gas (alcohol).

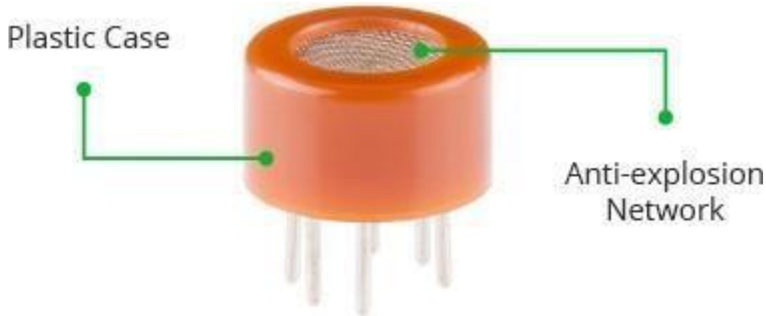

Figure 4.28 external structure of MQ3 alcohol sensor

It also provides protection for the sensor and filters out suspended particles so that only gaseous elements are able to pass inside the chamber.

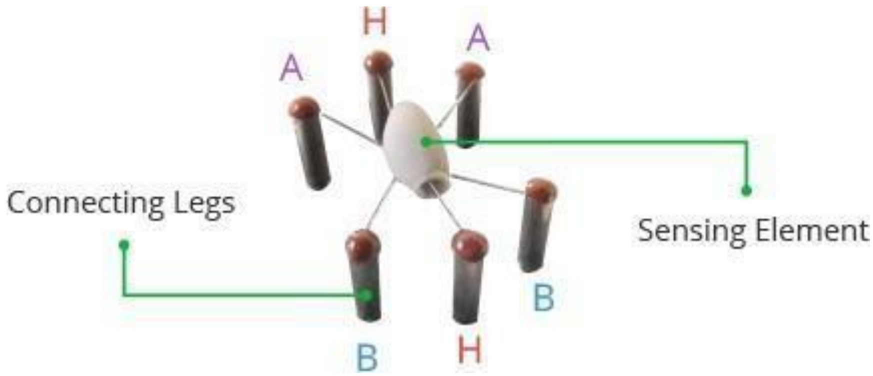

Figure 4.29 internal structure of MQ3 alcohol sensor

This is what the sensor looks like when the outer mesh is removed. The star-shaped structure is formed by the sensing element and six connecting legs that extend beyond the Bakelite base. Out of six, two leads (**H**) are responsible for heating the sensing element and are connected via a **Nickel-Chromium coil** (a well-known conductive alloy).

The remaining four leads (**A** & **B**) responsible for output signals are connected using **Platinum Wires**. These wires are connected to the body of the sensing element and convey small changes in the current that passes through the sensing element.

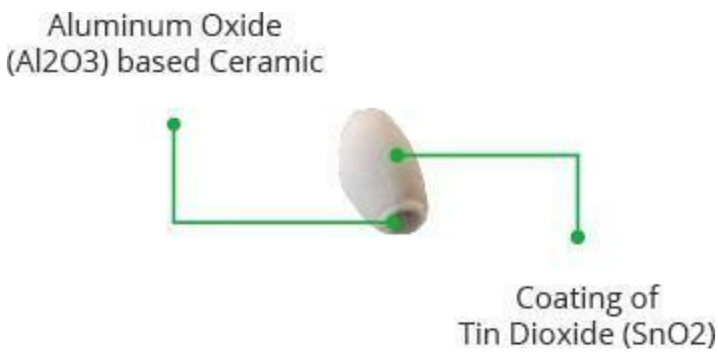

Figure 4.30 sensing element

The tubular sensing element is made up of **Aluminum Oxide** (AL_2O_3) based ceramic and has a coating of **Tin Dioxide** (SnO_2). Tin Dioxide is the most important material being sensitive towards alcohol. However, the ceramic substrate only increases the heating efficiency and ensures that the sensor area is continuously heated to the working temperature.

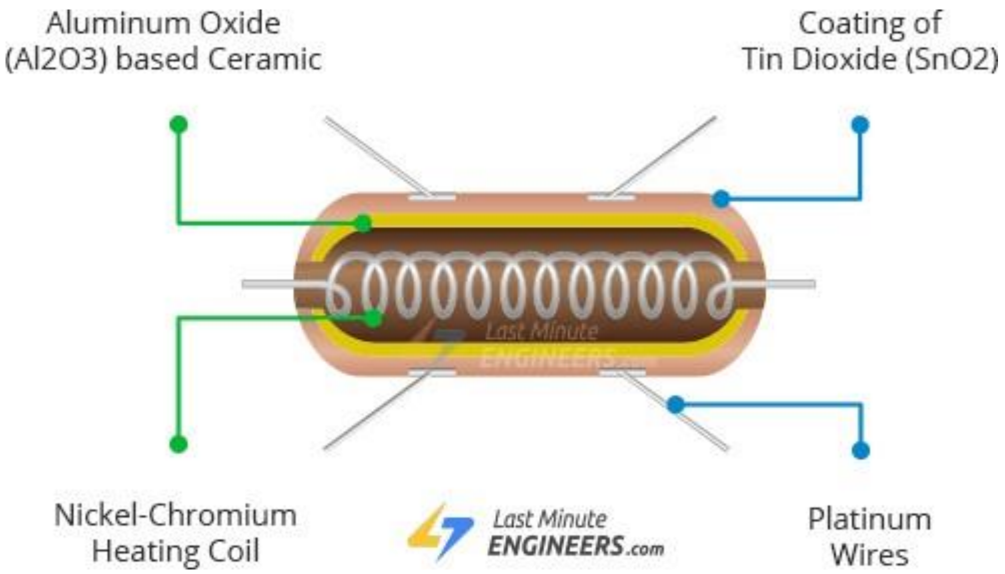

Figure 4.31 tabular sensing element

So, to summarize, the Nickel-Chromium coil and Aluminum Oxide based ceramic forms a **Heating System**; while Platinum wires and coating of Tin Dioxide forms a **Sensing System**.

How MQ3 Alcohol Sensor Works?

When the SnO_2 semiconductor layer is heated at high temperature, oxygen is adsorbed on the surface. In clean air, electrons from the conduction band in tin dioxide are attracted to oxygen molecules. This forms an electron depletion layer just below the surface of SnO_2 particles and forms a potential barrier. As a result, the SnO_2 film becomes highly resistive and prevents electric current flow.

In the presence of alcohol, however, the surface density of adsorbed oxygen decreases as it reacts with the alcohols; which lowers the potential barrier. Electrons are then released into the tin dioxide, allowing current to flow freely through the sensor.

MQ3 Alcohol Sensor Module Hardware Overview

Since the MQ3 alcohol sensor is not breadboard compatible, we recommend this handy little breakout board. It's very easy to use and comes with two different outputs. It not only provides a binary indication of the presence of alcohol but also an analog representation of its concentration in air.

Figure 3.32 MQ3 sensor

The analog output voltage provided by the sensor (at AO pin) varies in proportion to the alcohol concentration. The higher the alcohol concentration in the air, the higher the output voltage; Whereas lower concentration gives lower output voltage. The following animation shows the relationship between alcohol concentration and output voltage.

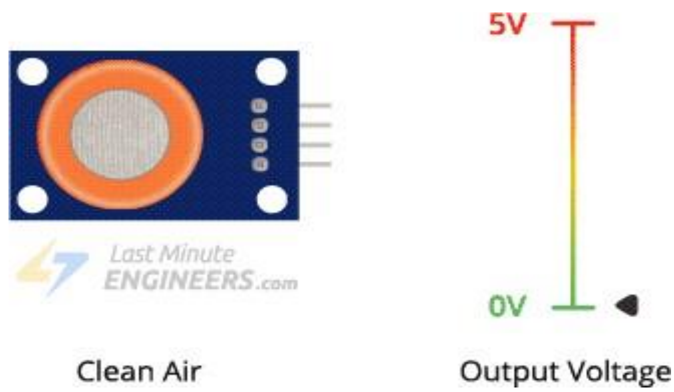

Figure 3.33 Digital Indication of alcohol concentration

The same analog signal is fed to a LM393 High Precision Comparator to digitize it and is made available at the Digital Output (DO) pin.

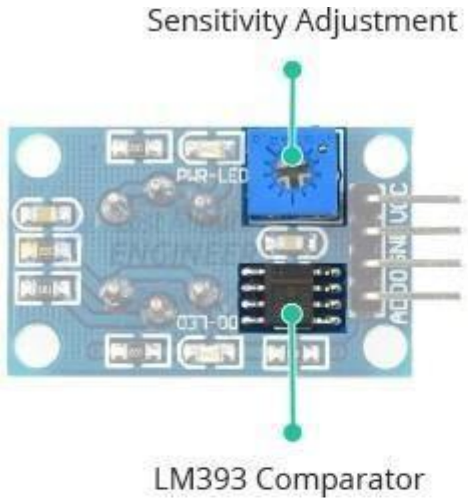

Figure 3.34 Back view of alcohol sensor

The module has a built-in potentiometer for adjusting the sensitivity of the digital output (DO). You can use it to set a threshold; so that when the alcohol concentration exceeds the threshold value, the module will output LOW otherwise HIGH.

This setup is very useful when you want to trigger an action when a certain threshold is reached. For example, when the alcohol concentration in the breath exceeds a threshold, you can tell if someone is drunk.

BUZZER:

Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of an iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through a resonator consisting of sound hole(s) and cavity and produces a loud sound.

Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on the primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

Recommended Driving Circuit for Magnetic Transducer

Introduction of Magnetic Buzzer (Transducer)

Specifications:

Rated voltage:	A magnetic buzzer is driven by 1/2 square waves (V o-p).
Operating voltage:	For normal operation. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
Consumption current:	The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Direct current resistance:	The direct current resistance is measured by the ammeter directly.
Sound output:	The sound output is measured by a decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
Rated frequency:	A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating temperature:	Keep working well between -30℃ and +70℃.

How to choose:

Driving methods	AX series with a built in drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.
Dimension	Dimension affects frequency, small size results in high frequency.
Voltage	Depend on V o-p (1/2 square waves)

Fixed methods	From the highest cost to the lowest- DIP, wires/ connector, SMD.
Soldering methods	AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

How to choose a buzzer

There are many different kinds of buzzers to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage	Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.
Consumption current	According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer starts to work.
Driving method	Both magnetic and piezo buzzer have a self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer needs to be driven by 1/2 square waves, and the piezo buzzer needs square waves to get better sound output.
Dimension	The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.
Connecting way	Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.
Sound Pressure Level (SPL)	Buzzer is usually tested on the SPL at the distance of 10 cm, if distance doubles, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit a very loud sound, for example, the common siren is mostly made of piezo buzzer.

Introduction of Piezoelectric Buzzer

Specifications:

Rated voltage	A piezoelectric buzzer is driven by square waves (V p-p).
Operating voltage	For normal operation. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption current	The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Capacitance	A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.
Sound output	The sound output is measured by a decibel meter. Applying rated voltage and square waves, and the distance of 10 cm.
Rated frequency	A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating temp.	Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AZ-xxxxS-x series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current. Besides, there are different tone natures for you to choose, such as continuous, fast pulse, and slow pulse.

Dimension: Dimension affects frequency, small size results in high frequency.

Voltage: Driven by square waves (V p-p), the higher voltage results in the higher SPL.

Pin Pitch: The numerous spec. for the piezo buzzers lead to the difficulty in finding a spec. in facsimile, therefore we suggest that you can firstly choose a spec. with the same pitch and similar frequency.

Introduction of Micro SpeakerHow to choose:

The factors which affect the SPL: the square measure of diaphragm, the amplitude of vibration, magnetic field intensity, power, impedance, resonant chamber, the pattern and the thickness of diaphragm, and the holes.

Power vs. SPL: Suppose all the conditions are the same, increasing the power does not mean the SPL will increase as well. We need to revise the diaphragm and the sound coil to load the higher power, but it leads to lower SPL instead.

Dimension vs. SPL: A larger speaker can vibrate more air, therefore it provides higher SPL. In addition, the thicker speaker can give wider amplitude of vibration which also leads to higher SPL.

Acoustics: What we request most is how much SPL a micro speaker can output.

Matching: It will be better to provide the power slightly higher than the rated power for the enlarged circuit.

Question for mechanism:

The volume of the resonant chamber: The general problem of the consuming products is that the resonant chambers are not big enough. We can only try to find space to enlarge the volume of the resonant chamber.

Sound Hole: Must be more than 1/8 of the diaphragm's area at least.

Airtight: The front and back sound fields of the speaker should be separated to avoid neutralization.

Shock absorber: When a speaker works the vibration will also happen at the same time. In order to reduce interference, it will do good to have some material between speaker and case to absorb the shock.

Mounting: The speakers are usually fixed on the case. Firmly fixed is important especially for the iron housing or the large size to avoid separating in the drop test.

How to choose the speaker

Dimension: To the micro speaker, size has a decisive influence on its volume. a 5mm difference of diameter might result in a double or half area of diaphragm, therefore the SPL is quite different. Besides, the thicker speaker has more space to vibrate the air, and usually has a bigger magnet, so it will be more powerful to push the air and emit louder sound.

Power: Mainly refers to how much power a speaker can bear, there is no direct relation to the SPL. The speaker with larger power needs to use thicker diaphragm and sound coil to bear larger power, which will lead to lower efficiency (SPL). Therefore, according to the mechanical design, try to select a larger speaker which matches the outputting power from the amplified circuit, then the best SPL would be emitted.

Impedance: Higher impedance can save more electricity; however, the SPL and the loaded power will go down. The reason is that we have to use thinner wire or to coil more, the front makes the power lower, and the after leads to heaviness and low efficiency.

The material of diaphragm: Most speakers (diameter less than 50mm) use mylar diaphragms, which are easily finished, cheaper and waterproof. However, mylar diaphragm is not good at heatproof and the sound is stiff.

The patterns of diaphragm: The speaker with concentric circles diaphragm is good for the speech sounds. Generally, the SPL is good at the frequency before 5-6 KHz, but will dramatically decrease after 6 KHz. On the other hand, the speaker with radiate diaphragm has average frequency response. Supposing other conditions are all the same, the SPL of the radiate diaphragm will be lower than the concentric circles one at the frequency before 6 KHz.

CHAPTER 5

RESULT ANALYSIS

Output

- This is the prototype of the project.
- The main unit of the project is associated alcohol sensor, WIFI module, Arduino uno, buzzer and LCD.
- The IOT application used is Mobile telnet application.
- Following figure shows the working of the kit as power is supplied and input gas is blown to verify the output on both LCD and the online application.

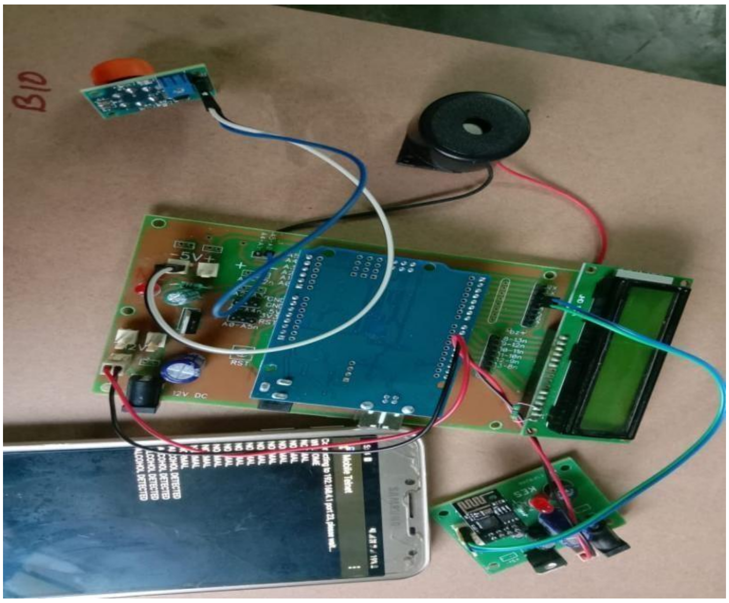

Figure 5.1 Prototype of the project

- The figure 6.2 is showing the display while connecting to the server.

- While connecting to the server it displays “WAITING FOR LINK”.

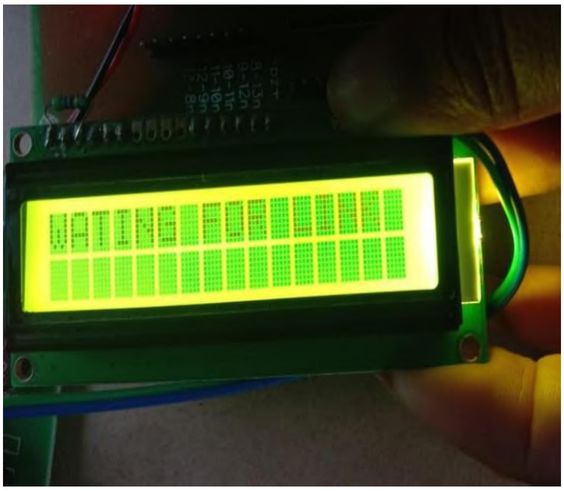

Figure 5.2 Connecting to server

- This figure 6.3 shows the application screen where the information is displayed

- It shows whether the person consumed alcohol or not

- NORMAL in the application screen indicate that there is no alcohol is detected

- ALCOHOL DETECTED in the application screen indicates that the person has consumed the alcohol.

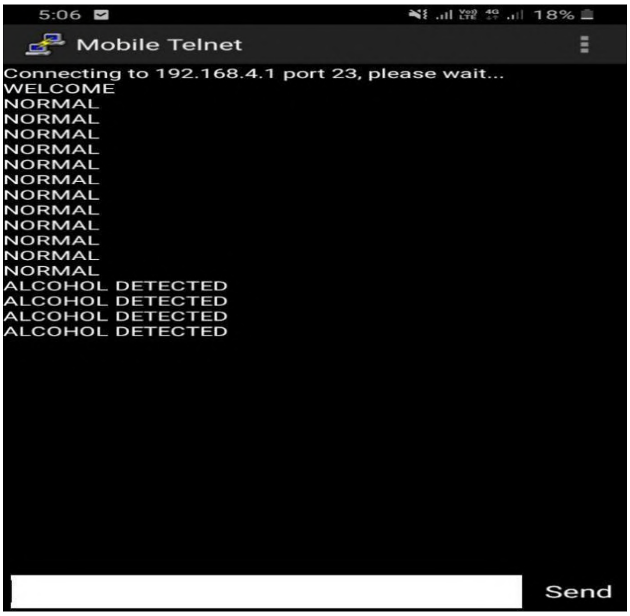

Figure 5.3 Application server

- **The condition used for the code is:**

```
int ad = analogRead(alc);

   lcd.clear();lcd.setCursor(0, 0);lcd.print("ALCOHOL:");lcd.print(ad);

 if(ad > 600 )

 {

     digitalWrite(buz,HIGH);

     lcd.clear();lcd.setCursor(0,1);lcd.print("ALCOHOL DETECTED");

     delay(100);

     sendwifi("ALCOHOL DETECTED \r\n",20);

     delay(2000);

 }
```

```
 else
{
   digitalWrite(buz,LOW);
  lcd.clear(); lcd.setCursor(0,1);lcd.print("NORMAL");
  delay(100);
  sendwifi("NORMAL \r\n",10);
  delay(2000);
```

The figure 5.4 here shows output NORMAL on the lcd screen

- It shows normal when no alcohol is detected by the sensor and the output is low.

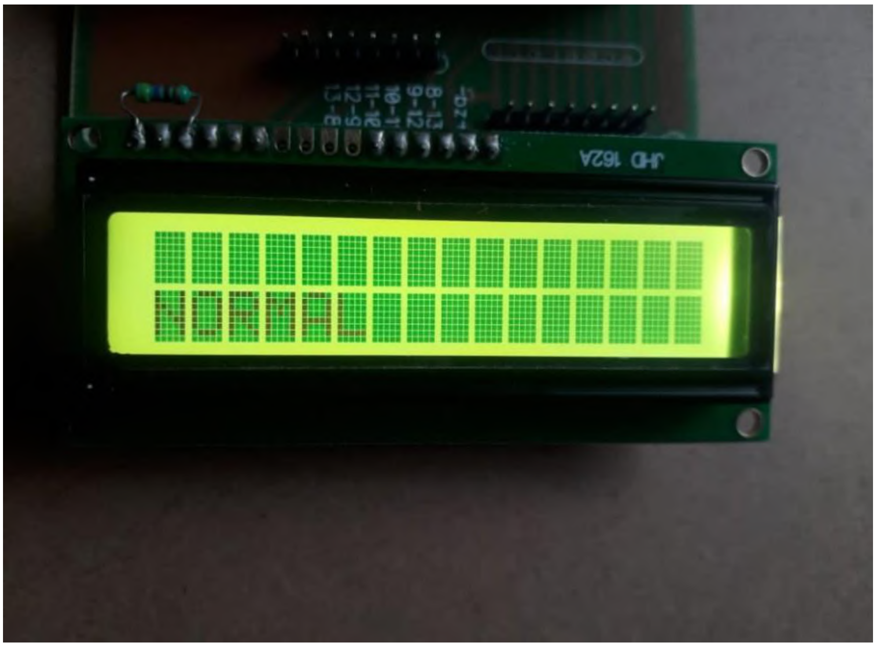

Figure 5.4 LCD displaying output NORMAL

CHAPTER 6

ADVANTAGES AND APPLICATIONS

Advantages

The designed system has several advantages

1. Easy to use.
2. Efficiency of output.
3. Safety of the passenger from accidents.
4. It is very much accurate to detect the presence of alcohol inside the vehicle.

Applications

This device can be used widely in

1. Automobile industry
2. Industries
3. Complex
4. Mall

Limitations

1. Fixing the camera for capturing drunker images is not possible.
2. The program written will not help to show the actual amount of alcohol consumed by the driver

CHAPTER 7

CONCLUSION & FUTURE ENHANCEMENT

Conclusion

In this project, an alcohol detection system was developed for road transportation safety in smart cities using Internet of Things (IoT) technology. This system not only curbs drunk driving by automatically shutting down the vehicle that contains the drunk driver but also allows for traffic authorities to easily locate the shutdown vehicles using the coordinates of the vehicle sent to the web server. The technologies which are used in the proposed system are good enough to ensure the perfect shut down and pick up of the drunk driven vehicle. There are no projects that cannot be improved.

Enhancements have to be carried out so as to improve the efficiency of this system. One of the improvements that could be made on this system in the future is that it should be made smaller. The smaller the system, the more convenient the alcohol system is, the more likely drivers will accept it. There should be proper positioning of the alcohol sensor so as to allow convenient reading of the driver's alcohol consumption quantity with or without the aid of the driver.

Some options for where the sensor can be placed include: (1) an element that can help differentiate the ethanol quantity in alcohol and perfumes should be introduced into the sensor so as to prevent the issue of the system being triggered due to use of large amount of perfume by the driver; (2) a cable can be put near the driver's seat and then connected with the ignition of the car. This means the alcohol detection system can be another key to the car. The driver should blow into the system before he/she starts the car. If the value of the alcohol concentration is above the system's threshold value, the system will stop the car starting. So a drunk driver would not be able to start the car which will prevent the behaviour of drunk driving. It is not only safe to the driver, but can ensure the passengers would not be hit because of the driver's drunk driving.

Future Enhancement

1. The future scope can be added as geofencing can be implemented to the device to get the actual status of the vehicle.
2. The camera can be added for the device for capturing drunker images and reporting it to the police.
3. One more feature can be added as a quick help admin for the women safety in the application.

CERTIFICATE

This is to certify that the major-project work entitled **"Arduino Based System to Measure Solar Power**" is a bonafide work carried out by D. Kiran Reddy (17K81A0474), M. Sudhakar (17K81A0491), P. Sharath (18K85A0411) in partial fulfilment of the requirements for the Degree of Bachelor of Technology in Electronics & Communication Engineering by the Jawaharlal Nehru

Technological University, Hyderabad during the academic year 2020-2021.

The results embodied in this report have not been submitted to any other University or Institution for the award of any degree.

INTERNAL GUIDE

Mrs. Sri Lakshmi
Assistant Professor,
Department of ECE.

HEAD of THE DEPARTMENT, ECE

Dr. B. Hari Krishna,
Professor.

EXTERNAL EXAMINER

ACKNOWLEDGEMENT

We sincerely thank the management of our college **St. MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work.

We derive our great pleasure in expressing our sincere gratitude to our principal **Dr. P. Santosh Kumar Patra** for his timely suggestions, which helped us to complete the project work successfully.

It is the very auspicious moment to express our gratitude to **Dr. B. Hari Krishna**, Head of the Department of ECE for his consistent encouragement during the progress of this project. We take it as a privilege to thank our project coordinator **Dr. A. Anand** Professor, department of ECE for the ideas that led to complete the project work and we also thank them for their continuous guidance, support and unfailing patience, throughout the course of this work.

We sincerely thank our project Internal guide **Mrs. Sri Lakshmi,** Assistant Professor**,** Department of ECE for guidance and encouragement in carrying out this project work.

DECLARATION

We, the students of **"Bachelor of Technology in Department of Electronics and Communication Engineering"**, session: 2017 – 2021, **St. Martin's Engineering College**, hereby declare that the project work entitled "**Arduino Based System to Measure Solar Power**" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

D. Kiran Reddy	**M. Sudhakar**	**P. Sharath**

ABSTRACT

The designed project measures different solar cell parameters like light intensity, voltage, current and temperature by using multiple sensor data acquisition. The project uses a solar panel to monitor sunlight and Arduino board which has ATmega family microcontroller attached to it. The project requires an LDR sensor for measuring light intensity, a voltage divider to measure voltage and a temperature sensor to measure the temperature. These measurements are then displayed by the microcontroller to a LCD screen. Thus, this system allows user to effectively monitor solar parameters using this system.

CHAPTER 1
INTRODUCTION

1.1. Introduction to the project:

Rising fossil fuel and burning fuel such as coal, global warming and severe weather conditions have compelled many nations to look for alternative sources to reduce reliance on fossil based fuels. Solar energy is one of the most promising renewable sources that is currently being used worldwide to contribute for meeting rising demands of electric power. [1] Solar power is a conversion of sunlight into electricity, sunlight was collect either directly by using photovoltaics or indirectly using concentrated of solar energy. [2] Photovoltaics was initially use as a power source for a small and medium-size applications from the calculator powered by a single solar cell to a remote homes powered by an off-grid rooftop photovoltaics system. As the cost of solar electricity has fallen, the number of grid-connected solar photovoltaics systems has grown into the millions and utility scale solar power stations with hundreds of megawatts are being built. Solar photovoltaic is becoming inexpensive, low-carbon technology to harness renewable energy from the sun. [3] This paper presented by Arindam Bose et. al [4] describe a potential a solar system using two set of stepper motor, the light sensor and the concave mirror. The purpose of this project to improve the power collection efficiency 65% with developing the track of solar panel perpendicular. This paper presented by Mohsen Taherbaneh et. al [5] proposed the method based on simulation of two fuzzy controllers in order to maximize the generate the output power of solar panel in a photovoltaic system. The output I-V curve from this project are the maximum current is 1.56A nad the maximum voltage are 20V with solar irradiance = 500W/m2 and temperature = 34.5°C. The results of the fuzzy-based maximum power point tracking with 23W with 51% and 11W with 24.5% from the nominal output power. On the other hand, the combination of fuzzy-based maximum power point tracking and fuzzybased sun tracking is 35W with 78% of the nominal output power. Yi-Hua Liu et.al in [6] presented the maximum power point tracking (MPPT) method for low power photovoltaic system, 87W PV system. The MPPT circuit using the low power operational amplifier (OPAMP) with high and low irradation line and an analog switch. The simple DC-DC converter using such as the interface the voltage from the PV system. The type of multi-crystalline solar cell KC85T with the nominal open-circuit voltage of 21.7V and the nominal voltage at the maximum power point of 17.4V. The simulation results shows with 1000W/m2 irradiance, 25°C and the maximum power is 87.46W. From experimental results with

1000W/m2 , the maximum power is 87.39W. The advantages of analog MPPT are very simple, the lowpower analog component, the fast speed and can using to all types of power convertes. This paper [7] propose the method the Fibonnaci search technique for narrow down possible locations. The results shows that 1000W/m2 is 112.4W with 13% efficiency of panel solar. Mohammad H. Moradi presented in [8] to improve the performance of the maximum power point tracking in solar panel. The PV panel with Aria Solar are 60W, with 25°C,1000W/m2 and the current is 2.5A and the voltage is 23.1V. The proposed algorithm are the set point calculation and the fine turning loops. The method was simulated with Matlab/Simulink and also development of the prototype. Concentration of solar energy are concentration of the light from the sun to a point by using lens or mirror and tracking system. The light from the sun also produce heat and if we concentrate at a point. The point will experience the heat produce from the sun [9-10]. This project are focus on measure the solar power using Arduino [10]. This design project are to measured parameters: light intensity, voltage and current and temperature using multiple sensor. The main part in this project are the solar panel, the light sensor, the temperature sensor, a voltage divider, the current sensor and the LCD screen to display.

CHAPTER 2
LITERATURE SURVEY

2.1 Literature Survey:

Title 1 - Design and Research of High Voltage Power Conversion System for Space Solar Power Station

Abstract:

To meet the needs of its characteristics, this paper studies the space high voltage power conversion system's circuit topology and the optimization design of its structure. In the first part, the Common space solar power station power management and distribution method is analyzed. And based on that, a new hybrid power system structure is presented, in which a power transmission bus-bar structure suited for space solar arrays is constructed and the modular multi-converter with serial-parallel combination control strategy is proposed. By applying this new structure, the high transformation ratio in the solar cell arrays and sub-arrays, the low power loss, the large power conversion with high power density and the high efficiency can all be achieved. In the second part, a new soft-switched isolated full-bridge converter is also proposed. And research is made based on the new converter, which includes the study on the transformer modular magnetic integration, the space temperature field and the thermal design. Finally, the simulation and experiment prove the correctness of the theoretical analysis.

Title 2 - Research on Reliability Evaluation of Power Generation System with Solar Thermal Power

Abstract:

The reliability assessment of hybrid power generation systems with new energy is of great significance for optimizing energy allocation. At present, most of the researches on reliability assessment focus on wind power, photovoltaics and their hybrid power generation, but there is little research on the reliability assessment of hybrid power generation systems including solar thermal power generation (STP). By expanding the reliability evaluation research of wind power and traditional wind power photovoltaic hybrid power generation systems, a reliability evaluation model including STP is established. Considering the operation

characteristics of thermal storage devices in STP system, a sequential Monte Carlo evaluation framework is adopted and random production simulation is performed for two intermittent power generation modes (wind power and STP). Therefore, the credible capacities of STP system with and without heat storage are evaluated when accessed to the grid separately or under hybrid power generation state.

Title 3 -A modelling case study of an island mode solar power plant

Abstract:

This paper deals with efficiency analysis of a solar power plant that is considered to be installed in island mode with 2kWp rated power. The test bed designed in Simulink © consists of solar panel, buck converter, and H-bridge inverter models all based to analytical concepts. The solar panel model is designed according to equation of a solar cell, and all the required parameters such as open circuit voltage, short circuit current etc are considered in order to modify the output power regarding to a commercial photovoltaic (PV) panel. The dc-dc conversion is performed with a buck converter where the optimal duty cycle is dynamically updated by a proportional-integral (PI) controlled generator. The settling time and dc voltage ripples are minimized to increase the efficiency of the dc-dc converter. On the other hand, the single-phase inverter is constructed with an H-bridge that is the most basic multilevel topology known ever. The main intention during the inverter operation was decreasing the total harmonic distortion (THD) ratios as much as possible. Therefore, the modulation scheme is particularly applied to decrease THD by eliminating side band harmonics. The line voltage is properly fixed to 220V/50Hz that is common in northern and central Europe. The THD ratio of the line voltage is measured at 0.03%, while the THD of the current is 0.82%. The power factor of the entire system is measured as 0.99 considering the 8.1° phase displacement between current and voltage waveforms. The analysis results verify the efficiency of the proposed solar power plant and its components.

Title 4 - Possibilities and limitations of measuring the energy of direct solar radiation

Abstract:

Previous research shows that the most of the energy needs in the near future is going to be satisfied mainly from conventional forms of energy, but it is important to take into account,

that in the period of preparation, design and implementation of power plants that use conventional forms of energy occurs, as a rule, a number of serious problems, limitations and conflict resolution around the many harmful effects on the environment. Energy analysis point to the fact that, except of work at the discovering of additional reserves and improving the procedures and technologies in the use of conventional energy sources, it is necessary to do much more researches on possibility for better and massive use of new, so-called alternative forms of energy, especially energy of direct solar radiation, wind and biomass. In order to avoid unnecessary loss of time and resources, with more intensive use of technological developments it is necessary that in each specific area and example make a quality research, measurement, evaluation, calculation and analysis of available resources, and only based on them, to plan the next steps for optimal satisfaction of fast-growing energy needs. In this paper, the possibilities of the most commonly used means and methods for measuring the energy of direct solar radiation, and their main advantages and disadvantages in specific conditions will be analyzed. Based on the review and analysis of available literature it will be carried out detailed evaluation and analysis of ways of selection suitable measurement methods for measurement locations and the use of different measurement parameters, necessary devices and equipment, taking into account the specific conditions of application. It will be given the results of measurements in Montenegro which will be compared with other methods for assessment of solar power at the specific location. According to those comparisons appropriate analysis will be conducted. Also, the aim of this work is to determine the optimum angles for the installation of solar collectors and photovoltaic cells in order to obtain maximal intensity of radiation at their surfaces.

Title 5 - Solar electric power for a better tomorrow

Abstract:

The promise of solar electricity based on the photovoltaic (PV) effect is well known, but these systems are not common all over the world. Consumers in the USA are well-known for their attraction to new technology, but PV power systems are still not appearing on roof-tops in the US. The reason may be that grid-connected roof top systems are too difficult to acquire, too difficult to integrate with the grid, too difficult to measure the energy produced and too expensive. The author argues that it is essential that PV power systems are made user-friendly, while reducing the component and system costs. Elegant PV technology must be reduced to practical systems that can be used by the average person everywhere. Choosing the right problem will help achieve the promise of photovoltaics. This paper describes a methodology to choose the right problems as an approach to PV development. Solar cell and PV power system examples are presented.

CHAPTER 3
INTRODUCTION ABOUT EMBEDDED SYSTEMS

Introduction:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

Block diagram of embedded system:

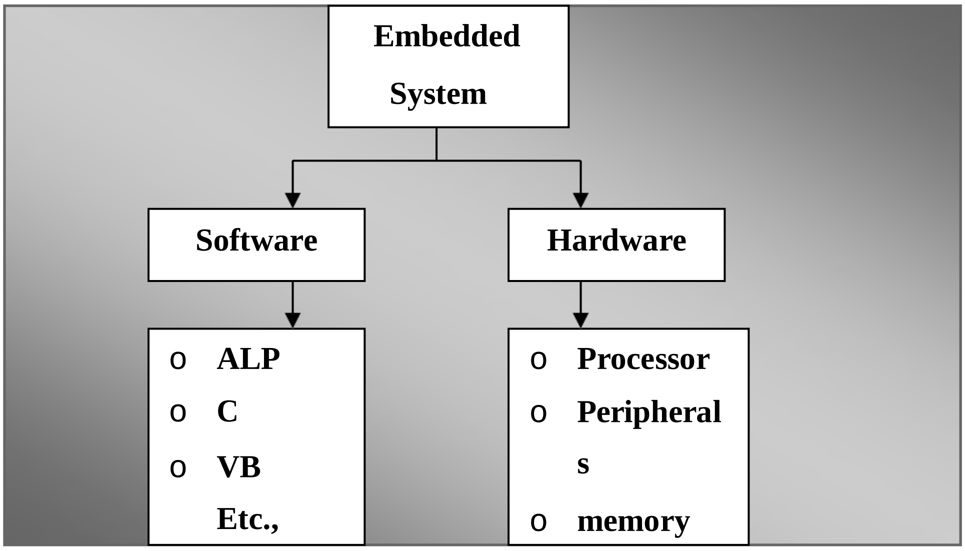

Figure 3.2.1 Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Micro Processor (μp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

Three Basic Elements of a Microprocessor:

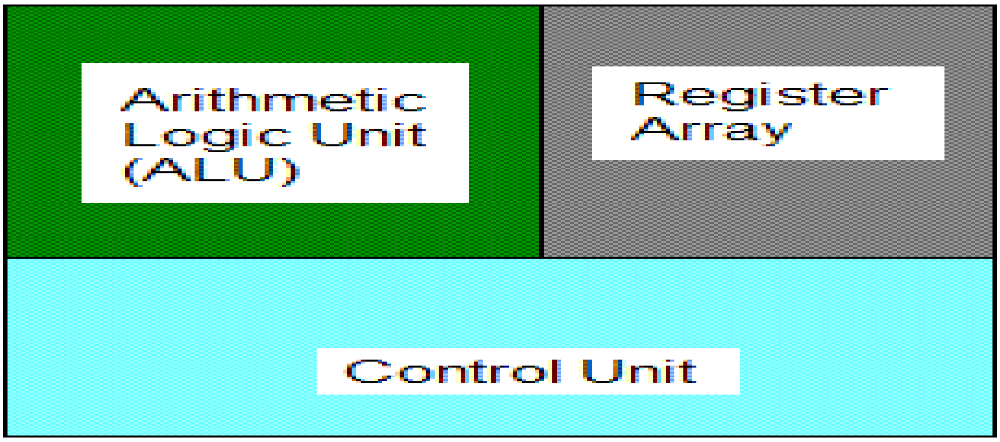

Figure 3.5.1 Three basic elements of a microprocessor

Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

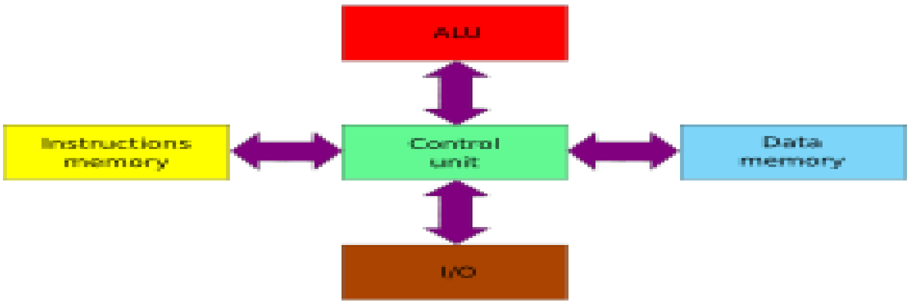

Figure 3.6.1 Harvard Architecture

Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

Von-Neumann Architecture:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

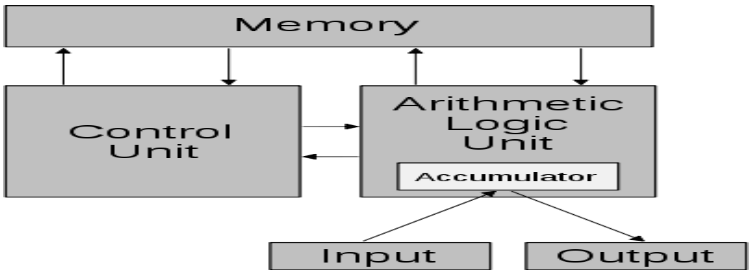

Figure 3.6.2.1 Schematic of the Von-Neumann Architecture

CHAPTER 4
MICRO CONTROLLER UNIT

ATMEGA328:

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8-bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)

SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Table 4.1.1 Atmega328 specifications

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

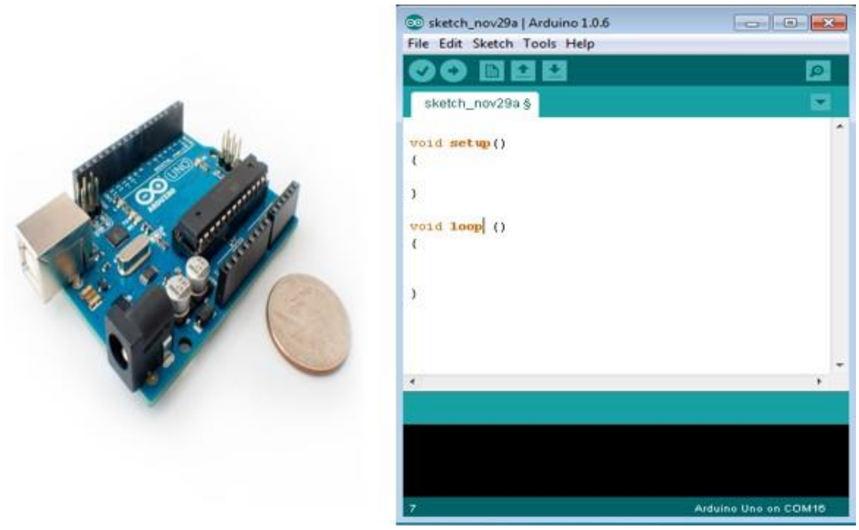

Figure 4.1.1 Arduino Uno

Board Types:

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2

Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header

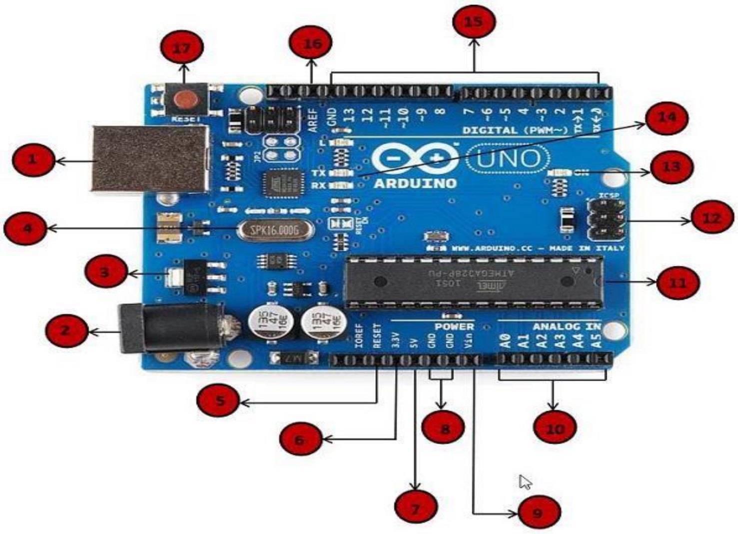
Table 4.4.3 Arduino boards based on AT91SAM3X8E microcontroller

4.2.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7,	**Pins (3.3, 5, GND, Vin)** 3.3V (6) − Supply 3.3 output volt

8, 9	5V (7) − Supply 5 output volt Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The

	TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Arduino Family:

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Figure 4.3.1 Arduino Family

Shields:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

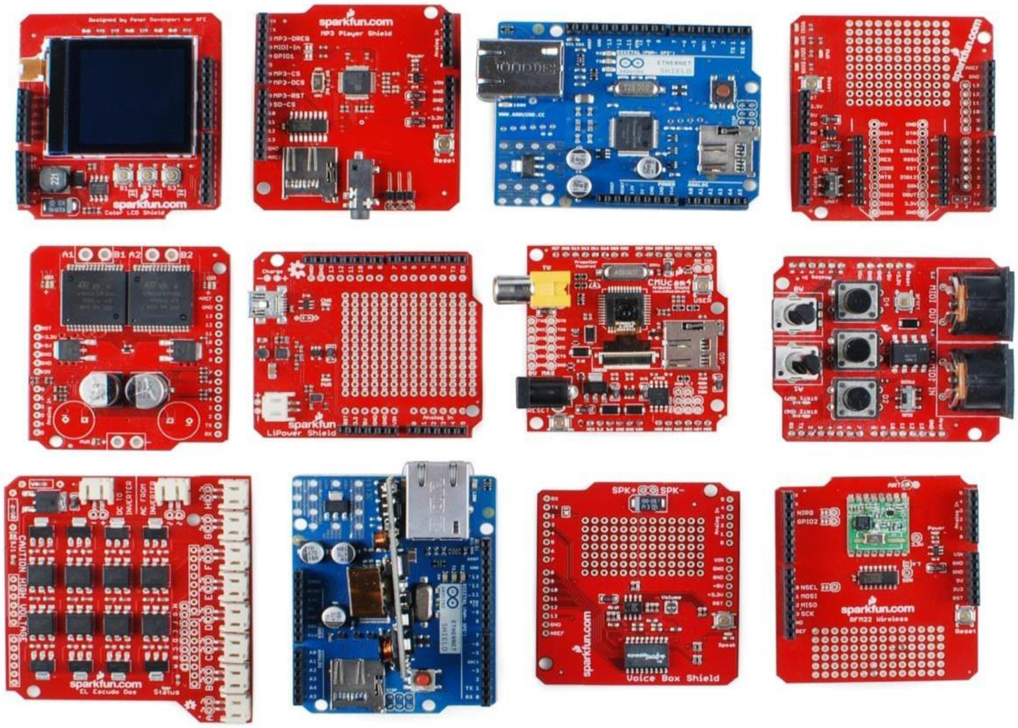


Figure 4.4.1 Arduino Shields

Pin Description of ATMEGA328:

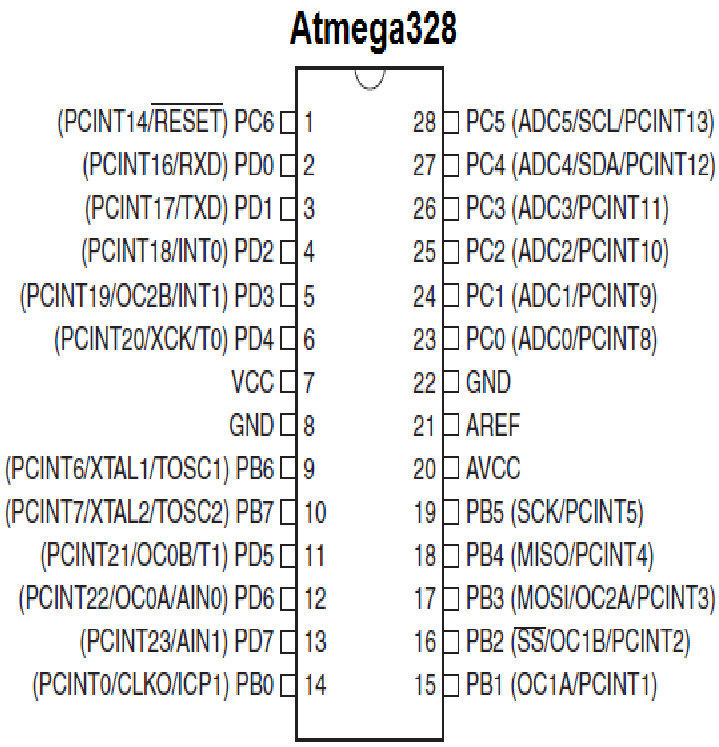

Figure 4.5.1 Pin description of ATMEGA328

Advantages of Arduino:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

Applications:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model.

CHAPTER 5

POWER SUPPLY UNIT

Introduction:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

Block Diagram of Power Supply:

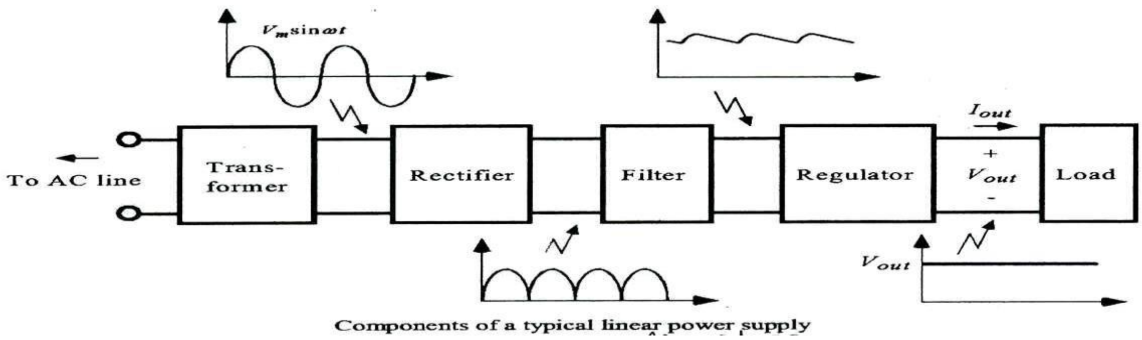

Figure 5.1.1.1 Block Diagram of Power Supply

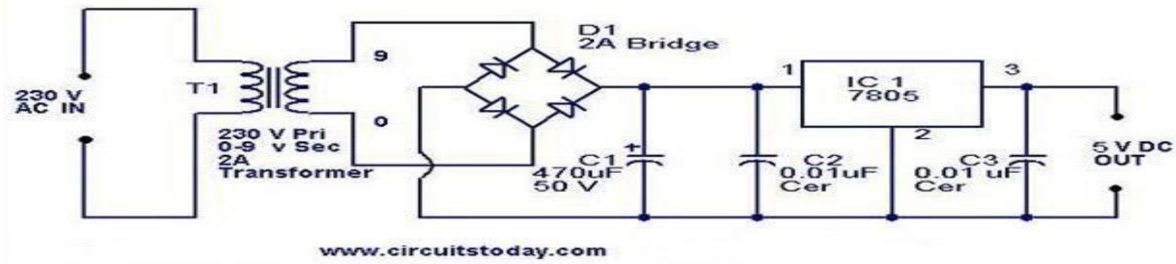

Figure 5.1.1.2 Schematic Diagram of Power Supply

Description of Power Supply:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

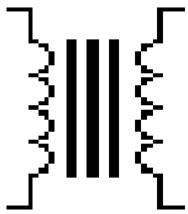

Figure 5.2.1 Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

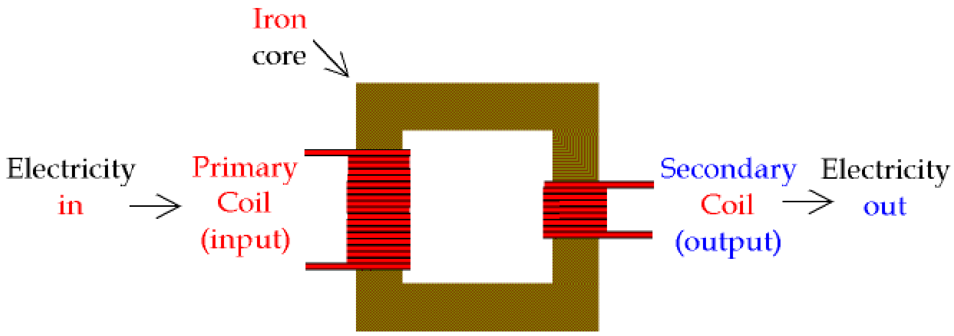

Figure 5.2.2 Transformer

Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

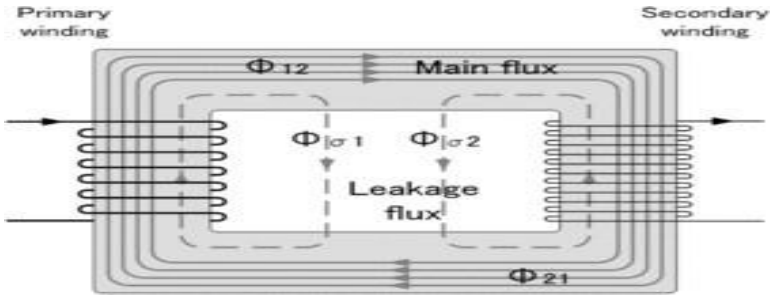

Figure 5.2.1.1 Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced E.M.F. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers is designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step-down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers is made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

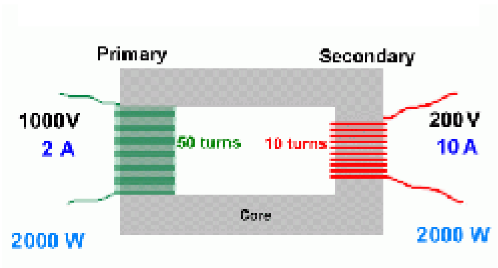

Figure 5.2.2.1 Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts, then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1kv and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step-down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step-up transformer is needed to use a 220v product in a country with a 110v supply. A step-up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So, a step-up transformer increases the voltage and a step-down transformer decreases the voltage.

The primary components for voltage transformation are the step-up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, Nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

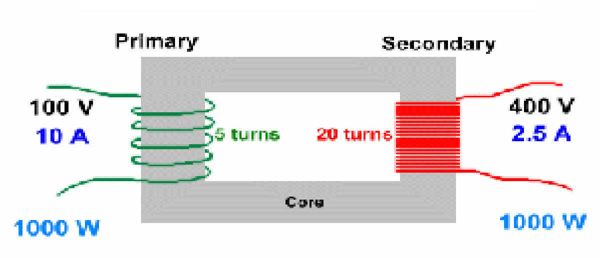

Figure 5.2.2.2 Step-Up Transformer

Diodes:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

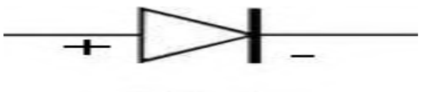

Figure 5.3.1 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

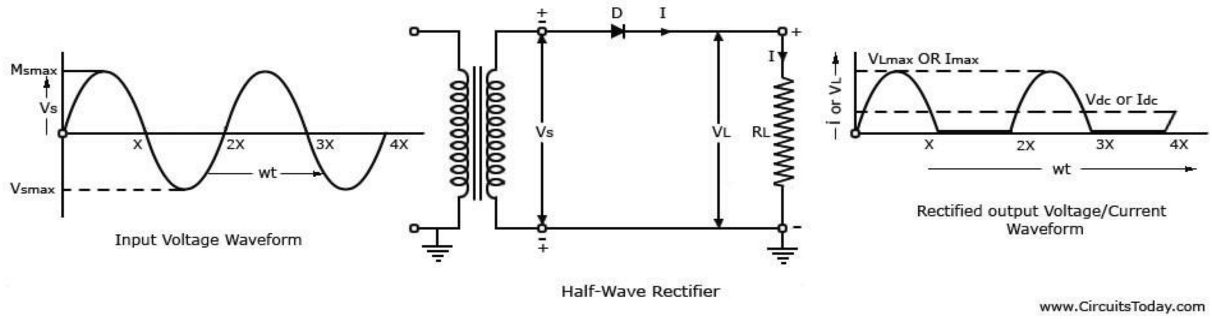

Figure 5.4.1 Half Wave Rectifier

Figure 5.4.1 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

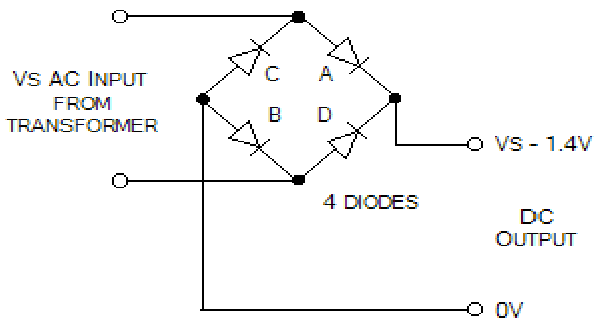

Figure 5.4.2 Full-Wave Rectifier

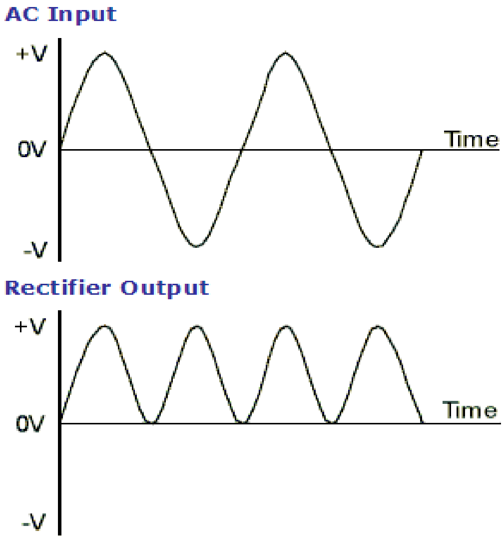

Figure 5.4.3 Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

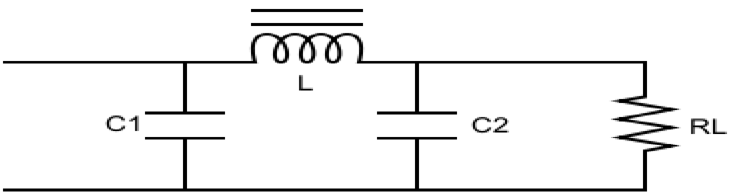

Figure 5.5.1 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result, the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

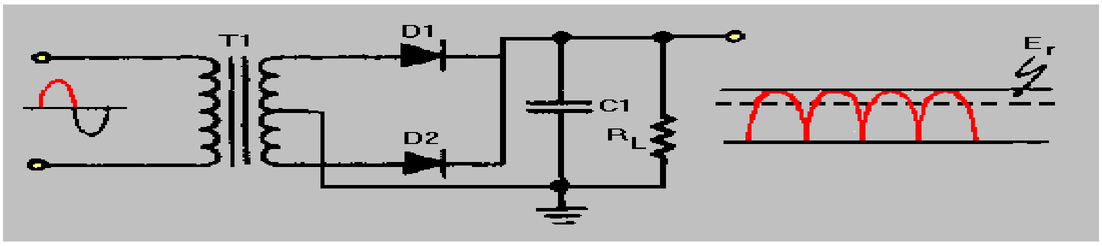

Figure 5.5.2 Centered Tapped Full-Wave Rectifier with a Capacitor Filter

Voltage Regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulators are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

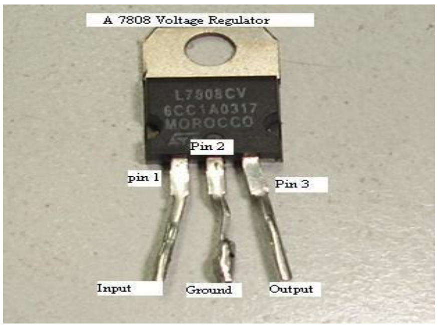

Figure 5.6.1 Regulator

HARDWARE

Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analogue or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

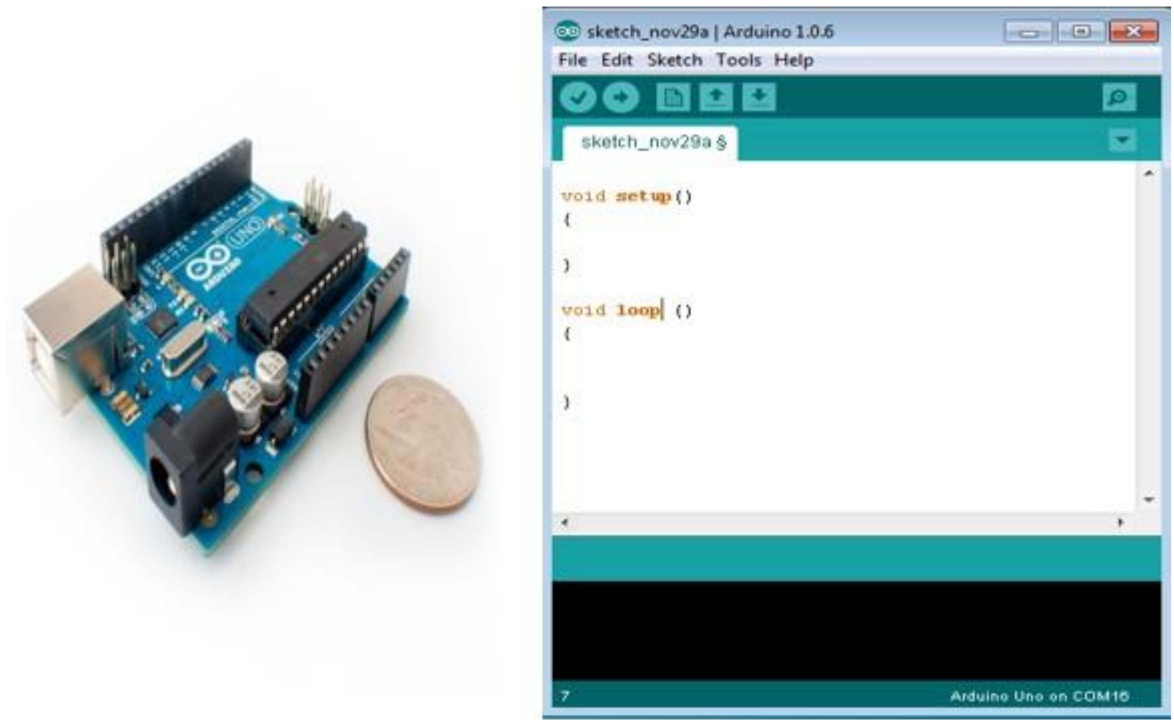

Figure 6.3.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Table 6.3.4 Arduino boards based on AT91SAM3X8E microcontroller

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

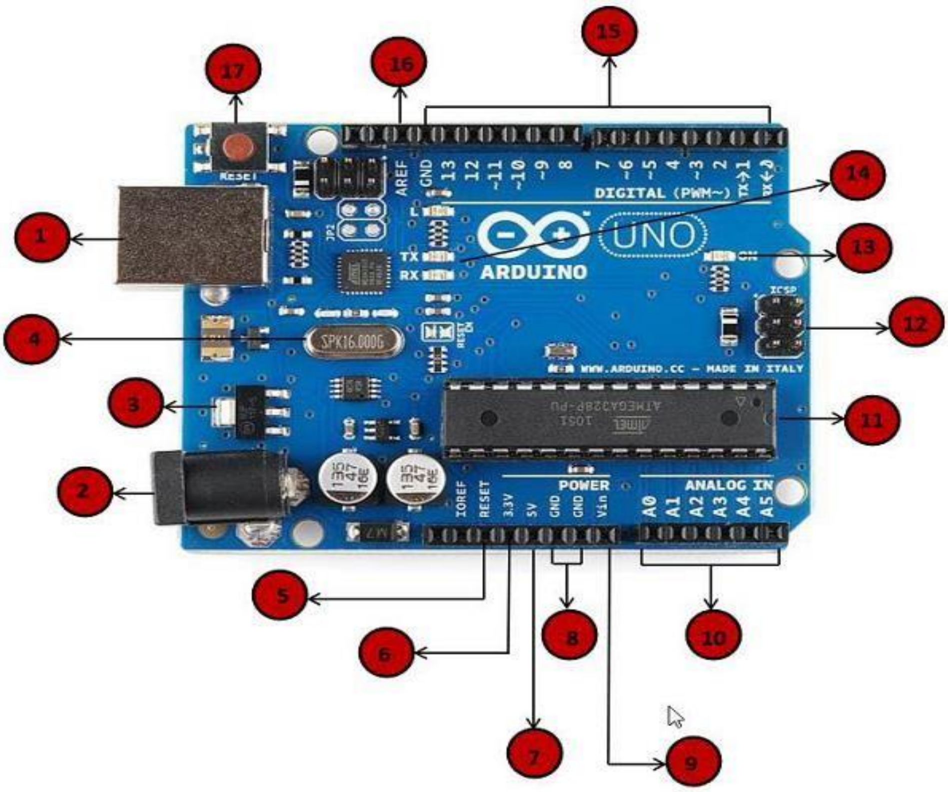

Figure 6.3.5 Arduino Board

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** 3.3V (6) − Supply 3.3 output volt 5V (7) − Supply 5 output volt Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.

11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

The term **solar panel** is used colloquially for a photo-voltaic **(PV) module**.

A PV module is an assembly of photo-voltaic cells mounted in a frame work for installation. Photo-voltaic cells use sunlight as a source of energy and generate direct current electricity. A collection of PV modules is called a PV Panel, and a system of Panels is an Array. Arrays of a photovoltaic system supply solar electricity to electrical equipment.

The most common application of solar energy collection outside agriculture is solar water heating systems.[1]

Photovoltaic modules use light energy (photons) from the Sun to generate electricity through the photovoltaic effect. Most modules use wafer-based crystalline silicon cells or thin-film cells. The structural (load carrying) member of a module can be either the top layer or the back layer. Cells must be protected from mechanical damage and moisture. Most modules are rigid, but semi-flexible ones based on thin-film cells are also available. The cells are connected electrically in series, one to another to a desired voltage, and then in parallel to increase amperage. The wattage of the module is the mathematical product of the voltage and the amperage of the module.

A PV junction box is attached to the back of the solar panel and functions as its output interface. External connections for most photovoltaic modules use MC4 connectors to facilitate easy weatherproof connections to the rest of the system. A USB power interface can also be used.

Module electrical connections are made in series to achieve a desired output voltage or in parallel to provide a desired current capability (amperes) of the solar panel or the PV system. The conducting wires that take the current off the modules are sized according to the ampacity and may contain silver, copper or other non-magnetic conductive transition metals. Bypass diodes may be incorporated or used externally, in case of partial module shading, to maximize the output of module sections still illuminated.

Some special solar PV modules include concentrators in which light is focused by lenses or mirrors onto smaller cells. This enables the use of cells with a high cost per unit area (such as gallium arsenide) in a cost-effective way.

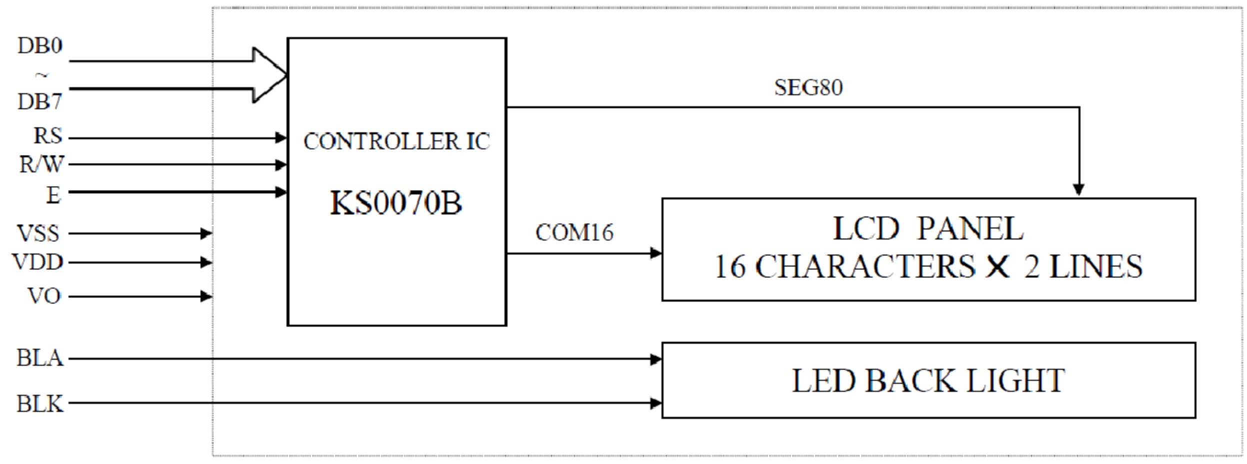
Solar panels also use metal frames consisting of racking components, brackets, reflector shapes, and troughs to better support the panel structure.[2]

16 * 2 Alphanumeric LCD

Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

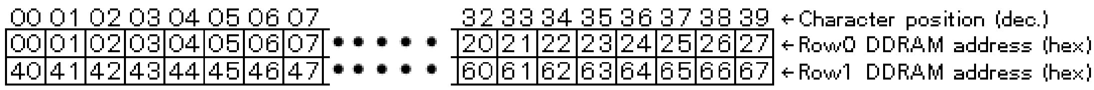
Block Diagram



Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. Userdefined character patterns are also available by mask-programmed ROM.

Busy Flag

Busy Flag is a status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

Instruction Register (IR) and Data Register (DR)

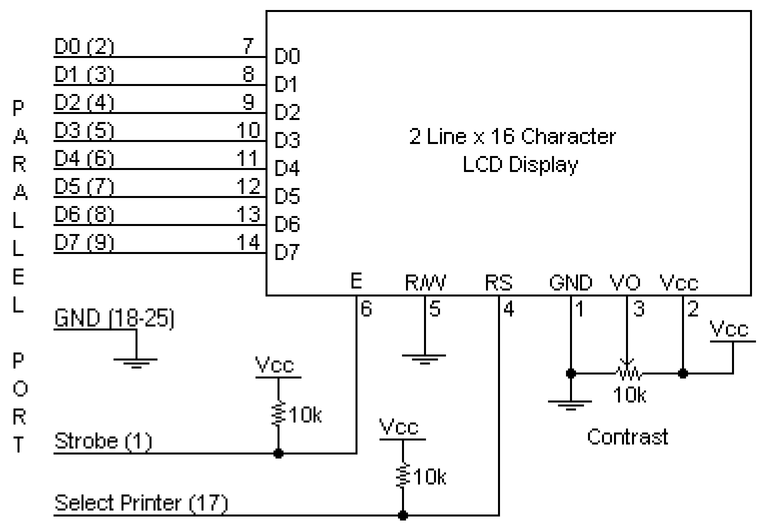
There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

Schematic



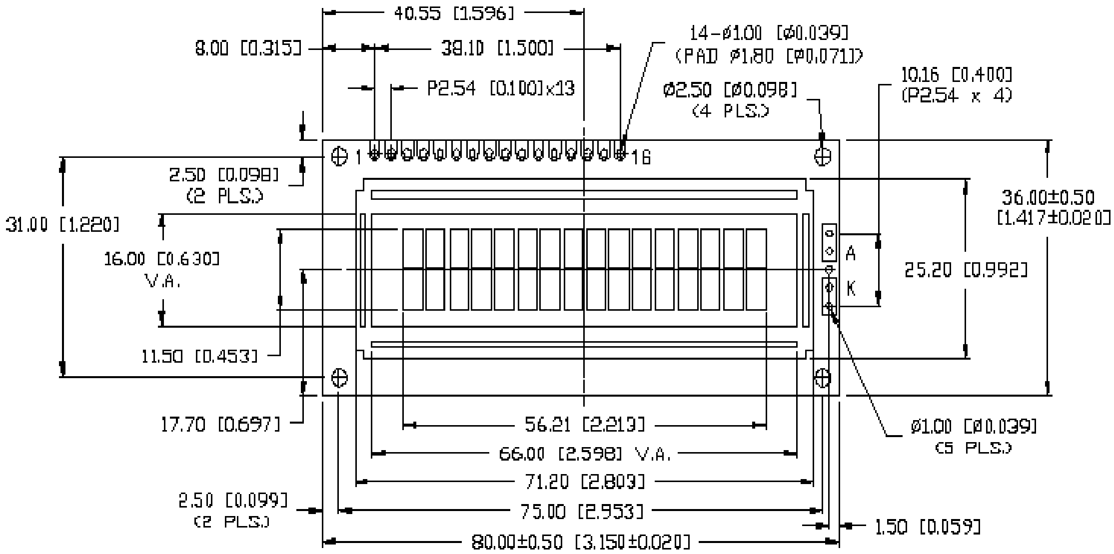
Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.

Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.



Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16-character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

Battery:

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and some kind of electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place. When the material in the cathode or anode is consumed or no longer able to be used in the reaction, the battery is unable to produce electricity. At that point, your battery is "dead." Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Figure 6.3.6 Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

Figure 6.3.7 Batteries come in a variety of shapes, sizes, and chemistries

History

The Term Battery

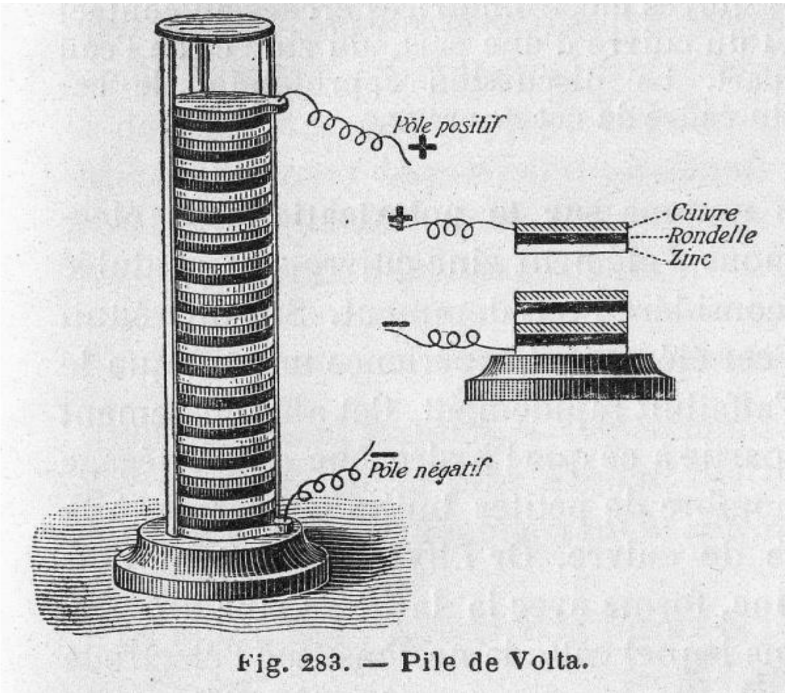
Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Battery of Leyden Jar "capacitors" linked together (Image courtesy of Alvin rune of Wikimedia Commons)

Invention of the Battery

One fateful day in 1780, Italian physicist, physician, biologist, and philosopher, Luigi Galvani, was dissecting a frog attached to a brass hook. As he touched the frog's leg with an iron scapel, the leg twitched. Galvani theorized that the energy came from the leg itself, but his fellow scientist, Alessandro Volta, believed otherwise.

Volta hypothesized that the frog's leg impulses were actually caused by different metals soaked in a liquid. He repeated the experiment using cloth soaked in brine instead of a frog corpse, which resulted in a similar voltage. Volta published his findings in 1791 and later created the first battery, the voltaic pile, in 1800.



The voltaic pile consisted of a stack of zinc and copper plates separated by cloth soaked in brine. Volta's pile was plagued by two major issues: the weight of the stack caused the electrolyte to leak out of the cloth, and the particular chemical properties of the components resulted in a very short life span (about an hour). The next two hundred years would be spent perfecting Volta's design and solving these issues.

Fixes to the Voltaic Pile

William Cruickshank of Scotland solved the leakage problem by laying the voltaic pile on its side to form the "trough battery."

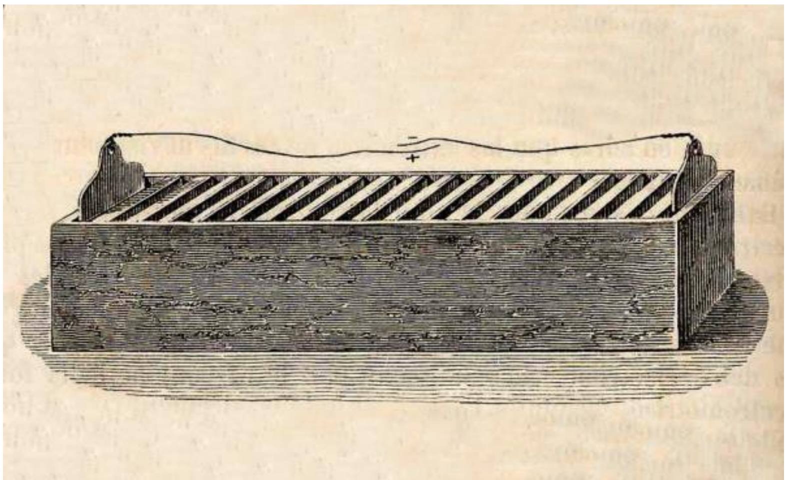


Figure 6.3.8 The trough battery solved the leakage problem of the voltaic pile

The second problem, short life span, was caused by the degradation of the zinc due to impurities and a build-up of hydrogen bubbles on the copper. In 1835, William Sturgeon discovered that treating the zinc with mercury would prevent degradation.

The British chemist John Frederic Daniell used a second electrolyte that reacted with the hydrogen, preventing buildup on the copper cathode. Daniell's two-electrolyte battery, known as the "Daniell cell," would become a very popular solution to providing power to the budding telegraph networks.

Figure 6.3.9 A collection of Daniell cells from 1836

The First Rechargeable Battery

In 1859, the French physicist Gaston Planté created a battery using two rolled sheets of lead submerged in sulfuric acid. By reversing the electrical current through the battery, the chemistry would return to its original state, thus creating the first rechargeable battery.

Later, in 1881, Camille Alphonse Faure improved Planté's design by forming the lead sheets into plates. This new design made the batteries easier to manufacture, and the lead acid battery saw wide-spread use in automobiles.

-> The design for the common "car battery" has been around for more than 100 years (Image courtesy of Emilian Robert Vicol of Wikimedia Commons).

The Dry Cell

Up until the late 1800s, the electrolyte in batteries was in a liquid state. This made battery transportation a very careful endeavor, and most batteries were never intended to be moved once attached to the circuit.

In 1866, Georges Leclanché created a battery using a zinc anode, a manganese dioxide cathode, and an ammonium chloride solution for the electrolyte. While the electrolyte in the Leclanché cell was still a liquid, the battery's chemistry proved to be an important step for the invention of the dry cell.

Carl Gassner figured out how to create an electrolyte paste out of ammonium chloride and Plaster of Paris. He patented the new "dry cell" battery in 1886 in Germany.
These new dry cells, commonly called "zinc-carbon batteries," were massed produced and proved hugely popular until the late 1950s. While carbon is not used in the chemical reaction, it performs an important role as an electrical conductor in the zinc-carbon battery.

-> 3V zinc-carbon battery from the 1960s (Image courtesy of PhFabre of Wikimedia Commons)

<- In the 1950s, Lewis Urry, Paul Marsal, and Karl Kordesch of the Union Carbide company (later known as "Eveready" and then "Energizer") replaced the ammonium chloride electrolyte with an alkaline substance, based on the battery chemistry formulated by Waldemar Jungner in 1899. Alkaline dry cell batteries could hold more energy than zinc carbon batteries of the same size and had a longer shelf life.

Alkaline batteries rose in popularity in the 1960s, overtook zinc-carbon batteries, and have since become the standard primary cell for consumer use.

-> Alkaline batteries come in many shapes and sizes (Image courtesy of Aney~commonswiki of Wikimedia Commons).

20th Century Rechargeable Batteries

In the 1970s, COMSAT developed the nickel-hydrogen battery for use in communication satellites. These batteries store hydrogen in a pressurized, gaseous form. Many man-made satellites, like the International Space Station, still rely on nickel-hydrogen batteries.

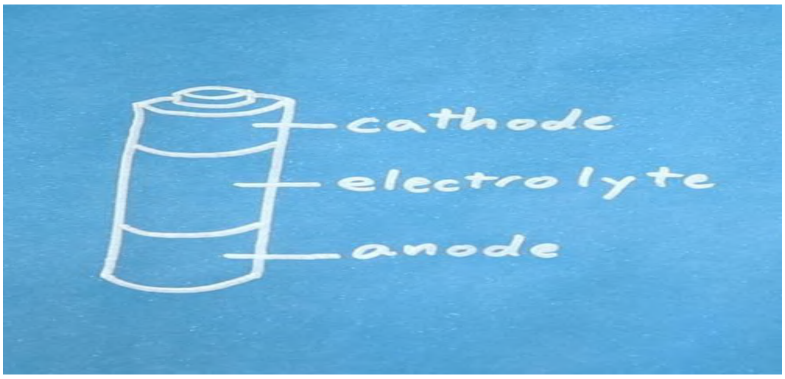
The research of several companies since the late 1960s resulted in the creation of the nickel-metal hydride (NiMH) battery. NiMH batteries were released to the consumer market in 1989, and provided a smaller, cheaper alternative to the rechargeable nickel-hydrogen cells.

Asahi Chemical of Japan built the first lithium-ion battery in 1985, and Sony created the first commercial lithium-ion battery in 1991. In the late 1990s, a soft, flexible casing was created for lithium-ion batteries and gave rise to the "lithium polymer" or "LiPo" battery.

The chemical reactions in the lithium polymer battery are essentially the same as those in the lithium-ion battery. Obviously, many more battery chemistries have been invented, manufactured, and become obsolete. If you would like to read more about modern, popular battery technologies, check out our Battery Technologies tutorial.

Components

Batteries are made up of three basic components: an **anode**, a **cathode**, and an **electrolyte**. A **separator** is often used to prevent the anode and cathode from touching, if the electrolyte is not sufficient. In order to store these components, batteries usually have some kind of **casing**.



OK, most batteries are not actually divided up in three equal sections, but you get the idea. A better cross-section of an alkaline cell can be found on Wikipedia.

Both the anode and cathode are types of **electrodes**. Electrodes are conductors through which electricity enters or leaves a component in a circuit.

Anode

Electrons flow out from the anode in a device connected to a circuit. This means that conventional "current" flows into an anode.

Figure 6.3.10 On batteries, the anode is marked as the negative (-) terminal

In a battery, the chemical reaction between the anode and electrolyte causes a build up of electrons in the anode. These electrons want to move to the cathode, but cannot pass through the electrolyte or separator.

Cathode

Electron's flow into the cathode in a device connected to a circuit. This means that conventional "current" flows out from a cathode.

Figure 6.3.11 On batteries, the cathode is marked as the positive (+) terminal

In batteries, the chemical reaction in or around the cathode uses the electrons produced in the anode. The only way for the electrons to get to the cathode is through a circuit, external to the battery.

Electrolyte

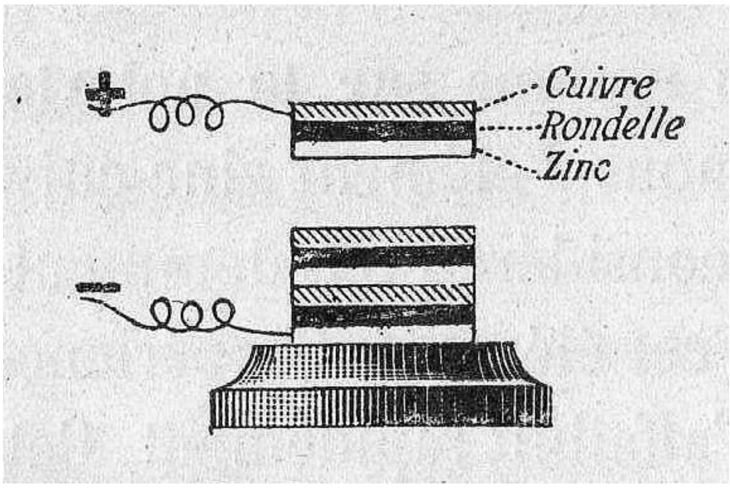
The electrolyte is the substance, often a liquid or gel, that is capable of transporting ions between the chemical reactions that happen at the anode and cathode. The electrolyte also inhibits the flow of electrons between the anode and cathode so that the electrons more easily flow through the external circuit rather than through the electrolyte.

-> Alkaline batteries can leak their electrolyte, potassium hydroxide, if subjected to high heat or reverse voltage (Image courtesy of Wiliam Davies of Wikimedia Commons)

<- The electrolyte is crucial in the operation of a battery. Because electrons cannot pass through it, they are forced to travel through electrical conductors in the form of a circuit that connect the anode to the cathode.

Separator

Separators are porous materials that prevent the anode and cathode from touching, which would cause a short circuit in the battery. Separators can be made from a variety of materials, including cotton, nylon, polyester, cardboard, and synthetic polymer films. Separators do not chemically react with either the anode, cathode, or electrolyte.



The voltaic pile used cloth or cardboard (separator) soaked in brine (electrolyte) to keep the electrodes apart. Ions in the electrolyte can be positively charged, negatively charged, and can come in a variety of sizes. Special separators can be manufactured that allow some ions to pass but not others.

Casing

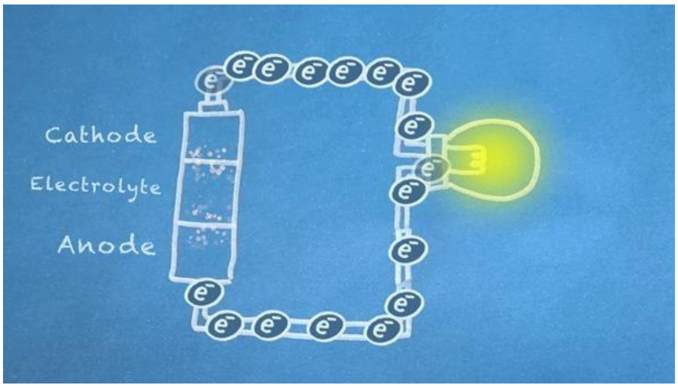
Most batteries need a way to contain their chemical components. Casings, otherwise known as "housings" or "shells," are simply mechanical structures meant to hold the battery's internals.

Figure 6.3.12 This lead-acid battery has a plastic casing

Battery casings can be made of almost anything: plastic, steel, soft polymer laminate pouches, and so on. Some batteries use a conducting steel casing that is electrically connected to one of the electrodes. In the case of the common AA alkaline cell, the steel casing is connected to the cathode.

Operation

Batteries generally require several chemical reactions in order to operate. At least one reaction occurs in or around the anode and one or more reactions occur in or around the cathode. In all cases, the reaction at the anode produces extra electrons in a process called **oxidation**, and the reaction at the cathode uses the extra electrons during a process known as **reduction**.



When the switch is closed, the circuit is complete, and electrons can flow from the anode to the cathode. These electrons enable the chemical reactions at the anode and cathode.

In essence, we are separating a certain kind of chemical reaction, a reduction-oxidation reaction or redox reaction, into two separate parts. Redox reactions occur when electrons are transferred between chemicals. We can harness the movement of electrons in this reaction to flow outside the battery to power our circuit.

Anode Oxidation

This first part of the redox reaction, oxidation, occurs between the anode and electrolyte, and it produces electrons (marked as e^-).

Some oxidation reactions produce ions, such as in a lithium-ion battery. In other chemistries, the reaction consumes ions, like in the common alkaline battery. In either case, ions are able to flow freely through the electrolyte where electrons cannot.

Cathode Reduction

The other half of the redox reaction, reduction, occurs in or near the cathode. Electrons produced by the oxidation reaction are consumed during reduction.

In some cases, like lithium-ion batteries, positively charged lithium ions produced during the oxidation reaction are consumed during reduction. In other cases, like alkaline batteries, negatively charged ions are produced during reduction.

Electron Flow

In most batteries, some or all of the chemical reactions can occur even when the battery is not connected to a circuit. These reactions can impact a battery's shelf life.

For the most part, the reactions will only occur at full force when an electrically conductive circuit is completed between the anode and cathode. The less resistance between the anode and cathode, the more electrons are allowed to flow, and the quicker the chemical reactions occur.

Sensor:

A sensor (also called detectors) is a device that measures a measurable attribute and converts it into a signal which can be read by an observer or by an instrument. For example, a mercury-in-glass thermometer converts the measured temperature into expansion and contraction of a liquid which can be read on a calibrated glass tube. A thermocouple converts temperature to an output voltage which can be read by a voltmeter.

Temperature Sensor:

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range.

The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 µA from its supply, it has very low self-heating, less than 0.1°C in still air.

Features

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts

- Less than 60 µA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

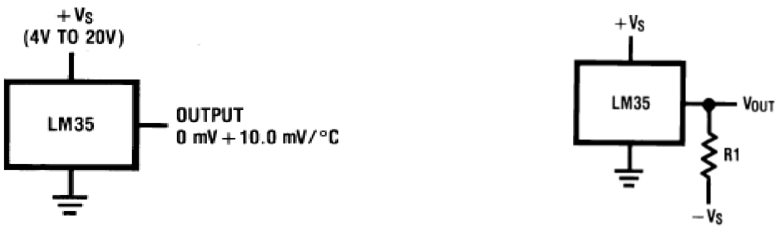


Figure 6.3.13 Temperature Sensor

LM35:

- ➢ LM35 is precision integrated circuit temperature sensor. Its output voltage is linearly proportional to temperature (in Celsius).
- ➢ The LM35 thus has an advantage over linear temperature sensors calibrated in° Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range
- ➢ It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 µA from its supply, it has very low self-heating, less than 0.1°C in still air.

The characteristic of this LM35 sensor is:

For each degree of centigrade temperature, it outputs 10milli volts. ADC accepts the output from LM35 and converts that data into digital form which is sent to microcontroller for further processing.

Temperature Sensing Circuit

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact. In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

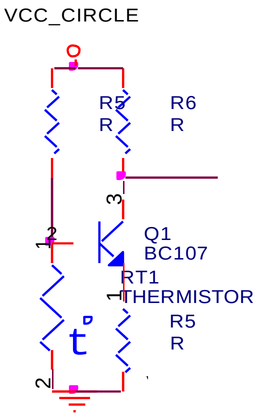

Figure 6.3.14 Temperature Sensing Circuit

Light Dependent Resistor

A photoresistor or light dependent resistor or cadmium sulfide (CdS) cell is a resistor whose resistance decreases with increasing incident light intensity. It can also be referred to as a photoconductor.

A photo resistor is made of a high resistance semiconductor. If light falling on the device is of high enough frequency, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, thereby lowering resistance.

A photoelectric device can be either intrinsic or extrinsic. An intrinsic semiconductor has its own charge carriers and is not an efficient semiconductor, e.g. silicon. In intrinsic devices the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electron across the entire bandgap. Extrinsic devices have impurities, also called dopants, added whose ground state energy is closer to the conduction band; since the electrons do not have as far to jump, lower energy photons (i.e., longer wavelengths and lower frequencies) are sufficient to trigger the device. If a sample of silicon has some of its atoms replaced by phosphorus atoms (impurities), there will be extra electrons available for conduction. This is an example of an extrinsic semiconductor.

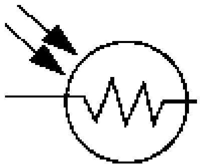

Figure 6.3.15 The symbol for a photoresistor

Applications:

Photoresistors come in many different types. Inexpensive cadmium sulfide cells can be found in many consumer items such as camera light meters, street lights, clock radios, alarms, and outdoor clocks.

They are also used in some dynamic compressors together with a small incandescent lamp or light emitting diode to control gain reduction.

Lead sulfide (PbS) and indium antimonide (InSb) LDRs (light dependent resistor) are used for the mid infrared spectral region. Ge:Cu photoconductors are among the best far-infrared detectors available, and are used for infrared astronomy and infrared spectroscopy.

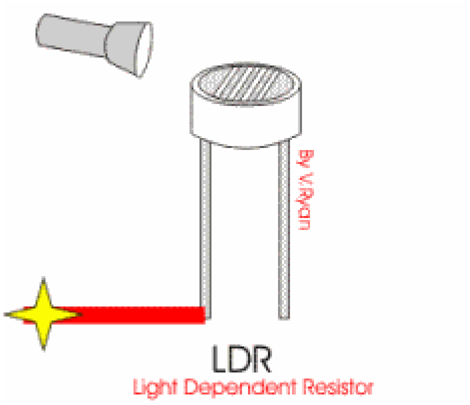
Transducers are used for changing energy types.

Figure 6.3.16 A light dependent resistor

A light dependent resistor is a small, round semiconductor. Light dependent resistors are used to re-charge a light during different changes in the light, or they are made to turn a light on during certain changes in lights. One of the most common uses for light dependent resistors is in traffic lights. The light dependent resistor controls a built in heater inside the traffic light, and causes it to recharge overnight so that the light never dies. Other common places to find light dependent resistors are in: infrared detectors, clocks and security alarms.

LDRs or Light Dependent Resistors are very useful especially in light/dark sensor circuits. Normally the resistance of an LDR is very high, sometimes as high as 1000 000 ohms, but when they are illuminated with light resistance drops dramatically.

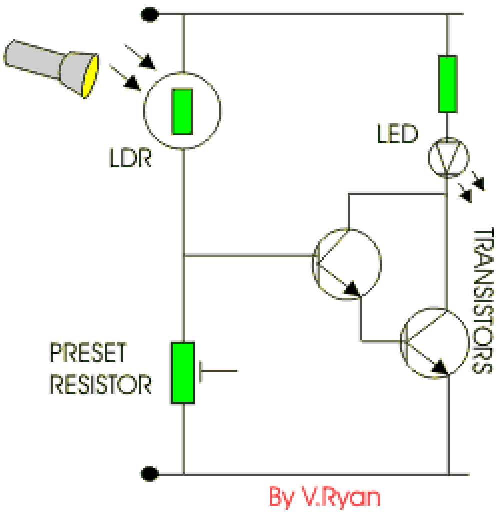
The animation opposite shows that when the torch is turned on, the resistance of the LDR falls, allowing current to pass through it.



Circuit Wizard software has been used to display, the range of values of a ORP12, LDR.

When a light level of 1000 lux (bright light) is directed towards it, the resistance is 400R (ohms).

When a light level of 10 lux (very low light level) is directed towards it, the resistance has risen dramatically to 10.43M (10430000 ohms).



This is an example of a light sensor circuit:

When the light level is low the resistance of the LDR is high. This prevents current from flowing to the base of the transistors. Consequently, the LED does not light.

However, when light shines onto the LDR its resistance falls and current flows into the base of the first transistor and then the second transistor. The LED lights.

The present resistor can be turned up or down to increase or decrease resistance, in this way it can make the circuit more or less sensitive.

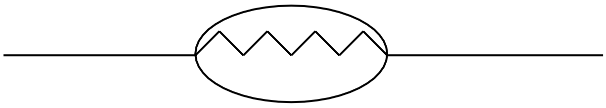


Figure 6.3.17 Schematic Symbol of LDR

The photo resistor, or Light Dependent Resistor, finds many uses as a low cost photo sensitive element and was used for many years in photographic light meters as well as other applications. Such as flame, smoke, and burgler detectors, card readers and lighting controls for street lamps.

Units for the light intensity are Lux or Lumence.

Basic structure:

Although there are many ways in which LDR's or photo resistors can be manufactured, ther are naturally a few more common methods that are seen. Essentially the LDR or photo resistor consists of a resistive material sensitive to light that is exposed to light. The photo resistive element comprises section of material with contacts at either end. Although many of the material used for light dependent resistors are semiconductors, when used as photo resistors, they are used only as a resistive element and there are no p-n junctions. Accordingly the devices purely passive.

A typical structure for a Light Dependent Resistor uses an active semiconductor layer that is deposited on an insulating substrate. The semiconductor is normally lightly doped to enable it to have the required level of conductivity. Contacts then placed either side of the exposed area. In many instances the area between the contacts is in the form of zig zag, or inter digital pattern. This maximizes the exposed area and by keeping the distance between the contacts small it enhances the gain.

It also possible to use a poly crystalline semiconductor that is deposited onto a substrate such as ceramic. This makes for a very low cost light dependent resistor.

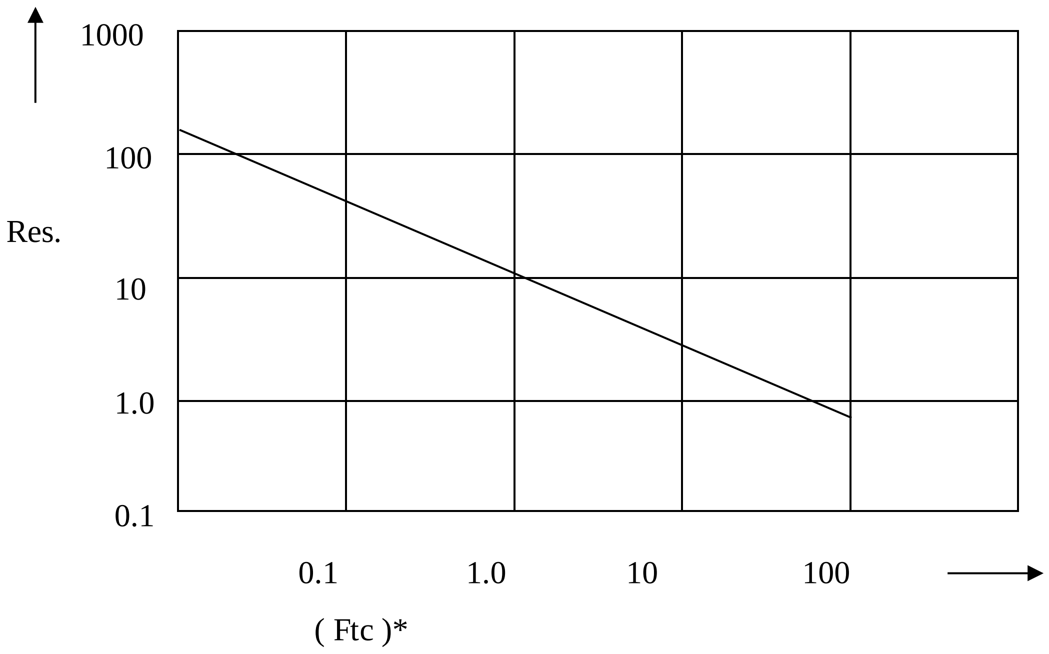
Operation:

Light Dependent Resistor made of a high resistance semiconductor, if light falling on the is of high enough efficiently, photon absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, thereby lowering resistance.

In intrinsic devices, the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electrons across the entire band gap. Extrinsic devices have impurities added, which have a ground state energy closer to the conduction band, since the electrons don't have so far to jump, lower energy photons (i.e. longer wavelengths and lower frequencies) will suffice to trigger the device.

Characteristics of LDR:

The characteristics of LDR are shown below. Here the resistance variations are shown as a function of illumination. The resistance of LDR decreases with increasing incident light



*1 Ftc = 10.764 lumens

Figure 6.3.18 Characteristics of LDR

LDR Applications:

LDR’s are very useful especially in light/dark sensor circuits. Normally the resistance of LDR is very high, sometimes as high as 1000k ohms, but when they are illuminated with light, resistance drops immediately.

1. Camera light meters.
2. Clock radios.
3. Security alarms.
4. Optical switches.
5. Far infrared detector.
6. Streetlights.

Testing circuit of LDR:

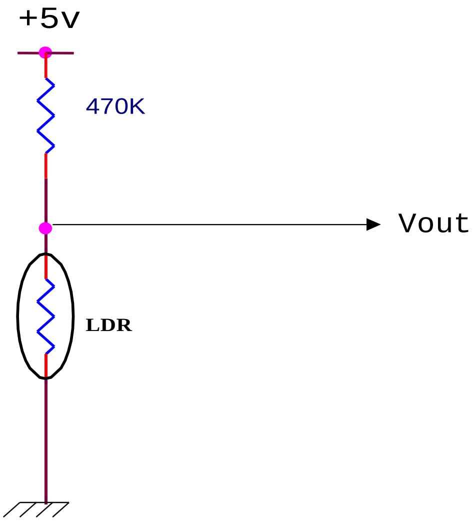


Figure 6.4.1 Testing Circuit of LDR

Voltage Monitoring Circuit

Transformer failures have many causes and one of the main causes is over voltage. The primary of the distribution transformer or any other transformer primary is designed to operate at certain specific voltage, if that voltage is more than the rated voltage, then immediately the transformer primary may burn because of over voltage. To protect the transformer, burning due to over voltage, this voltage monitoring circuit is used in this project work.

In this project work for generating high voltage, autotransformer is used so that the line voltage can be increased to more than 240V. For monitoring the line voltage, a step-down transformer of 3V secondary is used as a line voltage sensor. As this transformer primary voltage increases, according to that secondary voltage also raises, and this secondary voltage is rectified, filtered and it is applied to the analog to digital converter for converting the analog information in to the digital information.

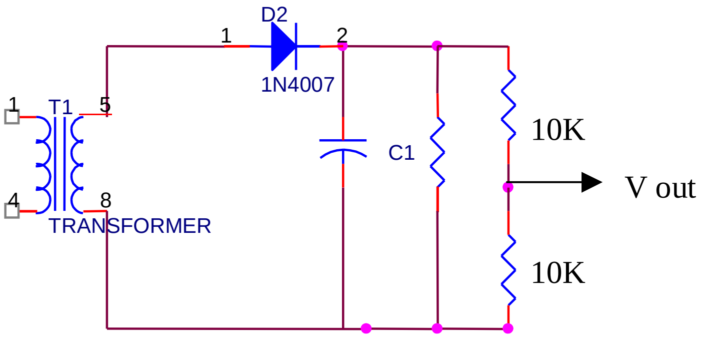

Figure 6.4.2 Schematic of Voltage Monitoring Circuit

CHAPTER 7
SOFTWARE EXPLINATION

Software Explanation:

Software Requirements

- Proteus simulation
- Arduino software
- Programming language

Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals
- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open-source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own

version

- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-
- Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software (IDE)
- ✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

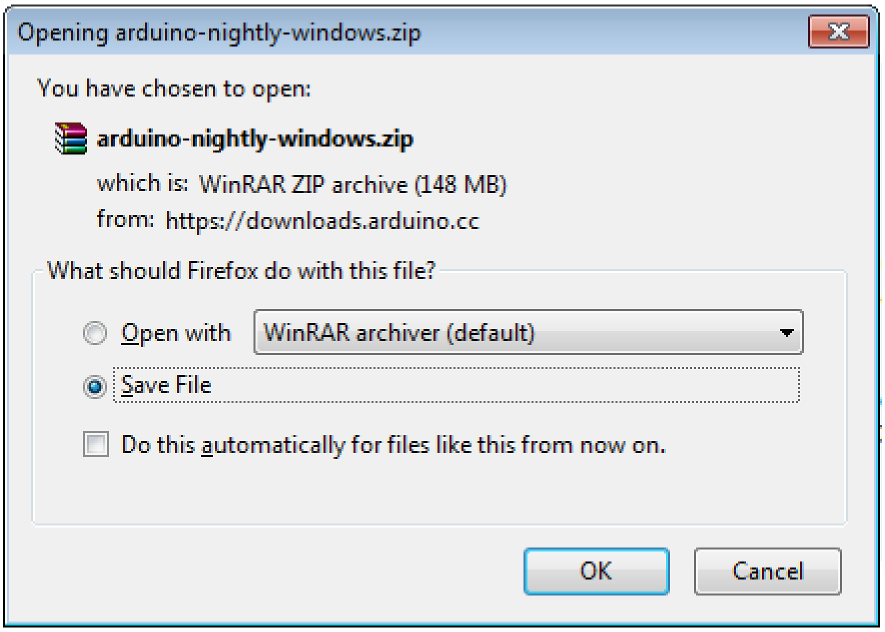
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



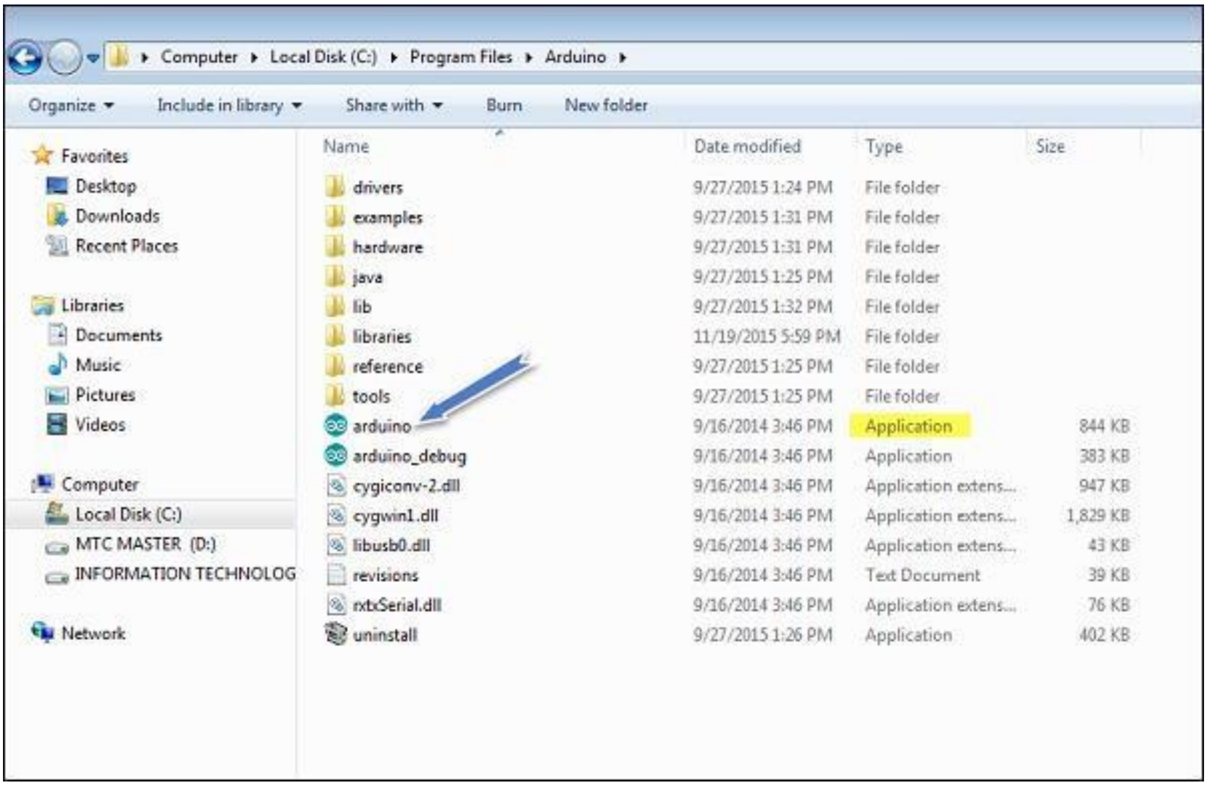
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

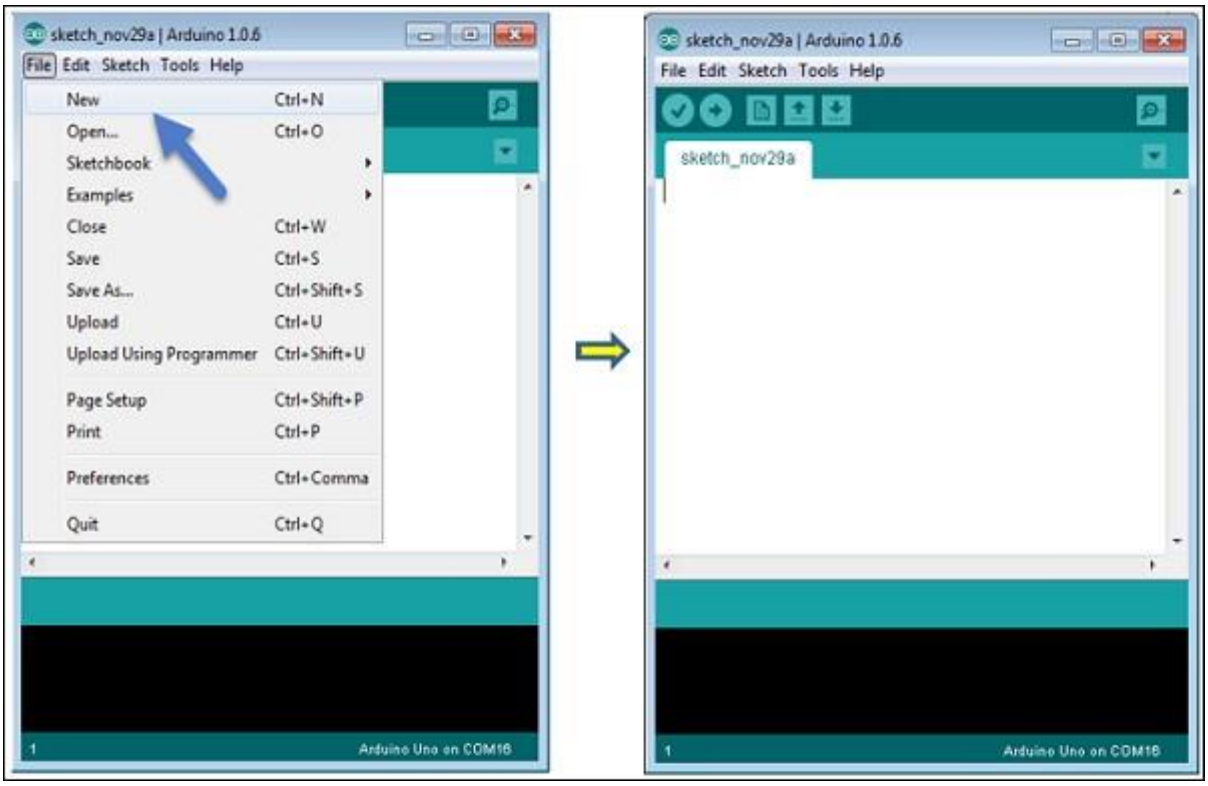


Step 5 − Open your first project.

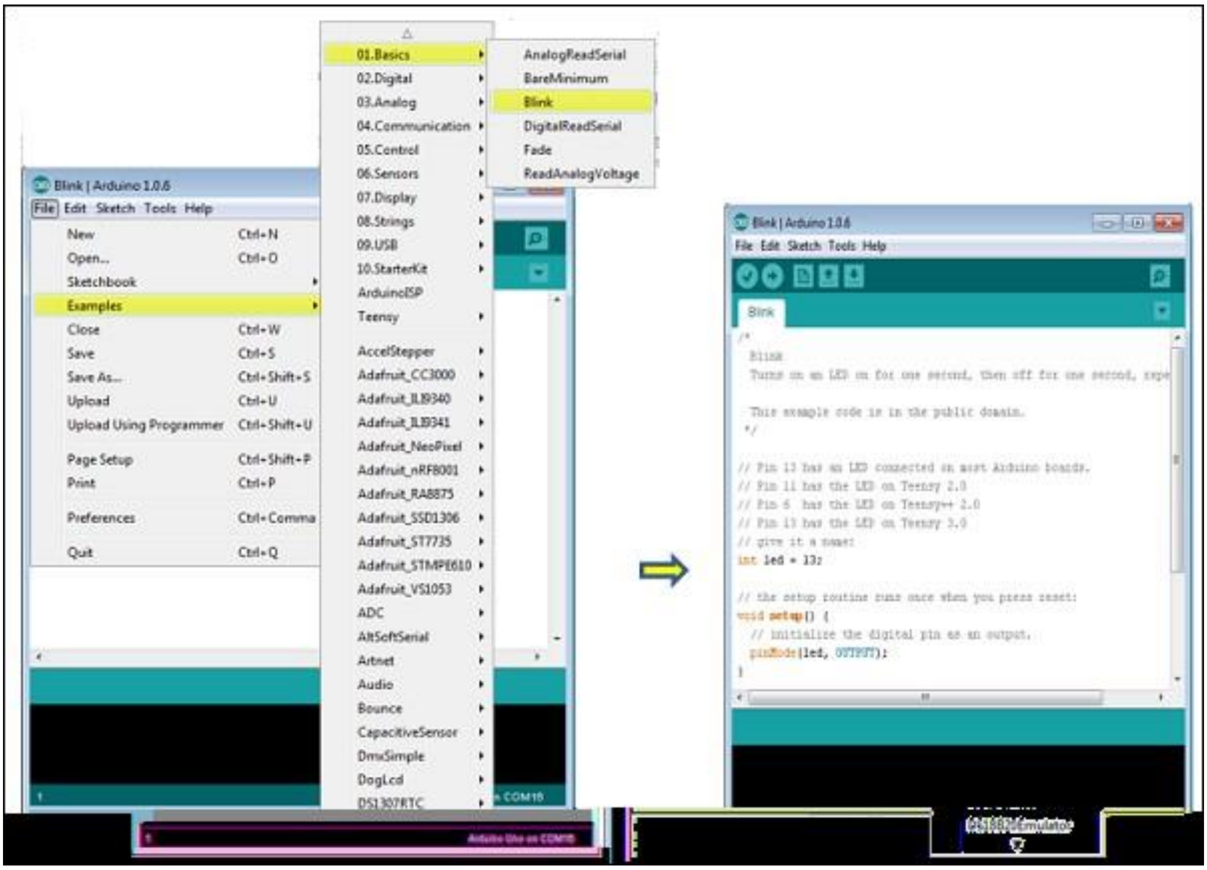
Once the software starts, you have two options

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

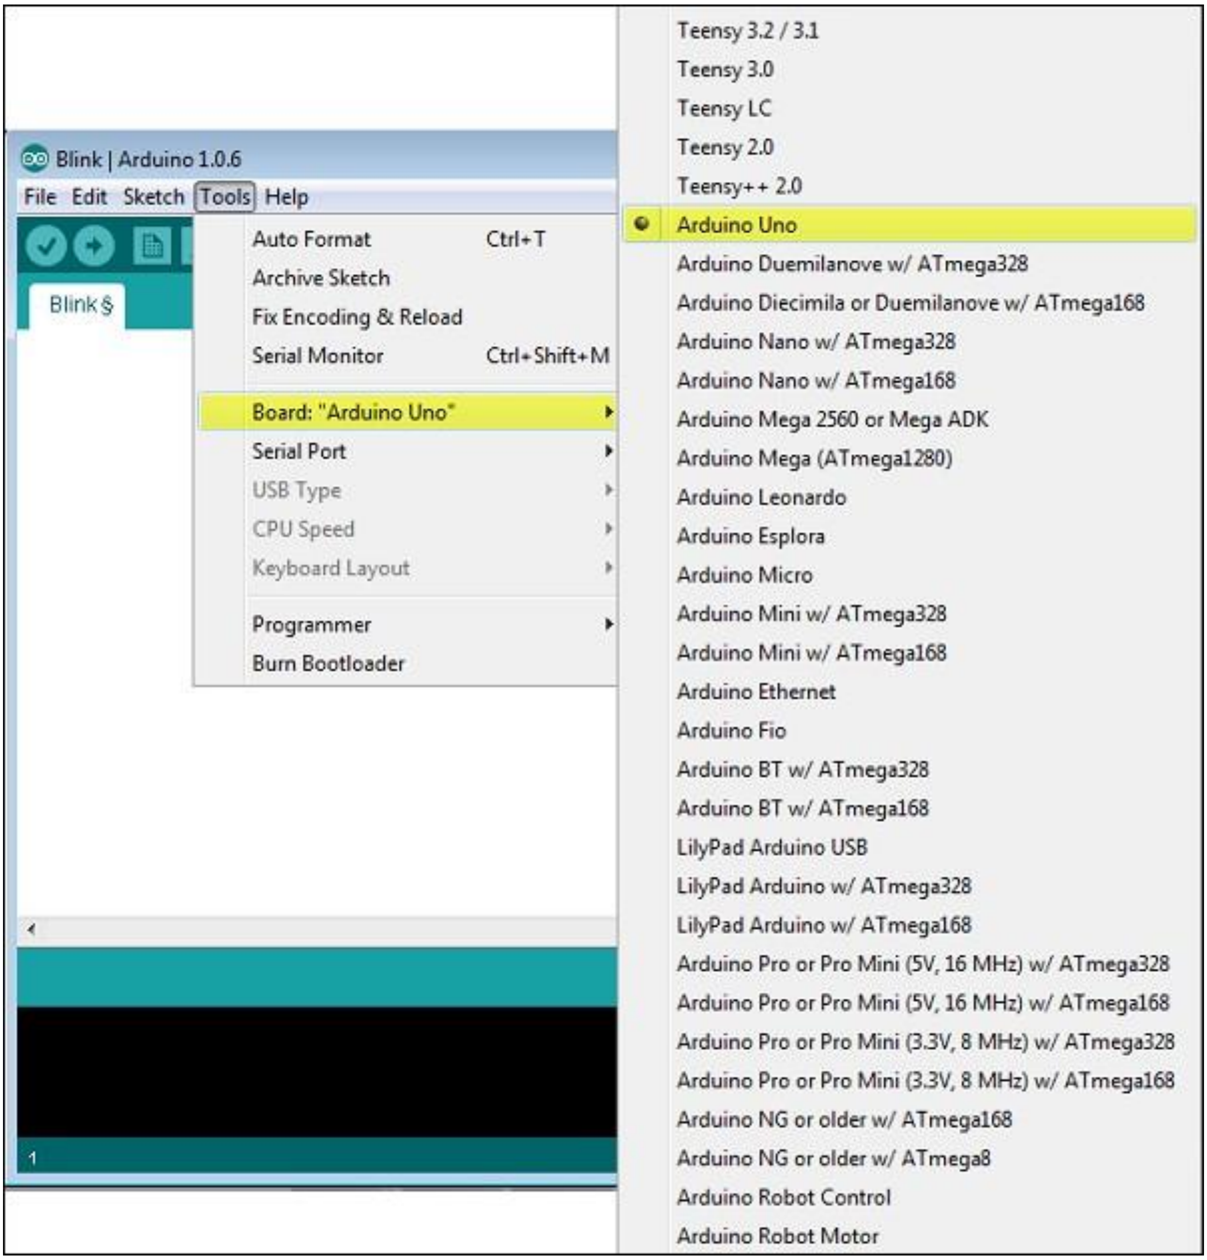


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

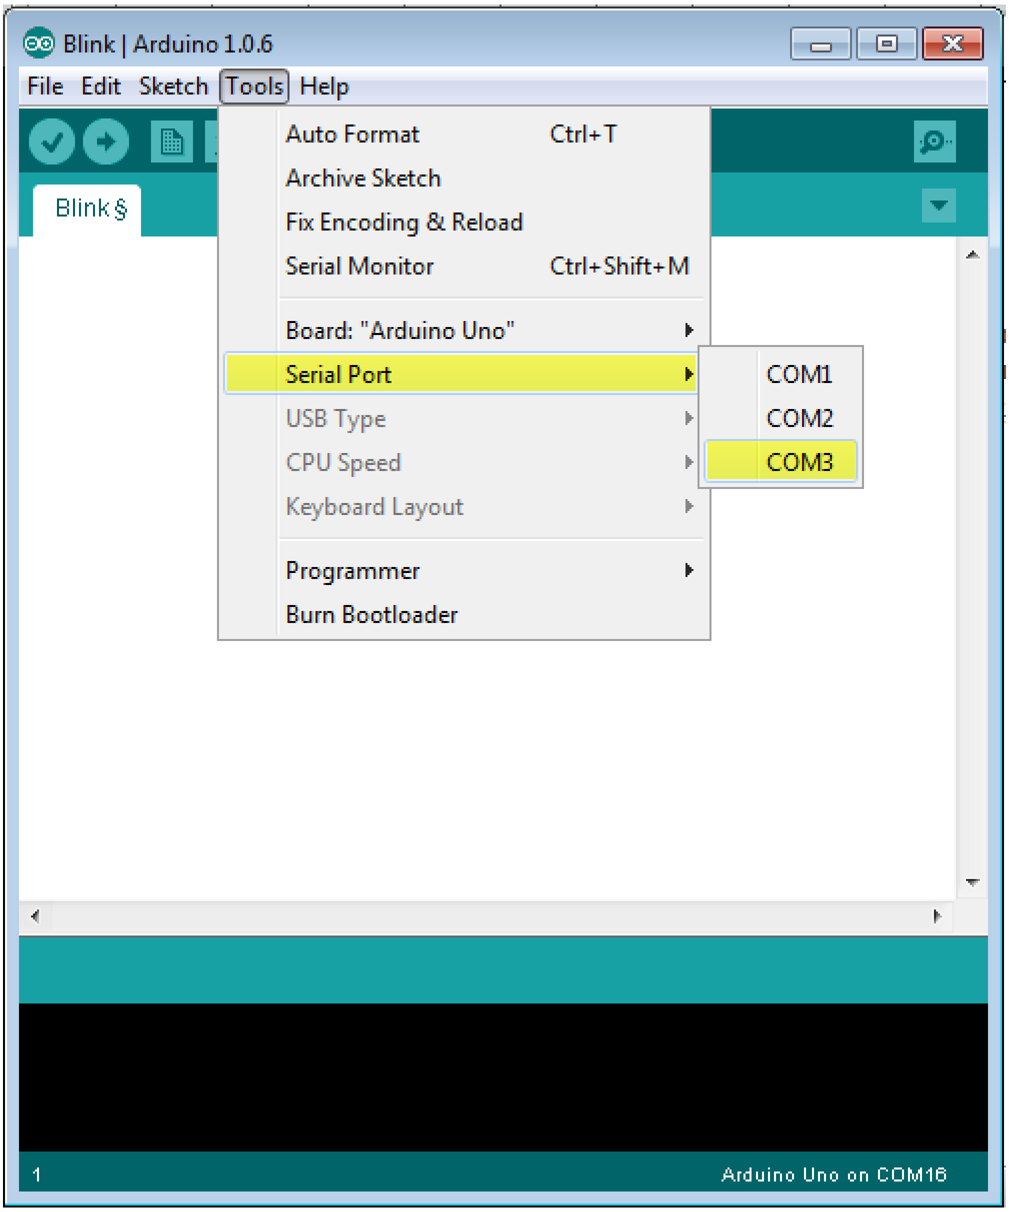


Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

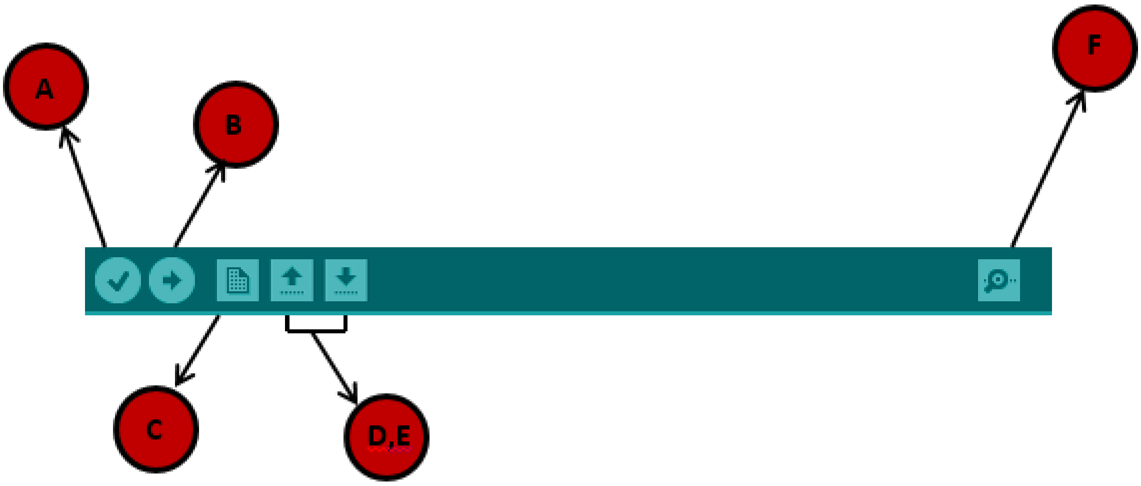
Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports).

To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

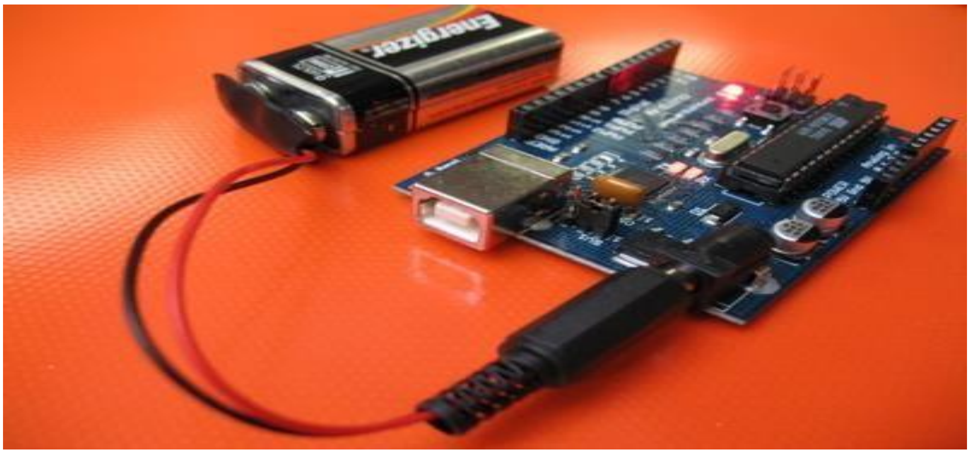


Figure 7.1.1.1 Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

Proteus:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus:

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features:

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select new design in File menu

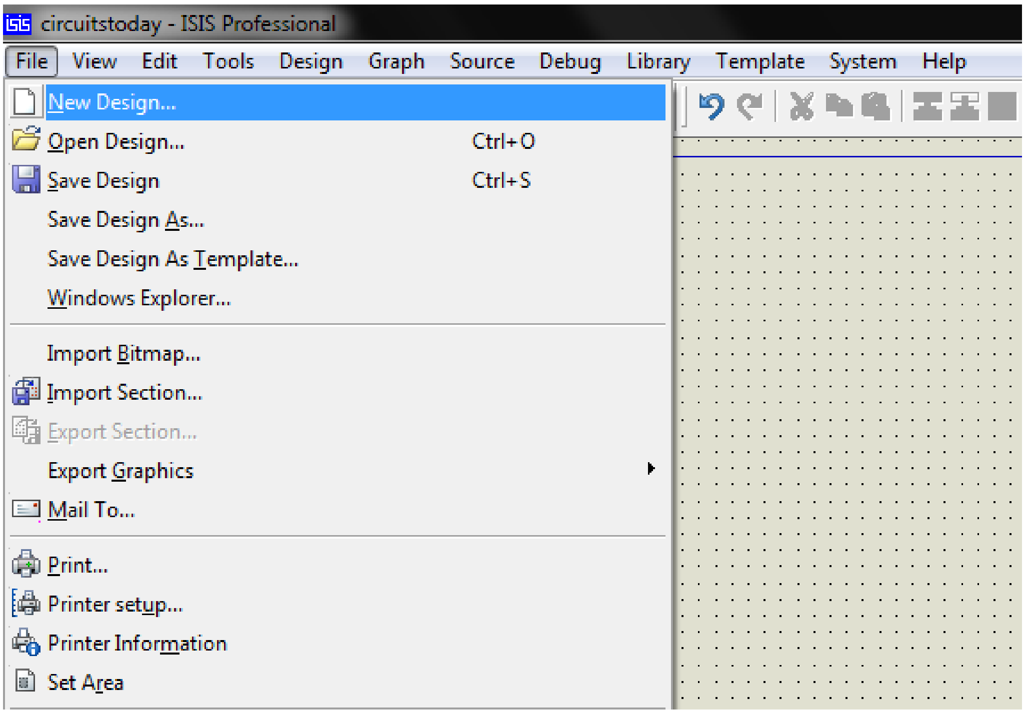

Figure 7.3.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

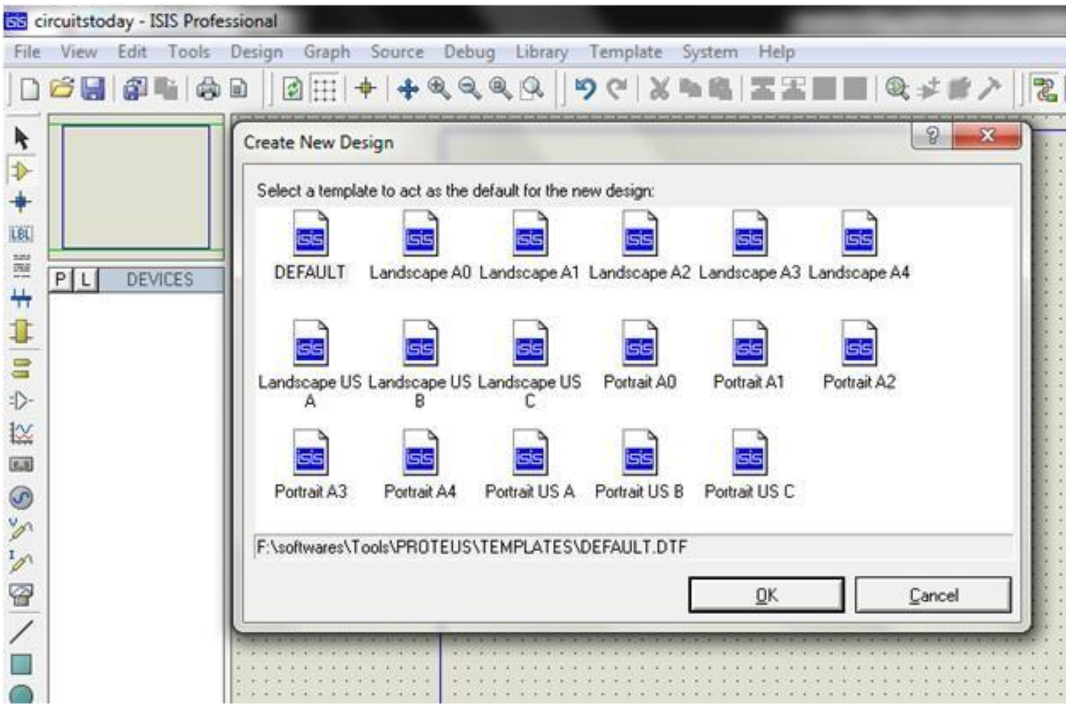

Figure 7.3.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

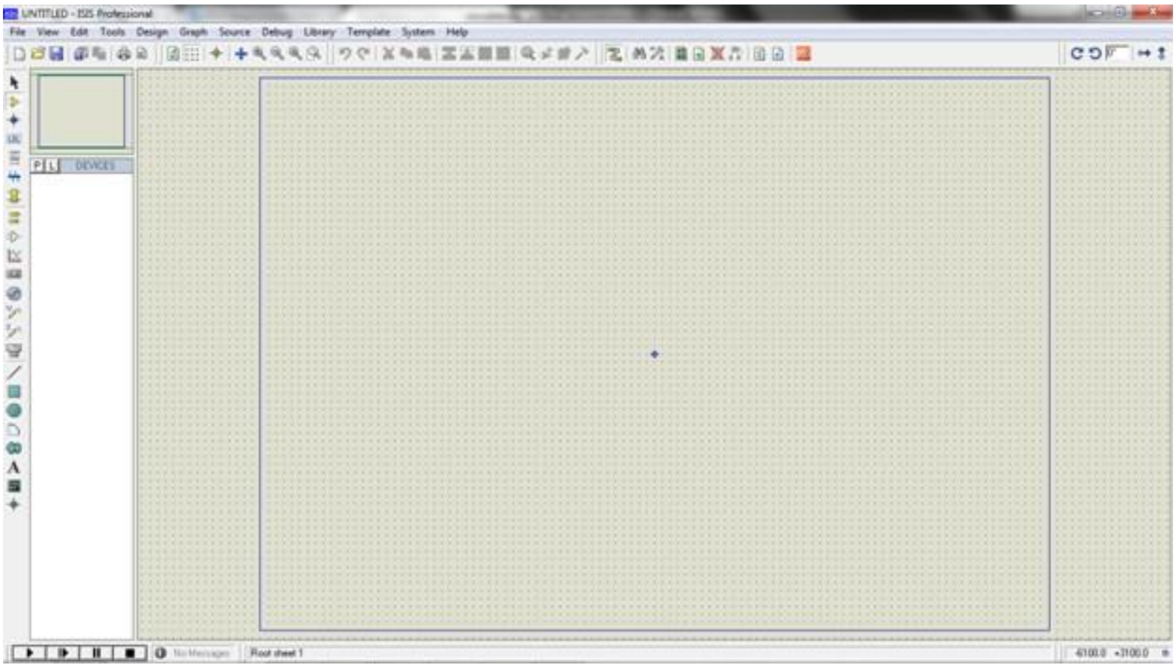

Figure 7.3.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

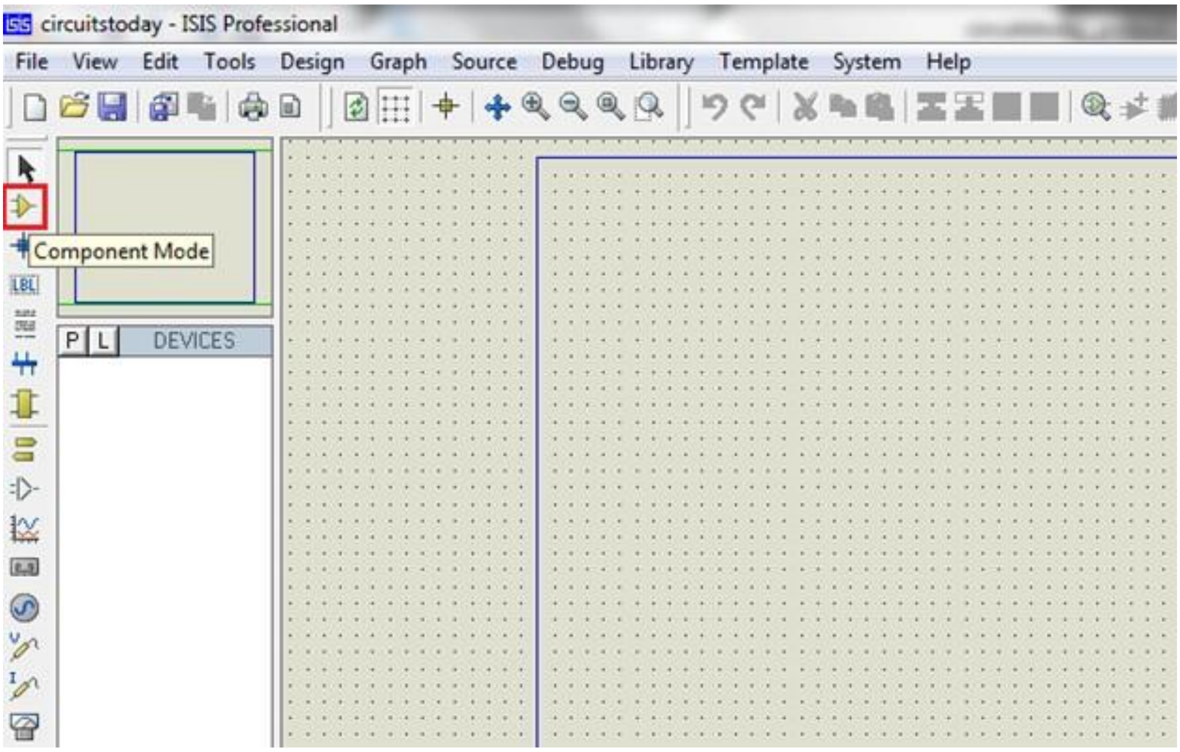

Figure 7.3.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

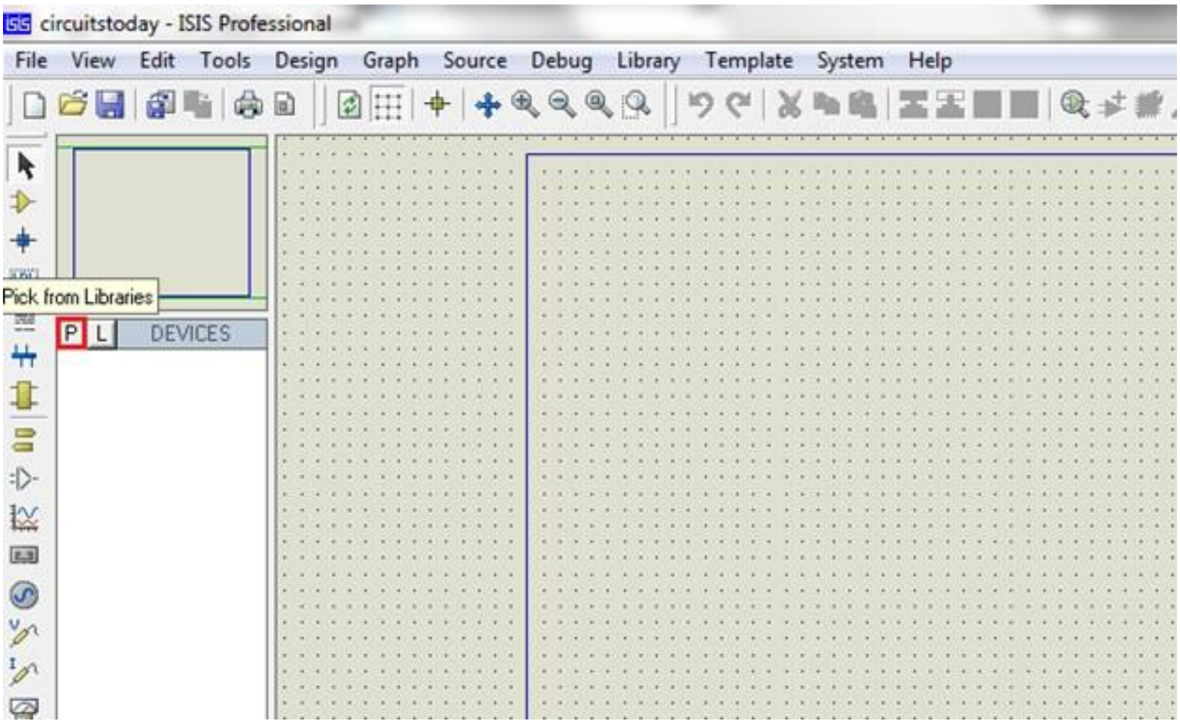

Figure 7.3.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

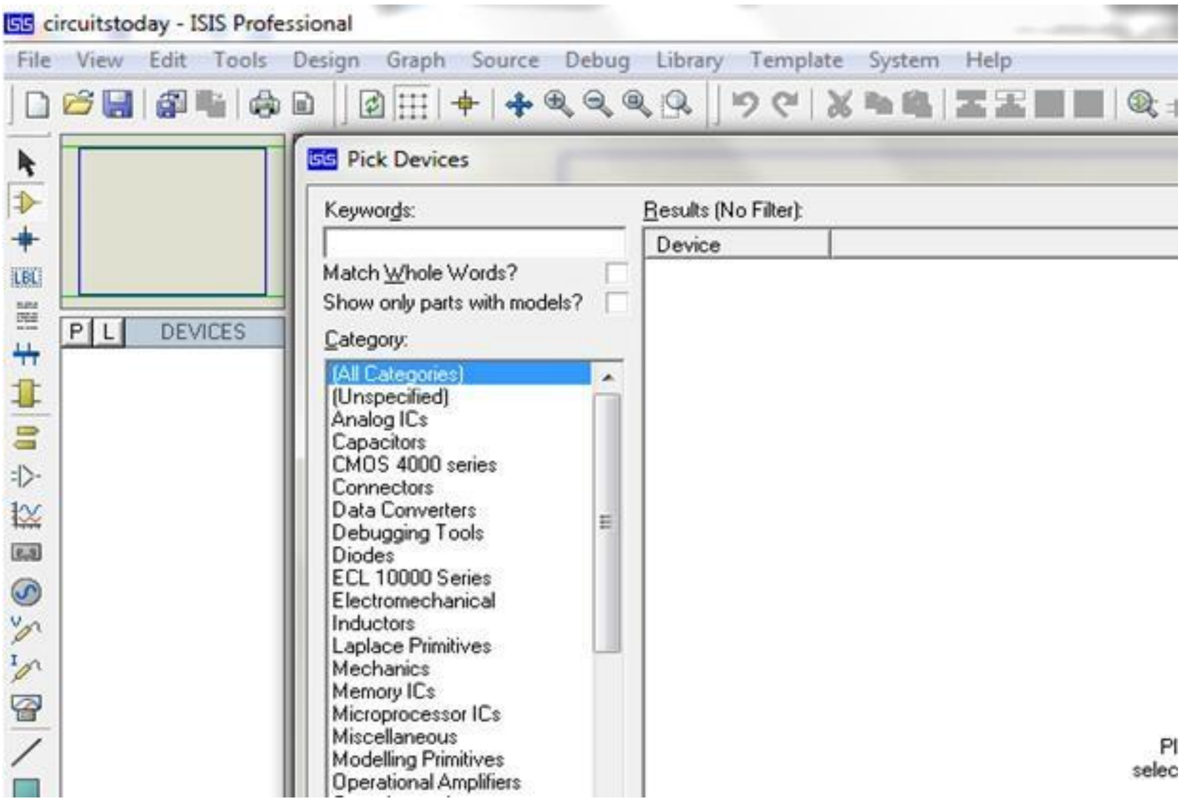

Figure 7.3.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

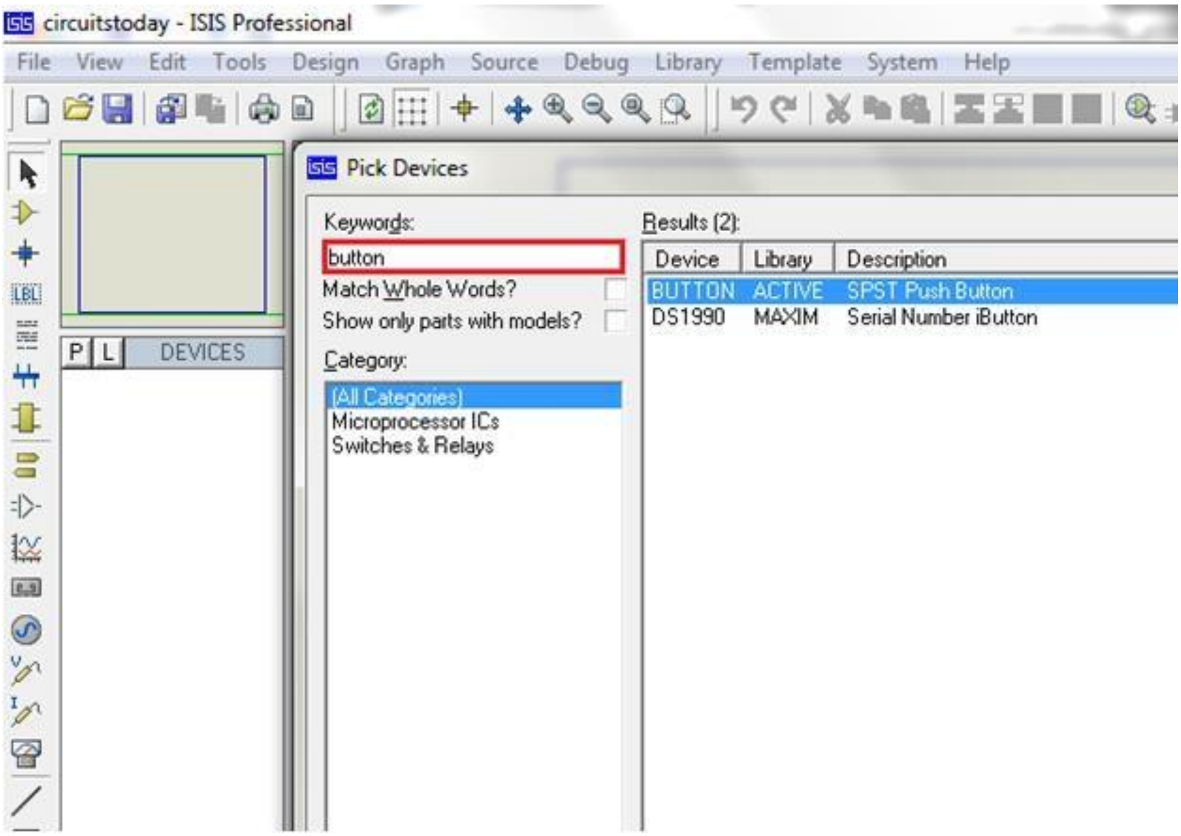

Figure 7.3.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

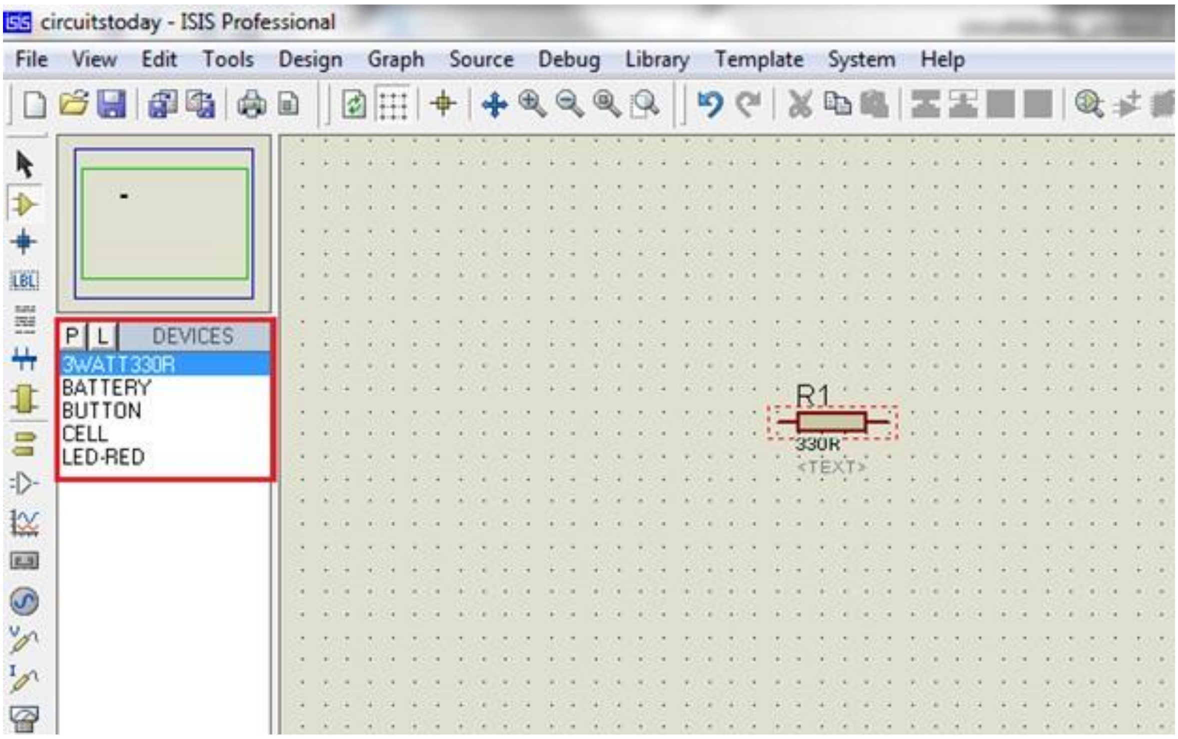

Figure 7.3.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

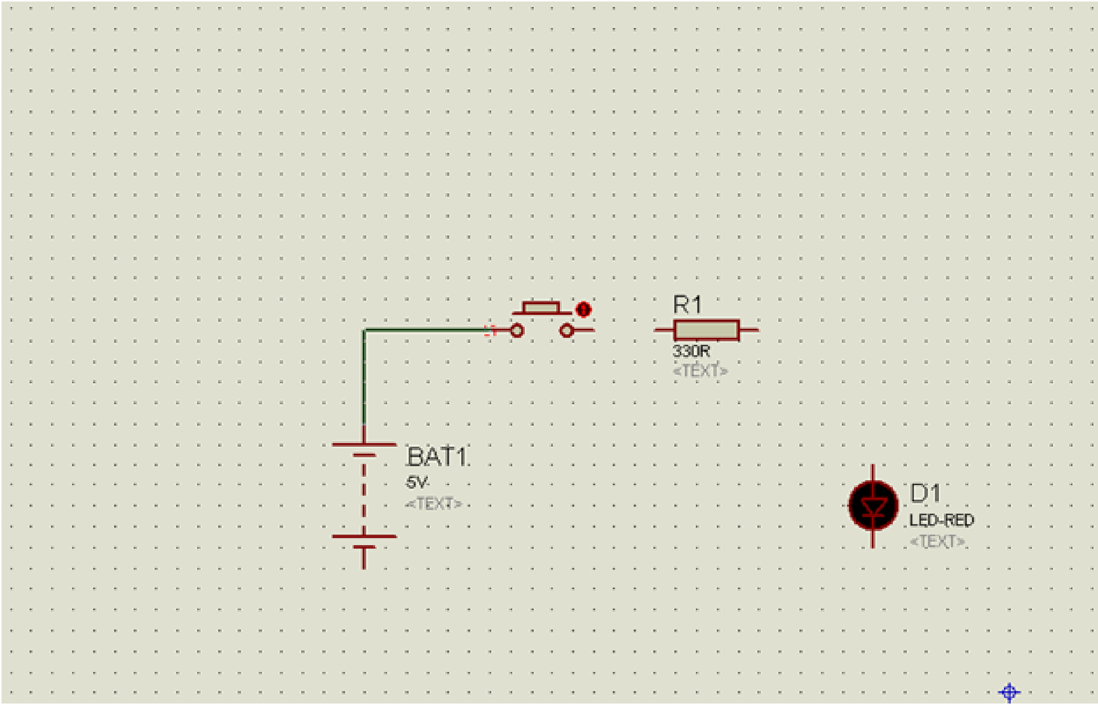

Figure 7.3.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

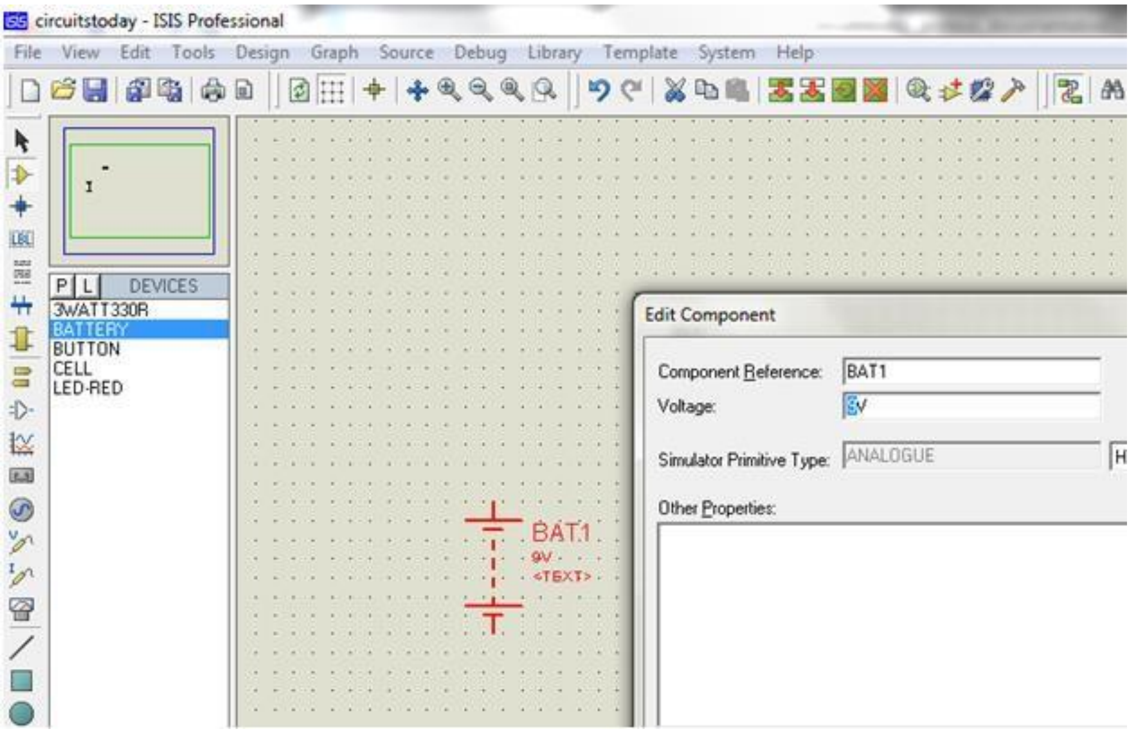

Figure 7.3.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

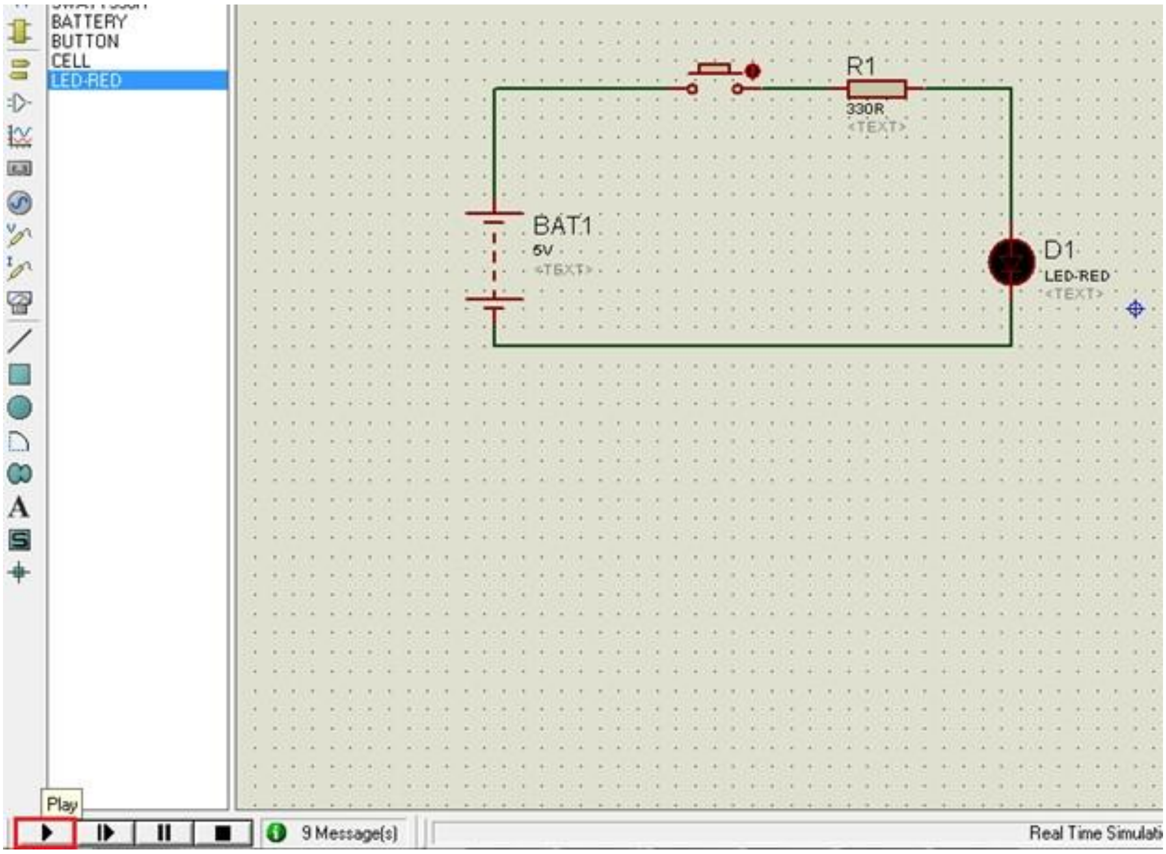

Figure 7.3.12 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

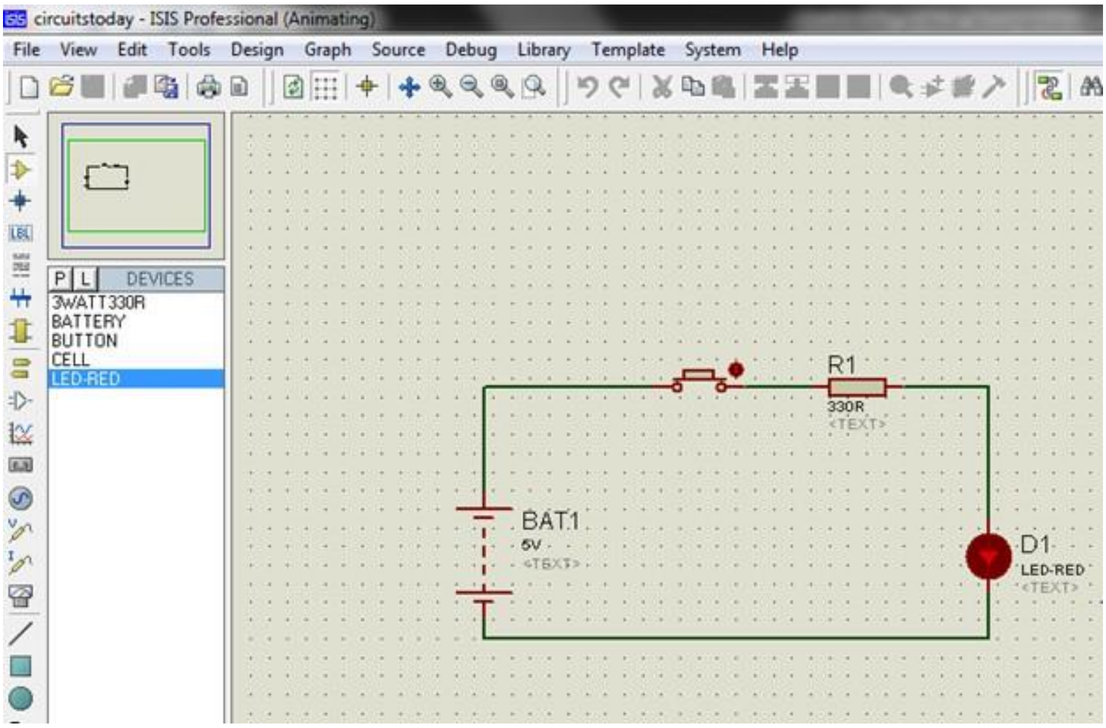

Figure 7.3.13 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

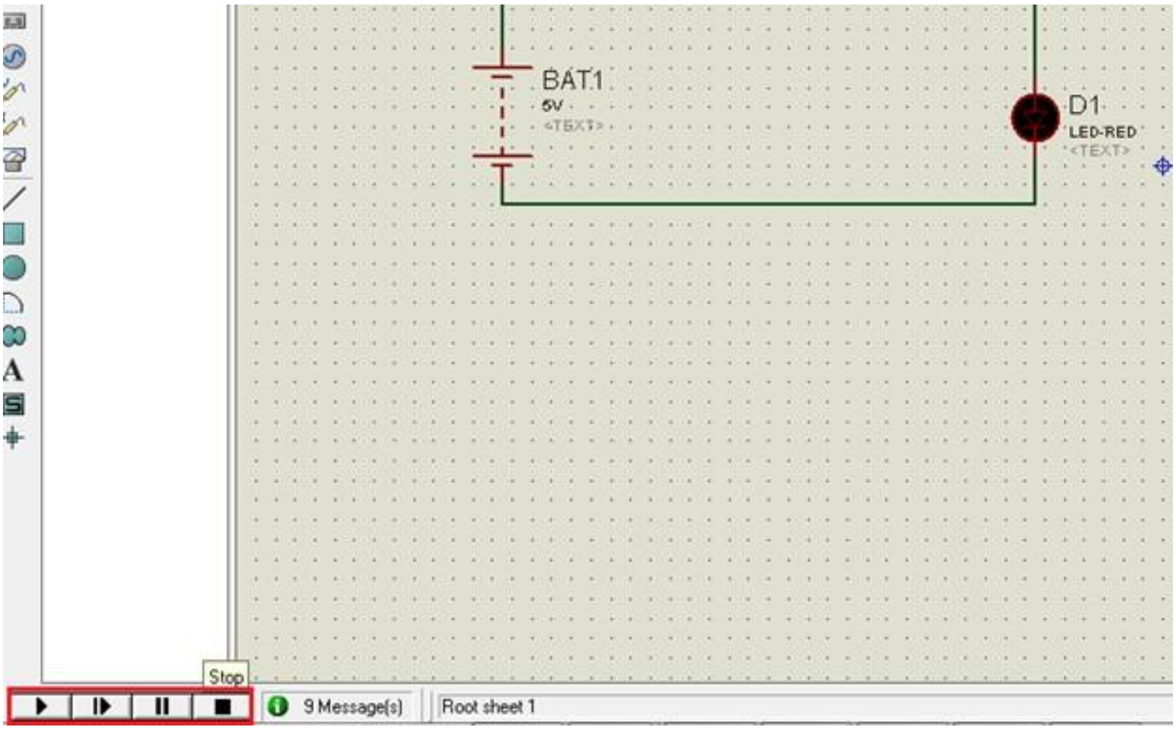

Figure 7.3.14 Simulation Step-Pause-Stop Buttons

Project Code:

```
#define TempPin A4
int TempValue;
#include<LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);

int ldr=A3;

const int voltageSensor = A5;
float vOUT = 0.0;
float vIN = 0.0;
float R1 = 30000.0;
float R2 = 7500.0;
int value = 0;
unsigned int count=0;
void setup()
{
  lcd.begin(16,2);
  lcd.clear();
  lcd.setCursor(0,0);
  lcd.print("Solar Energy");
  lcd.setCursor(0,1);
  lcd.print("Tracking System");
  pinMode(ldr,INPUT);
  delay(3000);
}
int ldr_s;
void loop()
{
  ldr_s=analogRead(ldr);

  TempValue = analogRead(TempPin); // Getting LM35 value and saving it in variable
  float TempCel = ( TempValue/1024.0)*500; // Getting the celsius value from 10 bit analog
value
  float TempFarh = (TempCel*9)/5 + 32; // Converting Celsius into Fahrenhiet
```

```
  value = analogRead(voltageSensor);
  vOUT = (value * 5.0) / 1024.0;
  vIN = vOUT / (R2/(R1+R2));
  lcd.clear();lcd.setCursor(0,0);
  lcd.print("Vtg=");lcd.print(vIN);
  lcd.setCursor(10,0);lcd.print("L:");lcd.print(ldr_s);
  lcd.setCursor(0,1);lcd.print("Temp:");lcd.print(TempCel);lcd.print((char)223);
  lcd.print("C");
  delay(1000);
}
```

CHAPTER 8

RESULT & CONCLUSION

Application of The Project:

- Used in industries.
- It is used solar power stations.
- Used in house hold solar inverters.

Advantages of The Project:

- Renewable Energy Source.
- Reduces Electricity Bills.
- Diverse Applications.
- Low Maintenance Costs.
- Technology Development.

Result:

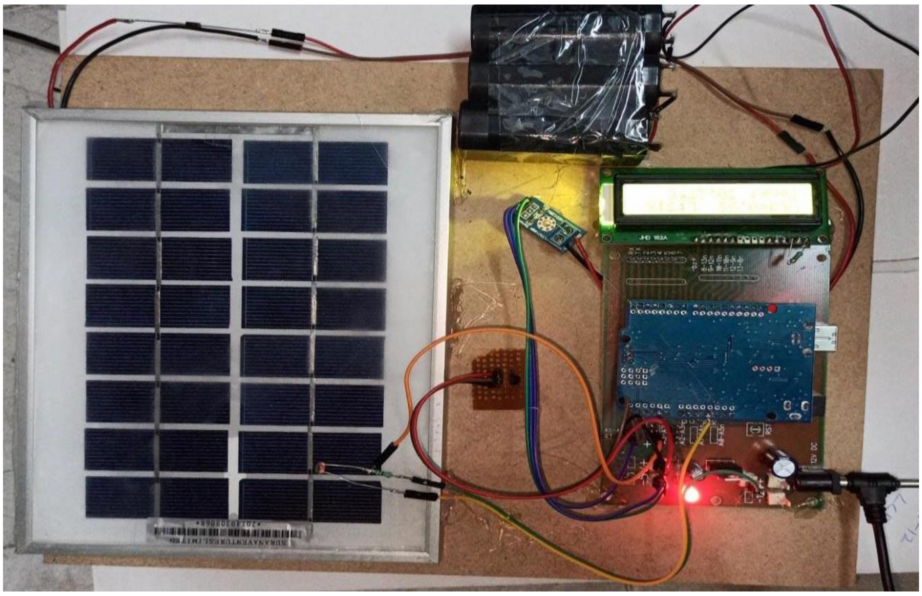

Figure 8.3.1 Prototype of the Project

Figure 8.3.1 Output 1

Initially when the Arduino board is turned on, the following message will be appeared as shown in figure 8.3.1.

Figure 8.3.2 Output 2

After measuring all the solar parameters, the values are displayed accordingly as shown in figure 8.3.2.

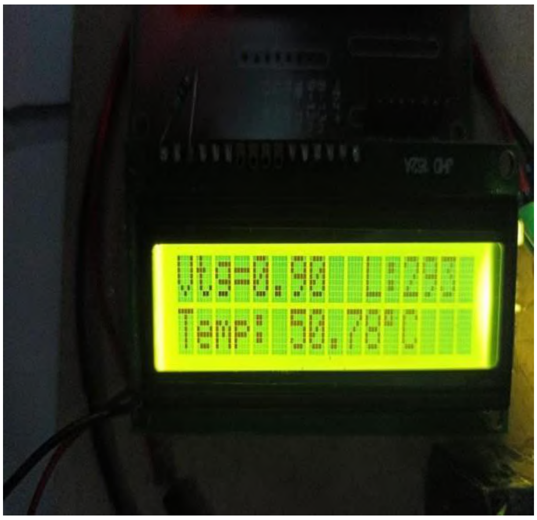

Figure 8.3.3 Output 3

The solar panel parameters will change for every 30 seconds. The varied values are shown in the figure 8.3.3.

Conclusion:

The proposed system stores the data from the solar photovoltaic system continuously, so it keeps track of the solar photovoltaic system and daily or monthly analysis becomes easy and efficient.

Using the analysis, it is possible to detect any fault occurring in the system as there would be inconsistency in the data generated by the system.

By solar tracking the solar panel is operated at its maximum efficiency all day.

Future Scope:

The controller requires an external supply to work but using the power generated from solar panel itself the controller's input power supply can be met.

For very large solar panel dual axis solar panel tracking can be done.

By analyzing the data, it is possible to predict the future values of parameters.

Artificial intelligence can be implemented using various machine learning algorithms that the system can become smart enough to take decisions about data and performance.

DECLARATION

We, the student of **Bachelor of Technology** in Department of ‘Electronics and Communication’, session: 2017 – 2021, St. Martin’s Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled LIQUID LEVEL MONITORING SYSTEM USING IOT WITH ULTRASONIC SENSOR is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1.D. Sai Nikitha (17K81A0475)

2.K.Sitha Ram Reddy (17K81A0481)

3.A.Naga Vamshi Reddy (17K81A0463)

ACKNOWLEDGEMENT

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.HariKrishna**, **Head &Professor**, the Dept. of Electronics and Communication for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept .Project Coordinator Dr.A.Anand Kumar** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide **Ms.E.Parvathi, Assistant Professor**, Department of ECE and our class project coordinator **Mr.Karthik, Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project work.

Finally,We are highly grateful and obliged to our **college level Project Coordinators Dr.Malayadri**, **Professor in IT** and **Dr.R.Santosh Kumar** , **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words..

ABSTRACT

Liquid Level Monitoring System Using IOT With Ultrasonic Sensor is a very innovative system which will inform the users about the level of liquid and will prevent it from overflowing. For this the system uses ultrasonic sensors placed over the containers to detect the liquid level and compare it with the container's depth. The system makes use of AVR family microcontroller, LCD screen, WIFI modem for sending data and a Ultrasonic sensor. The LCD screen is used to display the status of the level of liquid in the containers. Whereas an app is built to show the status to the user monitoring it. The app gives the level or percentage view of the containers and highlights the liquid level order to show the level of liquid. The LCD screen shows the status of the liquid level. Thus this system helps to prevent the wastage of water by informing about the liquid levels of the containers by providing message to the user through app(Telnet).

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

CHAPTER-1

INTRODUCTION

Overview Of The Project:

The present invention relates to the field in Liquid Level Monitoring. The goal of this research is to develop a smart system for estimating accurately the liquid level and prevent overflowing. The recent advancements in the area of IOT has provided solutions to measure the quantity and level of liquid in liquid transmission system using sensor based wireless technology. Our research team has developed a smart system that challenges the current system and provides the continuous monitoring of liquid level to the user.

This project IOT Liquid Level Monitoring system is a very innovative system which will inform the users about the level of liquid and will prevent it from overflowing. To demonstrate this the system makes use of ultrasonic sensors placed over the containers to detect the liquid level and compare it with the container's depth. The system makes use of AVR family microcontroller, LCD screen, Wifi modem for sending data. The system is powered by a 12V transformer. The LCD screen is used to display the status of the level of liquid in the containers. Whereas an app(TELNET) is built to show the status to the user monitoring it. The app gives a percentage or level view of the containers and highlights the liquid level in percentage in order to show the level of liquid. The LCD screen shows the status of the liquid level.. Thus this system helps to prevent the wastage of water by informing about the liquid levels of the containers by providing information to TELNET app.

The system proposes an IOT-enabled liquid monitoring system for all users that are connected to system. The liquid monitoring system monitors the level of the liquid by detecting the amount of liquid in the tank during the transfer of the liquid such as water, oil, milk etc.

Earlier in olden days a physical person has to stay beside the tank in order to monitor whether the tank is filled with water completely or not. The person might waste his precious time in order to do this. When it comes to petrol tanks and diesel tanks, the person need to climb the tank and check whether the tank is filled with petrol/diesel or not. When it comes to chemical industries the person need to climb the top of the tank by ladder which is at great distance and need to monitor physically. Even though a person is physically observed still there might be overflowing of liquid due to negligence of the person. In order to prevent all these we came up with an innovatie idea which is called liquid level monitoring using IOT.

IOT based Liquid level Monitoring project is designed in a way that it can be used to remotely monitor the level of liquid indoors and out, like measuring tanks, wells, ponds, canals, and streams. This system tells (or) informs user about the level of liquid and prevent it from overflowing.IOT based Liquid level monitoring project enables the user in level detection of any liquid and continuously monitor it – over the internet. The user can monitor continously in the app which is called TELNET about the status of liquid of container/tank.

OBJECTIVE OF THE STUDY:

The main aim of this system is to monitor the water level at rural areas so that they help in detecting the wastage of water and measures can be taken to avoid unnecessary overflowing of water in the areas where monitoring is a difficult task and the water can be saved for future generations.

One of the major problems faced by most of the countries is the issue of water scarcity in the world and wastage during transmission has been identified as a major culprit; this is one of the motivations for this research, to deploy computing techniques in creating a barrier to wastage in order to not only provide more financial gains and help the environment as well as the water cycle which in turn ensures that we save water for our future. IOT based Water Level Monitoring system is an innovative system which will inform the users about the level of liquid and will prevent it from overflowing.

Water Level Monitoring systems of course record the usage of water and the amount of liquid or water present in container or tanks..Thus this system helps to prevent the wastage of water by informing about the liquid levels of the containers to users through TELNET app.

SCOPE OF THE STUDY:

Technology nowadays has become an integrated part of people's lives. It has, and continues to influence many aspects of daily life and has allowed better social interaction, ease of transportation, the ability to indulge in entertainment and media and has helped in the development in medicine. The creation of many devices such as mobile phones and computers have caused many people to rely on technology to communicate with their friends, store information such as pictures, movies, documents, and music.

The internet has become a common interface that many devices use in order to simplify the daily life of many people giving the ability to search for information, store their own information in the cloud while also giving them better ways of managing information. From the time of its introduction, the number of people that use mobile phones and the internet to communicate with other people has increased dramatically to become one of the major means of communication

People with the help of smartphones can now connect to the internet withoutthe need for a computer, while still offering the same functionality but through different means. With the introduction of advanced software and hardware devices, smartphones are now powerful devices and have become an important part of people’s daily lives. A major aspect is how the Smartphone is able to connect and communicate with other devices.

A field that is recently gaining popularity is Water Level Monitoring which can also use smartphones as information or functionality hubs.

Im this system we use WIFI-module which acts as internet connectivity between the user and system. It acts as a channel for means of communication between user and system. The amount of liquid level data is send to user with the help of wifi module by using certain commands for transfer of data.

MATERIAL/COMPONENT REQUIREMENT:

HARDWARE REQUIREMENT:

- Arduino uno
- UltraSonic Sensor
- WIFI module
- Liquid Crystal Display

SOFTWARE REQUIREMENTS:

- ARDUINO IDE
- PROTEUS SOFTWARE

CHAPTER-2: LITERATURE SURVEY

1. Scarcity of water is one of the biggest issues revolving across the globe and water crisis is reaching the alarming level day by day. So, water conservation in one or the other way is gaining a significant importance. Mostly, now a days in urban as well as in rural areas water tank system is available. The biggest disadvantage of this system is the overflow of water from overhead tank and overrunning of water pump. Hence, in this work, it is tried to design an automatic water tank level and pump control system, which ensures several benefits. The sensor devices used in our system detects and controls the water level in the overhead tank and even in the pump. As per the level of water present in the overhead tank, the sensor senses the levels and sends different signals to the Arduino and the signals are used for switching ON and OFF the motor pump as per requirements. The Arduino will control the pump by preventing it from dry running. A buzzer is attached to the circuit, which will ring when the water reaches the critical level in the overhead tank.

2. The quality and quantity of water supplied by high-level water tank directly affect people's daily life. Most traditional water tanks use manual detection, which has high detection cost and low data accuracy. In order to ensure the safety and continuity of high-level water tank water supply, this paper designs a set of high-level water tank monitoring system based on Internet of things. The system adopts TDS sensor and ultrasonic sensor to monitor the water quality and water level of the water tank respectively, and transmits the data back to the monitoring center for real-time monitoring through ZigBee -a wireless communication protocol. The system can control water level automatically and alarm when water is polluted. It has strong practical value and significance that ensures the safety and stability of household water, and provides data support for the improvement of water tank water supply in the future.

3. This project IOT Liquid Level observance system could be a very innovative system that will inform the users regarding the amount of liquid and can stop it from overflowing. To demonstrate this system makes use of four containers. For this, the system uses ultrasonic sensors placed over the containers to observe the liquid level and compare it with the container’s depth. The system makes use of AVR family microcontroller, LCD screen, wireless local area network electronic equipment for causing knowledge and a buzzer. The system is steam-powered by a 12V electrical device. The liquid crystal display LCD digital display alphanumeric display screen is employed to display the standing of the amount of liquid within the containers. Whereas an online page is made to indicate the standing to the user observance it. The net page provides a graphical read of the containers and highlights the liquid level in color order to indicate the amount of the liquid. The liquid crystal display screen shows the standing of the liquid level. The system puts on the buzzer once the amount of liquid collected crosses the set limit. So this method helps to stop the wastage of water by informing regarding the liquid levels of the containers by providing a graphical image of the containers via an internet page.

4.This paper shows non-contact water level monitoring system implemented using LabVIEW and arduino. Water depth of the tank is measured by Ultrasonic sensor. Hence the water level present in the tank is known. Depending on the sensor reading LabVIEW program sends the data to arduino and through arduino board the pump is switched ON if the water level in the upper tank is low and pump is switched OFF if the water level is completely filled in the upper tank. The input to arduino board is from ultrasonic sensor. Arduino read the height and reports the water depth of the tank and the same is displayed in LabVIEW front panel. Advantage of this over other existing automatic system is it provides non-contact water level measurement using ultrasonic sensor, but existing automatic system using ss(stainless steel) sensor which is a contact type water level sensor and also these sensors quickly corroded by some chemicals. The same is present in LabVIEW using the graphical user interface for visualization, LabVIEW communicate with add on devices like arduino, ultrasonic sensor, pump through makerhub.

CHAPTER-3: INTRODUCTION ABOUT EMBEDDED SYSTEM

INTRODUCTION:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine..

BLOCK DIAGRAM OF EMBEDDED SYSTEM:

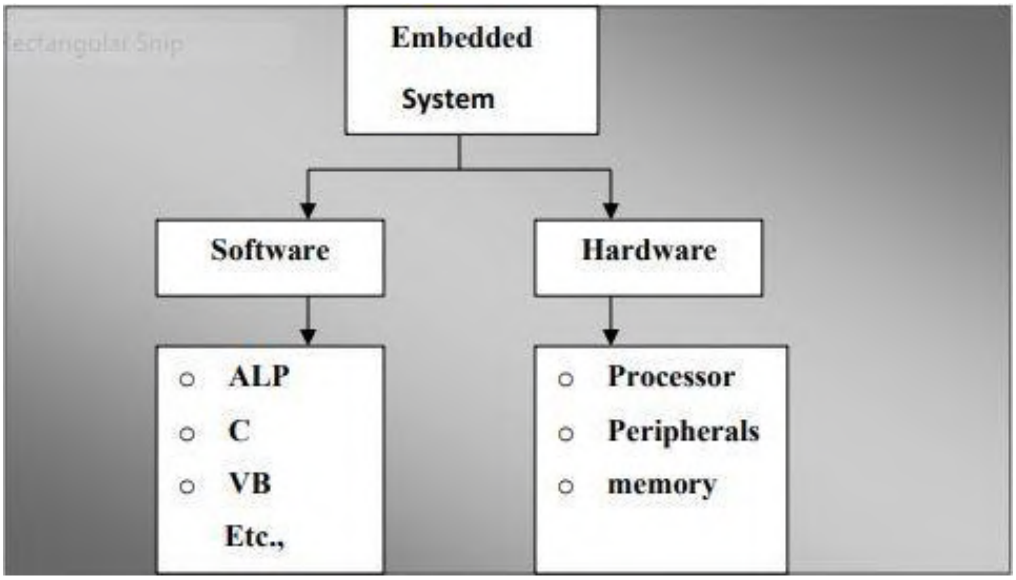

Fig 3.2.1 BLOCK DIAGRAM OF EMBEDDED SYSTEM

Software deals with the languages like ALP, C, and VB etc., and **Hardware** deals with Processors, Peripherals, and Memory

APPLICATIONS OF EMBEDDED SYSTEM:

• Manufacturing and process control

• Construction industry

• Transport

• Buildings and premises

• Domestic service

• Communications

• Office systems and mobile equipment

• Banking, finance and commercial

• Medical diagnostics, monitoring and life support

• Testing, monitoring and diagnostic systems

Micro Processor(μp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types:

- Micro Processor (μp)
- Micro controller (μc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

Three Basic Elements of a Microprocessor:

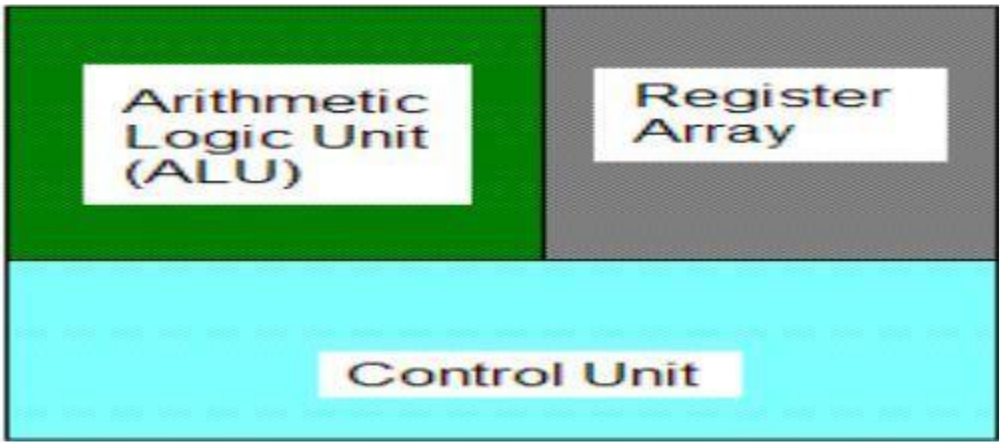

Fig 3.5.1 BASIC ELEMENTS OF MICRO PROCESSOR

Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

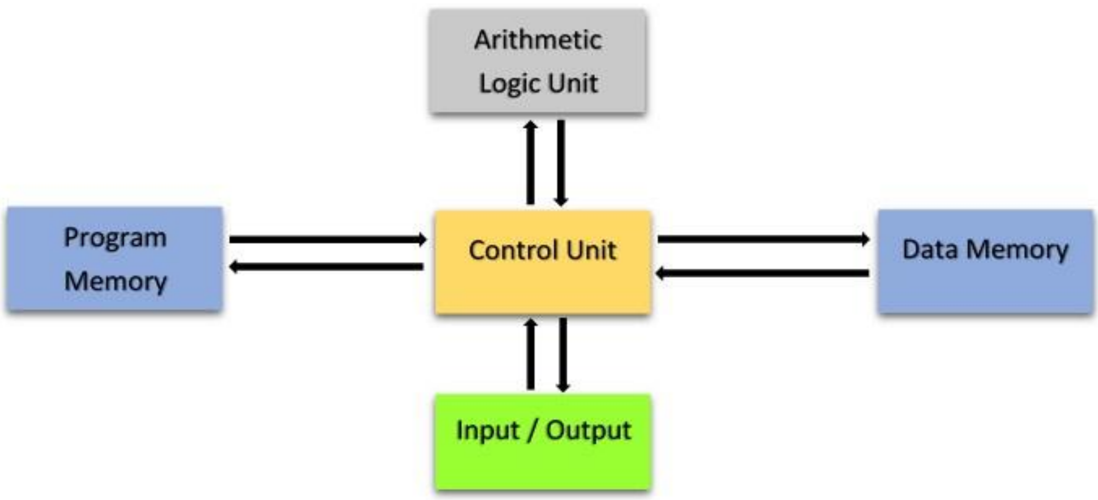

Fig 3.6.1 HARVARD ARCHITECTURE

Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

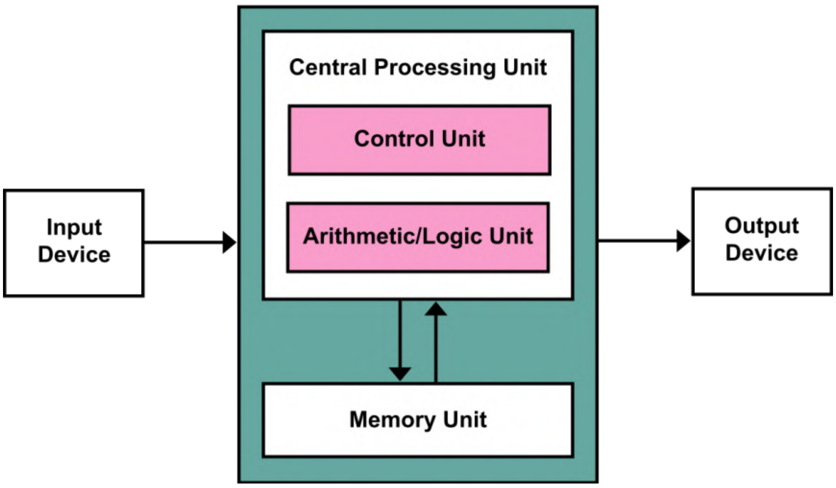

FIG3.6.2.1: VON-NEUMANN ARCHITECTURE

CHAPTER-4

HARDWARE DESCRIPTION

MICROCONTROLLER-ATMEGA328:

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	Atmel ATmega328
Operating Voltage (logic level)	5v
Input Voltage (recommended)	7v-12v
Input Voltage (limits)	6v-20v
Digital I/O Pins	14 (of which 6 provide PWM output)
Analog Input Pins	8
DC Current per I/O Pin	40mA
Flash Memory	32 KB of which 2 KB used by bootloader
SRAM	2KB
EEPROM	1KB
Clock Speed	16MHz
Dimensions	0.73" x 1.70"
Length	45 mm
Width	18 mm
Weight	5g

Table 4.1.1 ATMEGA SPECIFICATIONS

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board. The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software)
- .Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

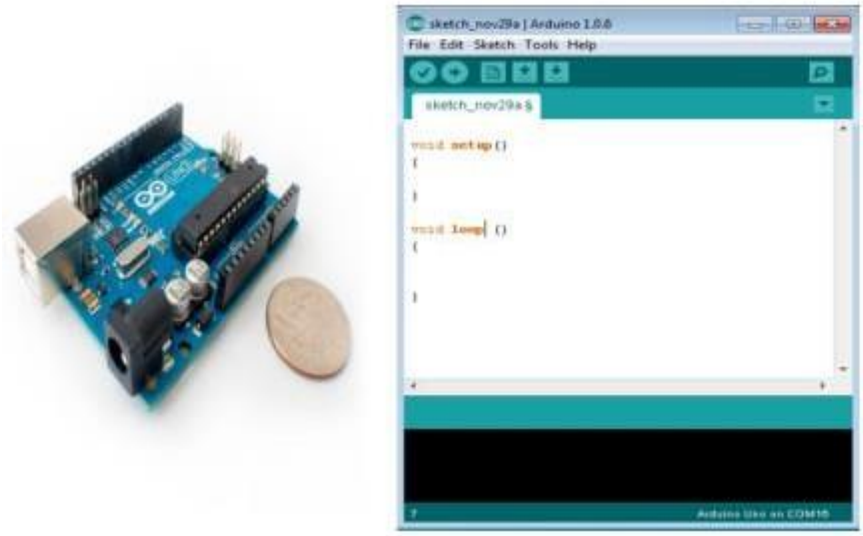

FIG 4.2.1 ARDUINO UNO

Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

4.3.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

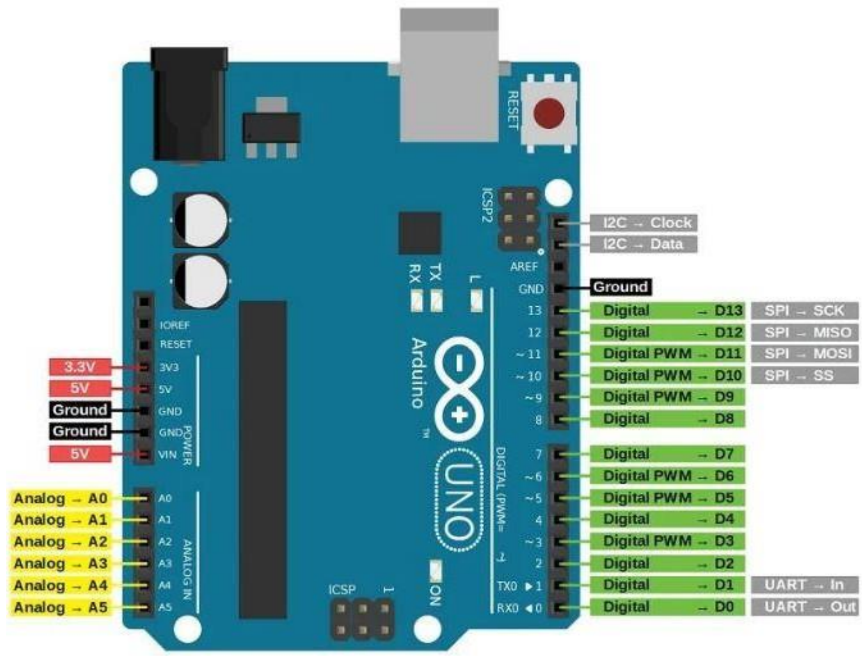

Fig 4.3.1.1 ARDUINI UNO BOARD

Vin: This is the input voltage pin of the Arduino board used to provide input supply from an external power source.

5V: This pin of the Arduino board is used as a regulated power supply voltage and it is used to give supply to the board as well as onboard components.

V: This pin of the board is used to provide a supply of 3.3V which is generated from a voltage regulator on the board

GND: This pin of the board is used to ground the Arduino board.

Reset: This pin of the board is used to reset the microcontroller. It is used to Resets the microcontroller.

Analog Pins: The pins A0 to A5 are used as an analog input and it is in the range of 0-5V.

Digital Pins: The pins 0 to 13 are used as a digital input or output for the Arduino board.

Serial Pins: These pins are also known as a UART pin. It is used for communication between the Arduino board and a computer or other devices. The transmitter pin number 1 and receiver pin number 0 is used to transmit and receive the data resp.

External Interrupt Pins: This pin of the Arduino board is used to produce the External interrupt and it is done by pin numbers 2 and 3.

PWM Pins: This pins of the board is used to convert the digital signal into an analog by varying the width of the Pulse. The pin numbers 3,5,6,9,10 and 11 are used as a PWM pin.

SPI Pins: This is the Serial Peripheral Interface pin, it is used to maintain SPI communication with the help of the SPI library. SPI pins include:

1. SS: Pin number 10 is used as a Slave Select
2. MOSI: Pin number 11 is used as a Master Out Slave In
3. MISO: Pin number 12 is used as a Master In Slave Out

4. SCK: Pin number 13 is used as a Serial Clock

LED Pin: The board has an inbuilt LED using digital pin-13. The LED glows only when the digital pin becomes high.

AREF Pin: This is an analog reference pin of the Arduino board. It is used to provide a reference voltage from an external power supply.

ARDUINO FAMILY:

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig 4.4.1 ARDUINO FAMILY

SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities - controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

PIN DESCRIPTION OF ATMEGA328

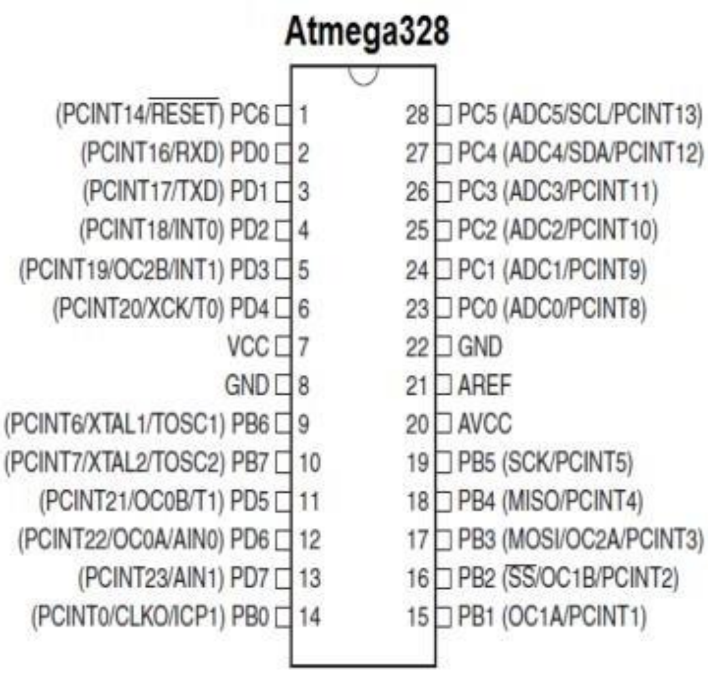

Fig4.6 .1 .PIN DIAGRAM OF ATMEGA

ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

POWER SUPPLY UNIT

INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

BLOCK DIAGRAM OF POWER SUPPLY:

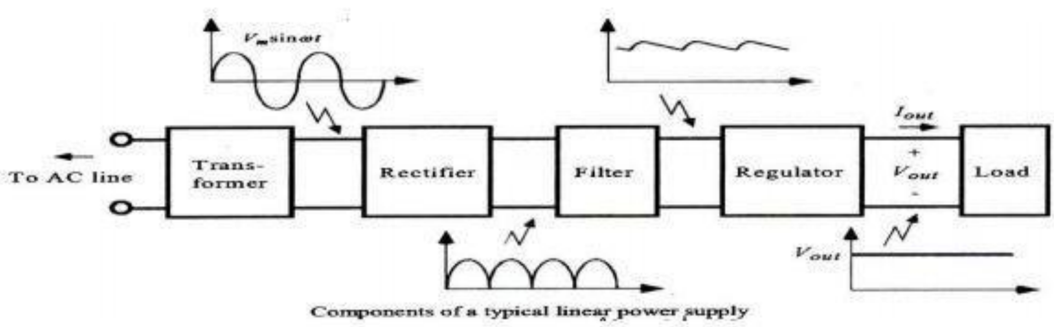

Fig 4.9.2.1 block diagram of power supply

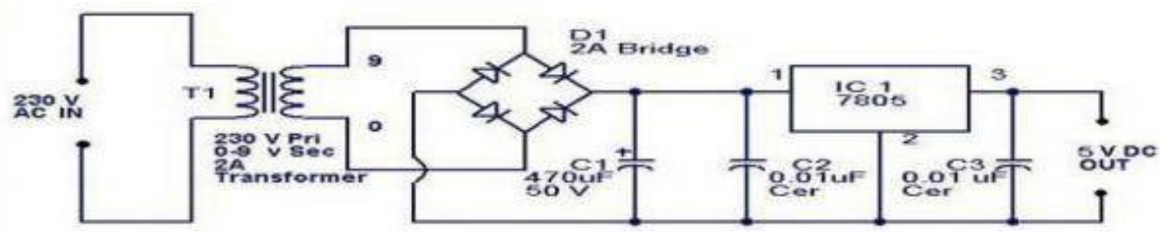

Fig 4.9.2.2 schematic diagram of power supply

DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy. A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or primary winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the secondary winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

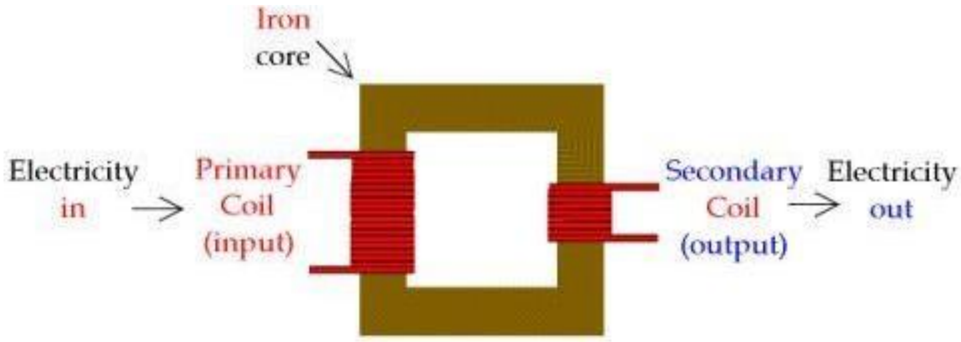

Fig 4.11.1 transformer

Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core

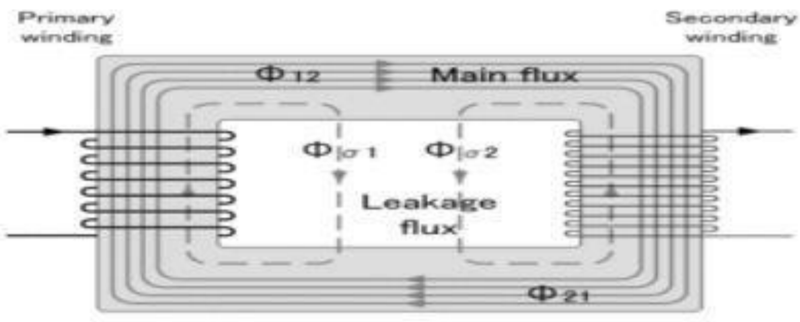

Fig 4.11.2.1 basic transformer

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

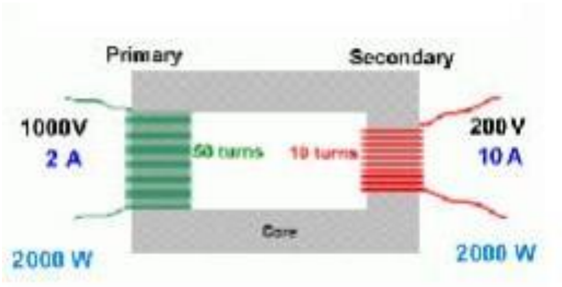

Fig 4.12.1.1 step down transformer

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years

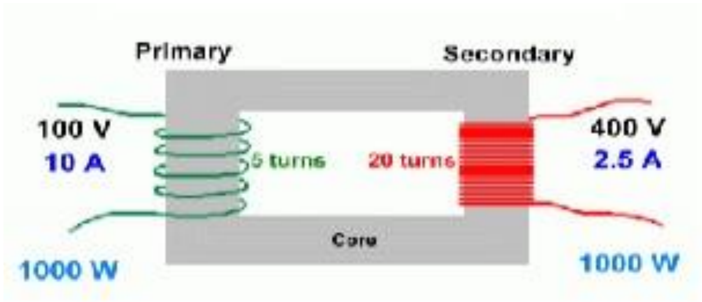

Fig 4.12.2.2 step up transformer

Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as 'half-wave' and 'full-wave' rectifiers. Both use components called diodes to convert AC into DC.

VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- ➢ Positive Voltage Series (78xx) and
- ➢ Negative Voltage Series (79xx)

78xx:’78’ indicate the positive series and ‘xx’indicates the voltage rating. Suppose 7805 produces the maximum 5V.’05’indicates the regulator output is 5V.

79xx:’78’ indicate the negative series and ‘xx’indicates the voltage rating. Suppose 7905 produces the maximum -5V.’05’indicates the regulator output is -5V.

LIQUID CRYSTAL DISPLAY(16 * 2)

INTRODUCTION:

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below

Display Data RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Busy Flag :

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact ammount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process

Instruction Register(IR) and Data Register(DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 x 2 Alphanumeric LCD Module Features:

Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing

• 61 x 15.8 mm viewing area

• 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line

• Can display 224 different symbols

• Low power consumption (1 mA typical)

• Powerful command set and user-produced characters

• TTL and CMOS compatible

• Connector for standard 0.1-pitch pin headers

Table 4.15.4.1 connector pin segments

ULTRASONIC SENSOR

INTRODUCTION

An ultrasonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal. Ultrasonic waves travel faster than the speed of audible sound (i.e. the sound that humans can hear). Ultrasonic sensors have two main components: the transmitter (which emits the sound using piezoelectric crystals) and the receiver (which encounters the sound after it has travelled to and from the target).

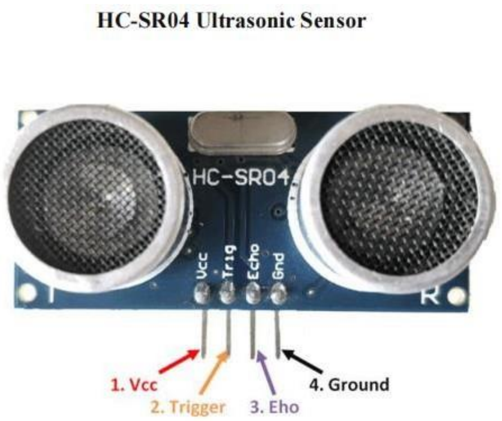

FIG 4.16 . 1: HCSR04 ULTRASONIC SENSOR

1	Vcc	The Vcc pin powers the sensor, typically with +5V
2	Trigger	Trigger pin is an Input pin. This pin has to be kept high for 10us to initialize measurement by sending US wave.
3	Echo	Echo pin is an Output pin. This pin goes high for a period of time which will be equal to the time taken for the US wave to return back to the sensor.
4	Ground	This pin is connected to the Ground of the system.

Table 4.16.1: Ultrasonic sensor pin configuration

HC-SR04 Sensor Features

• Operating voltage: +5V

• Theoretical Measuring Distance: 2cm to 450cm

• Practical Measuring Distance: 2cm to 80cm

• Accuracy: 3mm

• Measuring angle covered: <15°

• Operating Current: <15mA

• Operating Frequency: 40Hz

HCSR04 WORKING：

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4 pin module, whose pin names are Vcc, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver. The sensor works with the simple high school formula that

Distance = Speed × Time

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

FIG: ULTRASONIC RECEIVER MODULE

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

How to use the HC-SR04 Ultrasonic Sensor:

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

Power the Sensor using a regulated +5V through the Vcc ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to be made high for 10uS and then turned off. This action will trigger an ultrasonic wave at frequency of 40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information the distance is measured as explained in the above heading.

Applications

•Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot, path finding robot etc.

• Used to measure the distance within a wide range of 2cm to 400cm

• Can be used to map the objects surrounding the sensor by rotating it

• Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water.

CHAPTER 5

PROJECT IMPLEMENTATION

BLOCK DIAGRAM

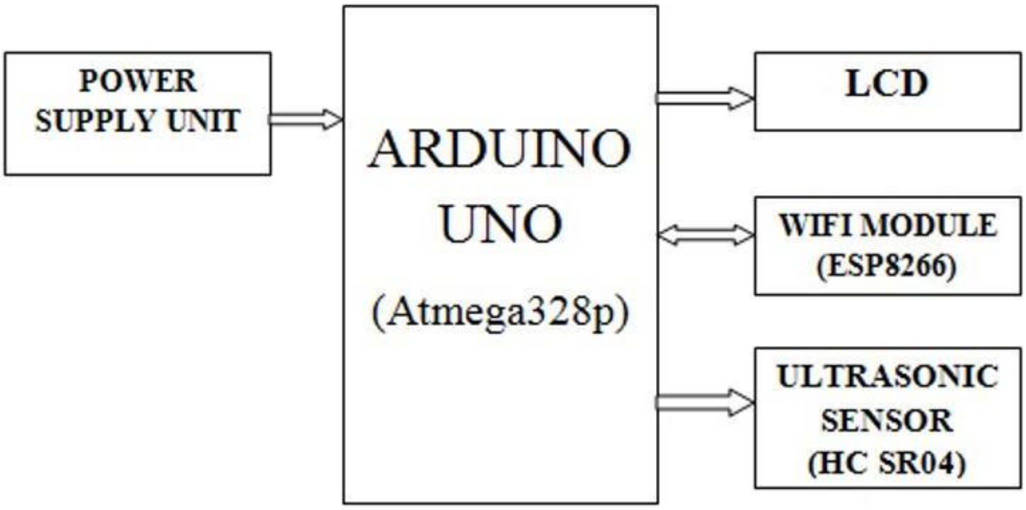

FIG 5.1:BLOCK DIAGRAM

SCHEMATIC DESIGN

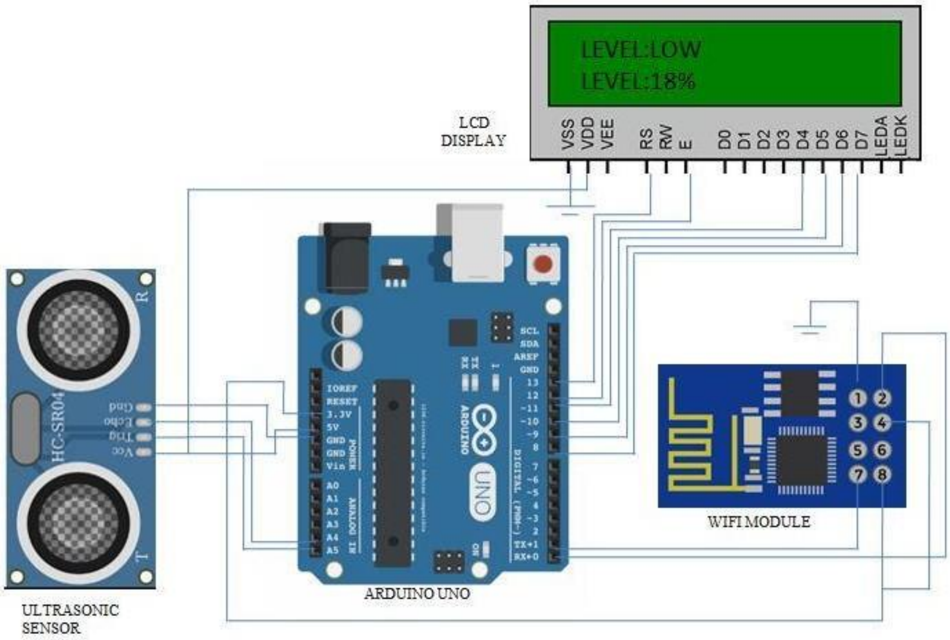

FIG 5.2 :SCHEMATIC DESIGN

- In the circuit the digital pins D13,D12,D11,D10,D9,D8 are connected to the liquid crystal display(LCD).
- The pins D2,D3 are connected to transmitter(TX) and receiver(RX) of wifi module respectively .
- The analog pins A5 and A4 are connected to rigger pin and echo pin of ultrasonic sensor respectively.
- The vcc of 5V is given to ultrasonic sensor and lcd display and vcc of 3.3V is given to wifi module.
- The pins D2 and D3 are connected to wifi module in order to send the usable data through internet.
- The obtained data can be reviewed and monitored through Telnet app.
- The wifi module transmits the data to telnet app by using some commands. These commands we are going to interface in aruduino ide.

SOFTWARE WORKFLOW

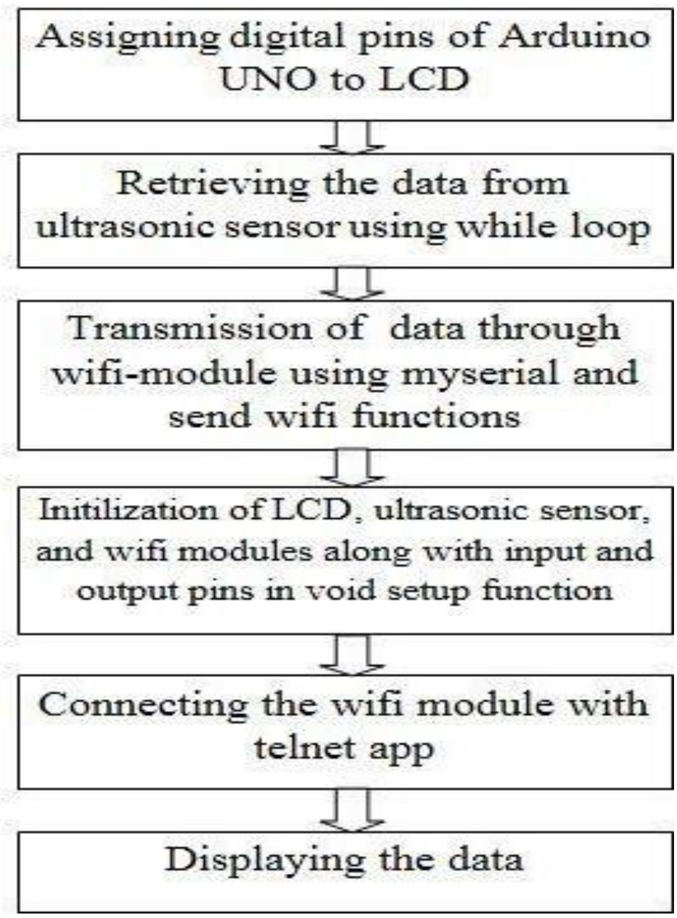

FIG 5.3:SOFTWARE WORKFLOW

The above workflow states what are the steps that we need to implement in software(ArduinoIDE) part to interface with hardware components.

FLOWCHART

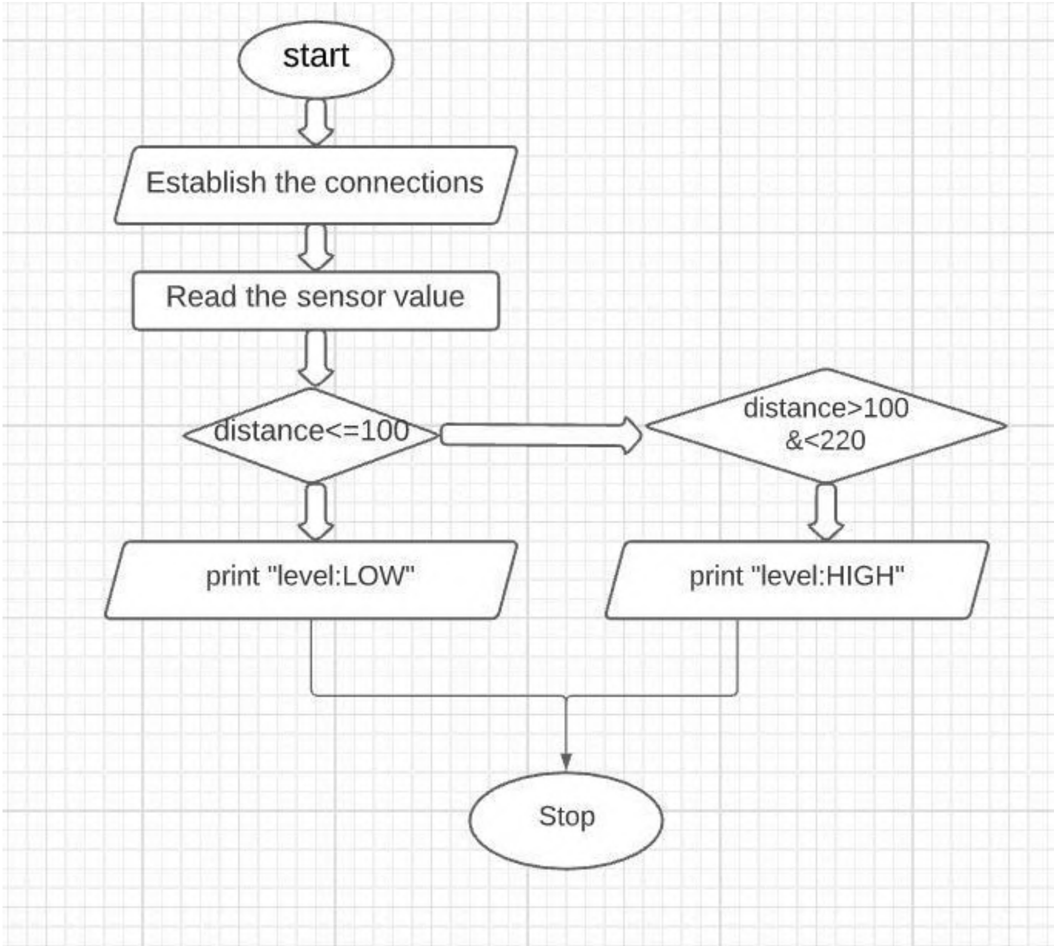

FIG 5.4.1:FLOWCHART

In above flow chart we can see that there are two conditions

If distance<=100 it is going to print low which means the level of liquid is low

If distance>100 &<200 it is going to print high which means the level of liquid is at peak stage.

Based on these two conditions the user will able to know whether the tank is full or not.

CHAPTER -6

SOFTWARE EXPLINATION

SOFTWARE EXPLANATION:

Software Requirements

- Proteus simulation
- Arduino software
- Programming language

Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals.

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

•Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

• Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

• Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

• Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based.

•Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version

• Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

• Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually. When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

FIG 6.4.1 : A TO B USB CABLE

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig 6.4.2:A to Mini-B cable

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

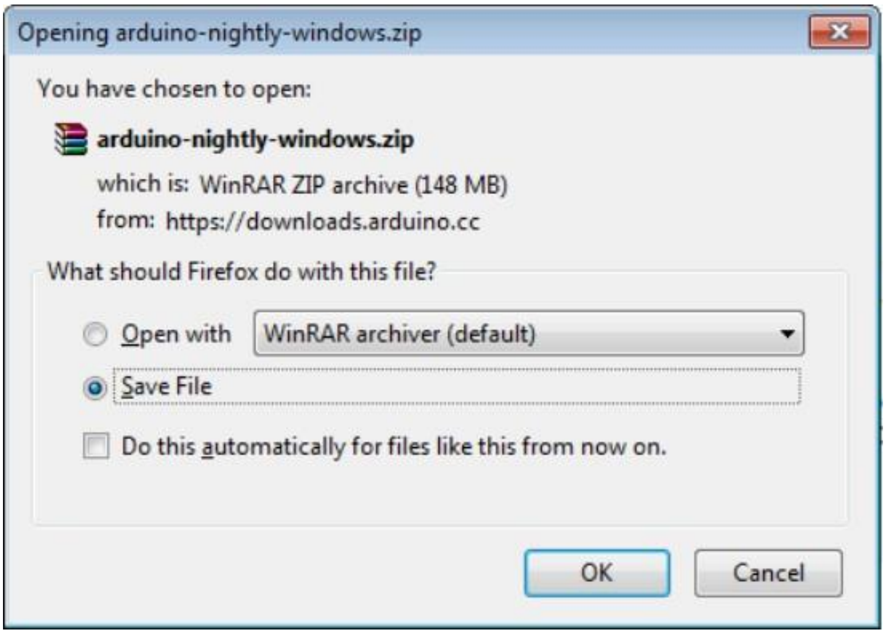

Fig 6.4.3: Opening Arduino

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper,a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

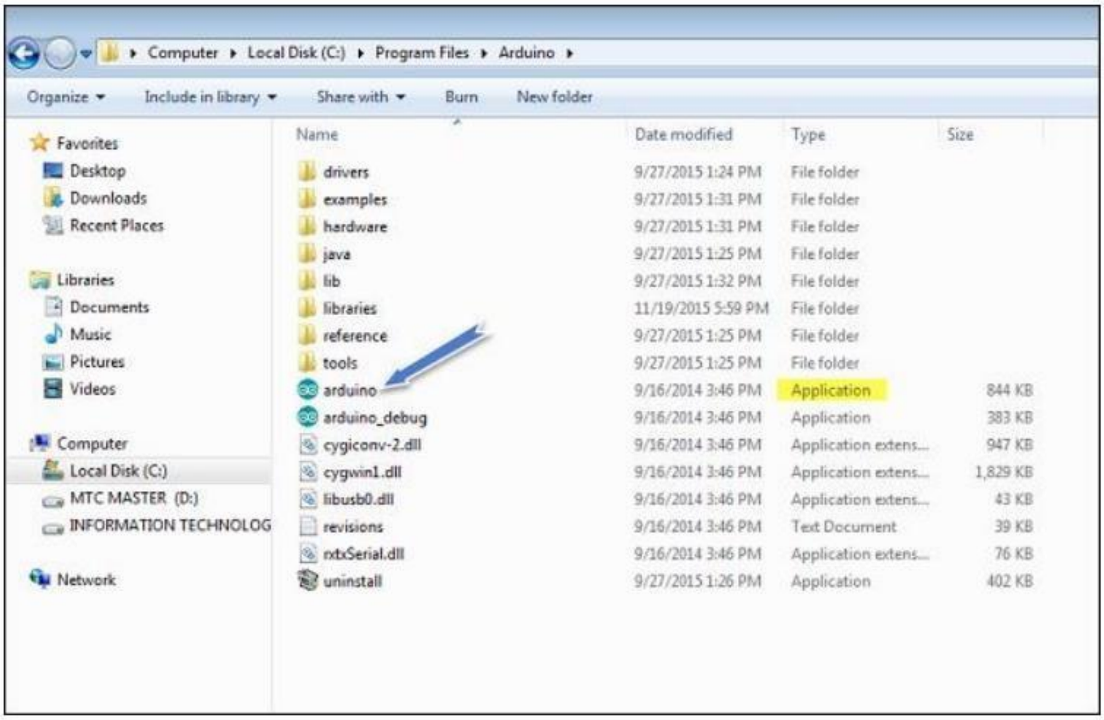

Fig 6.4.4:Arduino Application File

Step 5 − Open your first project.

Once the software starts, you have two options −

• Create a new project.

• Open an existing project example.

To create a new project, select File → **New**

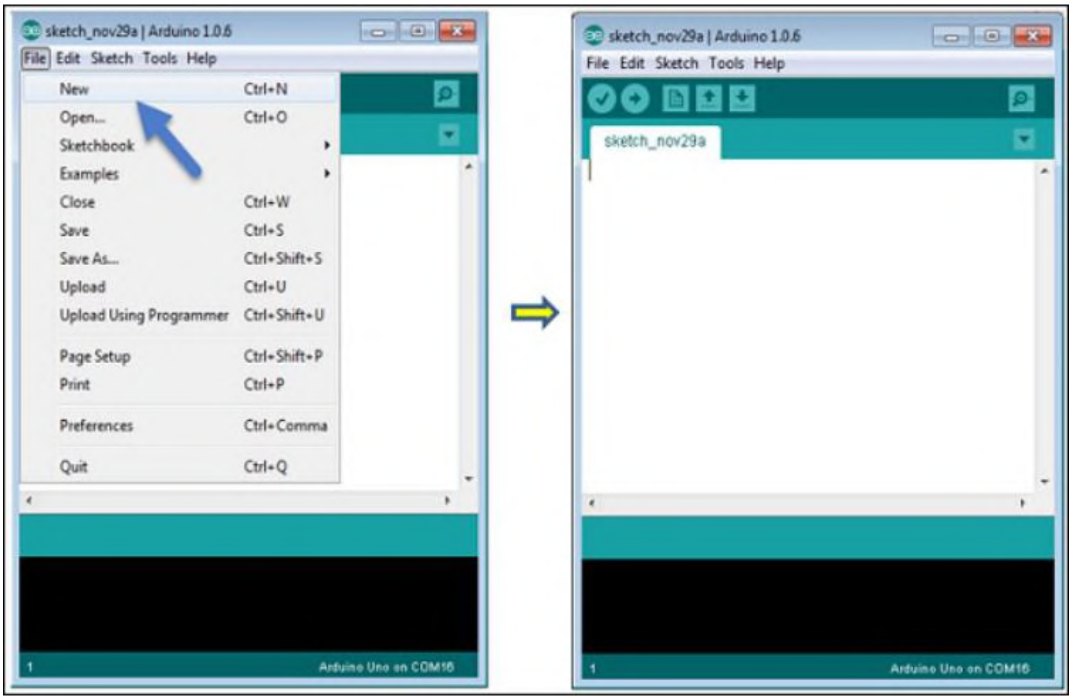

Fig 6.4.5: Opening a new file

To open an existing project example, select File → Example → Basics → Blink.

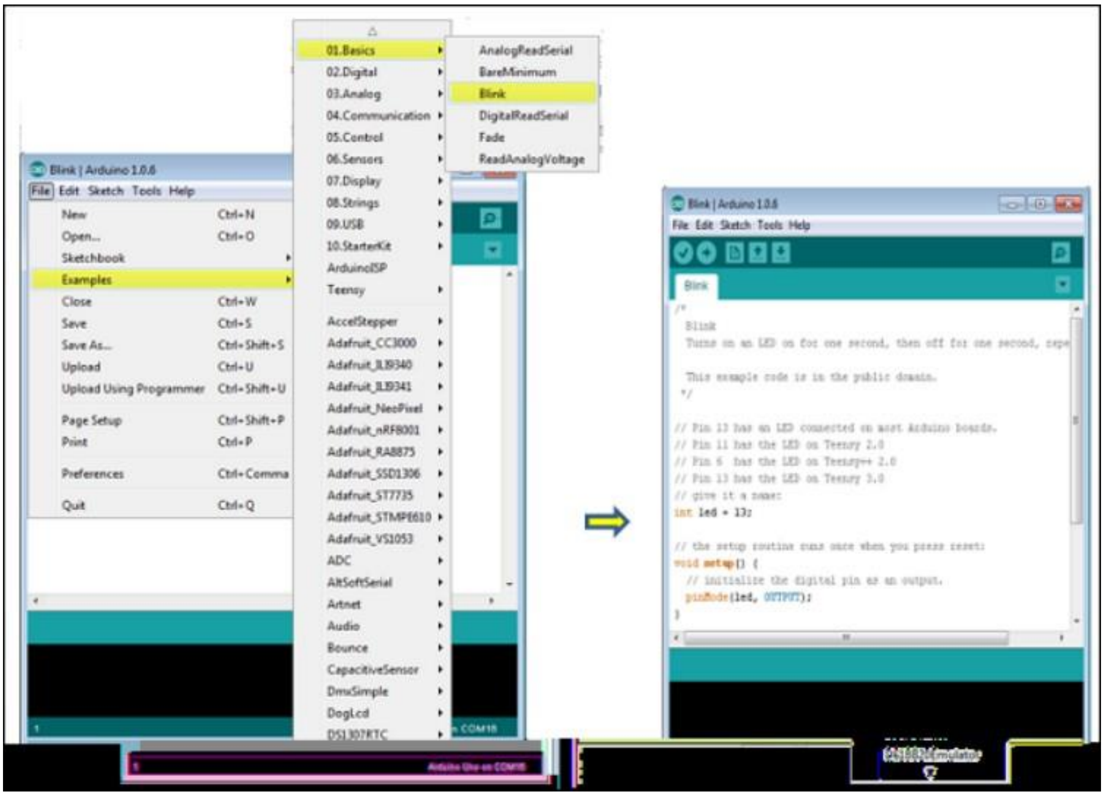

Fig 6.4.6:Examples related to Arduino

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer. Go to Tools → Board and select your board.

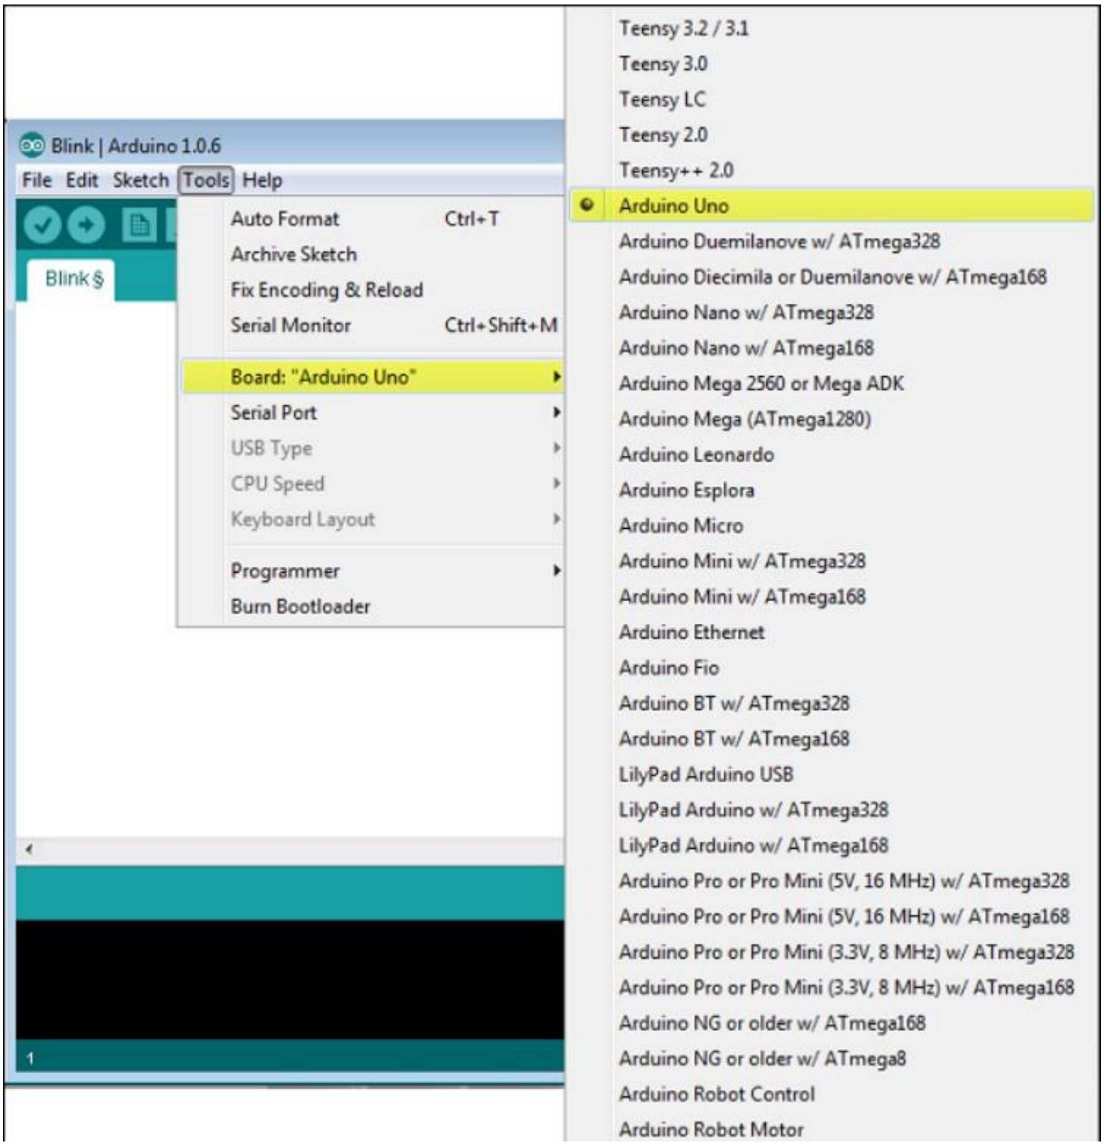

Fig 6.4.7:Basic Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

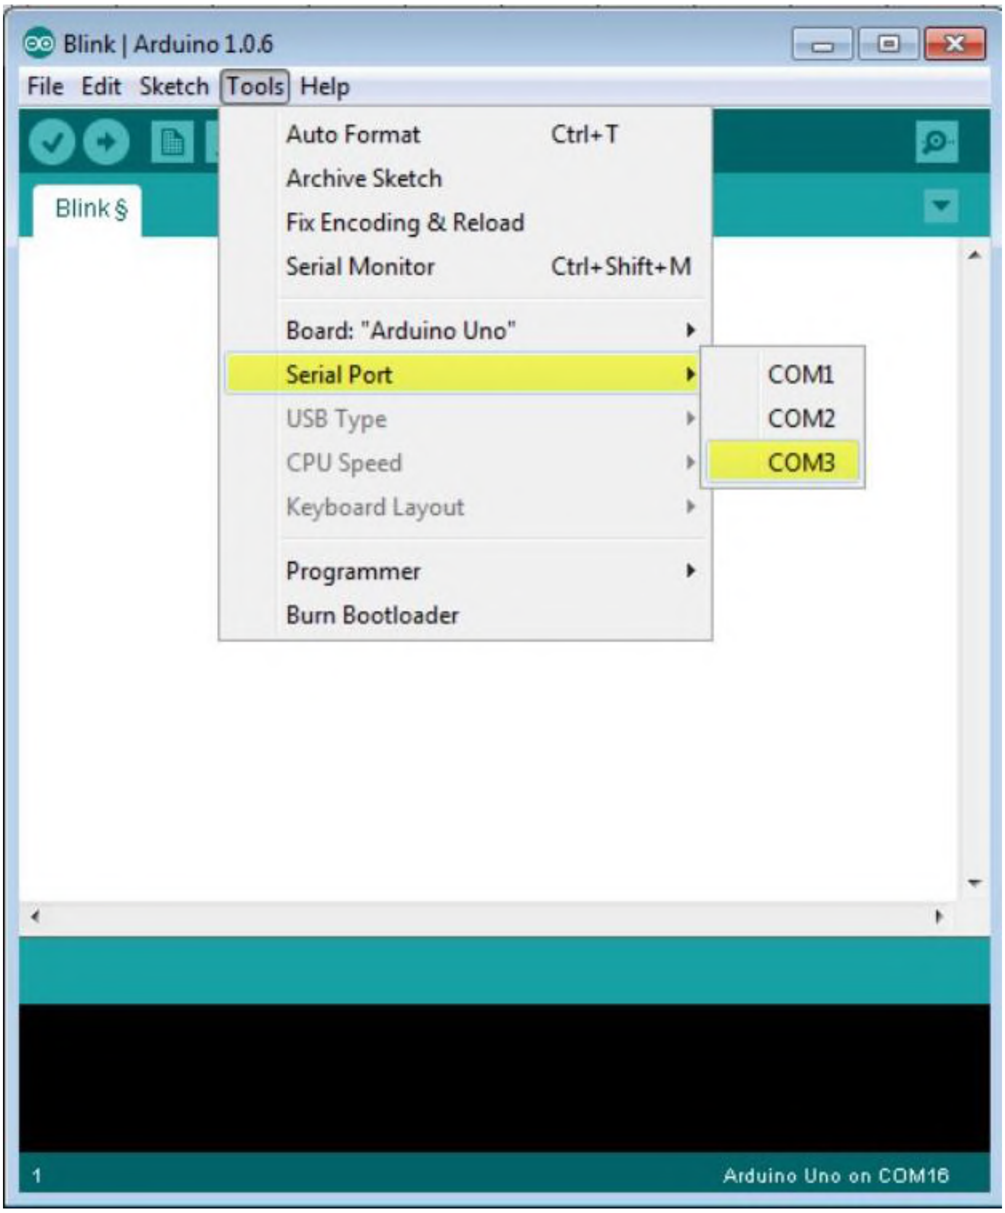

Fig 6.4.8 : Serial Port-COM3

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

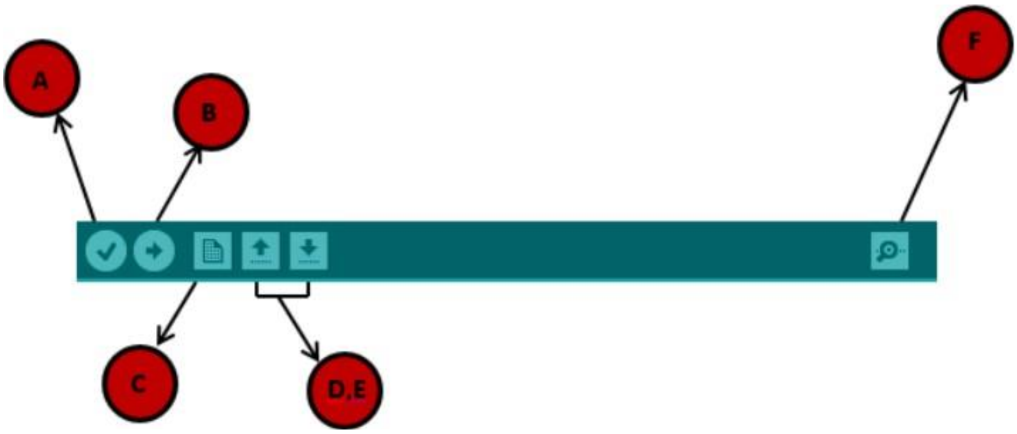

FIG 6.4.9: Uploading the program on board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

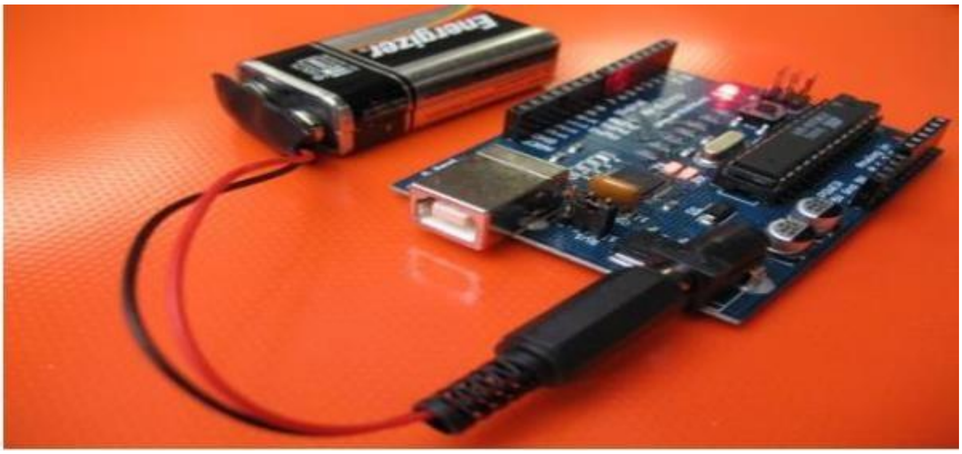

FIG 6.5.1:ARDUINO WITH BATTERY

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()

{

Serial.begin(9600);

Serial.println("Hello World");

}

void loop() {}
```

Fig 6.6.1 Arduino Programming Sketch

MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

Proteus:

Proteus is a simulation and design software tool developed by Lab centre

Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc. ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

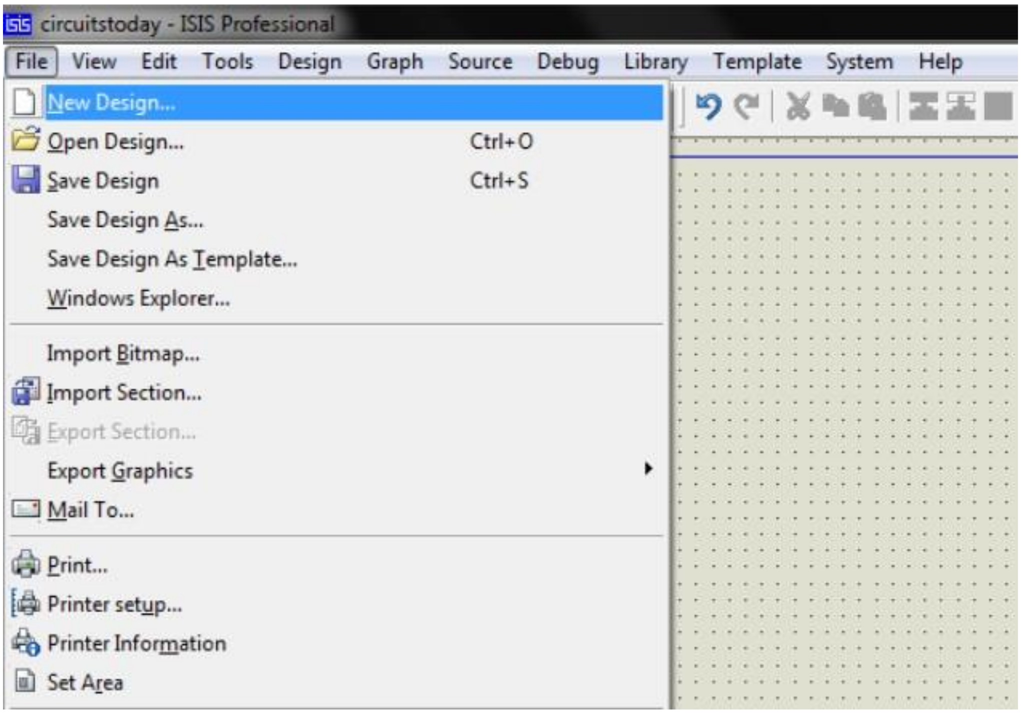

Fig 6.8.3.1:Proteus file menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a PopUp appears asking to select the template. It is similar to selecting the paper size while printing.

For now, select default or according to the layout size of the circuit.

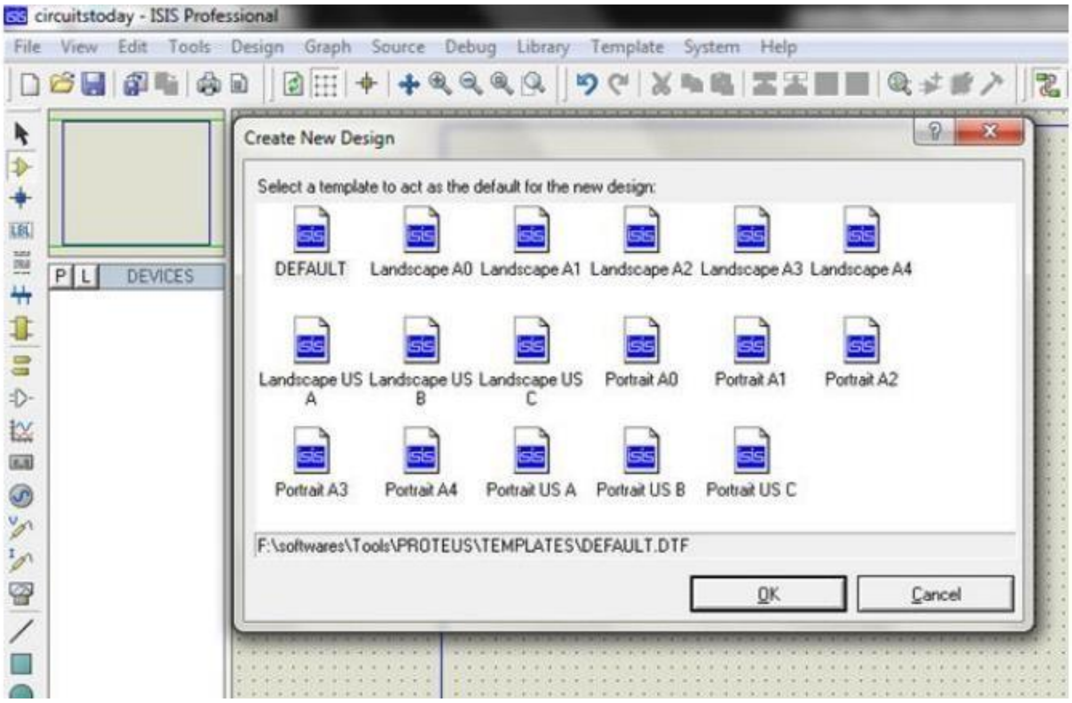

Fig 6.8.3.2:Proteus Default Select Template

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory

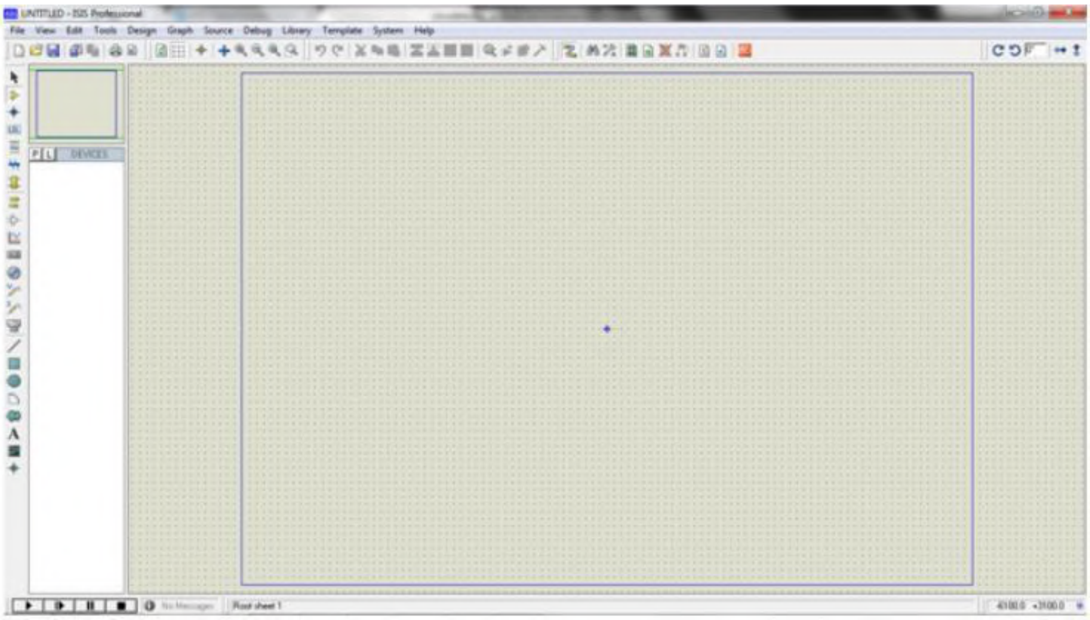

Fig6.8.3.3: Proteus design sheet

Step 4: To Select components, Click on the component mode button.

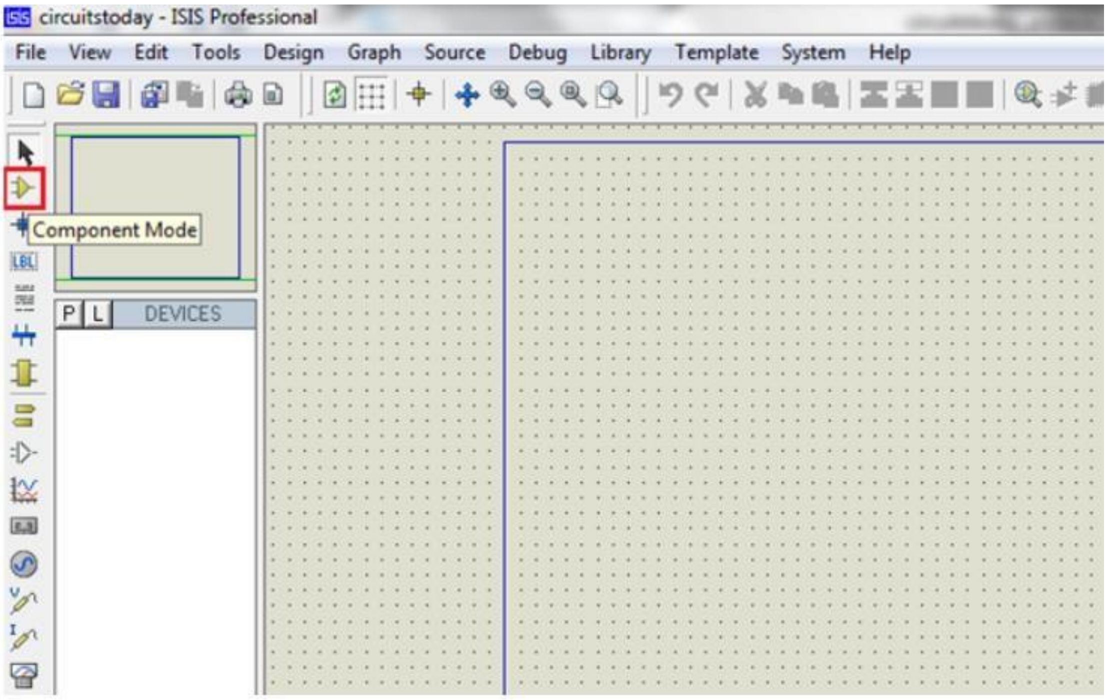

Fig 6.8.3.4: Component mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

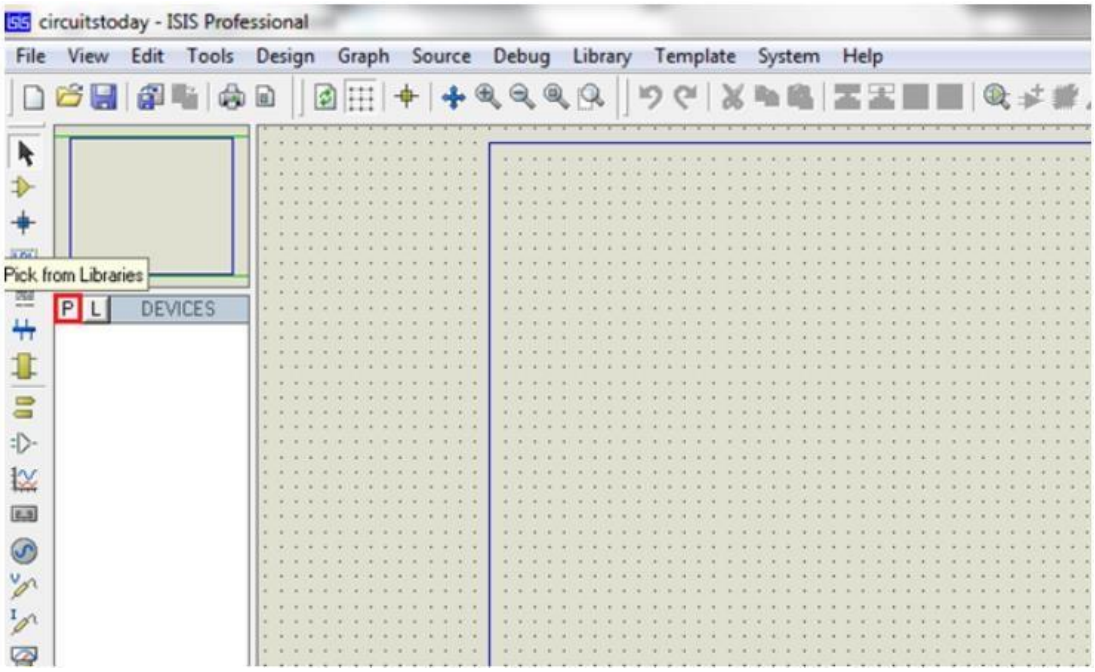

Fig6.8.3.5: Pick from libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

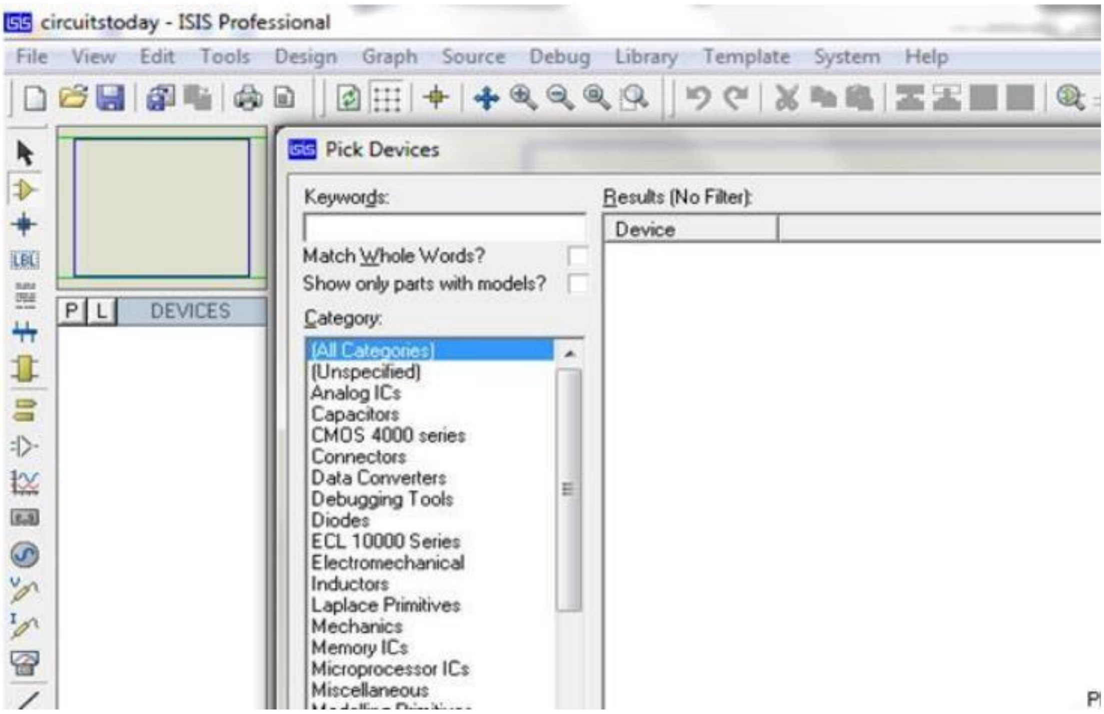

Fig 6.8.3.6:Keywords Textbooks

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

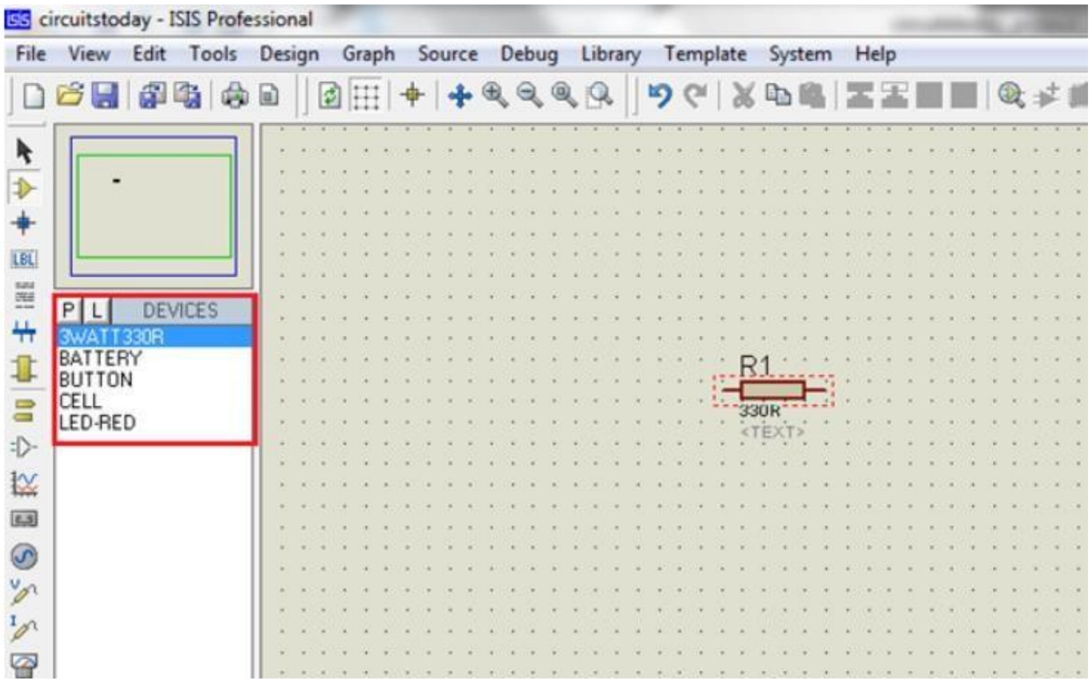

Fig 6.8.3.7:Component selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to

connect through wires. Left click from one terminal to other to make connection. Double rightclick on the connected wire or the component to remove connection or the component respectively.

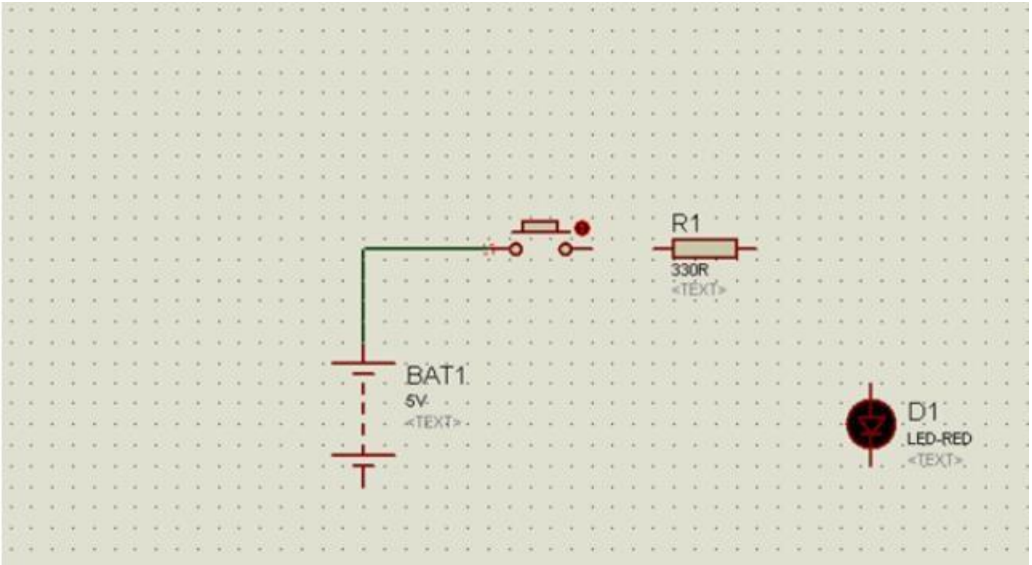

Fig 6.8.3.8: Component Properties selection

Double click on the component to edit the properties of the components and click on Ok.

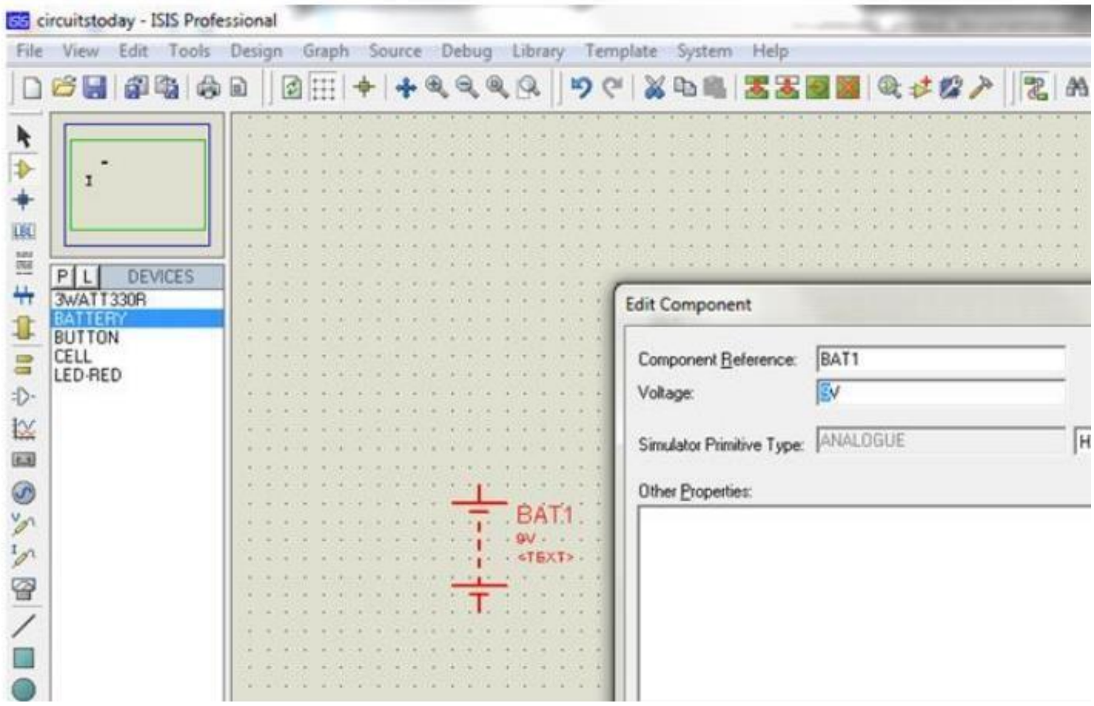

Fig 6.8.3.9: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

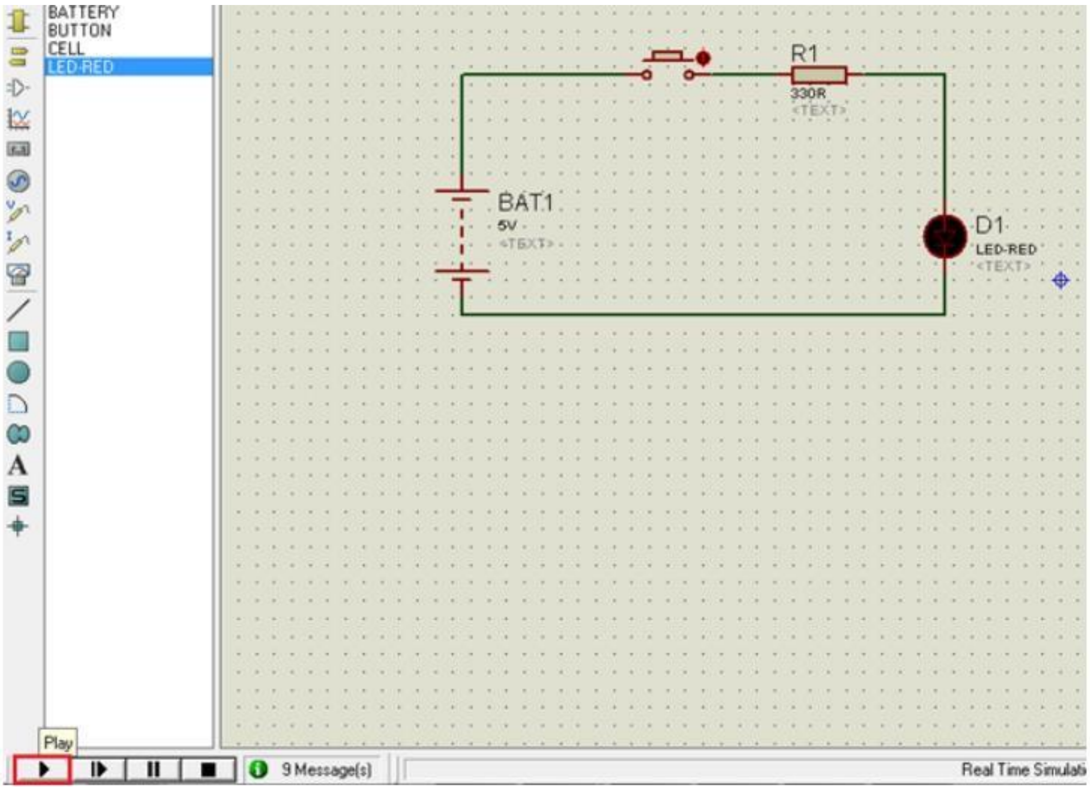

Fig 6.8.3.10:Simulation run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

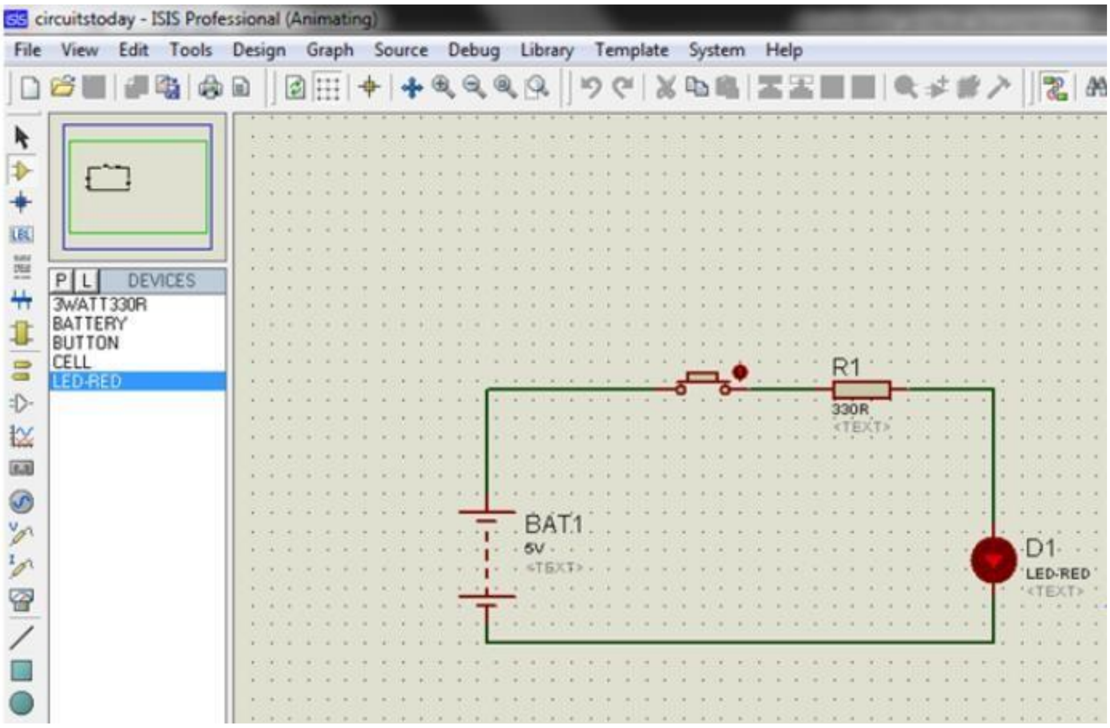

Fig 6.8.3.11 :Simulation Animating

Simulation can be stepped, paused or stopped at any time

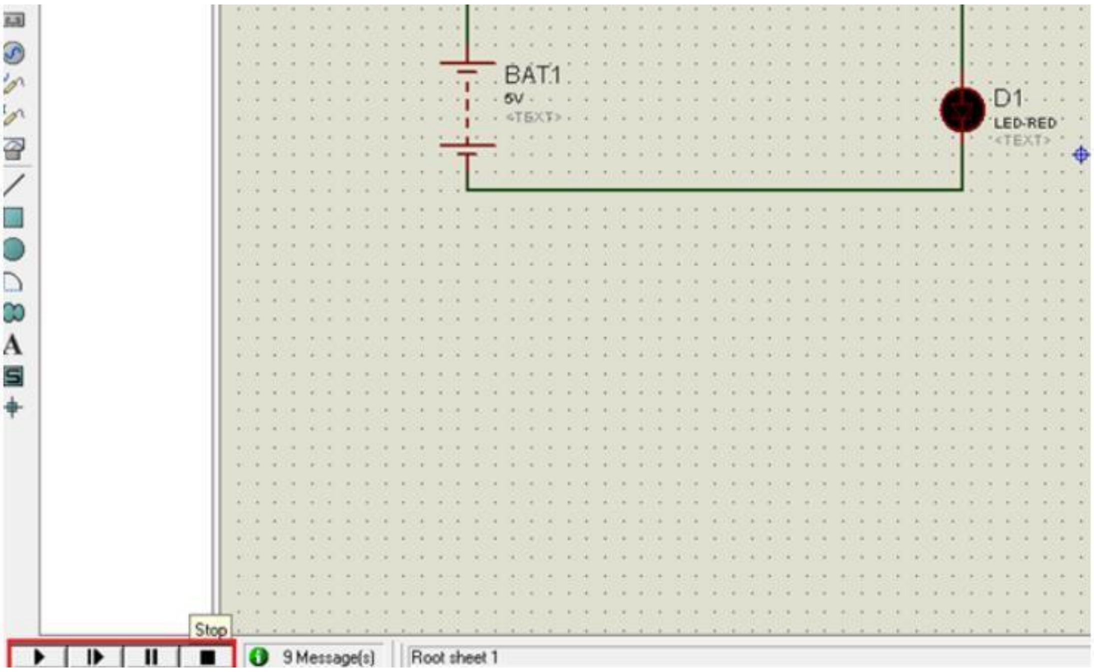

Fig 6.8.3.12: Stimulation Step -pause-stop button

Project Code:

 delay(1000);
}
```

CHAPTER 7: RESULTS

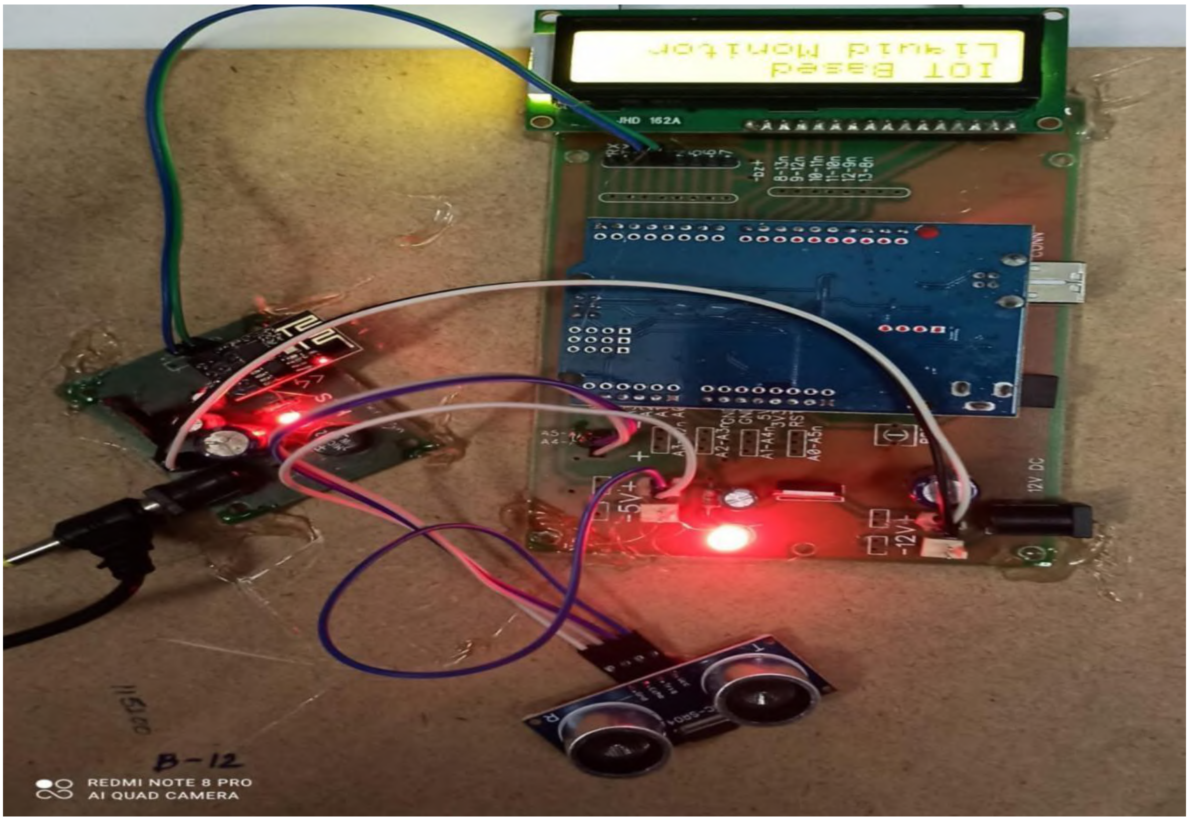

Fig7.1 : The circuit kit of the project

The Arduino UNO is connected to the system with a required code dumped in it.Through the functioning of ultrasonic sensor the level of liquid is analyzed and is sent to Arduino board to process and send the data to the LCD and wifi module. This Data is sent through internet using wifi module and this data can be accesed through telnet app on smart device such computer or smartphone which has a reliable internet connection

Fig7.2: LIQUID LEVEl IN TERMS OF PERCENRAGE

Here the LCD is showing the level of liquid in container in digital format.

FIG 7.3: LIQUID LEVGEL IN TERMS OF LEVEL

The liquid level is shown as low when level of liquid is less than 10% of the container.

CHAPTER 8:

CONCLUSION

Conclusion:

The IOT is one of the most rapidly growing technolgy as it helps us to live a better lives by connecting technologies together and conservation of liquids like water and fossil fuels is very important as they are not abundantly available,Which requires constant monitoring.In order make it possible we have come up with this project.The main motto of this project is to remotely monitor the liquid levels in a container with very less hardware.

Future Inhancements:

- This can be further developed to calculate the water consumption in a time period.
- This system can be implemented for more than one tank or container for example. This can be used with a connected set of tanks as well.
- Thereby especially the industrial firms can manage the water effectively.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our college management** for their kind support and permission to use the facilities available in the institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, our **beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna, Head & professor,** the **Dept. of Electronics and Communication Engineering** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Dept. Project Coordinator** Dr. **A. Anand, Assistant Professor, Dept.of ECE** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, Mr.**D.Prasad, Assistant Professor**, Department of ECE and our class project coordinator **Mr.Karthik,Assistant Professor**, Department of ECE for guidelines and encouragement in carrying out this project work.

We are highly grateful and obliged to our college level project coordinators **Dr.Maalydri, Professor in IT & Dr.R.Santhosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

ABSTRACT

This paper proposes an information hiding method to embed data while executing image enhancement steps. The 2D Median Filter is adapted and re-engineered to demonstrate the feasibility of this concept. In particular, the filtering embedding steps are performed for each pixel in a sliding window manner. Pixels enclosed within the predefined window (neighbourhood) are gathered, linearized and sorted. Then, the linearized pixels are divided into partitions, in which each partition is assigned to represent a certain sequence of bits. The performance of the proposed method is evaluated by using the BSD300 data set for various settings. The embedding capacity, image quality, data extraction error rate are reported and analyzed. Besides, the robustness of the proposed method against brute force attack is also discussed. In the best case scenario, when the window size is 7×7, ~ 0.97 bpp is achieved with acceptable image quality while having $\sim 3.5\%$ data extraction error rate.

INTRODUCTION

INTRODUCTION TO THE PROJECT

The earth is associate aquatic planet and the maximum amount as eightieth of its surface is roofed by water... Moreover, there is a strong interest in knowing what lies in underwater. Present days, an image of deep waters has a scope to large investigation to explore the underwater for sea floor expedition and navigation. Enthusiasm of underwater imaging includes the inspection of plants, seabed exploration, the search for wrecks up and to the exploration of natural resources. There were several issues faced by the human in the underwater, if he dives deep into the ocean and stay there for a long time to perform experimentation. [1]. Due to the above reasons, unmanned remote vehicles are used to sea floor exploration.

A. Historical Development

Underwater image quality improvement approaches present a path to magnify the object recognition in underwater surrounding. A heap of research started for the upgradation of image visual quality, but a little amount of work has been carried out in this area. In the deep waters, image quality is degrading due to poor illumination conditions and the light properties differ in water compared to air.[2]. There were several parameters which decreases the quality of an image in underground waters. So in order to remove all these effects
there are several techniques has been implemented and practiced.

B. Need for Pre process

Initially processing is necessary for deep water images due to their poor-quality during acquisition. Necessity for pre-processing of deep-water images [1] are discussed below:

(i) Quality of images taken from deep water is deteriorated due to light ray attributes like scattering and absorption of light.

(ii) Specificity of surroundings such as lighting inequalities, water torridness, and blue complexion is more or less influential when vehicles move.

(iii) Video or image captured from deep waters like unknown rigid scene, and the depth of the scene and low light sensitivity due to Marine snow etc.

TRADITIONAL TECHNIQUES FOR IMAGE ENHANCEMENT

There are several techniques which are used very frequently for processing the image to improve the visual quality. Some of them are as follows:

(i) Contrast Stretching (ii) Adaptive Histogram Equalization

A. Contrast stretching

The contrast stretching is a method to transform high intense region of image into brighter and less intense region into darker by using a predefined transformation function T(r) [2]. Generally, the underwater images will have less grey values. There are 256 grey values. '0' indicates black and '255' indicates white. In this method the current grey value of the image is stretched towards 255 i.e., from black to white, pixel by pixel. That means the contrast of the image is stretched, so that the quality of the image is improved for better vision.

For example:

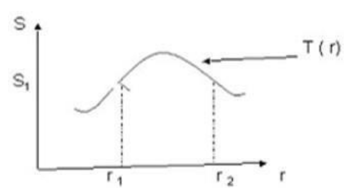

Fig.1.2 Two different gray levels look same

Here two different thresholds are considered for the entire image and the values between them are stretched to the maximum extent, so that the contrast increases. And more over by this method the entire global image contrast is enhanced.

Fig.1.2.1 (a) Raw image **(b) Enhanced image**

But the disadvantage here is that the transformation function is not unique. Depending on the application the suitable transformation function is chosen.

B. Adaptive histogram equalization

Adaptive histogram equalization is a PC based image processing technique which is used to improve the quality of image properties like contrast. It is similar to contrast stretching method but with a slight difference. It computes several intensities of specific gray value, each corresponding to a distinct portion of an image, and with the help of them intensities are rearranged by applying a suitable transformation function. For example, a simple transformation function such as each pixel transformed based on the histogram of a square surrounding the pixel [3]. Existing values will be mapped to new values keeping actual number of intensities in the resulting image equal or less than the original number of intensities. The transformation function applied on the histogram is proportional to the cumulative distributive function (CDF) of pixel values in the neighbourhood. Therefore it suits for enhancing the local details and enhancing the edge information of each region of an image.

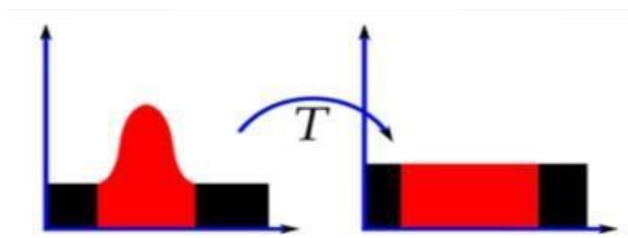

Fig.1.2.2. Histograms of an image before and after histogram equalization

Histogram equalization is a technique for changing the overall pixel intensities based on transformation function and contrast of an image. Histogram equalization is an effective technique which will benefit for the images with extreme contrast values. The limitation of this technique highlights the unwanted noise present in the background of an image and lead to loss in the information signal. It results in undesired effects in the resultant images [4].

Fig.1.2.3. (a) Raw image (b) Enhanced image

Here the noise in relatively homogeneous regions of the image are amplified which results in poor SNR. And also, only the local objects of the image are enhanced and the background is left unenhanced.

Image enhancement, as its name implies, improves the quality of image by means of emphasizing the desired details or removing/suppressing the undesired noisy/irrelevant information. Image enhancement plays a crucial role in digital image processing, and it has become one of the processes that takes place in any smart device after an image is captured. Some commonly deployed image enhancement techniques include contrast enhancement, image sharpening, smoothing, noise removal, to name a few. Each enhancement technique can either act as a standalone process to enhance the appearance of an image, or utilized as a pre-processing step before further analysis is carried out. In fact, image enhancement (commonly known as filter) is often utilized to enhance image quality before it is shared online on social media or communicated for consumption by a wider audience. However, image enhancement is particularly important when the received original/source image (e.g., from field reporter, amateur photographer) contains noise. While the noisy image is enhanced, the processes involved are not published or shared. One can also imagine the need to share specific tone-mapping operators as well as the parameters used when shrinking the dynamic range of a noisy high dynamic range image into the standard dynamic range. To accommodate this additional data, information hiding appears to be one of the commonly implemented solutions.

INTRODUCTION TO IMAGE PROCESSING

1.3.1. IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person. Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.3.1(a) General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

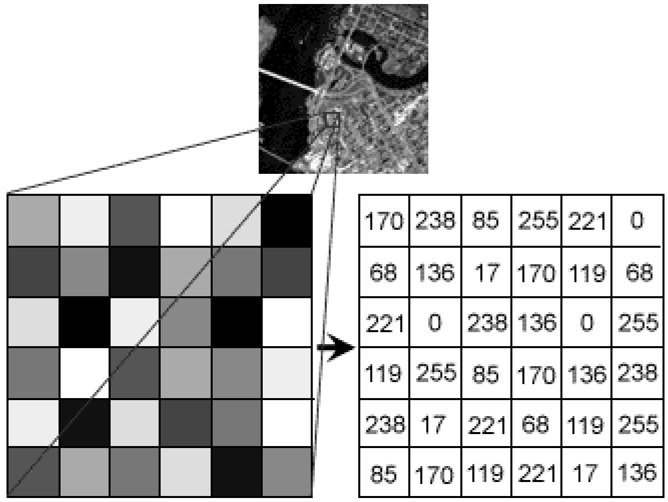

Fig 1.3.1(b) Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1
Transparency	Red	Green	Blue

Fig 1.3.2 Transparency image

IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

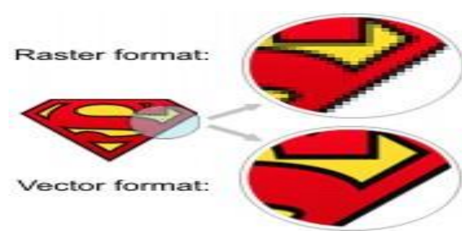

Fig1.3.3 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobes PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSIN

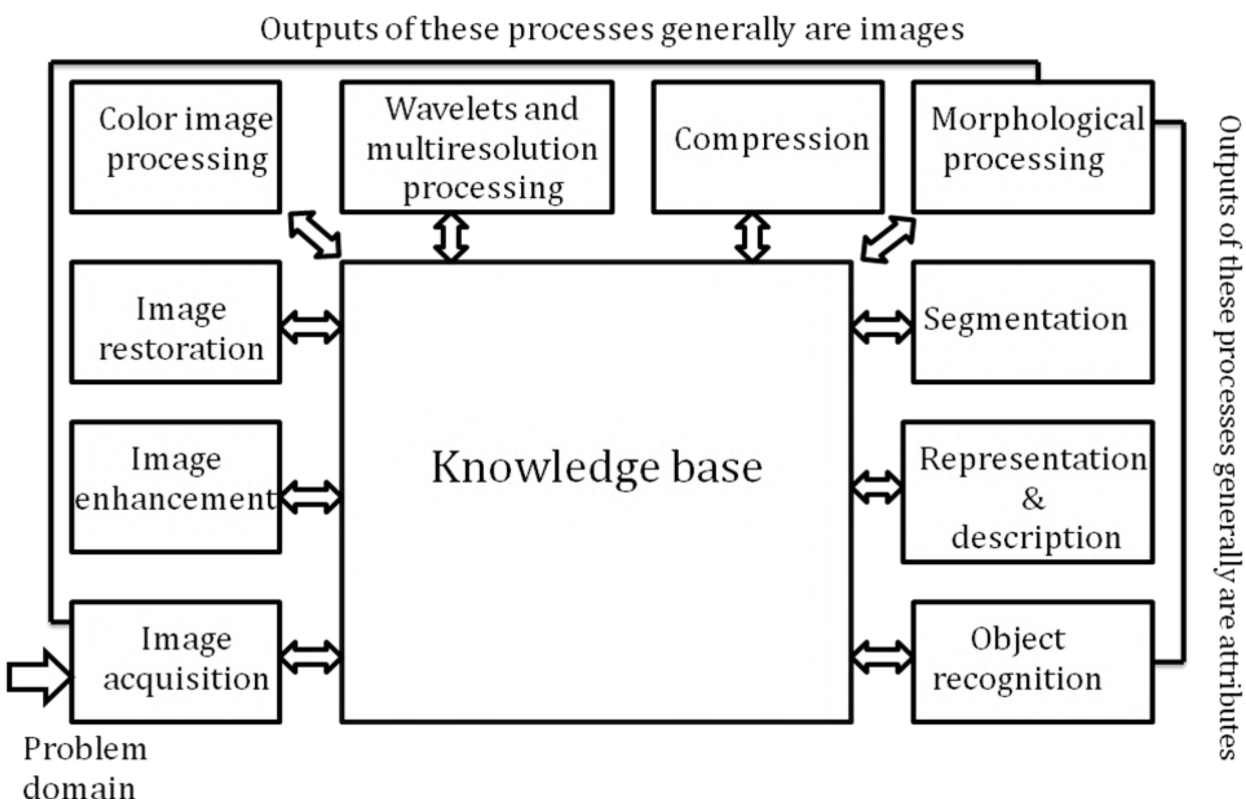

Fig 1.4.1 Image fundamental

Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig:1.4.2 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.4.3 Image enhancement

Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.4.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.4.5 Color & Gray scale image

Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform-based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

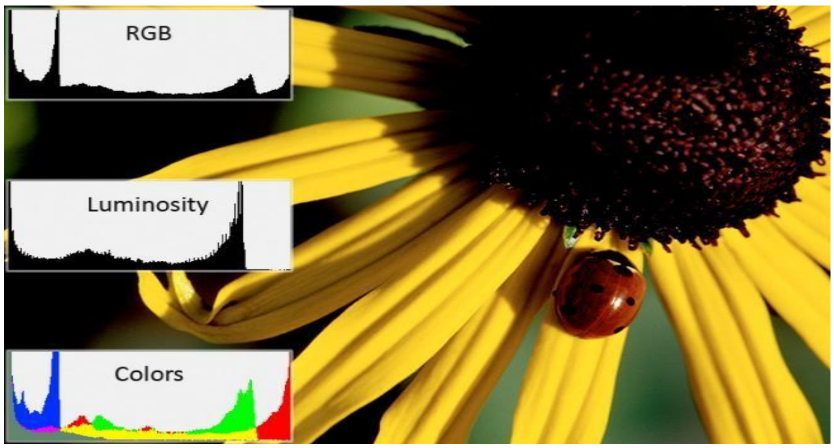

Fig 1.4.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called Multiresolution theory. Multiresolution theory incorporates and unifies techniques from a variety of

disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.4.8 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

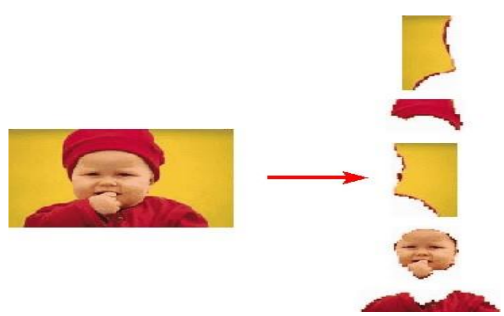

Fig 1.4.9 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

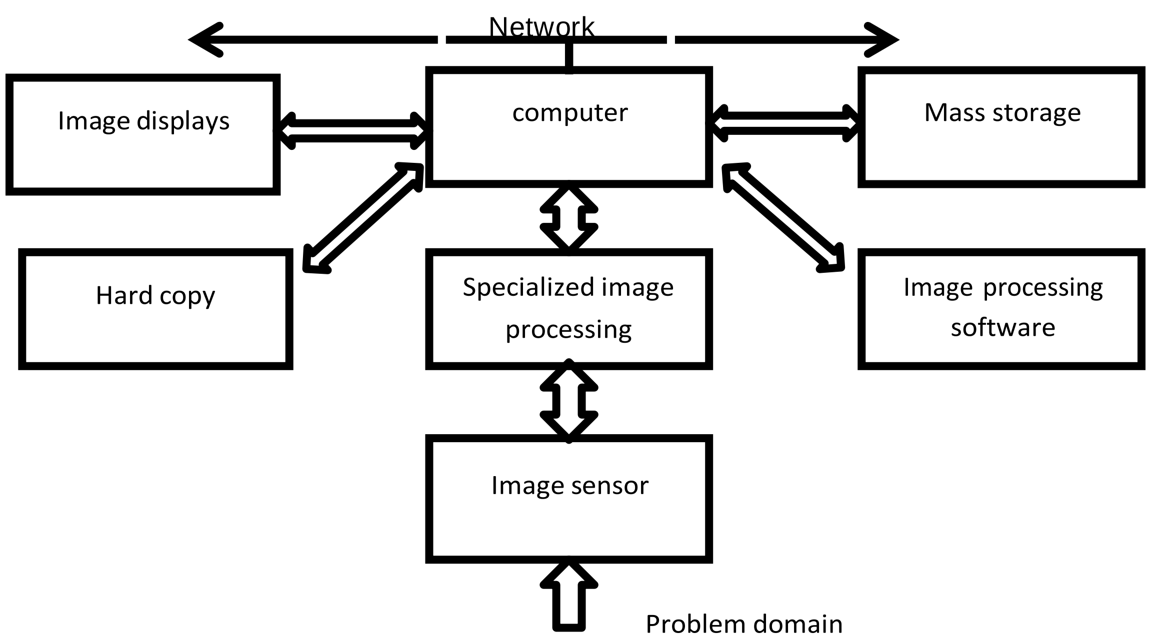

Fig 1.5 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications falls into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes).

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies. Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl$\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

gcm (i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image.

Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three-dimensional matrix that represents the probability of finding pixels of any two given colors at a distance 'd' apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance 'd' apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such database.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance 'd' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space.

The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights. One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi-channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vane) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV (i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU (i, j) and mcmLV (i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map.

Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

1.5.1 Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically, there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue.

The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors.

The saturation and intensity drop just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception.

Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray.

On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the purest form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel

NON-INTERVAL:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H, S, V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 & if \quad h \in [316,20] \\ 1 & if \quad h \in [21,40] \\ 2 & if \quad h \in [41,75] \\ 3 & if \quad h \in [76,155] \\ 4 & if \quad h \in [156,190] \\ 5 & if \quad h \in [191,270] \\ 6 & if \quad h \in [271,295] \\ 7 & if \quad h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 & if \quad s \in [0,0.2) \\ 1 & if \quad s \in [0.2,0.7) \\ 2 & if \quad s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 & if \quad v \in [0,0.2) \\ 1 & if \quad v \in [0.2,0.7) \\ 2 & if \quad v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram.

This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc...,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real -world image search system designers. As far as technological advances are concerned, growth in

Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods.

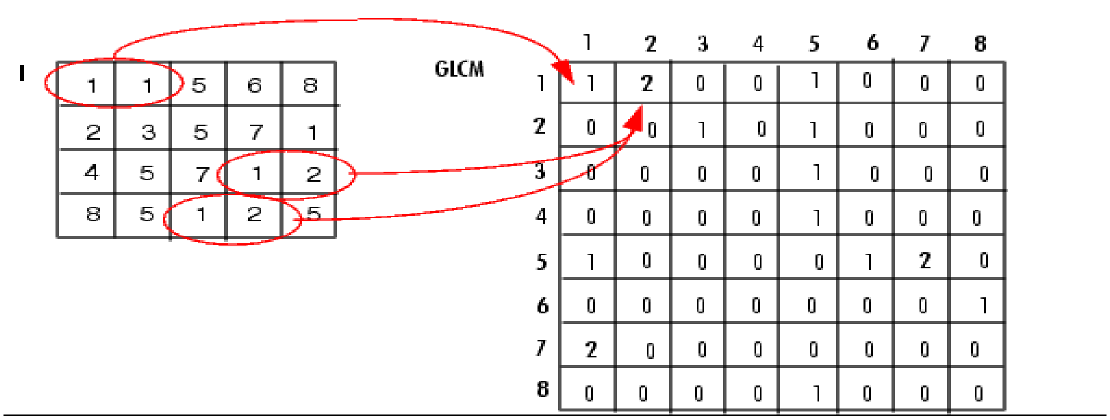
The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kofola's and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented to differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



1.6.4 overview of texture

DIGITAL IMAGE PROCESSING

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude off at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision. There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes.

Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two-dimensional function f (x, y) where x and y are spatial co-ordinates and the amplitude of ‘f’ at any pair of coordinates (x, y) is called the intensity of the image at that point.

1. Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle $[0, a] \times [0, b]$ I: $[0, a] \times [0, b] \rightarrow [0, \text{info})$

2. Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude.

Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

3. Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f (x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many images processing books, the image origin is defined to be at (xylem)= (0,0). The next coordinate values along the first row of the image are (xylem)= (0,1). It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row.

It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0)   f (0,1)   ………   f (0, N-1)

f (1,0)   f (1,1)   …………   f (1, N-1)

f (xylem)=   .   .   .

.   .   .

f (M-1,0)   f(M-1,1)................f (M-1, N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f (1,2)..........f (1, N)

f (2,1)   f (2,2).........f (2, N)

.   .   .

f =   .   .   .

f (M,1)   f(M,2).........f (M, N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f (p, q) denotes the element located in row p and the column q. For example, f (6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f (x, y), for mathematical expressions.

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread ('filename')

Format name	**Description**	**recognized extension**
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	. xwd

Table 1.7.4 Reading Images

Here filename is a spring containing the complete of the image file (including any applicable extension). For example, the command line " >> f = imread ('8. jpg')";

Reads the JPEG (above table) image chest Xray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

Name	**Description**
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integer in the range [0,255] (1byteper Element).
Uint16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).
Uint 32	unsigned 32_bit integers in the range [0, 4294967295]
Int 16	signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
Single	_precision floating _point numbers with values
Char	characters (2 bytes per elements).

TABLE 1.7.5 DATA CLASSSES

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 -bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1, with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

1.Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

2. Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s. Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical, we use the I logical function: is logical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions

3. Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1]. The length m of the map is equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double, then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

4.RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly, the range of values is [0,255] or [0, 65535]. For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible colors in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

Chapter 2

LITERATURE SURVEY

Literature Review on research area:

Steganographic methods on spatial domains using the XOR operator. Message insertion is performed with two first XOR operations imposed on the 1st and 8th bits and the second is on the 2nd, 7th bit. The result of the operation is then compared and used as a rule for inserting the message. The cover image used is a 512 * 512 grayscale image and three message sizes, 1024 bits, 2048 bits and 4096 bits. The value of PSNR obtained is about 69 dB with a message length of 4096 bits. proposing steganography on the image using the differencing bits technique on the 5th and 6th bits. If there is a difference in the 5th and 6th bits equal to the bits of the secret information then no change is made. Meanwhile, if there is a difference in value, the value changes to the 5th bit so that the value of the difference corresponds to the bit value in the secret information. The cover image used is grayscale image and colour image with size 512 * 512.

With this method obtained PSNR 51.17977 dB on Lena grayscale image and PSNR 52.3438 on Lena colour image, with a payload capacity of 262144 bits message proposed a combination of steganographic and cryptographic methods, with messages encrypted using the OTP method before being embedded on the LSB. To improve imperceptibility and secure embedding of messages is done on the image edge area. Image edge area detection is done by the Canny method. The cover image used is type JPEG with the size of 11035 bytes, while the message pinned 1024 bytes obtained PSNR 69.1106 dB.

In addition, the stego image quality is also measured by a histogram, where the cover image histogram and stego image are identical also proposes embedding messages in the image edge area. In his research combined steganography techniques using LSB and cryptographic techniques using DES. Before the image message is inserted, the message is encrypted using the DES method. The cover image used is a color image with the size 1024 * 1024, while the message is also a color image with size 64 * 64. The encrypted message is embedded in the image edge area detected by the Canny method.

Based on the results of this research, the average value of PSNR 72.21584 dB, which is obtained from five kinds of imagery.

Review of related literature:

Least Significant Bit (LSB) is a very popular method in the spatial domain of steganographic images. This method is widely used and continues to be developed to date, because of its advantages in steganographic image quality. However, the traditional LSB method is very simple and predictable. It needs a way to improve the security of hidden messages in this way. This research proposes a simple and safe way to hide messages in LSB techniques. Three times the XOR operation is done to encrypt the message before it is embedded on the LSB. To facilitate the process of encryption and decryption of messages, three MSB bits are used as keys in XOR operations. The results of this study prove that this method provides security to messages with very simple operation. The imperceptibility quality of the stego image is also excellent with a PSNR value above 50 db.There are many conventional information hiding methods, including Least Significant Bit (LSB) insertion, Histogram Shifting (HS) and Difference Expansion (DE), to name a few.

These techniques are studied extensively and many of their variants are proposed [1, 2, 3] to achieve a balance trade-off among embedding capacity, image quality, robustness against attacks, etc. However, these techniques are not widely adopted into the usual operations performed by the users, and often they are implemented as an additional step after the image is processed. In most cases, the user has to explicitly install or develop the data embedding algorithm to enable data embedding into the image of interest. Therefore, in this paper, we design an information hiding method as part of the image enhancement process. In other words, data can be inserted into the image while executing the image enhancement steps. As a proof of concept, the proposed method is demonstrated by using the Median Filter.

Conclusion on Reviews:

However, these techniques are not widely adopted into the usual operations performed by the users, and often they are implemented as an additional step after the image is processed.

In most cases, the user has to explicitly install or develop the data embedding algorithm to enable data embedding into the image of interest. Therefore, in this paper, we design an information hiding method as part of the image enhancement process. In other words, data can be inserted into the image while executing the image enhancement steps. As a proof of concept, the proposed method is demonstrated by using the Median Filter.

Chapter 3

Proposed system

Block Diagram:

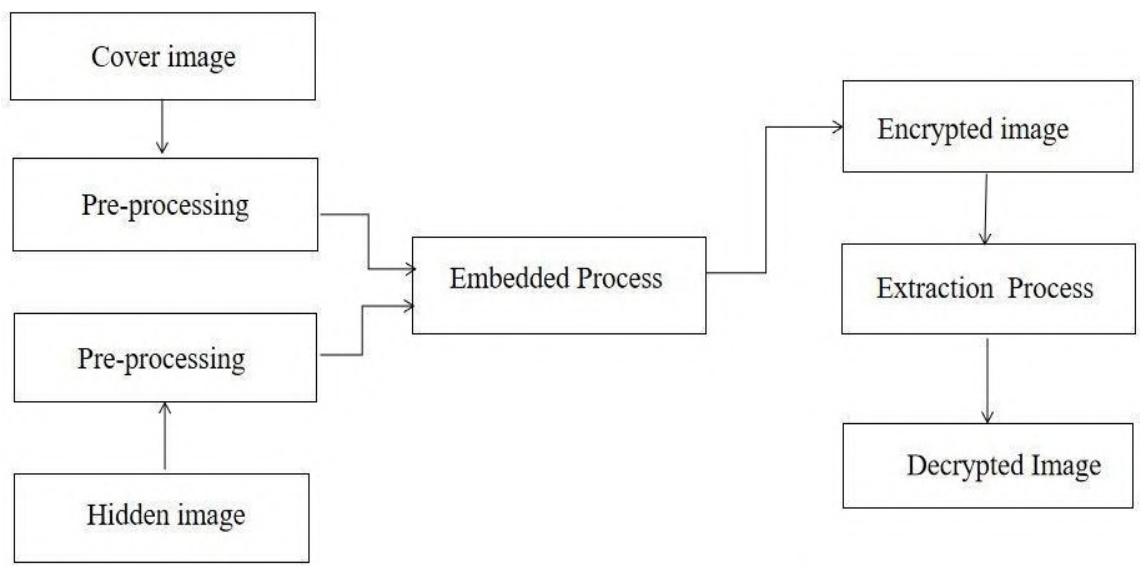


Fig :3.1 Block Diagram of the Proposed System

Median filter is commonly utilized for noise removal in image enhancement. Specifically, median filter focuses on a target pixel X, and considers the w × w-neighborhood pixels surrounding X.

These pixels are sorted, and the middle value is selected to replace the target pixel. The process is repeated for all pixels in the image.

This technique is feasible because noises are abrupt changes in an image and most natural images have more smooth areas in comparison to edges.

Median filter is particularly effective for salt-and-pepper and speckle noises.

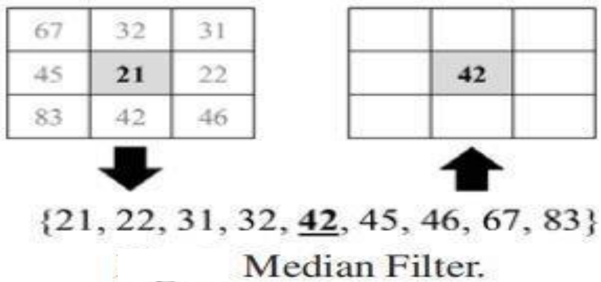
An example of median filter with w = 3, i.e., 3 × 3 neighborhood. Here, the neighborhood

N = {67, 32, 31; 45, 21, 22; 83, 42, 46}.

After the sorting step, the pixels are arranged in ascending order to produce

N = {21, 22, 31, 32, 42, 45, 46, 67, 83}.

Next, the middle value 42 (i.e., 5-th pixel value in this case) is selected to replace the initial target pixel, i.e., 21



Flow Chart:

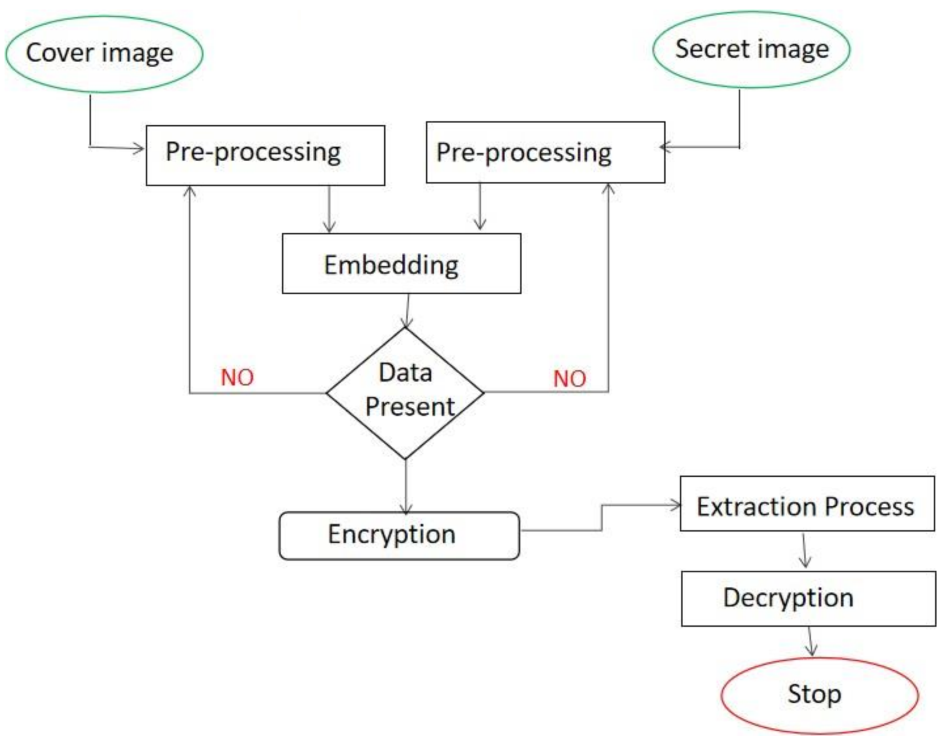


Fig 3.2 Flow Chart of image steganography

Data Embedding:

We re-engineer the conventional Median Filter algorithm to hide data expressed in binary representation. To ease the presentation, let M and N be the number of rows and columns in an 8-bit gray scale image, G. Then, let G (m, n) denote the (m, n)-th pixel in G, for m ∈ [1, M] and n ∈ [1, N]. Without loss of generality, let the to-be-embedded data Φ = {φj} be as sequence of 0's and 1's, where φj refers to the j-th bit of Φ. Next, for the target pixel X, the pixels within the w × w-neighborhood NX are gathered, sorted, stored in a temporary array Γ. Let γi denote the i-th pixel in the sorted array, where γi ≤ γi+1 for is = 1, 2, ··· , w2. Next, Γ is divided into r partitions to represent φj . When r = 2, two partitions are formed, where Γ0 consists of the first pixel to the w2/r- th pixel, and the second partition Γ1 has the rest of the pixels from Γ. Here, z refers to an integer less than or equal to z. Using the same example in Fig. 1, Γ0 = {21, 22, 31, 32} and Γ1 = {42, 45, 46, 67, 83}. If φj = '0, any pixel in Γ0 can be selected to replace the target pixel X. Else when φj = '1, a pixel from Γ1 will be selected. These steps are repeated to hide data φj in every pixel of the image. Finally, the output image with embedded data, G is generated.

Data Extraction:

During data extraction, G is processed one pixel at a time. Specifically, for each target pixel X = G (m, n), the same w × w-neighborhood, i.e., NX is considered. Similar to the embedding process, the pixels in NX are sorted and stored into a temporary array Γ. However, the pixel located in the middle of Γ, namely γ w2/2+1, is used as the threshold for data extraction. Specifically, if the target pixel X < γ w2/2+1, then '0' is extracted. Otherwise, if the target pixel X > γ w2/2+1, then '1' is extracted. The steps are repeated for each pixel in G to extract all the embedded data φj . It is noteworthy that, the pixel values within the neighborhood NX in G may not be the same as those within NX in G although both X and X are the (m, n)-th pixel in the respective images. Therefore, error could occur during decoding.

CHAPTER 4

Software Introduction:

Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs.

It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension. fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

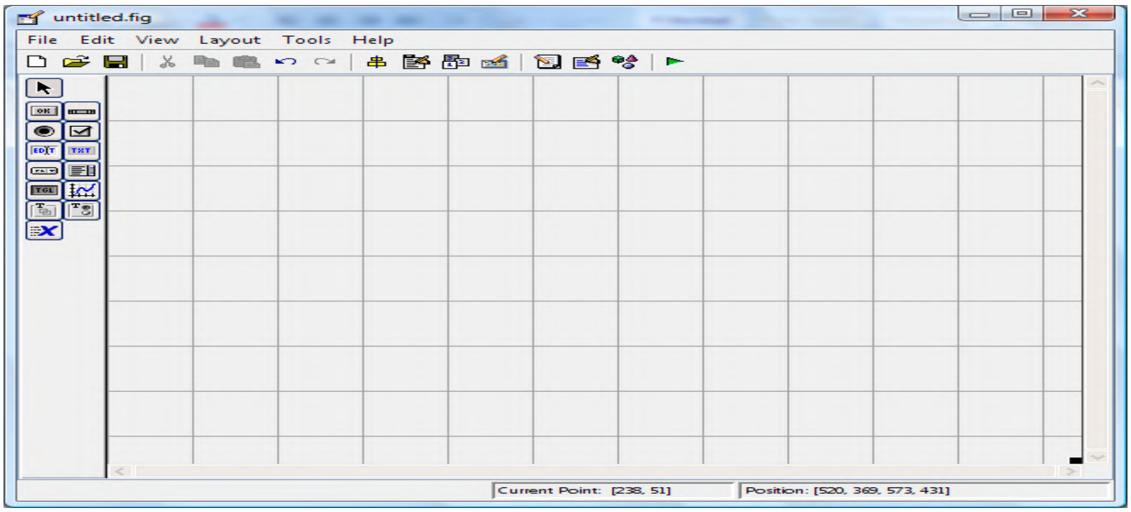

Fig:4.3 Blank Window

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed. GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few

Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

DEVELOPMENT ENVIRONMENT

4.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.

On a UNIX platform, to start MATLAB, type MATLAB at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example, emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Content's tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorite's tab - View a list of documents you previously designated as favorites.

Display Pane-After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go. Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace as from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a. mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

MANIPULATING MATRICES

Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Durer’s matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered. `

```
A =

   16    3    2   13

    5   10   11    8

    9    6    7   12

    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

Operators

Expressions use familiar arithmetic operators and precedence rule.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table: Operators

Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, for a list of more advanced mathematical and matrix functions, type help specfun help elmat.

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2- \varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

4.6.4 Table: Functions

GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uncontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

GUI Development Environment

The process of implementing a GUI involves two basic tasks.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uncontrol and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uncontrol's; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

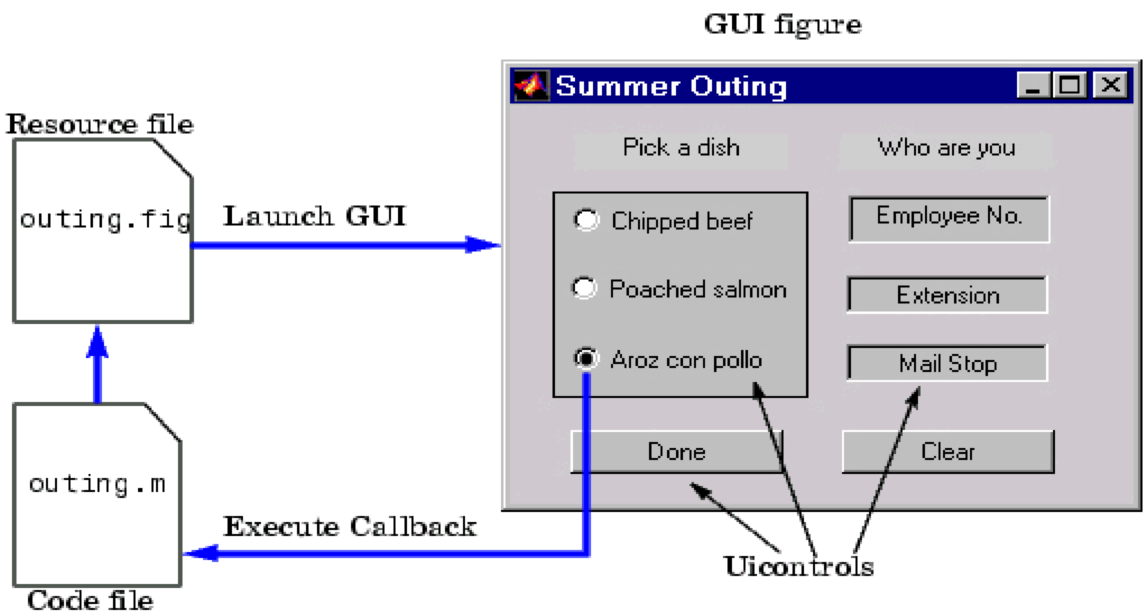

FIG 4.7.2 graphical user blocks

Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features).

The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as find obj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close button) before activating the GUI.

Programming the Callback When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file. function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

```
button_state = get(h,'Value');

if button_state == get(h,'Max')

   % Toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

a(:,:,1) = rand (16,128);

a(:,:,2) = rand (16,128);

a(:,:,3) = rand(16,128);

set (h,'CData’, a)

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback (h, event data, handles, varargin)

off = [handles. radiobutton2, handles. radiobutton3, handles. radiobutton4];

mutual exclude(off)

% Continue with callback

 .

 .

 .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback (h, eventdata, handles, varargin)

if (get(h,'Value') == get(h,'Max'))

   % Then checkbox is checked-take appropriate action

else

   % Checkbox is not checked-take appropriate action

end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback (h, event data, handles,varargin)

user string = get(h,'string');

% Proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns Nan. You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is Nan, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata, handles,varargin)

user entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg ('You must enter a numeric value','Bad Input','modal')

end

% Proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls display lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items. The String property contains the list of strings displayed in the list box. The first item in the list has an index of The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

List boxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure, you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu are fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback (h, event data, handles, varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback (h, event data, handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's Button-down callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button-down property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes (handles. axes1)

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axis. See GUI with Multiple Axes for an example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

Chapter 5

RESULT ANALYSIS

5.1 Results:

Experiments conducted in this research using grayscale image as the cover image, and binary image as a message, see Figure as cover images and as a message. The cover image and message image have the same size, 256 * 256 in size.
Here is a cover image used in this study:

Fig 5.1.1 Original Image

The hidden data should be robust against unauthorized extraction / viewing. In the simplest scenario, the attacker has the knowledge about the proposed method as well as the fact that only one fixed pixel pair with 2 partitions is used throughout the image to hide data. The number of possible cases (i.e., correctly guessing the threshold value used during the filter embedding step) to consider can be formulated as:

$\Lambda = [\, w2/r \times (w2/r + 1)] \times 2$

where in these two partitions, each consists of $w2/r$ pixels and $(w2/r + 1)$ pixels, respectively. The value 2 signifies that there is $r = 2$ cases to consider.

Chapter 6

APPLICATIONS AND ADVANTAGES

APPLICATIONS OF THE PROJECT:

- In Military applications
- In various Business Companies
- Protection of data alteration
- Access control system for digital content distribution
- Media Database system

ADVANATAGES OF THE PROJECT:

- It used in the way of hiding not the information but the password to reach that information.
- Messages do not attract attention to themselves i.e., difficult to detect. only receiver can detect.
- It can be done faster with large amount of software.
- This method featured security, capacity and robustness, the three needed aspects of steganography that makes it useful in hidden exchange of information through text documents and establishing secrets communication.

CHAPTER 7

CONCLUSION AND FUTURE ENHANCEMENT

CONCLUSION:

In this paper, data is embedded while executing the image enhancement steps performed on image. In particular, pixels within the neighbor for a target pixel is collected and sorted in ascending order. This pixel's list is then partitioned and each partition is assigned to represent data in bit(s). Performance of the proposed method is evaluated to identify trends and patterns. Trade-offs among embedding capacity, image quality and data extraction error rate are further discussed. Suggestions are provided to reduce the data extraction error rate and to enhance the robustness of the proposed method against unauthorized viewing. Under various settings, the proposed method can embed 0.99bpp when $w = 3$, and the lowest data extraction error rate is $\sim 3.5\%$ when $w = 7$.

FUTURE SCOPE:

Hence more attention needs to be given to increase the robustness of the embedding algorithm. Implementation of blind steganalysis techniques is difficult compared to targeted steganalysis. An implementation hybrid method which includes encryption and transforms would provide a better performance than the existing data hiding schemes. As future work, we will consider color image and investigate into the correlation among the RGB color channels for deploying the proposed filtering-embedding method.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics and Communication Engineering, session: <2017 - 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work Entitled **"IOT ENERGY METER WITH CURRENT, VOLTAGE AND COST MONITORING SYSTEM"** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

K Navitha 17K81A0482
C Rahul Reddy 17K81A0470
K Ganesh Kumar 17K81A0488

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our college management** for their kind support and permission to use the facilities available in the institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra**, our **beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna, Head & professor,** the **Dept. of Electronics and Communication Engineering** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Dept. Project Coordinator** Dr. **A. Anand, Assistant Professor, Dept.of ECE** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We are highly grateful and obliged to our college level project coordinators **Dr.Maalydri, Professor in IT & Dr.R.Santhosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

Finally, I am deeply indebted to my Mother, **Mrs.C.Latha**, my Father, **Mr.C.Rama Krishna Reddy**, my Brother, **Mr.C.Sai Kalyan Reddy** and to my family members for their moral support and continuous encouragement while carrying out this study. I dedicate this thesis to the almighty.

ABSTRACT

Observing and monitoring your power utilization for verification is a not a easy task today since regularly checking the meter room is not an easy task Well, it is very important to know whether you are charged likewise so the need is very sure. Well, we have made a system that allows users to monitor energy meter readings over IOT. Our proposed system utilizes an energy meter with a microcontroller system to monitor energy utilization. The meter is used to monitor units consumed, estimated cost, Line Voltage and current consumed. Simple web application shows the Live Output of these readings over the IOT. This enables users to effortlessly check the units consumed, Line Voltage and current consumed Live from anywhere through the app. In this way the energy meter observing framework enables the client to adequately check the power meter readings.

TABLE OF CONTENTS

LIST OF TABLES

CHAPTER 1

INTRODUCTION

Introduction

The energy consumption can be monitored by using an electric device called an Energy meter. The cost and the regular usage of Power consumption are informed to the user to overcome high bill usage. The Energy meter shows the amount of units consumed and transfers the data to both the customer and to the electrical board so this helps in reducing man-power. The user can check their Power usage from anywhere and at any time interval. The IoT is used to Turn on/off the household appliances using relay and Arduino interfacing. The objective of this system is to monitor the amount of electricity consumed. The distributor and the consumer both will be benefitted by eventually reducing the total Power consumption.

Project overview

Embedded System

An embedded system is a system which is going to do a predefined specified task and is even defined as a combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems include computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.
The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware.

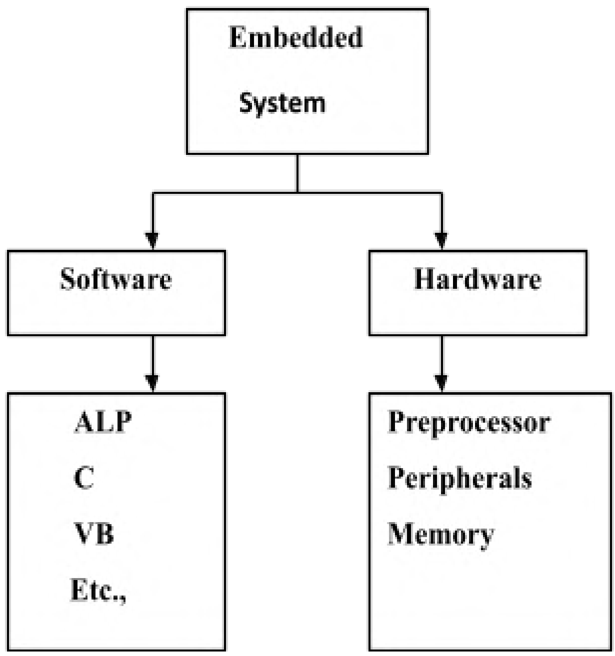

Figure 1: Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or addresses.

Peripherals: These are the external devices connected.

Processor: It is an IC which is used to perform some task.

Applications of embedded systems:

- Manufacturing and process control.
- Construction industry.
- Transport.
- Buildings and premises.
- Domestic service.
- Communications,
- Office systems and mobile equipment.
- Banking, finance and commercial.
- Medical diagnostics, monitoring and life support.
- Testing, monitoring and diagnostic systems.

Processors are classified into four types like:

- Microprocessor (µp)
- Microcontroller (µc)
- Digital Signal Processor (DSP)

- Application Specific Integrated Circuits (ASIC)

Microprocessor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

□ **Instruction set :** The set of instructions that the microprocessor can execute.

□ **Bandwidth :** The number of bits processed in a single instruction.

□ **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

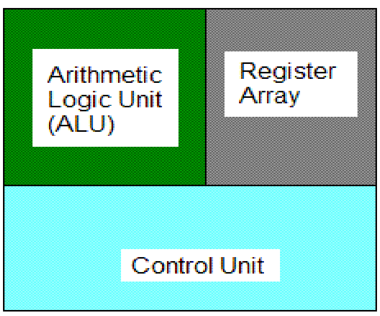

Figure 2: Elements of microprocessor.

Basic Elements of a Microprocessor:

Micro Controller (μc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.Microcontrollers are designed for embedded applications,

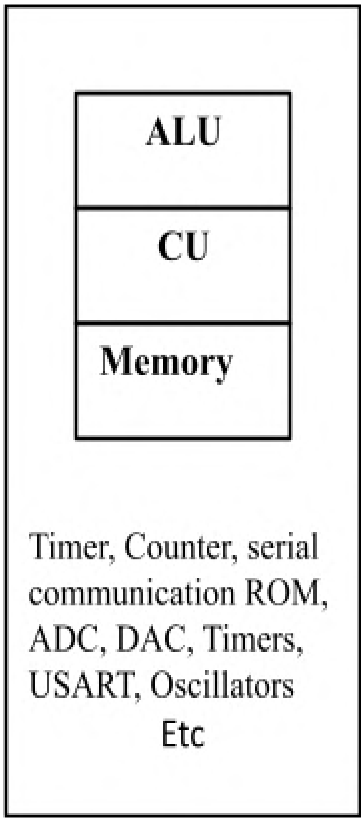

Figure 3: Block Diagram of Microcontroller (μc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operations. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function.

ASIC typically contains:

- □ CPU cores for computation and control.
- □ Peripherals to control timing critical functions.
- □ Memories to store data and programs.
- □ Analog circuits to provide clocks and interface to the real world which is analog in nature.
- □ I/Os to connect to external components like LEDs, memories, monitors etc.

Computer Instruction Set:

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer).

Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- □ A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- □ Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.

□ The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

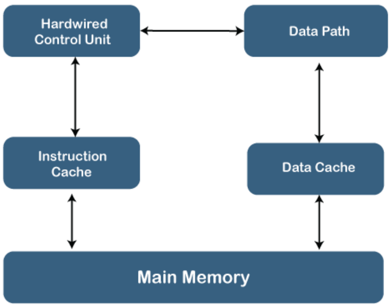

Figure 4(a): RISC Characteristics

RISC characteristics:

- **Simple instruction set:** In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.
- **Same length instructions:** Each instruction is the same length, so that it may be fetched in a single operation.
- **1machine-cycle instructions:** Most instructions are completed in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

Figure 4(b): RISC-V of India

Complex Instruction Set Computer (CISC)

CISC, which stands for Complex Instruction Set Computer, is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

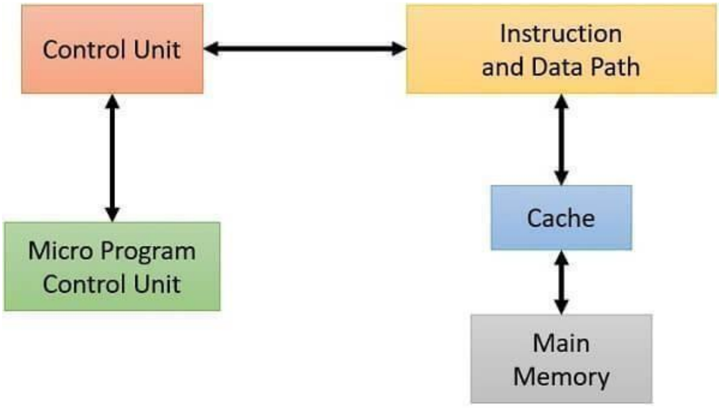

Figure 5(a): CISC architecture

The advantages of CISC

- At the time of their initial development, CISC machines used available technologies to optimize computer performance.
- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because microprogram instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

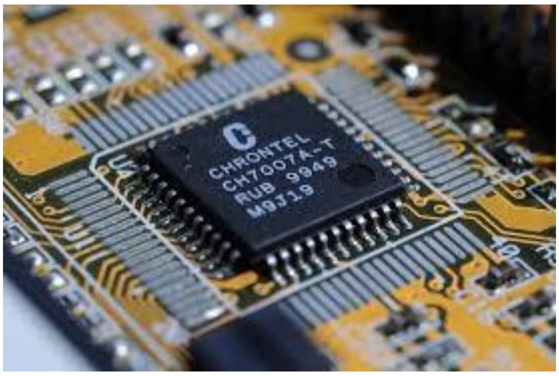

Figure 5(b): CISC chip

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version, so instruction set & chip hardware became more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence; approximately 20% of the available instructions are used in a typical program.
- CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture.
- Von-Neumann Architecture.

Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

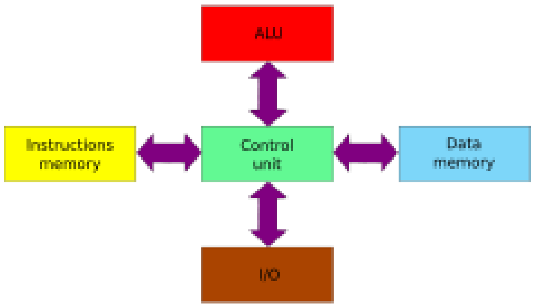

Figure 6: Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction prefetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Von-Neumann Architecture:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The Von-Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advanced over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patches to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

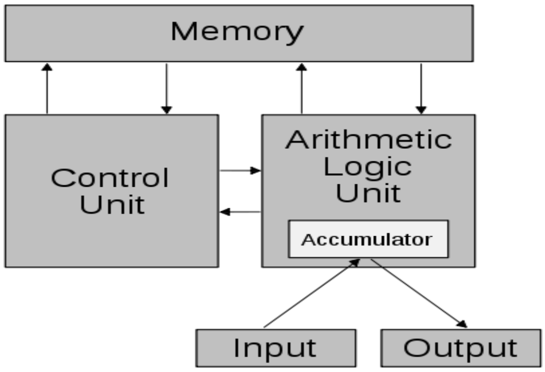

Figure 7: Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture:

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

Power Supply

Block Diagram:

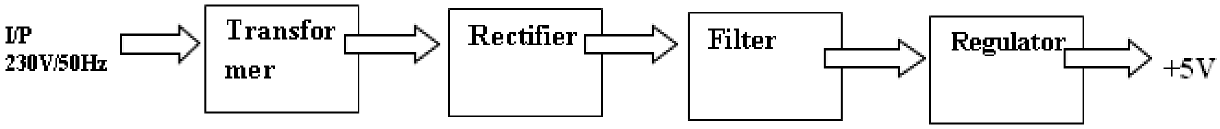

Figure 8: Block diagram of the Power Supply Unit

Description:

1.2.4.2(a) Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or primary winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the secondary winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

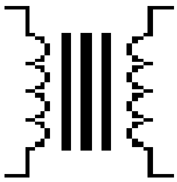

Figure 9: Transformer Symbol

(or)

Transformer is a device that converts one form of energy to another form of energy like a transducer.

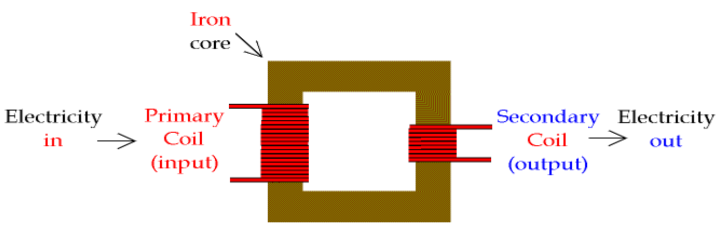

Figure 10: Transformer

Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

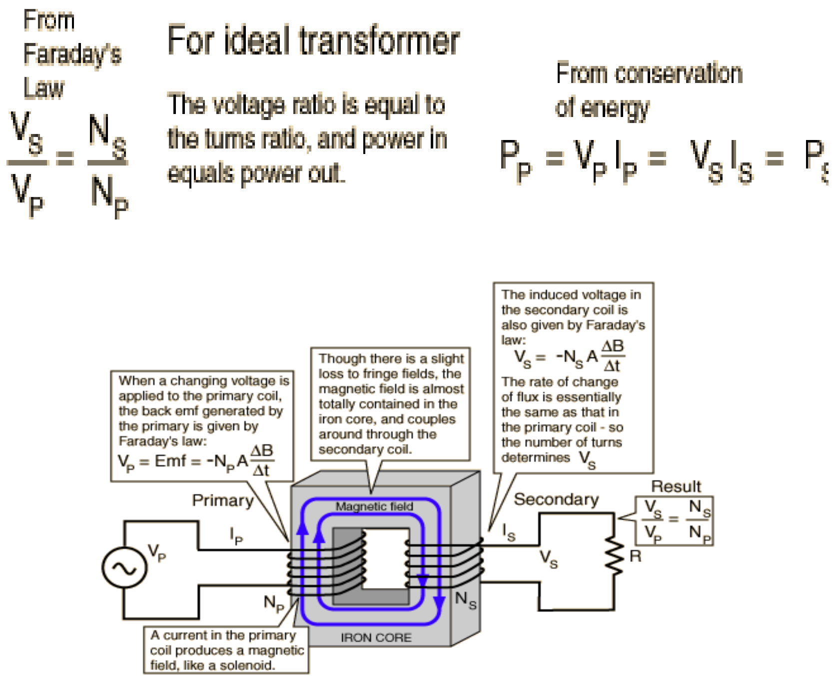

Figure 11: Basic Principle

Transformer Working:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in the figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

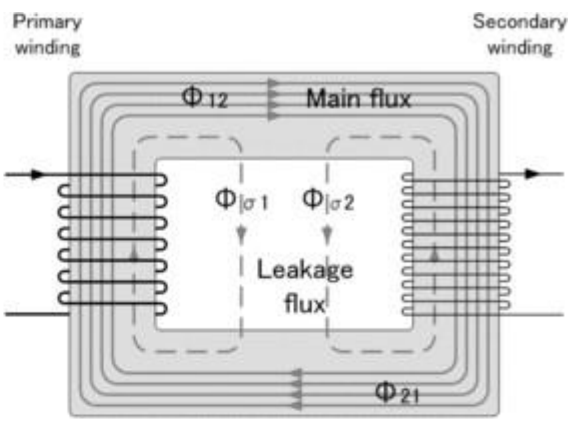

Figure 12: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer.
- Step-Down Transformer.

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. The turn's ratio of the two sets of windings determines the amount of voltage transformation.

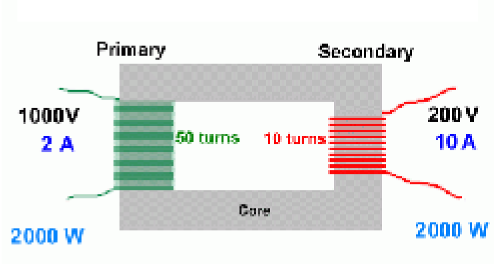

Figure 13: Step-Down Transformer

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phases smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground.

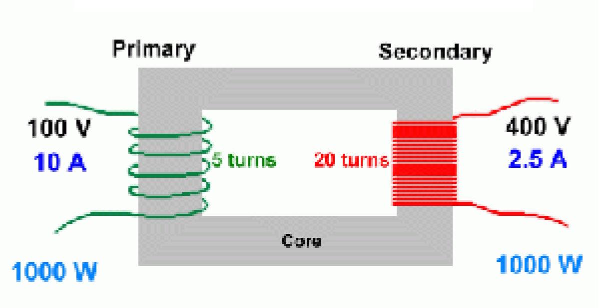

Figure 14: Step-Up Transformer

Applications:

Generally these Step-Up Transformers are used in industry applications only.

Turns Ratio and Voltage:

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages.

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

1.2.4.2(b) Diodes:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

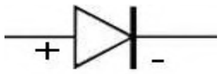

Figure 15: Diode Symbol

A diode is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

1.2.4.2(c) Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as 'half-wave' and 'full-wave' rectifiers. Both use components called diodes to convert AC into DC.

Half-wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in the figure .

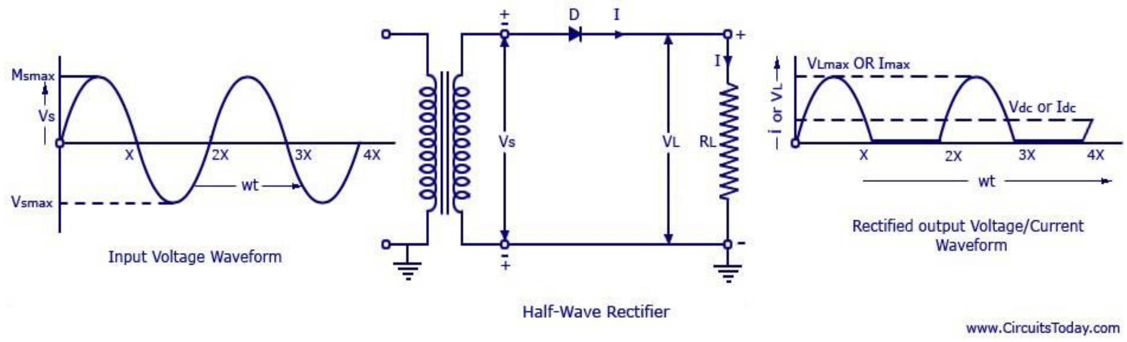

Figure 16: Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode,the peak output voltage will be 0.7V less than Vs.

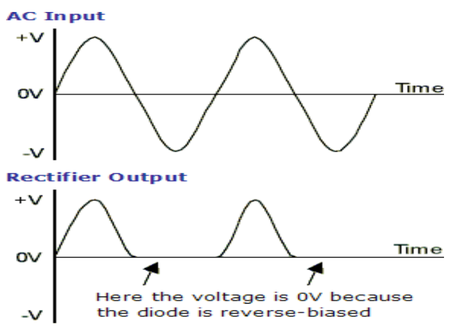

Figure 17: Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 19.

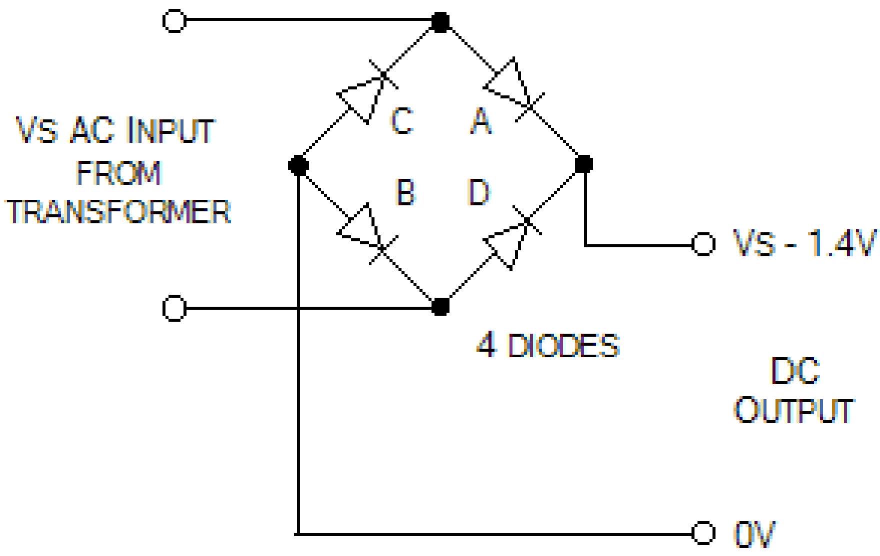

Figure 18: Full-Wave Rectifier

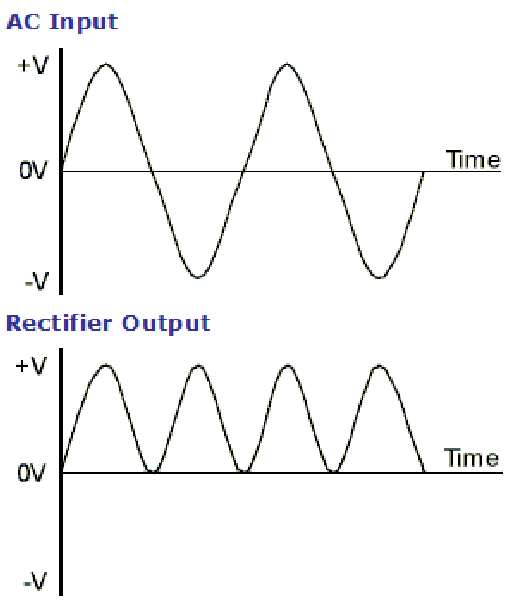

Figure 19: Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

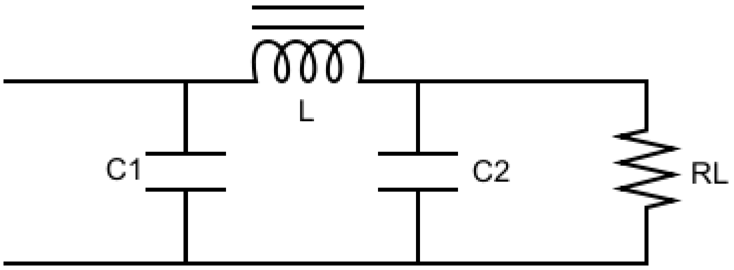

Figure 20: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

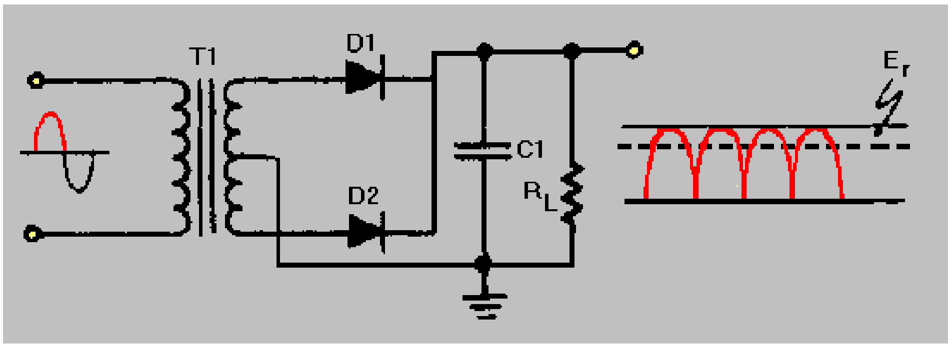

Figure 21: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

1.2.4.2(d) Voltage Regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulators.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx).

78xx:'78' indicates the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicates the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used as an input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pins. Through this pin we get the output.

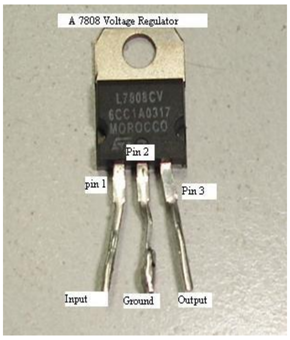

Figure 22: Regulator

Circuit Diagram:

CHAPTER 2

LITERATURE SURVEY

Anitha et al., [1] proposed Smart energy meter surveillance using IoT about IoT, internet of things as an emerging field and IoT based devices have created a revolution in electronics and IT. The foremost objective of this project is to create awareness about energy consumption and. efficient use of home appliances for energy savings. Due to manual work, the existing electricity billing system has major drawbacks. This system will give the information on meter reading, power cut when power consumption exceeds beyond the specified limit using IoT. The Arduino esp8266 microcontroller is programmed to perform the objectives with the help of IOT. It is proposed to overcome all the disadvantages in the already existing energy meter. All the details are sent to the consumer's mobile through the IoT and it is also displayed in the LCD. It is a time saving and it helps to eliminate human interference using IoT.

Devadhanishini et al., [2] Smart Power Monitoring Using IoT that Energy Consumption is a very important and challenging issue. Automatic Electrical Energy meter is used in large electric energy distribution systems. The integration of the Arduino WIFI and SMS provides the system as a Smart Power Monitoring system. Smart energy meters provide data for optimization and less the power consumption. This system also includes a motion sensor such that if there is no human in the house or house it will automatically turn off the power supply.

Mohammed Hosseiu et al., [3] presented a paper titled Design and implementation of smart meters using IoT describing the growth of IoT and digital technology. The future energy grid needs to be implemented in a distributed topology that can dynamically absorb different energy sources. IoT can be utilized for various applications of the smart grid consisting of power consumption, smart meter, electric power demand, side management and various areas of energy production. In this paper, the Smart Energy Metering(SEM) is explained as the main purpose of SEM is necessary for collecting information on energy consumption of household appliances and monitoring the environmental parameters and providing the required services to home users.

Himanshu K Patel et al., [4] demonstrated an Arduino based smart energy meter that removes human intervention in meter readings and bill generation thereby reducing the error that usually causes in India. The system consists of the provision of sending an SMS to users for update on energy consumption along with final bill generation along with the freedom of reload via SMS. The disconnection of power supply on demand or due to pending dues was implemented using a relay. The system employs GSM for bidirectional communication.

Bibek Kanti Barman, et al., [5] proposed smart meters using IoT for efficient energy utilization plays a very vital role for the development of smart grid in power systems. Hence proper monitoring and controlling of power consumption is a main priority of the smart grid. The energy meter has many problems associated with it and one of the key problems is there is no full duplex communication to solve this problem, a smart energy meter is proposed based on the Internet of Things. The smart energy meter controls and calculates the consumption of energy using ESP 8266 12E, a Wi-Fi module and sends it to the cloud from where the consumer or customer can observe the reading.Therefore, energy examination by the consumer becomes much easier and controllable. This system also helps in detecting energy loss. Thus, this smart meter helps in home automation using IoT.

Garrab et al., [6] proposed AMR approach for energy saving in Smart Grids using Smart Meter and partial Power Line Communication on the rising demand of energy. Smart meters are one of the proposed solutions for the Smart Grid. In this article, an AMR solution which gives detailed end-to-end application. It is based on an energy meter with low-power microcontrollerMSP430FE423A and the Power Line Communication standards. The microcontroller includes an energy metering module ESP430CEl.

CHAPTER 3

PROPOSED SYSTEM

Existing System

- Now-a-days to measure the electricity consumption, the electrical board hires persons who visit each home and records the reading manually which gives scope for corruption and human error in reading. No over power use alert system.
- The billing details are provided to consumers on a monthly basis.

Proposed System

- The Existing reading system is time consuming and it needs a number of laborers. The proposed project will eliminate the need for labor and it is cost efficient.
- The proposed system gives the information about the energy consumption in real time on an IOT dashboard on mobile application and PC, billing through IOT.
- This smart energy meter protects your home from bad supply, alerting the consumer and utility when the energy consumption exceeds the set limit.
- We can disconnect and reconnect the power through a mobile application when the consumers are out of station to prevent the waste age of energy.

Block Diagram

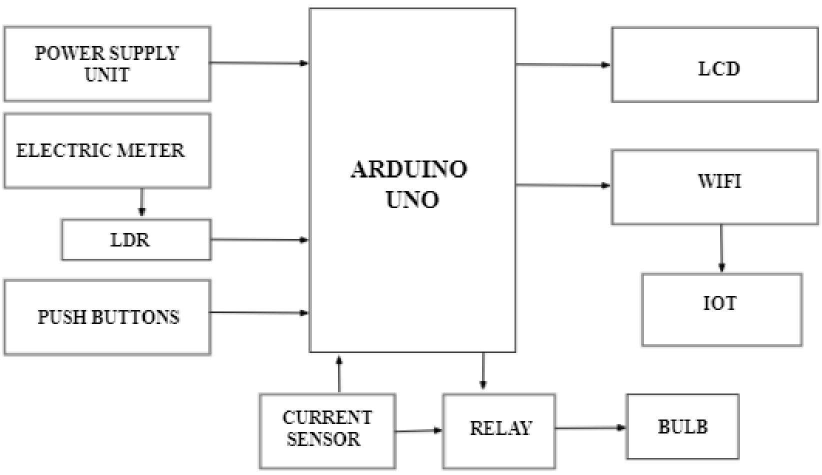

Figure 3.3: Block Diagram of IOT based Energy meter with current, voltage and cost monitoring system.

Schematic Diagram

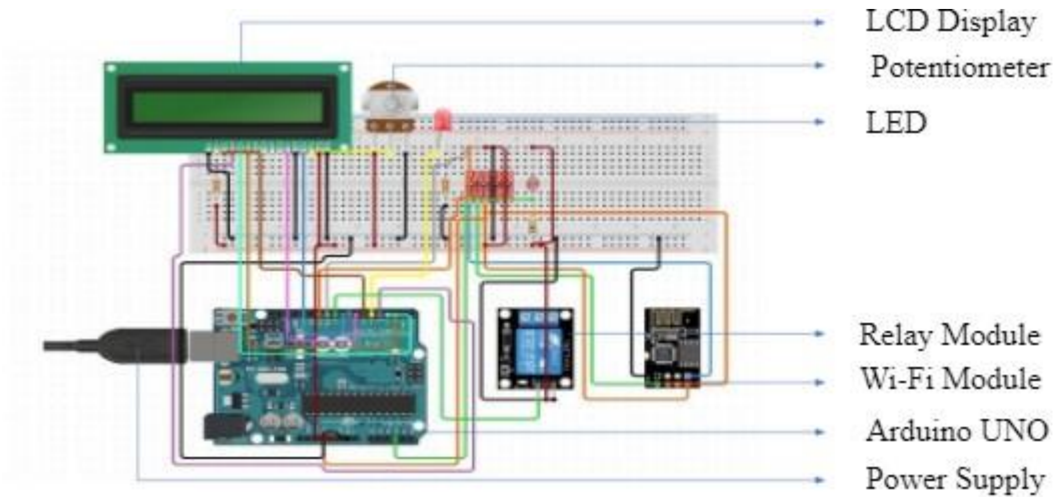

Figure 3.4 Schematic diagram of IOT Energy Meter with current, voltage and cost monitoring system

Explanation

The power supply is given to the arduino uno. All the required components are connected to the arduino.LDR is used to detect the blink of light on the electric meter. The blink of light indicates that there is a power supply. LDR detects the blink, sends the information to the LCD and wifi module, and the arduino which is being programmed acts as a medium. Every Blink indicates that a unit is consumed by the consumer. we get each and every count displayed on the LCD. We can set a limit for our energy consumption.

The consumed energy information is stored in the cloud using a wifi module. We can link the app to the ip address of the wifi module so that we can access the data. The consumer can access the data through an application from anywhere at any time. Within the App we get every information about the energy consumption, and if we set any limit for the energy consumption we get the warning notification as you have consumed maximum units. If it reaches the maximum limit it automatically stops the power supply. If we recharge it or pay the bill we will get the power supply and get the notification as recharge done in our app and it is also displayed on the LCD.

CHAPTER 4

SOFTWARE DESCRIPTION

Introduction to Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possesses a 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus:

It is a software suite containing schematic simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.
The designer can also develop 2D drawings for the product.

Features:

ISIS has a wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semiconductor relays, switches, real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps microcontrollers, processors, sensors etc.

ARES offers PCB design up to 14 inner layers, with surface mount and through hole packages. It is embedded with the footprints of different categories of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in ISIS can be directly transferred to ARES.

Starting a New Design:

Step 1: Open ISIS software and select New design in File menu

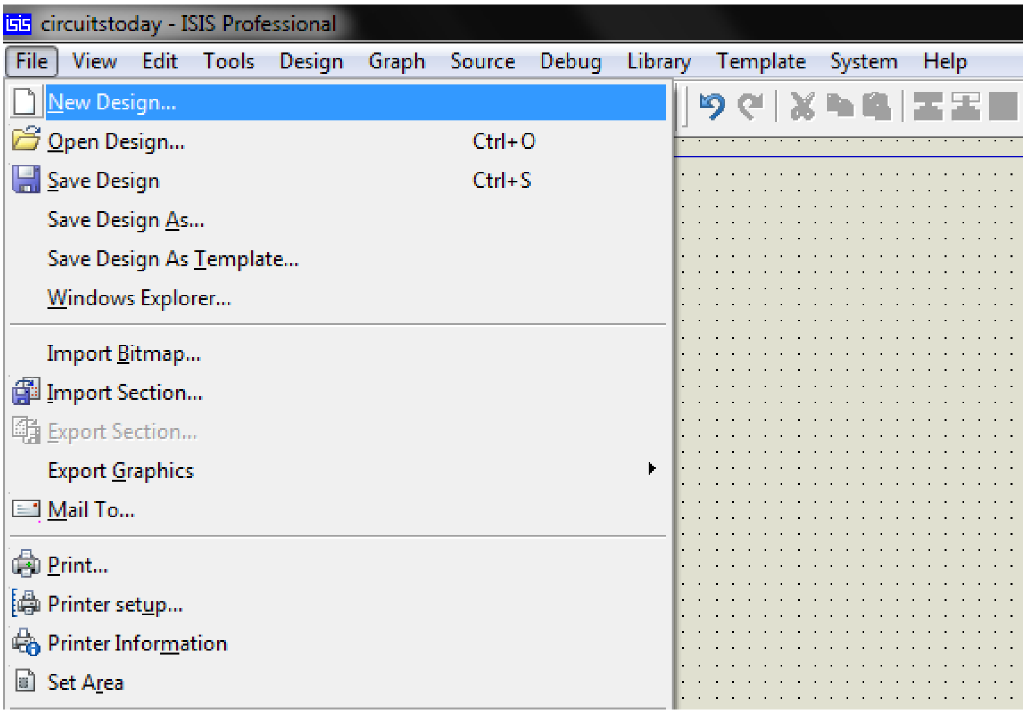

Figure 4.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

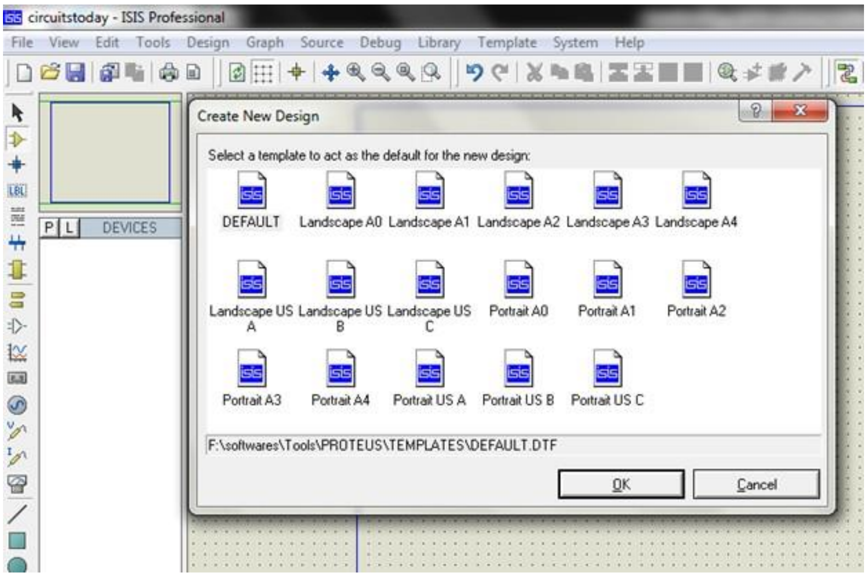

Figure 4.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

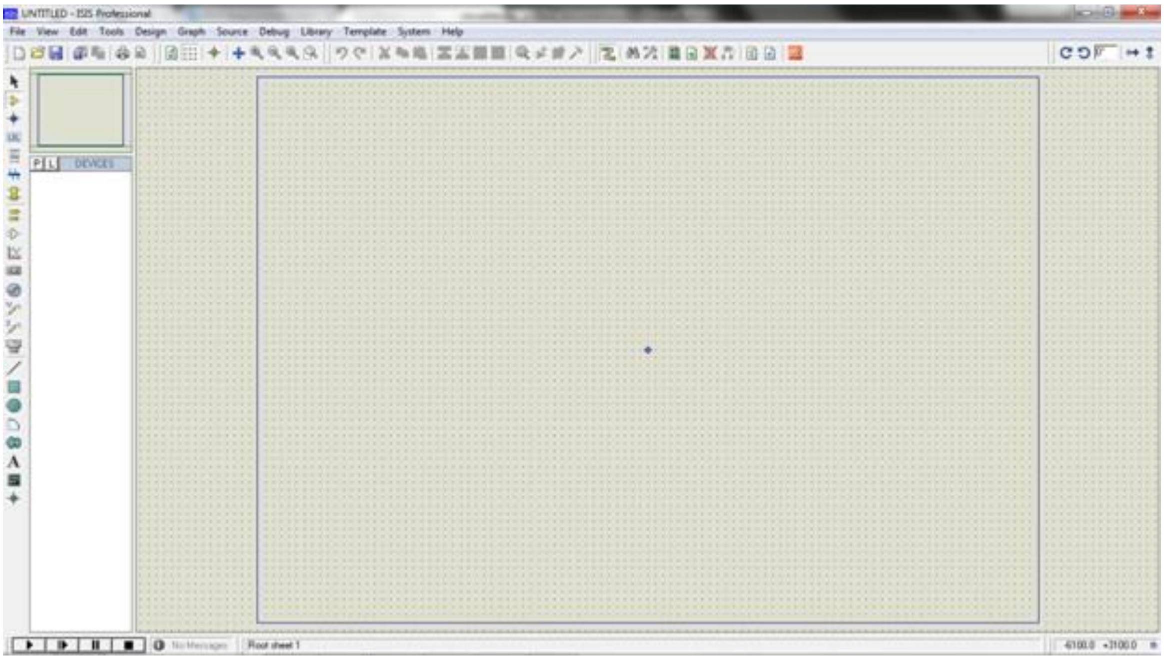

Figure 4.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

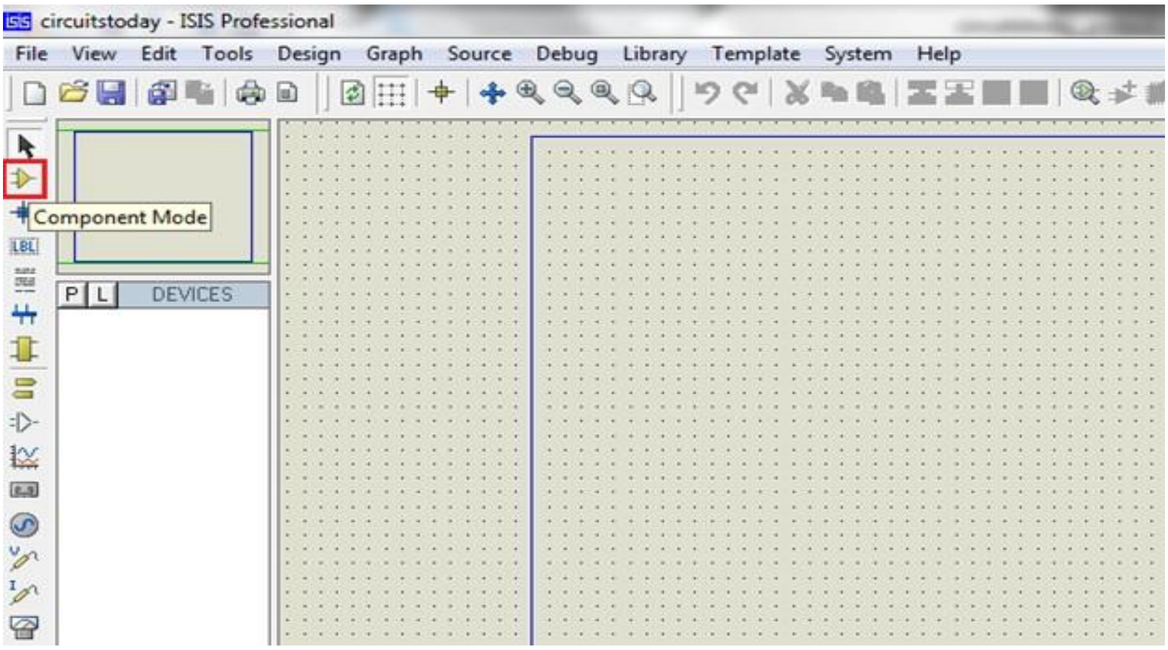

Figure 4.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

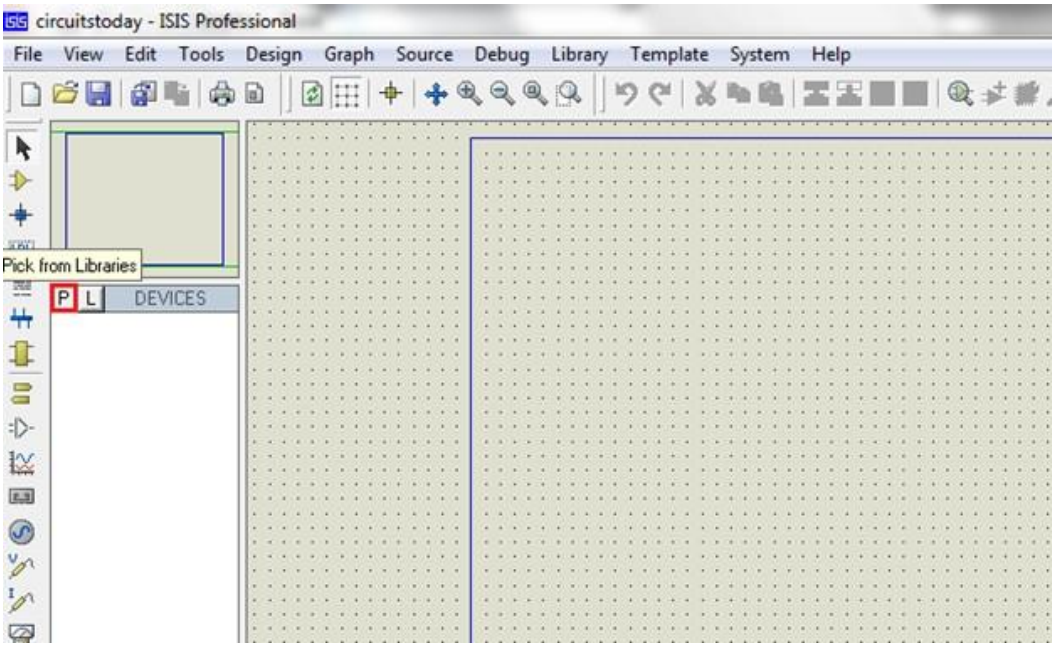

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in the Keywords text box.

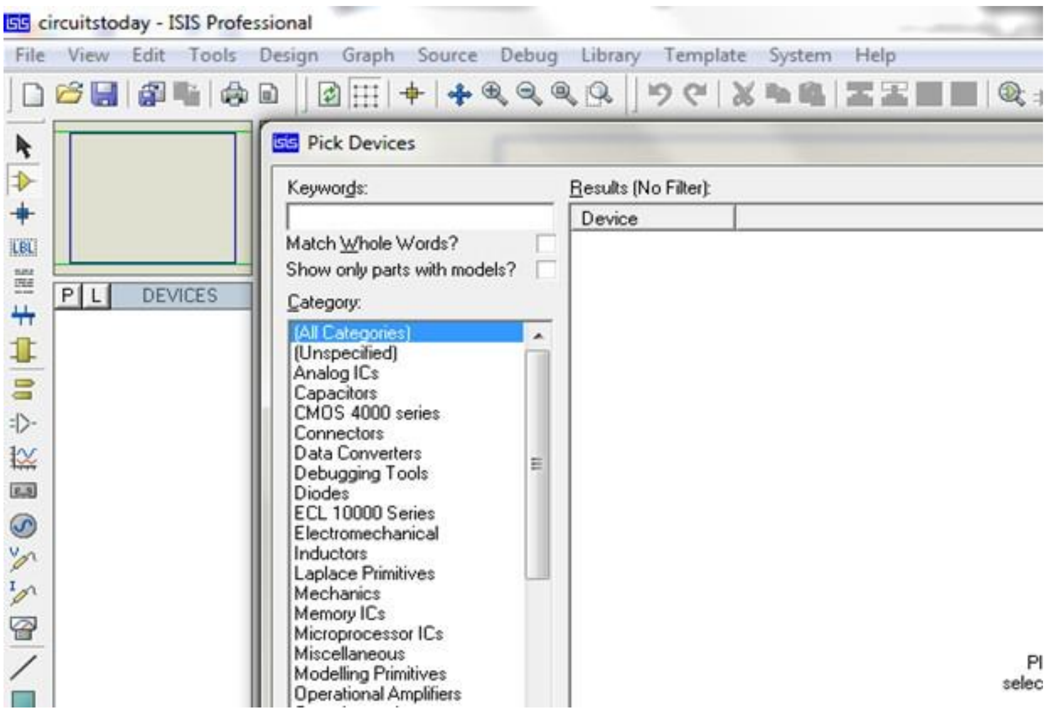

Figure 4.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

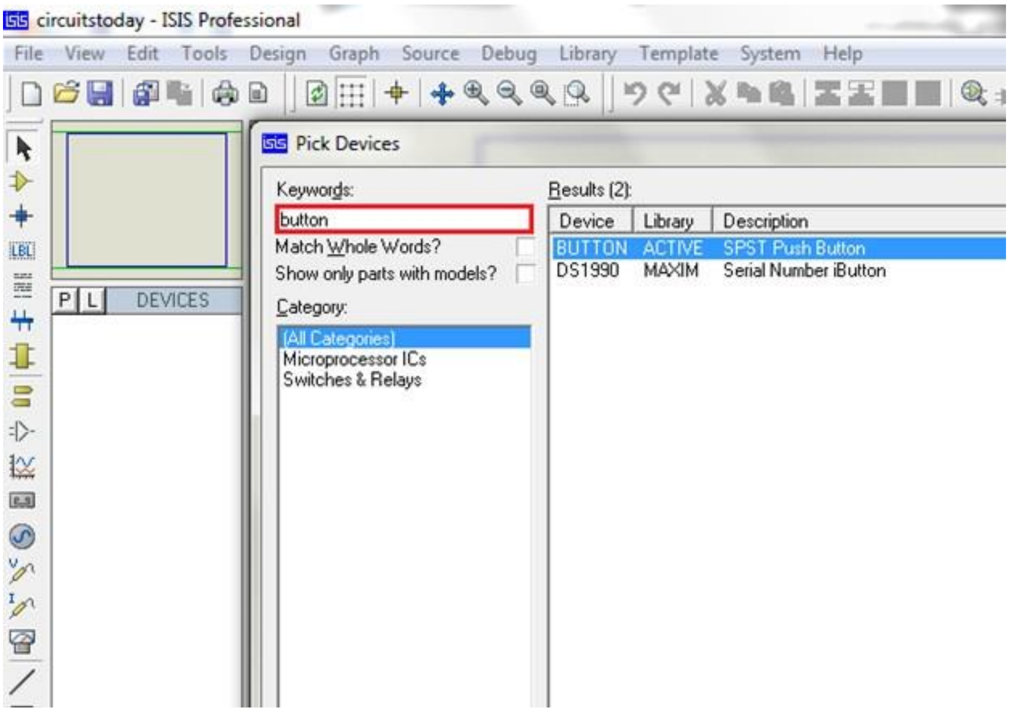

Figure 4.6(a) Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

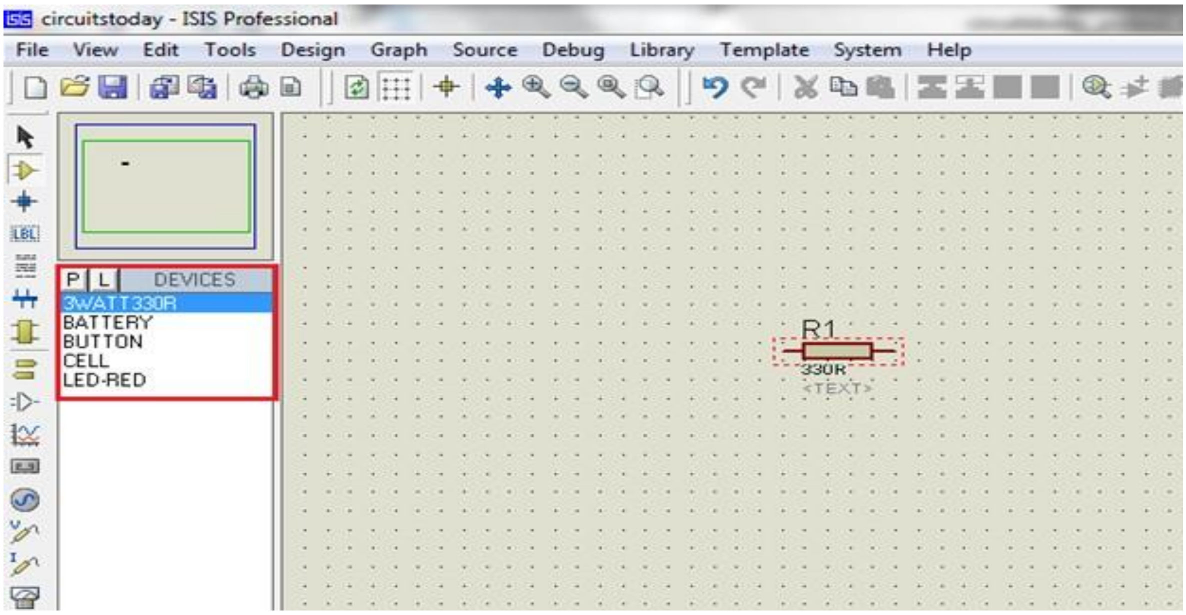

Figure 4.7 Component Selection

Place all the required components and route the wires, make connections.

Either selection mode above the component mode or component mode allows it to connect through wires. Left click from one terminal to another to make a connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

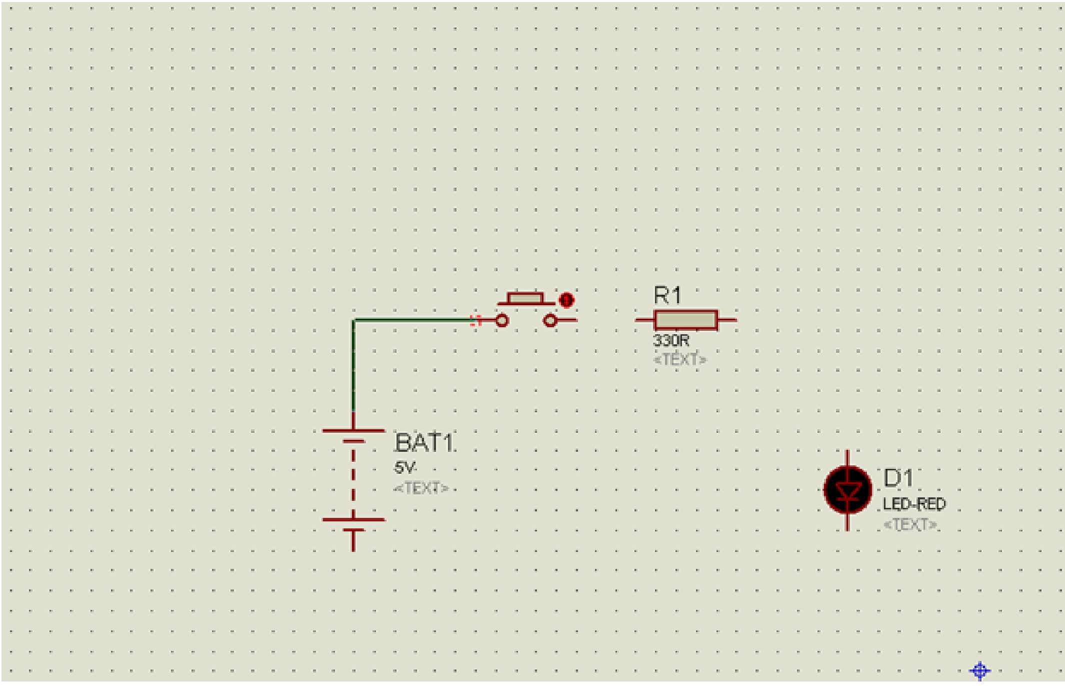

Figure 4.7(a) Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

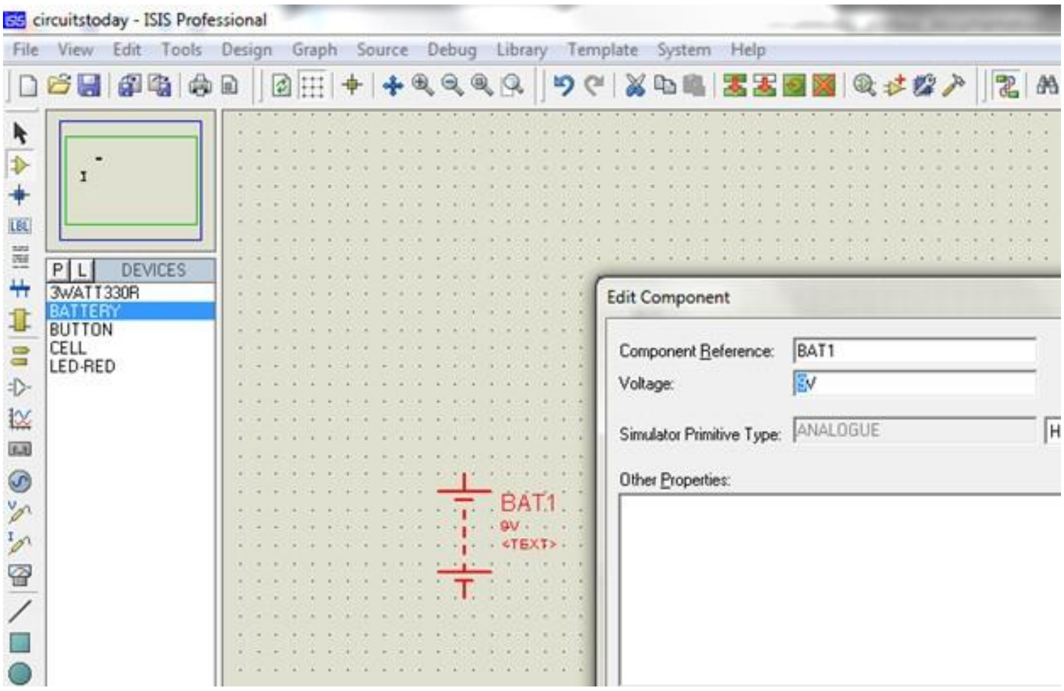

Figure 4.7(b) Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

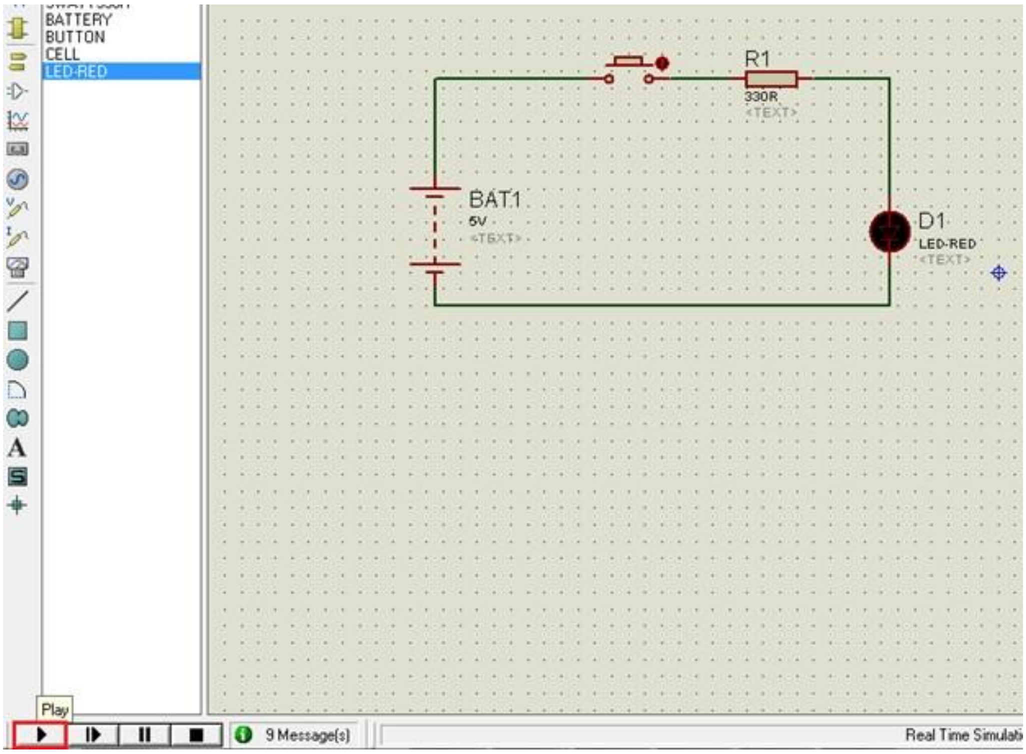

Figure 4.8 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make the LED glow.

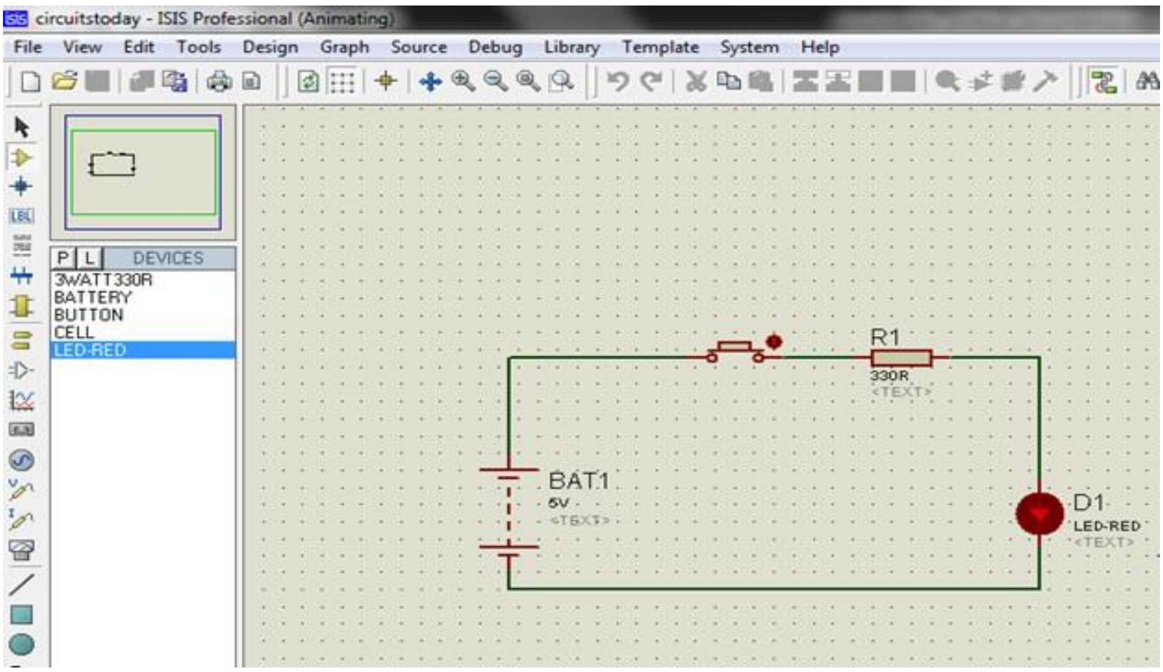

Figure 4.8(a) Simulation Animating

Simulation can be stepped, paused or stopped at any time.

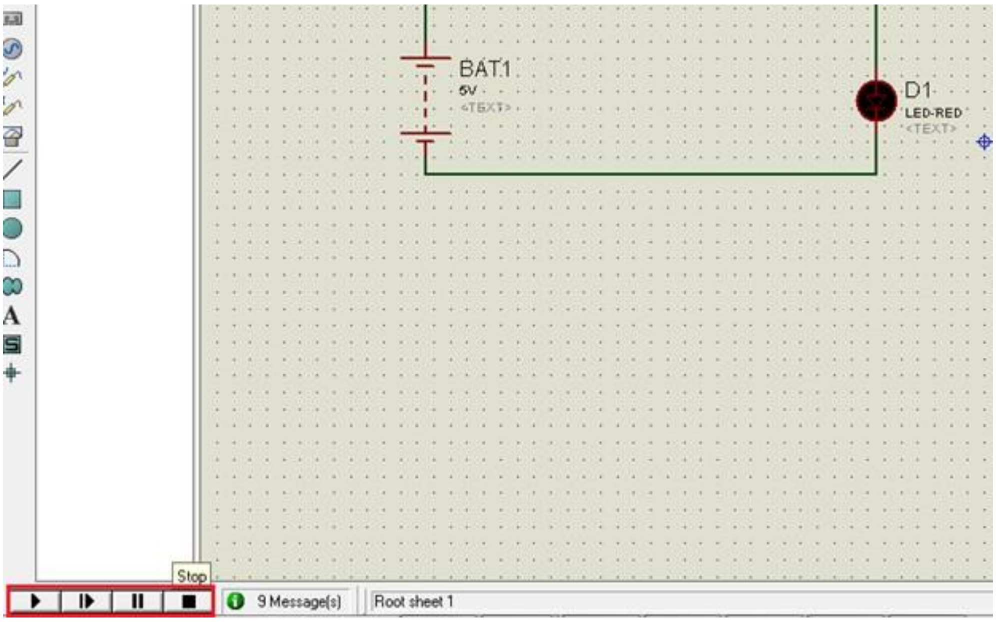

Figure 4.8(b) Simulation Step-Pause-Stop Buttons

Arduino IDE

The Arduino integrated development environment (IDE) is a cross-platform application(for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program avrdude to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]
Repository	github.com/arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux
Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

Installation:

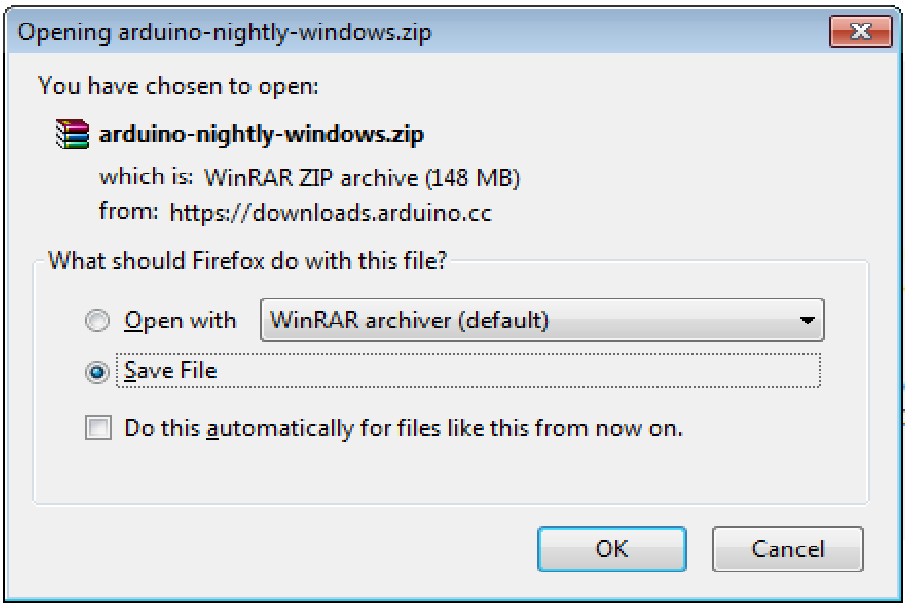
In this section, we will learn in easy steps how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



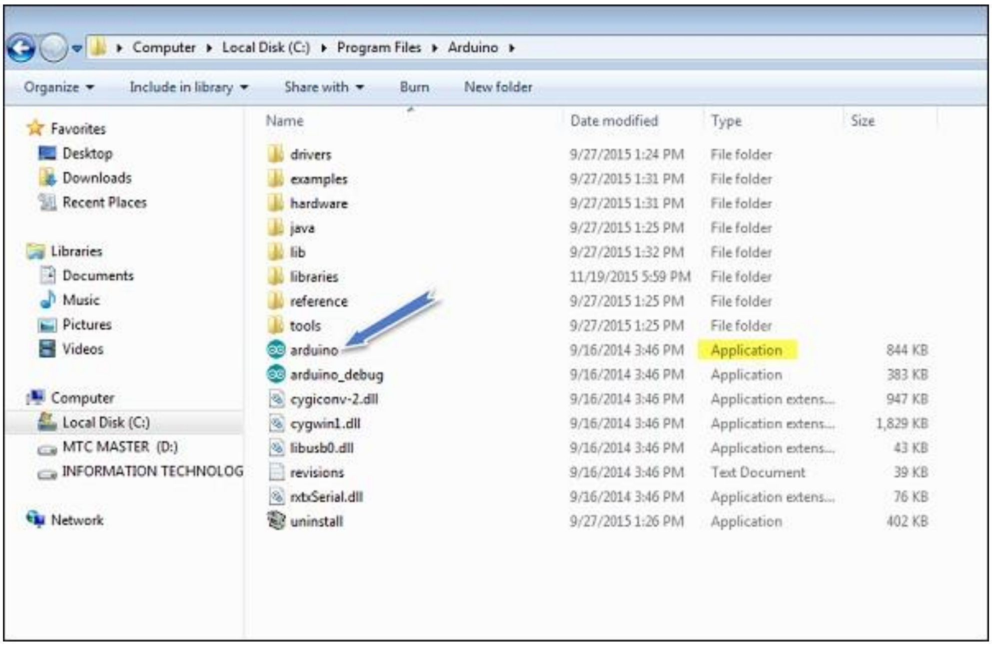
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

.

Step 4 − Launch Arduino IDE:

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

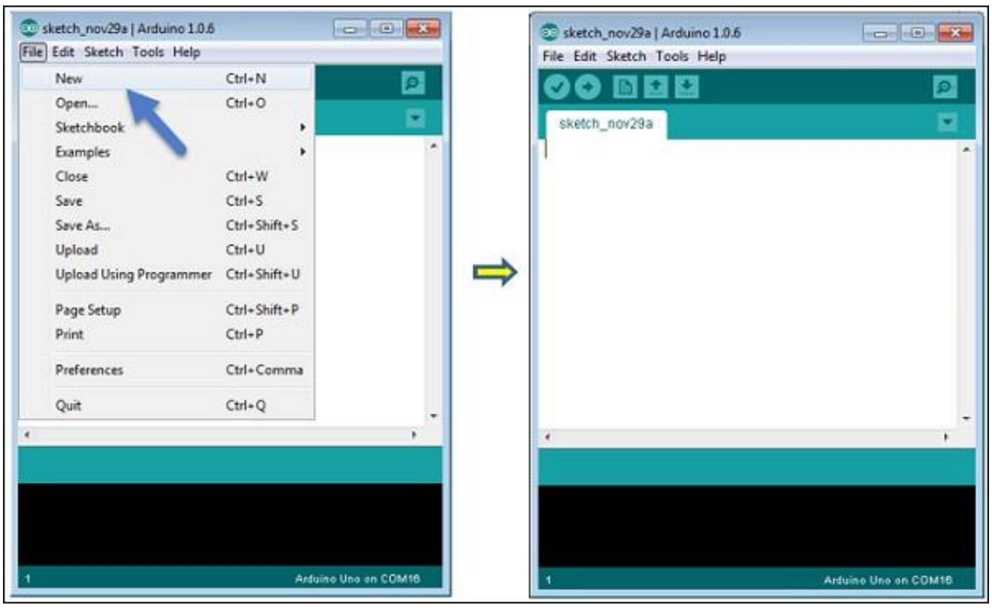


Step 5 − Open your first project.

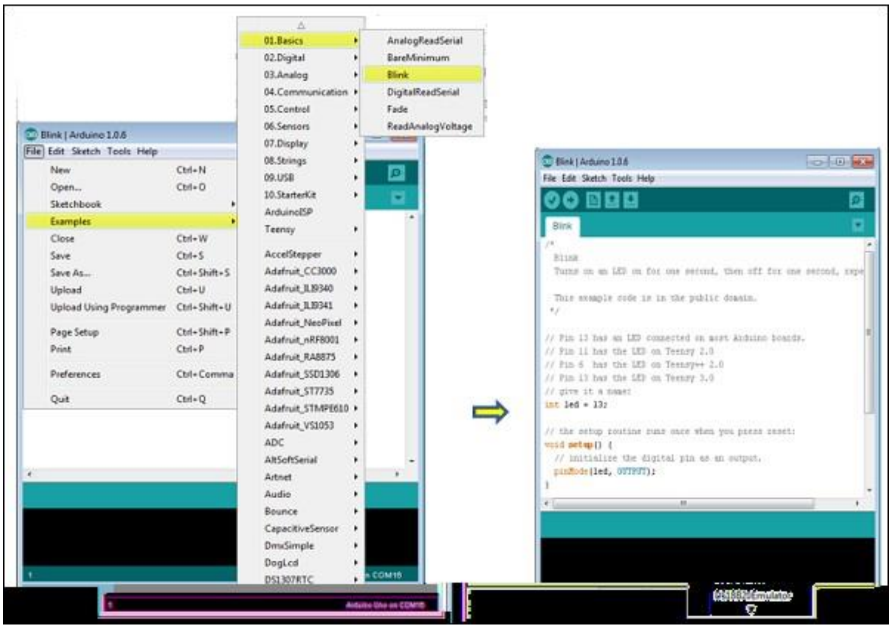
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

TO create a new prOject, select File → **New**.



TO Open an existing prOject example, select File → Example → Basics → Blink.

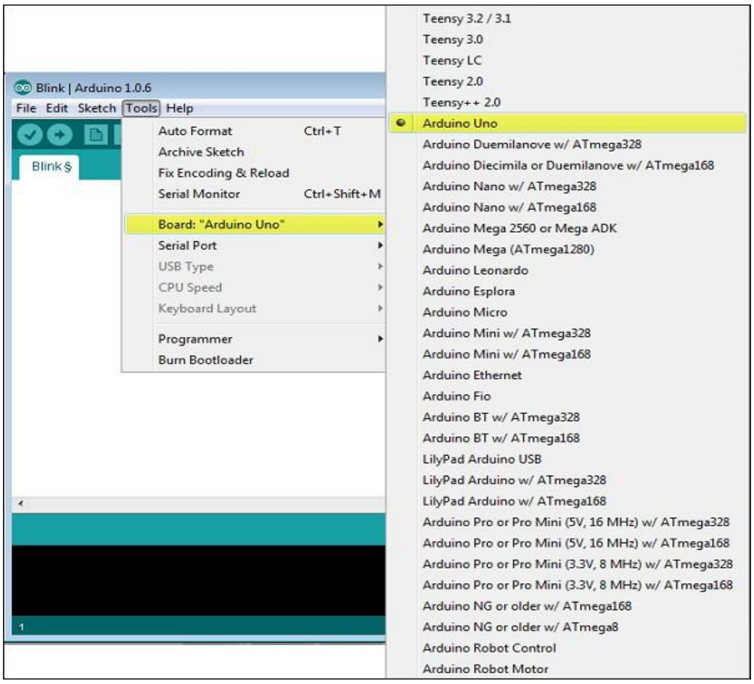


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

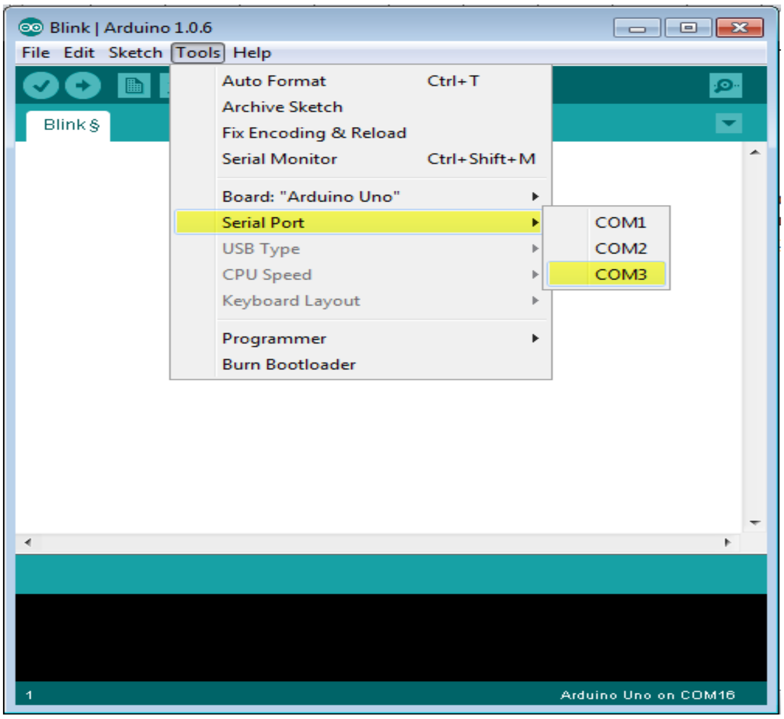
Go to Tools → Board and select your board.



Here, we have selected the Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

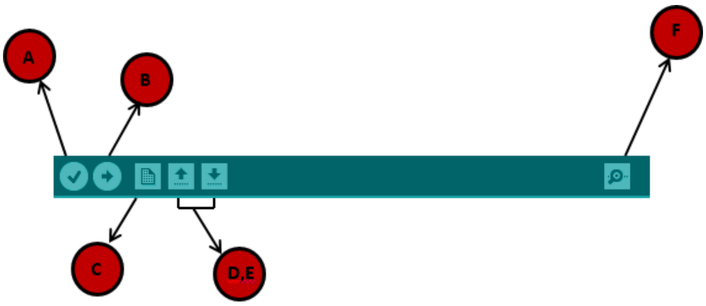
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to Tools → Serial Port menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

CHAPTER 5

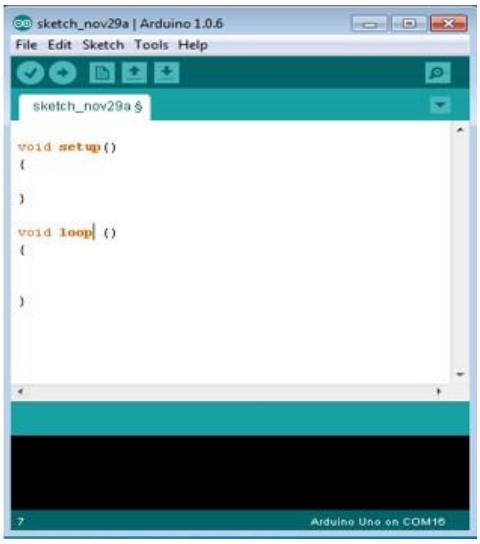
HARDWARE DESCRIPTION

Arduino UNO

Arduino is a prototype platform (open-source) based on easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connecting to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.



Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 5.1.1(a) Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 5v/16mhz		16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 5.1.1(b) Arduino boards based on ATMEGA32u4 microcontroller

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

Table 5.1.1(c) Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2 B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

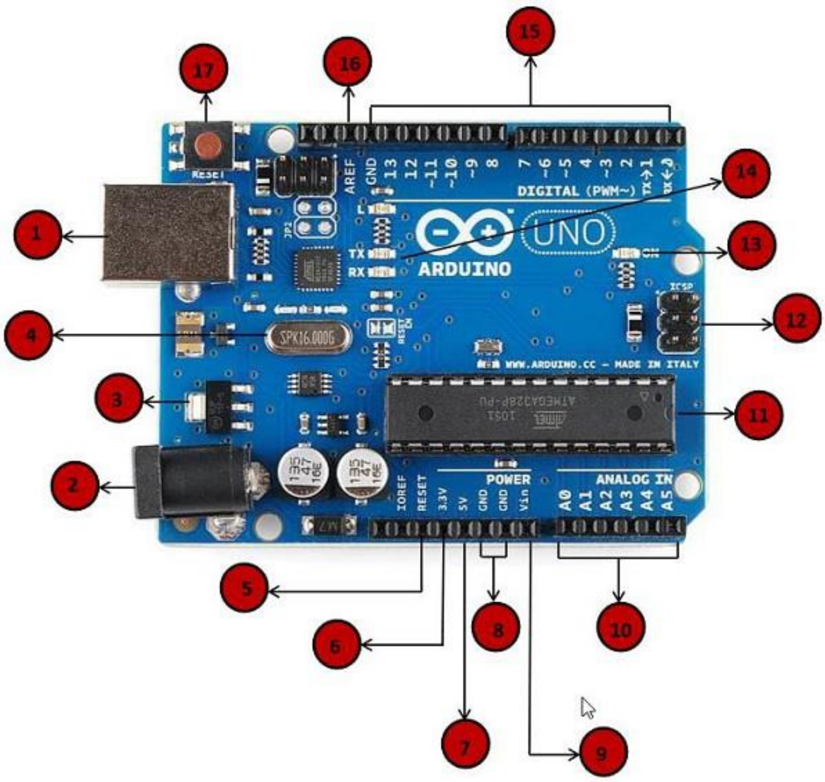
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have the majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.

5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with the Arduino board work fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often

	referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speeds while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Liquid Crystal Display (LCD):

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around the LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus the cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most,It however doesn't show the use of the Status Port as an input.. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic diagram:

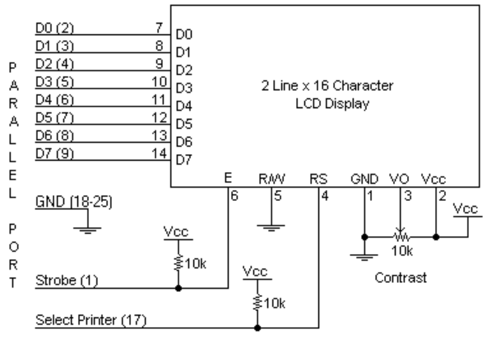


Figure 5.2.2 Schematic Diagram of LCD

- Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the R/W line of the LCD panel into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use an onboard +5 regulator. Remember a few decoupling capacitors, especially if you have trouble with the circuit working properly.
- Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output.As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing.
- 61 x 15.8 mm viewing area.
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line.
- Can display 224 different symbols.
- Low power consumption (1 mA typical).
- Powerful command set and user-produced characters.
- TTL and CMOS compatible.
- Connector for standard 0.1-pitch pin headers.

LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	NOT CONNECTED
16	NC	-	NOT CONNECTED

FEATURES:

• 5 x 8 dots with a cursor.

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V).

• 1/16 duty cycle.

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED).

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure: Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exist. "supertwist" types, for example, offer Improved contrast and viewing angles over the older "twisted nematic" types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either "electro-luminescent", requiring a high voltage inverter circuit, or simple LED illumination.

Pin Description

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers have 16 Pins (two pins are extra in both for back-light LED connections).

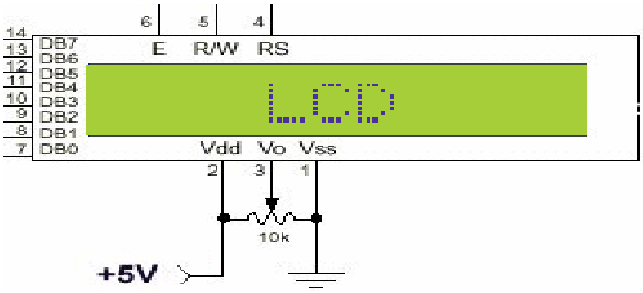

Figure 5.2.4(a) Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Fig 5.2.4(b) Pin Specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are writing commands, so RW will almost always be low.

Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

-1 Character

Writing data to the LCD:

1) Set R/W bit to low
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. A switch pack with a re-wiring is necessary.

LCD Commands:

There are some present command instructions in the LCD, which we need to send to the LCD through some microcontroller. Some important command instructions are given below:

Table 5.2.5(a) Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

ACS712 Current Sensor

The invention of electricity has led to a revolutionary change in the life of humans. We invented many innovative applications of electricity to make our daily life easier. Today almost all of our equipment runs on electricity. The flow of charge is known as Current. Different devices need a different amount of current based on their functional requirements. Some devices are so sensitive that they get damaged when a high amount of current is delivered to them. So, to save such a situation and monitor the amount of current required or being used in an application, measurement of current is necessary. This is where the Current Sensor comes into play. One such sensor is the ACS712 Current Sensor.

What is the ACS712 Current Sensor?

Current flowing through a conductor causes a voltage drop. The relation between current and voltage is given by Ohm's law. In electronic devices, an increase in the amount of current above its requirement leads to overload and can damage the device.

Measurement of current is necessary for the proper working of devices. Measurement of voltage is Passive task and it can be done without affecting the system. Whereas measurement of current is an Intrusive task which cannot be detected directly as voltage.

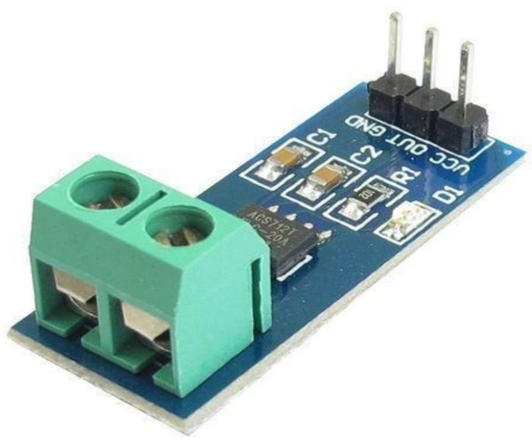

Figure 5.3 ACS712

For measuring current in a circuit, a sensor is required. ACS712 Current Sensor is the sensor that can be used to measure and calculate the amount of current applied to the conductor without affecting the performance of the system.

ACS712 Current Sensor is a fully integrated, Hall-effect based linear sensor IC. This IC has a 2.1kV RMS voltage isolation along with a low resistance current conductor.

Working Principle:

Current Sensor detects the current in a wire or conductor and generates a signal proportional to the detected current either in the form of analog voltage or digital output.

Current Sensing is done in two ways – Direct sensing and Indirect Sensing. In Direct sensing,to detect current, Ohm's law is used to measure the voltage drop occurring in a wire when current flows through it. A current-carrying conductor also gives rise to a magnetic field in its surroundings. In Indirect Sensing, the current is measured by calculating this magnetic field by applying either Faraday's law or Ampere law. Here either a Transformer or Hall effect sensor or fiber optic current sensor are used to sense the magnetic field.

ACS712 Current Sensor uses the Indirect Sensing method to calculate the current. To sense the current liner, a low-offset Hall sensor circuit is used in this IC. This sensor is located at the surface of the IC on a copper conduction path. When current flows through this copper conduction path it generates a magnetic field which is sensed by the Hall effect sensor. A voltage proportional to the sensed magnetic field is generated by the Hall sensor, which is used to measure current.

The proximity of the magnetic signal to the Hall sensor decides the accuracy of the device. Nearer the magnetic signal higher the accuracy. ACS712 Current Sensor is available as a small, surface mount SOIC8 package. In this IC current flows from Pin-1 and Pin-2 to Pin-3 and Pin-4. This forms the conduction path where the current is sensed. Implementation of this IC is very easy.

ACS712 can be used in applications requiring electrical isolation as the terminals of the conduction path are electrically isolated from the IC leads. Thus, this IC doesn't require any other isolation techniques. This IC requires a supply voltage of 5V. Its output voltage is proportional to AC or DC current. ACS712 has a nearly zero magnetic hysteresis.

Where Pin-1 to Pin-4 forms the conduction path, Pin-5 is the signal ground pin. Pin-6 is the FILTER pin that is used by an external capacitor to set the bandwidth. Pin-7 is the analog output pin. Pin-8 is the power supply pin.

Applications of ACS712 Current Sensor:

This IC can detect both AC and DC current so it has a wide range of applications. ACS712 is used in Peak detection circuits, circuits to increase gain, rectification application for AtoD converters, Overcurrent fault latch, etc…The filter pin provided by this IC is used to eliminate the attenuation effect in resistor divider circuits.

ACS712 is used in many industrial, commercial and communication applications. This IC is applicable for Automobile applications. Some of the typical applications of this IC can be found in motor control circuits, for load detection and management, SMPS, overcurrent fault protection circuits.

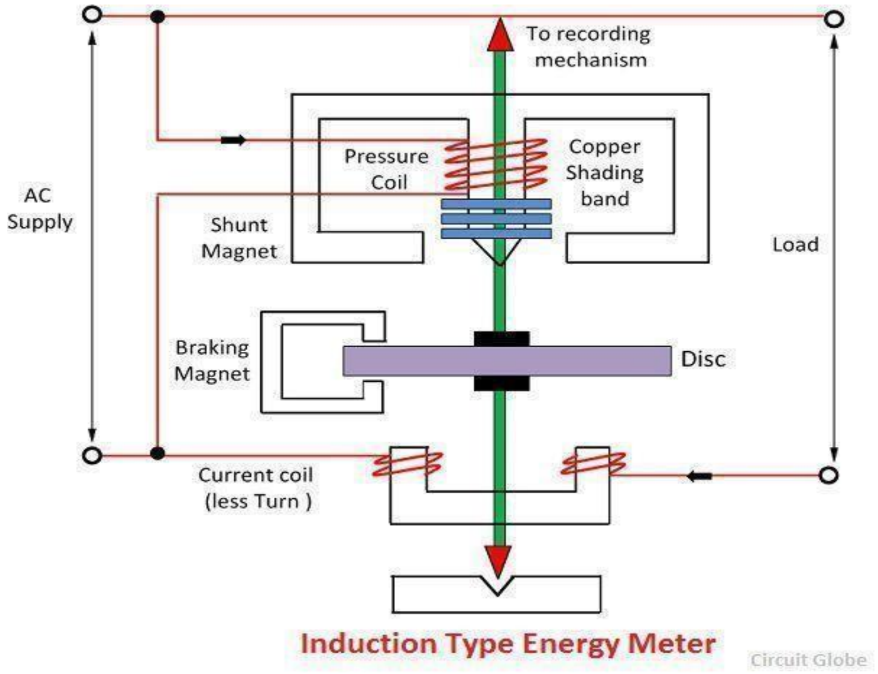
This IC can measure current for high voltage loads operating at 230V AC mains. To read the values it can be easily interfaced with the ADC of a microcontroller. What would be the value of output voltage provided by ACS712 when a DC load current is applied to it?

Energy Meter:

Definition: The meter which is used for measuring the energy utilised by the electric load is known as the energy meter. The energy is the total power consumed and utilised by the load at a particular interval of time. It is used in domestic and industrial AC circuits for measuring the power consumption.

Construction of Energy Meter:

The construction of the single phase energy meter is shown in the figure below.



The energy meter has four main parts. They are the

1. Driving System
2. Moving System
3. Braking System
4. Registering System

The detailed explanation of their parts is written below.

1. Driving System – The electromagnet is the main component of the driving system. It is the temporary magnet which is excited by the current flow through their coil. The core of the electromagnet is made up of silicon steel lamination. The driving system has two electromagnets. The upper one is called the shunt electromagnet, and the lower one is called the series electromagnet.

The series electromagnet is excited by the load current flow through the current coil. The coil of the shunt electromagnet is directly connected with the supply and hence carries the current proportional to the shunt voltage. This coil is called the pressure coil.The upper one is called the shunt electromagnet, and the lower one is called the series electromagnet.

The centre limb of the magnet has the copper band. These bands are adjustable. The main function of the copper band is to align the flux produced by the shunt magnet in such a way that it is exactly perpendicular to the supplied voltage.

2. Moving System – The moving system is the aluminium disc mounted on the shaft of the alloy. The disc is placed in the air gap of the two electromagnets. The eddy current is induced in the disc because of the change of the magnetic field. This eddy current is cut by the magnetic flux. The interaction of the flux and the disc induces the deflecting torque.

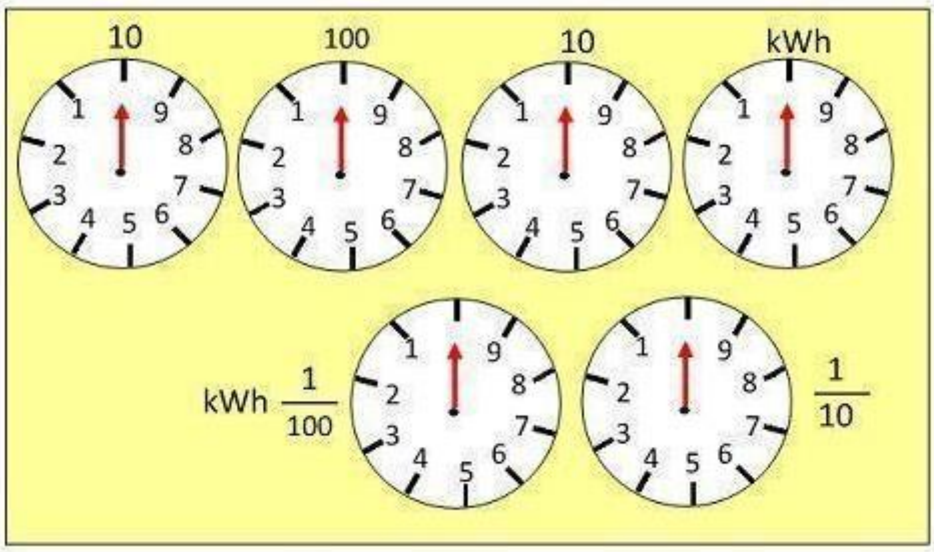
When the devices consume power, the aluminium disc starts rotating, and after some number of rotations, the disc displays the unit used by the load. The number of rotations of the disc is counted at a particular interval of time. The disc measured the power consumption in kilowatt hours.

3. Braking system – The permanent magnet is used for reducing the rotation of the aluminium disc. The aluminium disc induces the eddy current because of their rotation. The eddy current cuts the magnetic flux of the permanent magnet and hence produces the braking torque.

This braking torque opposes the movement of the disc, thus reducing their speed. The permanent magnet is adjustable due to which the braking torque is also adjusted by shifting the magnet to the other radial position.

4. Registration (Counting Mechanism) – The main function of the registration or counting mechanism is to record the number of rotations of the aluminium disc. Their rotation is directly proportional to the energy consumed by the loads in the kilowatt hour.

The rotation of the disc is transmitted to the pointers of the different dial for recording the different readings. The reading in kWh is obtained by multiplying the number of rotations of the disc with the meter constant. The figure of the dial is shown below.



Pointer Type of Register

Working of the Energy Meter:

The energy meter has the aluminium disc whose rotation determines the power consumption of the load. The disc is placed between the air gap of the series and shunt electromagnet. The shunt magnet has the pressure coil, and the series magnet has the current coil.The pressure coil creates the magnetic field because of the supply voltage, and the current coil produces it because of the current.

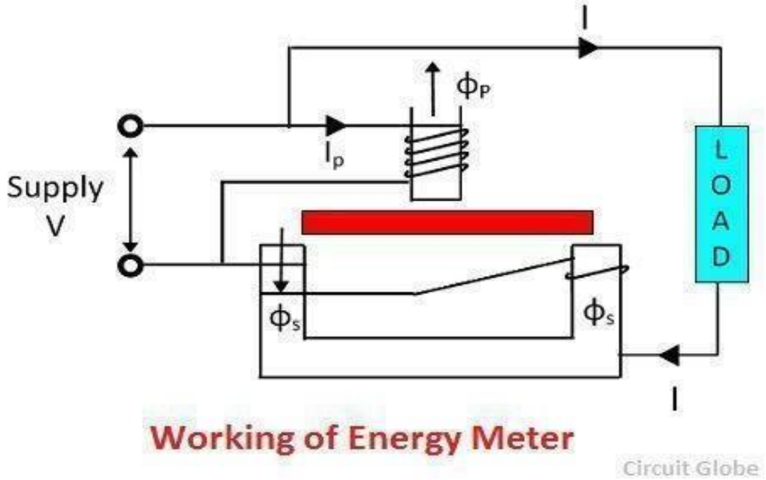
The field induced by the voltage coil is lagging by 90º on the magnetic field of the current coil because of which eddy current is induced in the disc. The interaction of the eddy current and the magnetic field causes torque, which exerts a force on the disc. Thus, the disc starts rotating.

The force on the disc is proportional to the current and voltage of the coil. The permanent magnet controls Their rotation. The permanent magnet opposes the movement of the disc and equalises it on the power consumption. The cyclometer counts the rotation of the disc.

The energy meter has the aluminium disc whose rotation determines the power consumption of the load. The disc is placed between the air gap of the series and shunt electromagnet.

Theory of Energy Meter:

The pressure coil has the number of turns which makes it more inductive. The reluctance path of their magnetic circuit is very less because of the small length air gap. The current I_p flows through the pressure coil because of the supply voltage, and it lags by 90º.



Working of Energy Meter

The I_p produces the two Φ_p which is again divided into Φ_{p1} and Φ_{p2}. The major portion of the flux Φ_{p1} passes through the side gap because of low reluctance. The flux Φ_{p2} goes through the disc and induces the driving torque which rotates the aluminium disc.

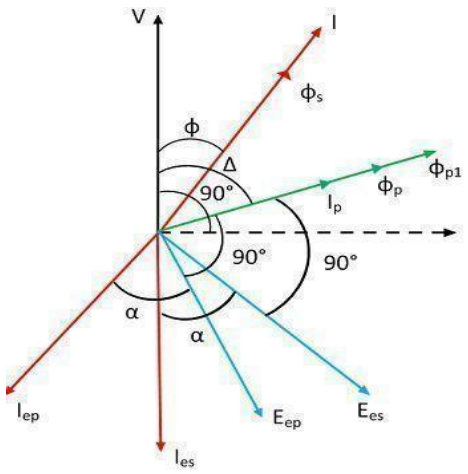
The flux Φ_p is proportional to the applied voltage, and it is lagged by an angle of 90º. The flux is alternating and hence induces an eddy current I_{ep} in the disc.

The load current passing through the current coil induces the flux Φ_s. This flux causes the eddy current I_{es} on the disc. The eddy current I_{es} interacts with the flux Φ_p, and the eddy current I_{ep} interacts with Φ_s to produce another torque. These torques are opposite in direction, and the net torque is the difference between these two.

The flux Φp2 goes through the disc and induces the driving torque which rotates the aluminium disc.

The flux Φp is proportional to the applied voltage, and it is lagged by an angle of 90º. The flux is alternating and hence induces an eddy current Iep in the disc.

The phasor diagram of the energy meter is shown in the figure below.



Phasor Diagram of Energy Meter

Circuit Globe

Let

V – applied voltage

I – load current

Ø – the phase angle of load current

I_p – pressure angle of load

Δ – the phase angle between supply voltage and pressure coil flux

f – frequency

Z – impedance of eddy current

a – the phase angle of eddy current paths

E_{ep} – eddy current induced by flux

I_{ep} – eddy current due to flux

E_{ev} – eddy current due to flux

I_{es} – eddy current due to flux

The net driving torque of the dis is expressed as

$$T_d \propto \varnothing_1 \varnothing_2 \frac{f}{Z} sin\beta cos\alpha = K_1 \varnothing_1 \varnothing_2 \frac{f}{Z} sin\beta cos\alpha$$

where K_1 – constant

Φ_1 and Φ_2 are the phase angles between the fluxes. For energy meters, we take Φ_p and Φ_s.

β – phase angle between fluxes Φ_p and Φ_p = $(\Delta - \Phi)$, therefore

$$Driving\ Torque, T_d = K_1 \emptyset_1 \emptyset_2 \frac{f}{Z} \sin(\Delta - \emptyset)\ cos\alpha$$

$$But\ \emptyset_p \propto V, and\ \emptyset_p \propto I$$

$$T_d \propto K_2 VI \frac{f}{Z} \mathrm{Sin}(\Delta - \emptyset) cos\alpha$$

If f, Z and α are constants,

$$T_d = K_3 VIsin(\Delta - \emptyset)$$

If N is steady speed, braking torque

$$T_B = K_4 N$$

At a steady state, the speed of the driving torque is equal to the braking torque.

$$K_4 N = K_3 VI(\Delta - \emptyset)$$

$$N = KVIsin(\Delta - \emptyset)$$

If $\Delta = 90^o$,

$$N = KVIsin(90° - \emptyset) = KVIcos\emptyset$$

Speed,

$$= K \times power$$

The speed of the rotation is directly proportional to the power.

$$Total\, number\, of\, revolution = \int Ndt = K\int VIsin(\Delta - \emptyset)$$

If $\Delta = 90^{o}$, total number of revolutions

$$= K\int VIcos\emptyset dt$$

$$= K\int power\ dt = K\ X\ energy$$

The three phase energy meter is used for measuring the large power consumption.

WIFI ESP8266:

Working:

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, and is designed to occupy a minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth coexistence interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

Note: The ESP8266 Module is not capable of 5-3V logic shifting and will require an external Logic Level Converter. Please do not power it directly from your 5V dev board. This ESP8266 WiFi Module Adaptor comes with an on-board logic level converter and 3.3V LDO regulator for easy interfacing to Arduino boards.

Features:

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)
- Default baud rate: 115200

LDR

Working

Photo resistors, also known as light dependent resistors (LDR), are light sensitive devices most often used to indicate the presence or absence of light, or to measure the light intensity. LDRs have a sensitivity that varies with the wavelength of the light applied and are nonlinear devices.

LDR is a component that has a (variable) resistance that changes with the light intensity that falls upon it. This allows them to be used in light sensing circuits.

When an LDR is exposed to a light of high intensity, the resistance value will decrease. It could drop from 1 MΩ to 2 kΩ. Circuit of a day/night switch npn transistor is the control device, and an LED is the output device. While the capacitor is charging, the LED1 will be ON.

The light energy produces more free electrons which increases the current for a certain voltage across the LDR which means a drop in resistance. Very little current will flow through it when it is cold. This means that its resistance increases as the temperature falls.

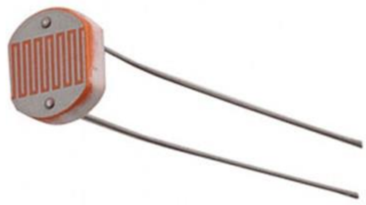


Figure 5.6 LDR

Specifications:

Electrical Characteristics

Parameter	Conditions	Min	Typ	Max	Unit
Cell resistance	1000 LUX 10 LUX	- -	400 9	- -	Ohm K Ohm
Dark Resistance	-	-	1	-	M Ohm
Dark Capacitance	-	-	3.5	-	pF
Rise Time	1000 LUX 10 LUX	- -	2.8 18	- -	ms ms
Fall Time	1000 LUX 10 LUX	- -	48 120	- -	ms ms
Voltage AC/DC Peak		-	-	320	V max
Current		-	-	75	mA max
Power Dissipation				100	mW max
Operating Temperature		-60	-	+75	Deg. C

Figure 5.6.2 LDR Specifications

Advantages:

LDR's are cheap and are readily available in many sizes and shapes. Practical LDRs are available in a variety of sizes and package styles, the most popular size having a face diameter of roughly 10 mm. They need very small power and voltage for its operation.

Disadvantages:

Highly inaccurate with a response time of about tens or hundreds of milliseconds.

CHAPTER 6

RESULT ANALYSIS

RESULT:

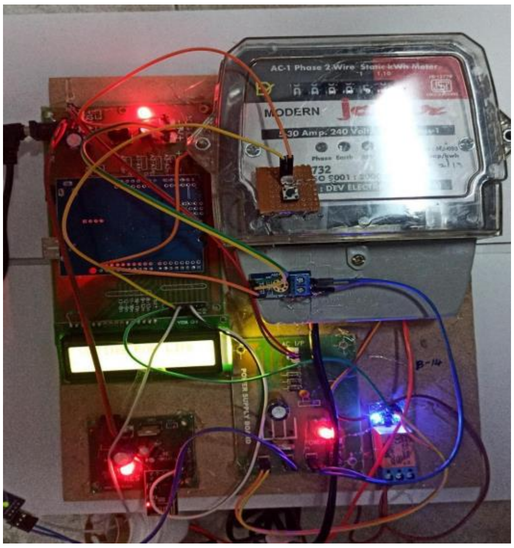

Figure.6 : IOT ENERGY METER WITH CURRENT, VOLTAGE AND COST MONITORING SYSTEM

CASE 1:

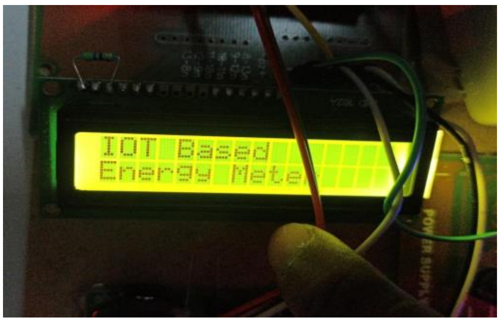

Figure.6.1: Welcome message

- This figure represents the welcome message instead of that we are displaying IOT Based Energy Meter.

CASE 2:

figure.6.2: LCD Displaying recharge update.

- This figure represents that the recharge is done and the unit's consumption has come to zero.
- Now the reading will start and it is displayed on the LCD screen.

CASE 3:

Figure 6.3 : LCD Displaying maximum units consumed.

- This figure represents that we have consumed maximum units so the power supply will be turned off.

- Once the recharge is done we will get the power supply again. So we get a warning message as maximum units are consumed on the LCD screen.

CASE 4:

Figure 6.4 : Displaying the notifications on a mobile application

- Connecting the mobile application with an IP address. Once it is connected we will receive the data through a wifi module which is connected to the system.
- For every reading we can see the notification within the app.
- Once it comes to a set limit we get warning notifications as max units consumed till we recharge it or pay the bill.
- We will receive the notification of recharge done as shown in figure.

CHAPTER 7

LIMITATIONS & ADVANTAGES

LIMITATIONS:

- We can't track or monitor the usage of our energy consumption at residency and industries.
- System has to be maintained manually.
- Managing and storing the vast quantities of metering data.
- Ensuring security of metering data.

ADVANTAGES:

- It provides accuracy in meter readings.
- This system helps in effectively controlling energy consumption and also avoids energy wastage.
- meter reading can be accessed from anywhere on the globe at any time.
- This system eliminates human involvement in energy management.
- It reduces the human interference to collect the monthly reading.

CHAPTER 8

CONCLUSION & FUTURE ENHANCEMENT

CONCLUSION:

- This system helps in controlling energy consumption and avoiding energy wastage.
- This IOT based energy meter plays a vital role in continuously monitoring the energy consumption and transferring the data to the server. This data can be accessed from anywhere on the globe at any time.

FUTURE ENHANCEMENT:

- It can be introduced in the department of power and energy and can be sanctioned for the collection of details of the consumption units for each and every customer.
- Further it can be linked with any payment gateway so that the electricity bill payment can also be done online with it.
