DECLARATION

We, the students of *Bachelor of Technology* ***in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "ALCOHOL DETECTION AND HEALTH MONITORING SYSTEM USING IOT" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.***

G. SUSMITHA (17K81A04B3)

B. JYESHNA (18K85A0412)

P.KIRAN KUMAR(18K85A0422)

ACKNOWLEDGEMETS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research andproviding us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head& Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our **dept. project coordinator Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our project internal guide **Mrs.Ch.Swathi, Assistant Professor**, Department of ECE and our class project coordinator **Mr.K.Karthik, Assistant Professor** Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinator **Dr.Maalayadri,Professor in IT** and **Dr.R.Santhosh Kumar ,Associate Professor in CSE,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

ABSTRACT

Factories, Offices, Hospitals, Military and other such industries need to monitor their staff/personnel follow all work ethics that include, not coming to premises under the influence of alcohol or under bad health conditions. This ensures proper work ethics are followed. So our proposed system allows for alcohol & health monitoring plus reporting system that monitors this and reports it to concerned personnel remotely over internet. Our system consists of an IOT based circuit system that uses a microcontroller based circuit system. The system has alcohol as well as blood pressure monitoring sensors to check for alcohol consumption as well as inappropriate blood pressure monitoring. This ensures no occurrences of accidents due to alcohol influence or bad health conditions

CHAPTER1

INTRODUCTION

1.1 OVERVIEWTOTHEPROJECT

Air and sound pollution is a growing issue these days. It is necessary to monitor air quality andkeep it under control for a better future and healthy living for all. Here we propose an air qualityas well as sound pollution monitoring system that allows us to monitor and check live air qualityas well as sound pollution in a particular areas through IOT. System uses air sensors to sensepresenceofharmfulgases/compoundsintheairandconstantlytransmitthisdatatomicrocontroller. Also system keeps measuring sound level and reports it to the online server overIOT. The sensors interact with microcontroller which processes this data and transmits it overinternet. This allows authorities to monitor air pollution in different areas and take action againstit.Alsoauthoritiescankeepawatchonthenoisepollutionnearschools,hospitalsandnohonkingareas, and if system detects air quality and noise issues it alerts authorities so they can takemeasuresto control the issue.

Ininfrastructureandindustrialplantstherapidgrowthcreatingenvironmentalissueslikepollution(Air, Water,Noise),climatechange,malfunctioningandhasgreatlyconsequencefortherequirement of an, operationally adaptable, efficient, cheap and smart monitoring systems. In thiscontextwherecombinationofmanychallengesofcomputerscience,wirelesscommunicationandelectronics; the Smart Sensor Networks are an emerging field of research. In this paper a solutionto monitor the air and noise pollution levels in industrial environment or by using wirelessembeddedcomputingsystemaparticularareaofinterestisproposed.ThetechnologylikeInternetof Things (IoT) is included in the form of solution which is outcome of merged field of computerscience and electronics. For monitoring the fluctuation of parameters like noise and air pollutionlevels from their normal levels in this case the sensing devices are connected to the embeddedcomputingsystem.Fortherequirementofcontinuousmonitoring,controllingandbehavioranalysisthismodelisadaptableanddistributiveforanyinfrastructuralenvironment.Fortwoor three parameters like noise, CO and radiation levels the implementation is tested with respect tothe normal behavior levels or given specifications which provide a monitoring over the pollutioncontrolto makethe environment smart and Eco-friendly.

1.2 MATERIALREQUIREMENT:

1.2.1 HARDWARE REQUIREMENT:

1. ArduinoUno
2. MQ3Alcohol sensor
3. Blood pressure sensor
4. LCDDisplay
5. ESP8266 Wi-Fi Module
6. Powersupply unit

1.2.2 SOFTWAREREQUIREMENT:

- ArduinoIDE
- Proteussoftware

1.3 PROCUMENTOFEQUIPMENT:

We brought all the required hardware components in a electronic manufacturing shop and beforeassemblingandinterfacinghardwarecomponentstoArduinoUNOmicro-controller,weconnected individual sensors to Arduino in Proteus Software and understood working of everyindividual sensor in Proteus Software. Now, we assembled all sensors and interfaced to ArduinoUNOmicro-controllerusingconnectingwiresthroughbreadboardandwewroteprogramtoworkall the hardware sensors in Arduino IDE, we understood the working of all sensors in a practicalway. We detected the alcohol level and monitored the blood pressure of the person and all theinformationis sent to theonlineserver.

1.4 INTRODUCTIONTO EMBEDDEDSYSTEM

An embedded system is a combination of computer hardware and software, either fixed incapability or programmable, designed for a specific function or functions within a larger system.Industrial machines, agricultural and process industry devices, automobiles, medical equipment,cameras, household appliances, airplanes, vending machines and toys, as well as mobile devices,are 2 possible locations for an embedded system. An embedded system is a dedicated computersystemdesignedforoneortwospecificfunctions.Thissystemisembeddedasapartofacomplet edevice system that includes, such as electrical and mechanical components [1]. The embeddedsystem is unlike the general-purpose computer, which is engineered to manage a wide range ofprocessingtasks.Becauseanembeddedsystemisengineeredtoperformcertaintasksonly,designengi neers may optimize size, cost, power consumption, reliability and performance. Embeddedsystems are typically produced on broad scales and share across a variety of environments andapplications.Anembeddedsystemisonethathas computer-hardwarewith softwareembeddedinit as one of its most important components. It is a dedicated computer-based system for anapplication or product. An embedded system has three main components. 1. It has hardware 2. Ithasmainapplicationsoftware.3.Ithasarealtimeoperatingsystem(RTOS)Anembeddedsystemhas software designed to keep in view three constraints: (i) Available system memory. (ii)Availableprocessorspeed.(iii)Theneedtolimitpowerdissipationwhenrunningthesystem.Anembe dded system is a system which is going to do a predefined specified task is the embeddedsystem and is even defined as combination of both software and hardware. A general-purposedefinition of embedded systems is that they are devices used to control, monitor or assist theoperationofequipment,machineryorplant."Embedded"reflectsthefactthattheyareanintegralpart of the system. At the other extreme a general-purpose computer may be used to control theoperation of a large complex processing plant, and its presence will be obvious. Some of thesecomputers are however very simple systems as compared with a personal computer [2]. The verysimplestembeddedsystemsarecapableofperformingonlyasinglefunctionorsetoffunctionstomee t a single predetermined purpose. In more complex systems an application program thatenablestheembeddedsystemtobeusedforaparticularpurposeinaspecificapplicationdetermines the functioning of the embedded system. The ability to have programs means that thesameembeddedsystemcanbeusedfora3varietyofdifferentpurposes[2].Insomecases,a microprocessor may be designed in such a way that application software for a particular purposecanbeaddedtothebasicsoftwareinasecondprocess,afterwhichitisnotpossibletomakefurtherc hanges. The applications software on such processors is sometimes referred to as firmware. Thesimplest devices consist of a single microprocessor (often called a "chip"), which may itself bepackaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC).Its input comes from a detector or sensor and its output goes to a switch or activator which (forexample) may start or stop the operation of a machine or, by operating a valve, may control theflow of fuel to an engine[3]. As the embedded system is the combination of both software andhardware.

1.4.1 HISTORYOFEMBEDDEDSYSTEM

Embedded systems date back to the 1960s. Charles Stark Draper developed an integrated circuit(IC) in 1961 to reduce the size and weight of the Apollo Guidance Computer, the digital systeminstalled on the Apollo Command Module and Lunar Module. The first computer to use ICs, ithelped astronauts collect realtime flight data. In 1965, Auto now a part of Boeing, developed theD-17B,the computer used in theMinuteman Imissileguidancesystem.

1.4.2 BLOCKDIAGRAMOF EMBEDDEDSYSTEM

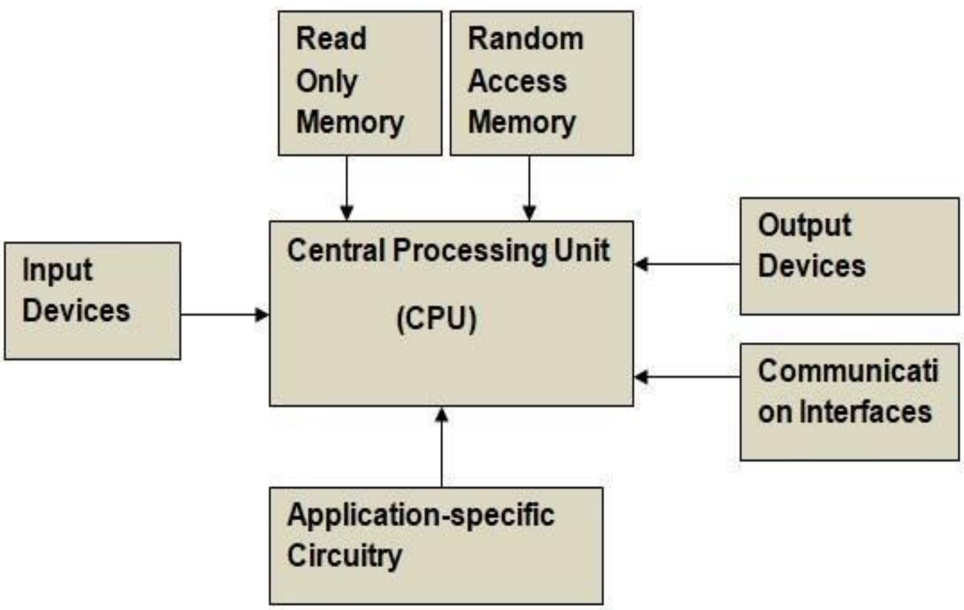

Fig.1.2.1:Blockdiagram ofembeddedsystem

SoftwaredealswiththelanguageslikeALP,C,andVBetc.,andHardwaredealswithProcessors,Peripherals,and Memory.

1.4.3 EMBEDDEDSYSTEMHARDWARE:

Embedded system hardware can be microprocessor- or microcontroller-based. In either case, anintegrated circuit is at the heart of the product that is generally designed to carry out computationforreal-timeoperations[4].Microprocessorsarevisuallyindistinguishablefrommicrocontrollers,butwhilethe microprocessoronlyimplementsacentralprocessingunit(CPU)and,thus,requiresthe addition of other components such as memory chips, microcontrollers are designed as self-containedsystems.

1.4.4 EMBEDDEDSYSTEMSOFTWARE:

A typical industrial microcontroller is unsophisticated compared to the typical enterprise desktopcomputer and generally depends on a simpler, less-memory intensive program environment. Thesimplest devices run on bare metal and are programmed directly using the chip CPU's machinecode language. Often, embedded systems use operating systems or language platforms tailored toembedded use, particularly where real-time operating environments must be served. At higherlevels of chip capability, such as those found in SoCs designers have increasingly decided thesystems are generally fast enough and the tasks tolerant of slight variations in reaction time thatnear-real-timeapproaches aresuitable.

1.4.5 EXAMPLESOFEMBEDDEDSYSTEM

1.4.6 TYPESOFEMBEDDEDSYSTEM

1. RealTimeSystems

Real-time systems are those which give a quick response to critical situations. They are used inmilitary, medical and industrial applications. Engineers working in these systems have highdemand is current days. To develop the real-time embedded system we require timing analysis,multitasking design, debugging, cross-platform testing and architecture design. In these systems,quickresponse is very important.

2. StandaloneEmbeddedSystem

This type of embedded system works for itself as a device without needing any interconnectedcomputer. It can take data in the form of Analog or digital signals. This system first process dataandthen outputs data bydisplaying on thescreen.

3. NetworkedEmbeddedSystem

Networked embedded systems are those systems which are connected to the network to giveoutputtotheattachedresources[5].Thedevicesinthenetworkedembeddedsystemareconnectedto the network with network interfaces. The network can be either a local area network (LAN) orawideareanetwork(WAN).

4. MobileEmbeddedSystem

Mobile embedded systems are limited in resources including memory. Examples of mobileembeddedsystems include

- Personaldigitalassistants(PDA)
- Cellularphones
- Mp3players
- Digitalcameras

5. Small-ScaleEmbeddedSystem

Small-scaleembeddedsystemsconsistof8-16bitmicrocontroller.Thissystemcanperformtasksatasmalllevel.Theyhaveon-chipROMandRAM.Smallscalesystemscanbeevenactivatedbythebattery.Thetoolsusedtodevelopsmall-scaleembeddedsystemsareaneditor,crossassembler,assembler and integrated development environment (IDE). The purpose of this system is notcomputation but to control as a computer embedded inside it. It behaves as a component of acomputer and its function is not to compute. The small-scale system is dedicated to some specifictask.

6. MediumScaleEmbeddedSystem

This embedded system has 16-32 bit microprocessor or microcontroller with external RAM andROM They can perform medium to complex level works. The integration between hardware andsoftwareiscomplexintheseembeddedsystems.Programminglanguagesusedtodevelopmediumscale embedded systems include Java, C, Visual C++, debugger, C++, RTOS, simulator, sourcecodeengineering tool and IDE.

7. SophisticatedEmbeddedSystem

The embedded system which can do large-scale works with multiple 32-64 bit chips is known assophisticated embedded systems[6]. They can perform distributed work on a large scale. Thecomplexity of hardware and software is very high in these systems. In sophisticated embeddedsystems, hardware and software are assembled together on large scale and designing of hardwareproductsis also includedin thesesystems.

1.4.7 APPLICATIONSOFEMBEDDEDSYSTEM

- Manufacturingandprocesscontrol
- Constructionindustry
- Transport
- Buildingsandpremises
- Domesticservice
- Communications
- Officesystemsandmobileequipment
- Banking,financeandcommercial
- Medicaldiagnostics,monitoringandlifesupport
- Testing,monitoringanddiagnosticsystems

1.5 MICROCONTROLLER

A microcontroller is a small computer on a single metal oxide semiconductor (MOS) integratedcircuit(IC)chip.AmicrocontrollercontainsoneormoreCPUsalongwithmemoryandprogrammableinput/outputperipherals.ProgrammemoryintheformofferroelectricRAM,NORflashorOTP ROMisalsooftenincludedonchip,aswellasasmallamountofRAM.Microcontrollers are designed for embedded applications, in contrast to the microprocessors usedinpersonalcomputersorothergeneralpurposeapplicationsconsistingofvariousdiscretechips[7].InmodernterminologyamicrocontrollerIs the similar placeholder chip (SoC). SoC may include a microcontroller as one of its components, but usually integrates itwith advanced peripherals like graphics processing unit (GPU), Wi-Fi module, or one or morecoprocessors.

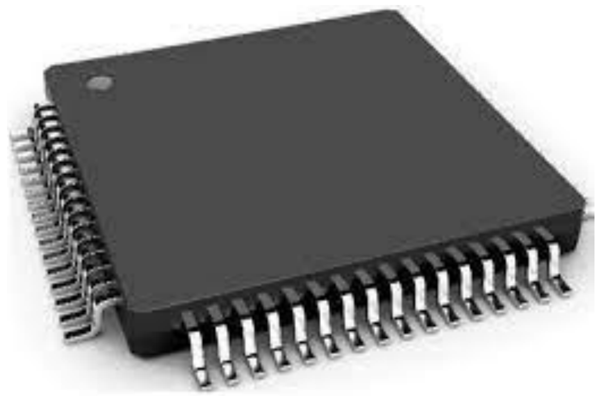

Fig.1.3.1:Microcontroller

Microcontrollers are used in automatically controlled products and devices, such as automobileenginecontrolsystems,implantablemedicaldevices,remotecontrols,officemachines,appliances,powertools,toysandotherembeddedsystems.Byreducingthesizeandcostcomparedtoadesignthatusesaseparatemicroprocessor,memory,andinput/outputdevices,microcontrollers make it economical to digitally control even more devices and processes. Mixedsignalmicrocontrollersarecommon,integratinganalogcomponentsneededtocontrolnon-digitalelectronicsystems.Inthecontextoftheinternetofthings,microcontrollersareaneconomicalandpopularmeansofdatacollection,sensingandactuatingthephysicalworldasedgedevices.Somemicrocontrollersmayusefour-bitwordsandoperateatfrequenciesaslowas4kHzforlowpowerconsumption (single-digit milliwatts or microwatts). They generally have the ability to retainfunctionalitywhilewaitingforaneventsuchasabuttonpressorotherinterrupt;powerconsumptionwhilesleeping(CPUclockandmostperipheralsoff)maybejustnanowatts,makingmanyofthemwellsuitedforlonglastingbatteryapplications[8].Othermicrocontrollersmayserveperformance-criticalroles,wheretheymayneedtoactmorelikeadigitalsignalprocessor(DSP),withhigher clock speeds and powerconsumption.

1.5.1 HISTORY

Theoriginsofboththemicroprocessorandthemicrocontrollercanbetracedbacktotheinventionof the MOSFET (metal-oxide-semiconductor field-effect transistor), also known as the MOStransistor. It was invented by Mohamed M. Atalla and DawonKahng at Bell Labs in 1959, andfirst demonstrated in 1960.9 The same year, Atalla proposed the concept of the MOS integratedcircuit,whichwasanintegratedcircuitchipfabricatedfromMOSFETs.By1964,MOSchipshadreachedhighertransistordensityandlowermanufacturingcoststhanbipolarchips[2].MOSchipsfurtherincreasedincomplexityataratepredictedbyMoore'slaw,leadingtolarge-scaleintegration (LSI) with hundreds of transistors on a single MOS chip by the late 1960s. Theapplication of MOS LSI chips to computing was the basis for the first microprocessors, asengineers began recognizing that a complete computer processor could be contained on a singleMOS LSIchip.

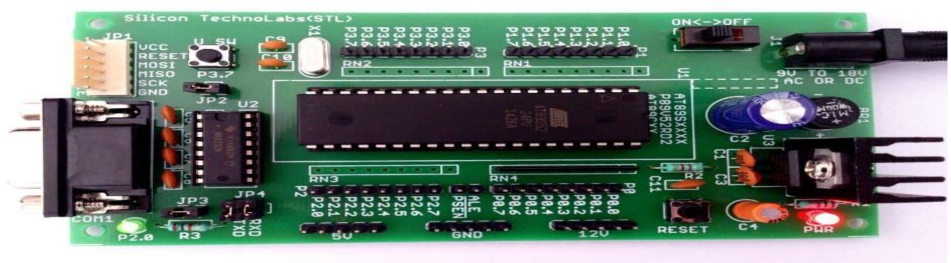

Fig.1.3.2:8051MicrocontrollerBoard

Most microcontrollers at this time had concurrent variants. One had EPROM program memory,with a transparent quartz window in the lid of the package to allow it to be erased by exposure toultravioletlight.Theseerasablechipswereoftenusedforprototyping.Theothervariantwaseitheramaskprogrammed ROMoraPROMvariantwhichwasonlyprogrammableonce.Forthelatter,sometimes the designation OTP was used, standing for "one-time programmable". In an OTPmicrocontroller,thePROMwasusuallyofidenticaltypeastheEPROM,butthechippackagehadno quartz window; because there was no way to expose the EPROM to ultraviolet light, it couldnotbeerased.Becausetheerasableversionsrequiredceramicpackageswithquartzwindows,they were significantly more expensive than the OTP versions, which could be made in lower-costopaqueplasticpackages.Fortheerasablevariants,quartzwasrequired,insteadoflessexpensive glass,foritstransparencytoultravioletlight—towhichglassislargelyopaque—butthemaincostdifferentiatorwas theceramicpackageitself.

In 1993, the introduction of EEPROM memory allowed microcontrollers (beginning with theMicrochip PIC16C84) to be electrically erased quickly without an expensive package as requiredforEPROM,allowingbothrapidprototyping,andin-systemprogramming.(EEPROMtechnologyhad been available prior to this time, but the earlier EEPROM was more expensive and lessdurable,makingitunsuitableforlow-costmass-producedmicrocontrollers.)Thesameyear,Atmelintroduced the first microcontroller using Flash memory, a special type of EEPROM. Othercompanies rapidly followed suit, with both memory types. Nowadays microcontrollers are cheapandreadilyavailable for hobbyists, withlargeonlinecommunitiesaroundcertainprocessors.

1.6 INTRODUCTIONTOINTERNETOFTHINGS

The Internet of things (IoT) describes the network of physical objects—a.k.a. "things"—that areembedded with sensors, software, and other technologies for the purpose of connecting andexchanging data with other devices and systems over the Internet.Things have evolved due to theconvergenceofmultipletechnologies,real-timeanalytics,machinelearning,ubiquitouscomputing,commoditysensors,andembeddedsystems.[1]Traditionalfieldsofembeddedsystems, wireless sensor networks, control systems, automation (including home and buildingautomation), and others all contribute to enabling the Internet of things. In the consumer market,IoT technology is most synonymous with products pertaining to the concept of the "smart home",including devices and appliances (such as lighting fixtures, thermostats, home security systemsand cameras, and other home appliances) that support one or more common ecosystems, and canbecontrolledviadevicesassociatedwiththatecosystem,suchassmartphonesandsmartspeakers.TheIoT can also be usedin healthcaresystems.

Internet of Things (IOT) is a network of devices that connect directly with each other to captureandsharedatathroughasecureservicelayerthatconnectstoacentralcommandandcontrolserverin the cloud. The closure\look suggest that the way people collect, record and analyze data—notjust in health care but in every industry today. The idea of devices connecting directly with eachotheris basically calledInternet of Things.

The Internet of Thingsalso a called the Internet of Objects, refers to a wireless network betweenobjects,usuallythenetworkwillbewirelessandself-configuring.InternetofThings(IOT)isoneof the major component advances in present time that links the internet with everyday sensor andworking devices. Smart objects play an important role in the Internet of Things vision, sinceembedded communication and information technology would have the potential to change theutility of these objects. Using sensors they are able to recognize their condition, and via built-inconnectingpower they would be ableto interact with each other.

1.6.1 BenefitsofIOT

Ubiquitousnetworks -:PersonalWi-Fionyour smartphonesandonmanyoftheotherdevices.Everyone(and everything) wants as well asneedsto be connected.

Connectedcomputing-:Wewantallofthedevices,smartphones,televisions(coloredorblackandwhite), dvd players, vehicles etc. to keep record of what we are doing, seeing, reading, and/orlistening to as we sway through the day, from one place to another – the handoffs from device todeviceis happeningalready.

Analytics-as-a-Service-: The API and App economies are already wide and growing whichenables to “do something interesting” as long as it can be connected to an API or can invoke anAppthatcarriesoutanetwork-basedservice.Thethingisadatageneratoraswellascollectorthatlearnsfrom,makesforecast,andmaybeeventakesdata-drivenactionsinresponsetothedatathatarecollected too.

Marketingautomation-: Smartphonecustomerengagement,geological-location,Apple’siBeacon etc. are all developing a network of knowledge and information regarding customers’locations, intentions, preferences, as well as buying patterns. Obviously, the degree of geologicallocation-basedknowledgeneedstomaintaintherightbalancebetweenuserprivacyaswellasthetimelydelivery ofimportantand significant products andservices to theparticularuser.

Supply Chain Analytics-: Delivering the just-in-time products at the time of need (inclusive ofthe use of RFID-based tracking). Significantly, everything is a customer (inclusive of machines,automobiles, manufacturing plants, ATM machines, etc.), as well as the IOT is monitoring,watching,as well as waiting forthe product needsto arise.

1.7 MOTIVATIONOFTHEPROJECT

In this era of modernization, technologies are advancing rapidly. Every day we realize some newtechnology coming in market to simplify our lives more than ever. Here this system is created tomakeonemoresysteminthefulfillmentofthegoalofsmartcity.Herethissystemusedto detect alcohol andmonitorthe blood pressure of the personandhelpsintakingmeasurestocontrolstheaccidents occurred to a person due to alcohol consumption and bad health condition.

CHAPTER2

LITERATURESURVEYANDEXISTINGMODELS

2.1 LITERATUREREVIEWONRESEARCHAREA:

1. Internet of Things (IoT) and cloud computing plays a vital role in today's Tele-monitoring health system. This system keeps track of patient's physiological parameters through collection of body sensors' data using Arduino board. The patient's health card are developed by the doctors and displayed on a webpage where doctors and patients can access and communicate each other without physical presence. Using cloud computing, the data can be stored, updated and accessed from anywhere in the world. It is very suitable for rural areas where medical facilities are not available.

2. Owing to costlier healthcare and long waiting time in hospitals, the concept of in-home patient monitoring system have been emerging in the recent years. This system collects data of various body parameters through biosensors, wearable devices and smart textiles and it transmits the data to central node server securely through Cipher text Policy Attribute Based Encryption (CP-ABE) method. In turn, the server shares the collected data to the hospitals for further treatment. It is very beneficial for elders and chronic patients who require continuous monitoring.

3. The specialized healthcare monitoring system for elderly people is a growing need in the aging population world. This system performs the alcohol detection and monitoring blood pressure by measuring the body parameters regularly and report the data to the higher officials. The result data are then displayed as statements in a web application where the persons can interact with each other. The main challenge is to make elders equipped with for growing new technology and become familiar towards smartphone and computers.

4. IoT based Smart healthcare with the help of smart devices and objects improves the healthcare monitoring system effectively, thus by reducing the inefficiencies of existing healthcare system. Smart devices with new and upgraded technologies enhances the data

accuracy to be collected, real-time accessibility of person's condition, intelligent integration of data collected, maintaining the integrated data smartly through cloud service, etc. IoT along with smart devices reduce complexity and complications in the healthcare system. The penetration of mobile technologies and smart devices over healthcare system cause huge impact on the world. The full-fledge utilization of M-health and E-health applications in today's world is made aware to the people for improving and maintaining the good quality of life. Apart from regular monitoring of persons condition through M-health system, the main objective is to educate them through recommendations of healthy eating habits and effective workout routines for improving their quality of healthy life.

5.In remote mobile health monitoring system, the person health parameters are recorded by a smart phone by eliminating an additional hardware and transmit data through a web interface. It facilitates end to end monitoring screen through three steps. Firstly, the real time health parameters are measured through wearable sensors and transmitted to a smart phone which shows the patient health status in graphical interface. Secondly, this system provides a data to family member and doctor through web interface for further monitoring.

2.2 REVIEWOFRELATEDLITERATURE:

The purpose of this project is to identify the alcohol consumption and health monitoring of a person by using alcohol sensor and blood pressure sensor and by observing the output through wifi module over internet, we as a society have to ensure that every person is maintaining minimum etiquette,Intoday'sworld,healthcareisthebiggestconcern,healthcare has a lot of effects on the wellbeing of the people. Our project is a small step to this biginitiative to ensure that accidents related to health stays under control. This project helps in detecting the alcohol consumption and blood pressure of a person. Our project will be a boon tothe society as our project will be making sure that every individual will be able to keep a track ofthe health from the website . It is the need of the hour to monitor health and keep it undercontrolforabetter futureand healthy living forall.

Themotiveofmakingasmartcitycanbefulfilledbyusingtechnology,thusmakingthelifebetterand also enhancing the quality of services, therefore meeting every individual's needs. Withmodern technology in fields of information and communication, it has become easy to interactwith the authorized people of city to tell the where abouts of the area or city, how well the city isdeveloping and how to make it possible to achieve a better life quality. In this system, anapplication was created to make one more step in the fulfillment of the goal. The components of alcohol and blood pressuretheiramountsarecalculatedandchecked.Iftheamountishigherthannormalthenthe officials are reported about it. After that the people are made to clear the area and taken to a safeplace.

2.3 CONCLUSIONONREVIEWS:

This projectfocuses on a real-time alcohol detection and healthcare monitoring system using IoT and cloud computing service which are more beneficial for elders and chronic diseases' patients. The current methods available for realization of Healthcare services are surveyed and the challenges that are part of realization are also highlighted. This project proposed an intelligent real-time patient health monitoring system that monitors the subject's vital parameters such as pressure, alcohol detection. Appropriate medications are suggested based on the diagnosis of the provided set of symptoms. The system sends an alert message to the caretakers in case of any abnormality through cloud. The system enables the caretaker to optimize the usage of available medical resources and minimize the costs in monitoring the persons. In the future, we will focus on improving wearing sensor experience by using softer materials and enabling controlled sharing of information among the doctors, the patient, and the patients' family through social networking paradigm.

CHAPTER 3PROJECTDESCRIPTION

3.1 BLOCKDIAGRAM:

The system is used for detecting alcohol consumtion and blood pressure.The system consistsof alcohol sensor to measure the concentration of alcohol and blood pressure sensorfor measuringbloo.These sensed information is transmitted to the Arduino and itprocess the information and continuously displays these values on the lcd display which isconnected to it, simultaneously this information is transmitted to the online server by the wi-fimodule.Byusingthewebsitethingspeakwecanmonitorthelevelofairandnoisepollutionintheenvironment. This allows authorities to monitor air pollution in different areas and take actionagainstit.

5.ESP8266Wi-FiModule

The ESP8266 WiFi Module is a self contained SOC with integrated TCP/IP protocol stack thatcan give any microcontroller access to your WiFi network. The ESP8266 is capable of eitherhosting an application or offloading all WiFi networking functions from another applicationprocessor. Each ESP8266 module comes pre-programmed with an AT command set firmware,meaning,youcansimplyhookthisuptoyourArduinodeviceandgetaboutasmuchWiFi-abilityas a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely costeffectiveboardwith a huge, and ever growing,community.

6. PowerSupplyUnit

Every electrical and electronic device that we use in our day-to-day life will require a powersupply.Ingeneral, weusean ACsupplyof 230V50Hz, butthispower hastobechangedintotherequired form with required values or voltage range for providing power supply to different typesof devices. There are various types of power electronic converters such as step-down converter,step-up converter, voltage 31 stabilizer, AC to DC converter, DC 25 to DC converter, DC to ACconverter, and so on. For example, consider the microcontrollers that are used frequently fordeveloping many embedded systems based projects and kits used in real-time applications. Thesemicrocontrollersrequirea5V DC supply.

3.2 SchematicDiagram

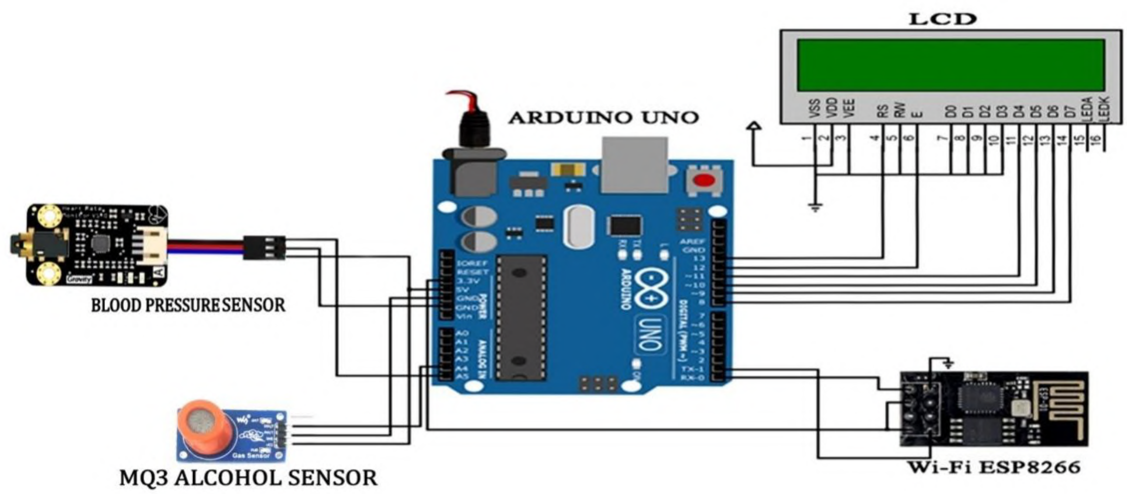

Fig.3.2.1:SchematicDiagram

3.2.1 SchematicExplanation

Arduino UNO has 6 analog pins from A0 to A6 which are generally input pins. It also has 14digitalpinsfrom0-13whicharetheoutputpins.Theanalog pinA4isconnectedtotheoutputpinof the mq2 gas sensor and analog pin A5 is connected to the output pin of the sound sensor. Thedigitalpins8-13is connectedtothelcdtodisplaytheoutputvalues.Herepin0isthereceiverpinand pin 1 is the transmitter pin. These pins are used for the esp8266 wi-fi module to transmit theinformationto the online server.

4.1.1 ARDUINOUNO

Arduino is an open-source electronics platform based on easy-to-use hardware and software.Arduinoboardsareabletoreadinputs-lightonasensor,afingeronabutton,oraTwittermessageand turn it into an output activating a motor, turning on an led, publishing as it reached a widercommunity, the Arduino board started something online. You can tell your board what to do bysending a set of instructions to the microcontroller on the board. To do so you use the Arduinoprogramminglanguage(basedWiring),theArduinoSoftware(IDE),basedonProcessing.ArduinowasbornattheareaInteractionDesignInstituteasaneasytoolforfastprototyping,aimedat students without a background in electronics and programming wearable, 3dprinting, andembedded environments. All Arduino boards are completely open-source, empowering fromeverydayobjectstocomplexscientificinstruments.Professionalgatheredaroundopen-sourceplatform, the software too is opensource, it is growing through the contributions of users worldwide,theArduino board is shown in below figure.

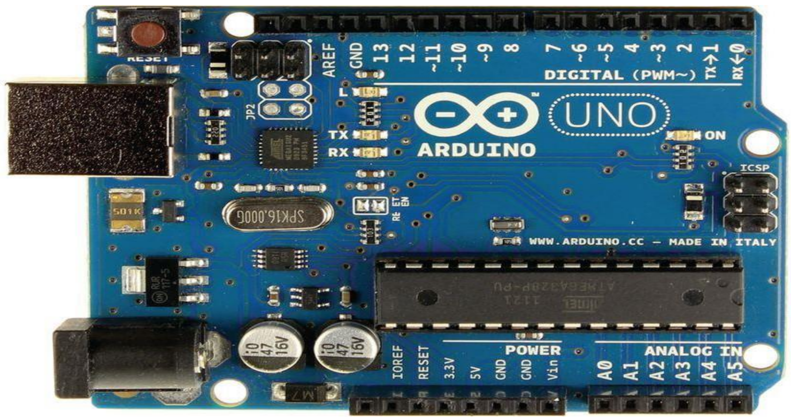

Fig.4.1.1:Arduinounoboard

4.1.1.1 WhyArduino?

Arduino Uno is inexpensive. Arduino is cross platform, its IDE can run on multiple OperatingSystemssuchasWindows,Macintosh,Linuxandmanymore.Ithassimpleandclearprogrammingenvironment.Itssoftwareandhardwareareopen-sourceandextensible,thatis,Arduinoprogramming can be expanded through C++ libraries and can also leap to AVR ‘C’ languageprogramming. It is simple and accessible to user experience, Arduino has been used in thousandsof different projects and applications. The Arduino software is easy-to-use for beginners, yetflexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and studentsuse it to build low cost scientific instruments, to prove the chemistry and physics principles or togetstartedwithprogrammingandrobotics.Designersandthearchitectsbuildinteractiveprototypes,musicians,artistsuseitforinstallationsandtoexperimentwithnewmusicalinstruments. Makers of course use it to build many of the projects exhibited at the Maker Faire,for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists,programmers can start tinkering just following the step by step I constructions of a kit or sharingideasonlinewithothermembersoftheArduinocommunity.Therearemanyothermicrocontrollers platforms available for physical computing. Parallax Basic Stamp, Netmedia'sBX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of thesetools take the messy details of microcontroller programming and wrap it up in an easy-tousepackage. Arduino also simplifies the process of working with microcontrollers, but it offers someadvantageforteachers,students,andinterestedamateursoverothersystems.•Inexpensive

Arduino boards are relatively inexpensive compared to other microcontroller platforms. The leastexpensive version of the Arduino module can be assembled by hand, and even the pre-assembledArduino modules cost less than $50 • Cross-platform The Arduino Software (IDE) runs onWindows, Macintosh OSX, and Linux operating systems. Most microcontroller systems arelimited to Windows. • Simple, clear programming environment The Arduino Software (IDE) iseasy-to-useforbeginners,yetflexibleenoughforadvanceduserstotakeadvantageofaswell.Forteachers,convenientlybasedontheProcessingprogrammingenvironment,sostudentslearningtoprograminthatenvironmentwillbefamiliarwithhowtheArduinoIDEworks.•OpensourceandextensiblesoftwareTheArduinosoftwareispublishedasopensourcetools,availableforextensionby experienced programmers. The language can be expanded through C++ libraries, and peoplewanting to understand the technical details can make the leap from Arduino to the AVR Cprogramminglanguageonwhichit'sbased.Similarly,youcanaddAVR-CcodedirectlyintoyourArduinoprogramsifyouwantto.•OpensourceandextensiblehardwareTheplansoftheArduinoboards are published under a Creative Commons license, so experienced circuit designers canmaketheirownversionofthemodule,extendingitandimprovingit.Evenrelativelyinexperienceduserscanbuildthebreadboardversionofthemoduleinordertounderstandhowitworksandsavemoneyand the parts ofArduino board is shown below

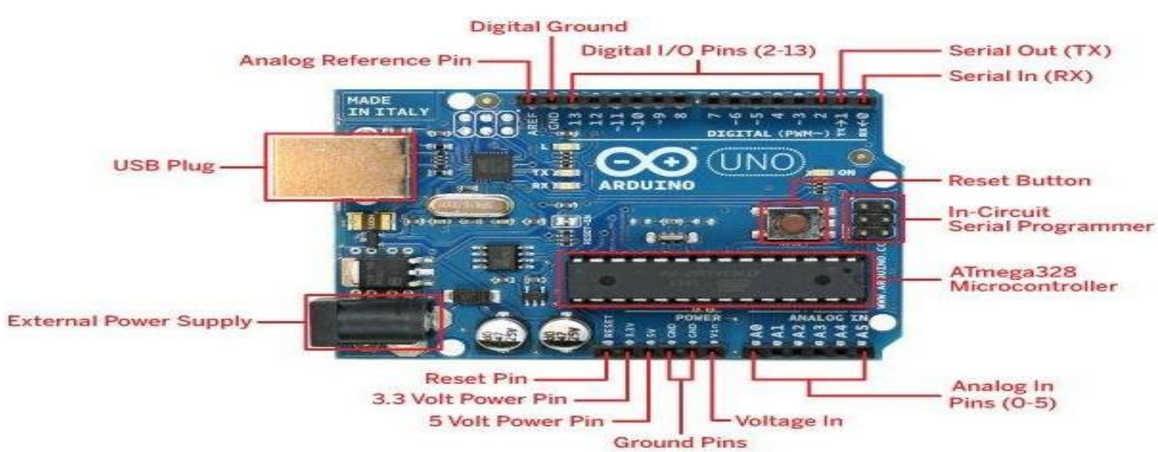

Fig.4.1.2:Arduinoboard description

4.1.1.2 Featuresof Arduino

Microcontroller	ATmega328
Operating Voltage	5V
Input Voltage	7-9V
Input Voltage (limits)	6-20V
Digital I/O Pins	14 (6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 mA
DC Current for 3.3V Pin	50 mA
Flash Memory	32 KB (ATmega328) (0.5 KB used by bootloader)
SRAM	2 KB (ATmega328)
EEPROM	1 KB (ATmega328)
Clock Speed	16 MHz

Table4.1.1:Featuresof Arduinouno

4.1.1.3 Programming

TheArduinoUnocanbeprogrammedwiththeArduinoSoftware(IDE).SelectArduinoUnofromtheToolsBoardAfteryourcodeiscompiledusingArduinoIDE,itshouldbeuploadedtothemainmicrocontroller of the Arduino UNO using a USB connection. Because the main microcontrollerdoesn't have a USB transceiver, you need a bridge to convert signals between the serial interface(UART interface) of the microcontroller and the host USB signals. The ATmega328 on theArduino Uno comes pre-programmed with a boot loader that allows you to upload new code to itwithouttheuseofanexternalhardwareprogrammer.ItcommunicatesusingtheoriginalSTK500protocol. You can also bypass the bootloader and program the microcontroller through the ICSP(In Circuit Serial Programming) header using Arduino are similar. The ATmega16U2 (or 8U2 intherev1&rev2boards)firmwaresourcecodeisavailableintheArduinorepository.TheATmega16U2 or8U2isloadedwithaDFUbootloader,whichcanbeactivatedbyOnRev1boards connecting the solder jumper on the back of the board and then resetting the 8U2. You can thenuse Atmel's FLIP software (Windows) or the DFU programmer (Mac OS X and Linux) to load anewfirmware.OryoucanusetheISPheaderwith anexternalprogrammer(overwritingtheDFUbootloader). Arduino is an opensource hardware platform that is being used by people around theglobeforbuildingelectronicsprojects.Itisanintegratedplatformwhichcontainsboththephysicaland programmable circuit otherwise known as microcontroller and a software (or IDE) that youcan run on your computer to write and upload the code onto the physical board. Arduino Board isquite popular among many people who want to get started with electronics, and unlike otherembedded system boards Arduino does not require any additional hardware to upload the code(generally known as programmer). The Arduino Program can be written and uploaded using theArduinoIDEthatneedsjustanUSBcabletoconnect.Sincetheinterfaceissimpleandcomplicacies are less Arduino is preferred by most of the aspiring engineers. Here we will try tounderstand about the Arduino Architecture and its functionalities. The processor of the ArduinoBoard uses Harvard Architecture for which the program code and program data have separatememory. The memory of it is divided into two namely program memory and data memory. Thedata will be stored in the data memory whereas the program code will be stored in the flashprogram memory. For ex: The Atmega328 microcontroller has 32kb of flash memory, 2kb ofSRAM,1kbofEPROMandoperatesat16MHzclockspeed.SomeoftheotherbasicfunctionsofArduin oare:

• Digitalwritepinisusedtowritethedigitalvalueof thegivenpin.

• Pinmodepinisusedtosetthepinto I/Omode.

• Analogreadpinreads andreturnsthevalue.

• Analogwritepinwritesthevalueofthepin

• Serial.Beginspinsetsthebeginningofserialcommunicationbysettingtherate ofbit

• Digitalreadpinreadsthedigitalvalueofgiven pin.

4.1.1.4 Advantages

Inexpensive-
Arduinoboardsarerelativelyinexpensivecomparedtoothermicrocontrollerplatforms.Theleastexpen siveversionoftheArduinomodulecanbeassembledbyhand,andeventhepre-assembled Arduino modules cost less than $50.

1. Cross-platform - The Arduino software runs on Windows, Macintosh OSX, and the Linuxoperatingsystems. Most microcontroller systemsarelimited to Windows.

2. Simpleprogrammingenvironment-HeretheArduinoprogrammingenvironmentiseasy-to-usefor beginners, yet flexible enough for advanced users to take advantage of as well. For teachers,it's conveniently based on the Processing programming environment, so students learning toprogramin that environmentwill befamiliar withthe look and feelof Arduino.

3. Opensourceandextensiblesoftware-
TheArduinosoftwareispublishedasopensourcetools,availableforextensionbyexperiencedprogram mers.ThelanguagecanbeexpandedthroughC++libraries, and people wanting to understand the technical details can make the leap from Arduinoto the AVR C programming language on which it's based. Similarly, you can add AVR-C codedirectlyinto yourArduino programs if youwant to

4. Open source and extensible hardware - The Arduino is based on Atmel's ATmega8 andATmega168microcontrollers.TheplansforthemodulesarepublishedunderaCreativeCommonsli cense, so experienced circuit designers can make their own version of the module, extending itand improving it. Even 19 relatively inexperienced users that can build the breadboard version ofthemodule in order to understand how it works and savemoney.

4.1.1.5 Applications

• ItisaneasyUSBinterface.Thisallowsinterface withUSBasthisislikeaserialdevice.

• The chip on the board plugs straight into your USB port and supports on your computer as avirtual serial port. The benefit of this setup is that serial communication is an extremely easyprotocol which is time-tested and USB makes connection with modern computers and makes itcomfortable.

• It is easy-to-find the microcontroller brain which is the ATmega328 chip. It has more numberof hardware features like timers, external and internal interrupts, PWM pins and multiple sleepmodes.

• It is an open source design and there is an advantage of being open source is that it has a largecommunityofpeopleusingandtroubleshootingit.Thismakeseasytohelpindebuggingprojects

. • It is 16MHz clock which is fast enough for most applications and does not speeds up themicrocontroller.

• Itisveryconvenienttomanagepowerinsideitandithadafeatureofbuilt-involtageregulation.This also be powered directly off a USB port without any external power. You can connect anexternalpower sourceofup to 12vand this regulates it to both5v and 3.3v.

• 13 digital pins and 6 analog pins. This sort of pins allows you to connect hardware to yourArduinoUnoboardexternally.Thesepinsareusedasakeyforextendingthecomputingcapabilityof the Arduino Uno into the real world. This has an ICSP connector for bypassing the USB portand interfacing the Arduino directly as a serial device. This port is necessary to re-boot load yourchipif it corrupts and can no longerused to yourcomputer.

• Ithas a32KBofflashmemoryforstoringyour code.

• Anon-boardledisattachedtodigitalpin13tomakefastthedebuggingofcodeandtomakethedebugprocesseasy finally it has the button toreset.

4.1.1.6 Power

TheArduinoUnocanbepoweredviathroughUSBconnectionorwithanexternalpowersupply.The power source is selected automatically. External (non-USB) power can come either from anAC-to-DC adapter (wall-wart) or battery. The adapter can be connected by plugging a 2.1mmcentre-positive plug into the board's power jack. Leads from a battery can be inserted in the Gndand Vin pin headers of the POWER connector. The board can operate on an external supply of

6to20volts.Ifsuppliedwithlessthan7V,however,the5Vpinmaysupplylessthanfivevoltsand theboardmaybeunstable.Ifusingmorethan12V,thevoltageregulatormayoverheatanddamagetheboard. Therecommended rangeis 7to 12 volts. the power pinsareas follows.

• VIN. The input voltage to the Arduino board when it's using an external power source (asopposed to 5 volts from the USB connection or other regulated power source). You can supplyvoltage through this pin, or, if supplying voltage via the power jack, access it through this pin. •5V. The regulated power supply used to power the microcontroller and other components on theboard.Thiscancomeeitherfrom VINviaanon-boardregulator,orbesuppliedbyUSBoranotherregulated5V supply.

• 3.3V.A3.3voltsupplygenerated bytheon-boardregulator.Maximum currentdrawis50mA.

• GND.Groundpins.

4.1.1.7 IntroductiontoAtmega328

ATmega328isaneight(8)bitMicrocontroller.Itcanhandlethedatasizedofuptoeight(8)bits.It is an AVR based micro-controller. Its built-in internal memory is around 32KB. It operatesranging from 3.3V to 5V. It has an ability to store the data even when the electrical supply isremoved from its biasing terminals. it is the excellent features include the cost efficiency and lowpower dissipation, programming lock for security purposes, real timer counter with the separateoscillatorandItisgenerallyornormallyusedinEmbeddedSystemsapplications.ATmega-328isshownin thefiguregivenbelow.

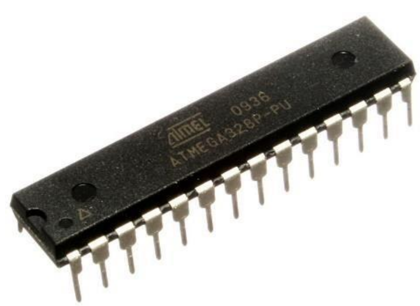

Fig.4.1.3:ATMega328 Microcontroller

4.1.1.8 ArduinoUNOAtmega328

The Arduino UNO is a micro controller board based on the ATmega. UNP means one in ItalianandisnamedtomarktheupcomingreleaseofthegivenArduino1.0ithas14digitalinput/outputpins , 6 analog inputs, 16MHz ceramic resonator. A USB connection. A power jack, An ICSPheaderandaresetbutton.itcontainsinformationeverythingneededtosupportthemicrocontroller.simplyconnectittoacomputerwithaUSB cableorpoweritwith aac-to-dcadapterorbatterytoget started. The UNO differs from all preceding boards in that it does not use the FTDI USBtoserial driver chip. Instead it features the ATMega 16U2ATMega 8U2 up to version instead R2)programmedasaUSB to-serial converter.

4.1.1.9 ArchitectureandWorkingof ArduinoUno

TheArduinoUNOcanbealsopoweredviatheUSBconnectionorwithanexternalpowersupply.The power source is selected automatically. External (non-USB) power can come either from anAC-to-DCadapterorbattery.Theadaptercanconnectedbyplugginga2.1mmcentrepositiveplugintothe board's power jack. Leads from a battery can be inserted in the Gnd and vin pin headersof the power connector. The board can operate on an external supply of 6to 20 volts. If suppliedwith less than 7v however, the 5v pin may supply less than five volts and the board may beunstable. If using more than 12v.the voltage regulator may overheat and damage the board. Therecommended range is 7 to 12 volts. The processor of the Arduino board uses the Harvardarchitecture where the program code and program data have separate memory. It consists of twomemoriessuchasprogrammemoryanddatamemory.Whereinthedataisstoredindatamemoryand the code is stored in the flash program memory. The Atmega328 microcontroller has 32kb offlashmemory,2kbofSRAM1kbofEPROMandoperateswitha16MHzclockspeed.Architectureof Atmega328 is shown below.

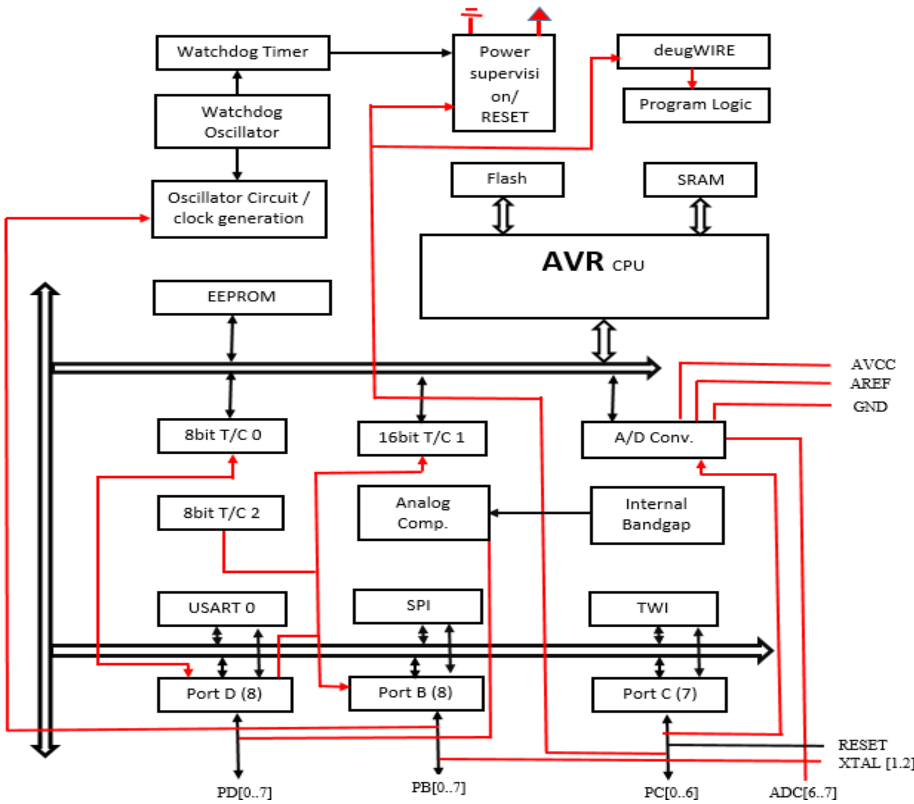

Fig.4.1.4:ATmega328PArchitecture

4.1.1.10 Atmega328PinsDescription

Functionsassociatedwiththepinsmustbeknowninordertousethedeviceappropriately.ATmega-328pins aredivided intodifferent portswhich aregiven in detailbelow.

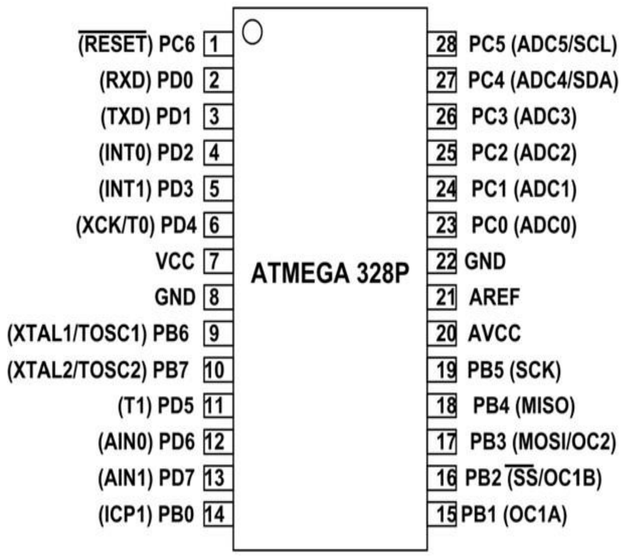

Fig.4.1.5:ATmega328P Ports

AVCCis asupply voltagepinforanalog todigital converter.

VCCis adigital voltage supply GNDdenotes Groundand it hasa0V.

PortAconsistsofthepinsfromPA0toPA7.Thesepinsserveasanaloginputtoanalogtodigitalconverters. If analog to digital converter is not used, port A acts as an eight (8) bit bidirectionalinput/output port.

Port B consists of the pins from PB0 to PB7. This port is an 8 bit bidirectional port having aninternalpull-up resistor.

PortCconsists ofthepins from PC0to PC7. Theoutputbuffers ofport C

PortDconsistsofthepinsfromPD0toPD7.Itisalsoan8bitinput/outputporthavinganinternalpull-upresistor. All of theAVR ports areshown in figuregiven below.

4.1.2 ALCOHOLSENSOR

- MQ3 is one of the most commonly used sensors in the MQ sensor series.
- It is a Metal Oxide Semiconductor (MOS) type of sensor. Metal oxide sensors are also known as Chemiresistors, because sensing is based on the change of resistance of the sensing material when exposed to alcohol.

- So by placing it in a simple voltage divider network, alcohol concentrations can be detected. MQ3 alcohol sensor works on 5V DC and draws around 800mW. It can detect Alcohol concentrations anywhere from 25 to 500 ppm.

Fig4.1.6:MQ3 AlcoholSensor

MQ3 is a heater-driven sensor. That’s why it is enclosed in two layers of fine stainless steel mesh called an Anti-explosion network. It ensures that heater element inside the sensor will not cause an explosion, as we are sensing flammable gas (alcohol). It also provides protection for the sensor and filters out suspended particles so that only gaseous elements are able to pass inside the chamber. This is what the sensor looks like when outer mesh is removed. The starshaped structure is formed by the sensing element and six connecting legs that extend beyond the Bakelite base. Out of six, two leads (H) are responsible for heating the sensing element and are connected via a NickelChromium coil (awell known conductive alloy). The remaining four leads (A & B) responsible for output signals are connected using Platinum Wires. These wires are connected to the body of the sensing element and convey small changes in the current that passes through the sensing element. The tubular sensing element is made up of Aluminum Oxide (AL2O3) based ceramic and has a coating of Tin Dioxide (SnO2). The Tin Dioxide is the most important material being sensitive towards alcohol. However, the ceramic substrate only increases the heating efficiency and ensures that the sensor area is continuously heated to the working temperature. So, to summarize, the Nickel-Chromium coil and Aluminum Oxide based ceramic forms a Heating System; while Platinum wires and coating of Tin Dioxide forms a Sensing System.

4.1.3 PowerSupply

Every electrical and electronic device that we use in our day-to-day life will require a powersupply.Ingeneral,weuseanACsupplyof230V50Hz,butthispowerhastobechangedintotherequiredformwithrequiredvaluesorvoltagerangeforprovidingpowersupplytodifferenttypesof devices. There are various types of power electronic converters such as step-down converter,step-up converter, voltage stabilizer, AC to DC converter, DC 25 to DC converter, DC to ACconverter, and so on. For example, consider the microcontrollers that are used frequently fordevelopingmanyembeddedsystemsbasedprojectsandkitsusedinreal-timeapplications.Thesemicrocontrollersrequire a5V DC supply.

4.1.4 LCD(Liquid CrystalDisplay)

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour ormonochromepixelsarrayedinfrontofalightsourceorreflector.Eachpixelconsistsofacolumn of liquid crystal molecules suspended between two transparent electrodes, and two polarizingfilters, the axes of polarity of which are perpendicular to each other. Without the liquid crystalsbetween them, light passing through one would be blocked by the other. The liquid crystal twiststhe polarization of light entering one filter to allow it to pass through the other. A program mustinteract with the outside world using input and output devices that communicate directly with ahumanbeing.OneofthemostcommondevicesattachedtoancontrollerisanLCDdisplay.Someof the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. Thismeans 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per lineby2 lines, respectively.

Many microcontroller devices use 'smart LCD'displaysto output visual information. LCDdisplays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is evenpossibletoproduceareadoutusingthe5X7dotspluscursorofthedisplay.TheyhaveastandardASCIIsetofcharactersandmathematicalsymbols.Foran8-bitdatabus,thedisplayrequiresa +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0) For a 4-bit data bus it onlyrequiresthesupplylinesplus6extralines(RSRWD7D6D5D4).WhentheLCDdisplayisnotenabled,datalinesaretri-stateandtheydonotinterferewiththeoperationofthemicrocontroller.

Pin No	Symbol	Level	Description

Table4.1.3:LCDcommands

4.1.5 BLOOD PRESSURESENSOR

- Blood Pressure can be measured both by invasive and non-invasive methods.
- In the non-invasive method, no piercing is required and is easy to use.
- Blood Pressure Sensor is used to measure the blood pressure using the non-invasive method.
- It is similar to sphygmomanometer but instead of the mercury column, a pressure sensor is used to detect the blood pressure.

Fig4.1.12 Blood pressureSensor

Applications

- This sensor is very important for High Blood Pressure patients, as it is also available as 'at-home' solid-state Blood Pressure Monitor.
- This system is portable.
- It is easy to carry and operate and highly useful in remote areas where medical facilities are not available.
- The main sensing element of this system is the pressure sensor present in the chuff. For an accurate and reliable measurement, this pressure sensor should be carefully selected.
- Honeywell's 26 PC SMT pressure sensor is one of the examples of pressure sensors used in this system.
- This sensor is small, low-cost and can measure higher values of pressure. This sensor is used directly with the printed circuit board and can measure pressure faster and more accurately.

As the sensor provides true surface mount capability, true installation cost of this sensor is very low

ADVANTAGE:

- Being non-invasive, this Sensor is safe to use. It is easier to use and can be monitored by any individual. Instead of watching the mercury levels and calculating pressure, this sensor makes the task easier by giving results automatically.

4.1.6 WIFIESP8266 MODULE:

- IntegratedTCP/IPprotocolstack
- IntegratedTRswitch,balun,LNA,power amplifierandmatchingnetwork
- IntegratedPLLs, regulators,DCXOandpowermanagementunits
- +19.5dBmoutput power in802.11b mode
- Powerdownleakagecurrentof<10uA
- Integratedlowpower32-bitCPUcouldbeusedasapplicationprocessor
- SDIO1.1/2.0, SPI,UART
- STBC,1×1MIMO,2×1MIMO
- A-MPDU&A-MSDUaggregation&0.4msguardinterval

- Wakeupandtransmit packetsin<2ms
- Standbypower consumption of<1.0mW (DTIM3)
- Defaultbaudrate:115200

4.2 SoftwareRequirement

- Arduinosoftware
- Programminglanguage

4.2.1 Arduinosoftware:

Arduinoisanopen-sourceprototypingplatformbasedon easy-to-usehardwareandsoftware.Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twittermessage - and turn it into an output - activating a motor, turning on an LED, publishingsomething online. You can tell your board what to do by sending a set of instructions to themicrocontroller on the board. To do so you use the Arduino programming language (based onWiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino hasbeenthebrainofthousandsofprojects,fromeverydayobjectstocomplexscientificinstruments. A worldwide community of makers - students, hobbyists, artists, programmers,and professionals has gathered around this open-source platform, their contributions haveaddeduptoanincredibleamountofaccessibleknowledgethatcanbeofgreathelp tonovicesandexpertsalike.ArduinowasbornattheIvreaInteractionDesignInstituteasaneasytoolforfast prototyping, aimed at students without a background in electronics and programming. Assoon as it reached a wider community, the Arduino board started changing to adapt to newneeds and challenges, differentiating its offer from simple 8-bit boards to products for IoTapplications, wearable, 3D printing, and embedded environments. All Arduino boards arecompletelyopen-source,empoweringuserstobuildthemindependentlyandeventuallyadaptthemtotheirparticularneeds.Thesoftware,too,isopen-source,anditisgrowingthroughthecontributionsof users worldwide.

4.2.1.1 WhyArduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands ofdifferent projects and applications. The Arduino 44 software is easy-to-use for beginners, yetflexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and studentsuse it to build low-cost scientific instruments, to prove chemistry and physics principles, or to getstarted with programming and robotics. Designers and architects build interactive prototypes,musicians and artists use it for installations and to experiment with new musical instruments.Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example.Arduinoisakeytooltolearnnewthings.Anyone-children,hobbyists,artists,programmers-canstart tinkering just following the step-by-step instructions of a kit, or sharing ideas online withothermembersoftheArduinocommunity.Therearemanyothermicrocontrollersandmicrocontroller platforms available for physical computing. Parallax Basic Stamp, Net media'sBX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of thesetools take the messy details of microcontroller programming and wrap it up in an easy-to-usepackage. Arduino also simplifies the process of working with microcontrollers, but it offers someadvantageforteachers, students, and interested amateurs over other systems:

• Inexpensive - Arduino boards are relatively inexpensive compared to other microcontrollerplatforms.TheleastexpensiveversionoftheArduinomodulecanbeassembledbyhand, andeventhepre-assembled Arduino modules cost less than$50

• Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linuxoperatingsystems. Most microcontroller systemsarelimitedto Windows.

• Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use forbeginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it'sconvenientlybasedontheProcessingprogrammingenvironment,sostudentslearningtoprogramint hat environment willbefamiliar with howtheArduinoIDEworks.

• Open source and extensible software - The Arduino software is published as opensource tools,availableforextensionbyexperiencedprogrammers.ThelanguagecanbeexpandedthroughC++li braries,andpeoplewantingtounderstandthetechnicaldetailscanmaketheleapfromArduino totheAVRCprogramminglanguageonwhichit'sbased.Similarly,youcanaddAVR-Ccodedirectlyinto yourArduino programs if youwant to.

• Opensourceandextensiblehardware-
TheplansoftheArduinoboardsarepublishedunderaCreativeCommonslicense,so experiencedcircuitdesignerscanmaketheir ownversion

• Of the module, extending it and improving it. Even relatively inexperienced users can build thebreadboardversion of themodulein order tounderstand how it worksandsavemoney

• GettingStartedwithArduinoandGenuinoproducts.

• InstalltheArduinoSoftware(IDE)onWindowsPCs-

• Thisdocumentexplains howto installtheArduinoSoftware(IDE)onWindows machines.

• DownloadtheArduino Software(IDE)

• Proceedwithboardspecificinstructions.

4.2.1.2 HowtoDownload theArduinoSoftware(IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) andtheZippackages.Wesuggestyouusethefirstonethatinstallsdirectlyeverythingyouneedtousethe Arduino Software (IDE), including the drivers. With the Zip package you need to install thedrivers manually. When the download finishes, proceed with the installation and please allow thedriverinstallation process when youget a warning from theoperating system.

4.2.1.3 Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer andpreparethe board to receivethe program viaUSB cable.

Step1−FirstyoumusthaveyourArduinoboard(youcanchooseyourfavoriteboard)andaUSBcable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, orDiecimila,youwillneedastandardUSBcable(A plug toBplug),thekindyouwouldconnect toaUSB printeras shown in the following image.

Fig.4.2.1:USB CableAplug toB plug

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in thefollowingimage.

Fig.4.2.2:USB Cable Aplug to Mini-B plug

Step2−DownloadArduinoIDESoftware.

You can get different versions of Arduino IDE from the Download page on the Arduino Officialwebsite. You must select your software, 47 which is compatible with your operating system(Windows,IOS, or Linux). Afteryour filedownload is complete,unzip thefile.

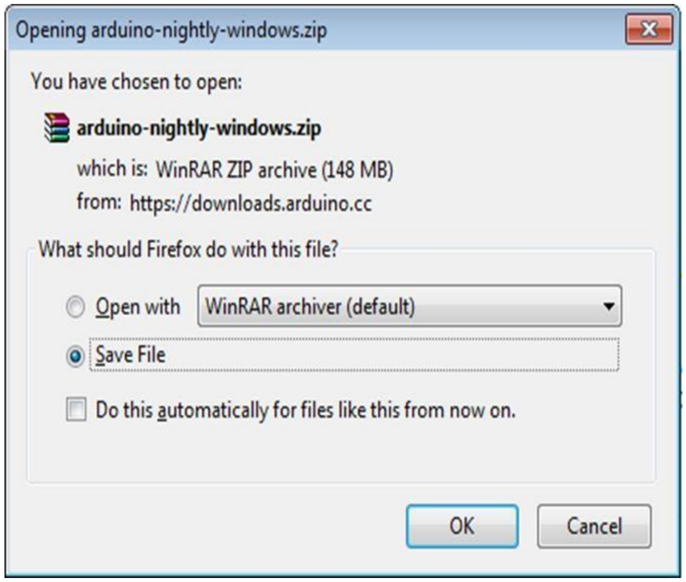

Fig.4.2.3:UnzipofArduinoIDEsoftware

Step3−Powerupyourboard.

TheArduinoUno,Mega,DuemilanoveandArduinoNanoautomaticallydrawpowerfromeither, the USB connection to the computer or an external power supply. If you are using anArduino Diecimila, you have to make sure that the board is configured to draw power from theUSB connection. The power source is selected with a jumper, a small piece of plastic that fitsonto two of the three pins between the USB and power jacks. Check that it is on the two pinsclosestto the USB port.

ConnecttheArduinoboardtoyourcomputerusingtheUSBcable.ThegreenpowerLED(labeledPWR) shouldglow.

Step4−LaunchArduinoIDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside thefolder,youcanfindtheapplicationiconwithaninfinitylabel(application.exe).Double-clicktheiconto start theIDE.

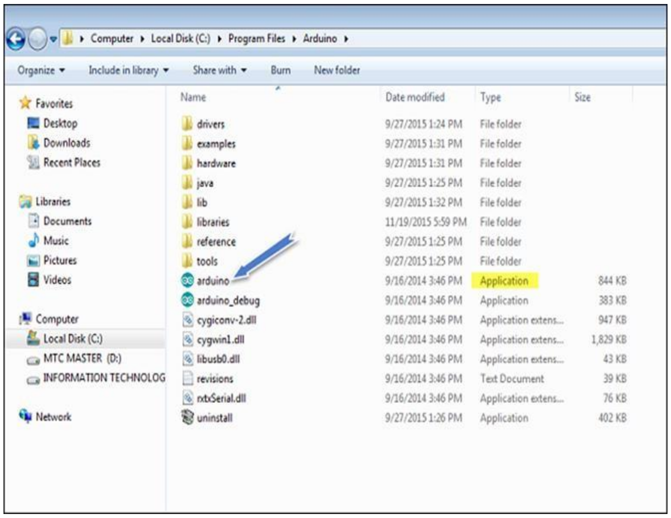

Fig.4.2.4:Open IDEsoftware

Step5−Openyourfirstproject.

Oncethe softwarestarts,you havetwo options:

• Createanewproject

.•Openanexistingprojectexample.

Tocreateanewproject,selectFile→New.

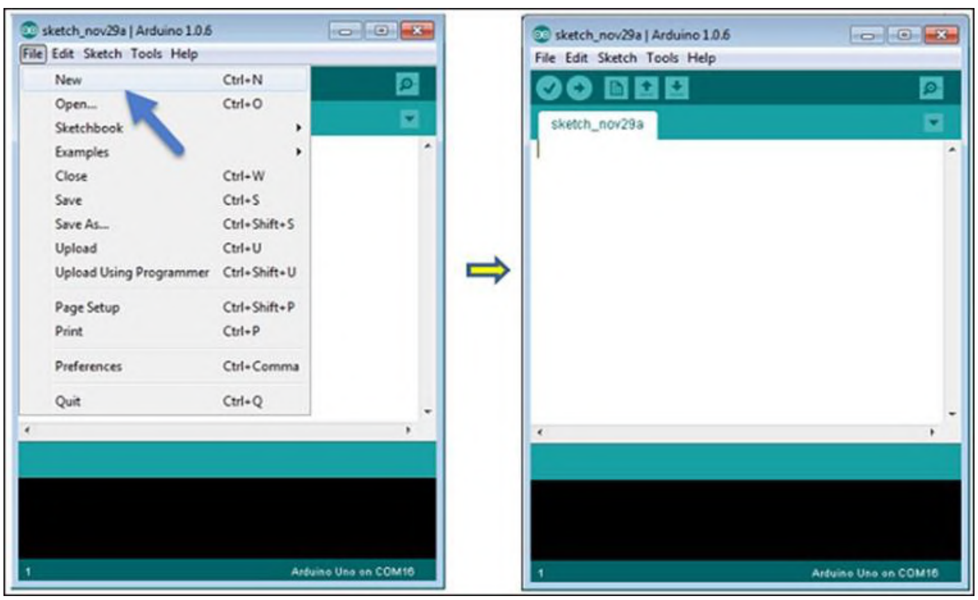

Fig.4.2.5:OpenFirstProject

Toopenanexistingprojectexample,selectFile→ Example→Basics→Blink.

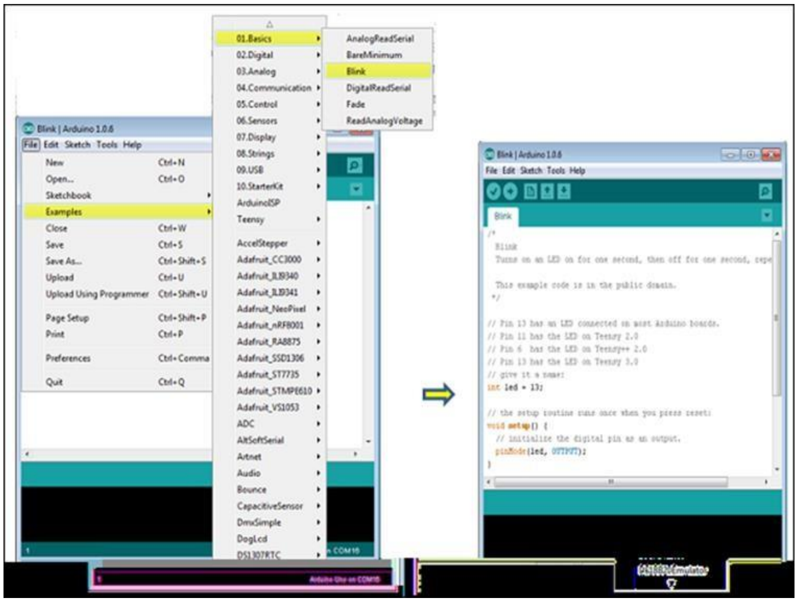

Fig.4.2.6:Openexisting Project

Here, we are selecting just one of the examples with the name Blink. It turns the LED on and offwithsome timedelay. You can selectany otherexamplefrom thelist.

Step 6 − Select your Arduino board. To avoid any error while uploading your program to theboard, you must select the correct Arduino board name, which matches with the board connectedtoyour computer. Go toTools→ Board and select your board.

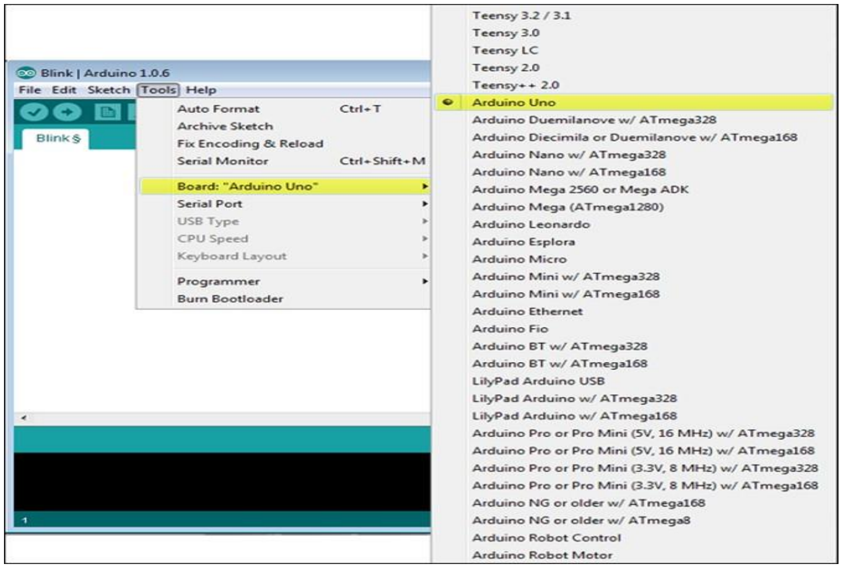

Fig.4.2.7:SelectionofArduinoboard

Here,wehaveselectedArduinoUnoboardaccordingtoourtutorial,butyoumustselectthenamematchingtheboard that youareusing.

Step 7 − Select your serial port. Select the serial device of the Arduino board. Go to Tools →SerialPortmenu.ThisislikelytobeCOM3orhigher(COM1andCOM2areusuallyreservedforhardwareserialports).Tofindout,youcandisconnectyourArduinoboardandre-openthemenu,theentrythatdisappearsshouldbeoftheArduinoboard.Reconnecttheboardandselectthatserialport.

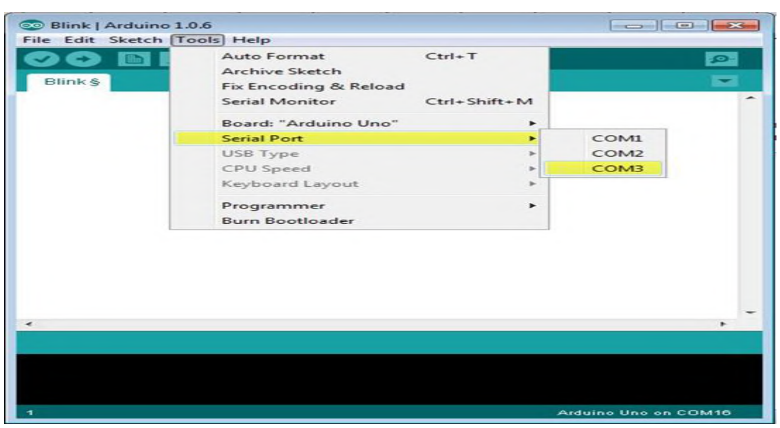

Fig.4.2.8:SelectionofSerialPort

Step8−Uploadtheprogram toyourboard.

Beforeexplaininghowwecanuploadourprogramtotheboard,wemustdemonstratethefunctionofeach symbol appearing in theArduinoIDEtoolbar.

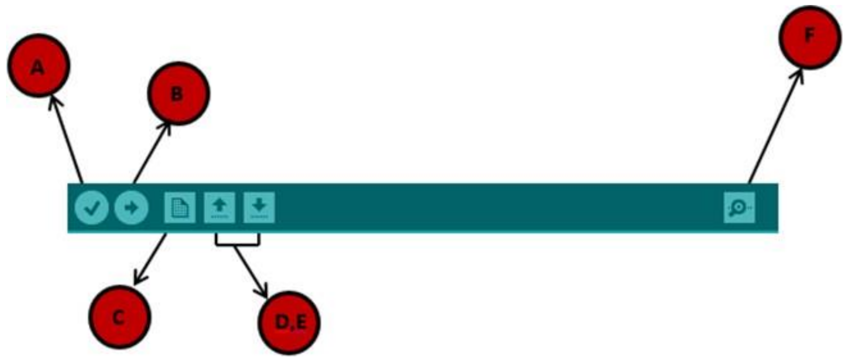

Fig.4.2.9: Uploading the program to boardA−Used to check if thereis any compilation error.

B − Used to upload a program to the Arduino board.C−Shortcut usedto create anewsketch.

D − Used to directly open one of the example sketch.E−Used to saveyoursketch.

F−Serialmonitorusedtoreceiveserialdatafromtheboardandsendtheserialdatatotheboard.Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see theRXandTXLEDsontheboard,flashing.Iftheuploadissuccessful,themessage"Doneuploading"will appear in thestatusbar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset buttonphysicallyontheboard, immediatelybeforeclickingthe uploadbuttonon theArduinoSoftware.

4.2.2 Proteus

4.2.2.1 Proteus

ProteusisasimulationanddesignsoftwaretooldevelopedbyLabcentreElectronicsforElectricaland Electronic circuit design. It also has 2D CAD drawing feature. It deserves to bear the tagline“Fromconcept to completion”.

4.2.2.2 AboutProteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is thesoftware used to draw schematics and simulate the circuits in real time. The simulation allowshuman access during run time, thus providing real time simulation. ARES is used for PCBdesigning. It has the feature of viewing output in 3D view of the designed PCB along withcomponents.Thedesigner can also develop 2D drawings forthe product.

4.2.2.3 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurementand analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring oftheparametersofthecircuit,switches,displays,loadslikemotorsandlamps,discretecomponentslike resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductorswitches,relays,microcontrollers,processors,sensorsetc.ARESoffersPCBdesigningupto14innerlayers,withsurfacemountandthroughholepackages. Itisembeddedwiththefootprints of different category of components like ICs, transistors, headers, connectors and otherdiscretecomponents.ItoffersAutoroutingandmanualroutingoptionstothePCBDesigner.Theschematicdrawn in theISIS can bedirectly transferredARES.

4.2.2.4 StartingNewDesign

Step1:OpenISISsoftwareandselect NewdesigninFilemenu

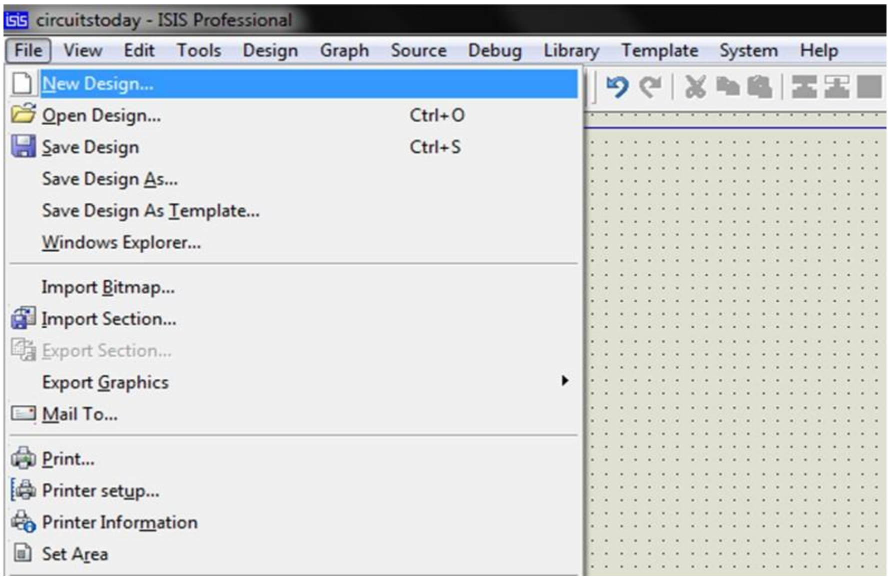

Fig.4.2.12:Proteusfilemenu

Step2: Adialogueboxappearstosavethecurrentdesign.However,wearecreatinganewdesignfile so you can click Yes or No 57 depending on the content of the present file. Then a Pop-Upappears asking to select the template. It is similar to selecting the paper size while printing. Fornow,select default or according to thelayoutsizeof thecircuit.

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better tocreateanewfolderforeverylayoutasitgeneratesotherfilessupportingyourdesign.However,itisnot mandatory.

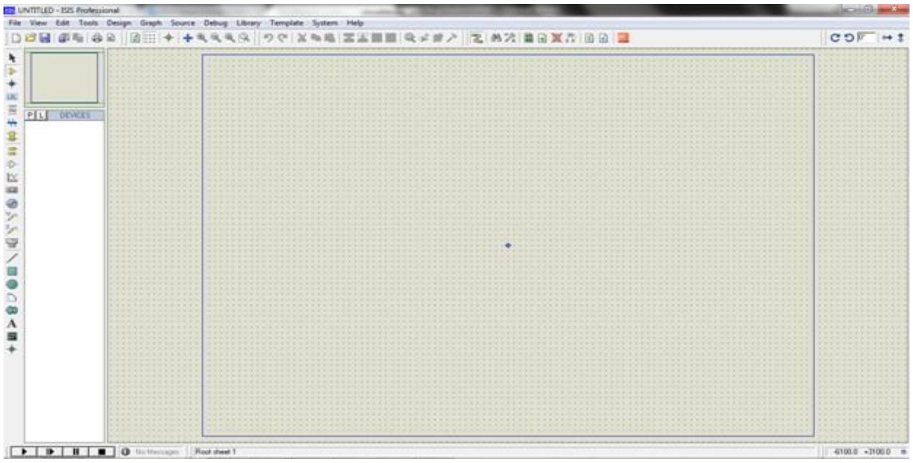

Fig.4.2.13:ProteusDesignSheet

Step4: To Selectcomponents, Clickon thecomponent modebutton.

Step5: ClickonPickfromLibraries.Itshowsthecategoriesofcomponentsavailableandasearchoptionto enter thepart name.

Step6: Selectthecomponentsfromcategories ortypethe partnamein Keywordstextbox.

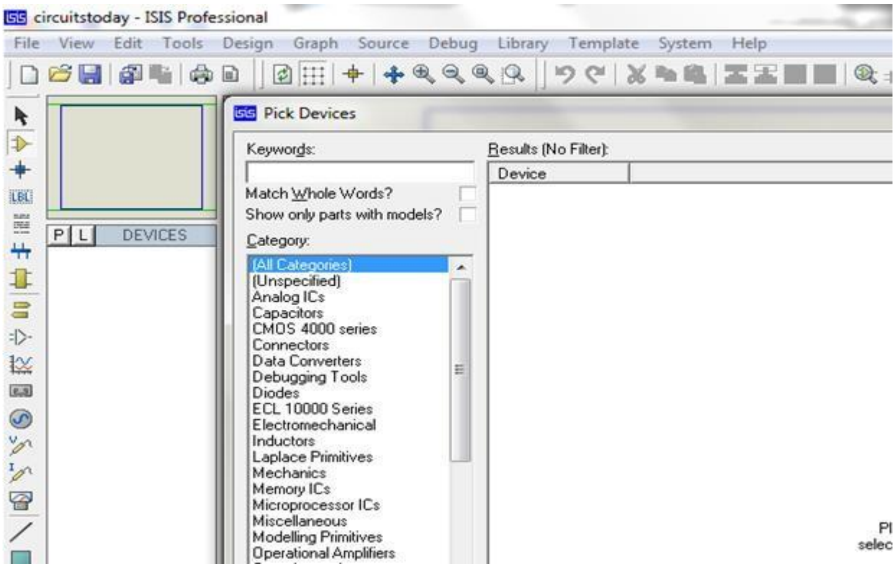

Fig.4.2.14:KeyTextbox

Step 7: The selected components will appear in the devices list. Select the component and placeitinthedesignsheetbyleft-click.Placealltherequiredcomponentsandroutethewiresi.e.,makeconnections. Either selection mode above the component mode or component mode allows toconnect through wires. Left click from one terminal to other to make connection. Double right-clickontheconnectedwireorthecomponenttoremoveconnectionorthecomponentrespectively.

Step8: After connectingthecircuit, clickonthe playbuttonto runthesimulation.

CHAPTER5

SOFTWARETESTINGANDCODEIMPLEMENTATION

5.1 SOFTWARETESTING

SoftwareTestingisaprocessofexecutingtheapplicationwithanintenttofindanysoftwarebugs.It is used to check whether the application met its expectations and all the functionalities of theapplicationisworking.Thefinalgoaloftestingistocheckwhethertheapplicationisbehavinginthewa yitissupposedtounderspecifiedconditions.Allaspectsofthecodeareexaminedtocheckthe quality of application. The primary purpose of testing is to detect software failures so thatdefects may be uncovered and corrected. The test cases are designed in such way that scope offinding thebugs is maximum.

5.2 TESTINGLEVELS

Therearevarioustestinglevelsbasedonthespecificityoftest.

- Unit testing: Unit testing refers to tests conducted on a section of code in order to verify thefunctionalityof that piece ofcode.This isdoneatthefunction level.
- Integration Testing: Integration testing is any type of software testing that seeks to verify theinterfaces between components against a software design. Its primary purpose is to expose thedefectsassociated with theinterfacing of modules.
- System Testing: System testing tests a completely integrated system to verify that the systemmeetsits requirements.
- Acceptancetesting:Acceptancetestingteststhereadinessofapplication,satisfyingallrequirements.

• Performancetesting:Performancetestingistheprocessofdeterminingthespeedoreffectiveness of a computer, network, software program or device such as response time ormillionsof instructions per secondetc.

5.3 SYSTEMTESTCASES

Atestcaseisasetoftestdata,preconditions,expectedresultsandpostconditions,developedfora test scenario to verify compliance against a specific requirement. We have designed andexecuted afew test casestocheck if theproject meetsthefunctional requirements.

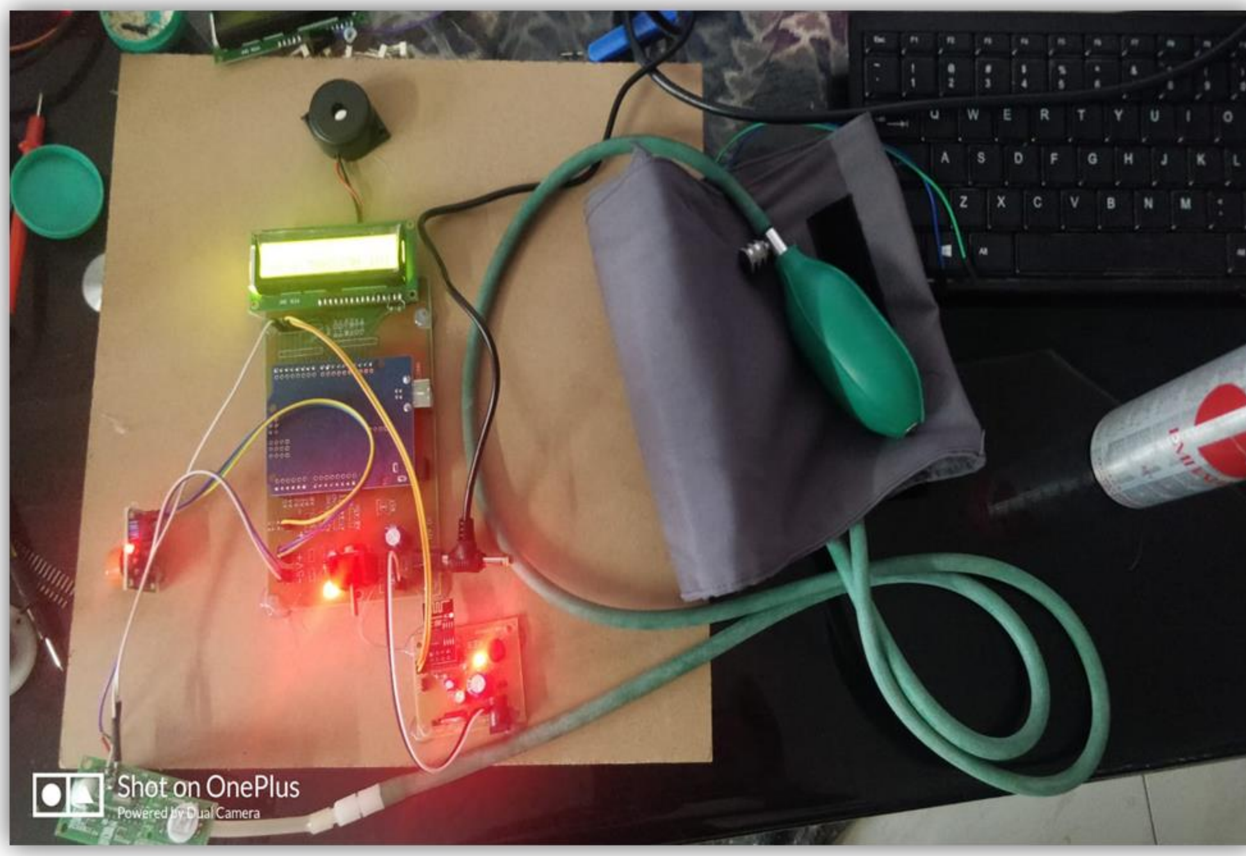

Fig 6.1:TheHardwaresetupoftheproposed system

6.1.1 Displayingnormalreadingvalues onthelcd

Gas sensor and sound sensor sense the concentration of harmful gases and level of intensity ofsound in the environment continuously and sends that information continuously to the Arduinouno. Now the Arduino uno which is brain of this project takes the information from the sensorsand transmits that values to the lcd for displaying them. The below figure represents lcd displaythat displaying normal readings of the sensors and this values are normal range of concentrationofharmful gasesand intensityofsoundthatdoesn't cause any harm tothelivingbeings.

CHAPTER7

APPLICATIONSANDADVANTAGES

7.1 APPLICATIONSOFTHEPROJECT:

- IOT Healthcare is the most demanding field in the medical area.
- This project is for elderly people in our home. Also for the senior citizen living alone or living with 1 or 2 members.
- This project really proves helpful when family members need to go out for some emergency work.
- Disable patients can use this project. Disable patients who find it really difficult to go to doctors on a daily basis or for those patients who need continuous monitoring from the doctor.

7.2 ADVANTAGESOFTHEPROJECT:

- IOT Monitoring proves really helpful when we need to monitor & record and keep track of changes in the health parameters of a person over a period of time.
- So with the IOT health monitoring, we can have the database of these changes in the health parameters. Doctors can take the reference of these changes or the history of the patient while suggesting the treatment or the medicines to the patient.
- Hospital stays are minimized due to Remote Patient Monitoring.
- Hospital visits for normal routine checkups are Minimized.

CHAPTER-8

CONCLUSIONANDFUTUREENHANCEMENT

8.1 CONCLUSION:

The system developed patient monitoring based on Internet of things, is an alternative that can be used to help patients with chronic diseases. Likewise with this set of solutions the aim is to improve the quality of life of patients, not just monitoring them, but also to enable direct them to improve their eating habits and workout routines. The context model developed for the system proved to be efficient when making inferences related to the context, such as recommendations for taking measures through sensors, as well as recommendations and workout routines tips to improve the eating habits of patients.

8.2 FUTURESCOPE:

We can add a GPS module in IOT patient monitoring using the Arduino Uno and the Wi-Fi module project. This GPS module will find out the position or the location of the patient using the longitude and latitude received. Then it will send this location to the cloud that is the IOT using the Wi-Fi module. Then doctors can find out the position of the patient in case they have to take some preventive action.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics and Communication Engineering, session 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **EXTENSIVE CAPACITY SIMULATIONS OF MASSIVE MIMO CHANNELS FOR 5G MOBILE COMMUNICATION SYSTEM** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1) Ms.S Ramya (17K81A04A7)
2) Mr.SVS Manoj Kumar (17K81A04B1)
3) Mr.S Aravind (17K81A04B2)

// ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B.Hari krishna**, **Head &Professor**, the Dept. of Electronics & Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept .project coordinator Mr.G.Upender** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

2. SVS Manoj Kumar
3 S Aravind

Abstract

In this work, an analytic extension of massive MIMO capacity for 5G mobile communication systems is firstly developed. Then, the capacity limit and multiplexing gain are investigated in simulations for different massive MIMO configurations. Furthermore, the two calculated metrics are performed as a function of SNR taking into account the transceiver impairments. On the one hand, an analytic expression of the capacity under uncorrelated Rayleigh fading channel is developed as a function of SNR and OFDM subcarriers number. On the other hand, simulation results are carried out based on the deterministic and uncorrelated fading Rayleigh channel showing that the capacity limit is up bounded by [50-57] bit/s/Hz for a multiplexing gain equal to 256. Finally, three metrics are used to characterize the massive MIMO for the uncorrelated fading channel with a multiplexing gain of (4,4), (16,16), (64,64), (128,128) and (256,256), respectively. Likewise, a trade-off is observed between the capacity limit and the tolerable SNR value for massive MIMO transmission while increasing the multiplexing gain.

Keywords—Massive MIMO, 5G, signal detection, bit error rate, computational complexity.

CHAPTER-1

INTRODUCTION

Laptops, mobile data traffic has observed an exponential growth during the past few years, and this growth is expected in next few years as well. With the increase in the number of mobile users, not only the mobile traffic has increased but every user wants higher data rate with more accuracy and reliability. This considerable amount of mobile data traffic is challenging to manage with current technologies. Future generation network called fifth generation (5G) must accommodate this huge traffic and address the current limitation of data rates reliability, and efficiency. Currently, many technologies are trying to answer all these problems in mobile communication, but none have found an optimal solution. On the top of that, these technologies must take complexity, energy efficiency, reliability into account while designing the new system. Recently, a technology called massive MIMO has been proposed, which uses hundreds or even thousands of antennas at the base station, and it can serve tens of user simultaneously [1]. These thousands of antennas focus the transmission and reception of signal onto smaller region and help the system to achieve high diversity and multiplexing gains to improve reliability and increase data rate [2]. In massive MIMO systems, a user sends pilot towards the base station and based on these pilot signals base station estimates the channel between it and the user. The base station should have knowledge of channel during both uplink and downlink as massive MIMO is a technology that is dependent upon spatial

multiplexing [3]. There are several advantages of using these systems such as high spectral efficiency, antenna array gain, high reliability, robustness to internal jamming and interference and energy efficiency. Along with these advantages, Massive MIMO comes up with certain challenges as well, and one of the major challenges that massive MIMO is facing is high computational complexity and poor bit error rate (BER) performance during received signal detection at the base station which due to the higher number of antennas at the base station and more number of users. In Massive MIMO, all the signal transmitted by the user terminals superimpose at the base station and thus interfere with each other. There are several algorithms or methods for Massive MIMO detection and non- linear detectors like sphere detector, and successive interference cancellation detector are computationally very complex. Therefore, these methods are not recommended. Linear detectors are computationally less complex than non-linear detector, but the performance is much degraded. All the conventional detection methods like Maximum Likelihood detection (ML), Minimum mean square error detection

(MMSE), Zero-forcing detection (ZF) are not very efficient in terms of performance and complexity. During detection, these linear methods include inversion of high dimensional matrices which drastically increases the complexity of the system and this complexity increases exponentially with more number of antennas. [4]. In this paper, we present a low complex and efficient algorithm for detection of Massive MIMO systems which is based upon modified Approximate Message Passing(AMP) algorithm.

Wireless data traffic had been dramatically increasing over the past few ears. None the less, the existing techniques are not satisfying with the users' needs in terms of the emergence of applications for daily routines (e.g., proximity aware services). Therefore, there is a wave of popular interest to seek for new paradigms to deal with this problem. In the coming fifth generation (5G) cellular networks, emerging technologies will lead to both disruptive architectural and component design changes.For instance ,in 5G wireless communication systems, diverse researchers study different aspects of millimeter wave transmission, which are plentiful because spectrums have become scarce at microwave frequencies. Massive multiple-input multiple-output, which could increase the system throughput is proposed to utilize a very high number of antennas. We know that 2G–3G–4G cellular networks were built under the design premise of having complete control from the infrastructure side.However, this assumption should be dropped in the 5G systems. The base-station-centric architecture of cellular systems may change, and intelligence at the device side, within different layers of protocol stack, should be exploited, for example, by allowing device-todevice (D2D) connectivity.

Device-to-device communication defined as a direct communication between two mobile users without traversing the base station or the core network is considered to be a promising technique, which also offloads the increasing data traffic into user equipments (UEs). In a traditional cellular network, it is implicitly implied that two parties willing to establish the same call will not be in close proximity to each other. Therefore, all communications must go through the base station. However, in the age of data, mobile users in today's cellular networks are potentially in range for direct communications using high data rate services. Thus, D2D communication, which can decrease latency and increase resource utilization had been proposed as a means of taking advantage of the physical proximity of communicating devices. Figure 1 shows a simple example of D2D communication. The majority of the literatures in D2D communication proposed to use the cellular spectrum for both D2D and cellular communication. Most of these previous studies have focused on issues such as resource allocation and interference mitigation. Although, few existing studies have investigated the D2D access procedure. Here we review the literatures related to device discovery and access procedure. In TR 22.803, the D2D discovery is categorized into several types, which are summarized in. In addition, the D2D discovery procedure and long-term evolution (LTE)-based design are also discussed in. Yanget al. proposed a distributed peer discovery protocol for LTE-A networks.In, they provided an overview of the new agreements in third generation partners hipproject LTE radioaccess networks related to evaluation methodology and channel modeling for D2D discovery and communications. Hong et al. proposed a D2D discovery and link setup procedure and analyzed its performance in terms of energy consumption and delay by utilizing the measurement results of real LTE smartphones. However, all of the existing works lack the overall performance analysis based on the Markov process model. In this work, we will provide the system model based on the Markov process and present the performance analysis. Moreover,we give our proposal on theVienna Matlab platform, which is a system level Matlab simulator developed by Vienna University of Technology and obtain the simulation results.

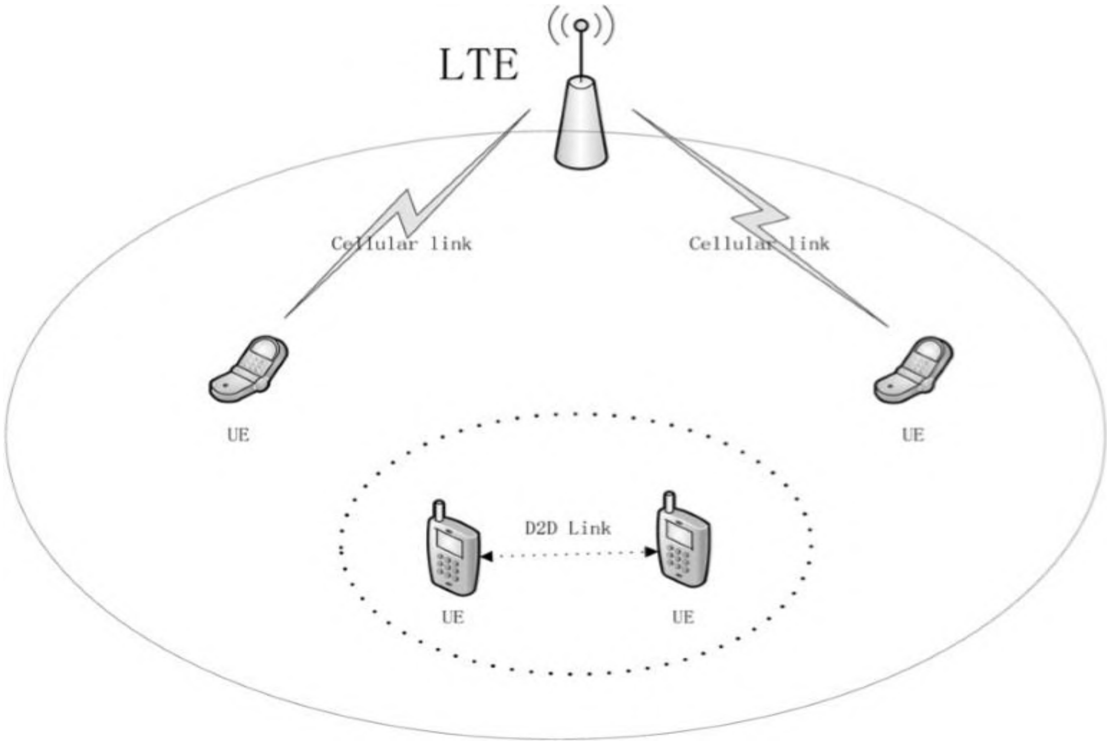

Figure 1.1. An example of device-to-device communication in a cellular network. LTE, long-term evolution.

CHAPTER-2

5G CELLUAR NETWORK

5G (from "5th Generation") is the latest generation of cellular mobile communications. It succeeds the 4G (LTE-A, WiMax), 3G (UMTS, LTE) and 2G (GSM) systems. 5G performance targets high data rate, reduced latency, energy saving, cost reduction, higher system capacity, and massive device connectivity. The first phase of 5G specifications in Release-15 will be completed by April 2019 to accommodate the early commercial deployment. The second phase in Release-16 is due to be completed by April 2020 for submission to the International Telecommunication Union (ITU) as a candidate of IMT-2020 technology.

The ITU IMT-2020 specification demands speeds up to 20 Gbit/s, achievable with wide channel bandwidths and massive MIMO. 3rd Generation Partnership Project (3GPP) is going to submit 5G NR (New Radio) as its 5G communication standard proposal. 5G NR can include lower frequencies (FR1), below 6 GHz, and higher frequencies (FR2), above 24 GHz and into the millimeter waves range. However, the speed and latency in early deployments, using 5G NR software on 4G hardware (non-standalone), are only slightly better than new 4G systems, estimated at 15% to 50% better. Simulation of standalone eMBB deployments showed improved throughput between 2.5×, in the FR1 range, and nearly 20×, in the FR2 range.

Overview

Like the earlier generation 2G, 3G, and 4G mobile networks, 5G networks are digital cellular networks, in which the service area covered by providers is divided into a mosaic of small geographical areas called *cells*. Analog signals representing sounds and images are digitized in the phone, converted by an analog to digital converter and transmitted as a stream of bits. All the 5G wireless devices in a cell communicate by radio waves with a local antenna array and low power automated transceiver (transmitter and receiver) in the cell, over frequency channels assigned by the transceiver from a common pool of frequencies, which are reused in geographically separated cells. The local antennas are connected with the telephone network and the Internet by a high bandwidth optical fiber or wireless backhaul connection. Like existing cellphones, when a user crosses from one cell to another, their mobile device is automatically "handed off" seamlessly to the antenna in the new cell.

Their major advantage is that 5G networks achieve much higher data rates than previous cellular networks, up to 10 Gbit/s; which is faster than current cable internet, and 100 times faster than the previous cellular technology, 4G LTE. Another advantage is lower network latency (faster response time), below 1 ms (millisecond), compared with 30 - 70 ms for 4G. Because of the higher data rates, 5G networks will serve not just cellphones but are also envisioned as a general home and office networking provider, competing with wired internet providers like cable. Previous cellular networks provided low data rate internet access suitable for cellphones, but a cell tower could not economically provide enough bandwidth to serve as a general internet provider for home computers.

5G networks achieve these higher data rates by using higher frequency radio waves, in or near the millimeter wave band from 30 to 300 GHz, whereas previous cellular networks used frequencies in the microwave band between 700 MHz and 3 GHz. A second lower frequency range in the microwave band, below 6 GHz, will be used by some 5G providers, but this will not have the high speeds of the new frequencies. Because of the more plentiful bandwidth at millimeter wave frequencies, 5G networks will use wider frequency channels to communicate with the wireless device, up to 400 MHz compared with 20 MHz in 4G LTE, which can transmit more data (bits) per second. OFDM (orthogonal frequency division multiplexing) modulation is used, in which multiple carrier waves are transmitted in the frequency channel, so multiple bits of information are being transferred simultaneously, in parallel.

Millimeter waves are absorbed by gases in the atmosphere and have shorter range than microwaves, therefore the cells are limited to smaller size; 5G cells will be the size of a city block, as opposed to the cells in previous cellular networks which could be many kilometers across. The waves also have trouble passing through building walls, requiring multiple antennas to cover a cell. Millimeter wave antennas are smaller than the large antennas used in previous cellular networks, only a few inches long, so instead of a cell tower 5G cells will be covered by many antennas mounted on telephone poles and buildings. Another technique used for increasing the data rate is massive MIMO (multiple-input multiple-output). Each cell will have multiple antennas communicating with the wireless device, each over a separate frequency channel, received by multiple antennas in the device, thus multiple bitstreams of data will be transmitted simultaneously, in parallel. In a technique called *beamforming* the base station computer will continuously calculate the best route for radio waves to reach each wireless device, and will organise multiple antennas to work together as phased arrays to create beams of millimeter waves to reach the device. The smaller, more numerous cells makes 5G network infrastructure more expensive to build per square kilometer of coverage than previous cellular networks. Deployment is currently limited to cities, where there will be enough users per cell to provide an adequate investment return, and there are doubts about whether this technology will ever reach rural areas.

The new 5G wireless devices also have 4G LTE capability, as the new networks use 4G for initially establishing the connection with the cell, as well as in locations where 5G access is not available.

The high data rate and low latency of 5G are envisioned as opening up new applications in the near future. One is practical virtual reality and augmented reality. Another is fast machine-to-machine interaction in the Internet of Things. For example, computers in vehicles on a road could continuously communicate with each other, and with the road, by 5G.

Performance targets

5G systems in line with IMT-2020 specifications are expected to provide enhanced device and network-level capabilities, tightly coupled with intended applications. The following eight parameters are key capabilities for IMT-2020 5G:

Capability	Description	5G target	Usage scenario
Peak data rate	Maximum achievable data rate	20 Gbit/s	eMBB
User experienced data rate	Achievable data rate across the coverage area (hotspot cases)	1 Gbit/s	eMBB
User experienced data rate	Achievable data rate across the coverage area	100 Mbit/s	eMBB
Latency	Radio network contribution to packet travel time	1 ms	URLLC
Mobility	Maximum speed for handoff and QoS requirements	500 km/h	eMBB/URLLC
Connection density	Total number of devices per unit area	10^6/km^2	MMTC
Energy efficiency	Data sent/received per unit energy consumption (by device or network)	Equal to 4G	eMBB
Spectrum efficiency	Throughput per unit wireless bandwidth and per network cell	3–4x 4G	eMBB
Area traffic capacity	Total traffic across coverage area	1000 (Mbit/s)/m^2	eMBB

Table 2.2.1 Performance Parameters of 5G network

Note that, for 5G NR, according to 3GPP specification when using spectrum below 6 GHz, the performance would be closer to 4G.

Usage scenario

ITU-R have defined three main types of usage scenario that the capability of 5G is expected to enable. They are Enhanced Mobile Broadband (eMBB), Ultra Reliable Low Latency Communications (URLLC), and Massive Machine Type Communications (mMTC).

Enhanced Mobile Broadband (eMBB)

Enhanced Mobile Broadband (eMBB) refers to the use case of using 5G as an evolution to 4G LTE mobile broadband services with faster connection with higher throughput and more capacity. 5G would need to deliver higher capacity, enhance connectivity, and higher user mobility to match these demands, which would require capabilities in the above table with eMBB mark to deliver.

Ultra Reliable Low Latency Communications (URLLC*)*

Ultra-Reliable Low-Latency Communications (URLLC) refers to the use case of using 5G in mission-critical applications such as factory automation, where uninterrupted and robust exchange of data is of the utmost importance.

Massive Machine Type Communications (mMTC)

Massive Machine-Type Communications (mMTC) refers to the wide area IoT use cases consisting of large numbers of low-cost devices with high requirements on scalability and increased battery lifetime.

Advantages

2.7.1.Speed

5G promises superior speeds in most conditions to the 4G network. Qualcomm presented a simulation at Mobile World Congress that predicts 490 Mbit/s median speeds for 3.5 GHz 5G Massive MIMO and 1.4 Gbit/s median speed for 28 GHz mmWave. 5G NR speed in sub-6 GHz bands can be slightly higher than the 4G with a similar amount of spectrum and antennas, though some 3GPP 5G networks will be slower than some advanced 4G networks, such as T-Mobile's LTE/LAA network, which achieves 500+ Mbit/s in Manhattan.

The 5G specification allows LAA (License Assisted Access) as well but it has not yet been demonstrated. Adding LAA to an existing 4G configuration can add hundreds of megabits per second to the speed, but this is an extension of 4G, not a new part of the 5G standard.

Low communication latency

Network latency is the time it takes to pass a message from sender to receiver. 5G will have much lower latency than previous cellular networks; below 1 millisecond, compared with 30 - 70 ms for 4G.

New use cases

Features of 5G network, including extreme high bandwidth, ultra low latency, and high density connections, are expected to enable many new use cases that are impossible to be done via older network standards. (See Usage scenario) 5G can also increase the effectiveness of ecommerce vendors' activities.

CHAPTER-3

Device-to-Device (D2D) communication

Device-to-Device (D2D) communication in cellular networks is defined as direct communication between two mobile users without traversing the Base Station (BS) or core network. D2D communication is generally non-transparent to the cellular network and it can occur on the cellular frequencies (i.e., inband) or unlicensed spectrum (i.e., outband).

In a traditional cellular network, all communications must go through the BS even if communicating parties are in range for proximity-based D2D communication. Communication through BS suits conventional low data rate mobile services such as voice call and text messaging in which users are seldom close enough for direct communication. However, mobile users in today's cellular networks use high data rate services (e.g., video sharing, gaming, proximity-aware social networking) in which they could potentially be in range for direct communications (i.e., D2D). Hence, D2D communications in such scenarios can greatly increase the spectral efficiency of the network. The advantages of D2D communications go beyond spectral efficiency; they can potentially improve throughput, energy efficiency, delay, and fairness.

Data delivery in non-cooperative D2D communication

Existing data delivery protocols in D2D communications mainly assume that mobile nodes willingly participate in data delivery, share their resources with each other, and follow the rules of underlying networking protocols. Nevertheless, rational nodes in real-world scenarios have strategic interactions and may act selfishly for various reasons (such as resource limitations, the lack of interest in data, or social preferences).

For example, if a node has limited battery resources or the cost of the network bandwidth delivered by mobile network operators is high, it would not willingly relay data for others until appropriate incentives are provided. Meanwhile, malicious nodes may attack the network in different ways to disturb the normal operation of the data transmission process. An adversary, for example, may drop received messages but produce forged routing metrics or false information with the aim of attracting more messages or decreasing its detection probability. This issue becomes more challenging when colluding attackers boost their metrics to deceive the attack detection systems. Dealing with non-cooperative mobile nodes is very challenging because of the distributed network model and intermittent access of nodes to central authorities.

D2D applications

D2D Communications is used for

1. Local Services: In local service, user data is directly transmitted directly between the terminals and doesn't involves network side, e.g. social media apps, which are based on proximity service.

2. Emergency communications: In case of natural disasters like hurricanes, earthquakes etc., traditional communication network may not work due to the damage caused. Ad-hoc network can be established via D2D which could be used for such communication in such situations.

3. IoT Enhancement: By combining D2D with Internet of things (IoT) , a truly interconnected wireless network will be created. Example of D2D-based IoT enhancement is vehicle-to-vehicle (V2V) communication in the Internet of Vehicles (IoV). When running at high speeds, a vehicle can warn nearby vehicles in D2D mode before it changes lanes or slows down.

CHAPTER-4

Device discovery

The players are adverting their network services and presence information through two protocols:

- Bonjour
- SSDP / UPnP (added in firmware 4.1.0 and Elementi 2018)

Elementi is using the information advertised by the players through any of these two protocols to list the players under Devices tab in Browse panel. If device discovery doesn't work for any reason, the players can be manually added into Elementi.

Both services are using multicast packets, which are restricted to the local area network where the players are located (thus the PC running Elementi must be in the same LAN), might get discarded on WiFi network (especially when crowded) and don't work over VPN connection.

Notes:

- On HMP350, HMP300 and DiVA players, both services can be disabled from Control Center > Network page, should the security policy requires that.
- Discovery across subnetworks is normally prohibited - to activate it, either enable multicast routing of SSDP on the site (applies to SpinetiX players with firmware 4.1.0 or later) or install an mDNS reflector (Avahi has this capability) on the gateway between the subnetworks.

SSDP / UPnP

- Added in firmware 4.1.0 and Elementi 2018.
- Universal Plug and Play (UPnP) is a set of networking protocols that permits networked devices, such as SpinetiX players, personal computers, printers, Internet gateways, Wi-Fi access points and mobile devices to seamlessly discover each other's presence on the network and establish functional network services for data sharing and communications. UPnP discovery protocol, known as Simple Service Discovery Protocol (SSDP), accomplishes the advertisement and discovery of network services and presence information without assistance of server-based configuration mechanisms, such as DHCP or DNS, and without special static configuration of a network host.
- SSDP / UPnP removes the dependency on Bonjour name resolution as IP addresses are used to contact players discovered via UPnP. Furthermore, HMP350, HMP300 and DiVA players show up in the Windows Explorer's Network view in Windows computers when Network Discovery is enabled.

- UPnP uses UDP port 1900 and all used TCP ports are derived from the SSDP alive and response messages.

  Bonjour

- Bonjour is Apple Inc's implementation of zero-configuration networking (zeroconf), a group of technologies that includes service discovery, address assignment, and hostname resolution. Bonjour locates devices such as SpinetiX players, printers, other computers, and the services that those devices offer on a local area network using multicast Domain Name System (mDNS) service records and DNS Service Discovery (DNS-SD).

Information advertised

- The HMP advertises the following services using Bonjour (via mDNS):

http._tcp on port 80 with name "HMP - _device name_";

- This is the standard service web browsers look for.

TXT records:

- path=/ (standard way to signify URL path)
- webdav._tcp on port 81 with name "HMP - _device name_"

This is the standard service WebDAV clients look for.

TXT records:

- path=/ (standard way to signify URL path)
- spx-hmp._tcp on port 80 with name "_device name_"

TXT records:

- txtvers=1 (standard way to support future changes)
- cport=81 (this is the content server port)
- mode= one of

normal when running normally

safe when started in safe mode

recovery when in recovery console

- serial=_serial number_ (e.g., 001d5000001a)
- firmware=_firmware version_ (e.g., 2.1.0-0.1.7844)
- model=_model_ (e.g. HMP100, HMP130 or HMP200)

spx-im._tcp on the port used by the network API (usually 1234)

This is only advertised if the network API is enabled

The device name is the name of the device as configured in Control Center.

Web browser

Discovery from a web browser is simple if a Bonjour finder is installed (native with Safari). For instance with Internet Explorer open the Bonjour tab, all the HMP devices in the local network will be listed as "HMP - _device name_".

If the Bonjour finder is not available then one can just type spx-hmp-_serial_number_.local. (e.g., spx-hmp-001d5000001a.local.) in the URL bar of the browser, this should open the device's Control Center.

Command line

If the Bonjour service is installed one can use the command line dns-sd tool to browse the local network.

To discover all HMP devices type (the device names will be listed under the Instance Name column)

```
dns-sd -B _spx-hmp._tcp
```

To look up a particular HMP device type (replace instance name by the name returned using the -B option). It will return the device address as spx-hmp-_serial_number_.local

```
dns-sd -L "instance name" _spx-hmp._tcp
```

To know the IP address of a device you can use ping like the following (it will show the IP address)

```
ping spx-hmp-_serial_number_.local.
```

CHAPTER-5

MARKOV PROCESS

A **Markov chain** is a stochastic model describing a sequence of possible events in which the probability of each event depends only on the state attained in the previous event.

In probability theory and related fields, a **Markov process**, named after the Russian mathematician Andrey Markov, is a stochastic process that satisfies the Markov property (sometimes characterized as "memorylessness"). Roughly speaking, a process satisfies the Markov property if one can make predictions for the future of the process based solely on its present state just as well as one could knowing the process's full history, hence independently from such history; i.e., conditional on the present state of the system, its future and past states are independent.

A Markov chain is a type of Markov process that has either a discrete state space or a discrete index set (often representing time), but the precise definition of a Markov chain varies. For example, it is common to define a Markov chain as a Markov process in either discrete or continuous time with a countable state space (thus regardless of the nature of time), but it is also common to define a Markov chain as having discrete time in either countable or continuous state space (thus regardless of the state space).

Markov studied Markov processes in the early 20th century, publishing his first paper on the topic in 1906. Random walks based on integers and the gambler's ruinproblem are examples of Markov processes. Some variations of these processes were studied hundreds of years earlier in the context of independent variables. Two important examples of Markov processes are the Wiener process, also known as the Brownian motion process, and the Poisson process, which are considered the most important and central stochastic processes in the theory of stochastic processes, and were discovered repeatedly and independently, both before and after 1906, in various settings. These two processes are Markov processes in continuous time, while random walks on the integers and the gambler's ruin problem are examples of Markov processes in discrete time.

Markov chains have many applications as statistical models of real-world processes, such as studying cruise control systems in motor vehicles, queues or lines of customers arriving at an airport, exchange rates of currencies, storage systems such as dams, and population growths of certain animal species. The algorithm known as PageRank, which was originally proposed for the internet search engine Google, is based on a Markov process.

Markov processes are the basis for general stochastic simulation methods known as Markov chain Monte Carlo, which are used for simulating sampling from complex probability distributions, and have found extensive application in Bayesian statistics.

The adjective **Markovian** is used to describe something that is related to a Markov process.

A Markov chain is a stochastic process with the Markov property. The term "Markov chain" refers to the sequence of random variables such a process moves through, with the Markov property defining serial dependence only between adjacent periods (as in a "chain"). It can thus be used for describing systems that follow a chain of linked events, where what happens next depends only on the current state of the system.

The system's state space and time parameter index need to be specified. The following table gives an overview of the different instances of Markov processes for different levels of state space generality and for discrete time v. continuous time:

	Countable state space	Continuous or general state space
Discrete-time	(discrete-time) Markov chain on a countable or finite state space	Harris chain (Markov chain on a general state space)
Continuous-time	Continuous-time Markov process or Markov jump process	Any continuous stochastic process with the Markov property, e.g., the Wiener process

Table 5.1 Markov processes for different levels

Note that there is no definitive agreement in the literature on the use of some of the terms that signify special cases of Markov processes. Usually the term "Markov chain" is reserved for a process with a discrete set of times, i.e., a discrete-time Markov chain (DTMC), but a few authors use the term "Markov process" to refer to a continuous-time Markov chain (CTMC) without explicit mention. In addition, there are other extensions of Markov processes that are referred to as such but do not necessarily fall within any of these four categories (see Markov model). Moreover, the time index need not necessarily be real-valued; like with the state space, there are conceivable processes that move through index sets with other mathematical constructs. Notice that the general state space continuous-time Markov chain is general to such a degree that it has no designated term.

While the time parameter is usually discrete, the state space of a Markov chain does not have any generally agreed-on restrictions: the term may refer to a process on an arbitrary state space. However, many applications of Markov chains employ finite or countably infinite state spaces, which have a more straightforward statistical analysis. Besides time-index and state-space parameters, there are many other variations, extensions and generalizations (see Variations). For simplicity, most of this article concentrates on the discrete-time, discrete state-space case, unless mentioned otherwise.

The changes of state of the system are called transitions. The probabilities associated with various state changes are called transition probabilities. The process is characterized by a state space, a transition matrix describing the probabilities of particular transitions, and an initial state (or initial distribution) across the state space. By convention, we assume all possible states and transitions have been included in the definition of the process, so there is always a next state, and the process does not terminate.

A discrete-time random process involves a system which is in a certain state at each step, with the state changing randomly between steps. The steps are often thought of as moments in time, but they can equally well refer to physical distance or any other discrete measurement. Formally, the steps are the integers or natural numbers, and the random process is a mapping of these to states. The Markov property states that the conditional probability distribution for the system at the next step (and in fact at all future steps) depends only on the current state of the system, and not additionally on the state of the system at previous steps.

Since the system changes randomly, it is generally impossible to predict with certainty the state of a Markov chain at a given point in the future. However, the statistical properties of the system's future can be predicted. In many applications, it is these statistical properties that are important.

A famous Markov chain is the so-called "drunkard's walk", a random walk on the number line where, at each step, the position may change by +1 or −1 with equal probability. From any position there are two possible transitions, to the next or previous integer. The transition probabilities depend only on the current position, not on the manner in which the position was reached. For example, the transition probabilities from 5 to 4 and 5 to 6 are both 0.5, and all other transition probabilities from 5 are 0. These probabilities are independent of whether the system was previously in 4 or 6.

Another example is the dietary habits of a creature who eats only grapes, cheese, or lettuce, and whose dietary habits conform to the following rules:

- It eats exactly once a day.
- If it ate cheese today, tomorrow it will eat lettuce or grapes with equal probability.
- If it ate grapes today, tomorrow it will eat grapes with probability 1/10, cheese with probability 4/10 and lettuce with probability 5/10.
- If it ate lettuce today, tomorrow it will eat grapes with probability 4/10 or cheese with probability 6/10. It will not eat lettuce again tomorrow.

This creature's eating habits can be modeled with a Markov chain since its choice tomorrow depends solely on what it ate today, not what it ate yesterday or any other time in the past. One statistical property that could be calculated is the expected percentage, over a long period, of the days on which the creature will eat grapes.

A series of independent events (for example, a series of coin flips) satisfies the formal definition of a Markov chain. However, the theory is usually applied only when the probability distribution of the next step depends non-trivially on the current state.

Markov property

The Markov property refers to the memoryless property of a stochastic process.

A stochastic process has the Markov property if the conditional probability distribution of future states of the process depends only upon the present state, not on the sequence of events that preceded it.

FORMAL DEFINITION

Discrete-time Markov chain

A discrete-time Markov chain is a sequence of random variables X_1, X_2, X_3, ... with the Markov property, namely that the probability of moving to the next state depends only on the present state and not on the previous states

$$\Pr(X_{n+1} = x \mid X_1 = x_1, X_2 = x_2, \ldots, X_n = x_n) = \Pr(X_{n+1} = x \mid X_n = x_n)$$
$$\Pr(X_1 = x_1, \ldots, X_n = x_n) > 0\,.$$

The possible values of X_i form a countable set S called the **state space** of the chain.

Markov chains are often described by a sequence of directed graphs, where the edges of graph n are labeled by the probabilities of going from one state at time n to the other states at time $n + 1$, $\Pr(X_{n+1} = x \mid X_n = x_n)$. The same information is represented by the transition matrix from time n to time $n + 1$. However, Markov chains are frequently assumed to be time-homogeneous (see variations below), in which case the graph and matrix are independent of n and are thus not presented as sequences.

Continuous-time Markov chain

A continuous-time Markov chain $(X_t)_{t \geq 0}$ is defined by a finite or countable state space S, a transition rate matrix Q with dimensions equal to that of the state space and initial probability distribution defined on the state space. For $i \neq j$, the elements q_{ij} are non-negative and describe the rate of the process transitions from state i to state j. The elements $q_{ii}$are chosen such that each row of the transition rate matrix sums to zero, while the row-sums of a probability transition matrix in a (discrete) Markov chain are all equal to one.

CHAPTER-6

ACCESS PROCEDURE

5G NR Initial Access Procedure between UE and gNB including beam management. All the messages exchanged between UE and gNB in 5G NR Initial Access procedure i.e. Random Access Procedure are described. It is also known as initial cell search procedure.

5G NR (New Radio) is the latest cellular wireless technology developed to deliver 10 times fast data rate compare to LTE (i.e. 4G) technology. It follows 3GPP specifications release 15 and above. In this page we will understand initial access procedure i.e. random access procedure. It helps to get the initial uplink grant for UE and helps in performing synchronization with the gNB (i.e. network). It covers Random Access procedure initialization, Random Access Resource selection, Random Access Preamble transmission, Random Access Response reception, Contention Resolution and Completion of the Random Access procedure.

6.1 Beam Management in 5G NR

Beam management procedure is used in 5G NR in order to acquire and maintain a set of TRxP (s) and/or UE beams which can be used for DL and UL transmission/reception. TRxP stands for Transmission Reception Point. Reference signals are used for beam management. In IDLE mode, 5G NR uses PSS, SSS and PBCH DMRS where as in CONNECTED mode it uses CSI-RS (in the downlink) and SRS (in the uplink).

Following operations are performed in 5G NR beam management procedure. They are applied to both the modes viz. SA (StandAlone) and NSA (Non StandAlone).

- Beam Sweeping: It refers to the covering a spatial area with a set of beams transmitted and received according to pre-specified intervals and directions.
- Beam measurement: It refers to evaluation of the quality of the received signal at the gNB or at the UE. Different metrics could be used such as RSRP, RSRQ and SINR or SNR for this purpose.
- Beam determination: It refers to the selection of the suitable beam or beams either at the gNB or at the UE, according to the measurements obtained with the beam measurement procedure.

• Beam reporting: It refers to the procedure used by the UE to send beam quality and beam decision information to the Radio Access Network (RAN).

Random Access Procedures are of two types viz. contention based and contention free. The messages exchanged in these procedures are depicted in the following figure-2.

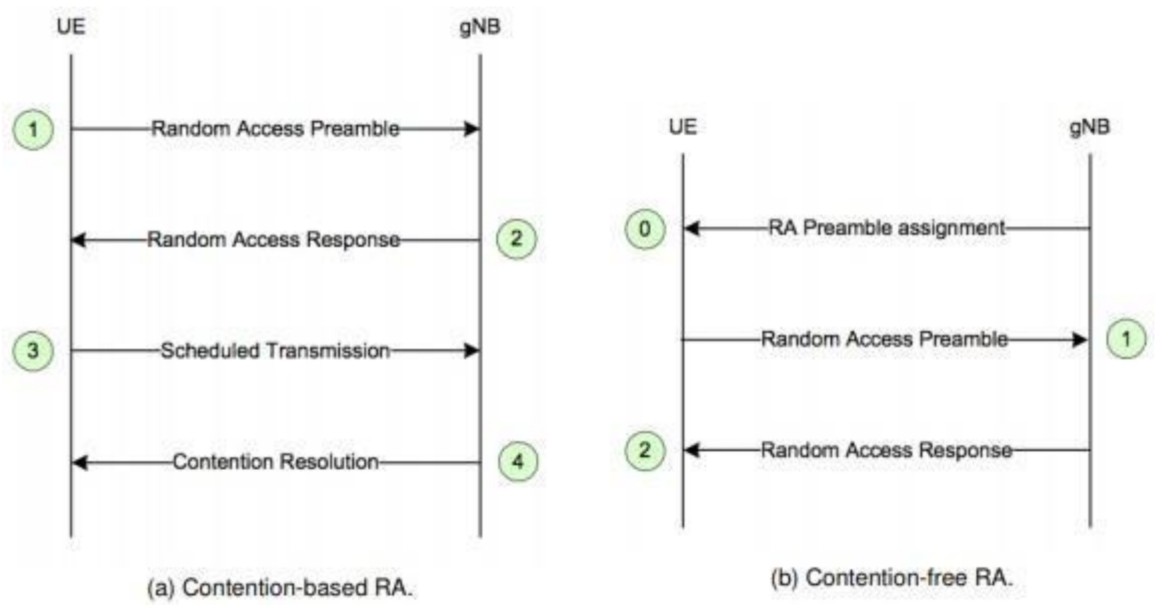

Figure 6.1.1 Random Access Procedures

Contention based RA is applied when UE is not yet synchronized or lost its synchronizaton. Contention free is appled when UE was perviously synchronized to another gNB. Both the precudures rely on transmission of random access preamble from UE to gNB. The preamble is transmitted on specific time/frequency resources which are indicated by gNB to UEs on control channels.

5G NR Initial Access Procedure between UE and gNB

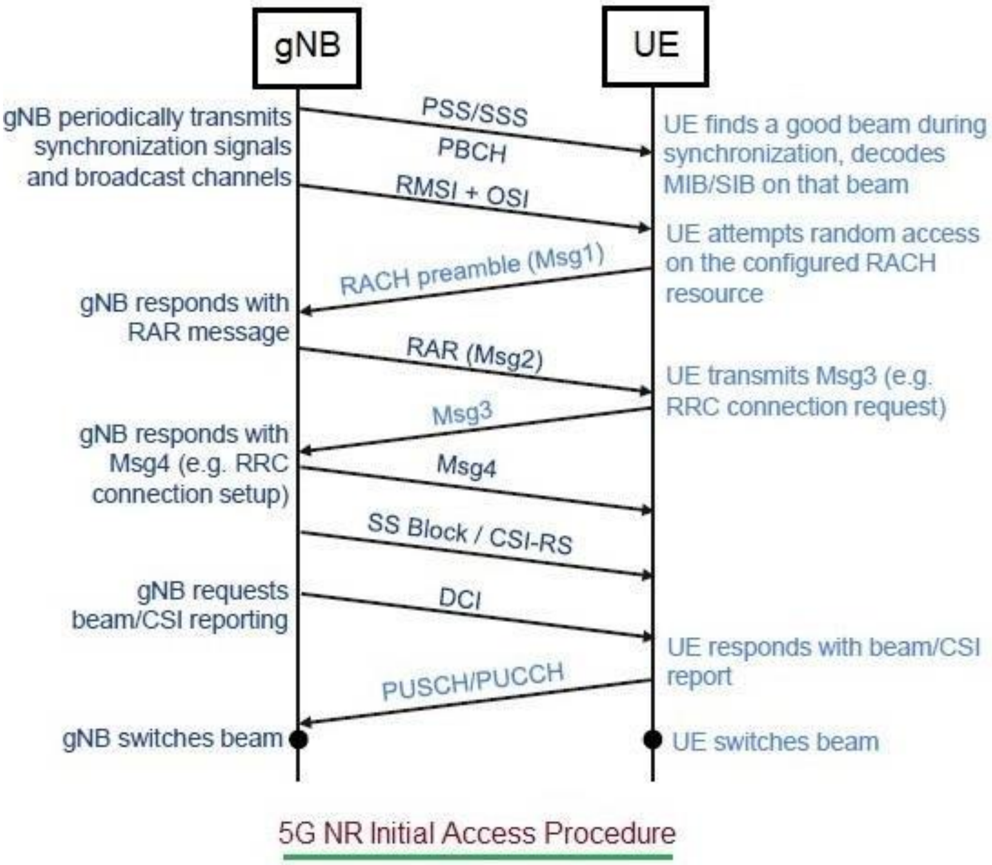

Figure 6.1.2 5G NR Initial Access Procedure

The following steps describe the messages exchanged between the UE and gNB during initial access procedure or random access procedure.

➤As shown in the figure-3, gNB (i.e. 5G NR Base Station) periodically transmits SS blocks carrying synchronization signals (PSS, SSS) and broadcast channels (PBCH) using beam sweeping. One SS block contains 1 symbol PSS, 1 symbol SS and 2 symbols PBCH. SS burst carry one or multiple SS blocks. Both PSS and SSS combination help to identify about 1008 physical-cell identities.

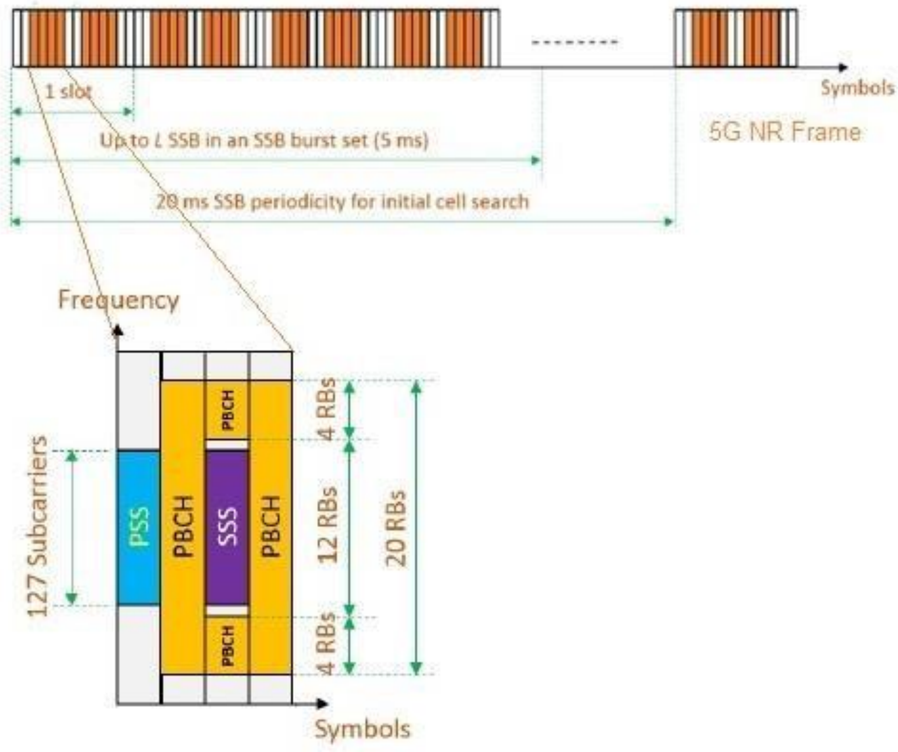

Figure 6.1.3 5G NR Frame

➤UE does beam measurements and determines best beam during sychronization. Consecutively UE decodes 5G NR system informations viz. MIB/SIB on that beam. Minimum SI (System Informations) is carried onto PBCH channel. The rest of the Remaining Minimum System Information (RMSI) is carried on PDSCH. The numerology used for RMSI is indicated in PBCH payload. CORESET is dedicated for RMSI scheduling. CORESET is not confined within PBCH Bandwidth. There is an RMSI PDCCH monitoring window associated with SS/PBCH block, which recurs periodically. OSI (Other System Information) contains on-demand the system information delivery. OSI is carried on PDSCH using same numerology as used for RMSI.

➤UE uses same beam and attempts random access by transmitting RACH preamble (i.e. Message#1) on the configured RACH resource. The gNB responds with RAR ("RA Response") message.

This is Message#2.

➤ The UE transmits Message#3 (i.e. RRC Connection Request). The gNB responds with Message#4(i.e.RRC-Connection-Setup).

➤As shown UE receives SS block and CSI-RS which it uses for generation of beam/CSI report.

➤The gNB requests beam/CSI reporting with the help of DCI (Downlink Control Information). UE responds with beam/CSI report as requested by gNB on PUSCH/PUCCH.

➤ Once the random access procedure is completed, dedicated connection is established between UE and gNB with dedicated connection ID.

➤Either gNB or UE switches beam based on SNR (Signal to Noise Ratio).

CHAPTER-7

BEAM-MANAGEMENT

Even though 3GPP would not preclude the use of Sub 6 GHz deployment of 5G(NR), at least based on the current status it seems that most of the deployment would be in very high frequency (milli meter wave) and this high frequency deployment would be one of the most important characteristics of 5G (NR).

Why we need Beam ?

Mostly by Nature of the wave (by Physics), when we use low and mid range of frequency, we can transmit a signal in all direction (as in (A)) or relatively wide angles (as in (B)). However, when we use very high frequency, we would not have much choice except using a huge antenna array. As a result of using this kind of huge antenna array, the resulting radiation would be a beam as in (C). Refer to Why Massive MIMO page for the details of this background.

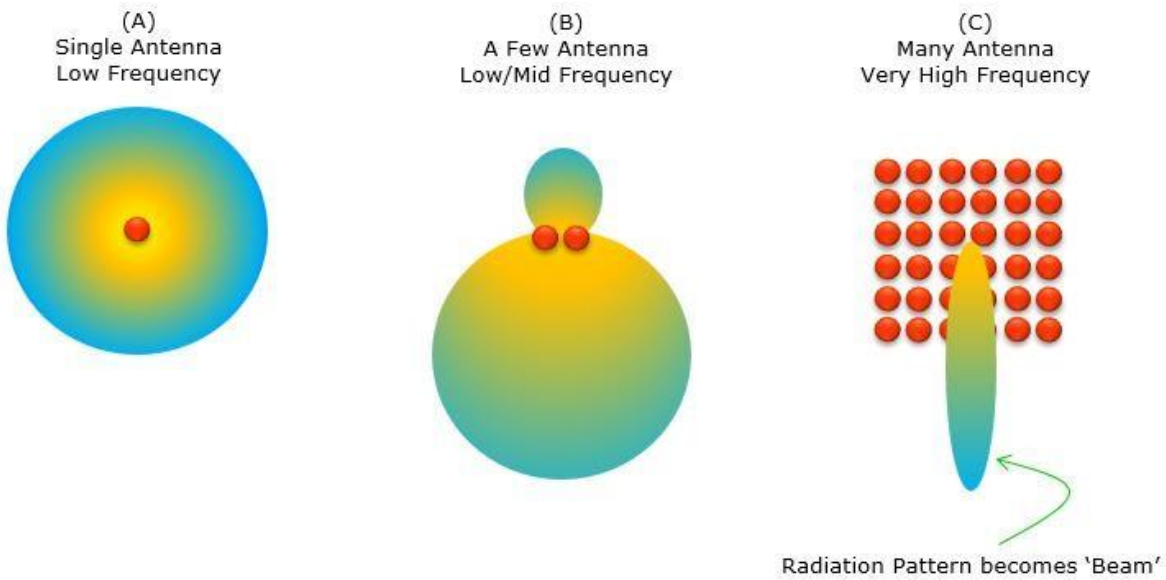

Figure 7.1 Radiation pattern of frequencies

Why Beam Management / Beam Control ?

I don't think transmitting signal in Beam in high frequency deployment would be the matter of choice. It is a kind of 'MUST' implementation. In case of low / mid frequency region without using massive antenna array (as in (A) / (B)), a single transmission would cover a lot of UEs simultaneously. However, when the radiation become beam-shaped as (C), it is very difficult to cover multiple UEs in single transmission unless those multiple UEs are located in very close proximity. To handle this problem, we need a very sophisticated idea of managing/controlling the beam to cover the multiple devices scattered in all directions and the management/control mechanism should be different depending on the situations . All of these collection of idea would fall into the title of "Beam Management" in the specification.

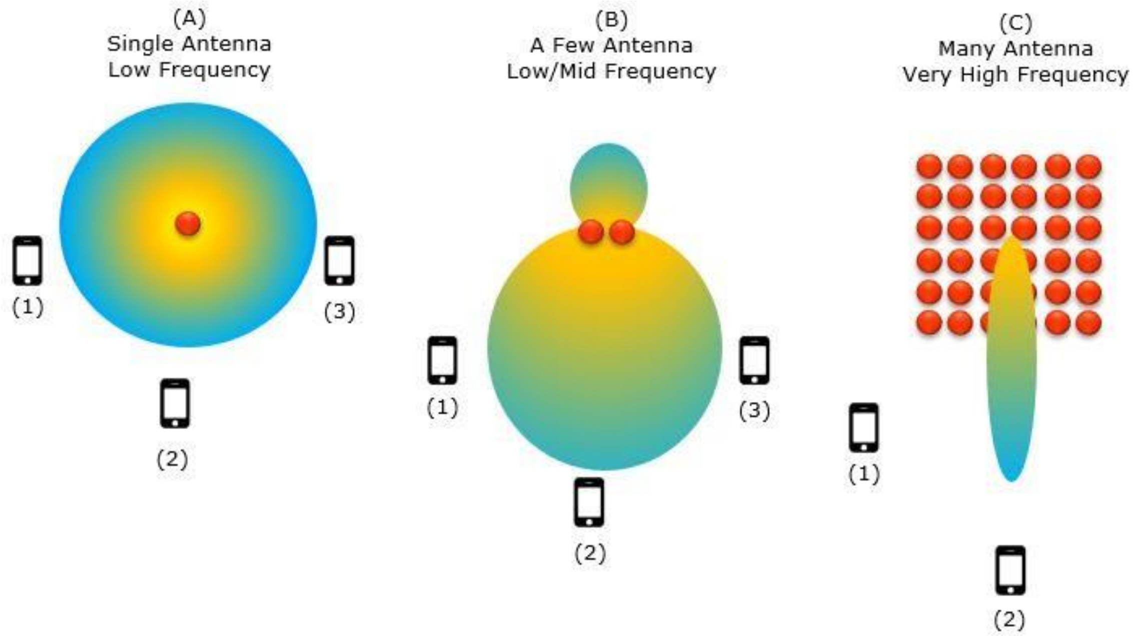

Figure 7.1.2 Beam Management/Control

Beam Management/Control for each specific situation will be described in separate pages with relavent situation (like Beam Management during Synchronization, Beam Management during Initial Attach, Beam Management in connected status etc). In thise page, I would describe on general idea.

Beam Management/Control when a transmitter has no information on the location of the reciever

Now let's look into a more specific cases where the Beam Management/Control become crucial. As an example, let's think of following case. There is a Base Station with Massive MIMO operating at the very high frequency. There is a UE around the Base Station and you are just about to turning on the UE. Once the UE is turned on, it would start Synchronization process. For this step, the Base Station would transmit the special signal called Synchronization

Signal and the signal should be able to reach to every UEs around the base station. However, here comes a serious problem with the base station sending signal in Beam. It is the fact that the signal beam can point to a very narrow area and it cannot cover a very wide area at the same time. Simply put, now you have the following question.

Figure 7.1.3 Base Station and Signal reach

What would be the answer for this ? If everything works as you draw in power point, you may draw a solution as follows. You may want to transmit a lot of beams in all direction simultaneously. Looks good ? Looks like a flower :).

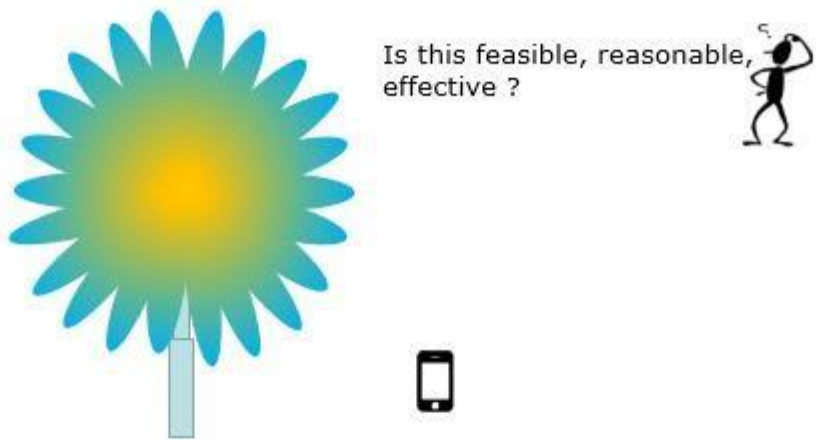

Figure 7.1.4 Beam Capability

Would the solution above be feasible, reasonable and effective ? The simple answer is NO (I would not explain why. You may easily guess why).

Then what can be another idea (possible soultion) for the problem ? There can be multiple ideas and proposals, but the most popular proposal as of now seems to be that the base station transmit the beam to a specific direction at a specific time and then change the direction a little bit in a next time frame and so on until it can scan all the area it should cover.

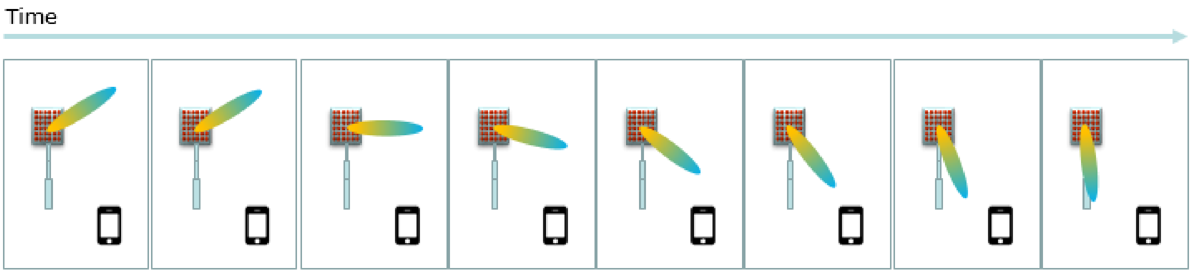

Figure 7.1.5 Beam Directions at different times

Then, the next question would be "how to reflect / implement this concept in the radio frame design ?". I would not go too much detail on this until this is explicitely determined in 3GPP TS (Technical Specification) document, but you can get the general ideas on various options /proposals from TDocs listed in Reference Section.

// Now that 3GPP Technical Specification on Beam Management has been released and I could write on this mechanism based on the formal specification. You may jump to NR Beam Management in a Nutshell section and read from there if you are interested in the formal specification.

Beam Management/Control when the connection is already established

Now let's talk about more serious case of Beam Management. In terms of 3GPP TDocs, Beam Management handles mostly with this topic (Beam Management during the connected states) and the one mentioned in previous section are described as a part of the topic Cell Search / Initial Access.

Once UE gets into a connection states with a Network, at least one beam (or multiple beam) is properly in connection between UE and the network. Theretically there can be so many different ways in which UE and Network beam is connected, but we can reduce it down to roughly four differences case as shown below.

In case 1, UE and Network is connected through a single TRP (Tx/Rx Point) and a single beam.
In case 2, UE and Network is connected through multiple TRP (Tx/Rx Point) and a single beam for each TRP.
In case 3, UE and Network is connected through a single TRP (Tx/Rx Point) and multiple beams
In case 4, UE and Network is connected through multipe TRP (Tx/Rx Point) and multiple beams for each TRP

You may think of many other cases and ask "How about this case ? How about that case ?". Whatever you think of and whatever you are asking, I think all of those would be valid thinking and valid question until 3GPP reach a explicit conclusion. So keep asking and try to find your own answers until you see the explicit 3GPP specification.

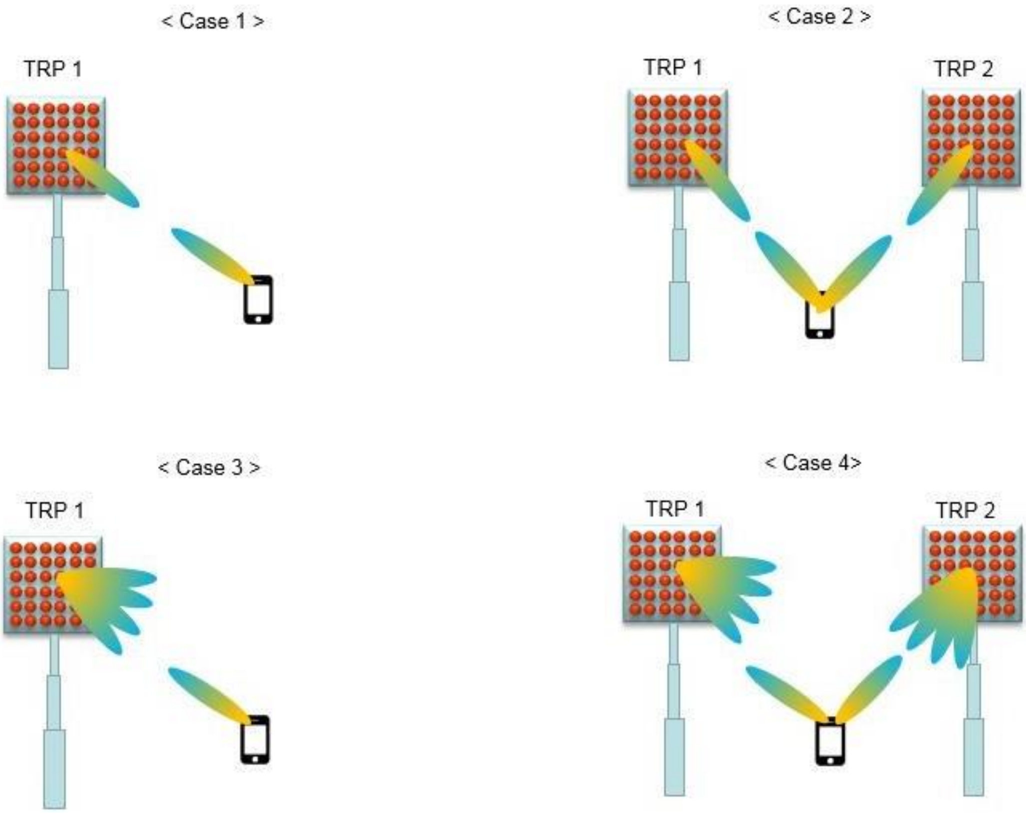

Figure 7.1.6 Beam network in different cases

Now the important and tough task is to maintain the connection. For this, I would not write much details until 3GPP specifies it in detail. Sorry for skipping too much with the execuse of

3GPP specification unavailability :). But I don't want to write many things now and rewrite too much after 3GPP Technical Specification come out. For now, my purpose is to give you very broad and general idea, and let you know what you may need to study in further details if you are really interested in technical details. For this purpose, I will list up most of TDocs about each topics in Reference section, so that you can get more detailed idea proposed by many companies / organizations in the industry.

The general idea of the beam management during the connected states would be

i) Network transmit a specific reference signal for beam management

ii) UE detect the signal and perform some measurement and send feedback to Network

As you may notice, the general idea would be very similar to CSI report mechanism that are currently used in current LTE. However, a lot of details are yet to be determined. For example,

i) Baseband Signal (Symbol) generation formula

ii) Resource Allocation mapping (How to allocate these reference symbols to which specific resource element)

iii) How often UE need to perform these measurement

iv) How UE report the measurement result ? (via RRC messages ? or via MAC / PHY layer transactions ?)

NOTE : Now that the technical specification on all of the questions listed above has been released and I wrote a few separate pages regarding this topic. Refer to CSI RS signal page and CSI Report page for further details based on 3GPP technical specification.

NR Beam Management in a Nutshell

If you ask me to explain about NR Beam Management in a few seconds, I would summarize the whole process in an illustration as shown below. As you see here, Beam Management plays important role in two period - During RACH procedure and After the call connection.

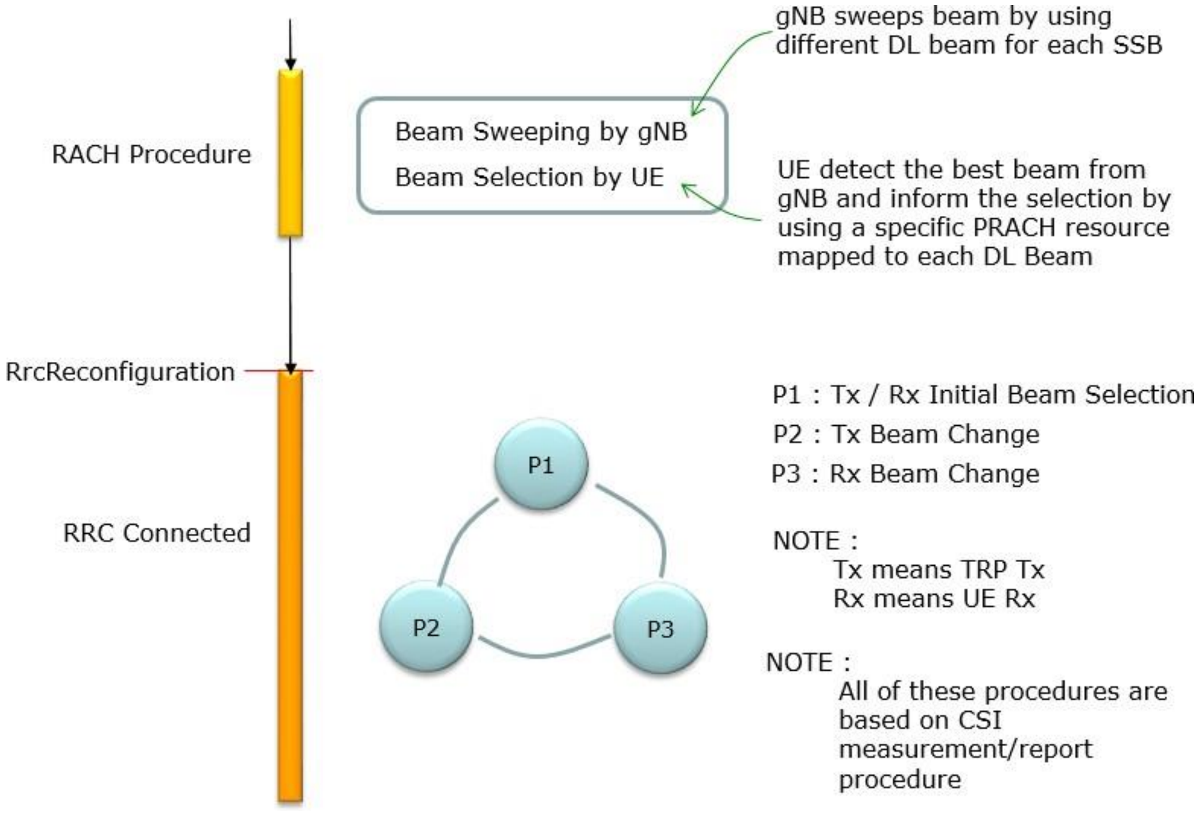

Figure 7.1.7 Beam Configuration

Where to point my beam ?

We can think of this question in terms of two different cases : transmitting case and receiving case.

When transmitting,

Now let's think of which direction a gNB or UE has to point its beam when they try to transmit the signal ?
The answer is simple. They (gNB or UE) has to transmit the signal in the direction that can reach the reciever with the best signal quality'.

Then you would have another question. How can they(gNB or UE) figure out which direction is the one that can reach the reciever with the best signal quality ?
Now the answer would be a little bit trickier, but the big picture is as follows.

- When gNB is transmitting, gNB figure out this direction by evaluating the quality of a specific reference signal of multiple beam from UE. gNB evaluate the quality of the reference signal from each of the multiple beam and chose the best one. The reference signal from UE is called SRS.
- When UE is transmitting, UE figure out this direction by evaluating the quality of a specific reference signal of multiple beam from gNB. UE evaluate the quality of the reference signal from each of the multiple beam and chose the best one. The reference signal from gNB in this case can vary depending on situation. Sometimes it can be SSB and sometimes it can be CSI-RS. (NOTE : CSI-RS play many different roles in addition to beam management and very complex topic. Refer to CSI-RS signal generation and CSI report page for further details).

  NOTE : This kind of estimation of reference signal quality should be done sometime before they transmit signal.

3GPP TR 38.802 (V14.2.0)-6.1.6.1 describes on this situation as follows :

- TRP is able to determine a TRP Tx beam for the downlink transmission based on TRP’s uplink measurement on TRP’s one or more Rx beams
- UE is able to determine a UE Tx beam for the uplink transmission based on UE’s downlink measurement on UE’s one or more Rx beams

  NOTE : TRP is a transmission point of a gNB.

When recieving,

Now let's think of which direction a gNB or UE has to point its beam when they try to recieve signal ? (In this case, the word 'beam' may be a little misleading because the reciever does not form any real beam. So it would be better to change the phrase 'to point its beam' to 'to tune its reciever to a certain direction').

The answer is simple. They (gNB or UE) has to tune their reciever in the direction in which they can receive the signal from the transmitter with best quality.

Then you would have another question. How can they(gNB or UE) figure out which direction is the one in which they can receive the signal from the transmitter with best quality ?

Overall logic is as follows :

- When gNB receiving signal from UE, (before doing this) gNB is supposed to get the information of the best direction from UE in the form of CSI report.
- When UE receiving signal from gNB, (before doing this) UE is supposed to get the information of the best direction from gNB (gNB has detected the best direction based on the measurement of SRS signal quality of multiple beams from UE and indicates the UE of the best direction).

3GPP TR 38.802 (V14.2.0)-6.1.6.1 describes on this situation as follows :

- TRP is able to determine a TRP Rx beam for the uplink reception based on UE’s downlink measurement on TRP’s one or more Tx beams.
- UE is able to determine a UE Rx beam for the downlink reception based on TRP’s indication based on uplink measurement on UE’s one or more Tx beams.

P1, P2, P3 - What is It ?

As illustrated in Beam Management in a Nutshell, P1/P2/P3 are a set of processes that are designed for beam management while in connected state.

I will talk about a high level view on these processes in this section. For further details, you would need to understand the very details on CSI report for Beam Management which is another huge topic and will be described in a separate page here.

According to 38.802-6.1.6.1, P1/P2/P3 are stated as follows.

P-1*: is used to enable UE measurement on different TRP Tx beams to support selection of TRP Tx beams/UE Rx beam(s). For beamforming at TRP, it typically includes a intra/inter-TRP Tx beam sweep from a set of different beams. For beamforming at UE, it typically includes a UE Rx beam sweep from a set of different beams.*

Does this make sense to you ? It may take time to get clear understanding on this. Following illustration is my understanding/interpretation of this statement.

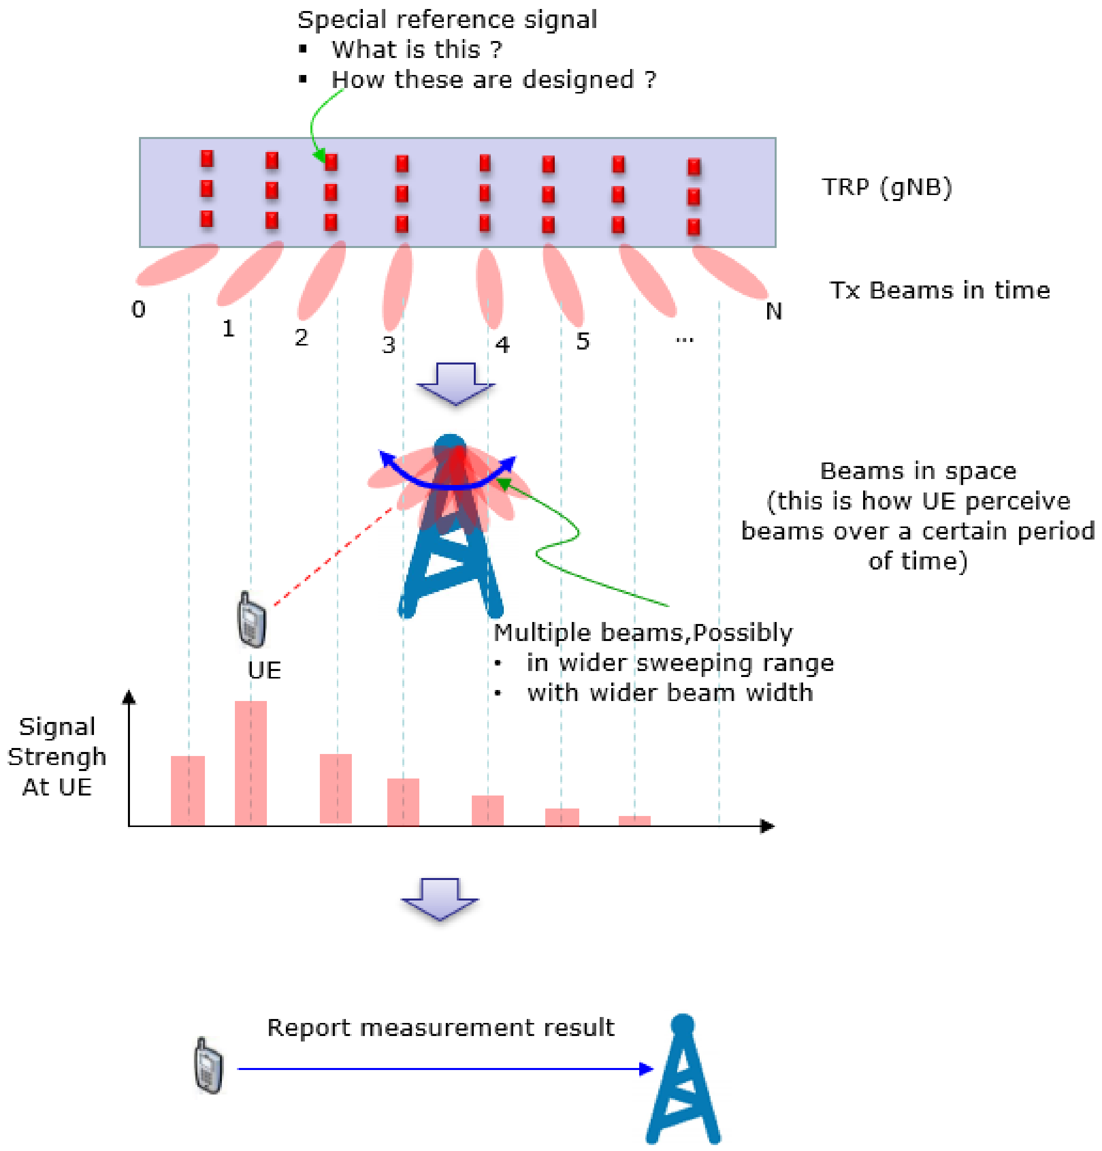

Figure 7.1.8 Beam Process 1

P-2: *is used to enable UE measurement on different TRP Tx beams to possibly change inter/intra-TRP Tx beam(s). From a possibly smaller set of beams for beam refinement than in P-1. Note that P-2 can be a special case of P-1.*

Following is my understanding on this process in illustration.

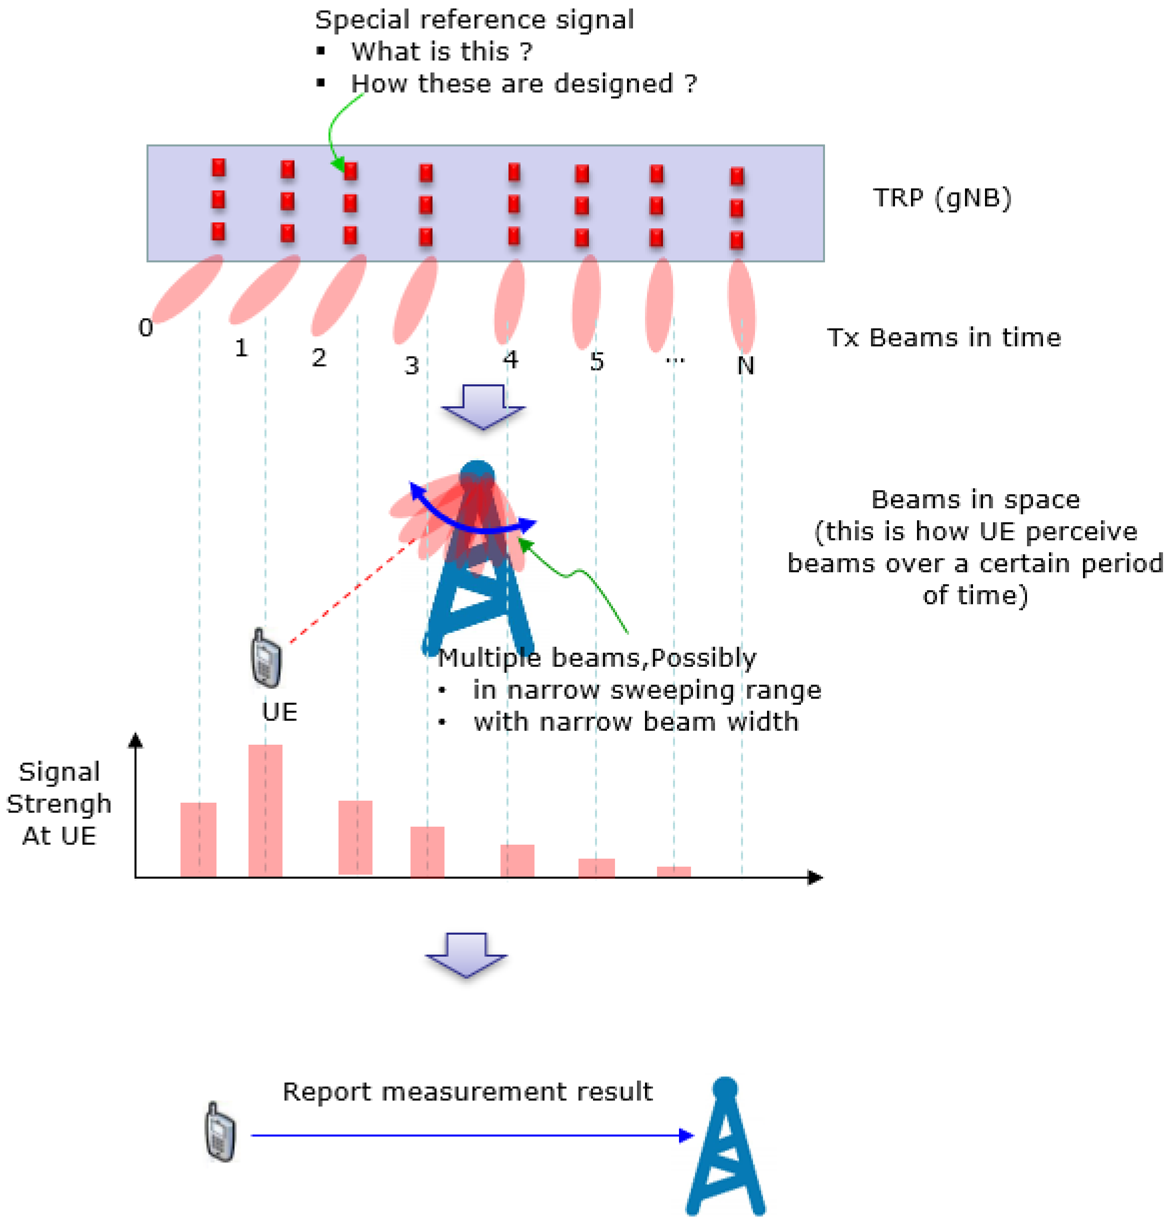

Figure 7.1.9 Beam Process 2

P-3*: is used to enable UE measurement on the same TRP Tx beam to change UE Rx beam in the case UE uses beamforming*

Following is my understanding on this process in illustration.

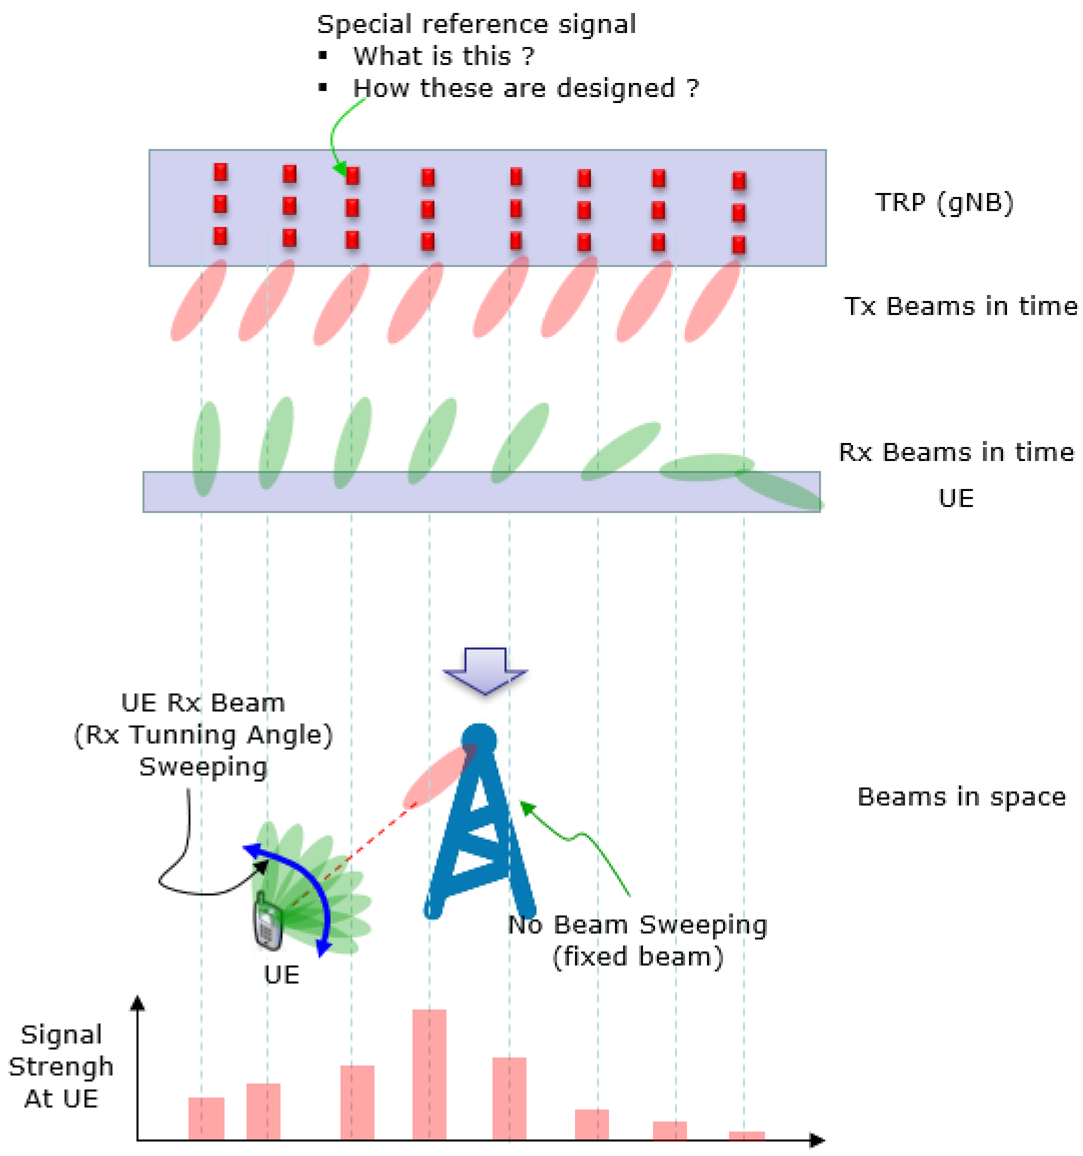

Figure 7.2.1 Beam Process 1

CHAPTER-8

SOFTWARE USED

Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation.

- Typical uses include
- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN. The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation. MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment:**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files. Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based Mfunction is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed. To launch GUIDE from the MATLAB command window, type guide filename Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.

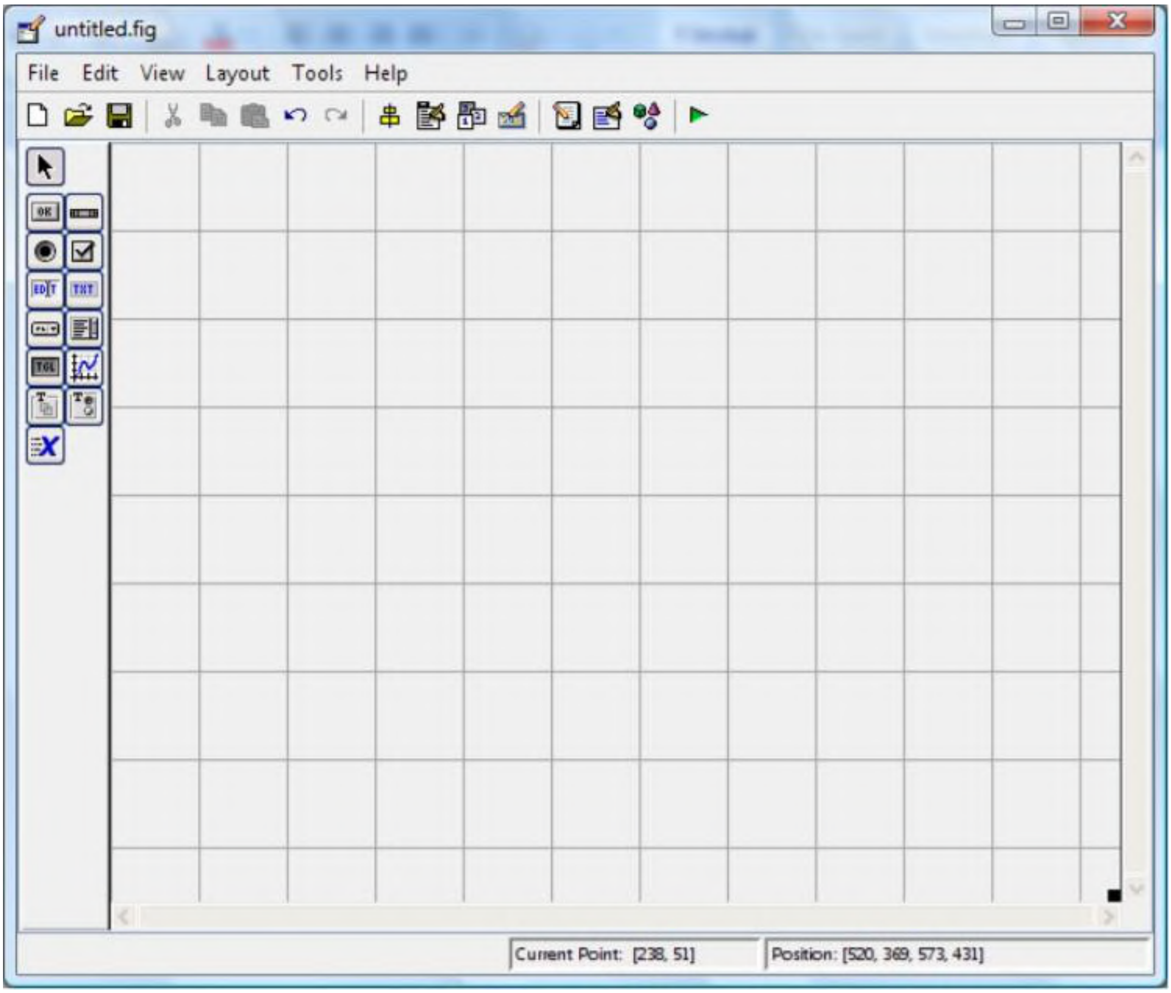

Figure 8.3.1 matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed. GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Getting Started:

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos. At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

2.4.1 Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

DEVELOPMENT ENVIRONMENT

8.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop. You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools.

The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go. Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system.

Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session.

To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic textediting, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint

CHAPTER-9

SYSTEM MODEL

The massive MIMO architecture is composed of a transmitter, a matrix channel and a receiver as shown in Fig.1. On the one hand, the transmitter design includes a pre-coder with closed-loop MIMO system, cooperative beamforming schema (i.e., in low SNR case, the best strategy is to use the largest eigen-mode only) and time-reversal for frequency channel.

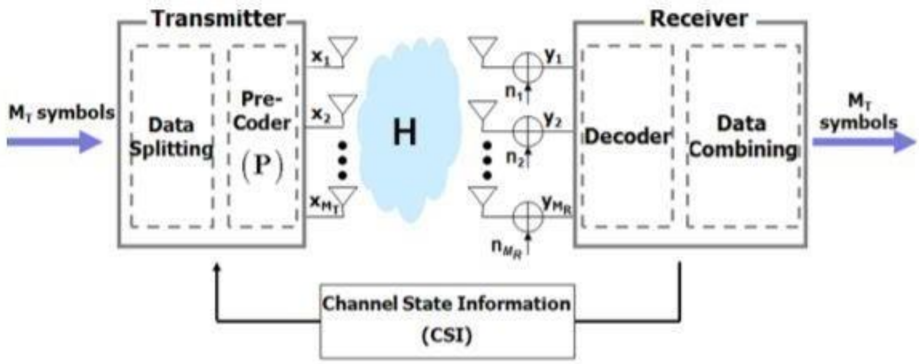

Figure 9.1.1. Massive MIMO architecture.

On the other hand, receiver design involves a decoder and a data combining sub-component. In addition, channel state information (CSI) knowledge can enhance the MIMO system spectral efficiency and reduce potentially the receiver complexity [20]. In the state-of-the-art, there are three different kind of situations concerning the quantity and quality of the CSI available at the transmitter side can be identified: i) No CSI: the transmitter does not have any knowledge of any parameter concerning the channel or the interferences at the receiver. In this case, a reasonable transmitter strategy consists in utilizing space-time codes; ii) Perfect CSI: the transmitter has full knowledge of the instantaneous channel realization and, possibly, of the interferences statistics at the receiver. In this case, since complete information is available, there are many possible strategies and optimization criteria to carry out the design depending on the detection method at the receiver or on the performance metric; iii) Imperfect CSI: the transmitter has inaccurate knowledge about the parameters describing the channel. For example, the transmitter may be informed of an erroneous channel ( ). For the case of imperfect CSI, two main strategies can be considered, either the transmitter is designed to attain the maximum performance level for the worst possible situation of the channel among the ones that are compatible with the CSI (i.e., maximin or worst-case approach) or the transmitter is designed to have the best mean performance averaged over the unknown parameters of the CSI (statistical or Bayesian approach) . In this paper, we consider the case of an imperfect CSI.

As depicted in Fig. 2, the generalized MIMO channel can be expressed by

$$y = \sqrt{SNR}\, H(x - \eta_t) + n \qquad (1)$$

where SNR, H, x,ηt and n are the signal-to-noise-ratio, MIMO matrix channel, the mismatch between the intended signal x and the signal radiated by the transmitter and circularsymmetric complex Gaussian noise, respectively.

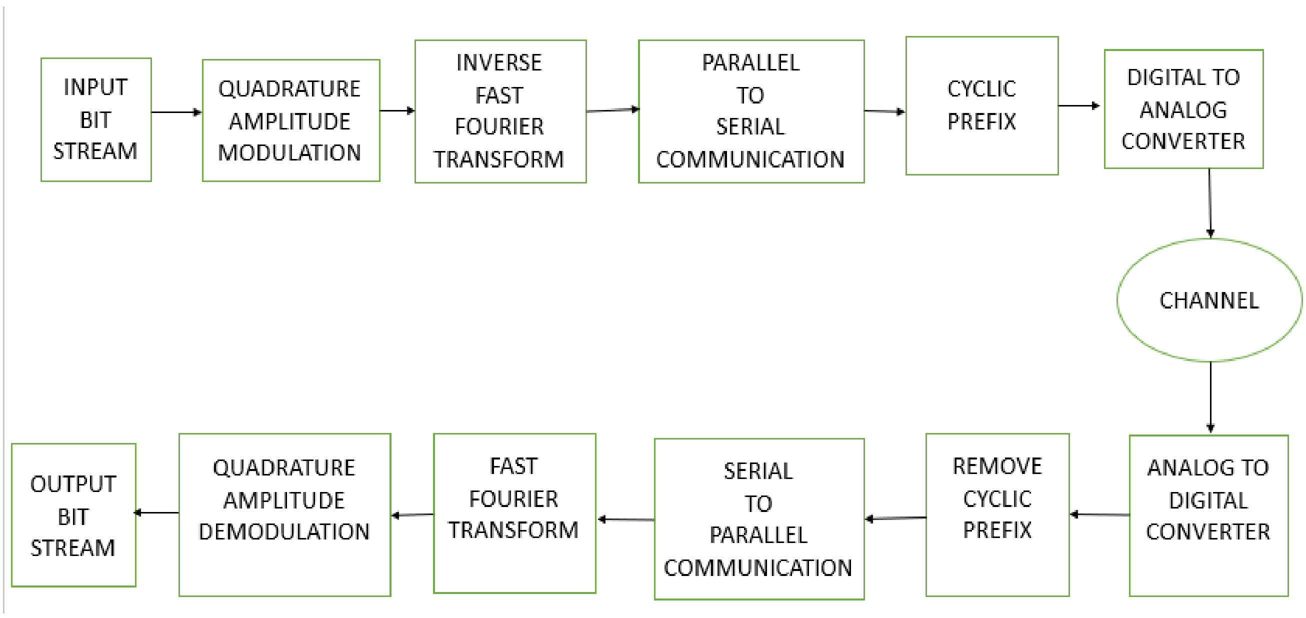

Figure 9.1.2 Block Diagram for Massive MIMO channel.

CHAPTER 10

ACCESS PROCEDURE MODELING AND PERFORMANCE ANALYSIS

Device-to-device communication is a promising technology that reuses the cellular spectrum effectively and improves network throughput significantly; thus, the users whom intend to initiate D2D communication would have higher priority than cellular users. In cellular networks, the core networks set the fixed maximum back-off time for the cellular users. However, in our proposal, we utilized the binary exponential back-off algorithm for the D2D users and defined the minimum contending window .(CW_{min})as 1. In order to ensure the priority of the D2D UE, we assumed that the allowable maximum collision times is smaller than that defined in the LTE-Advance specification. Moreover, the selection of the binary back-off algorithm simplified the design of the device because it just made few modifications based on the 801.11 model. In this paper, we denote p as the collision probability for the D2D users' access, m as the maximum number of collisions, and W_0 as the equivalent representation of CW_{min}. The binary back-off procedure can be considered as the two dimensional discrete time Markov process {s(t),b(t)} s(t) is the collision times counter and s(t) ϵ(0,m),m ϵ Z^+_0.b(t) is the back-off times for the UE, b(t) ϵ[0,Wi-1],Wi =2^i, and i ϵ [0,m]. The state transition diagram is illustrated in Figure 4.

As Figure 4 indicates, the one step of transition probability could be written as

$$P\{i, k-1 | i, k\} = 1, k \in [0, W_i - 1], i \in [0, m] \quad (2)$$

$$P\{0, k | i, 0\} = \frac{1-p}{W_0}, k \in [0, W_0 - 1], i \in [0, m] \quad (3)$$

$$P\{i, k | i-1, 0\} = \frac{p}{W_i}, k \in [0, W_i - 1], i \in [1, m] \quad (4)$$

$$P\{m, k | m, 0\} = \frac{p}{W_m}, k \in [0, W_m - 1] \quad (5)$$

Equation (2) indicates that the probability of reducing k to k -1 is 1, at the beginning of every time slot. Equation (3) calculated the probability that, after transmitting a frame successfully, the UE's status is transferred

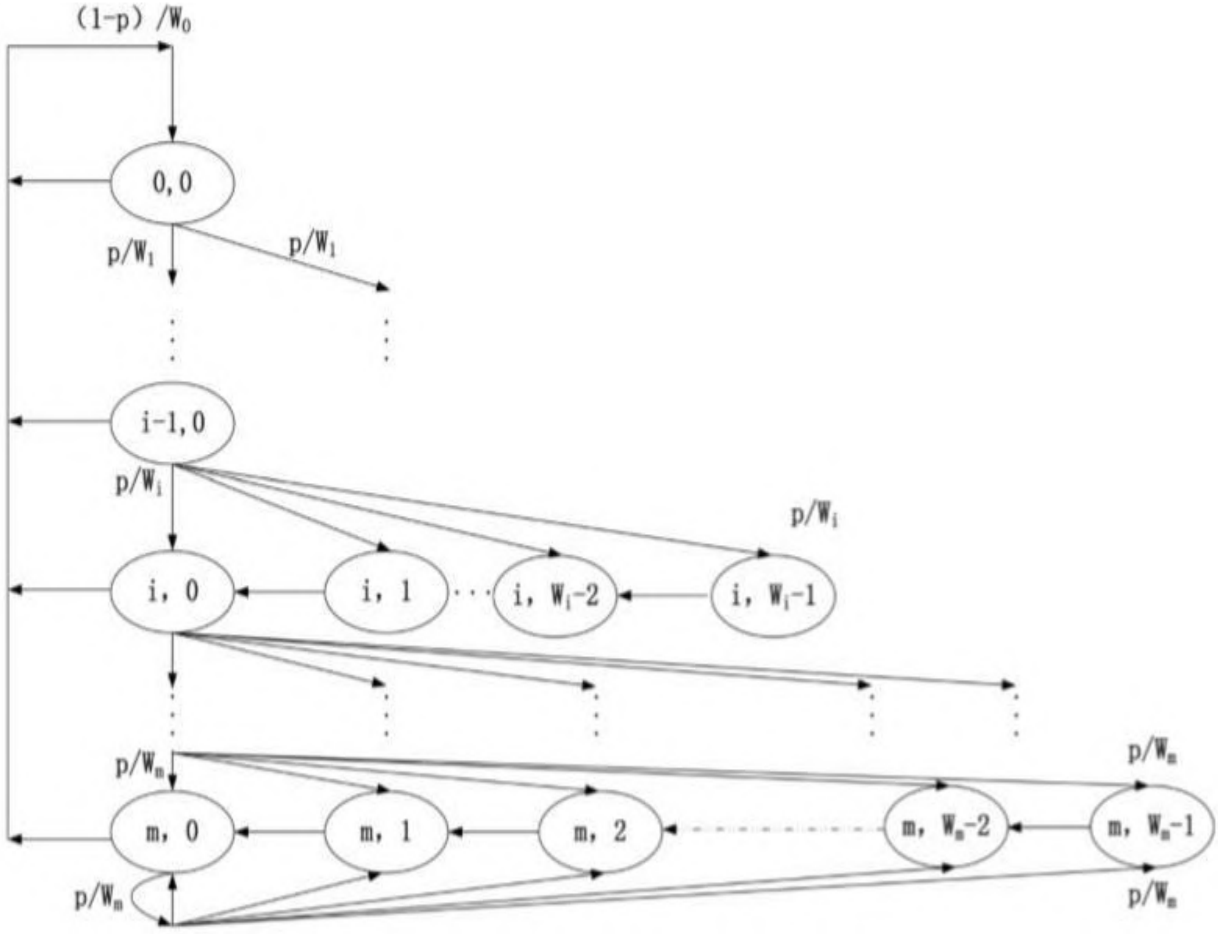

Figure 4. A state transition diagram of Markov process{s(t),b(t)}.

from (i,0) to (0,k). Similarly, Equation (4) is the probability of UE's status transferring from (i-1,0) to (i,k) after failing to transmit a frame. The probability of UE's status from (m,0) to (m,k) is expressed in Equation (5) when the allowable collision times reached the maximum value m. We assume $b_{i,k}$, presented as Equation (6) is the stationary distribution of the Markov process. According to Figure 4, we can have Equations (7) and (8). From Figure 4, we can observe that(bm,0)contains two parts of transition probability, one is from (b_{m-1},0) to(b_m,0) and the other is from (b_m,0)to (b_m,0).

$$b_{i,k} = \lim_{t\to\infty} P\{s(t) = i, b(t) = k\},$$
$$i \in [0, m], k \in [0, W_i - 1] \tag{6}$$

$$b_{i-1,0} \times p = b_{i,0} \Rightarrow b_{i,0} = p^i \times b_{0,0}, i \in [1, m] \tag{7}$$

$$\begin{aligned} &pb_{m-1,0} + pb_{m,0} = b_{m,0} \Rightarrow \\ &\quad pb_{m-1,0} = (1-p)b_{m,0} = p^m \times b_{0,0} \Rightarrow \\ &\quad b_{m,0} = \frac{p^m \times b_{0,0}}{1-p} \end{aligned} \tag{8}$$

According to the stationary distribution theorem, we can obtain (bi,k) from the following:

$$b_{i,k} = \frac{W_i - k}{W_i} \times \begin{cases} (1-p)\sum_{j=0}^{m} b_{j,0} & i = 0 \\ p \times b_{i-1,0} & 0 < i < m \\ p \times (b_{m-1,0} + b_{m,0}) & i = m \end{cases} \tag{9}$$

Because $\sum_{j=0}^{m} b_{j,0} = \frac{b_{0,0}}{1-p}$, Equation (9) can be rewritten as

$$b_{i,k} = \frac{W_i - k}{W_i} \times b_{i,0}; i \in [0, m]; k \in [0, W_i - 1] \tag{10}$$

In addition, the summation of each stationary distribution is 1; thus, we can have

$$
\begin{aligned}
1 &= \sum_{i=0}^{m} \sum_{k=0}^{W_i-1} b_{i,k} \\
&= \sum_{i=0}^{m} b_{i,0} \sum_{k=0}^{W_i-1} \frac{W_i - k}{W_i} = \sum_{i=0}^{m} b_{i,0} \times \frac{W_i + 1}{2} \qquad (11) \\
&\times \frac{b_{0,0}}{2} \left[\left(\sum_{i=0}^{m-1} (2p)^i + \frac{(2p)^m}{1-p} \right) + \frac{1}{1-p} \right]
\end{aligned}
$$

Transforming Equation (11) to another expression form, we can obtain $b_{0,0}$ as

$$
b_{0,0} = \frac{2(1-2p)(1-p)}{(1-2p)(\mathrm{CW}_{\min}+1) + \mathrm{pCW}_{\min}(1-(2p)^m)} \qquad (12)
$$

Here, we define τ as the transmitting probability, which results in

$$
\begin{aligned}
\tau &= \sum_{i=0}^{m} b_{i,0} = \frac{b_{0,0}}{1-p} \\
&= \frac{2(1-2p)(1-p)}{(1-2p)(\mathrm{CW}_{\min}+1) + \mathrm{pCW}_{\min}(1-(2p)^m)}
\end{aligned} \qquad (13)
$$

We assume that the procedure of D2D users' access satisfies Poisson distribution; thus, the probability of k D2D UEs simultaneously initiating access requests at every access slot is expressed as

$$
p_k = \frac{(\lambda/N)^k}{k!} e^{-(\lambda/N)}, \lambda > 0, k = 0, 1, 2 \ldots \qquad (14)
$$

In Equation (14), λ is the intensity of users asking for simultaneous access and N is the number of preambles. The access collision probability can be given as

$$\begin{aligned} p = p_c &= 1 - p_k(0) - p_k(1) \\ &= 1 - (1 + (\lambda/N))e^{-(\lambda/N)} \end{aligned} \tag{15}$$

Substituting Equation (15) into (13), we can obtain

$$\tau = \frac{2(1-2p_c)}{(1-2p_c)(\mathrm{CW_{min}}+1) + \mathrm{p_c CW_{min}}(1-(2p_c)^m)} \tag{16}$$

Thus, we have

$$p_c\tau(2p_c)^m - 4p_c + 3p_c\tau - 2\tau + 2 = 0 \tag{17}$$

When a large number of UEs start to access simultaneously, we know that frequent collision will occur. In this paper, we propose the control scheme to ensure the acceptable access probability , which is expressed as

$$\alpha\tau(t) + (1-\alpha)\tau(1-t) \geq \rho \tag{18}$$

where αis the weighted factor, τ(t), and τ(t-1) is the user's access probability at t and t -1 time slot and ρ is the access threshold. Based on this constraint, we could obtain the controllable access probability denoted by P_{ctrl}, as expressed in Equation (19), which can adjust the user's access probability in the next time slot if Equation (18) is not satisfied. Otherwise, P_{ctrl}=1.

$$P_{\mathrm{ctrl}} = \frac{\alpha\tau(t) + (1-\alpha)\tau(t-1)}{\rho} \tag{19}$$

CHAPTER-12
CONCLUSION

In this paper, an investigation of the massive MIMO system model was presented for both deterministic and uncorrelated Rayleigh fading channels in the context of 5G mobile communications systems. An extension of analytic capacity expression was demonstrated for the uncorrelated Rayleigh fading channels taking into account SNR and subcarrier number. Moreover, two metrics are used in simulation to characterize massive MIMO; average finite SNR multiplexing gain and average capacity. It was demonstrated also that there's saturation of the massive MIMO system under the high SNR region and the finite capacity limit is independent of the channel distribution. Additionally, the massive MIMO capacity is proportional to the multiplexing gain over the whole SNR range, thus leading to an upper bound of capacity limit equal to 41 bit/s/Hz and 57 bit/s/Hz for a multiplexing gain of 4 and 256, respectively. Finally, three metrics were presented to determine the limit of massive MIMO in terms of average finite SNR, capacity and the maximum tolerable SNR for (4,4), (16,16), (64,64), (128,128) and (256,256) configurations, respectively. Therefore, by increasing the multiplexing gain a trade-off between capacity limit and tolerable SNR value is observed.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our college management** for their kind support and permission to use the facilities available in the institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, our **beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna, Head & professor,** the **Dept. of Electronics and Communication Engineering** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Dept. Project Coordinator** Dr. **A. Anand, Assistant Professor, Dept.of ECE** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project guide, **Mr. M.Thirupathi, Assistant Professor,** Department of ECE and our class project coordinator **Mr. K. Karthik, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level project coordinators **Dr.Malayadri, Professor in IT & Dr.R.Santhosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

ABSTRACT

The accuracy of image classification networks decreases substantially in noisy situations such as low light environments. A simple solution to this problem is to integrate an image denoising network as a pre-processing operation before classification and then to retrain the classifier to improve the classification accuracy. However, this straightforward approach suffers from excessive training time because the denoising network requires the entire dataset to conduct end-to-end training. In this paper, instead of using classification accuracy as a loss function, we propose using the difference of the outputs of the hidden layer of the image classification network. This loss function, known as feature loss or perceptual loss, allows us to train the denoising network using only limited images containing extremely few classes from the dataset. The experimental results show that the proposed method dramatically improves the classification accuracy, when we use only a few classes (from 2.5% to 10% of the original dataset) for training. This approach is effective on previously unseen classes even when the image classifier network has been changed by fine-tuning.

INTRODUCTION

Introduction :

A DNN (deep neural network) is a versatile framework for performing a variety of image processing and computer vision tasks. In particular, DNNs have achieved significant successes in image classification [1, 2, 3]. However, a wellknown drawback of these classifiers is that they are highly sensitive to low-level image degradations such as noise, blur, and compression artifacts. For example, noise is inevitable when applying a pretrained image classification network to images captured by surveillance cameras operated in low light conditions. However, retraining the image classifier network itself for each type of degradation is prohibitively expensive due to the extremely high computational complexity. A simple and straightforward solution to this problem is to use a DNN-based image denoising network [4, 5, 6, 7, 8] as a pre-processing step before image classification. A similar approach involves building cascading networks to address low-level vision tasks such as denoising and high-level vision asks (image classification, image retrieval, semantic segmentation) was proposed in [9, 10, 11].

Historical Development:

Liu et al. proposed a cascaded network architecture in [10] that included an image denoising network and an image classification network. Because the training of the denoising network was performed using an end-to-end approach, they adopted cross entropy as their loss function, which requires images representing all the classes in the dataset for training. In the case of ILSVRC 2012, the dataset contains 1,000 classes. Thus, the method proposed in [10] still suffers from long training times. Consequently, a natural question arises: does training the denoising network truly require the entire image dataset?

In this study, we propose a new method for training cascading image denoising and image classification networks using images belonging to only a few classes. Unlike the method in [10], which uses the classification results as the loss function, our proposed method uses the output vector of the hidden layer (feature vector) of the image classification network for the loss function. We train our denoising network to output a feature vector similar to the output feature vector of the original image. We reveal that only a few classes (from 2.5% to 10%) in the original dataset are sufficient to train a denoising network that can improve the classification accuracy even under severe noise. We also show that the proposed method performs well even when the classification network is fine-tuned to a dataset with completely unknown classes. The adopted loss function is not new. Using a feature vector for the loss function is called feature loss or perceptual loss [12] and has been used in many studies [11, 13]. In particular, the study in [11] uses feature loss to train a cascaded network similar to ours. However, in these methods, feature loss is used to reconstruct visually pleasing outputs. To the best of our knowledge, this is the first study to reveal that feature loss enables us to train a classification-aware denoising network from very few classes. The contributions of this paper are summarized as follows: • Using feature loss allows the training process to improve the classification accuracy of the denoising network using only images that represent extremely small percentages of the classes in the dataset. • Even if the image classification network has been changed by fine-tuning on images belonging to totally unseen classes, our denoising network can improve the classification accuracy on noisy images.

INTRODUCTION TO IMAGE PROCESSING

IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—suchas cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

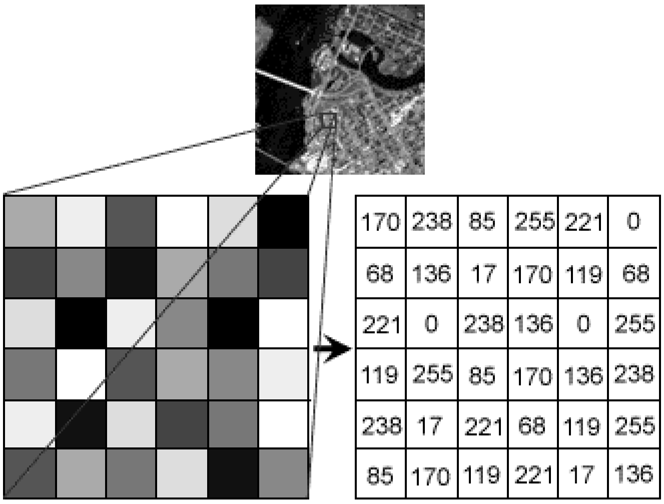

Fig 1.2 Image pixel

Each pixel has a colour. The colour is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1

IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

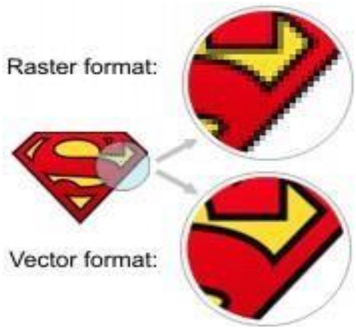

Fig 1.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save themin their own native format.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, misunderstandings and misinformation. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factors combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several newtechnological trends promise to further promote digital image processing. These include parallel processing mode practical by low-cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

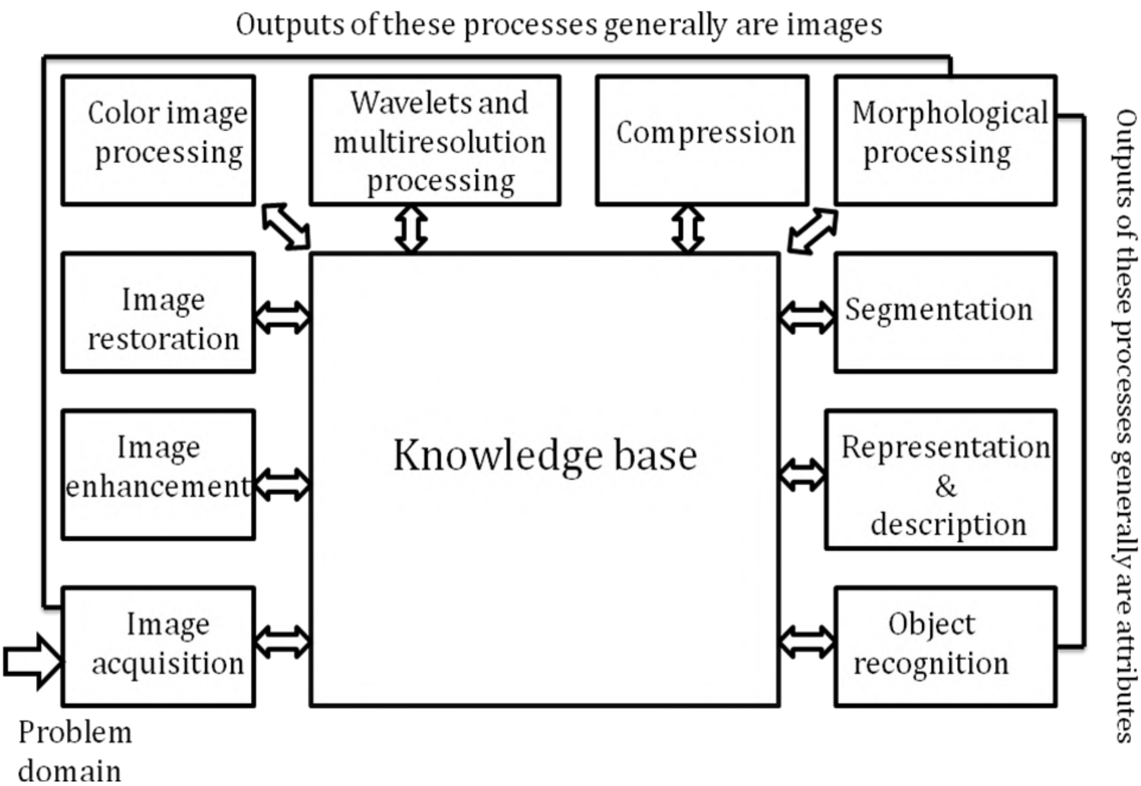

Fig 1.6 Image fundamental

Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.7 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.8 digital camera cell

Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.9 Image enhancement

Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.10 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

Colour image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.11 Color & Gray scale image

Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform-based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

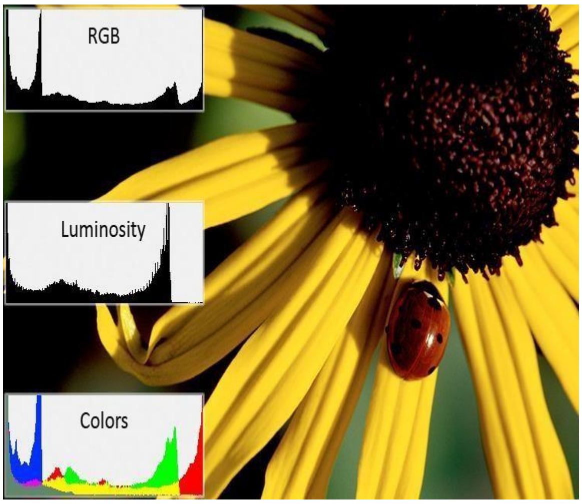

Fig .1.12 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.13 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

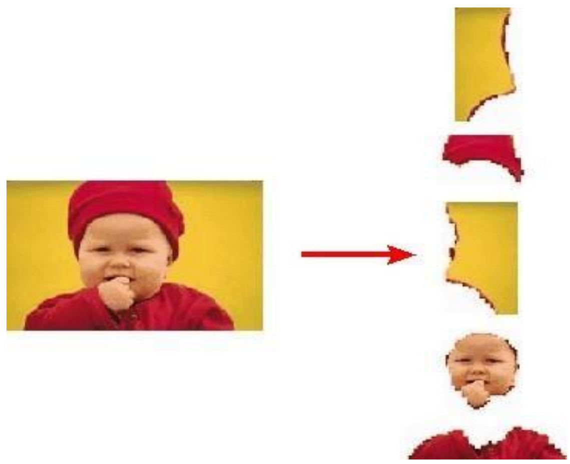

Fig 1.14 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an interrelated to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented pre-processing techniques using MATLAB. The knowledge base also can be quite complex, such as an interrelated to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application.

This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located but it also aids in feedback operations between modules through the knowledge base. We implemented pre-processing techniques using MATLAB.

COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

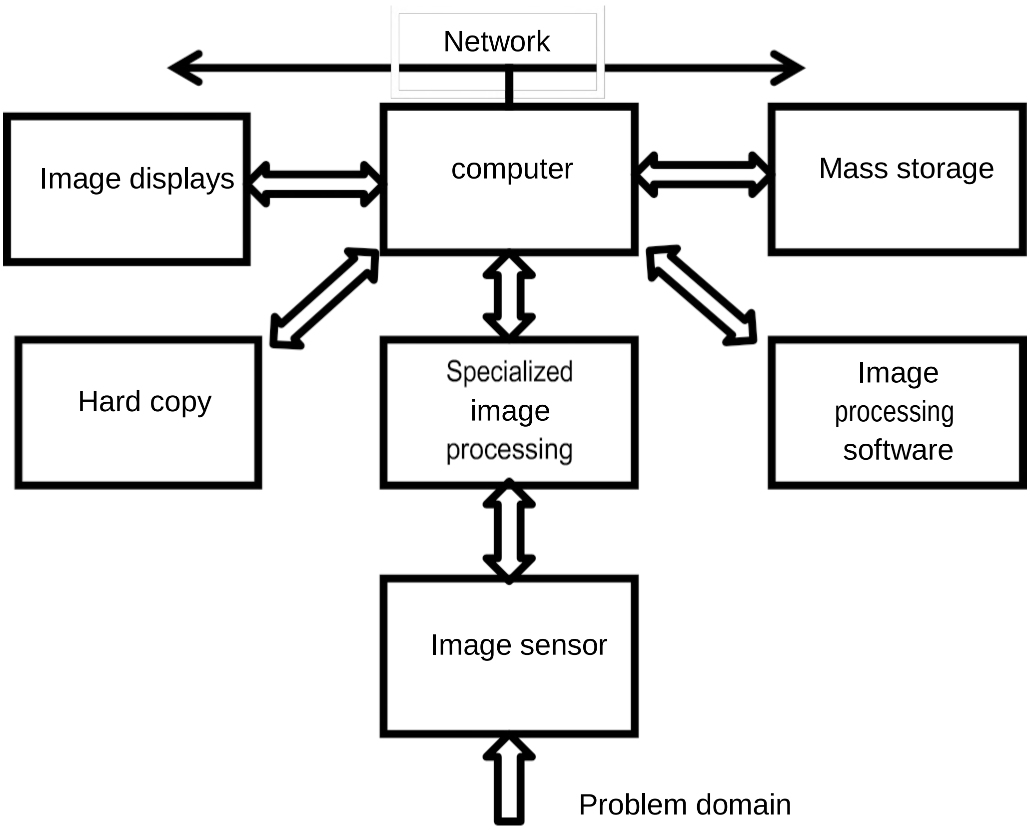

Fig 1.15 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

  With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

  Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle. This type of hardware sometimes is called a front-end subsystem,

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

  One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

  Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are their requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighbourhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbour in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual Gray levels, where gl∈{0, . . ., GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \Pr((\mathrm{gl}\ \ \mathrm{gl}$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbour Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbour is j. One GCM matrix is generated for each possible neighbourhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three-dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation. Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, HL\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbours at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD; CCMND) .

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights. One of the challenges of this approach is to determine suitable weights since these are highly application dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi-channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbour Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighbourhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbours of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighbourhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbour, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighbouring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically, there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex processwith rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON-INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H, S, V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

G = Qs*Qv*H+Qv*s+V

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 & if \quad h \in [316, 20] \\ 1 & if \quad h \in [21, 40] \\ 2 & if \quad h \in [41, 75] \\ 3 & if \quad h \in [76, 155] \\ 4 & if \quad h \in [156, 190] \\ 5 & if \quad h \in [191, 270] \\ 6 & if \quad h \in [271, 295] \\ 7 & if \quad h \in [296, 315] \end{cases} \qquad S = \begin{cases} 0 & if \quad s \in [0, 0.2) \\ 1 & if \quad s \in [0.2, 0.7) \\ 2 & if \quad s \in [0.7, 1) \end{cases} \qquad V = \begin{cases} 0 & if \quad v \in [0, 0.2) \\ 1 & if \quad v \in [0.2, 0.7) \\ 2 & if \quad v \in [0.7, 1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, which quantize the whole color space for the 72 kinds of the main colors. So, we can handle 72 bins of one-dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

1.10IMAGE RETRIEVAL:

Image retrieval is nothing, but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc.,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real-world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

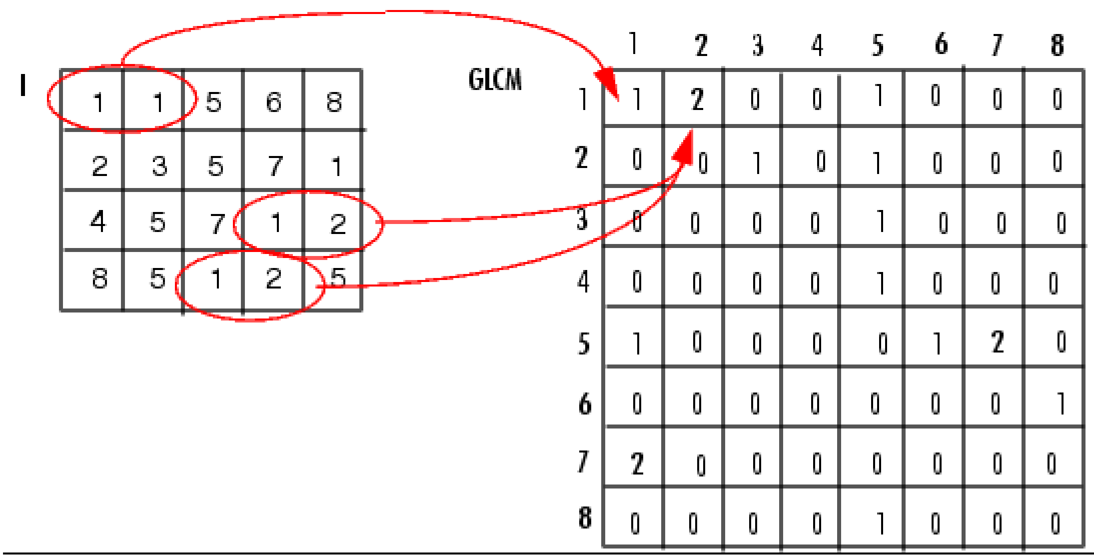
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

1.11.OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented to differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude off at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images, but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two-dimensional function f (x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b] I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f (x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0)   f(0,1)   ………..   f (0, N-1)

f (1,0)   f (1,1)   …………   f (1, N-1)

f (xylem)=   .   .   .

.   .   .

f (M-1,0)   f(M-1,1)................. f (M-1, N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f (1,2)........... f (1, N)

f (2,1)   f (2,2)........... f (2, N)

.   .   .

f =   .   .   .

f (M,1) f(M,2) ……. f (M, N)

Where f (1,1) = f (0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f (p, q) denotes the element located in row p and the column q. For example, f (6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Format Name	**Description**	**Recognized Extension**
TIFF	Tagged image file format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Table 1.1: Image Formats

Here filename is a spring containing the complete of the image file (including any applicable extension). For example, the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chest Xray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8-bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name	**Description**
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255] (1byte per Element).
Uint16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).
Uint 32	unsigned 32_bit integers in the range [0, 4294967295] (4 bytes per element).
Int8	signed 8_bit integers in the range [-128,127] 1 byte per element)
Int 16	signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
Int 32	Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single   single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char   characters (2 bytes per elements).

Logical   values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1, with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1. Intensity images.
2. Binary images.
3. Indexed images.
4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB. A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s. Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical, we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1. Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1]. The length m of the map is equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer into map. If x is of class double, then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as "stack" of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly, the range of values is [0,255] or [0, 65535]. For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

Chapter 2

LITERATURE SURVEY

Literature survey on research area:

In this study, we propose a new method for training cascading image denoising and image classification networks using images belonging to only a few classes. Unlike the method in [10], which uses the classification results as the loss function, our proposed method uses the output vector of the hidden layer (feature vector) of the image classification network for the loss function. We train our denoising network to output a feature vector similar to the output feature vector of the original image. We reveal that only a few classes (from 2.5% to 10%) in the original dataset are sufficient to train a denoising network that can improve the classification accuracy even under severe noise. We also show that the proposed method performs well even when the classification network is fine-tuned to a dataset with completely unknown classes. The adopted loss function is not new. Using a feature vector for the loss function is called feature loss or perceptual loss [12] and has been used in many studies [11, 13]. In particular, the study in [11] uses feature loss to train a cascaded network similar to ours. However, in these methods, feature loss is used to reconstruct visually pleasing outputs. To the best of our knowledge, this is the first study to reveal that feature loss enables us to train a classification-aware denoising network from very few classes. The contributions of this paper are summarized as follows: • Using feature loss allows the training process to improve the classification accuracy of the denoising network using only images that represent extremely small percentages of the classes in the dataset. • Even if the image classification network has been changed by fine-tuning on images belonging to totally unseen classes, our denoising network can improve the classification accuracy on noisy images.

Review of related literature:

Image denoising is one of the most basic undertakings in image preparing for better examination and vision. There are numerous sorts of noise which can diminish the nature of images. The Speckle noise which can be displayed as multiplicative noise, primarily happens in different imaging framework because of arbitrary variety of the pixel esteems. It very well may be defined as the duplication of arbitrary qualities with the pixel esteem. Images are a characteristic route for people to consider spatial data, and burrow ital images are a characteristic portrayal of spatial information. Like every recorded signal, advanced images are regularly ruined by noise, expanding the trouble with which human spectators or PC calculations can extricate the valuable basic data. Despite the fact that noise can be relieved by improved image securing equipment, in certain modalities, for example, intelligible imaging, the noise is an innate aspect of the imaging cycle. Fig. 1.1 Image denoising model. There are two principle purposes for getting this gauge. To start with, the noise sifting can be proceeded as a prehandling venture for additional machine investigation, for example, scene division, object identification, or visual following. Besides, denoised images are simpler to decipher by human spectators, helping in errands, for example, arranging ice types in SAR images, or surveying blood vessel malady in ultrasound images. Multiplicative noise or spot noise happened in different imaging frameworks because of irregular variety of pixel esteems. Albeit various reclamation strategies were proposed in writing like Wiener filtering and Lee filtering to denoise such sort of uproarious images, anyway these techniques are not giving promising outcomes as far as PSNR, MSE and SNR. If there should arise an occurrence of denoising the attribute of the framework just as the sort of noise is known heretofore. The image s(x,y) is obscured by the direct activities causing the noise n(x,y) to include or duplicate with the image. The uproarious image at that point goes through a denoising strategy and produces the denoised image z(x,y). How close the image z(x,y) is to the first image relies upon the noise levels and the denoising calculation use.

CONCLUSION:

This examination work presents an extensive survey of literature on image denoising based on prior work. Image Noise is random variation of brightness or color in an image. It can be produced by any circuitry such as sensor, scanner or digital camera. Image noise is an undesirable 37 INTERNATIONAL JOURNAL OF INNOVATIVE TRENDS IN ENGINEERING (IJITE) ISSN: 2395-2946 ISSUE: 93, VOLUME 69, NUMBER 01, SEPTEMBER 2020 signal, it’s produce by image capturing device that add extra information. In many cases, it reduces image quality and is especially significant when the objects being imaged are small and have relatively low contrast. This random variation in image brightness is designated noise. This noise can be either image dependent or image independent

CHAPTER-3

PROJECT DESCRIPTION

Existing Method:

In [10], Liu et al. proposed connecting a denoising network and an image classification network and revealed that cascading two networks is mutually beneficial: improving both the classification accuracy and the visual appearance of the denoised image. They used VGG16 as the image classification network and a U-Net [14]-based network as the denoising network. The loss function of the cascaded network, which is the weighted sum of cross entropy and mean squared error (MSE). (1where xi is a i-th clean image, and yi is a corresponding noisy image obtained by adding Gaussian noise with a standard deviation of σ to each pixel in xi. Let ui be a one-hot vector of the ground truth label of xi. VGG16 and the image denoising network are denoted by C(·) and D(·; Θ), respectively, and Θ represents all the trainable parameters of D. The first term of the loss function is the cross entropy e(·) between the classification result of the noisy image and the corresponding grand truth u. Thus, we can improve the classification accuracy by minimizing this term. The second term is used to improve the subjective quality of the denoised images. The balance between these terms is controlled by the parameter λ.

Proposed Method:

In this section, we introduce a new learning method for the denoising network to improve the classification accuracy of the cascaded network that requires only a few data classes. Our cascaded network, shown in Fig. 1, consists ofthe denoising network and the image classification network. To overcome Fig. 1. The network architectureof the proposed method. We use a feature vector for our loss function instead of the final classification result. the problem of CDnN, we use the output of the hidden layer in VGG16 (feature vector) to train the denoising network. We use a 4,096-dimensional vector immediately before the 1,000- class classification of VGG16 as our feature vector. We split VGG16 into two parts before and after the final layer and denote them as featureNet and classNet. Thus, our feature vector can be considered as the output of featureNet. The loss function of the proposed method.

BLOCK DIAGRAM:

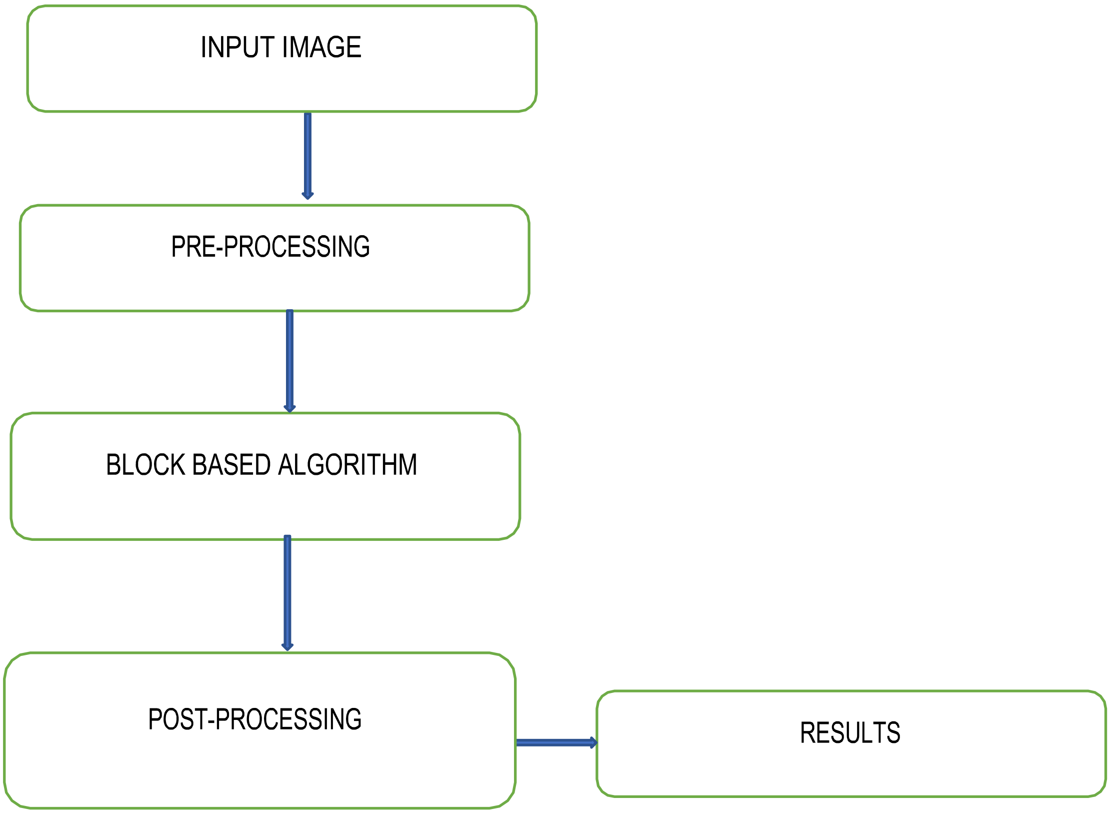


Fig 3.1: Block Diagram

Image denoising :

We used the ILSVRC2012 training and validation sets to train the cascaded network and the test images to evaluate the classification accuracy. A preprocessing operation (cropping and pixel value shifting) for VGG16 [1] was applied during the training procedure. First, we obtained noisy input images by adding additive Gaussian noise (σ = 15, 30, 45, 60) to all the images in the dataset. The top-1 and top-5 classification accuracies of VGG16 for the noisy images are shown in the leftmost column of Table 2. The results show that the accuracy decreases rapidly as the noise level increases. Then, we applied DnCNN [4], CDnN, and FDnN (ours) to the noisy images and obtained the corresponding classification accuracies on the denoised images. We use sets of classes (25, 50, 75, and 100) randomly chosen from the ILSVRC2012 training set. Then, we chose 650 and 10 images randomly from each class for training and validation, respectively. The learning rate for the denoising network was initial set to 0.001 and multiplied by 0.2 after 30, 60 and 90 epochs. The training was completed at 100 epochs. We chose the model that yielded the best validation accuracy for subsequent testing. We trained all the denoising networks with each noise level. Table 2 shows all the resulting classification accuracies, revealing the effectiveness of the proposed method (VGG16 + FDnN) on every class and at each noise level. Notably, when only a few classes are used for training, the accuracy gap between FDnN and CDnN increases. Fig. 2 shows the original, noisy, and two denoised images by DnCNN and FDnN. DnCNN (c), successfully denoises the images, but they appear somewhat over-smoothed. In contrast, the denoised images by FDnN (d), appear to still contain some noise. Table 2 shows that the accuracy is higher when using FDnN than when using DnCNN. These results suggest that the remaining noise contributes to improving the classification accuracy

Steps for the Proposed Method:

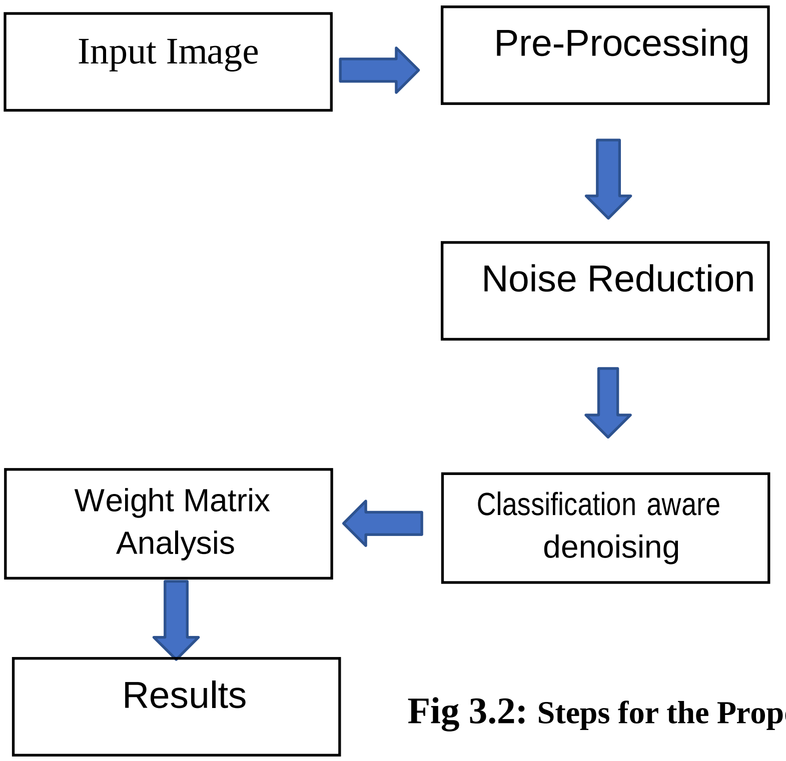

Fig 3.2: Steps for the Proposed Method

METHODOLOGY:

In this section, we introduce a new learning method for the denoising network to improve the classification accuracy of the cascaded network that requires only a few data classes. Our cascaded network, shown in Fig. 1, consists of the denoising network and the image classification network. To overcome

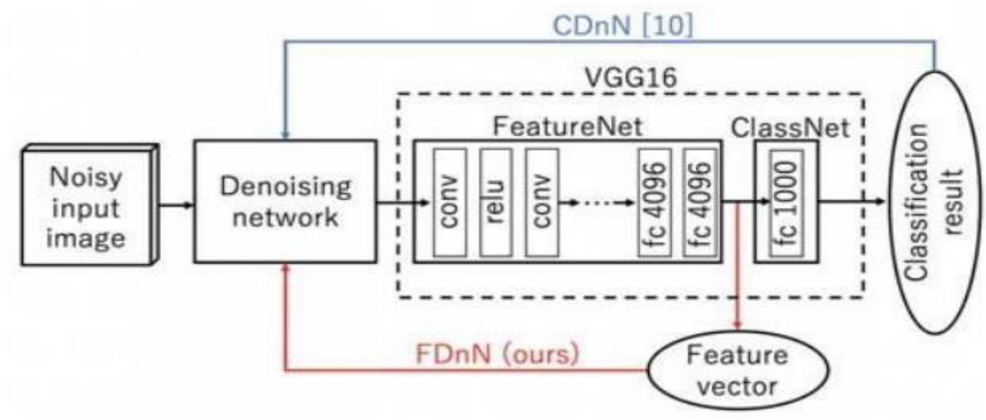

Fig. 1. The network architecture of the proposed method. We use a feature vector for our loss function instead of the final classification result.

Fig 3.3:Network Architecture Of Proposed Method

the problem of CDnN, we use the output of the hidden layer in VGG16 (feature vector) to train the denoising network. We use a 4,096-dimensional vector immediately before the 1,000- class classification of VGG16 as our feature vector. We split VGG16 into two parts before and after the final layer and denote them as featureNet and classNet. Thus, our feature vector can be considered as the output of featureNet. The loss function of the proposed method is defined as follows:

$$L_{\mathrm{f}}(\Theta) = \sum_i \| F(D(\boldsymbol{y}_i; \Theta)) - F(\boldsymbol{x}_i)) \|_2^2,$$

where F(·) is a map corresponding to featureNet. Eq. (3) shows that our loss function is defined by the MSE between the denoised and the original image. We denote the denoising network that is optimized by the above loss function as the feature-oriented denoising network (FDnN). Because the feature vector potentially contains more information than the classification results, we expect that training with the loss function shown in Eq. (3) should improve the classification accuracy for unknown classes. We also conduct some preliminary experiments to find the best layer from which to extract the feature vector; however, we found no other layers that improve the classification performance other than the 4,096-dimensional feature vector described above.

CHAPTER 4

Software Introduction:

Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others. Areasin which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

The MATLAB system:

The MATLAB system consists of five main parts

Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully

customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension.fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

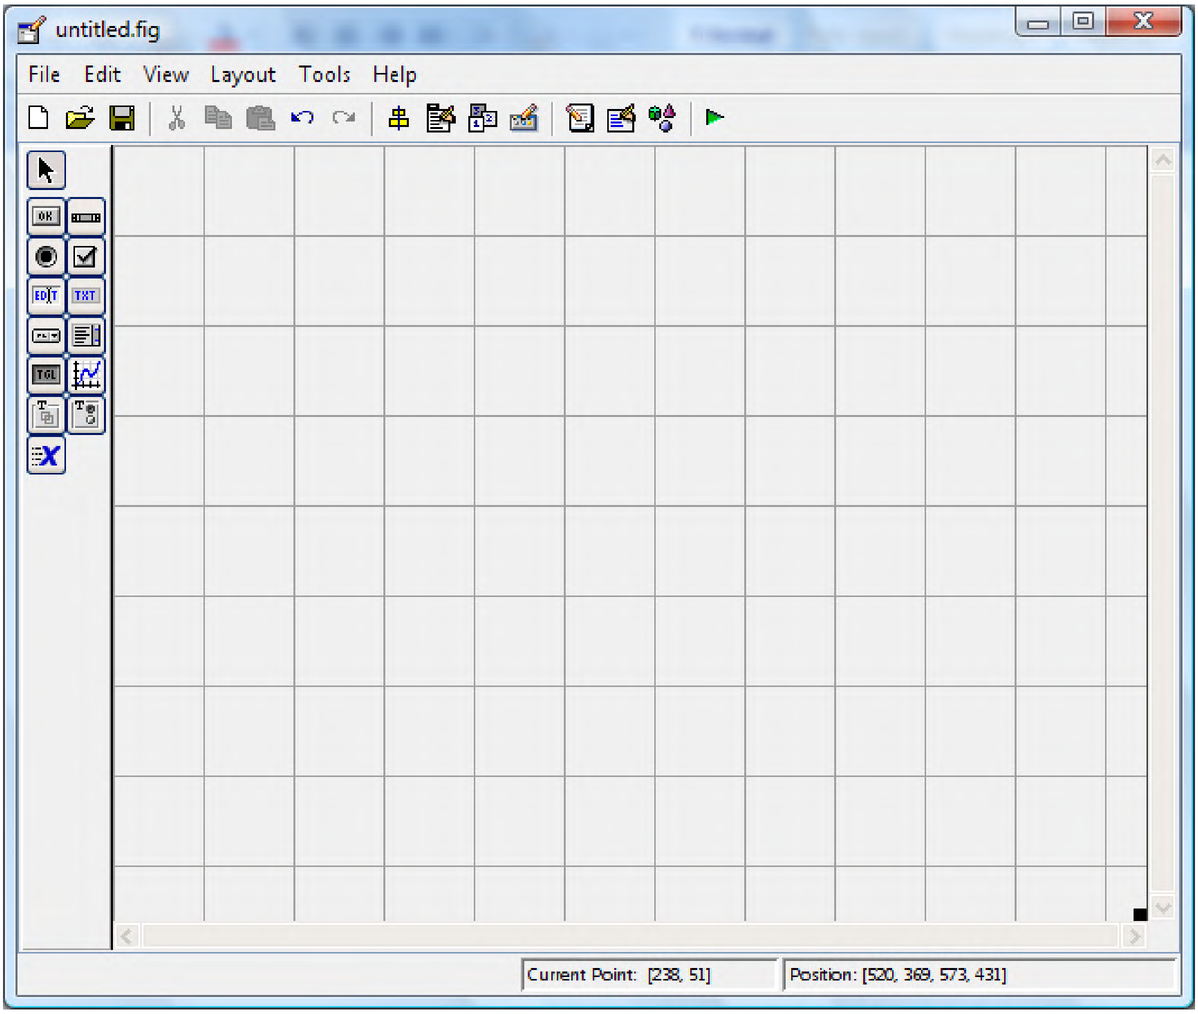

Fig 4.1: GUI

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

DEVELOPMENT ENVIRONMENT

4.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, andresizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History

- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example, !emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentations for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Content's tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favourite's tab - View a list of documents you previously designated as favourites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favourites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace as from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a.mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

MANIPULATING MATRICES

Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

16    3    2   13

5   10   11    8

9    6    7   12

4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to itsimply as A.

Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3 -99 0.0001

9.6397238 1.60210e-20 6.02252e23

1i -3.14159j 3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 4.1: Operators

Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built in. They are part of the MATLAB core, so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sign, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 4.2: Functions

GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied, and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or howthey work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

GUI Development Environment

The process of implementing a GUI involves two basic tasks.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

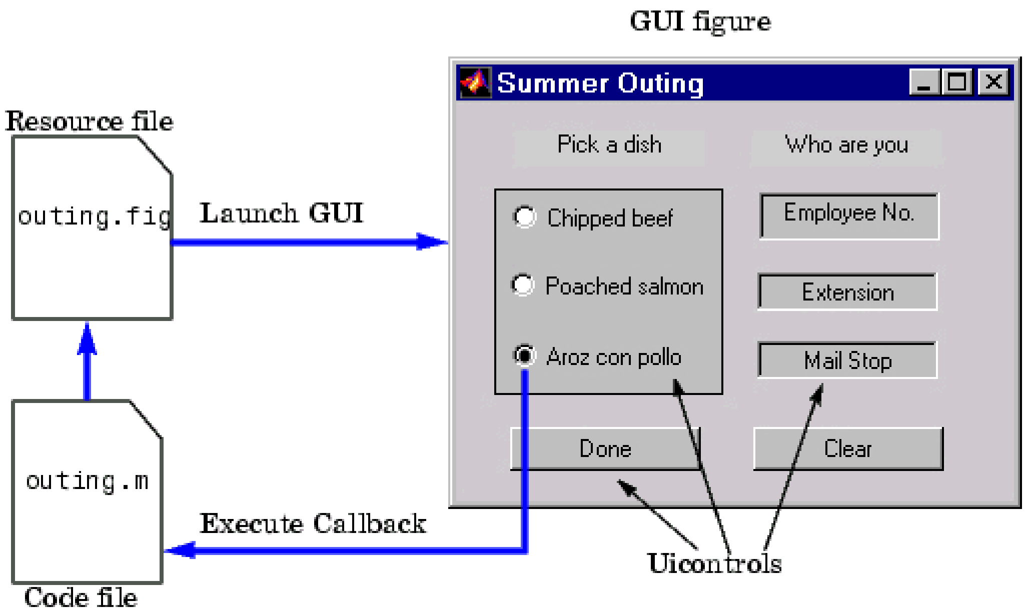

FIG 3.7.2 graphical user blocks

Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes

- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle buttonis depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

% toggle button is pressed

elseif button_state == get(h,'Min')

% toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behaviour

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

function mutual_exclude(off)

set(off,'Value',0)

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

This structure is an input argument to all radio button callbacks.

function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

.

.

.

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked ornot checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

% then checkbox is checked-take approriate action

else

% checkbox is not checked-take approriate action

end

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback (h, eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text call back routine to execute. This behaviour is consistent with the respective platform conventions. Clicking on other components in the GUI execute the call back.

Static Text

Static text controls display lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the call back routine associated with it.

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no call back routines associated with them and only ui controls can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The List box Top property defines which string in the list displays as the topmost item when the list box is not large enough to display all list entries. List box Top is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non integer values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure, you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback (h, eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback (h, eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled, and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes (handles. axes1)

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to targeta different axes. See GUI with Multiple Axes for and example that uses two axes.

You can do this using the axes command and the handles structure.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

Chapter 5

RESULTS

- At first we will get the input image as ouput in the first figure widow. Now we can see some noise in the image.

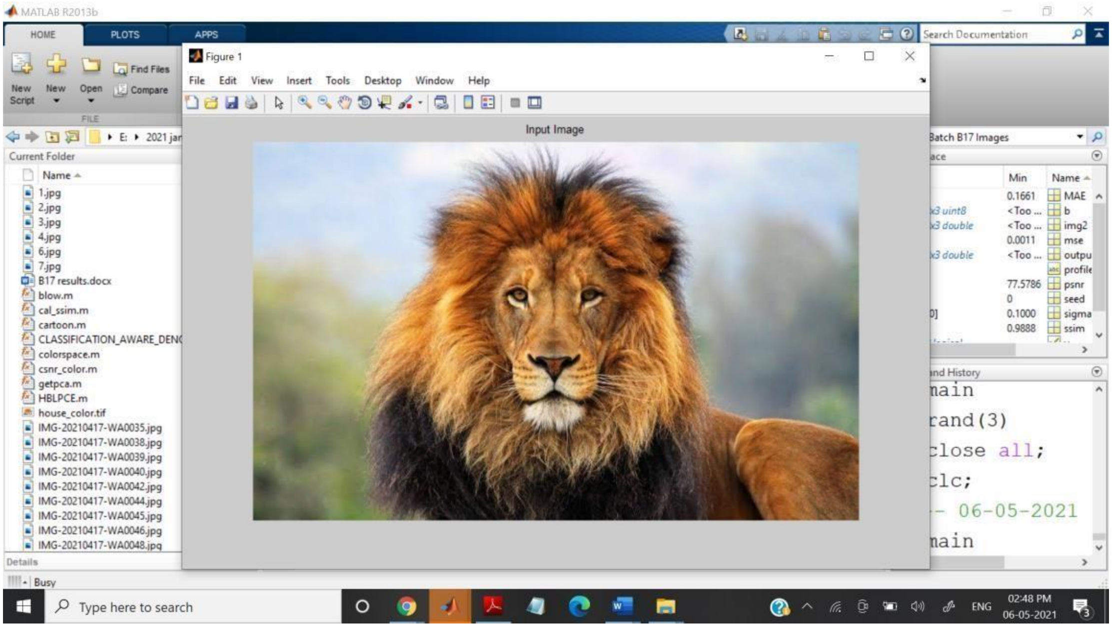

Fig 5.1:Input Image

- In the second figure the histogram equalization occurs for the given image

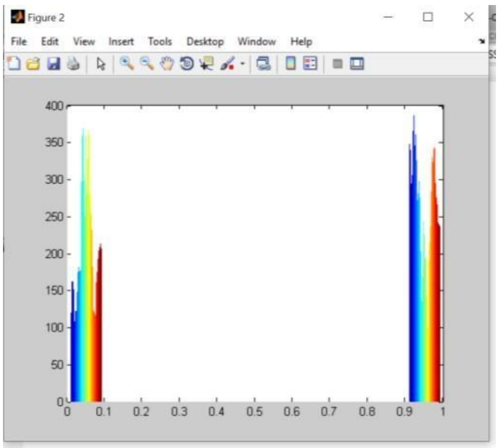

Fig 5.2:Histogram Equaliztion

- In the third figure window left side image is the noise added image which is more than the input image.

5.1 Final Output:

In the right side image i.e., Classification aware denoising image output this is the final output which is an required image

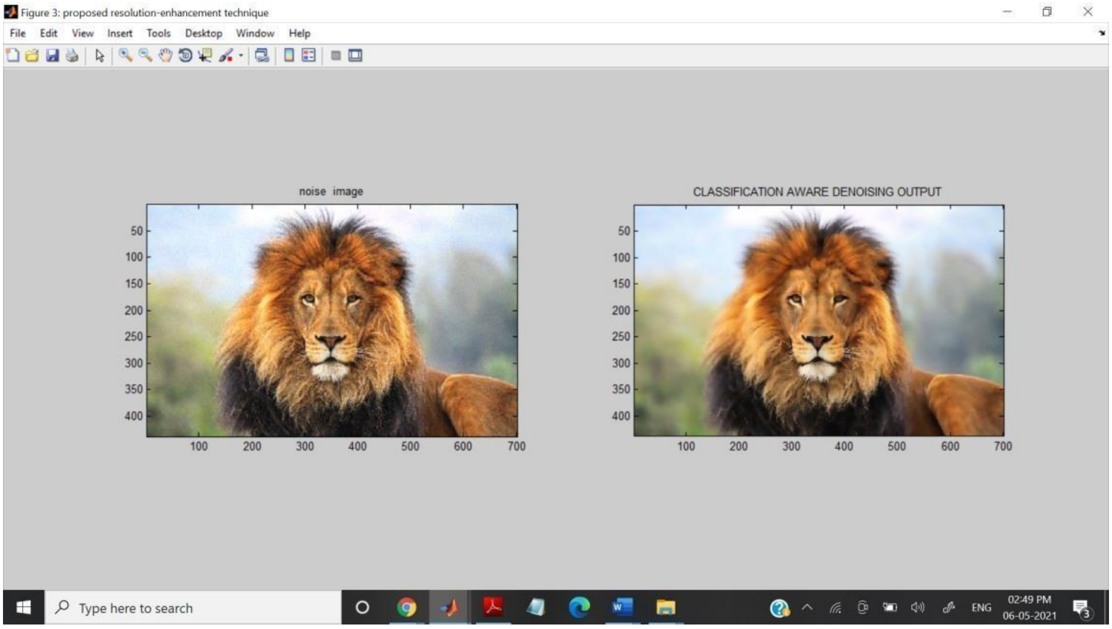

Fig 5.3: a) Noised Image

b) Classification aware denoising image

Chapter 6

LIMITATIONS & ADVANTAGES

Limitations:

- Requires a large amount of data — if you only have thousands of example, deep learning is unlikely to outperform other approaches.
- The disadvantage is that the amount of operations of such a model is comparatively huge. It takes a lot of time not only to train a model, but also to use it. Unless you can speed the computation up using e.g. CUDA cores of NVidia GPU, it's not very practical. Even with CUDA technology, you may probably forget e.g. real-time processing of video frames. So if you are able to train a simpler model and reach good enough.
- CNN do not encode the position and orientation of object. Lack of ability to be spatially invariant to the input data. Lots of training data is required.

Advantages:

- The main advantage of DNN compared to its predecessors is that it automatically detects the important features without any human supervision.
- The huge advantage of multi-layered models such as the DNNs is that on each layer, different level of visual information is processed.
- Lower layers process (detect) very local features; just small parts of curves etc. The higher you get, the more complex features are concerned. And you can still interpret the functionality of the network relatively well.
- Commonly, to adapt a model to new purpose, its lower layers are kept and you only train the higher ones to infer the features for the particular case. That speeds the training up a lot.

Chapter 7

CONCLUSION & FUTURE ENHANCEMENT

CONCLUSION:

- In this paper, we proposed a new method for training an image-classification-aware denoising method that requires only a very small subset of the classes in the original dataset.
- The experimental results show that the proposed method drastically improves the classification accuracy under noisy conditions even when we apply the denoised network to a dataset containing completely unseen classes.
- Our method provides a plug-and-play denoising network for image classification networks in various severe environments without retraining the whole classification network.

FUTURE ENHANCEMENT:

- The increasing demand for high image quality in mobile devices brings forth the need for better computational enhancement techniques, and image denoising in particular.

// ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. Project coordinator Mr.K.Karthik** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Guide **Mr. P. Pavan Kumar**, **Assistant Professor in ECE** advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

This project concern to a process for monitoring the condition of train tracks and more specifically has the object of the identification of defects detected by monitoring equipment on the tracks to be examine to allow maintenance crews to subsequently find these defects. When the supply is given to the device, the DC motor gets start through relay driver circuit. Two IR sensors are fixed in front of the train which is used to find out the crack on the track. Each sensor will produce the signal related to the position with the rail. If the track position is normal both the sensor gives the constant sensed output. If any sensor misses their output condition to fail then there is defect on that side. The sensor will inform this by giving alarm and sends information to the smart phone android app in IOT based via WIFI Module. Ultrasonic sensor is used to detect the obstacle in the track if any obstacle detected means the Arduino automatically transmits the message to nearby station via IOT using WIFI module.

CHAPTER 1
INTRODUCTION

OVERVIEW OF THE PROJECT

In Indian railway scenario, most commercialized transport is being carried out by the railway network and therefore any problem in the same has the capacity to induce major damage to the economy-notwithstanding the societal effect of loss of life. This paper put forward a cost effective yet robust solution to the problem of railway crack detection utilizing a method that is unique in the sense. This project discusses the technical and design aspects in detail and also provides the proposed robust crack detection.

Present industry is increasingly shifting towards automation. The two basis components of current industrial automations are programmable controller and robot. In order to support the monotonous work and to serve the mankind, there is a general tendency to develop an intelligent operation.PIC Microcontroller is the heart of the device which handles all the sub devices connected over it. The microcontroller has been used here. It has flash type reprogrammable memory and some peripheral devices to play this project perform. IR sensor is used to detect the crack in rail road, when the crack is detected motor of the train will stop thus the train stops and this information is sent as a message to nearby station by using Wi-Fi module. Then Ultrasonic is used for the surveying process. Then other important component is PIR sensor it is used to detect the presence of humans in track. A practical methodology to non-destructively localize cracks and estimate the sizes of the cracks in beam-type structures using changes in frequencies. Utilizing simple components like IR Transmitter and Receiver based crack detector assembly is very useful in railway crack detection.

Crack detection method has been explored which uses microwave sensors to observe the rail surface. When a cracked rail is encountered along the route, the circuit will be interrupted or open, resulting in a changed flux pattern. Crack detection method in railway system utilizes the change in infrared emission of the rail surface during the passage of a train wheel. Initial data from this infrared method are dispense from studies of both laboratory-based three-point bend specimen and a short section of rail. This paper proposes a work of detecting the crack in the railway track using IOT and also presents the details of the implementation results of the robust crack detection system utilizing simple components inclusive of a Wi-fi module and IR, Ultrasonic based crack detector assembly. The proposed methodology has been designed for robust implementation in the Indian scenario.

STATEMENT OF THE PROJECT

Indian Railways have been in the news albeit for wrong reasons. With the rapid increase in passenger and goods traffic, the frequency of train accidents is increasing very fast. This has raised serious doubts in the public mind about safety of Rail travel and the general health of the railway network.

The credibility of an organisation with a long and proud history of nation building seriously eroded. In such a situation it is but natural to ask where the Railways are heading. On an average the Railways report 20 major collisions, 350 derailments and around 80 level crossing accidents in a year.

There are several factors which are responsible for increasing number of railway accidents; some outstanding being gaps or cracks in the railway tracks and also some of them will try to cross the railway track without noticing the train and thus accidents happen.

Worried about the increasing rate of accidents and loss of life and property resulting from these accidents. Railway is one of the most significant transportation modes of our country but it is a matter of great sorrow that, railway tracks of our country are very prone. The cracks and other problems with the rails generally go unnoticed due to improper maintenance and irregular manual track line monitoring that is being carried out in the current situation.

Nowadays system have some limitations, if the bridge or track damaged, that information goes to railway authority people, they notifies and informs to the corresponding trains it will takes more time informing those information.

AIMS AND OBHECTIVE OF THE STUDY

The main objective is to define any railway track fault using this system, which is implemented in effective and will also function efficiently. This method will be helpful in regular track checking as it is more convenient than the handheld checking system. The current system has a railway labourers walking on the railway tracks and detecting the fault manually. In this project we are using arduino for control action to make system we are connecting Ultrasonic sensors and IR sensors to detect the obstacle and we are connecting dc motors, wi-fi module is used. This requires a lot of time and labour. So we are using a Ultrasonic sensors and IR sensors for railway track crack detection. The testing vehicle consists of motors driven by a motor driver. The IR, and Ultrasonic sensor which is connected to the Arduino. Message will be sent to the nearby station i.e through telnet app via wi-fi module

SCOPE OF THE STUDY

Through our proposed system, we need to establish more modern and secure railway system. Present industry is increasingly shifting towards automation. The two basis components of current industrial automations are programmable controller and robot. The microcontroller has been used here. IR sensor is used to detect the crack in rail road. The Ultrasonic sensor is used to detect the object and at what distance the object is from rail.

The main scope of the project is to detect mis-alignment and the gaps on the track. It also detect the object present in-front of the train at a distance. The mis-alignments and gaps are detected using IR sensors. Similarly the objects in-front of the train is identified using Ultrasonic sensor. By this we can reduce the physical errors present on the track.

MATERIAL REQUIREMENT

HARDWARE REQUIREMENT

- Arduino UNO
- Ultrasonic Sensor
- IR sensor

- L293D Motor driver
- Motor
- WI-FI Module
- Liquid Crystal Display
- Power Supply
- Battery

SOFTWARE REQUIREMENT

- Arduino IDE
- Proteus Software

PROCUMENT OF EQUIPMENT

We brought all the required hardware components in a electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO microcontroller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software.

Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way

We calculated distance of object i.e object detection and gap i.e crack detection and displayed on LCD and also updated on Server i.e in Telnet app. So, it will be visible to Railway Authority. If sensors detects object or any gap in the railway track then the train will stop.

CHAPTER 2
LITERATURE SURVEY

LITERATURE REVIEW ON RESEARCH AREA

The main objective of the track crack detection and health monitoring in base station between two signals any track is broken, cut the track, and any fault means signal is transmitted to signal engineer, because 5volt power will be passing to track. This technique used only for base station. Microcontroller: ATmega162 The ATmega162 is a low-power CMOS 8-bit microcontroller based on the AVR enhanced RISC architecture. By executing powerful instructions in a single clock cycle, the ATmega162 achieves throughputs approaching 1 MIPS per MHz allowing the system designed to optimize power consumption versus processing speed. IR sensors are also used to identify the crack in the railway.

Existing System: According to Indian Railways currently the method used in railways for crack detection is an inspection by foot, Trollies, locomotives, and rear vehicles. There are two types of track recording car one mechanical and the other electronic. These cars make a continuous record of track geometry under load conditions. The car moves on the track and checks if there is any wear and tear on the tracks. They also use IR sensor, but it is not very accurate because manual work is not possible for every railway network. A system gang patrolling is also used which is implemented by foot along the tracks during the rainy season. Saurabh Srivastava and his teammates have proposed a vehicle for detecting crack using IR sensor array assembly which tracks the exact location of faulty tracks and informs to the nearby railway station. The team from SRM group of colleges Lucknow has proposed a system that detects cracks using Arduino mega power by solar panel along with the laser source. They have also used GSM and GPS module to give an exact location of the crack to authorities via SMS and a link to open location on Google Maps. Rizvi Aliza Raza has presented a model in IJARIIT which is capable of taking pictures of the track and compare it with the old database and also sends a message to the authorities about the fault detected.

REVIEW ON RELATED LITERATURE

The cracks and other problems with the rails generally go unnoticed due to improper maintenance and irregular manual track line monitoring that is being carried out in the current situation. Nowadays system have some limitations, if the bridge or track damaged, that information goes to railway authority people, they notify and informs to the corresponding trains it will take more time informing the information. In the literature survey, the commonly employed rail crack detection schemes in foreign countries are usually ultrasonic or eddy current based techniques which are the reasonably good accuracy in most cases. However, the one characteristic which the above-mentioned methods have in common is that they are both expensive, which makes them ineligible for implementation in the current Indian scenario. Also, the ultrasonic can only inspect the core of materials; that is, the method cannot check for surface and near surface cracking where many of the faults are located. Many of the most serious defects that can develop in the rail head can be very difficult to detect using the currently available inspection equipment. This system is mainly concerned in identifying the cracks in railway tracks and helps to prevent the accidents without manual power. It’s not only concentrated on finding damaged tracks but also helpful to find out the derailment and the exact place where it is. In this technical solution offered by many companies in the detection of cracks in rails involve periodic maintenance coupled with occasional monitoring usually once a month or in a similar time frame. But the robotics possesses the inherent advantage of facilitating monitoring of rail tracks on a daily basis during nights, when the usual train traffic is suspended. Further, that the simplicity of this idea and easy availability of the components make for implementation on a large scale with very little initial investment.

CONCLUSIONS ON REVIEWS

The simplicity of this work ensures robustness of operation and also the design has been carefully modified to permit rugged operation. Another disadvantage that can be attributed to the conventional commercially available testing equipment’s is that they are heavy which poses a practical limitation. This important disadvantage has been rectified in robotics project as the design is simple and sensible enabling the device to be easily portable. While designing the mechanical parts of the robot, due consideration has been given to the variable nature of the tracks and the unique challenges possessed by the deviations in the Indian scenario. For example, in areas near road crossings the outer part of the track is usually covered with cement. Also, there is always the problem of rocks obstructing the path on the inside parts of the rails. So the specialized wheels that have been provided in robot that has taken into account and are specifically designed to overcome this aforementioned problem. The railway track crack detection is used to detect the crack whiles the train running on the track. The proposed system is used to detect the crack on railway track before 10km.

CHAPTER 3

PROJECT DESIGN

BLOCK DIAGRAM OF THE PROJECT

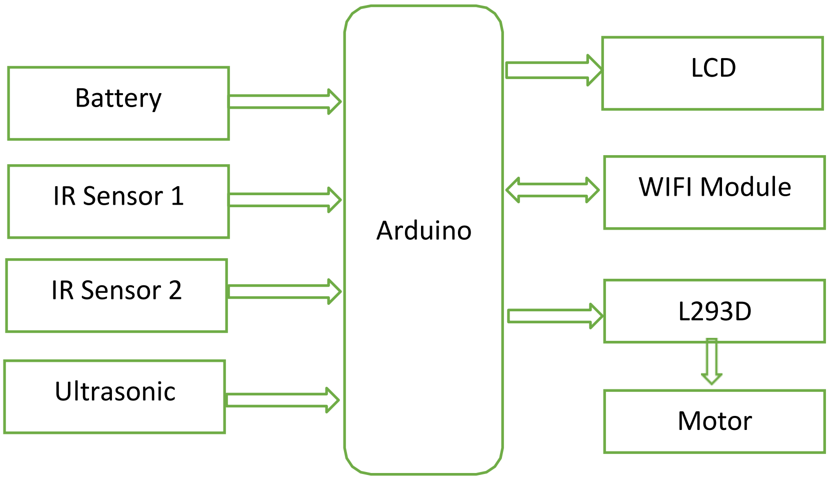

Fig.3.1 Block diagram of the project

HARDWARE REQUIREMENT

- Arduino UNO
- ESP8266 Wi-Fi Module
- Liquid Crystal Display
- Ultrasonic Sensor
- IR Sensor
- L293D Driver motor
- Motor

ARDUINO UNO

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to

ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Table 3.3: Atmega328 specifications

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready- made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board. The key features are −

- Arduino boards are able to read Analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).

- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.

BOARD DESCRIPTION

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

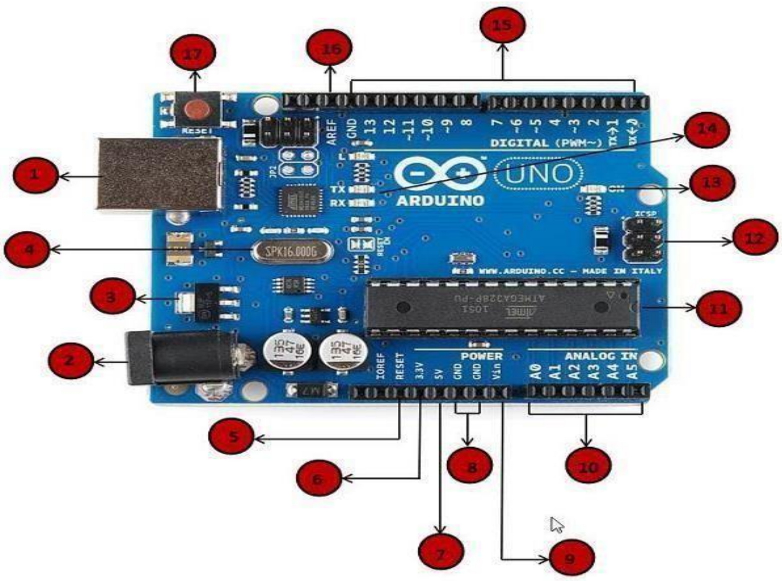

Fig 3.3.1 Board Description

TABLE 3.3.1 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit.

	•Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

PIN DESCRIPTION OF ATMEGA328

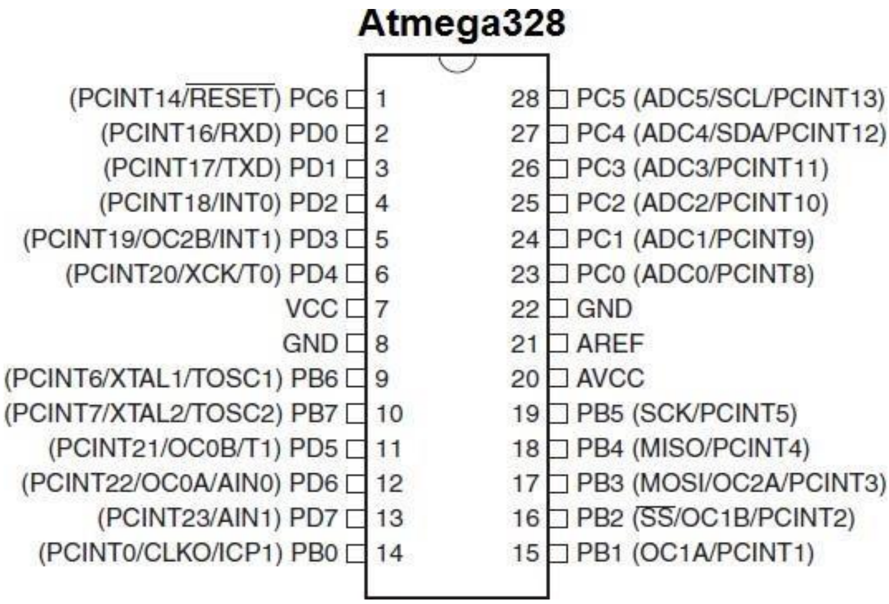

Fig 3.3.2 Pin description pf ATMEGA328

ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the

prevailing programming language libraries and may be extended and changed. For beginners, it is very simple to use.

APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model .

WI-FI MODULE

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IoT devices. We've featured several projects using this module, such as **How To Make Smart Home Electronics: A Smart Mailbox** and **How To Read Your Arduino's Mind: Building A Childproof Lock**. This tutorial will walk you through setting up ESP8266 Wi-fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

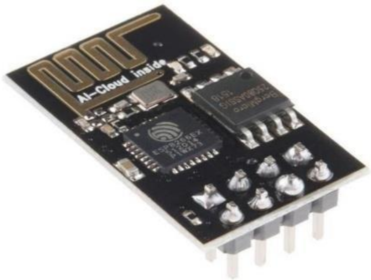

Fig 3.4.1 ESP8266 Wi-Fi Module

FEATURES OF ESP8266

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as thisone. For prototyping, I chose to just use jumper wires.

STRUCTURE AND PIN CONFIGURATION

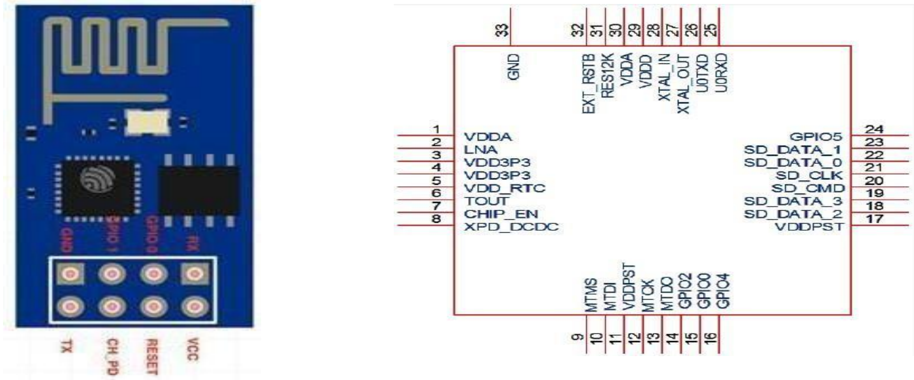

Fig 3.4.3 structure and pin configuration

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V VCC (VCC cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wi-fi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

HOW TO CONNECT ESP8266 WI-FI MODULE

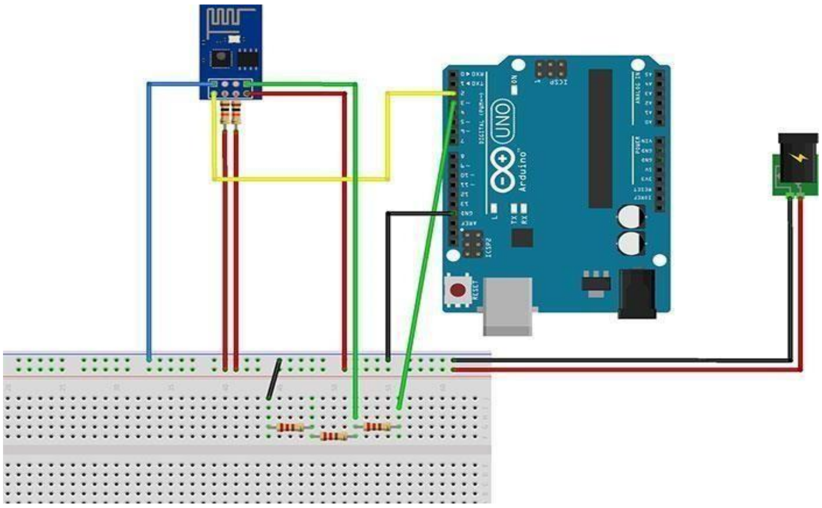

Fig 3.4.4 connection of ESP8266 wi-fi module

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
- Breadboard and jumper wires

A couple of features of this circuit stand out immediately.

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the VCC and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

APPLICATIONS

- IOT Projects
- Access Point Portals
- Wireless Data logging
- Smart Home Automation
- Learn basics of networking
- Portable Electronics
- Smart bulbs and Sockets

16 * 2 ALPHANUMERIC LCD

WHAT IS LCD

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

BLOCK DIAGRAM

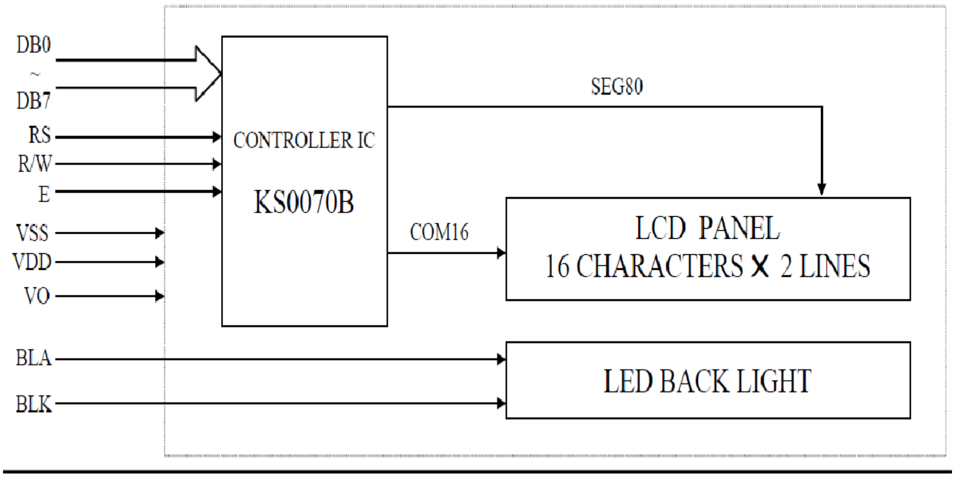

Fig 3.5.2 Block diagram of 16*2 LCD

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

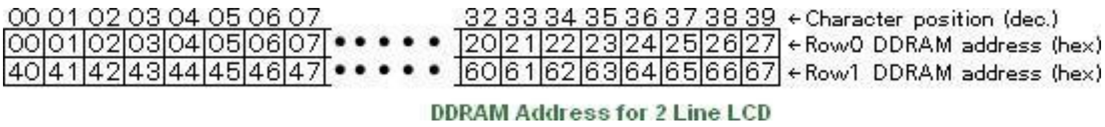

Fig.3.5.3 DDRAM addresses of 2 Line LCD

CHARACTER GENERATOR ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

BUSY FLAG

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 X 2 ALPHANUMERIC LCD MODULE FEATURES

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

SCHEMATIC DIAGRAM

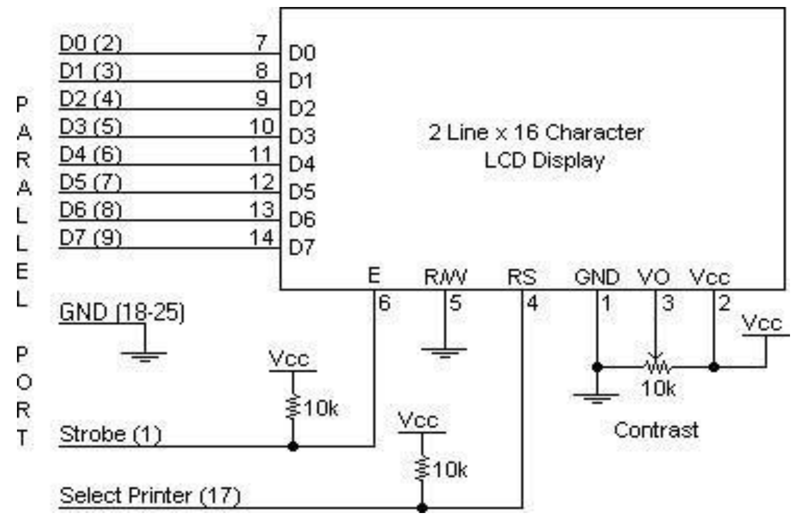

Fig 3.5.7 Schematic Diagram of LCD

SPECIFICATIONS

Table 3.5.8 Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.

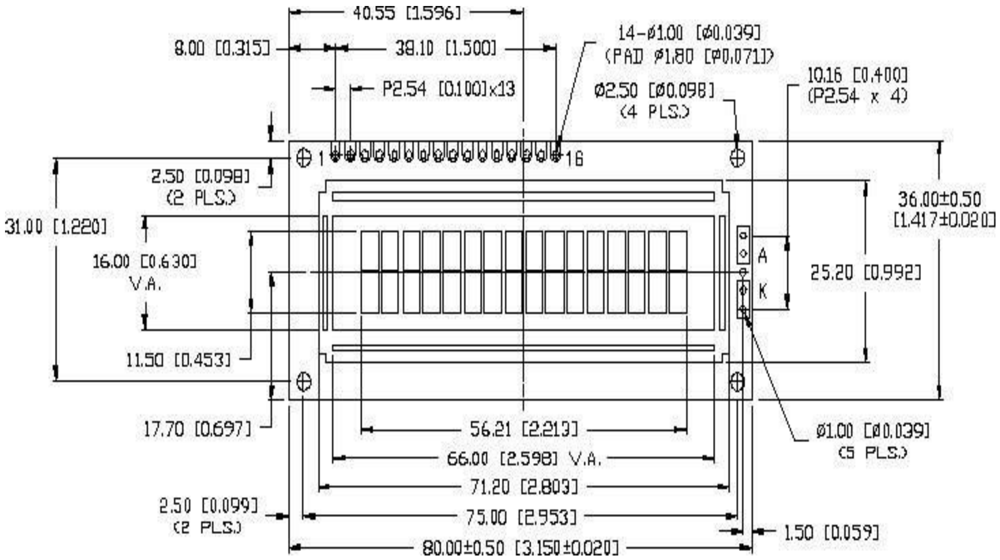

Fig.3.5.9 Connector pin diagram

CIRCUIT DESCRIPTION

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16-character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

APPLICATIONS

- In most of the applications that's have only small values to show, uses the LCD.
- Most of the commercial meters use this module to represent the data output.
- In the toys and developing projects, it is still vastly in use.
- In black and white printers, it helps to show the printer settings and status.

ULTRASONIC SENSOR

WHAT IS ULTRA SONIC SENSOR?

An ultrasonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal.

Fig 3.6.1 Ultrasonic sensor

WORKING PRINCIPLE

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4pin module, whose pin names are VCC, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications, where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver. The sensor works with the simple high school formula that

Distance = Speed × Time

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

Fig 3.6.2 Ultrasonic sensor working principle

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic-wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

PIN CONFIGURATION

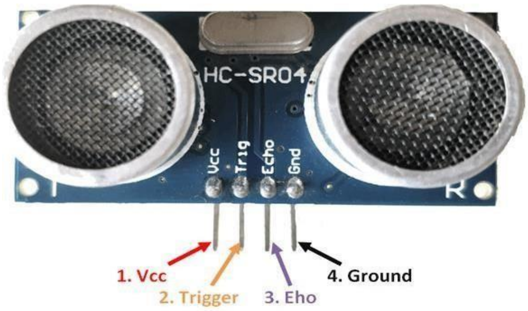

Fig 3.6.3 Pin Configuration

Table 3.6.3 Pin Configuration

Pin Number	Pin Name	Description
1	VCC	The VCC pin powers the sensor, typically with +5V
2	Trigger	Trigger pin is an Input pin. This pin has to be kept high for 10us to initialize measurement by sending US wave.

3	Echo	Echo pin is an Output pin. This pin goes high for a period of time which will be equal to the time taken for the US wave to return back to the sensor.
4	Ground	This pin is connected to the Ground of the system.

HOW TO USE THE HC-SR04 ULTRASONIC SENSOR

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

Power the Sensor using a regulated +5V through the VCC ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to be made high for 10uS and then turned off. This action will trigger an ultrasonic wave at frequency of 40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information, the distance is measured as explained in the above heading.

SPECIFICATIONS

- Operating voltage: +5V
- Theoretical Measuring Distance: 2cm to 450cm
- Practical Measuring Distance: 2cm to 80cm
- Accuracy: 3mm
- Measuring angle covered: <15°
- Operating Current: <15mA
- Operating Frequency: 40Hz

APPLICATIONS

- Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot path finding robot etc.
- Medical ultrasonography.
- Burglar Alarms.
- Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water

INFRARED SENSOR

WHAT IS IR SENSOR?

IR sensor is an electronic device, that emits the light in order to sense some object of the surroundings. An IR sensor can measure the heat of an object as well as detects the motion. Usually, in the infrared spectrum, all the objects radiate some form of thermal radiation. These types of radiations are invisible to our eyes, but infrared sensor can detect these radiations.

Fig 3.7.1 IR Sensor

WORKING PRINCIPLE OF IR SENSOR

There are different types of infrared transmitters depending on their wavelengths, output power and response time. An IR sensor consists of an IR LED and an IR Photodiode, together they are called as Photo-Coupler or Opto-Coupler.

IR Transmitter or IR LED

Infrared Transmitter is a light emitting diode (LED) which emits infrared radiations called as IR LED's. Even though an IR LED looks like a normal LED, the radiation emitted by it is invisible to the human eye.

Fig 3.7.2.1 Infrared LED

IR Receiver or Photodiode

Infrared receivers or infrared sensors detect the radiation from an IR transmitter. IR receivers come in the form of photodiodes and phototransistors. Infrared Photodiodes are different from normal photo diodes as they detect only infrared radiation. Below image shows the picture of an IR receiver or a photodiode,

Fig 3.7.2.2 Infrared Photodiode

Different types of IR receivers exist based on the wavelength, voltage, package, etc. When used in an infrared transmitter – receiver combination, the wavelength of the receiver should match with that of the transmitter.

An Infrared Sensor works in the following sequence:

- IR source (transmitter) is used to emit radiation of required wavelength.
- This radiation reaches the object and is reflected back.
- The reflected radiation is detected by the IR receiver.
- The IR Receiver detected radiation is then further processed based on its intensity. Generally, IR Receiver output is small and amplifiers are used to amplify the detected signal.

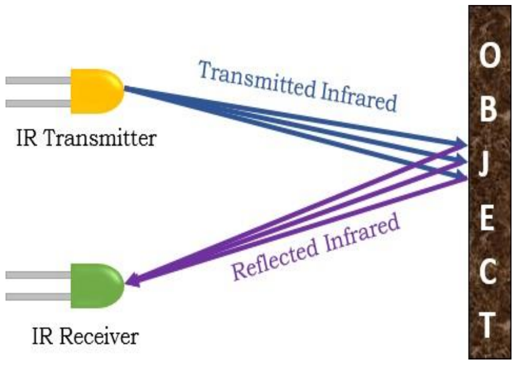

Fig 3.7.2.3 Working of IR Sensor

When the IR transmitter emits radiation, it reaches the object and some of the radiation reflects back to the IR receiver. Based on the intensity of the reception by the IR receiver, the output of the sensor defines.

Principle of operation

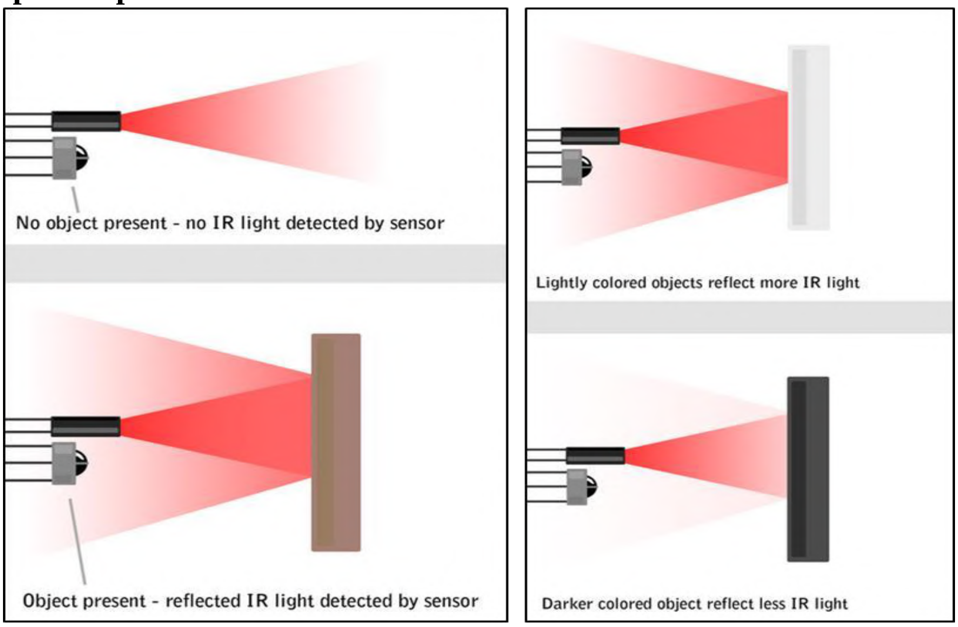

Fig. 3.7.2.4 Principle of operation

The IR transmitter sends an infrared signal that, in case of a reflecting surface (e.g. white color), bounces off in some directions including that of the IR receiver that captures the signal detecting the object.

When the surface is absorbent (e.g., black color) the IR signal isn't reflected and the object cannot be detected by the sensor. This result would occur even if the object is absent.

TYPES OF INFRARED SENSOR

IR sensors can be classified in two types based on presence of IR source:

- Active Infrared Sensor
- Passive Infrared Sensor

Active Infrared Sensor

Active Infrared Sensor contains both transmitter and receiver. Most of the cases LED or laser diode is used as source. LED for non-imaging IR sensor and laser diode for imaging IR sensor are used.

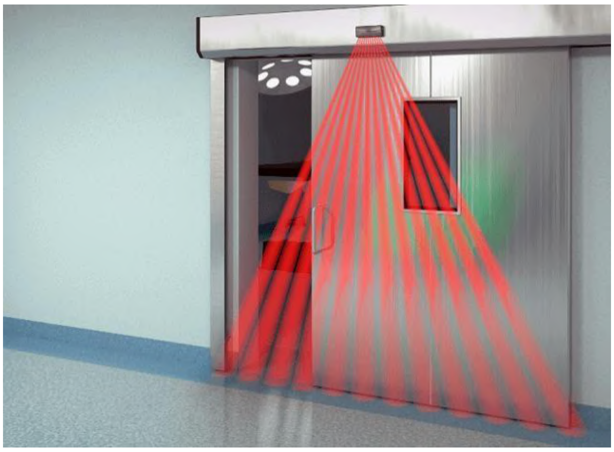

Fig. 3.7.3.1 Active Infrared Sensor

Active IR Sensor works by radiating energy, received and detected by detector and further processed by signal processor in order to fetch information required. Examples of Active IR Sensor: Break Beam Sensor, Reflectance Sensor.

Passive Infrared Sensor

Passive Infrared Sensor contains detectors alone. There won't be a transmitter component. These type of sensors use object as IR source/ transmitter. Object radiates energy and it is detected by IR receivers. A Signal processor is then used to interpret the signal to fetch information required. Example of Passive IR Sensor: Thermocouple-Thermopile, Bolometer, Pyro-Electric Detector, etc.

Fig3.7.3.2 Passive Infrared Sensor

There are two types of Passive Infrared Sensor:

- Thermal Infrared Sensor
- Quantum Infrared Sensor

Thermal Infrared Sensor

Thermal Infrared sensors are independent of wavelength. They use heat as energy source. Thermal detectors are slow with their detection time and response time.

Fig 3.7.3.3 Infrared Sensor as Heat Sensing Device

Quantum Infrared Sensor

Quantum Infrared Sensor are dependent on wavelengths. They have high detection time and response time. These type of IR sensors require frequent cooling for precise measurement.

PIN CONFIGURATION

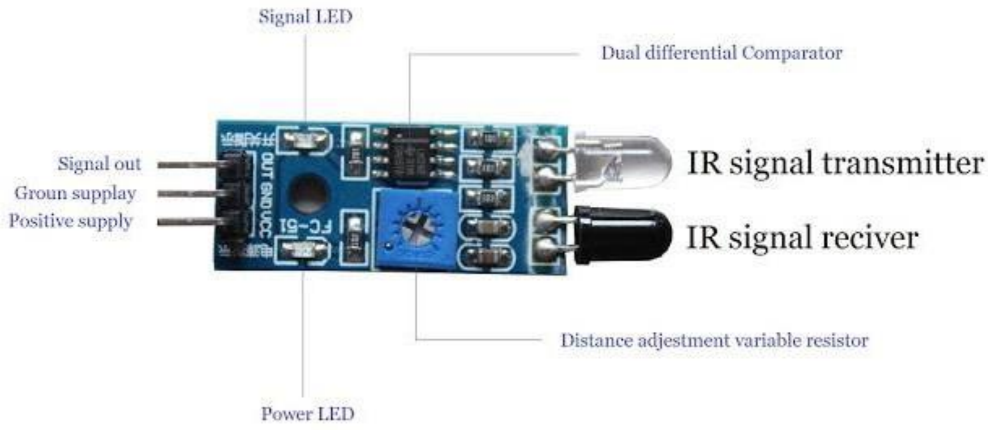

Fig 3.7.4 Pin configuration

Table 3.7.4 Pin Configuration

Pin No.	Pin Name	Description
1	VCC	Power Supply Input
2	GND	Power Supply Ground
3	OUT	Active High Output

SPECIFICATIONS

- 5VDC Operating voltage
- I/O pins are 5V and 3.3V compliant
- Range: Up to 20cm
- Adjustable Sensing range
- Built-in Ambient Light Sensor
- 20mA supply current

Applications of Infrared Sensor

- Proximity Sensor
- Item Counter
- Human Body Detection
- Gas Analyzers
- Water Analysis
- Rail Safety

L293D MOTOR DRIVER

WHAT IS L293D MOTOR DRIVER?

L293D is a typical Motor driver or Motor Driver IC which allows DC motor to drive on either direction. L293D is a 16-pin IC which can control a set of two DC motors simultaneously in any direction. It means that you can control two DC motor with a single L293D IC.

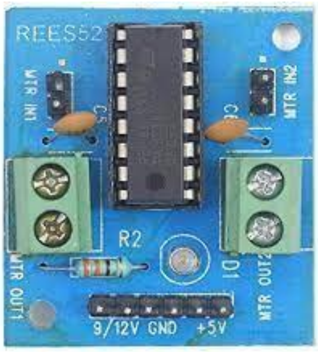

Fig 3.8.1 L293D Motor Driver

WORKING OF L293D

It works on the concept of H-bridge. It is a circuit which allows the voltage to be flown in either direction. As voltage need to change its direction for being able to rotate the motor in clockwise or anticlockwise direction, Hence H-bridge IC are ideal for driving a DC motor.

In a single L293D chip there are two h-Bridge circuit inside the IC which can rotate two dc motor independently. Due its size it is very much used in robotic application for controlling DC motors.

There are two Enable pins on l293d. Pin 1 and pin 9, for being able to drive the motor, the pin 1 and 9 need to be high. For driving the motor with left H-bridge you need to enable pin 1 to high. And for right H-Bridge you need to make the pin 9 to high. If anyone of the either pin1 or pin9 goes low then the motor in the corresponding section will suspend working. It’s like a switch.

NOTE: you can simply connect the pin16 VCC (5v) to pin 1 and pin 9 to make them high.

PIN CONFIGURATION

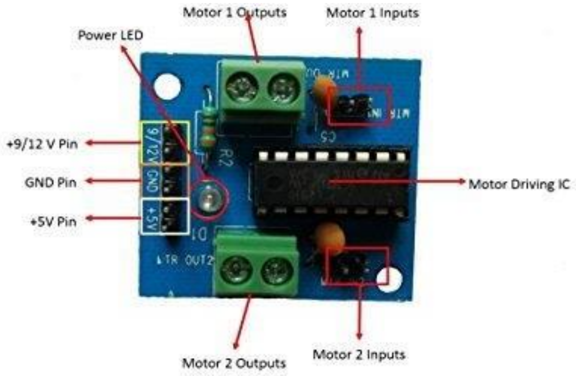

Fig 3.8.3 Pin Configuration

Table 3.8.3 L293D Pin Configuration

Pin Number	Pin Name	Description
1	Enable 1,2	This pin enables the input pin Input 1(2) and Input 2(7)
2	Input 1	Directly controls the Output 1 pin. Controlled by digital circuits
3	Output 1	Connected to one end of Motor 1
4	Ground	Ground pins are connected to ground of circuit (0V)
5	Ground	Ground pins are connected to ground of circuit (0V)
6	Output 2	Connected to another end of Motor 1
7	Input 2	Directly controls the Output 2 pin. Controlled by digital circuits
8	Vcc2 (Vs)	Connected to Voltage pin for running motors (4.5V to 36V)
9	Enable 3,4	This pin enables the input pin Input 3(10) and Input 4(15)
10	Input 3	Directly controls the Output 3 pin. Controlled by digital circuits
11	Output 3	Connected to one end of Motor 2
12	Ground	Ground pins are connected to ground of circuit (0V)
13	Ground	Ground pins are connected to ground of circuit (0V)
14	Output 4	Connected to another end of Motor 2
15	Input 4	Directly controls the Output 4 pin. Controlled by digital circuits
16	Vcc2 (Vss)	Connected to +5V to enable IC function

Where to use L293D IC

The L293D is a popular 16-Pin Motor Driver IC. As the name suggests it is mainly used to drive motors. A single L293D IC is capable of running two DC motors at the same time; also the direction of these two motors can be controlled independently. So if you have motors which has operating voltage less than 36V and operating current less than 600mA, which are to be controlled by digital circuits like Op-Amp, 555 timers, digital gates or even Micron rollers like Arduino, PIC, ARM etcthis IC will be the right choice for you.

HOW TO USE A L293D MOTOR DRIVER IC

Using this L293D motor driver IC is very simple. The IC works on the principle of Half H-Bridge, let us not go too deep into what H-Bridge means, but for now just know that H bridge is a setup which is used to run motors both in clock wise and anticlockwise direction. As said earlier this IC is capable of running two motors at the any direction at the same time.

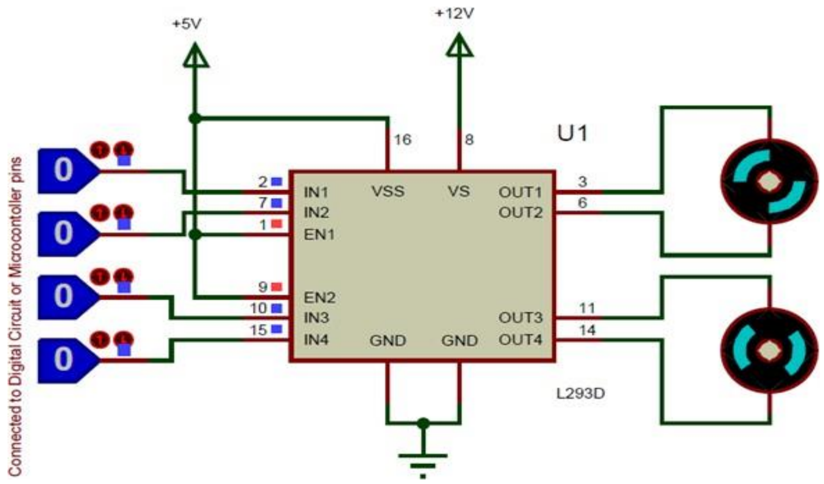

Fig 3.8.4 Motor driver IC

All the Ground pins should be grounded. There are two power pins for this IC, one is the Vss(Vcc1) which provides the voltage for the IC to work, this must be connected to +5V. The other is Vs(Vcc2) which provides voltage for the motors to run, based on the specification of your motor you can connect this pin to anywhere between 4.5V to 36V, here I have connected to +12V.

The Enable pins (Enable 1,2 and Enable 3,4) are used to Enable Input pins for Motor 1 and Motor 2 respectively. Since in most cases we will be using both the motors both the pins are held high by default by connecting to +5V supply. The input pins Input 1,2 are used to control the motor 1 and Input pins 3,4 are used to control the Motor 2. The input pins are connected to the any Digital circuit or microcontroller to control the speed and direction of the motor.

SPECIFICATIONS

- Can be used to run Two DC motors with the same IC.
- Speed and Direction control is possible
- Motor voltage Vcc2 (Vs): 4.5V to 36V
- Maximum Peak motor current: 1.2A
- Maximum Continuous Motor Current: 600mA
- Supply Voltage to Vcc1(vss): 4.5V to 7V
- Transition time: 300ns (at 5Vand 24V)
- Automatic Thermal shutdown is available
- Available in 16-pin DIP, TSSOP, SOIC packages

APPLICATIONS

- Used to drive high current Motors using Digital Circuits
- Can be used to drive Stepper motors
- High current LED’s can be driven
- Relay Driver module (Latching Relay is possible)

MOTORS

WHAT IS MOTOR?

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
- AC motor, an electric motor that is driven by alternating current

- Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
- Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction

- DC motor, an electric motor that runs on direct current electricity
- Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
- Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
- Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
- Servo motor, an electric motor that operates a servo, commonly used in robotics
- Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

TYPES OF MOTORS

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

AC Motors

The most common and simple industrial motor is the three phase AC induction motor, sometimes known as the "squirrel cage" motor. Substantial information can be found about any motor by checking its (nameplate).

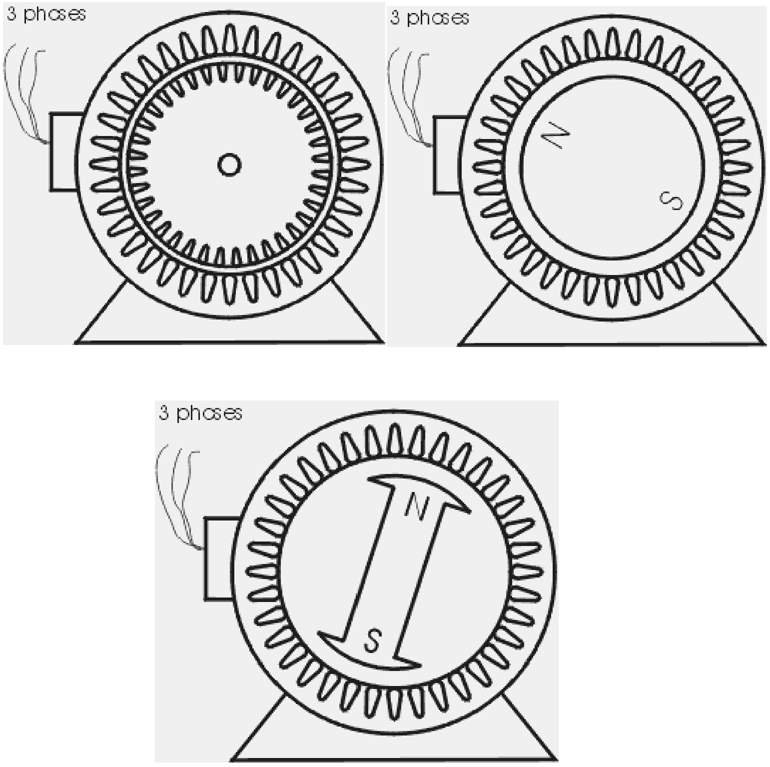

Fig 3.9.2 AC Motors

Advantages

- Simple Design
- Low Cost
- Reliable Operation
- Easily Found Replacements
- Variety of Mounting Styles
- Many Different Environmental Enclosures

Simple Design

The simple design of the AC motor -- simply a series of three windings in the exterior (stator) section with a simple rotating section (rotor). The changing field caused by the 50 or 60 Hertz AC line voltage causes the rotor to rotate around the axis of the motor.

The speed of the AC motor depends only on three variables:

1. The fixed number of winding sets (known as poles) built into the motor, which determines the motor's base speed.
2. The frequency of the AC line voltage. Variable speed drives change this frequency to change the speed of the motor.
3. The amount of torque loading on the motor, which causes slip.

Low Cost

The AC motor has the advantage of being the lowest cost motor for applications requiring more than about 1/2 hp (325 watts) of power. This is due to the simple design of the motor. For this reason, AC motors are overwhelmingly preferred for fixed speed applications in industrial applications and for commercial and domestic applications where AC line power can be easily attached. Over 90% of all motors are AC induction motors. They are found in air conditioners, washers, dryers, industrial machinery, fans, blowers, vacuum cleaners, and many, many other applications.

Reliable Operation

The simple design of the AC motor results in extremely reliable, low maintenance operation. Unlike the DC motor, there are no brushes to replace. If run in the appropriate environment for its enclosure, the AC motor can expect to need new bearings after several years of operation. If the application is well designed, an AC motor may not need new bearings for more than a decade.

Easily Found Replacements

The wide use of the AC motor has resulted in easily found replacements. Many manufacturers adhere to either European (metric) or American (NEMA) standards. (For Replacement Motors)

Variety of Mounting Styles

AC Motors are available in many different mounting styles such as:

- Foot Mount
- C-Face
- Large Flange
- Vertical
- Specialty

DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjunction with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparable AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

Easy to control torque

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

Simple, cheap drive design

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance trade-offs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirement's).

Disadvantages

- Expensive to produce
- Can't reliably control at lowest speeds
- Physically larger
- High maintenance
- Dust

WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.

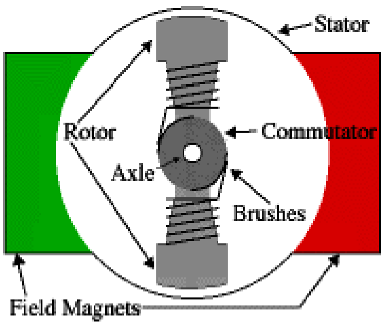

Fig 3.9.3.1 Working od DC motor

Principle

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously.

When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that Beamer will see), the external magnetic field is produced by high-strength permanent magnets. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator. You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).

Construction and Working

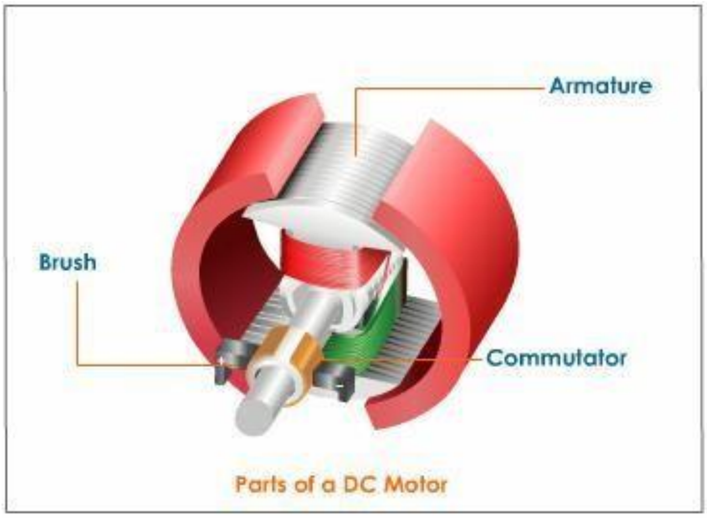

Fig 3.9.3.2 Parts of DC motor

Parts of a DC Motor

Armature

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

Commutator

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.

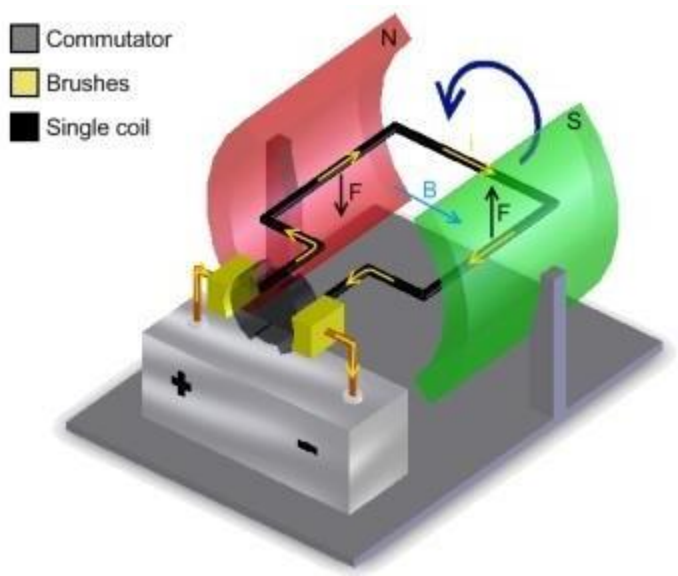

Fig 3.9.4 DC Motor

Brushes

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

PARAMETRS OF THE DC MOTRS

1. Direction of rotation
2. Motor Speed
3. Motor Torque
4. Motor Start and Stop

Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.

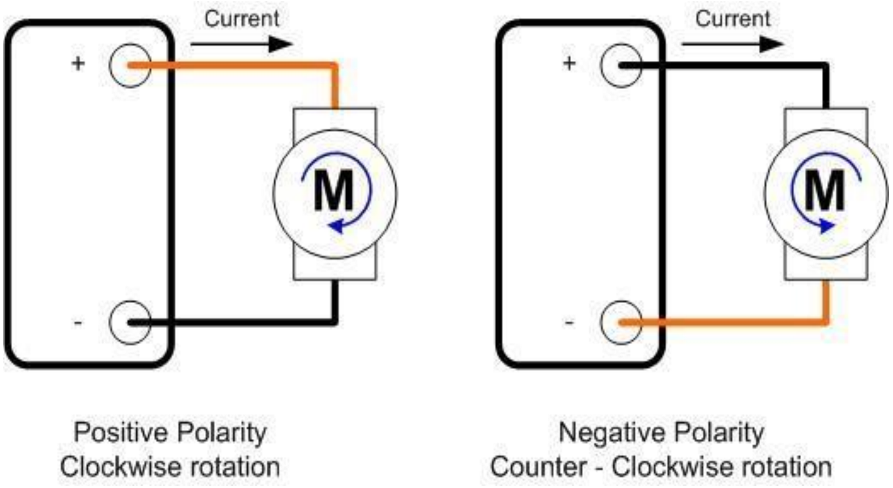

Fig 3.9.5.1 Direction of rotation

DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.
- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

DC Motor Speed

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as atract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attaction will try to take place. As a result, motor speed is directly proportional to applied voltage.

Motor Speed Curve

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will simply not move. This is because the magnetic field strength is not enough to overcome friction. Once friction is overcome, motor speed will start to increase as voltage increase.

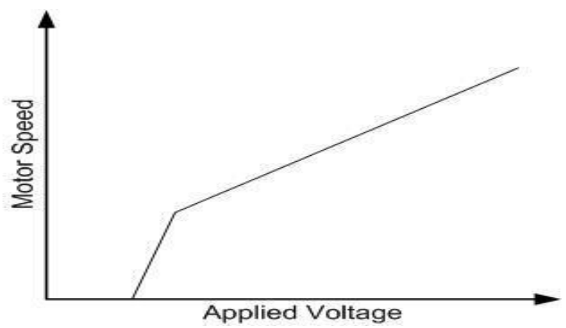

Fig 3.9.5.2 Motor speed curve

Motor Torque

In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.

Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy can not be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

$P = IV$

Where P is power, I is motor current and V is motor voltage

Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current. As you increase load (or torque requirements) current must also increase.

Motor Loading

One aspect about DC motors which we must not forget is that loading or increase of torque can not be infinite as there is a point in which the motor simply can not move. When this happens, we call this loading "Stalling Torque". At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

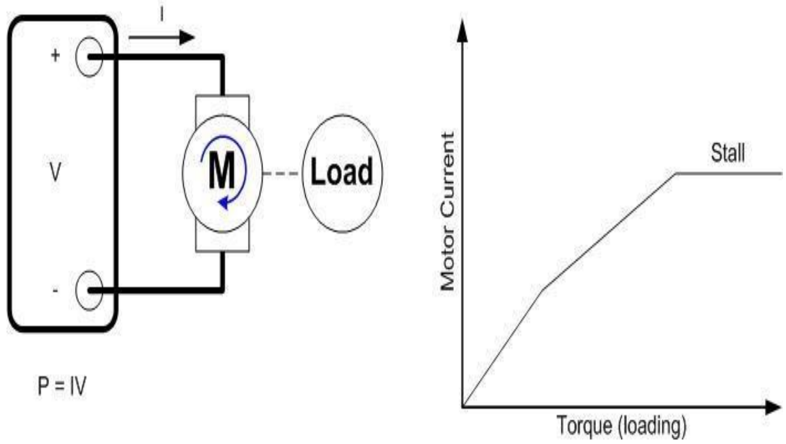

Fig 3.9.5.3 Motor loading

Motor Start and Stop

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

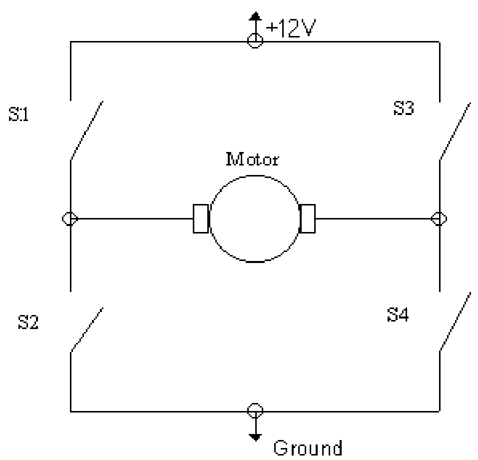
Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current can not change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.

Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.

Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs. The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back EMF is directly proportional to speed, making Back EMF = 0, also means making speed = 0.

MOTORDRIVER CIRCUIT

The name "H-Bridge" is derived from the actual shape of the switching circuit which control the motion of the motor. It is also known as "Full Bridge". Basically, there are four switching elements in the H-Bridge as shown in the figure below.



H-Bridge Switch

Switches Closed	Motor
S1 S3	Off
S2 S4	Off
S1 S4	Forward
S3 S2	Reverse

Fig 3.10.1 H bridge

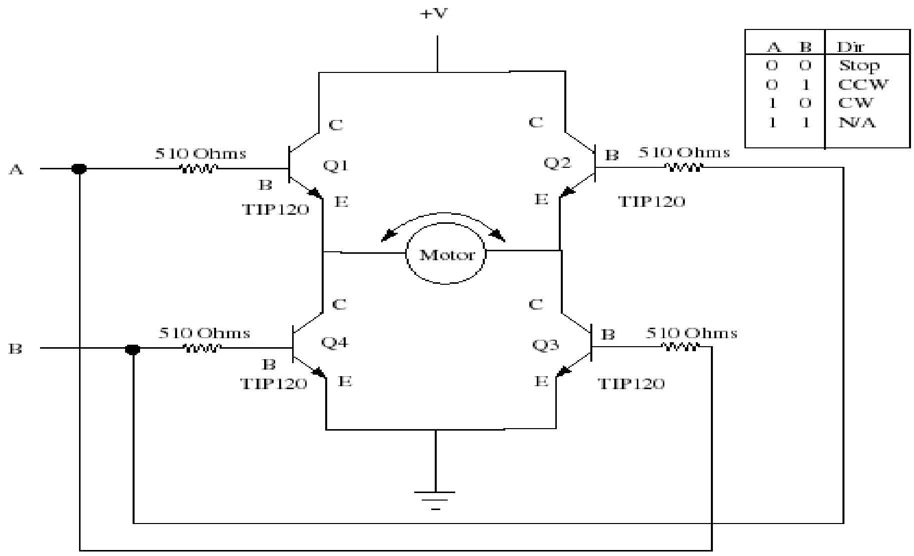


Fig 3.10.2 circuit diagram of motor driver

As you can see in the figure above there are four switching elements named as "High side left", "High side right", "Low side right", "Low side left". When these switches are turned on in pairs motor changes its direction accordingly. Like, if we switch on High side left and Low side right then motor rotate in forward direction, as current flows from Power supply through the motor coil goes to ground via switch low side right. This is shown in the figure below.

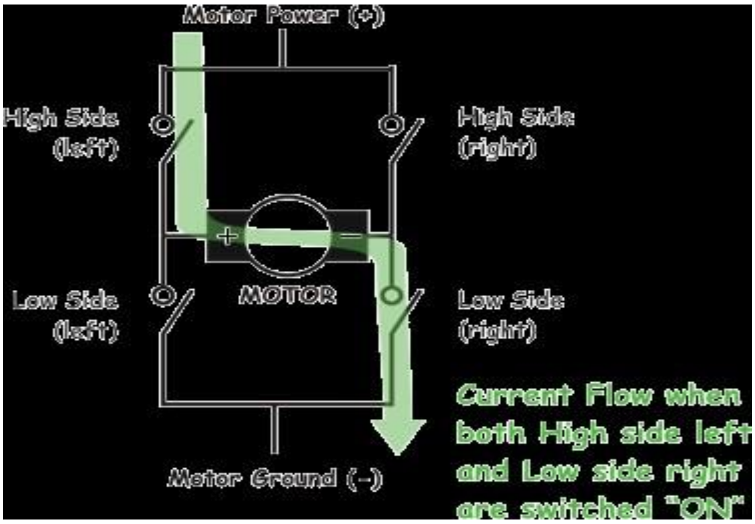

Fig 3.10.3 Working of motor driver

Similarly, when you switch on low side left and high side right, the current flows in opposite direction and motor rotates in backward direction.

This is the basic working of H-Bridge. We can also make a small truth table according to the switching of H-Bridge explained above.

Truth Table				
High Left	High Right	Low Left	Low Right	Description
On	Off	Off	On	Motor runs clockwise
Off	On	On	Off	Motor runs anti-clockwise
On	On	Off	Off	Motor stops or decelerates
Off	Off	On	On	Motor stops or decelerates

Table 3.10 Truth table of motor driver

As already said, H-bridge can be made with the help of transistors aswell as MOSFETs, the only thing is the power handling capacity of the circuit.If motors are needed to run with high current then lot of dissipation is there.

So head sinks are needed to cool the circuit.

CHAPTER 4

EMBEDDED SYSTEMS

EMBEDDED SYSTEMS

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

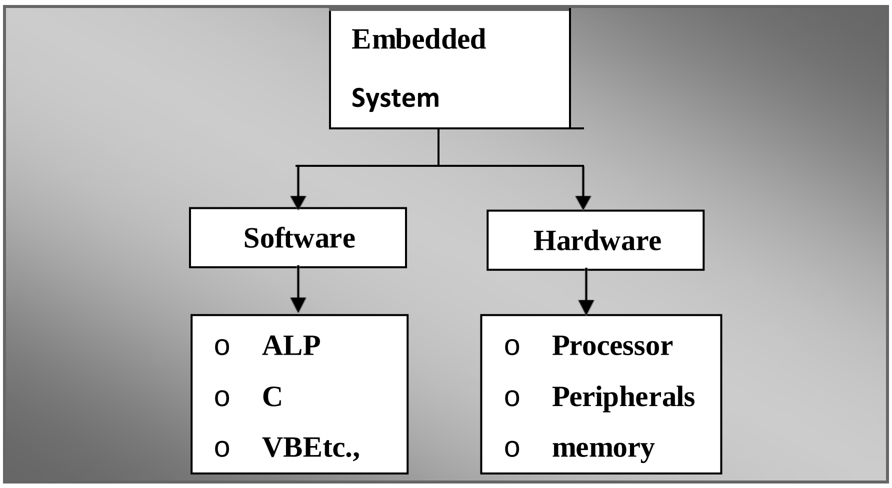

Fig 4.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

APPLICATIONS OF EMBEDDED SYSTEMS

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

MICRO PROCESSOR (µp)

WHAT IS MICRO PROCESSOR?

A silicon chip that contains a CPU, In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most work stations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection system for automobiles.

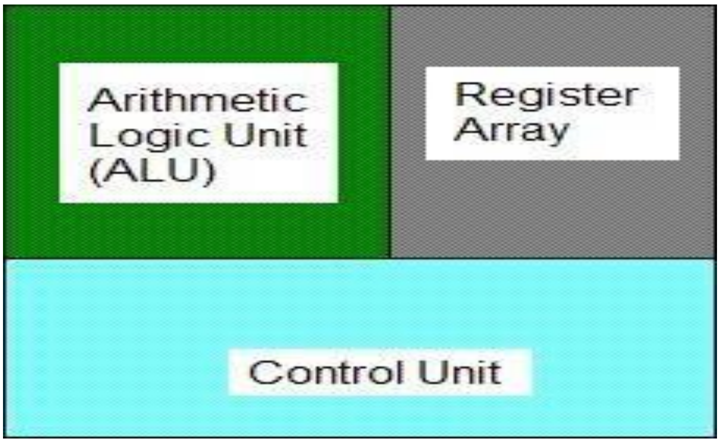

Fig.4.3.1 Three basic elements of a microprocessor

WORKING OF MICRO PROCESSOR

A microprocessor accepts binary data as input, processes that data, and then provides output based on the instructions stored in the memory. The data is processed using the microprocessor's ALU (arithmetical and logical unit), control unit, and a register array. The register array processes the data via a number of registers that act as temporary fast access memory locations. The flow of instructions and data through the system is managed by the control unit.

MICRO CONTROLLER

WHAT IS MICRO CONTROLLER?

A microcontroller is a compact integrated circuit designed to govern a specific operation in an embedded system. A typical microcontroller includes a processor, memory and input/output (I/O) peripherals on a single chip.

Sometimes referred to as an embedded controller or microcontroller unit (MCU), microcontrollers are found in vehicles, robots, office machines, medical devices, mobile radio transceivers, vending machines and home appliances, among other devices. They are essentially simple miniature personal computers (PCs) designed to control small features of a larger component, without a complex front-end operating system (OS).

WORKING OF MICRO CONTROLLER

A microcontroller is embedded inside of a system to control a singular function in a device. It does this by interpreting data it receives from its I/O peripherals using its central processor. The temporary information that the microcontroller receives is stored in its data memory, where the processor accesses it and uses instructions stored in its program memory to decipher and apply the incoming data. It then uses its I/O peripherals to communicate and enact the appropriate action.

Microcontrollers are used in a wide array of systems and devices. Devices often utilize multiple microcontrollers that work together within the device to handle their respective tasks.

For example, a car might have many microcontrollers that control various individual systems within, such as the anti-lock braking system, traction control, fuel injection or suspension control. All the microcontrollers communicate with each other to inform the correct actions. Some might communicate with a more complex central computer within the car, and others might only communicate with other microcontrollers. They send and receive data using their I/O peripherals and process that data to perform their designated tasks.

DIGITAL SIGNAL PROCESSORS

A digital signal processor (DSP) is a specialized microprocessor chip, with its architecture optimized for the operational needs of digital signal processing. DSPs are fabricated on MOS integrated circuit chips. They are widely used in audio signal processing, telecommunications, digital image processing, radar, sonar and speech recognition systems, and in common consumer electronic devices such as mobile phones, disk drives and high-definition television(HDTV) products.

The goal of a DSP is usually to measure, filter or compress continuous real-world Analog signals. Most general-purpose microprocessors can also execute digital signal processing algorithms successfully, but may not be able to keep up with such processing continuously in real-time. Also, dedicated DSPs usually have better power efficiency, thus they are more suitable in portable devices such as mobile phones because of power consumption constraints. DSPs often use special memory architectures that are able to fetch multiple data or instructions at the same time. DSPs often also implement data compression technology, with the discrete cosine transform(DCT) in particular being a widely used compression technology in DSPs.

APPLICATION SPECIFIC INTEGRATED CIRCUITS(ASIC)

An application-specific integrated circuit (ASIC) is an integrated circuit(IC) chip customized for a particular use, rather than intended for general-purpose use. For example, a chip designed to run in a digital voice recorder or a high-efficiency bit coin miner is an ASIC. Application-specific standard product(ASSP) chips are intermediate between ASICs and industry standard integrated circuits like the7400 series or the4000 series. ASIC chips are typically fabricated using metal-oxide semiconductor(MOS) technology, as MOS integrated circuit chips.

HARVARD ARCHITECTURE

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark Irelay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

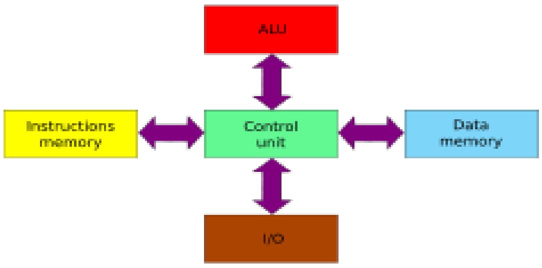

Fig.4.7 Harvard Architecture

USES OF THE HARVARD ARCHITECTURE

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where trade-offs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

Digital signal processors(DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. TexasInstrumentsTMS320C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARMCortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

VON-NEUMANN ARCHITECTURE:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit(CPU) and a single separate storage structure("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture. The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

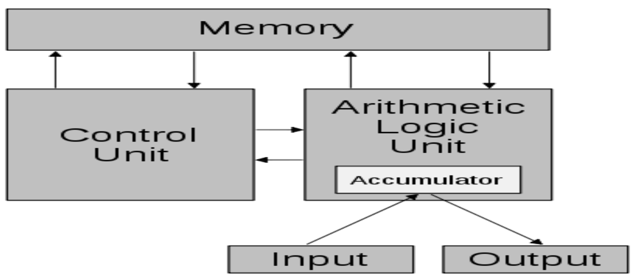

Fig4.7.2 Schematic of the Von-Neumann Architecture

SOFTWARE EXPLANATION

SOFTWARE REQUIREMENTS:

- Arduino software
- Programming language
- Proteus simulation

ARDUINO SOFTWARE

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments.

A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to- use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

Open source and extensible hardware - The plans of the Arduino boards are published under

- a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money •Getting Started with Arduino and Genuine products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

- Download the Arduino Software (IDE)
- Proceed with board specific instructions.

HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE)

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

INSTALLATION

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.8.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.4.8.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

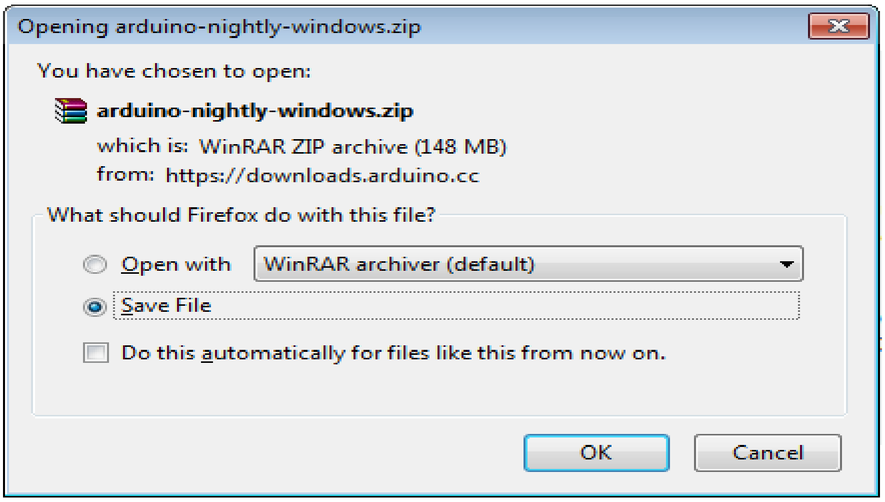

Fig.4.8.4.3 Download Arduino IDE Software Step

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

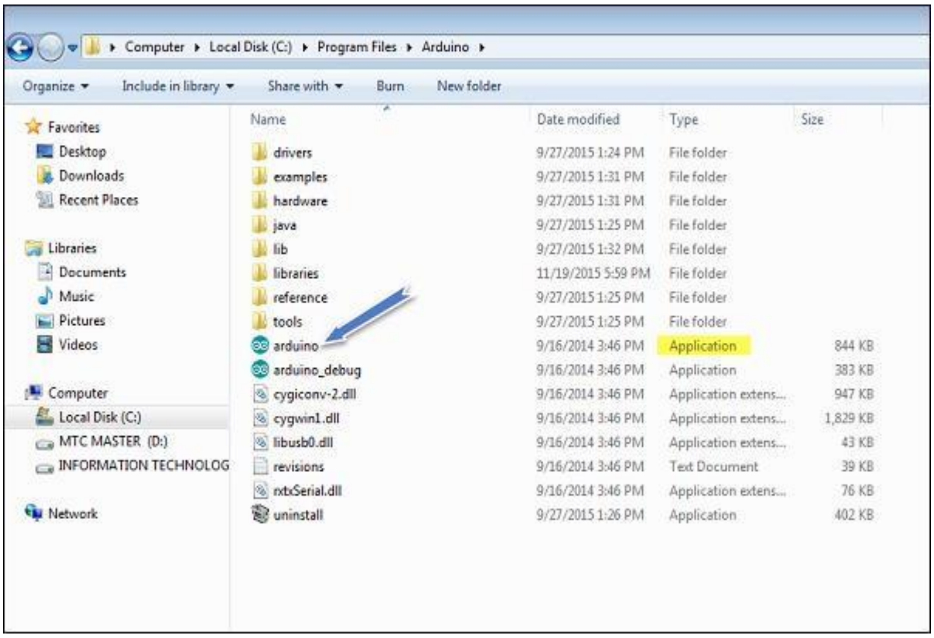

Fig.4.8.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

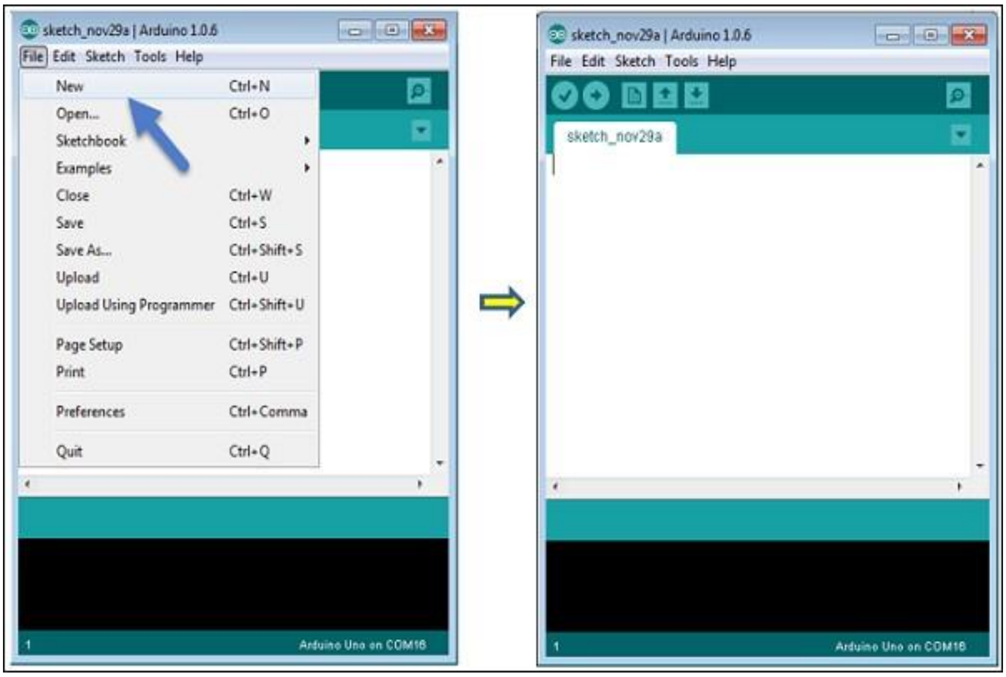

Fig.4.8.4.5 Open your first project

To open an existing project example, select File → Example → Basics → Blink.

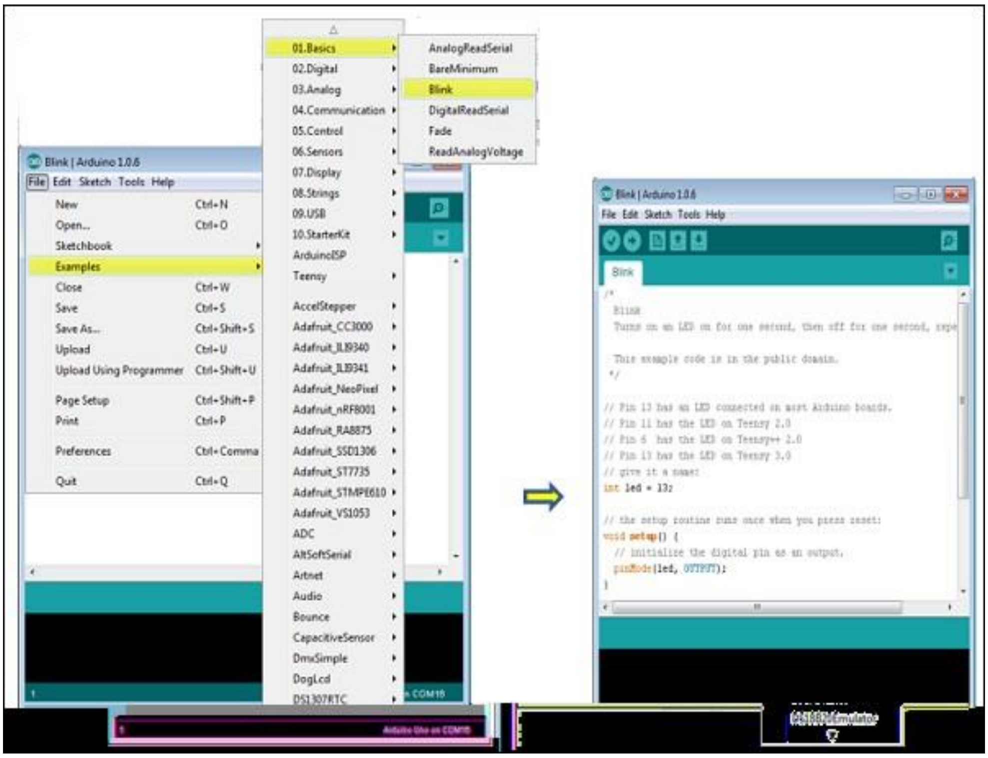

Fig.4.8.4.6 Open your first program

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

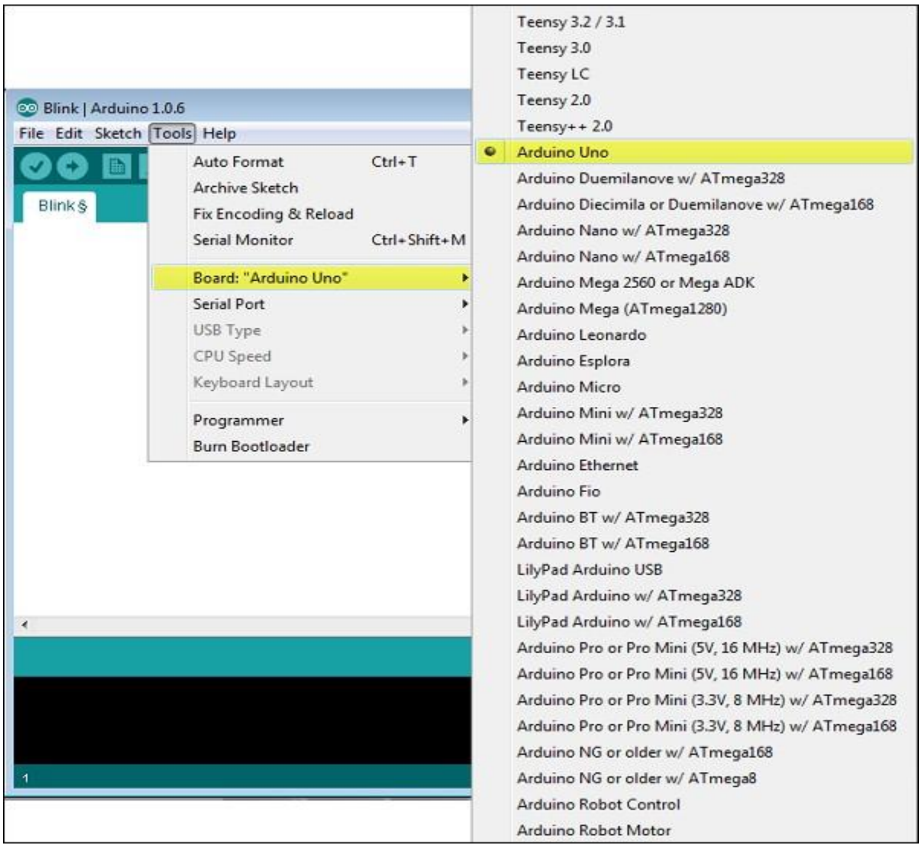

Fig.4.8.4.7 Select your Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

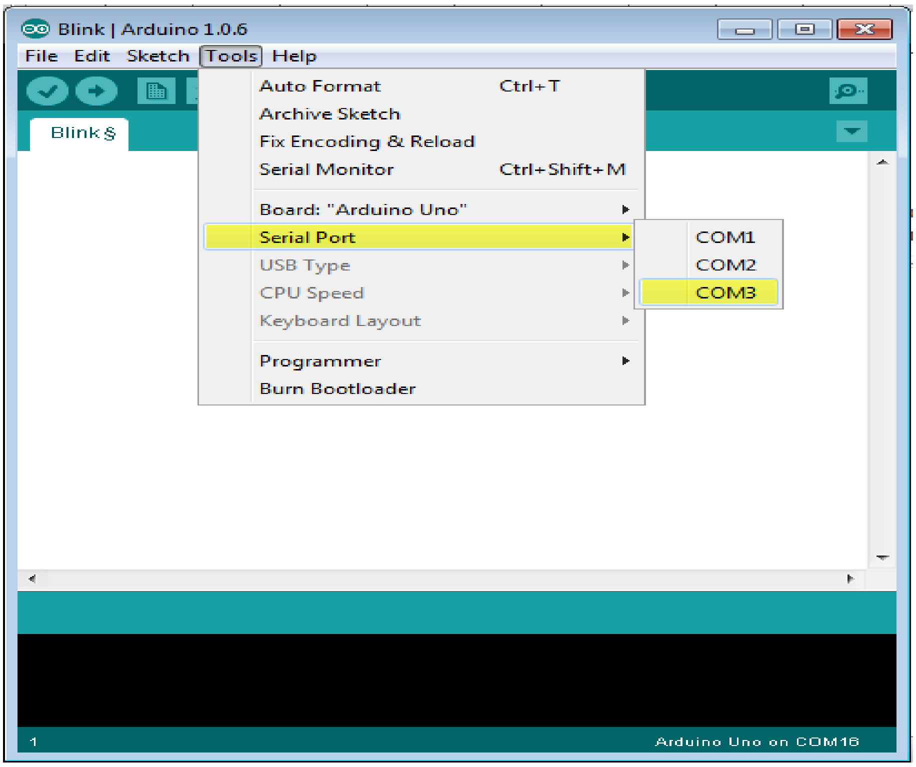

Fig.4.8.4.8 Select your serial port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

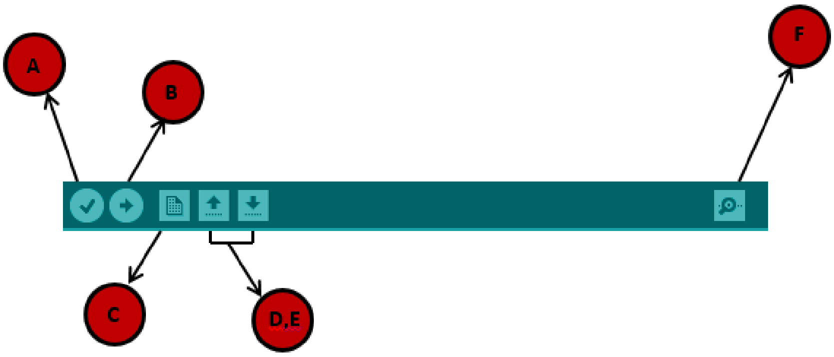

Fig.4.8.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

CONNECTING A BATTERY

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 fromwww.jameco.com.Here is what this looks like.

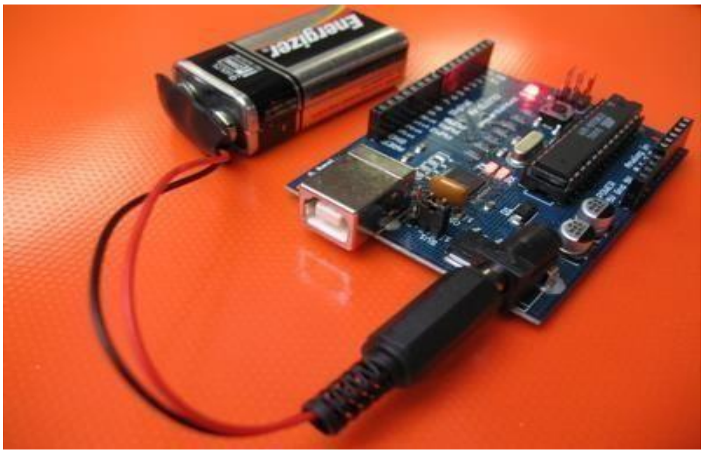

Fig.4.8.5.1 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC.

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi- colons appear at the end of command lines.

```
void setup()
{
  Serial.begin(9600);
  Serial.println("Hello World");
}
void loop() {}
```

Fig.4.8.5.2 Example Program

MC PROGRAMMING LANGUAGE: EMBEDDED C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc.

are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

PROTEUS

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

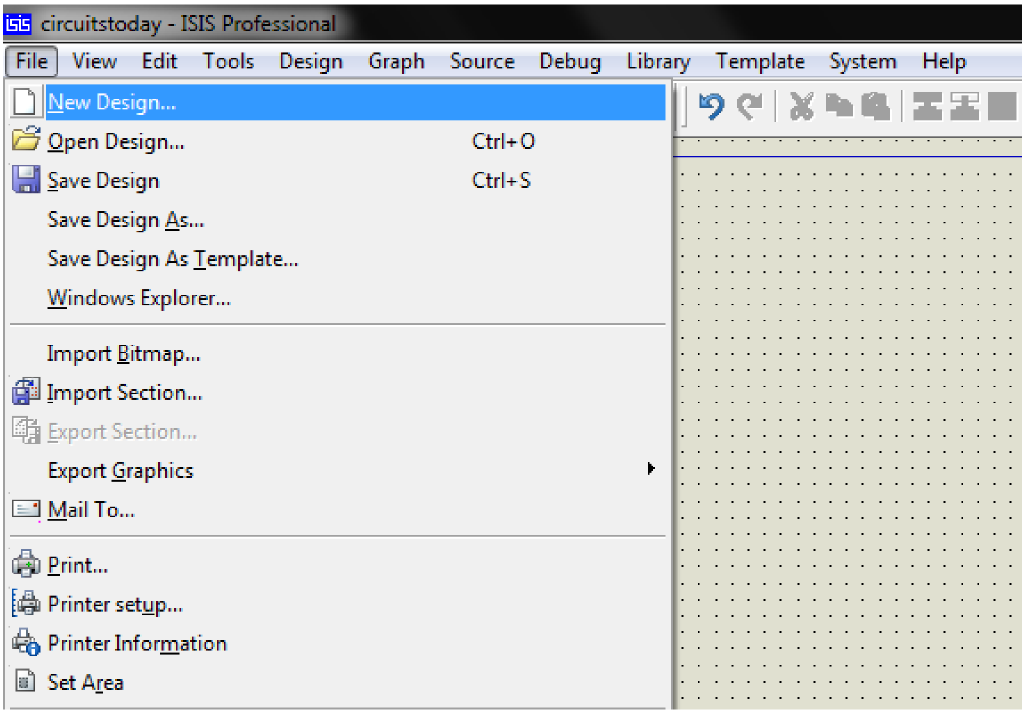

Fig 4.10.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

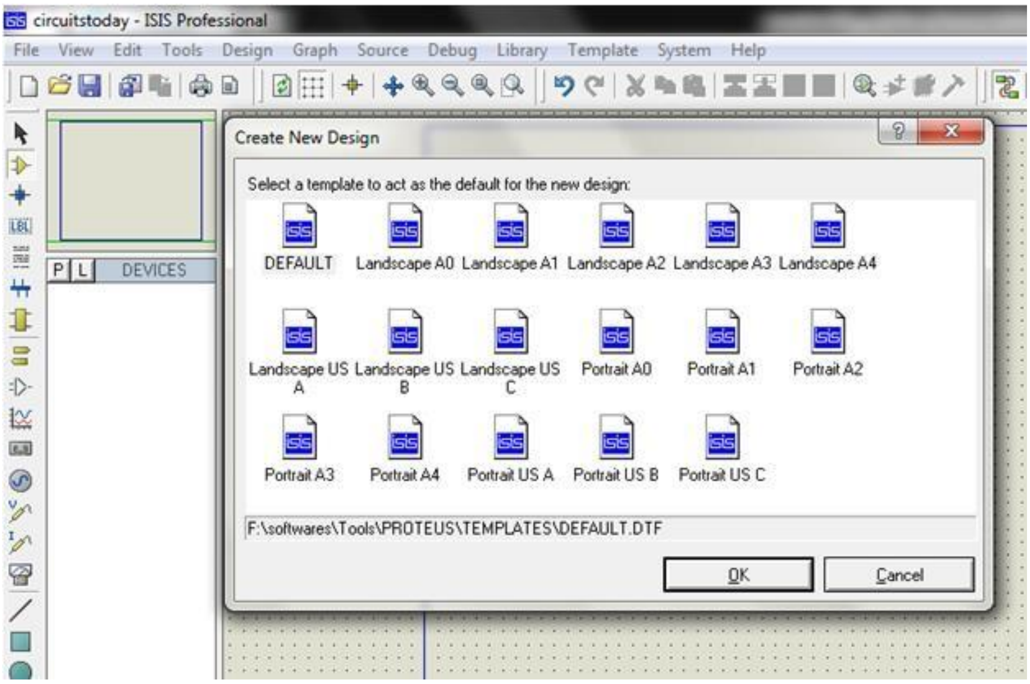

Fig 4.10.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

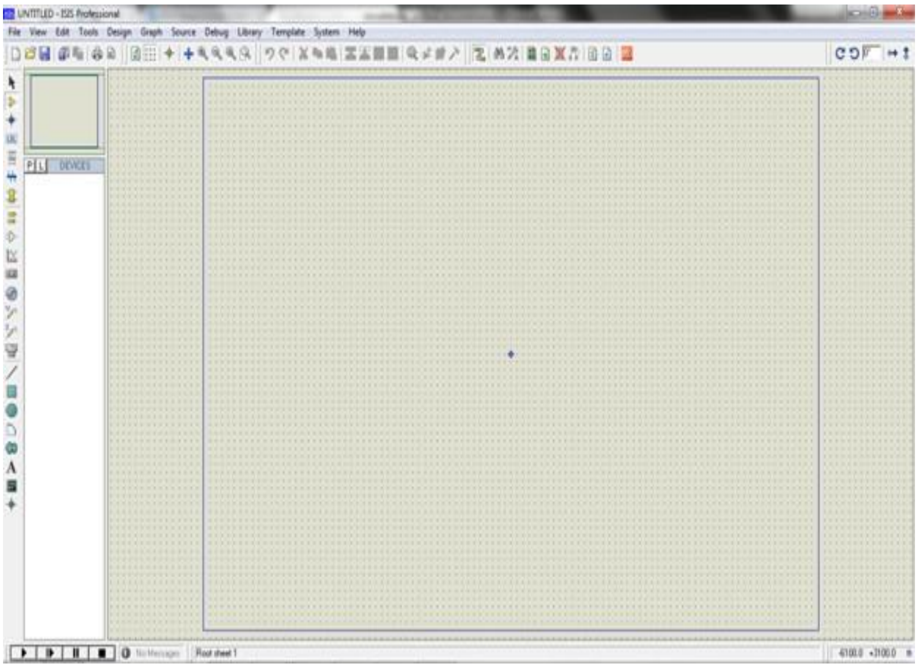

Fig 4.10.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

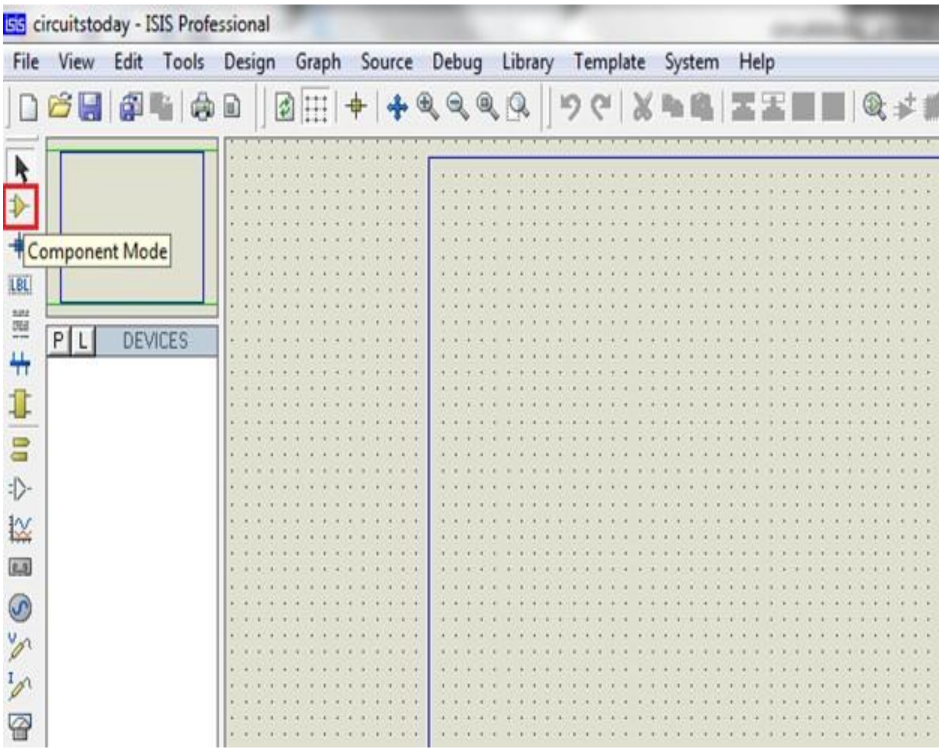

Fig4.10.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

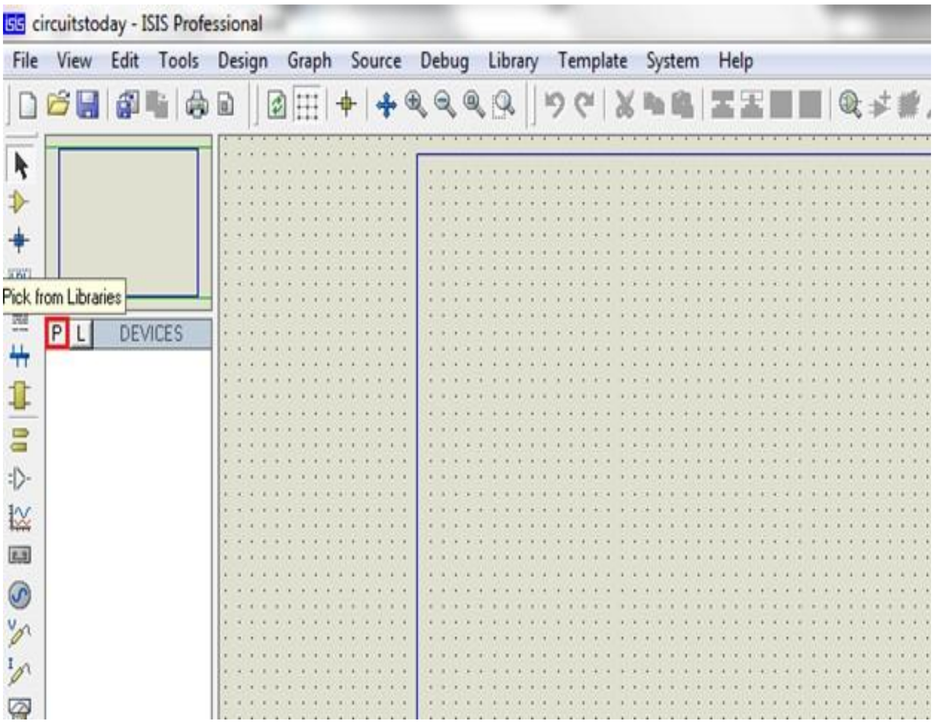

Fig 4.10.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

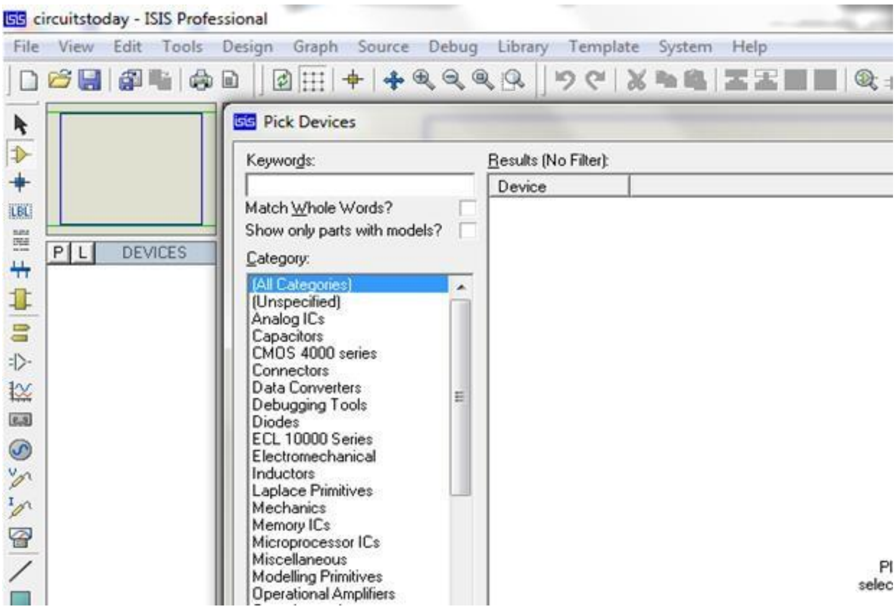

Fig 4.10.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

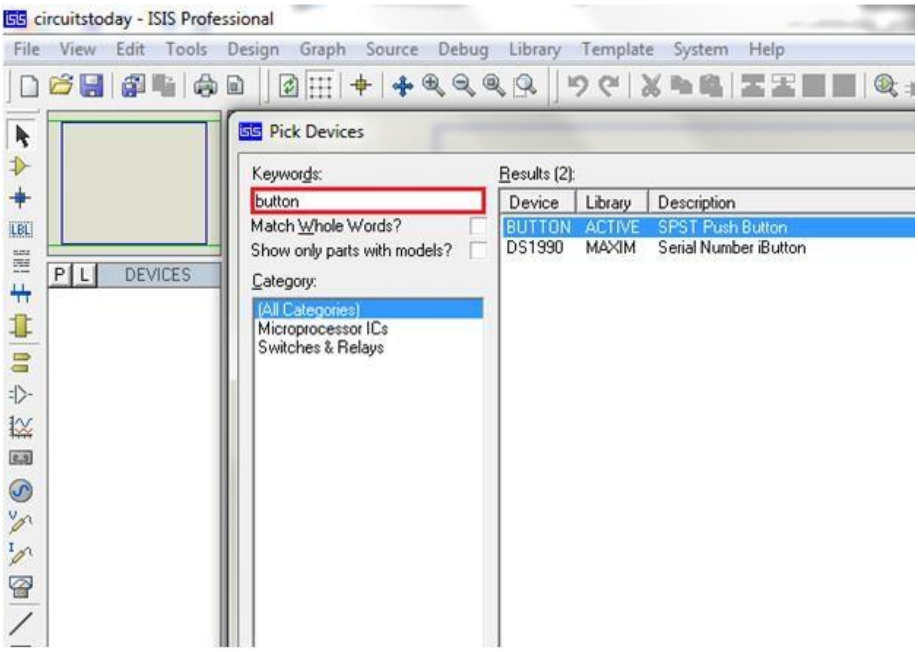

Fig 4.10.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

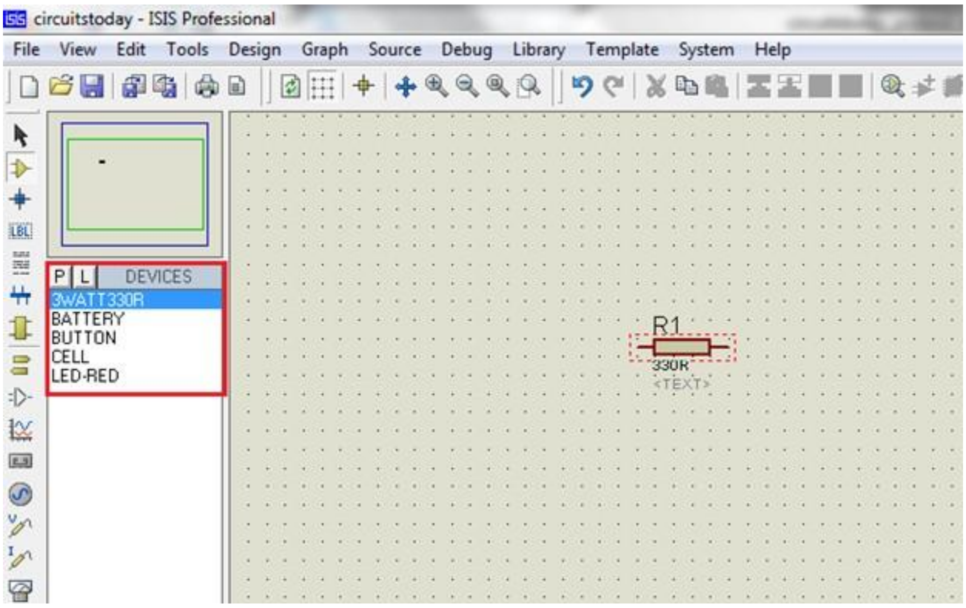

Fig 4.10.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

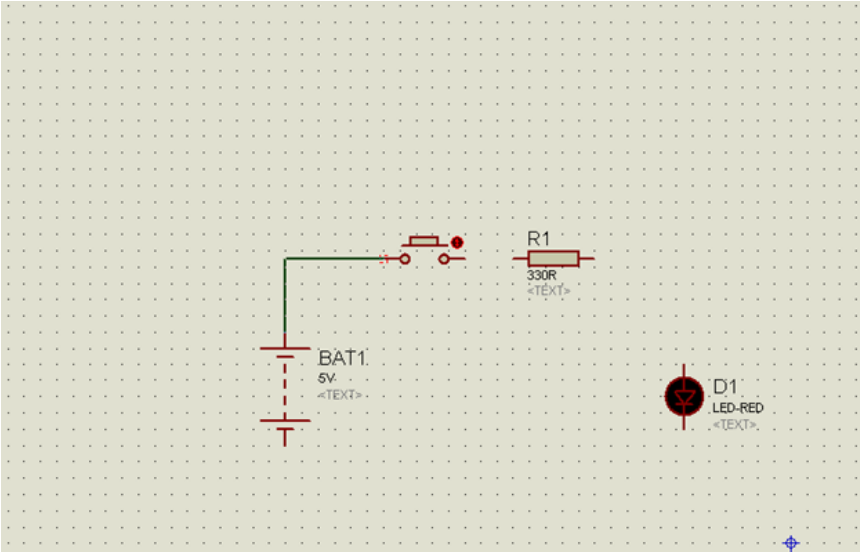

Fig 4.10.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

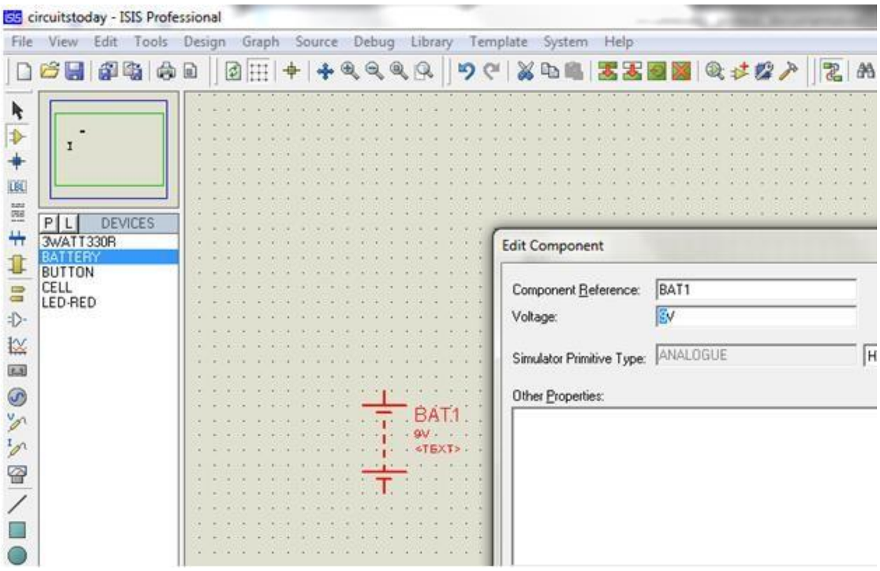

Fig 4.10.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

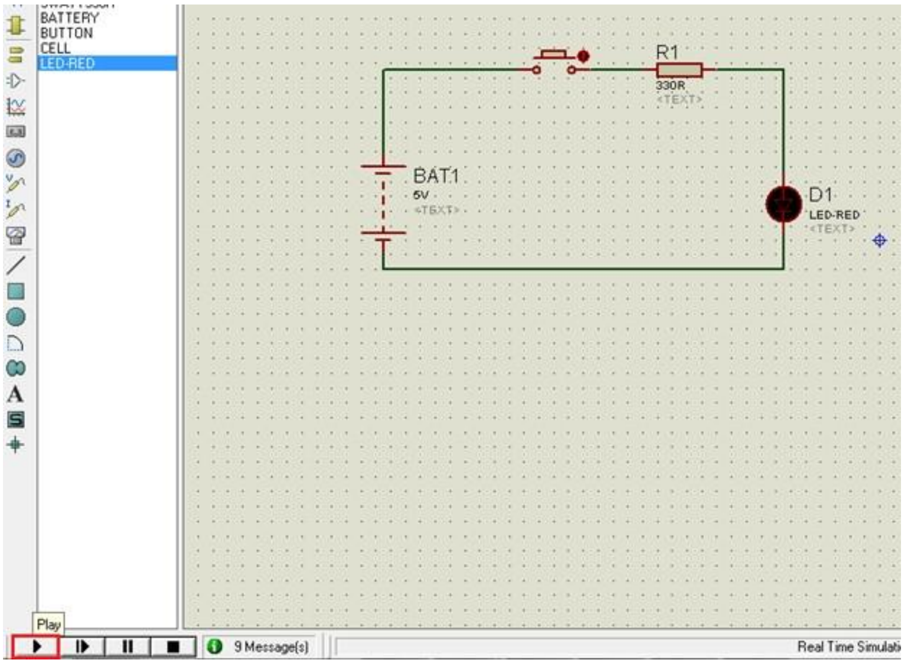

Fig 4.10.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

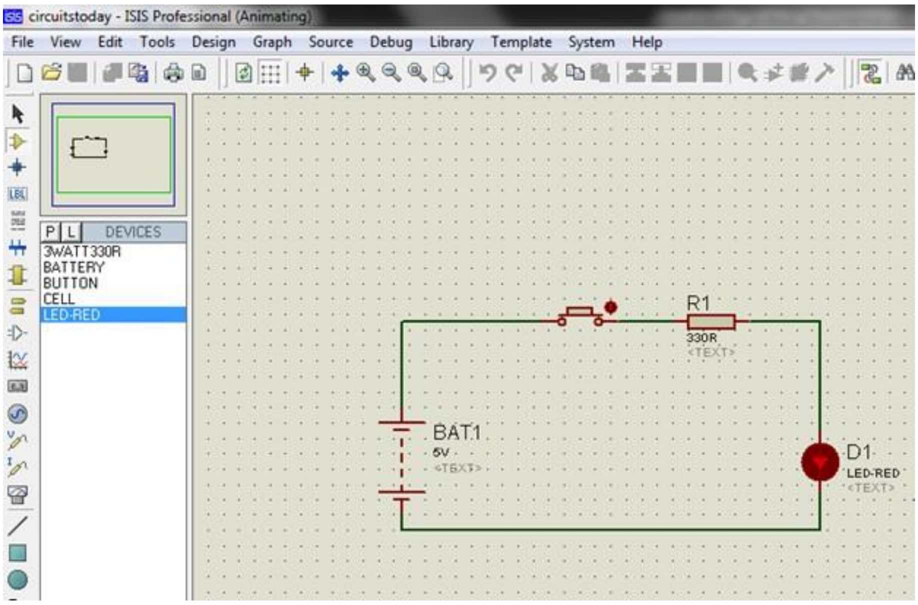

Fig 4.10.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

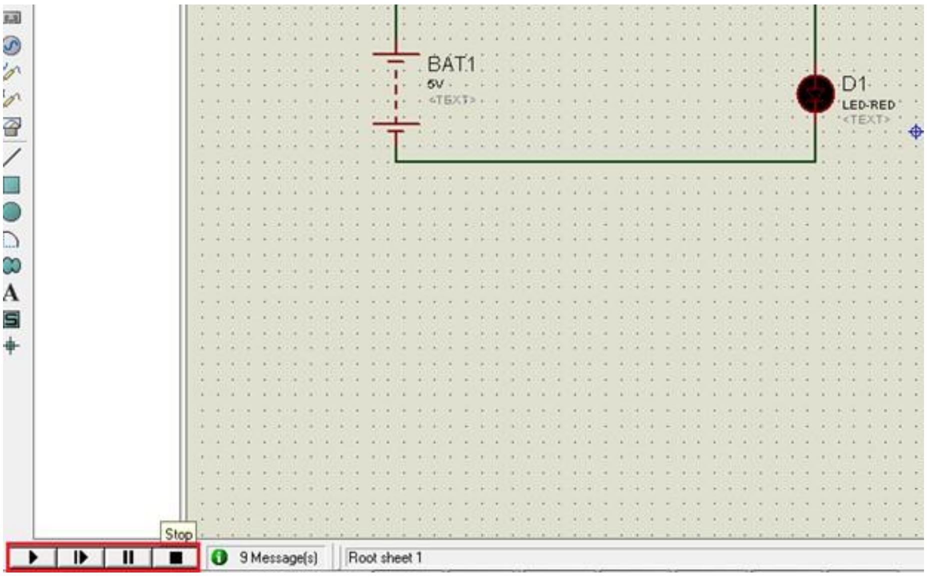

Fig 4.10.13 Simulation Step-Pause-Stop Buttons

Telnet is an application protocol used on the Internet or local area network to provide a bidirectional interactive text-oriented communication facility using a virtual terminal connection. User data is interspersed in-band with Telnet control information in an 8-bit byte oriented data connection over the Transmission Control Protocol (TCP).

Telnet was developed in 1969 beginning with RFC 15, extended in RFC 855, and standardized as Internet Engineering Task Force (IETF) Internet Standard STD 8, one of the first Internet standards. The name stands for "**teletype network**".

Historically, Telnet provided access to a command-line interface on a remote host. However, because of serious security concerns when using Telnet over an open network such as the Internet, its use for this purpose has waned significantly in favor of SSH.

CHAPTER 5

PROJECT TESTING

SOFTWARE TESTING

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

PROJECT CODE

IMPLEMENTATION OF

CODE:

```
#include<LiquidCrystal.h>
#include<SoftwareSerial.h>
LiquidCrystal
lcd(13,12,11,10,9,8);

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

CONCLUSION

Despite railway is the country's prime mode of transportation, the Indian Railways have to contended with doubtful safety records. By the usage of a smart way of fault detection in railway tracks, this will have a remarkable have an effect on the protection of the tracks which will assist in stopping train accidents to a very large extent. The regions where manual assessment is beyond the realm of imagination, as, in profound coal mine shafts, mountain areas, and thick woodland locales can be effectively done utilizing this framework. This system is placed on the trains so that every area gets monitored and along with the rescue team the driver also gets a notification so he would be able to make quick decisions due to which many lives would be saved. This will help in the support for checking the state of the rail tracks with no mistakes and along these lines keeping up the tracks in great condition. So, the maintenance of the tracks is easier. It also avoiding train mishaps to a very large extent.

FUTURE ENHANCEMENT

In the future, the proposed system will also be connected to networking & communication device. So, if any fault is detected the system will automatically broadcast the location and type of fault to every train coming on that route. If the broadcast is done, then the other trains can be diverted or blocked off (Stopped) to avoid any inconvenience. Along with it, the system will conjointly use deflectors, so that if there's any high curvature track then the deflectors can transmit the waves in keeping with the curve. The main objective of the system is to provide cost effective railway track crack detection system with greater accuracy and High speed information transferring after crack detection. The detected crack will be get updated through GPS and GSM.

CERTIFICATE

This is to certify that the major-project work entitled **"ROBOTIC VEHICLE CONTROLLED BY HAND GESTURE USING ARDUINO**" is a bonafide work carried out by **Sadam Veekshith (17K81A04A8), Perika Akanksha (17K81A04A3), Pote Akhil Kumar (17K81A04A4)** in partial fulfillment of the requirements for the degree of **Bachelor of Technology in Electronics & Communication Engineering** by the Jawaharlal Nehru Technological University, Hyderabad during the academic year 2020-21.

The results embodied in this report have not been submitted to any other University or Institution for the award of any degree.

INTERNAL GUIDE	**HEAD OF THE DEPARTMENT**
Ms. P .Pushpa	Dr. B. Hari Krishna,
Assistant professor.	Professor
Department of ECE	

ACKNOWLEDGEMENT

We sincerely thank the management of our college **St. MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work.

We derive our great pleasure in expressing our sincere gratitude to our principal **Dr.P. Santosh Kumar Patra** for his timely suggestions, which helped us to complete the project work successfully.
It is the very auspicious moment we would like to express our gratitude to **Dr. B. Hari Krishna**,Head of the Department, ECE for his consistent encouragement during the progress of this project.

We take it as a privilege to thank our overall project coordinator **Dr. A. Anand**,Professor, department of ECE for the ideas that led to complete the project work and we also thank them for their continuous guidance, support and unfailing patience, throughout the course of this work.

We sincerely thank to our project coordinator **Mr. K. Karthik,** Assistant professor**,** Department of ECE for guidance and encouragement in carrying out this project work.

We sincerely thank to our project internal guide **Ms. P. Pushpa**, assistant professor, Department of ECE for her guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project CoordinatorsDr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

Robotic vehicle controlled by the hand movement mainly benefits the disabled person, as those person with the hand gesture moves to the direction they Want to go without pressing any Axis. The circuit is the same as that of the old post and there is only a slight change in circuit, here we need to program the circuit. So I will be using an Arduino as the programming platform. To recognize the gestures made I will be using an accelerometer sensor. This system includes a glove which has a receiver data which will be mounted on the top with Atmega microcontroller interfaced to the accelerometer and it is supposed to be worn by the user while using this machine. The circuit on the vehicle includes WIFI(esp8266) and Driver IC to operate the motors. The commands that are received by the IC on the circuit are sent to the wifi which forwards the command to the local network application. The command from application wifi then gets transmitted to the Arduino microcontroller which decodes the command and makes the vehicle move in the direction specified by the user.

CHAPTER-1
INTRODUCTION

CHAPTER-1

1.Introduction:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system.

The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip"), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware.

1.1Block Diagram of Embedded Systems:

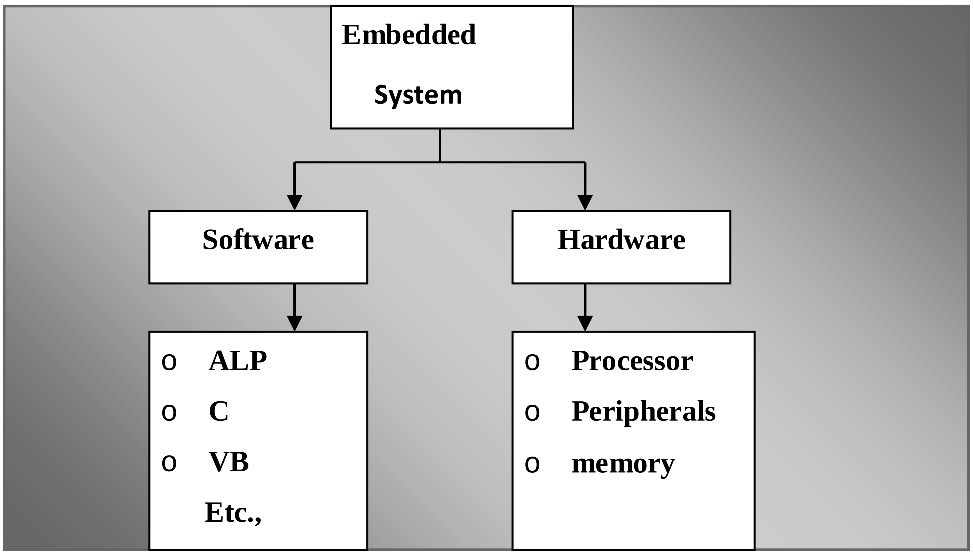

Fig.1.1: Block Diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

1.2 Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems.

1.3 Micro Processor(µp):

A siliconchip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digitaldevices, from clock radios to fuel-injection systems for automobiles.

1.3.1 Processors are classified into four types like:

- ➢ Micro Processor (μp)
- ➢ Micro controller (μc)
- ➢ Digital Signal Processor (DSP)
- ➢ Application Specific Integrated Circuits (ASIC)

1.4 Three Basic Elements of a Microprocessor:

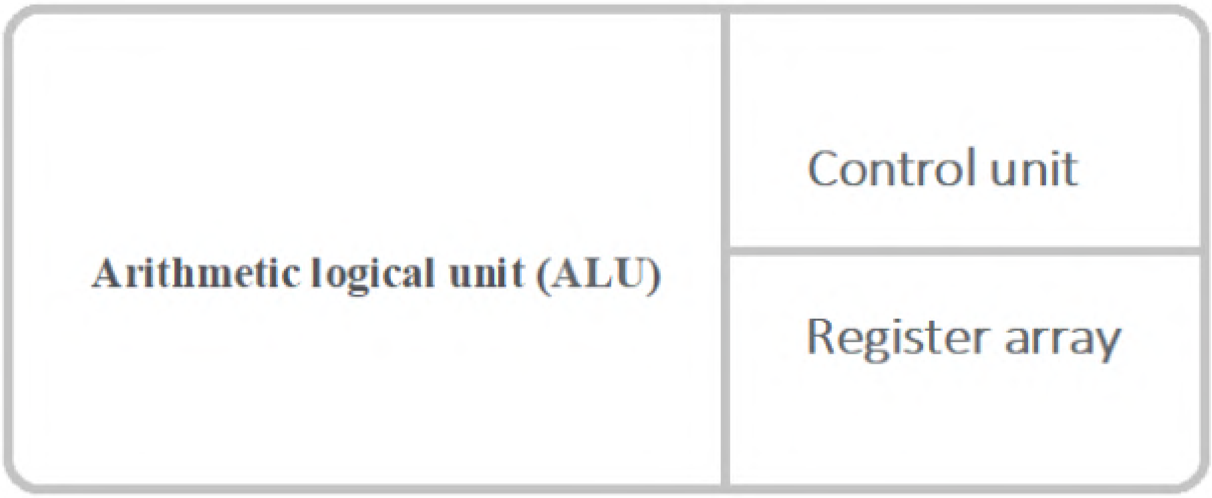

Fig.1.2: Three Basic Elements of a Microprocessor.

1.5 Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not bootitself.

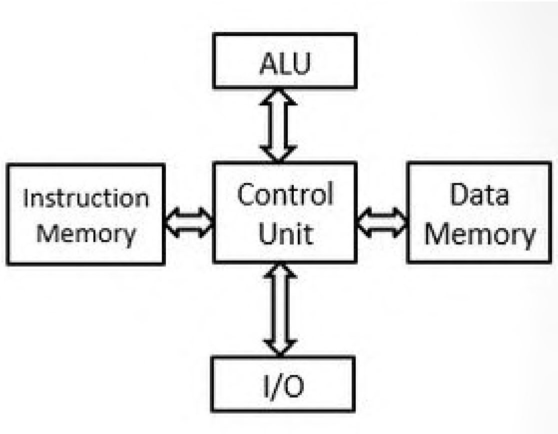

Fig.1.3: Harvard Architecture.

1.5.1 Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

1.5.2 Von-Neumann Architecture:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientistJohn von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

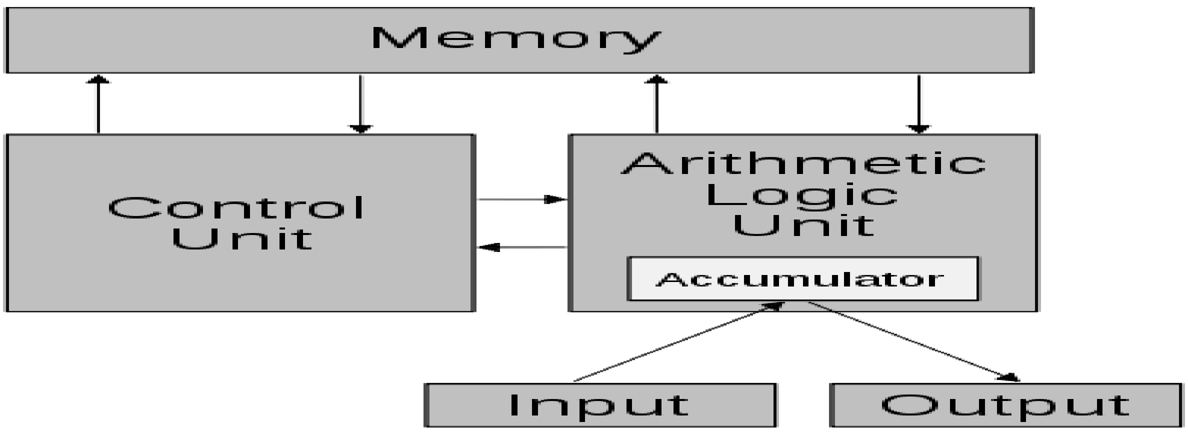

Fig.1.4: Schematic of the Von-Neumann Architecture.

1.6 Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

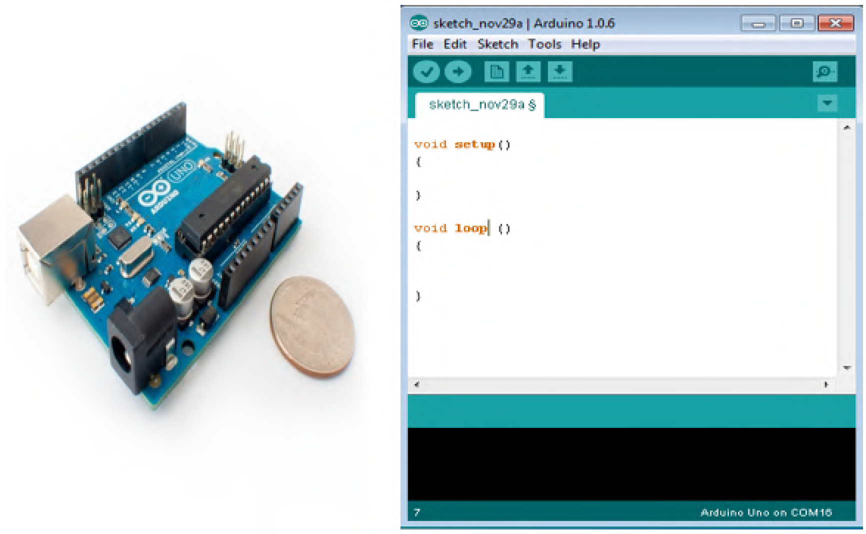

Fig 1.5 Arduino Uno and IDE.

1.6.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

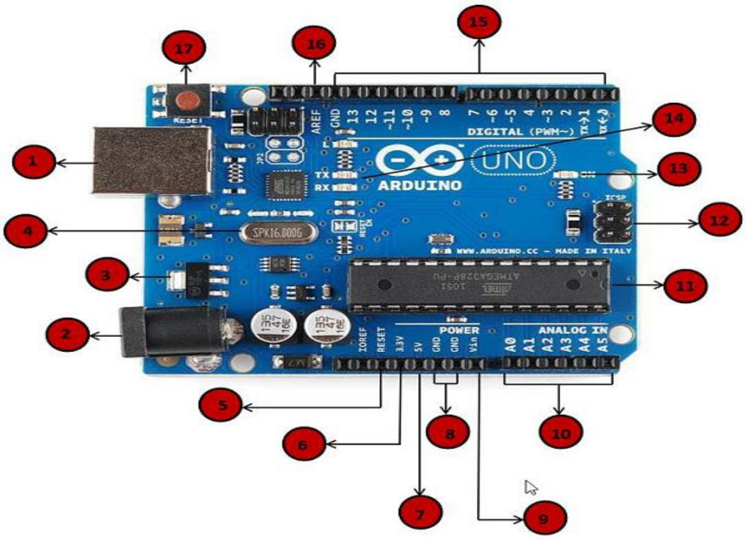

Fig 1.6.Arduino Uno.

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).

6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.

14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table1.1:Arduino Board Description.

1.7 Advantages of Arduino:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

1.8 Applications:

Arduino is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed.

1.9 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

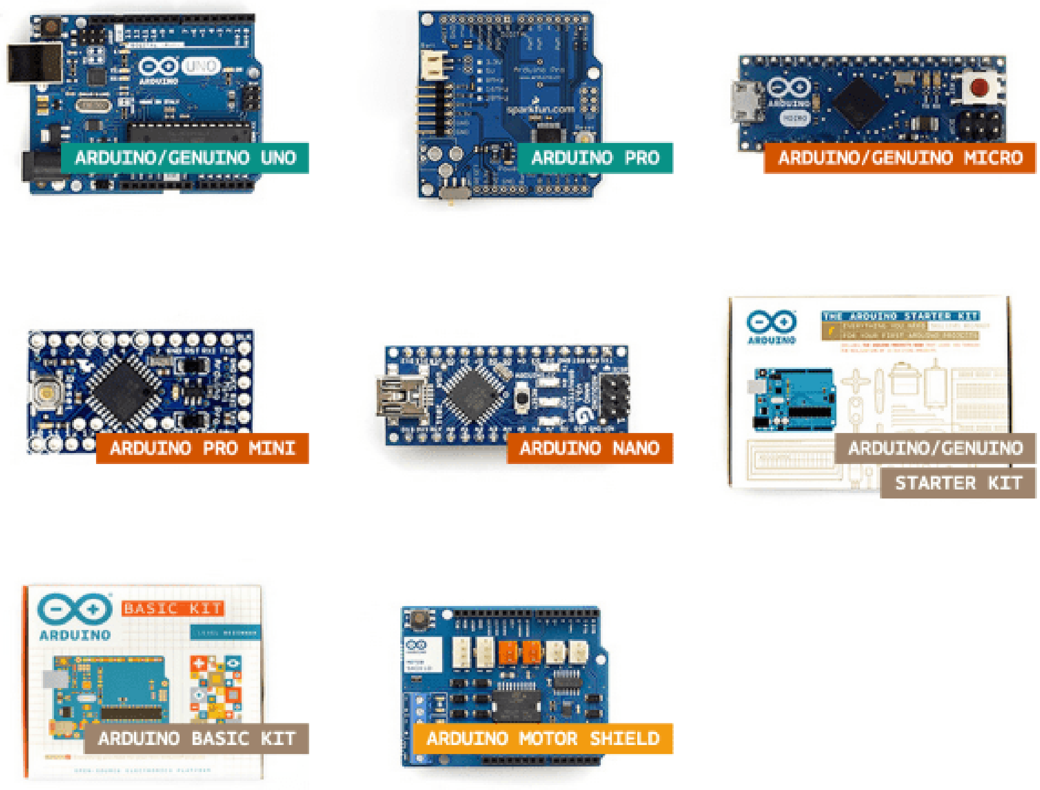

Fig.1.7: Arduino Family

1.10 SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

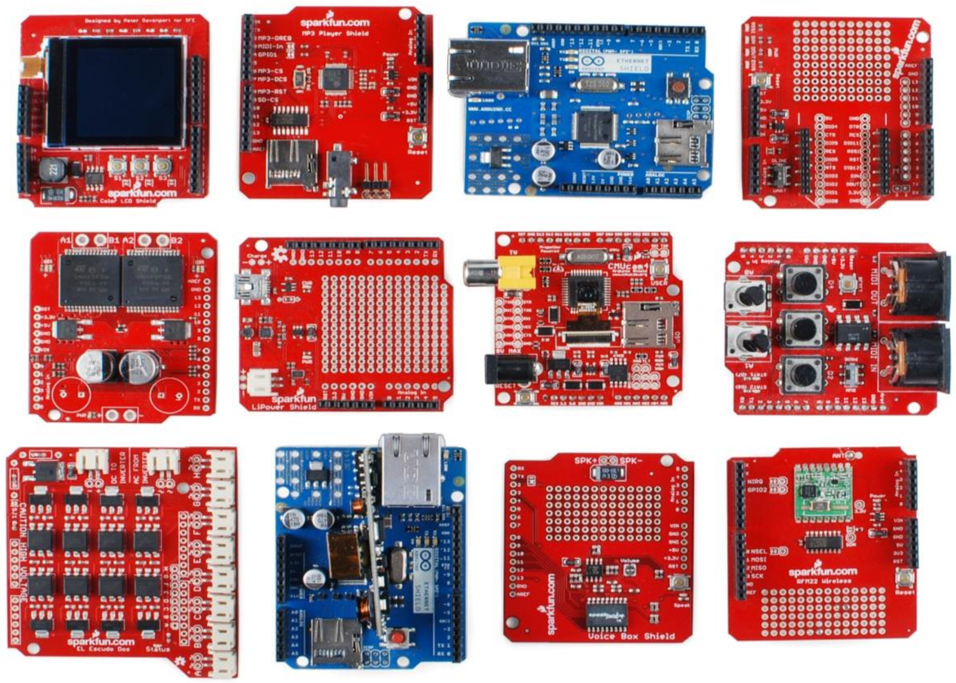

Fig.1.8: Arduino Shields

1.11 PIN DESCRIPTION OF ATMEGA328

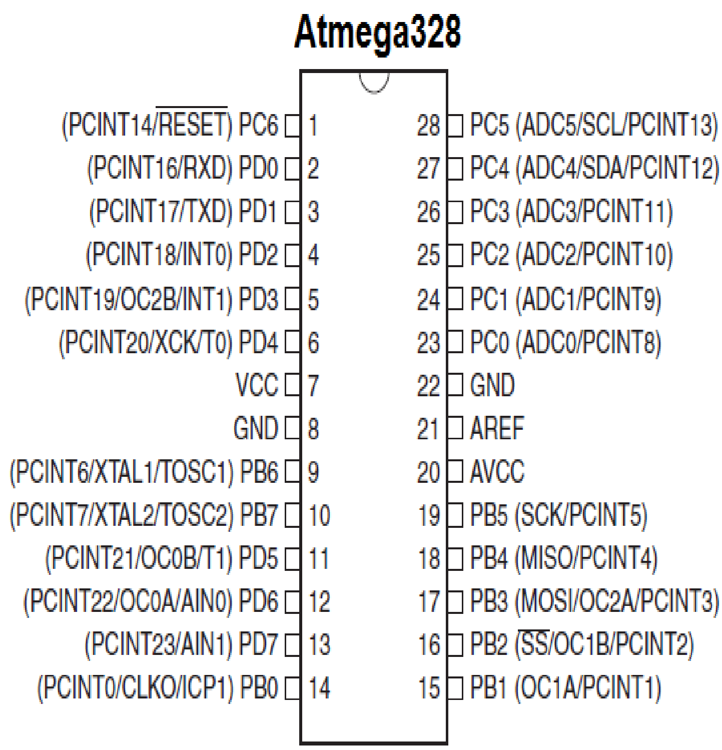

Fig.1.9: Pin description of ATMEGA328

1.12 INTRODUCTION OF POWER SUPPLY:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

1.13 BLOCK DIAGRAM OF POWER SUPPLY:

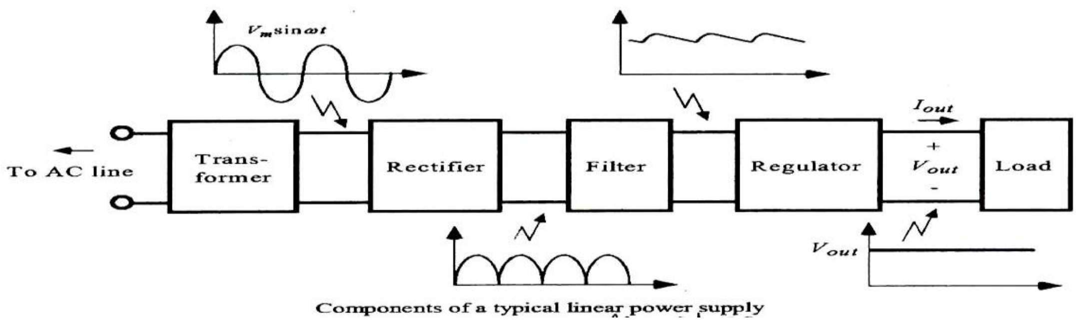

Fig.1.10: Block Diagram of Power Supply

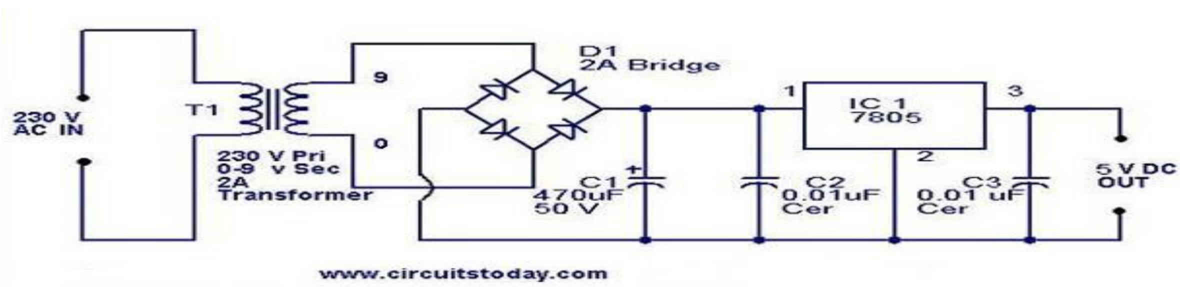

Fig.1.11: Schematic Diagram of Power Supply

1.14 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert aa different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

1.15 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupledconductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

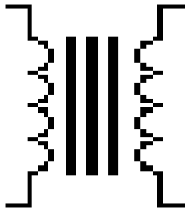

Fig.1.12: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

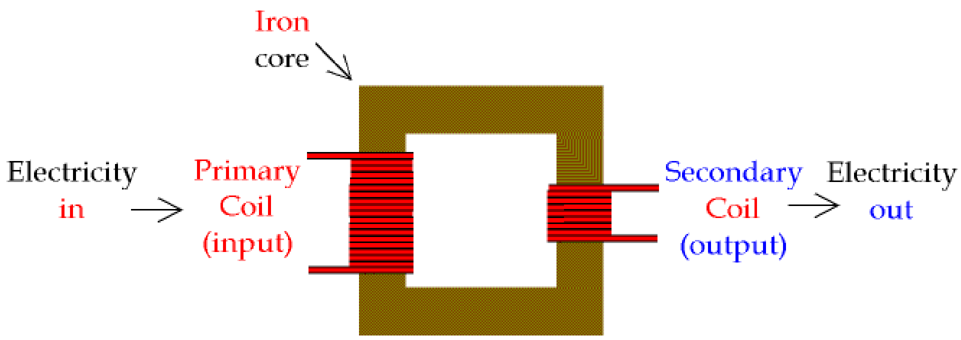

Fig.1.12(a): Transformer

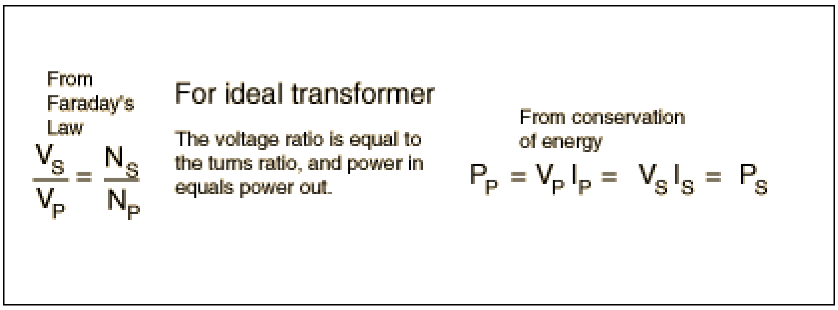
1.16 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an ironcore to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.



1.17 Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

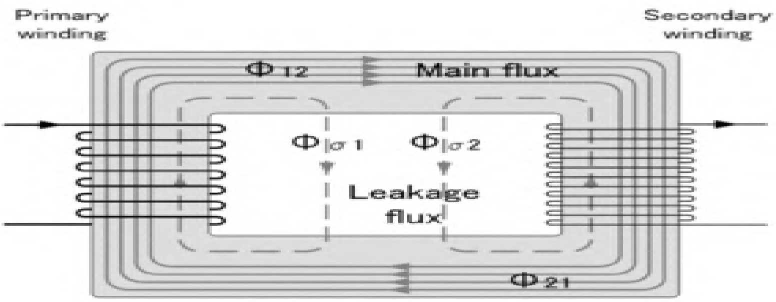


Fig.1.13: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

1.18 Classification of Transformer:

➢ Step-Up Transformer

➢ Step-Down Transformer

1.18.1 Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

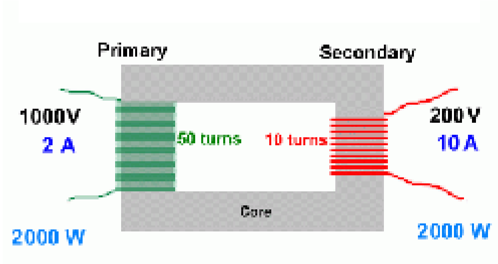

Fig.4.2.2: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1

1.19 Software:

The open-source Arduino Software (IDE) makes it easy to write code and upload it to the board. This software can be used with any Arduino board.

CHAPTER-2
LITERATURE SURVEY

CHAPTER-2

2.1 Literature Survey:

Robotics is a field concerned with the “intelligent connection of perception of action”. The most common manufacturing robot is the robotic arm with different degree of freedom. Today, these humanoids perform many functions to assist humans in different undertakings such as space missions, driving and monitoring high speed vehicles. They are called Humanoids because they resemble humans. The idea of this paper is to change perception of controlling robotic arm. This paper provides a way to get rid of old fashioned remote controls and gives an intuitive technique for implementation of Semi- Humanoid Gesture controlled robot. The motion sensors used are - flex and accelerometer (used in mobile phones for tilting motion). It includes two robotic arms which are exactly similar to human arms (with 5 fingers), increasing sensitivity of the system, a moving platform and a camera for capturing real time video. The prime aim of the system is to design a system in such a way that user can operate the robot with the ease through gestures. This involves movement of both robotic arms and platform in synchronous with user's hand and leg gestures respectively.

This paper illustrates the design and implementation of a robotic vehicle that can be controlled from all directions by using the hand movement with a wireless camera that is installed at the top of the vehicle to broadcast wireless live streaming to the user end. Therefore, it removes the hassle of gesture recognition and image processing technique or even the use of switches or joysticks to control the movement of a robot in different directions and provides a wireless surveillance facility to the user. There are mainly three parts of this propose system; the transmitter, the receiver and the live streaming section. The transmitter section detects the movement of the hand in x and y axis by using an accelerometer sensor, processed by Arduino Uno, and transmits those signals to the receiver section by using RF module. The receiver section receives those signals via RF module, decoded by the Arduino Uno, and the motor driver, which is connected to the Arduino Uno and moves the robotic vehicle in all directions according to the decoded signals. Finally, in order to perform live streaming operation - a common network (Wi-Fi), a laptop, Raspberry pi, and two software, namely Virtual Network Computing (VNC) and Foundation Internet Nouvelle Generation (FING) are used to ensure the surveillance feature for the user.

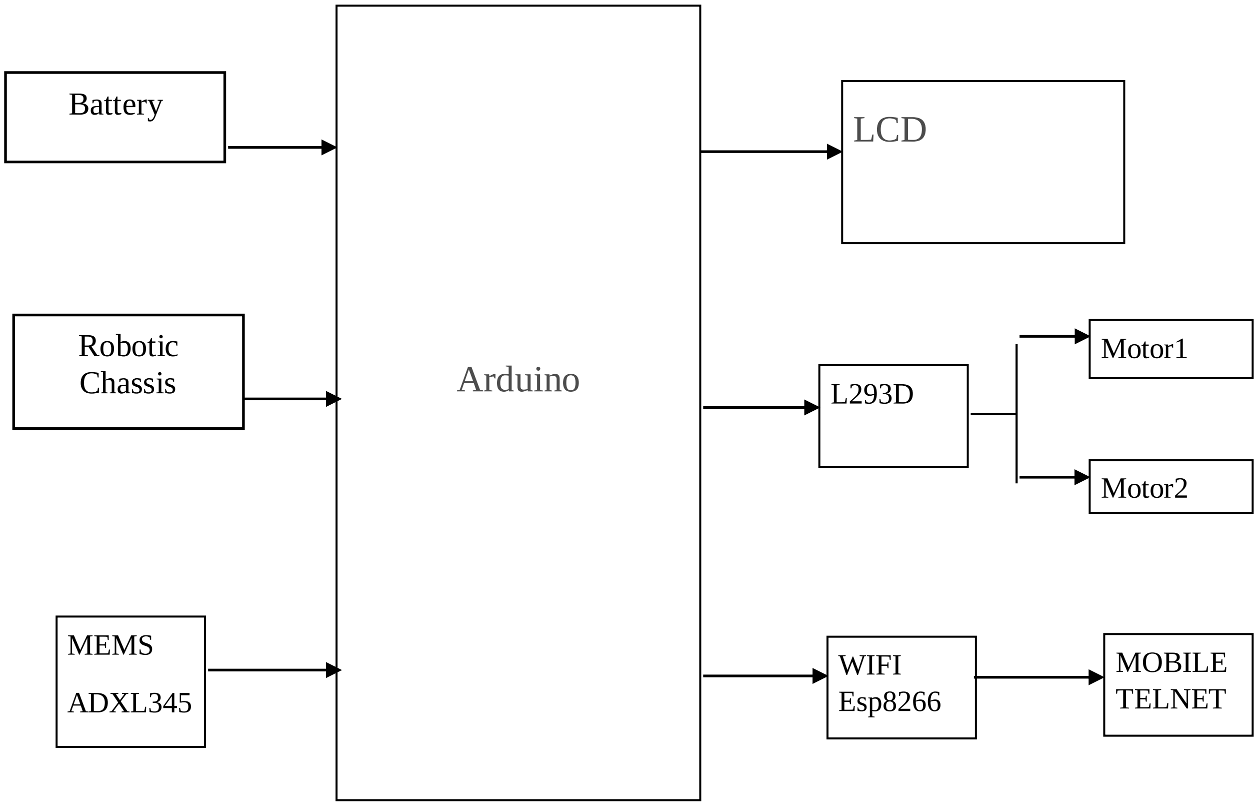
Robotics is one of the emerging fields nowadays. It can be defined as a design gadget which can assist humans in their day-to-day activities and help them by amalgamating electronics and mechanical engineering. Robots are assuming a significant number of jobs over sectors like construction, military, medical, etc. Various attempts have been implemented to make interfaces among users and PCs put together frameworks based on human gestures. These gesture based interfaces can substitute the regular interface gadgets. In the wake of making some essential robots like a line follower robot or a computer-controlled robot, human gestures can operate these types of robots and therefore an accelerometer based Hand Gesture Robot is on the rise. This technique will reduce the dichotomy between the digital and physical world. In this paper, we will see how a robot can move by using Hand Gestures.

This paper explains the solar grass cutter using hand gesture, solar powered robotic grass cutting machine that eliminates the obstacles and could be accessed from every direction by utilizing hand gesture through remote camera which is introduced to the highest point of the motor-vehicle to communicate remote gushing to the users end. The system uses a 6v batteries to drive both the motor vehicle movement and the grass cutter engine. The system also uses solar panels to charge the battery, so that no additional battery is required. The grass cutter and vehicle motors are interfaced with a microcontroller's family which controls all the motors running. It is also interfaced with ultrasonic sensor to track the object. There are essentially three parts of the framework; the transmitter; the receiver and the live gushing area.

CHAPTER-3
PROPOSED SYSTEM

CHAPTER-3

3.1 Block Diagram:



3.2 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).

- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

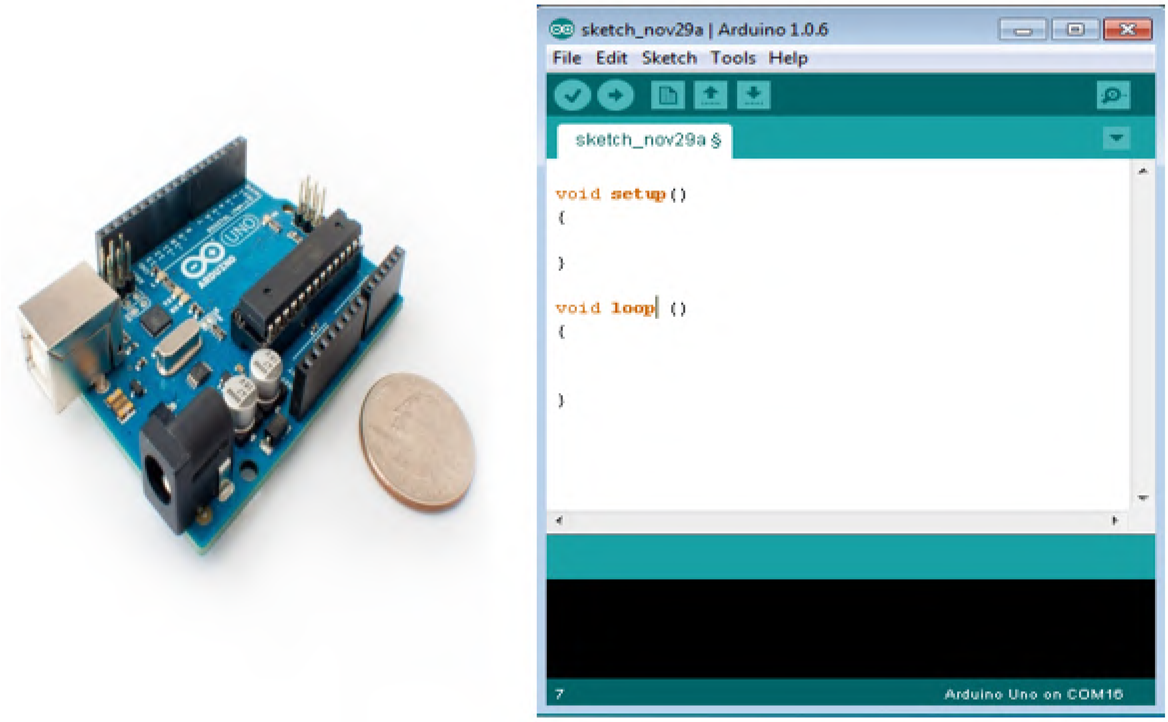


Fig 3.1 Arduino UNO and IDE

3.2.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2

Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3.1 Arduino boards based on ATMEGA328 microcontroller

3.3 16 * 2 Alphanumeric LCD

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

3.3.1 16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

Schematic

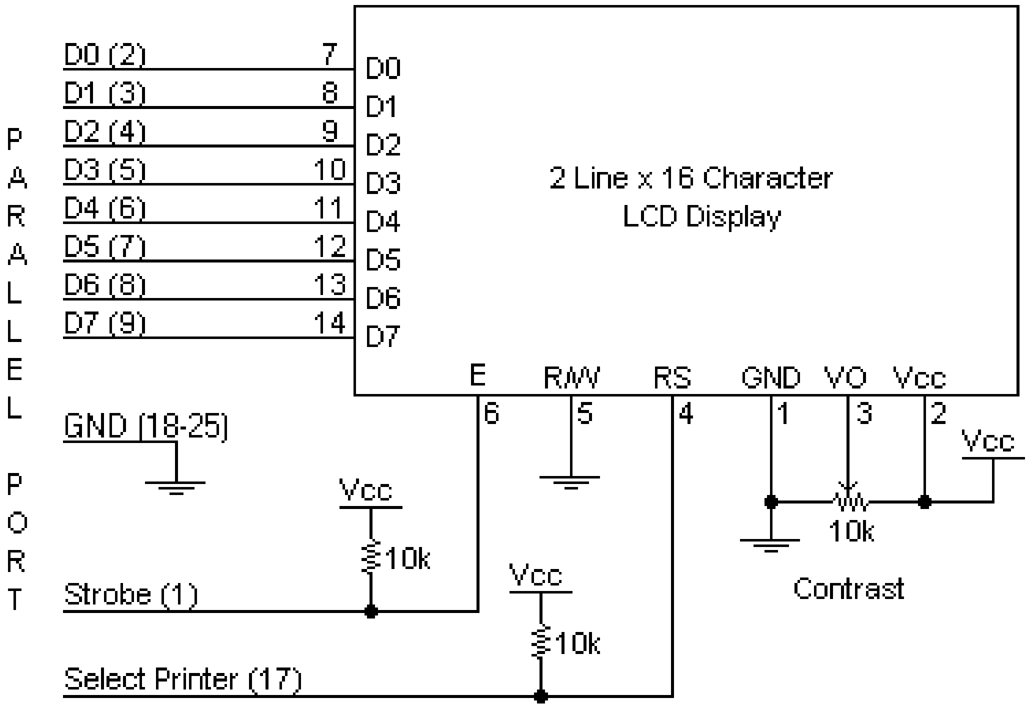

Fig 3.2 Schematic Diagram of LCD

3.3.2 Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.

Note2: Pin 14 is marked with a "1" on the back of the PCB. Do not get confused by this.

Table3.3 Specifications

3.4 Battery:

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and some kind of electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place.

Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Fig 3.2: Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

3.4.1 History

Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Fig 3.3 Leydan jar

Battery of Leyden Jar "capacitors" linked together (Image courtesy of Alvinrune of Wikimedia Commons)

3.5 Wifi Module:

The ESP8266 is a low-cost WiFi module that can be integrated easily into IoT devices. We've featured several projects using this module, such as How To Make Smart Home Electronics: A Smart Mailbox and How To Read Your Arduino's Mind: Building A Childproof Lock. This tutorial will walk you through setting up ESP8266 Wifi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

3.5.1 What is ESP8266?

The ESP8266 is a small WiFi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a WiFi network.

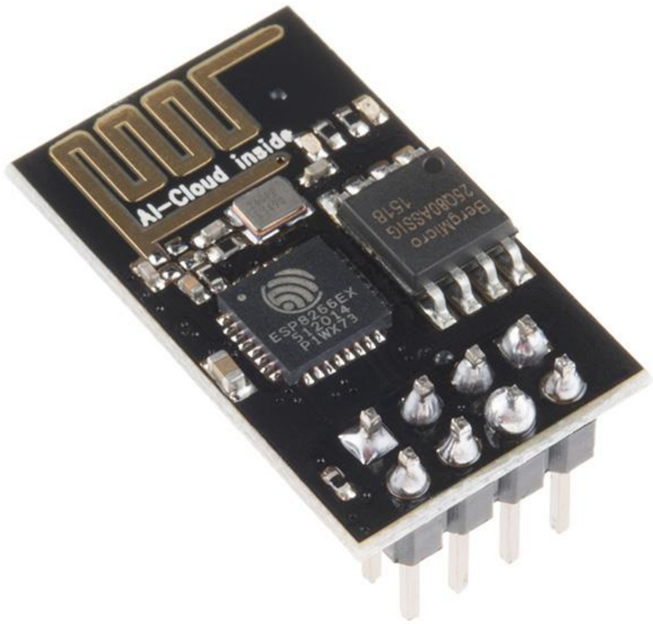

Fig 3.4. ESP8266 ESP-01 module

ESP-01 Features

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266's pins are according to the following diagram:

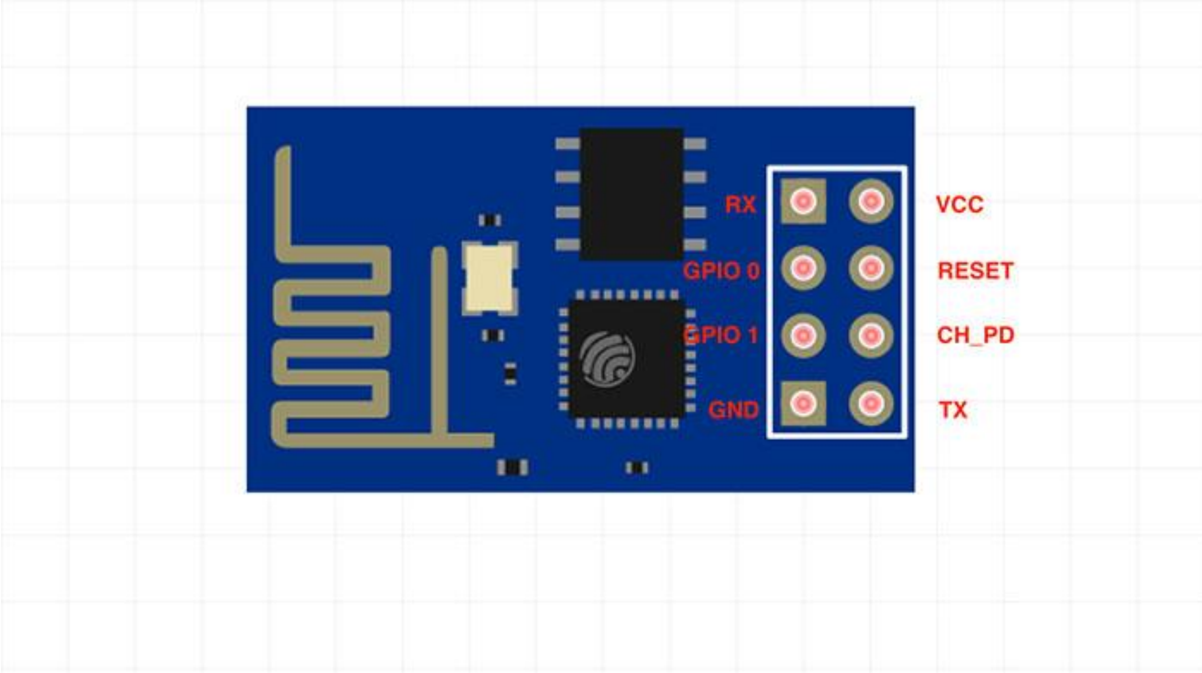

Fig 3.5 ESP8266 Pinout

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wifi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

Use the following diagram to connect the ESP8266 module to the Arduino:

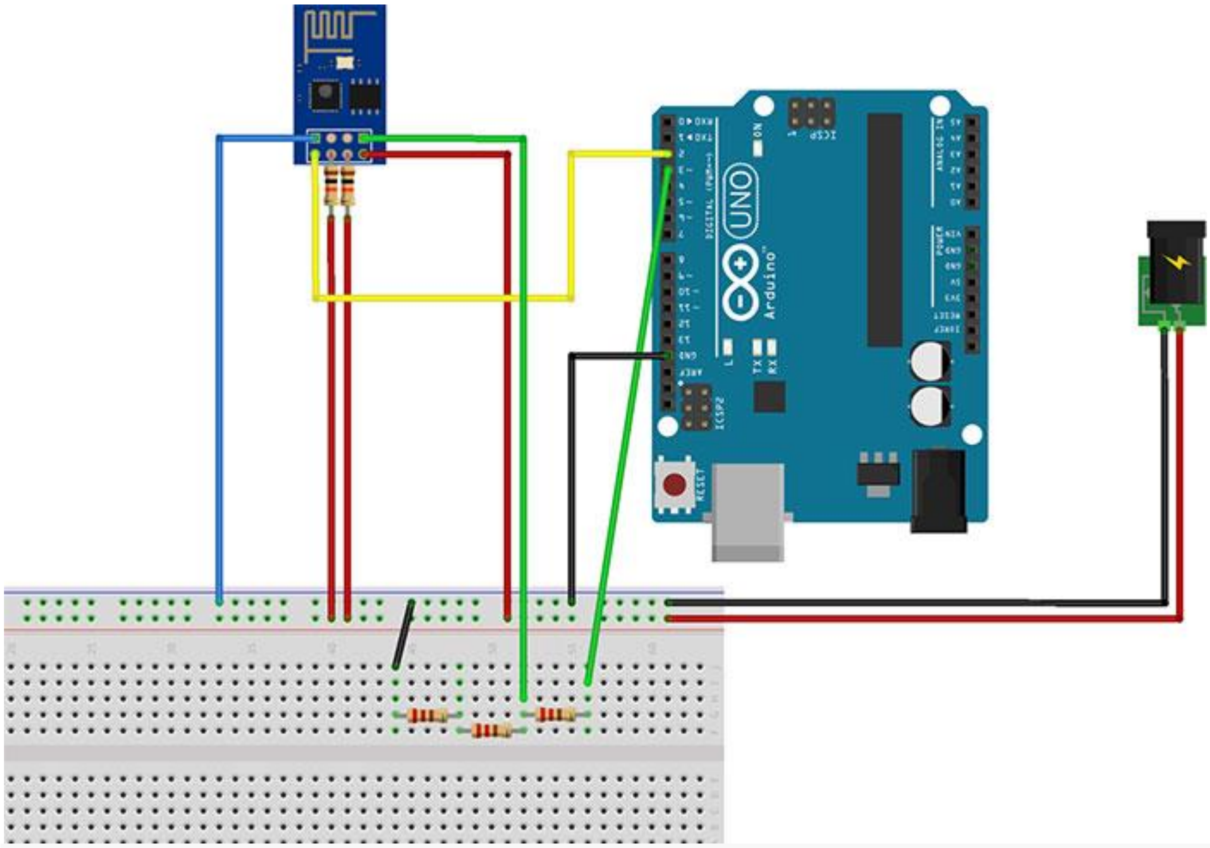

Fig 3.6 Connection between ESP8266 and Arduino Uno

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
    - You can use something like this: https://www.sparkfun.com/products/114
- Breadboard and jumper wires

A couple of features of this circuit stand out immediately.

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the Vcc and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

3.6 MEMS:

The ADXL345 is a low-power, 3-axis MEMS accelerometer modules with both I2C and SPI interfaces. The Adafruit Breakout boards for these modules feature on-board 3.3v voltage regulation and level shifting which makes them simple to interface with 5v microcontrollers such as the Arduino.

The ADXL345 features 4 sensitivity ranges from +/- 2G to +/- 16G. And it supports output data rates ranging from 10Hz to 3200Hz.

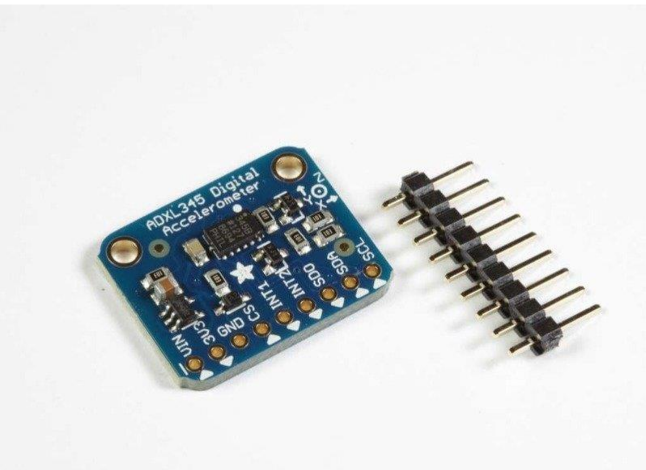

Fig3.7: ADXL345 Sensor

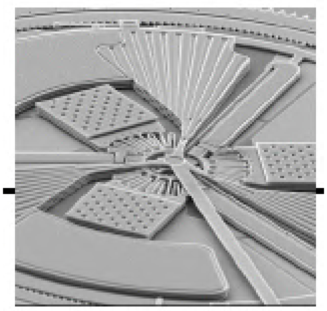
The sensor consists of a micro-machined structure on a silicon wafer. The structure is suspended by polysilicon springs which allow it to deflect smoothly in any direction when subject to acceleration in the X, Y and/or Z axis. Deflection causes a change in capacitance between fixed plates and plates attached to the suspended structure. This change in capacitance on each axis is converted to an output voltage proportional to the acceleration on that axis.

Introduction :

Microelectromechanical systems (MEMS) is the technology of the very small, and merges at the nano-scale into nano-electromechanical systems. MEMS are also referred to as micro-machines (in Japan), or Micro Systems Technology - MST (in Europe).MEMS is an emerging technology which uses the tools and techniques that were developed for the Integrated Circuit industry to build microscopic machines. These machines are built on standard silicon wafers. The real power of this technology is that many machines can be built at the same time across the surface of the wafer, with no assembly required. Since it is a photographic-like process, it is just as easy to build a million machines on the wafer as it would be to build just one.

MEMS is the integration of mechanical elements, sensors, actuators, and electronics on a common silicon substrate through micro-fabrication technology. While the electronics are fabricated using integrated circuit (IC) process sequences (e.g., CMOS, Bipolar, or BICMOS processes), the micro-mechanical components are fabricated using compatible "micro-machining" processes that selectively etch away parts of the silicon wafer or add new structural layers to form the mechanical and electromechanical devices.

Imagine a machine so small that it is imperceptible to the human eye. Imagine working machines no bigger than a grain of pollen. Imagine thousands of these machines batch fabricated on a single piece of silicon, for just a few pennies each. Imagine a world where gravity and inertia are no longer important, but atomic forces and surface science dominate. Imagine a silicon chip with thousands of microscopic mirrors working in unison, enabling the all optical network and removing the bottlenecks from the global telecommunications infrastructure. You are now entering the microdomain, a world occupied by an explosive technology known as MEMS. A world of challenge and opportunity, where traditional engineering concepts are turned upside down, and the realm of the "possible" is totally redefined.



A truly amazing MEMS device. It is a sophisticated MEMS Thermal Actuator

Fig 3.8 MEMS Thermal Actuator

MEMS are quietly changing the way you live, in ways that you might never imagine. The device that senses your car has been in an accident, and fires the airbag is a MEMS device. Most new cars have over a dozen MEMS devices, making your car safer, more energy efficient, and more environmentally friendly. MEMS are finding their way into a variety of medical devices, and everyday consumer products.

MEMS are quietly changing the way you live, in ways that you might never imagine. The device that senses your car has been in an accident, and fires the airbag is a MEMS device. Most new cars have over a dozen MEMS devices, making your car safer, more energy efficient, and more environmentally friendly. MEMS are finding their way into a variety of medical devices, and everyday consumer products.

Microelectronic integrated circuits can be thought of as the "brains" of a system and MEMS augments this decision-making capability with "eyes" and "arms", to allow Microsystems to sense and control the environment. Sensors gather information from the environment through measuring mechanical, thermal, biological, chemical, optical, and magnetic phenomena. The electronics then process the information derived from the sensors and through some decision making capability direct the actuators to respond by moving, positioning, regulating, pumping, and filtering, thereby controlling the environment for some desired outcome or purpose. Because MEMS devices are manufactured using batch fabrication techniques similar to those used for integrated circuits, unprecedented levels of functionality, reliability, and sophistication can be placed on a small silicon chip at a relatively low cost.

3.6.1 THEORY OF OPERATION

The ADXL103/ADXL203 are complete acceleration measurement systems on a single, monolithic IC. The ADXL103 is a single-axis accelerometer, and the ADXL203 is a dual-axis accelerometer. Both parts contain a polysiliconsurfacemicromachined sensor and signal conditioning circuitry to implement an open-loop acceleration measurement architecture. The output signals are analog voltages proportional to acceleration. The ADXL103/ADXL203 are capable of measuring both positive and negative accelerations to at least ±1.7 *g*. The accelerometer can measure static acceleration forces such as gravity, allowing it to be used as a tilt sensor.

The sensor is a surfacemicromachinedpolysilicon structure built on top of the silicon wafer. Polysilicon springs suspend the structure over the surface of the wafer and provide a resistance against acceleration forces. Deflection of the structure is measured using a differential capacitor that consists of independent fixed plates and plates attached to the moving mass. The fixed plates are driven by 180° out-of-phase square waves. Acceleration deflects the beam and unbalances the differential capacitor, resulting in an output square wave whose amplitude is proportional to acceleration. Phase-sensitive demodulation techniques are then used to rectify the signal and determine the direction of the acceleration. The output of the demodulator is amplified and brought off-chip through a 32 kΩ resistor. At this point, the user can set the signal bandwidth of the device by adding a capacitor. This filtering improves measurement resolution and helps prevent aliasing.

Pin configuration and function description

3.7 MOBILE TELNET:

Telnet is a client-server protocol based on character-oriented data exchange over TCP connections. Telnet enables remote control of computers via text-based inputs and outputs. For this reason, a client-server connection is established as a default via the TCP protocol and port 23, where the remote-controlled device acts as a server and waits for commands. The Telnet client, the controlling instance in this process (also referred to as remote access or login), can be installed on a particular device, as well as on an ordinary computer. However, the presentation of the transmitted information differs, depending on the device. This protocol can also be used to manage applications that do not have a graphical interface.

As early as 1969 (during the nine months of work on ARPANET), the development of Telnet (Teletype Network) was practically completed. But it was only in 1973 that the protocol allowing access to remote computers first received its final specification in RFC 495 (Request for Comments). It was implemented by most platforms as the official standard of the Internet Engineering Task Force (IETF).

The kernel protocol and the basic working methods and extensions are characterized in the more recent standards RFC 854 and RFC 855.

3.7.1 How and where is Telnet used?

One of the main reasons for developing the remote protocol was that computer systems at that time were still really expensive and not easily accessible for everyone. Another reason was their extreme size, which meant that they were bound to specific locations. In order to make computer resources available at universities and companies, Unix was developed at the end of the 1960s as a suitable operating system and Telnet as an appropriate protocol service. This meant that any user that had the right authorization, could start, manage, and use applications on the powerful large computers for their own personal use.

3.7.2 Access to databases

Over many years, Telnet also played a crucial role for institutions that work with large databases: for example, in libraries, the protocol was an elementary building block of online catalogs published in the 1980s, which are better known as OPAC (Online Public Access Catalog). Initially, these digital publication databases, which followed the traditional card catalogs, were still accessible in the libraries' local networks via terminals. As the internet started becoming more and more successful, it was also possible to access them via locally usable web interfaces, whose communication means was supported by the Telnet protocol in many cases.

3.8 MOTORS

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
    - AC motor, an electric motor that is driven by alternating current
        - Synchronousmotor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
        - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction
    - DC motor, an electric motor that runs on direct current electricity
        - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source

        - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
    - Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
    - Servo motor, an electric motor that operates a servo, commonly used in robotics
    - Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

CHAPTER-4
SOFTWARE AND FUNCTIONS

4.1 Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments.

A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open-source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Fidgets, MIT's Handy-board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money. Getting Started with Arduino and Genuineproducts

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software(IDE)

✓ Proceed with board specific instructions.

4.1.1How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

4.1.2 Installation:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig4.1:USB cable(A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig4.2 : USB cable (A plug to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

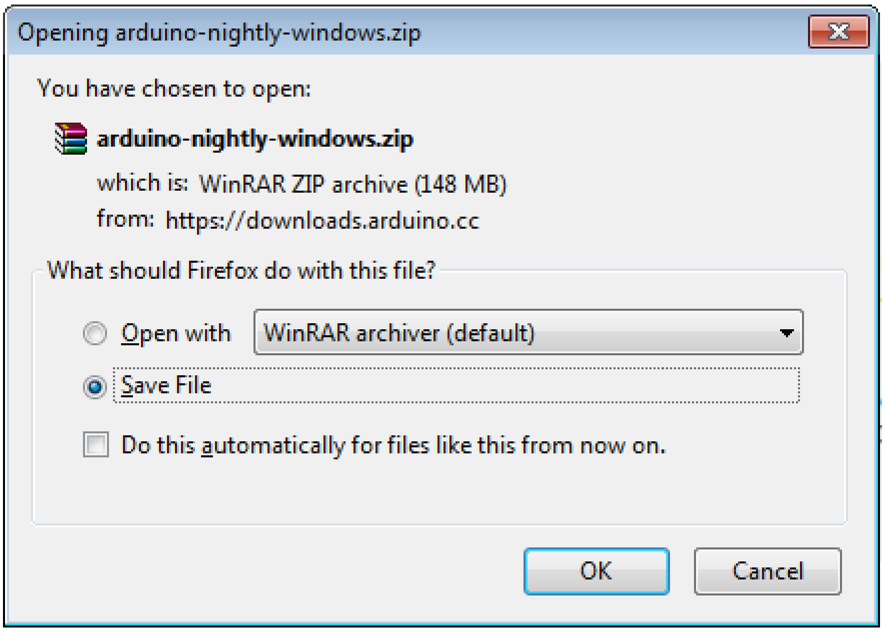

Fig4.3:Installation window of Arduino ide

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power fromthe USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

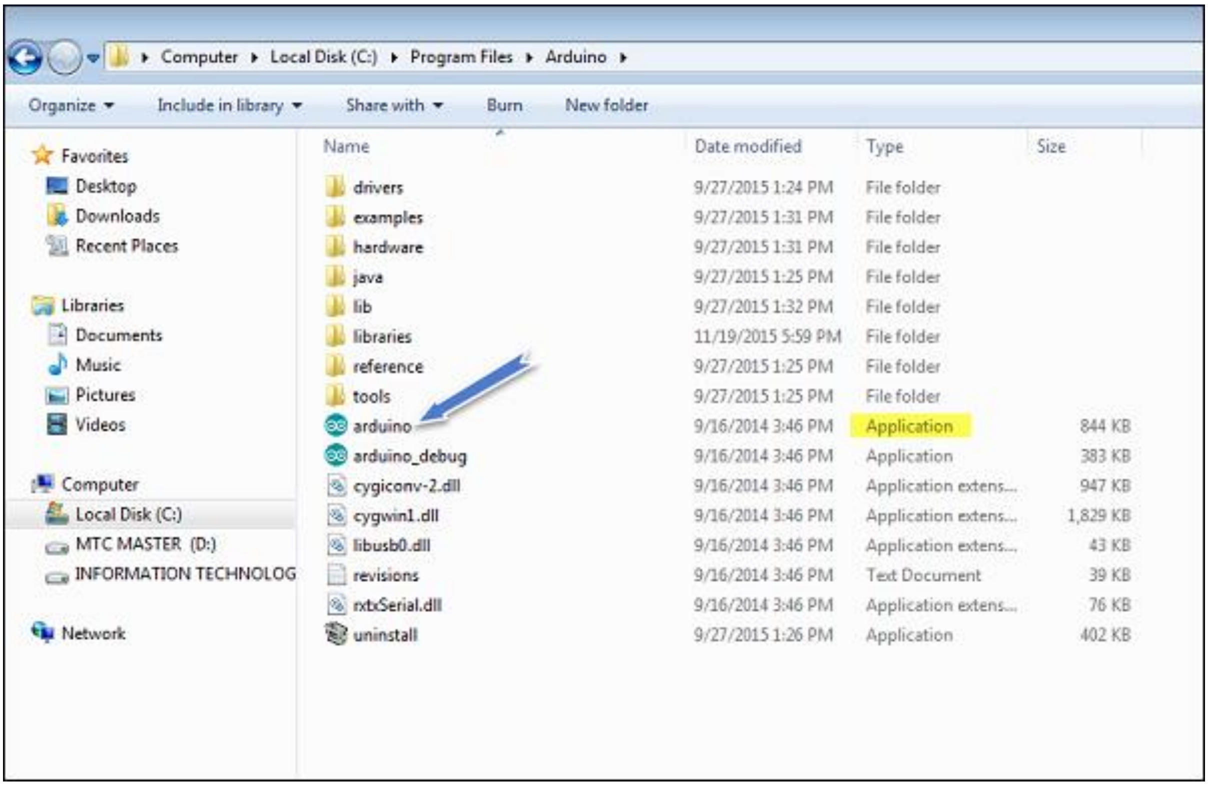

Fig4.4: Window showing how to open arduino ide software

Step 5 – Open your first project.

Once the software starts, you have two options –

- Create a new project.
- Open an existing project example.

To create a new project, select File → New

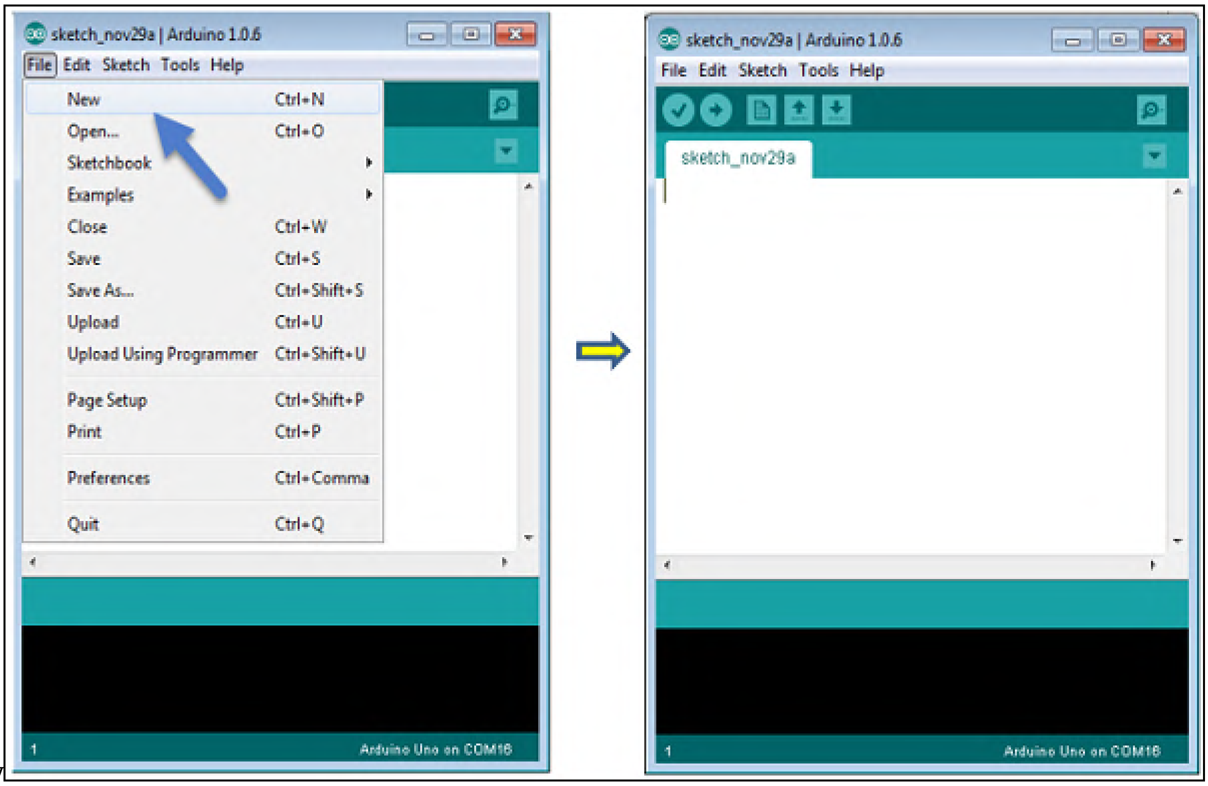

Fig4.5:Window Showing Creating New Project

To open an existing project example, select File → Example → Basics → Blink.

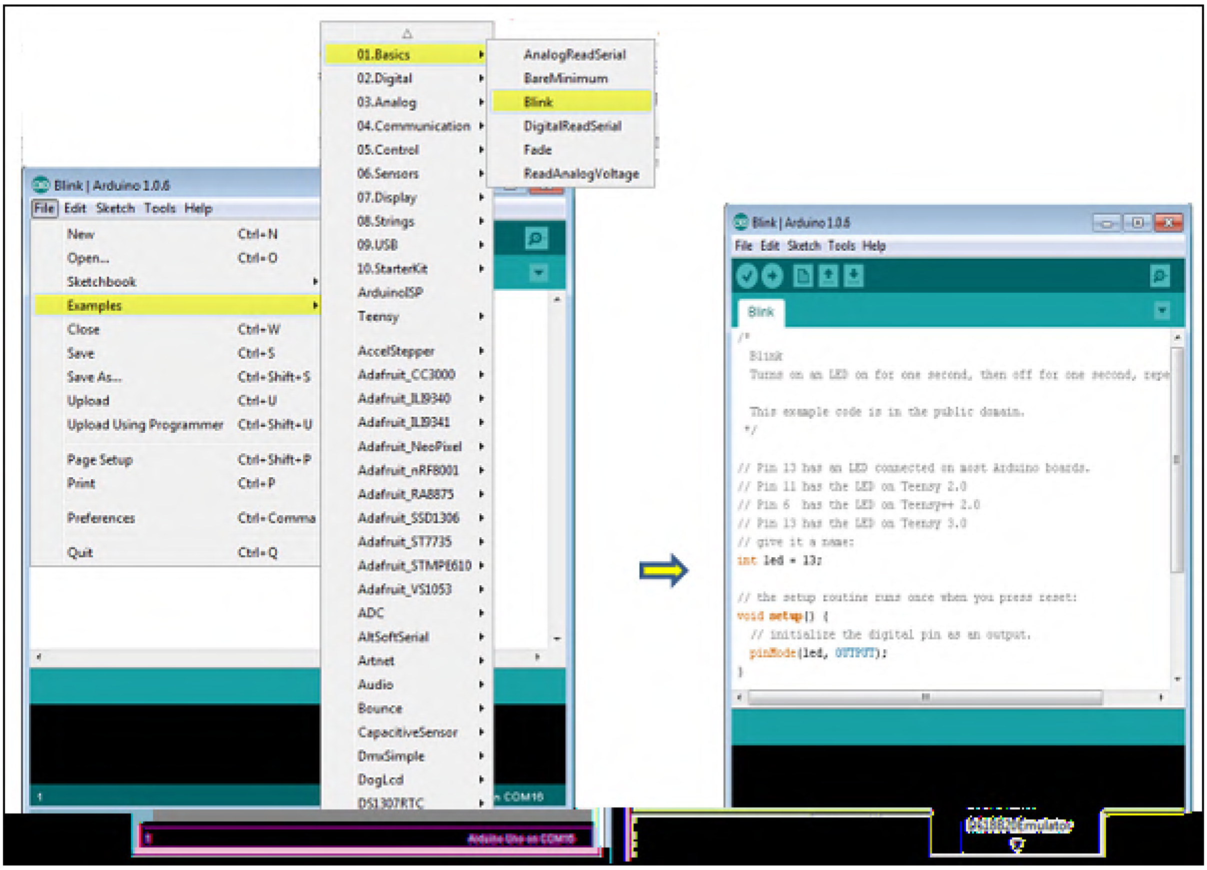

Fig.4.6:Window Showing Opening Existing Project.

Here, we are selecting just one of the examples with the name Blink. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 – Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

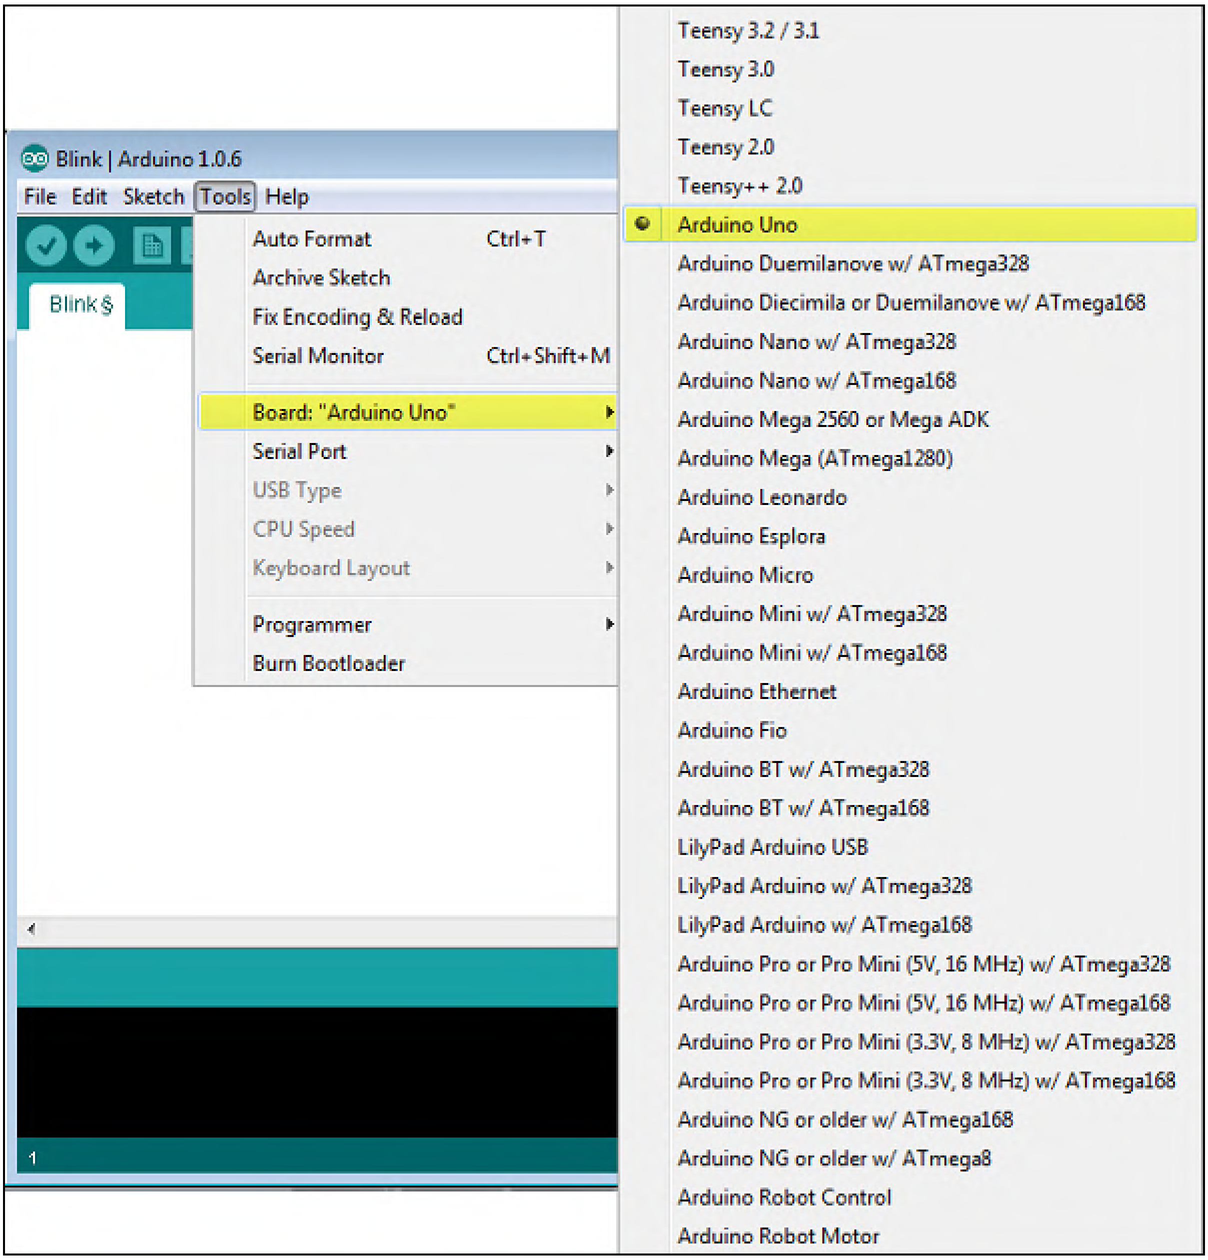

Fig4.7: Window Showing Selection of Boards

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial** Port menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

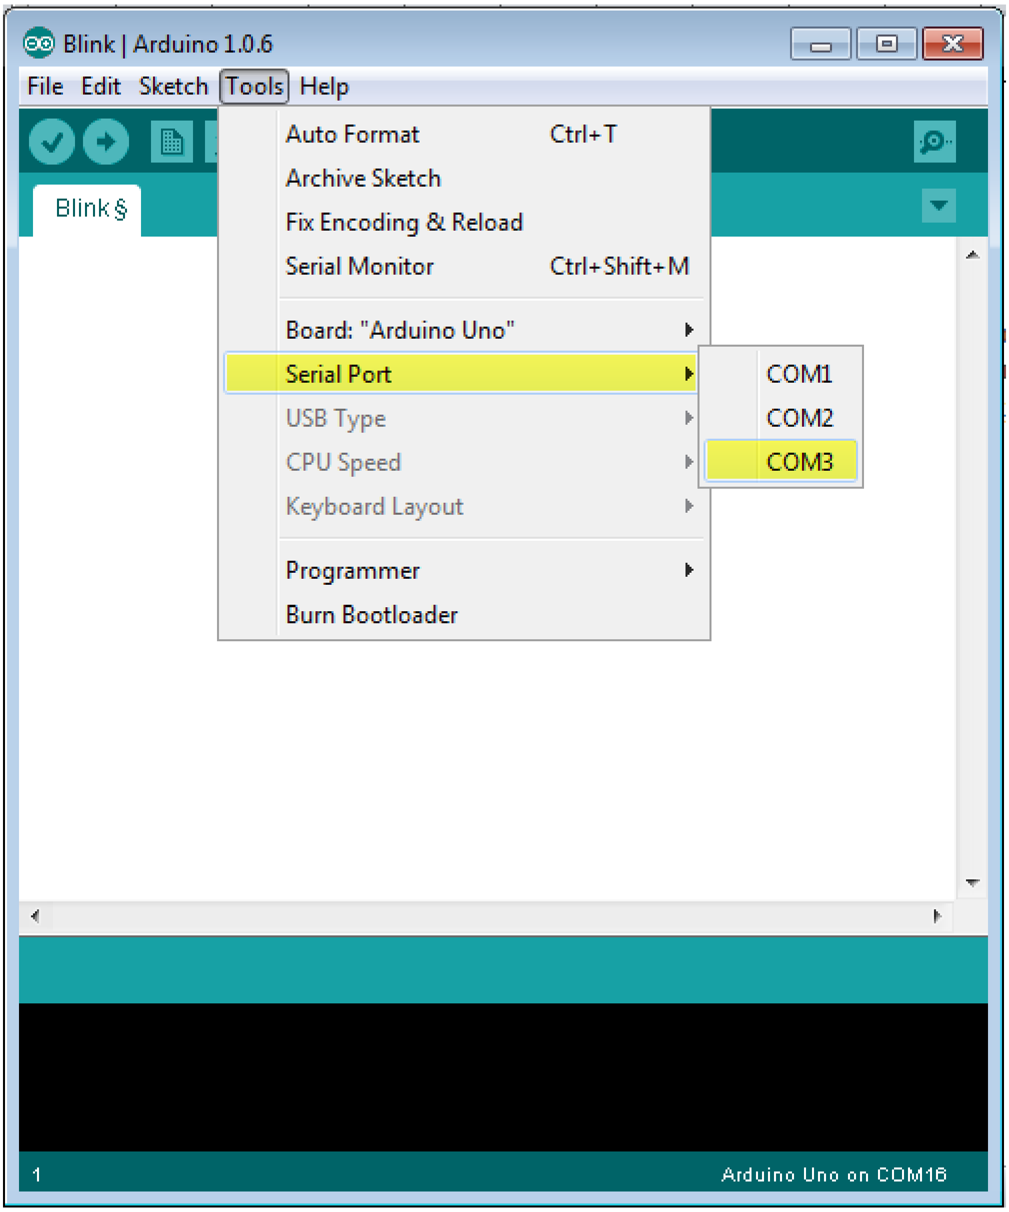

Fig4.8:Window Showing Selection of Ports

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

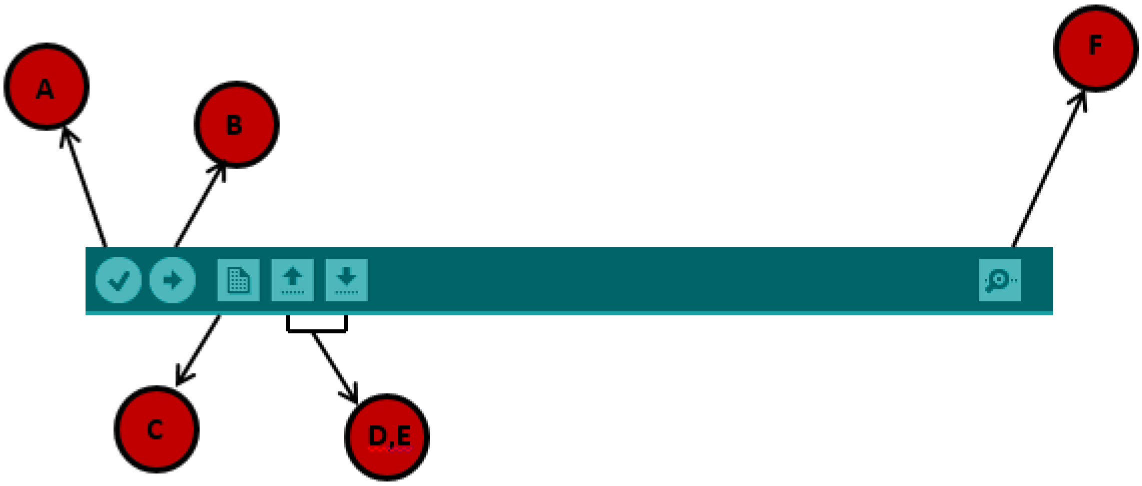

Fig4.9: Explanation of Options In Arduino Ide

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

4.2 MC Programming Language: Embedded C :

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

4.3 Code Implementation:

```
#include<SoftwareSerial.h>
#include<LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);
#include <SoftwareSerial.h>

CHAPTER-5
OUTPUT SCREENSHOTS

5.1 Results:

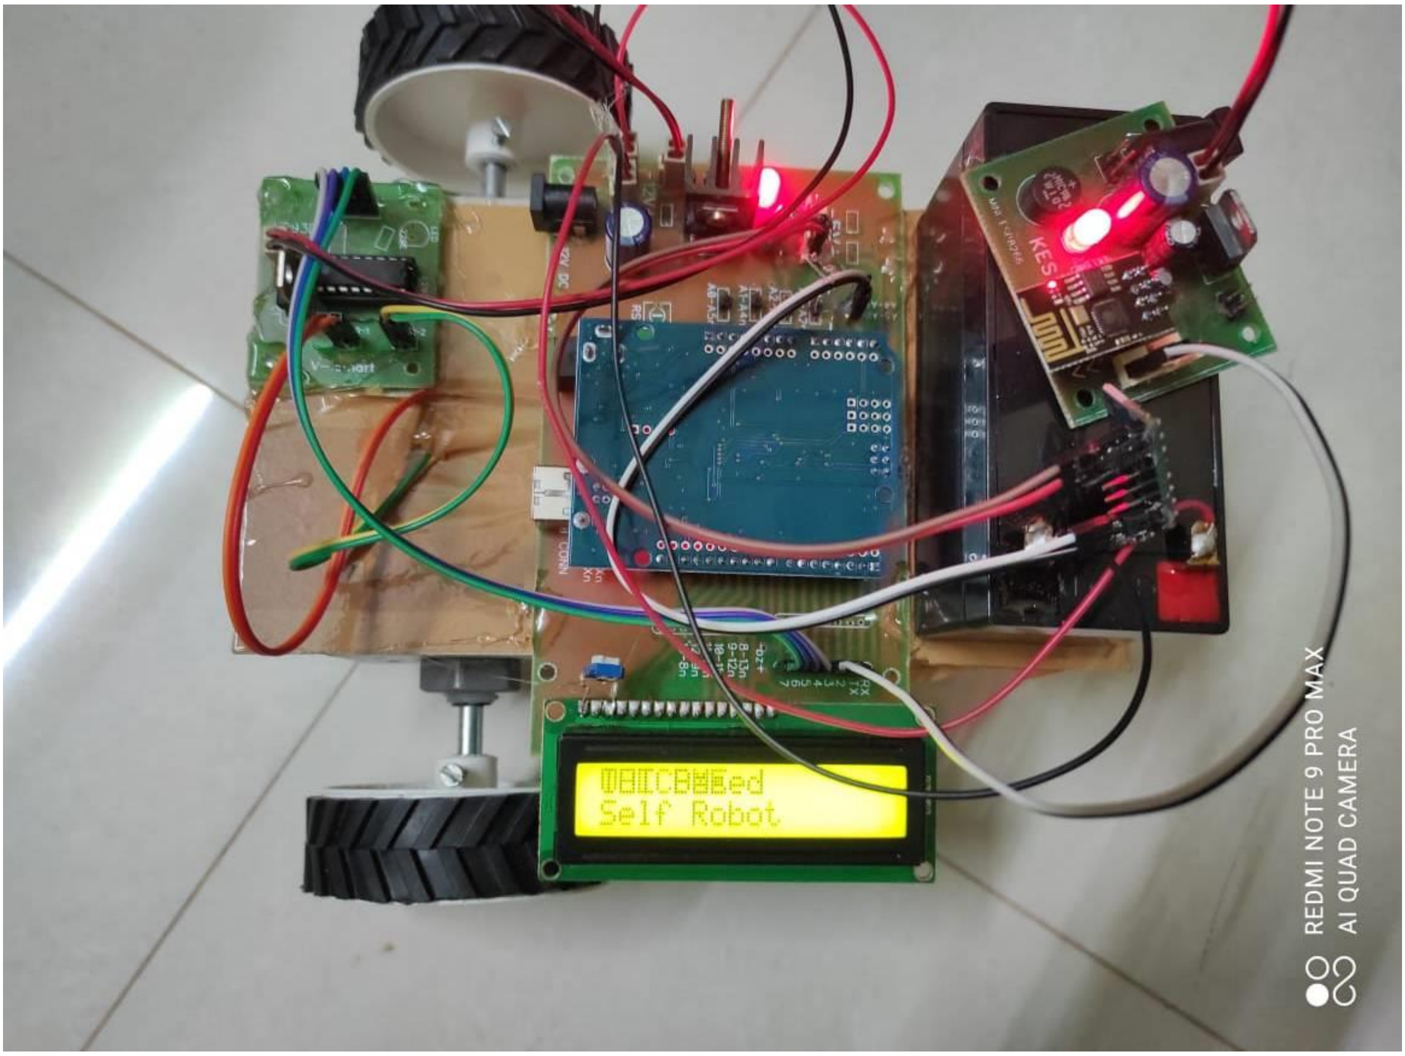

Fig 5.1:Vehicle Operating as Self Robot

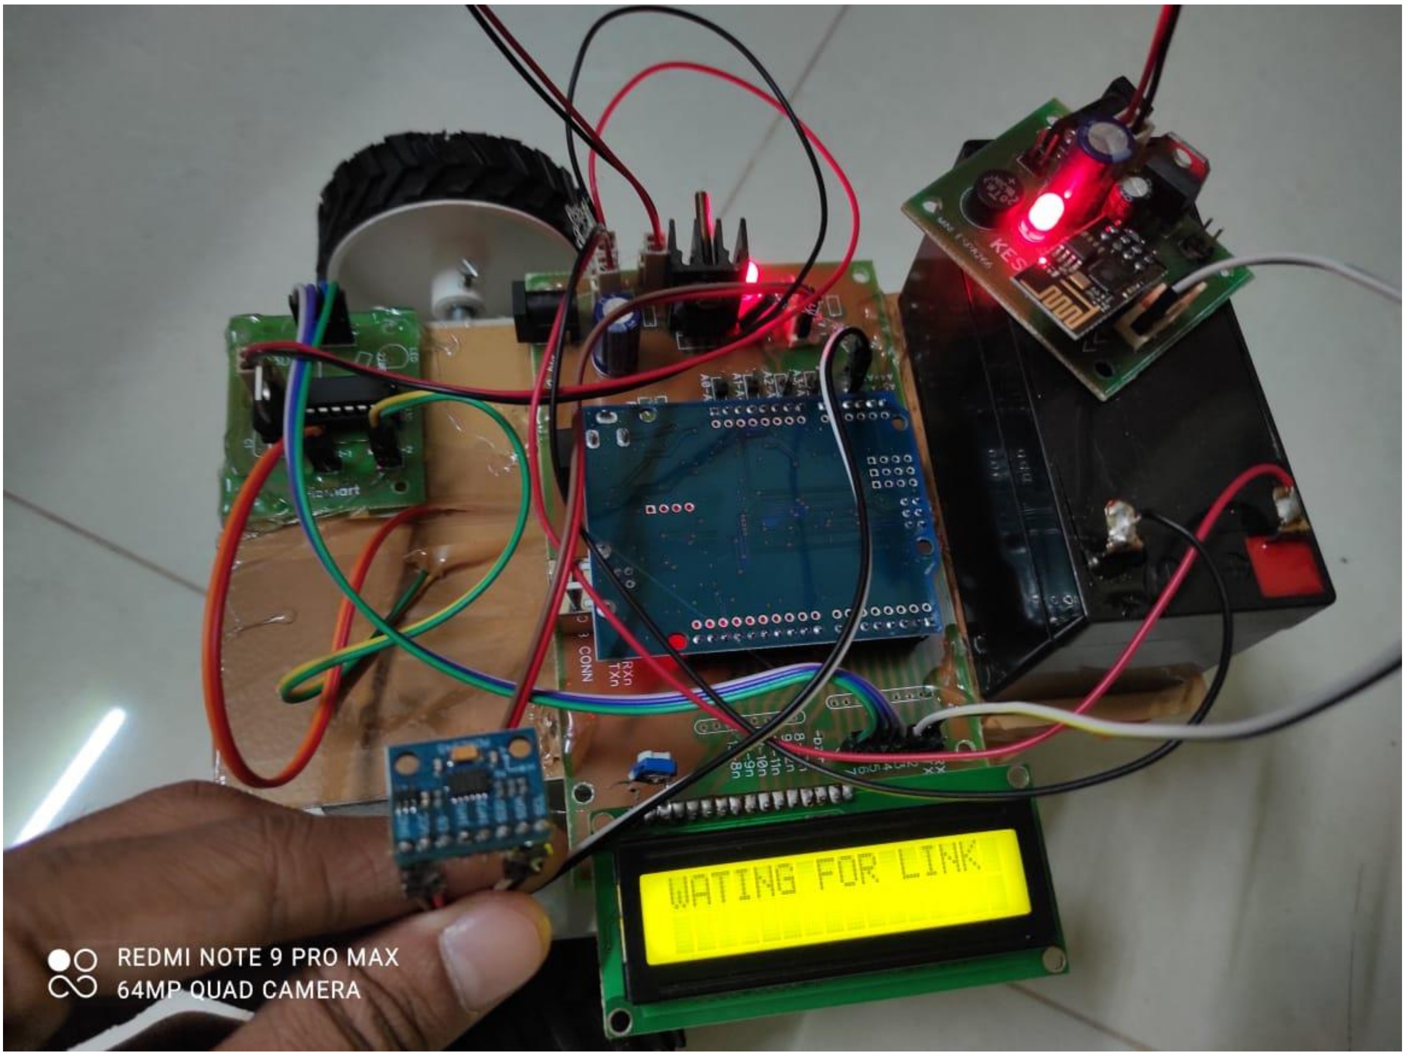

Fig:5.2:Vehicle Operating over IOT

CHAPTER-6
APPLICATIONS AND ADVANTAGES

6.1 Advantages:

There are many advantages of the gesture control technology over limitations.In this document i will clear you what are the advantages of gesture control technology.The advantages of gesture control Technology adds weight to advantages of outproject.Some of the advantages of our project are listed below

- Speed and sufficient reliable for recognition systems
- Good performance with complex background.
- The system successfully recognize static and dynamic gestures and could be applied to mobile robot.
- Simple fast and easy to implement and can be applied to real systems and play games.
- Absolutely no training is required.
- Inexpensive.

6.2 Applications:

- **Bomb Detonation**: Robots allow the close examination of devices, without endangering people. Once the device has been examined, the robot may then render the bomb inert. If not, errors can be avoided by using the robot itself to detonate the bomb and safeguard human life. It is not just bombs that the robots disable, but also devices that could detonate landmines or unexploded munitions.
- **Radioactive Environment:** When dealing with radioactive materials, robots can be used to keep humans safe from genetic mutations and fatal diseases that may occur from radiations. They can be used in labs, nuclear power plants or in areas that have been damaged by nuclear energy. There are different types of robots that are used in areas of different kinds of radiations - alpha, beta and gamma. Robots with properly automated controllers can also be used to control nuclear power plants and hence can be used to avert nuclear power plant disasters like one that occurred at Chernobyl. Robots can also be used for the disposal of radioactive waste.
- **Medical application**: Robot-mediated health care has paved the way for safe and hygienic medicine. Robots play an integral role in the battle against infectious diseases as they have the capability to disinfect a room of any bacteria and viruses within minutes. Robots, unlike humans, cannot catch infectious diseases. They are agnostic to specific infectious agents and do not contribute to medically-resistant strains. With the rise in antibiotic-resistant bacteria and outbreaks of deadly infections like Ebola, more healthcare facilities are using robots to clean and disinfect surfaces.
- **Space Rovers**: Robots are the latest intelligent systems that have helped us with outer space exploration. Robotic unmanned space crafts are used to perform multiple functions in the extra –terrestrial world; including object recognition, image evaluation and terrain modeling. They involve AI-based methods for autonomous navigation and mission planning in unknown terrain and AI-based support systems for

scientific experiments. The most famous robots used in the outer space applications are the Mars rovers of NASA.

- **Surgical Assistance and Rehabilitation Systems**: Robots today have the abilities to assist surgeons with performing complex operations, typically minimally invasive procedures to avoid infections and outbreaks. 3DHD technology provides surgeons with enhanced natural stereo visualization, along with improved reality. Robotic links also play a crucial role in the speedy recovery of patients with disabilities, including improved mobility, strength, coordination, and overall quality of life.

Some of other application are:

1. Vehicle Navigation
2. Marine Navigation
3. Fleet Management
4. Base Services
5. Auto Pilot
6. Personal Navigation
7. Travel Equipment
8. Track Equipment
9. System and Mapping Applications

6.3Future Scope:

Further developments like replace robotic vehicle by robotic arm with an IP or WiFi based camera in the receiver section. By this way perform the task, the arm can be fixed to rover that provides movement to the system wirelessly, which may be helpful for the end user to monitor or track the movement of the vehicle and performance of the robotic arm. This system provides an opportunity to increase adaptability and opens up new application areas and reduces the gap between the physical world and digital world with an output more intuitive.This kind of system will have many applications in many fields which can change the era of technology, some of them are listed below

- Bomb diffusion applications
- fireworks
- Match Industries
- Industries which include Heat Treatment.

CHAPTER-7

CONCLUSION

CHAPTER-7

7.1 Conclusion:

The objective of this paper has been achieved which was developing the hardware and software for a gesture based vehicle. Gesture based interactions allow human computer interaction to be in a natural way as well as in intuitive manner. Therefore people were able to control the robot and gripper intuitively with hand motions. This type of control could improve productivity, reduce the effects of repetitive motions and improves safety. The performed usability study points out that the system is well-suited for the pick and place operations for physically impaired people and in laboratory environments and can be used where the humans are unable to sustain in the dangerous or harsh environments. This system can also be used in defense to load or diffuse bombs under emergency or war situation and cleaning agent in sewage and drainages.

BONAFIDE CERTIFICATE

This is to certify that the project entitled "Combustible gas detection with GSM Alert using Arduino" is being submitted by **1.Mr. Gudise Saiteja (17K81A0479), 2.Ms.Jaggari Manasa (17K81A0480) 3.Mr.Meka Raja (17K81A0494) 4.Mr.Nadimidhoddi Vikram (17K81A0497)**in partial fulfillment of the requirement for the award of the degree of **BACHELOR OF TECHNOLOGY IN ELECTRONICS AND COMMUNICATION ENGINEERING** is recorded of Bonafide work carried out by them. The result embodied in this report have been verified and found satisfactory.

Internal Guide	**Head of the Department**
Mrs.G Vinatha Department of Electronics and Communication Engineering	Dr. Hari Krishna Department of Electronics and Communication Engineering

Internal Examiner **External Examiner**

DECLARATION

We, The Students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2017-2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project work entitled '**COMBUSTIBLE GAS DETECTION WITH GSM ALERT UDING ARDUINO**' is the outcome of our own Bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Gudise Saiteja	Jaggari Manasa	Meka Raja	Vikram

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his valuable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to, **Dr. Hari Krishna**, **Head &Professor** the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our dept. **Project Coordinator Dr. A. Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We Sincerely thank our Project Internal Guide, **Mrs. G Vinatha, Assistant Professor,** Department of ECE and our class Project Coordinator **Mr. K Karthik, Assistant Professor,** Department of ECE for Guidance and Encouragement in carrying out this Project work. Finally, we are highly grateful and obliged to our College Level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1. Gudise Saiteja(17K81A0479)
2. Jaggari Manasa(17K81A0480)
3. Meka Raja(17K81A0494)
4. Nadimidhoddi Vikram(17K81A0497)

ABSRACT

Combustible gases are a very common reason for blasts and fire accidents, causing large damage to life and property. So here we propose an automated gas detection and alerting system that alert users wherever they are using SMS message. So for this purpose we use a PIC microcontroller along with Combustible gas sensor, LCD display, GSM modem for sending message and buzzer. The system is powered by a 12V power supply. The system constantly scans the gas sensor to detect leakages. As soon as gas is detected at the sensor, it produces an equivalent voltage and signals the microcontroller. The microcontroller on reading the signal checks the amount of gas detected, on detecting gas above certain level it then goes into alert mode. The system now displays the status of the event occurred on an LCD display, also sounds a buzzer to alert. It now uses the GSM modem to send an SMS message to the user/authority to inform about the situation so required action can be taken for it.

CHAPTER-1

INTRODUCTION

1.1. Overview to the project:

There are numerous answers for fireplace accidents that agencies continually endorse. Smoke detectors, hearth alarms, hearth extinguishers and sprinklers are examples of those gadgets. On reflection, those devices can also alert or prevent the unfold of fire but they do not save you hearth injuries, and that alone is a main downside already. This have a look at makes a speciality of the LPG fuel and the way to save you it from causing greater injuries. There's a want to build a system that aids people's negligence of their surroundings even as stopping the begin of conflagration. The device also implements a shut-off mechanism which acts as the first line of defence inside the prevention of the coincidence ought to there be an absence of individual inside the residence. Liquefied Petroleum fuel is constituent of Butane and Propane gases, which can be distinctly inflammable in nature. The LPG is an odorless gasoline and hence the addition of Ethanethiol allows it to show case a smell throughout its leakage. An ideal gasoline sensor may be used to feel the leakage of an LPG from cars, industries, homes and different residential regions. If there is a leakage of LPG, we will effortlessly perceive by using its concentration through the gasoline sensor and by using upward push in temperature. The LPG is broadly used for home functions such as boiling, heating and cooking. some human beings can also have a low sense of scent and in such instances they'll now not be able to respond for the gasoline concentration present. Consequently, a protection primarily based LPG detection system is crucial to provide alertness, protection and protection from any harmful fuel leakage injuries. The incidents which include Kumbakonam and Bhopal fuel tragedy were the examples of the arena’s worst fuel leakage injuries. This leakage detection gadget detects the fuel leakage and additionally stops the gasoline deliver together with an alarm and a GSM alerts the required person. The fuel sensor we used right here identifies the toxic gases other than LPG and its voltage goes LOW when there's a leakage of any toxic fuel. LOW signal is despatched to a microcontroller which in flip sends those alerts to the buzzer hence, rising an alarm. After some milliseconds, the fuel leakage message is sent to the user identified mobile range thru GSM module.

INTRODUCTION ABOUT EMBEDDED SYSTEMS

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.
The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.
The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

Block diagram of embedded system:

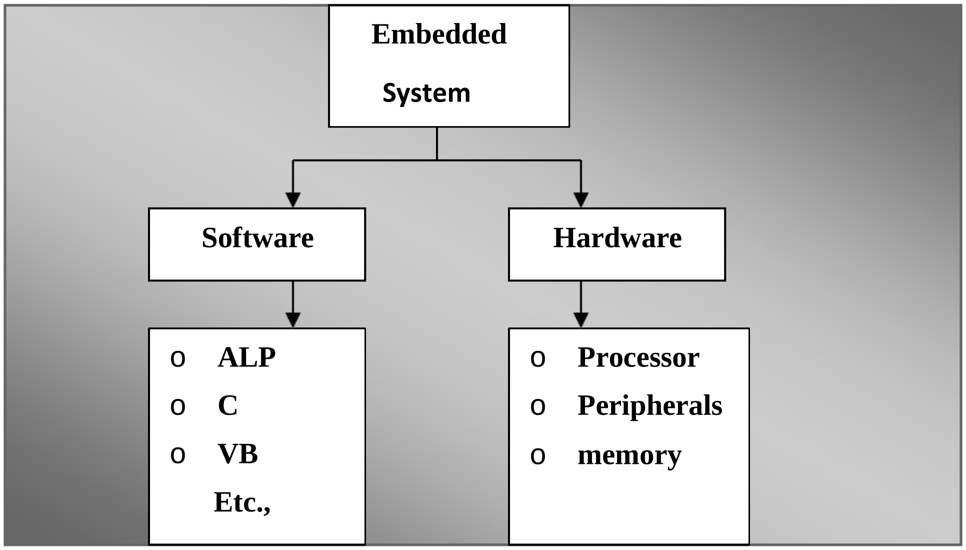

Fig.1.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic system.

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

Three Basic Elements of a Microprocessor:

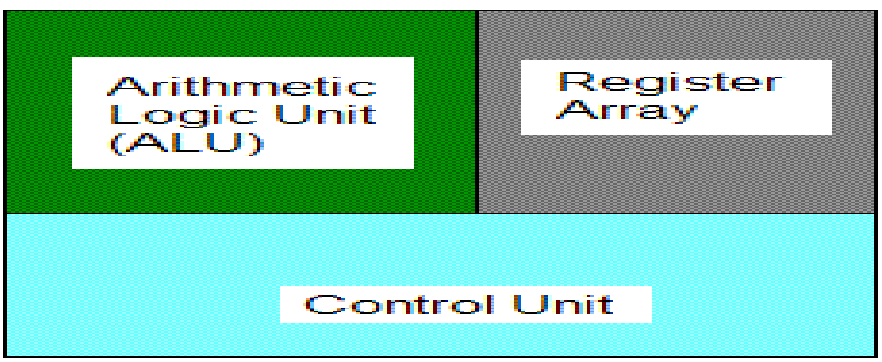

Fig.1.2: Three basic elements of a microprocessor

Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

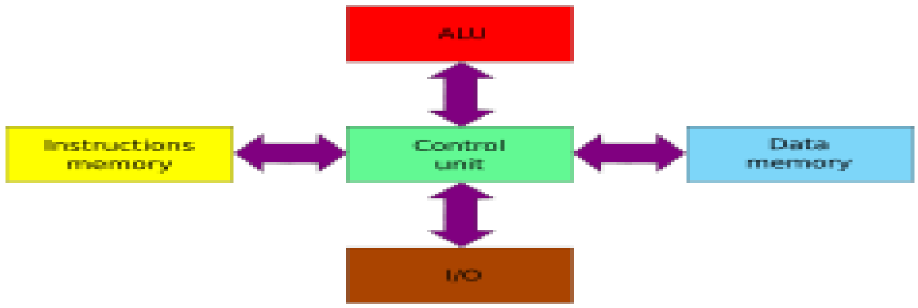

Fig.1.3: Harvard Architecture

Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

➢ Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

➢ Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

MICRO CONTROLLER UNIT

ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltag	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Specifications:

Table 1.1: Atmega328 specifications

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

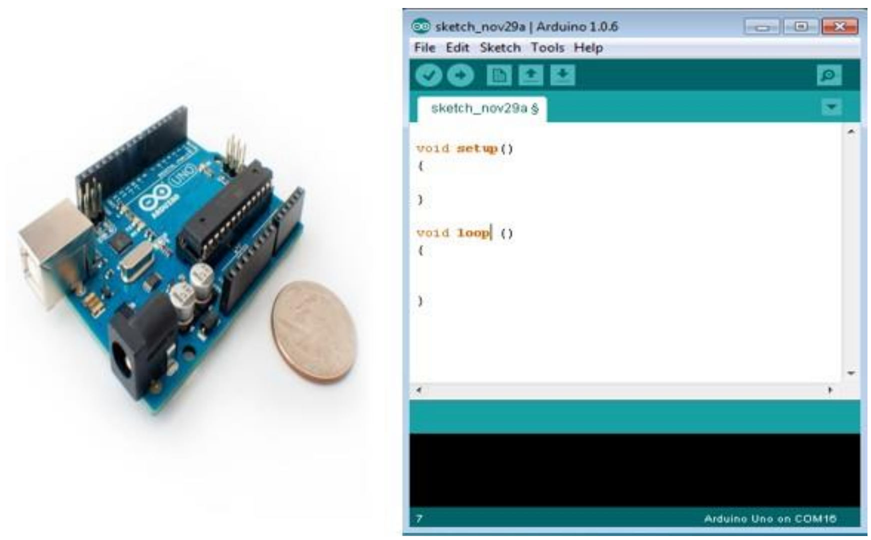

Fig 1.4 Arduino Uno hardware

Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Board Name	**Operating V**	**Clock Sp**	**Digital i/**	**Analog In**	**PWM**	**UART**	**Program Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB ATMega1

Table 1.5 Arduino boards based on AT91SAM3X8E microcontroller

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

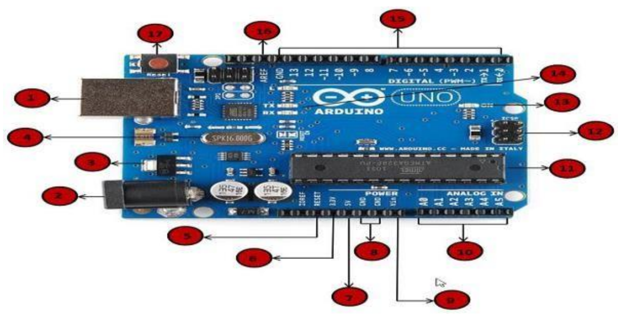

Fig:1.5 Broad description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need t connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and st the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate The answer is, by using the crystal oscillator. The number printed on top of the Arduino cr 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can re UNO board in two ways. First, by using the reset button (17) on the board. Second, you can c an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the from an analog sensor like the humidity sensor or temperature sensor and convert it into a value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your The main IC (integrated circuit) on the Arduino is slightly different from board to boar

	microcontrollers are usually of the ATMEL Company. You must know what IC your board has loading up a new program from the Arduino IDE. This information is available on the top of For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), could be considered as an "expansion" of the output. Actually, you are slaving the output de the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that you is powered up correctly. If this light does not turn on, then there is something wrong w connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible fo communication. Second, the TX and RX led (13). The TX led flashes with different speed sending the serial data. The speed of flashing depends on the baud rate used by the board. RX during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Modulation) output. These pins can be configured to work as input digital pins to read logic va or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins label can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference v (between 0 and 5 Volts) as the upper limit for the analog input pins.

ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.1.6: Arduino Family

SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

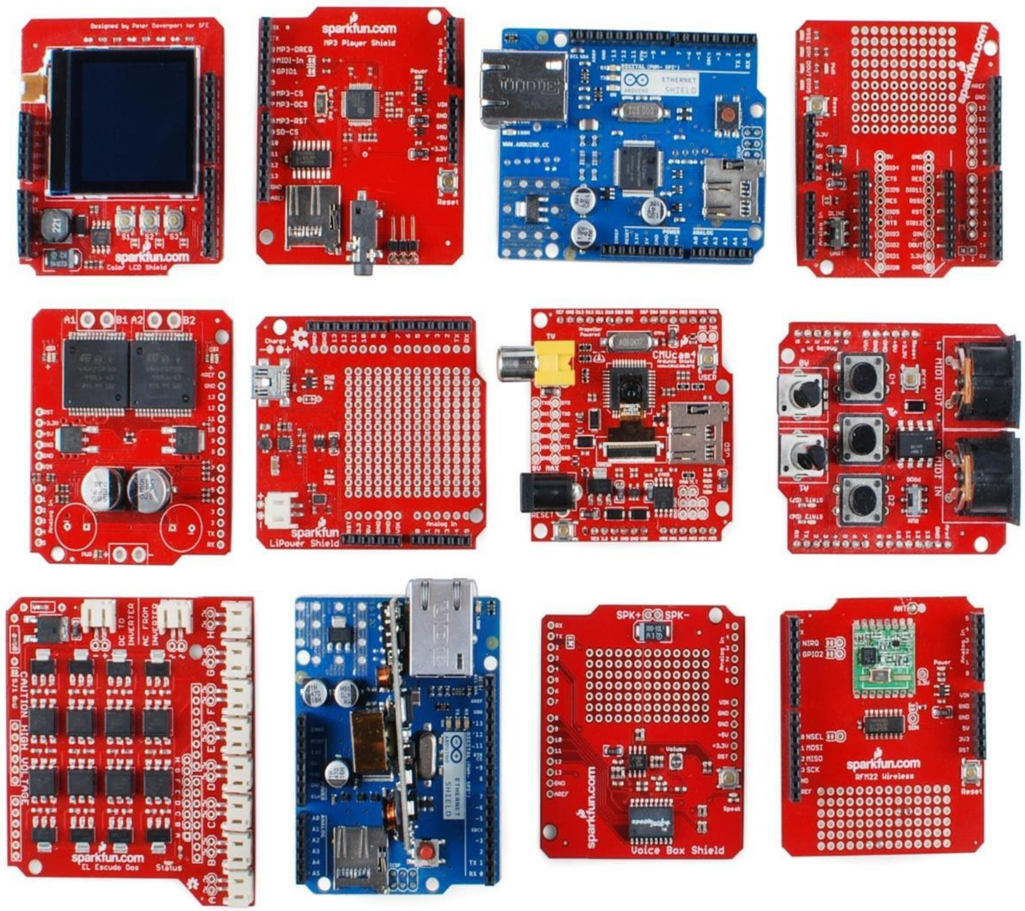

Fig.1.7: Arduino Shields

PIN DESCRIPTION OF ATMEGA328

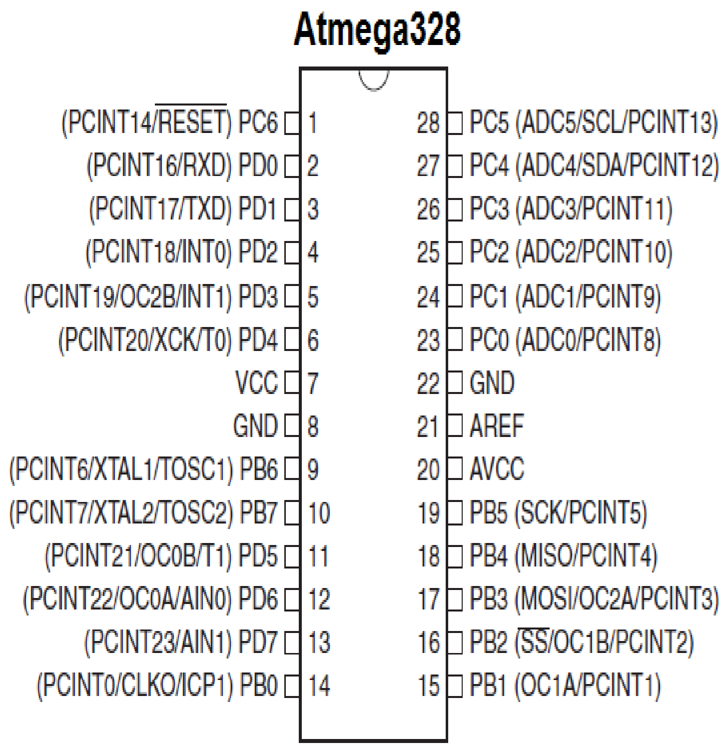

Fig.1.8: Pin description of ATMEGA328

ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

CHAPTER 2
LITERATURE SURVEY

We purpose a system to come across LPG fuel leakage situation and offer a security alert to supposed customers. We right here endorse to build the gadget the use of a MQ5 gas detection sensor. If the LPG sensor senses any gas leakage from storage, gas sensor is going stumble on it this sign is monitored by using the microcontroller and it will perceive the gasoline leakage. Now the micro controller is turn on LED and Buzzer.

After few milli seconds put off microcontroller instructions driving force circuitry for exhaust fan to turn the fan on to release the gasoline out door from the room and concurrently microcontroller commands every other circuitry a relay circuitry to shut the fuel knob. In our proposed machine we designed two motive forces circuitry one to power motor to close knob. And any other is relay circuitry in which replay is used to switched on and rancid for exhaust fan. Microcontroller is programmed by using Embedded C Language. It's for the complete controller of the task. It controls the exhaust fan, LED, Buzzer and when the LPG leak takes place. The entire output ports of the microcontroller is used for this.

Literature review on research area

In 1982, the European Conference of Postal and Telecommunications Administrations (CEPT) created the Group Special Mobile (GSM) to develop a standard for a mobile telephone system that could be used across Europe. In 1987, a memorandum of understanding was signed by 13 countries to develop a common cellular telephone system across Europe. Finally the system created by SINTEF lead by Torleiv Maseng was selected.

In 1989, GSM responsibility was transferred to the European Telecommunications Standards Institute (ETSI) and phase I of the GSM specifications were published in 1990. The first GSM network was launched in 1991 by Radiolinja in Finland with joint technical infrastructure maintenance from Ericsson.

By the end of 1993, over a million subscribers were using GSM phone networks being operated by 70 carriers across 48 countries. As of the end of 1997, GSM service was available in more than 100 countries and has become the *de facto* standard in Europe and Asia.

Conclusion on the Review

- A number of reviews on the subject of gas leakage detection techniques were done in the past either as part of research papers/technical reports on a certain leak detection method and other gas related subjects.

- Ch. Manohar Raju and N. Sushma Rani, 2008; they introduce an android based automatic gas detection and indication robot. They proposed prototype depicts a mini mobile robot which is capable to detect gas leakage in hazardous places.

- Whenever there is an occurrence of gas leakage in a particular place the robot immediately read and sends the data to android mobile through wireless communication like Bluetooth.

- We developed an android application for android based smart phones which can receive data from robot directly through Bluetooth.

- The application warns with an indication whenever there is an occurrence of gas leakage and we can also control the robot movements via Bluetooth.

- Pal-Stefan Murvaya, Ioan Sileaa, 2008; they told in their survey on gas leak detection and localization techniques various ways to detect the gas leakage. They introduce some old or new technique to detect the gas. The proposed techniques in this paper are non-technical methods, hardware based methods which includes acoustic methods, optical methods and active methods.

CHAPTER 3

PROJECT DESIGN

Block Diagram

There are numerous answers for fireplace accidents that agencies continually endorse. Smoke detectors, hearth alarms, hearth extinguishers and sprinklers are examples of those gadgets. On reflection, those devices can also alert or prevent the unfold of fire but they do not save you hearth injuries, and that alone is a main downside already. This have a look at makes a speciality of the LPG fuel and the way to save you it from causing greater injuries. There's a want to build a system that aids people's negligence of their surroundings even as stopping the begin of conflagration. The device also implements a shut-off mechanism which acts as the first line of defence inside the prevention of the coincidence ought to there be an absence of individual inside the residence. Liquefied Petroleum fuel is constituent of Butane and Propane gases, which can be distinctly inflammable in nature.

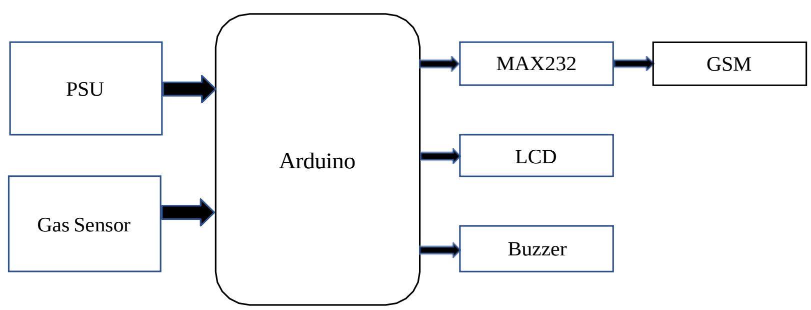

Fig.3.1 block diagram

The blocks of the circuit are:

1.Arduino Uno

2.MQ 2 gas sensor

3.Buzzer

4.LCD display

5.GSM Module

6.Power Supply Unit

1.Arduino UNO

Arduino is opensource software. Arduino Uno is a microcontroller, ATmega328Pcontain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2.MQ2 gas sensor

Gas sensors main aim is to sense hazardous gases that evolve its surroundings. It detects the concentrations of combustible gas in the air and outputs its reading as an analog voltage. The sensor can measure concentrations of flammable gas of 300 to 10,000 ppm. The sensor can operate at temperatures from -20 to 50°C and consumes less than 150 mA at 5 V. This sensor is connected to LCD and when there is a leakage of gas this sensor senses and a message is displayed on the LCD indicating the leakage of gas. This sensor is also connected to a buzzer and the buzzer sounds whenever the gas leakage is detected.

3. Buzzer

Typical uses of buzzers include alarm devices, timers and confirmation of user input such as a mouse click or keystroke.

4. LCD

The LCD is used to display when ever there is a gas leakage or fire detected in the area. When ever there is a gas leakage the Arduino that is connected to the sensor and LCD sends a message to LCD to display 'Gas leakage'. When there is fire outbreak the Arduino again sends a message to LCD to display 'Fire Detected' notifying us if there is a gas leakage or fire detected in the vicinity.

5. GSM

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services.

GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. It supports voice calls and data transfer speeds of up to 9.6 kbit/s, together with the transmission of SMS (Short Message Service).

6. Power Supply Unit

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage 31 stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

Schematic Diagram

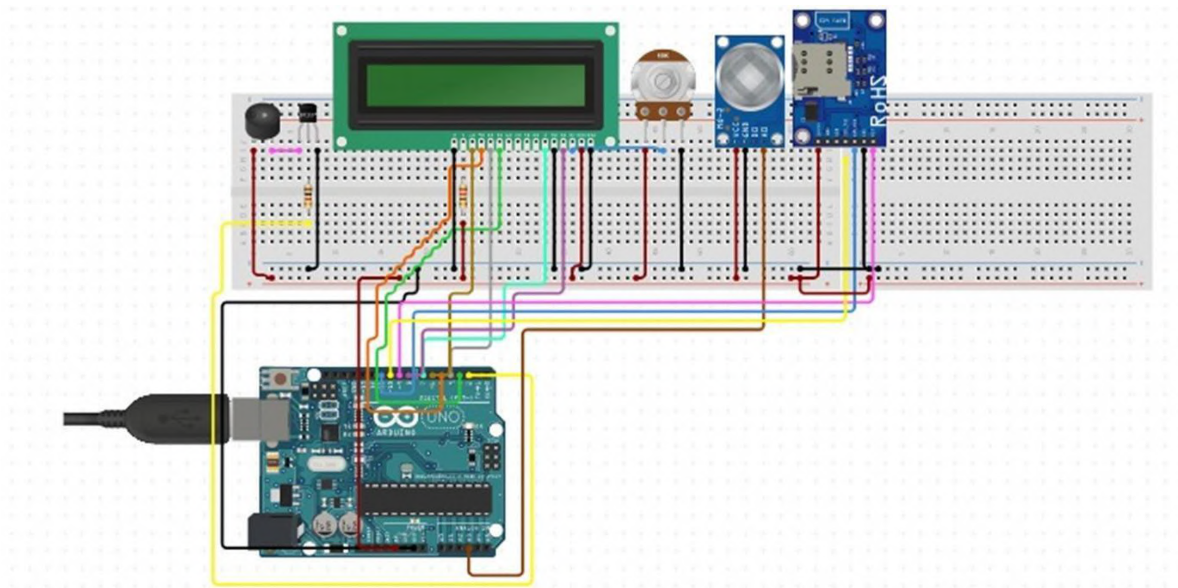

FIG:3.2 Schematic Diagram

Explanation of Schematic Diagram

The circuit mainly uses the gas sensor and Arduino to detect and smoke and gas leak. This low signal is monitored by the microcontroller and sends the signal to GSM Module to send messages as “Gas leakage” to a mobile number written in code. We can also use SIM900 or any other GSM Module instead of SIM800.

CHAPTER 4

PROJECT IMPLEMENTATION

1 Hardware Description

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

00	01	02	03	04	05	06	07		32	33	34	35	36	37	38	39	← Character position (dec.)
00	01	02	03	04	05	06	07	• • • • •	20	21	22	23	24	25	26	27	← Row0 DDRAM address (hex)
40	41	42	43	44	45	46	47	• • • • •	60	61	62	63	64	65	66	67	← Row1 DDRAM address (hex)

DDRAM Address for 2 Line LCD

Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

Busy Flag

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i. e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

Instruction Register (IR) and Data Register (DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing

- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

GSM :

Definition of GSM:

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services.

GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. It supports voice calls and data transfer speeds of up to 9.6 kbit/s, together with the transmission of SMS (Short Message Service).

GSM Frequencies

GSM networks operate in a number of different frequency ranges (separated into GSM frequency ranges for 2G and UMTS frequency bands for 3G). Most 2G GSM networks operate in the 900 MHz or 1800 MHz bands. Some countries in the Americas (including Canada and the United States) use the 850 MHz and 1900 MHz bands because the 900 and 1800 MHz frequency bands were already allocated. Most 3G GSM networks in Europe operate in the 2100 MHz frequency band. The rarer 400 and 450 MHz frequency bands are assigned in some countries where these frequencies were previously used for first-generation systems.

GSM-900 uses 890–915 MHz to send information from the mobile station to the base station (uplink) and 935–960 MHz for the other direction (downlink), providing 124 RF channels (channel numbers 1 to 124) spaced at 200 kHz. Duplex spacing of 45 MHz is used. In some countries the GSM-900 band has been extended to cover a larger frequency range. This 'extended GSM', E-GSM, uses 880–915 MHz (uplink) and 925–960 MHz (downlink), adding 50 channels (channel numbers 975 to 1023 and 0) to the original GSM-900 band.

Time division multiplexing is used to allow eight full-rate or sixteen half-rate speech channels per radio frequency channel. There are eight radio timeslots (giving eight burst periods) grouped into what is called a TDMA frame. Half rate channels use alternate frames in the same timeslot. The channel data rate for all 8 channels is 270.833 Kbit/s, and the frame duration is 4.615 ms.

The transmission power in the handset is limited to a maximum of 2 watts in GSM850/900 and 1 watt in GSM1800/1900. GSM operates in the 900MHz and 1.8GHz bands in Europe and the 1.9GHz and 850MHz bands in the US. The 850MHz band is also used for GSM and 3G in Australia, Canada and many South American countries. By having harmonized spectrum across most of the globe, GSM's international roaming capability allows users to access the same services when travelling abroad as at home. This gives consumers seamless and same number connectivity in more than 218 countries.

Terrestrial GSM networks now cover more than 80% of the world's population. GSM satellite roaming has also extended service access to areas where terrestrial coverage is not available.

Mobile Telephony Standards

Standard	Generation	Frequency band	Throughput	
GSM	2G	Allows transfer of voice or low-volume digital data.	9.6 kbps	9.6 kbps
GPRS	2.5G	Allows transfer of voice or moderate-volume digital data.	21.4-171.2 kbps	48 kbps
EDGE	2.75G	Allows simultaneous transfer of voice and digital data.	43.2-345.6 kbps	171 kbps
UMTS	3G	Allows simultaneous transfer of voice and high-speed digital data.	0.144-2 Mbps	384 kbps

1G: The first generation of mobile telephony (written **1G**) operated using analogue communications and portable devices that were relatively large. It used primarily the following standards:

- **AMPS** (Advanced Mobile Phone System), which appeared in 1976 in the United States, was the first cellular network standard. It was used primarily in the Americas, Russia and Asia. This first-generation analogue network had weak security mechanisms which allowed hacking of telephones lines.
- **TACS** (Total Access Communication System) is the European version of the AMPS model. Using the 900 MHz frequency band, this system was largely used in England and then in Asia (Hong-Kong and Japan).
- **ETACS** (Extended Total Access Communication System) is an improved version of the TACS standard developed in the United Kingdom that uses a larger number of communication channels.

The first-generation cellular networks were made obsolete by the appearance of an entirely digital second generation.

Second Generation of Mobile Networks (2G)

The second generation of mobile networks marked a break with the first generation of cellular telephones by switching from analogue to digital. The main 2G mobile telephony standards are:

- GSM (*Global System for Mobile communications*) is the most commonly used standard in Europe at the end of the 20^{th} century and supported in the United States. This standard uses the 900 MHz and 1800 MHz frequency bands in Europe. In the United States, however, the frequency band used is the 1900 MHz band. Portable telephones that are able to operate in Europe and the United States are therefore called **tri-band**.
- **CDMA** (*Code Division Multiple Access*) uses a spread spectrum technique that allows a radio signal to be broadcast over a large frequency range.
- **TDMA** (*Time Division Multiple Access*) uses a technique of time division of communication channels to increase the volume of data transmitted simultaneously. TDMA

technology is primarily used on the American continent, in New Zealand and in the Asia-Pacific region.

With the 2G networks, it is possible to transmit voice and low volume digital data, for example text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*). The GSM standard allows a maximum data rate of 9.6 kbps.

Extensions have been made to the GSM standard to improve throughput. One of these is the **GPRS** (*General Packet Radio System*) service which allows theoretical data rates on the order of 114 Kbit/s but with throughput closer to 40 Kbit/s in practice. As this technology does not fit within the "3G" category, it is often referred to as **2.5G**

The **EDGE** (*Enhanced Data Rates for Global Evolution*) standard, billed as **2.75G**, quadruples the throughput improvements of GPRS with its theoretical data rate of 384 Kbps, thereby allowing the access for multimedia applications. In reality, the EDGE standard allows maximum theoretical data rates of 473 Kbit/s, but it has been limited in order to comply with the IMT-2000 (*International Mobile Telecommunications-2000*) specifications from the ITU (*International Telecommunications Union*).

3G

The IMT-2000 (*International Mobile Telecommunications for the year 2000*) specifications from the International Telecommunications Union (ITU) defined the characteristics of **3G** (third generation of mobile telephony). The most important of these characteristics are:

1. High transmission data rate.
2. 144 Kbps with total coverage for mobile use.
3. 384 Kbps with medium coverage for pedestrian use.
4. 2 Mbps with reduced coverage area for stationary use.
5. World compatibility.
6. Compatibility of 3rd generation mobile services with second generation networks.

3G offers data rates of more than 144 Kbit/s, thereby allowing the access to multimedia uses such as video transmission, video-conferencing or high-speed internet access. 3G networks use different frequency bands than the previous networks: 1885-2025 MHz and 2110-2200 MHz.

The main 3G standard used in Europe is called **UMTS** (*Universal Mobile Telecommunications System*) and uses **WCDMA** (*Wideband Code Division Multiple Access*) encoding. UMTS technology uses 5 MHz bands for transferring voice and data, with data rates that can range from 384 Kbps to 2 Mbps. **HSDPA** (*High Speed Downlink Packet Access*) is a third generation mobile telephony protocol, (considered as "3.5G"), which is able to reach data rates on the order of 8 to 10 Mbps. HSDPA technology uses the 5 GHz frequency band and uses WCDMA encoding.

Introduction to the GSM Standard

The **GSM** (*Global System for Mobile communications*) network is at the start of the 21st century, the most commonly used mobile telephony standard in Europe. It is called as Second Generation (2G) standard because communications occur in an entirely digital mode, unlike the first generation of portable telephones. When it was first standardized in 1982, it was called as **Group Special Mobile** and later, it became an international standard called **"Global System for Mobile communications"** in 1991.

In Europe, the GSM standard uses the 900 MHz and 1800 MHz frequency bands. In the United States, however, the frequency band used is the 1900 MHz band. For this reason, portable telephones that are able to operate in both Europe and the United States are called **tri-band** while those that operate only in Europe are called **bi-band**.

The GSM standard allows a maximum throughput of 9.6 kbps which allows transmission of voice and low-volume digital data like text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*).

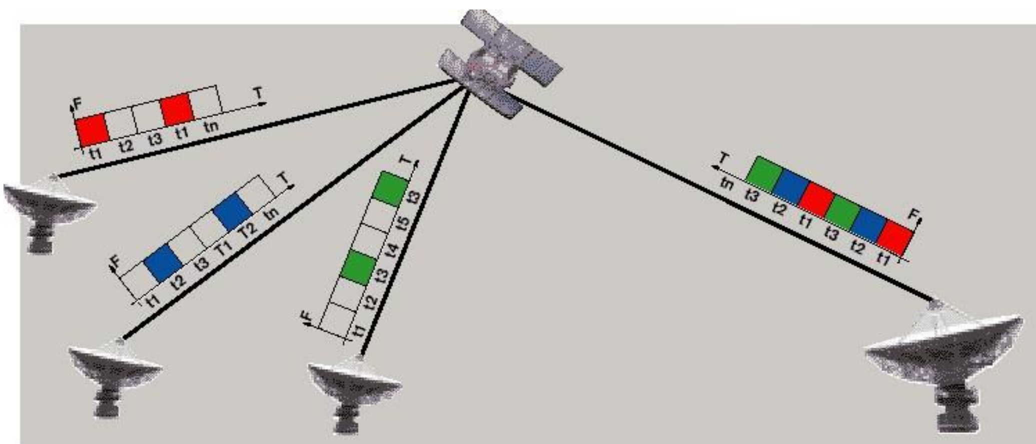
GSM Standards:

GSM uses narrowband TDMA, which allows eight simultaneous calls on the same radio frequency. There are three basic principles in multiple access, FDMA (Frequency Division Multiple Access), TDMA (Time Division Multiple Access), and CDMA (Code Division Multiple Access). All three principles allow multiple users to share the same physical channel. But the two competing technologies differ in the way user sharing the common resource.

TDMA allows the users to share the same frequency channel by dividing the signal into different time slots. Each user takes turn in a round robin fashion for transmitting and receiving over the channel. Here, users can only transmit in their respective time slot.

TDMA in brief:

In late1980's, as a search to convert the existing analog network to digital as a means to improve capacity, the cellular telecommunications industry association chose TDMA over FDMA. Time Division Multiplex Access is a type of multiplexing where two or more channels of information are transmitted over the same link by allocating a different time interval for the transmission of each channel. The most complex implementation using TDMA principle is of GSM's (Global System for Mobile communication). To reduce the effect of co-channel interference, fading and multipath, the GSM technology can use frequency hopping, where a call jumps from one channel to another channel in a short interval.



Time Division Multiple Access

Fig:4.1.1 Time Division Multiple Access

TDMA systems still rely on switch to determine when to perform a handoff. Handoff occurs when a call is switched from one cell site to another while travelling. The TDMA handset constantly monitors the signals coming from other sites and reports it to the switch without caller's awareness. The switch then uses this information for making better choices for handoff at appropriate times. TDMA handset performs hard handoff, i.e., whenever the user moves from one site to another, it breaks the connection and then provides a new connection with the new site.

Advantages of TDMA:

There are lots of advantages of TDMA in cellular technologies.

1. It can easily adapt to transmission of data as well as voice communication.
2. It has an ability to carry 64 kbps to 120 Mbps of data rates. This allows the operator to do services like fax, voice band data and SMS as well as bandwidth intensive application such as multimedia and video conferencing.
3. Since TDMA technology separates users according to time, it ensures that there will be no interference from simultaneous transmissions.
4. It provides users with an extended battery life, since it transmits only portion of the time during conversations. Since the cell size grows smaller, it proves to save base station equipment, space and maintenance.

TDMA is the most cost effective technology to convert an analog system to digital.

Disadvantages of TDMA:

One major disadvantage using TDMA technology is that the users has a predefined time slot. When moving from one cell site to other, if all the time slots in this cell are full the user might be disconnected. Likewise, if all the time slots in the cell in which the user is currently in are already occupied, the user will not receive a dial tone.

The second problem in TDMA is that it is subjected to multipath distortion. To overcome this distortion, a time limit can be used on the system. Once the time limit is expired, the signal is ignored.

The concept of cellular network

Mobile telephone networks are based on the concept of **cells**, circular zones that overlap to cover a geographical area. Cellular networks are based on the use of a central transmitter-receiver in each cell, called a "**base station**" (or *Base Transceiver Station*, written **BTS**). The smaller the radius of a cell, the higher is the available bandwidth.

So, in highly populated urban areas, there are cells with a radius of a few hundred meters, while huge cells of up to 30 kilometers provide coverage in rural areas.

In a cellular network, each cell is surrounded by 6 neighbouring cells (thus a cell is generally drawn as a hexagon). To avoid interference, adjacent cells cannot use the same frequency. In practice, two cells using the same frequency range must be separated by a distance of two to three times the diameter of the cell.

Architecture of the GSM Network

In a GSM network, the user terminal is called a **mobile station**. A mobile station is made up of a **SIM** (*Subscriber Identity Module*) card allowing the user to be uniquely identified and a mobile terminal. The terminals (devices) are identified by a unique 15-digit identification number called **IMEI** (*International Mobile Equipment Identity*). Each SIM card also has a unique (and secret) identification number called **IMSI** (*International Mobile Subscriber Identity*). This code can be protected using a 4-digit key called a *PIN code*.

The SIM card therefore allows each user to be identified independently of the terminal used during communication with a base station. Communications occur through a radio link (air interface) between a mobile station and a base station.

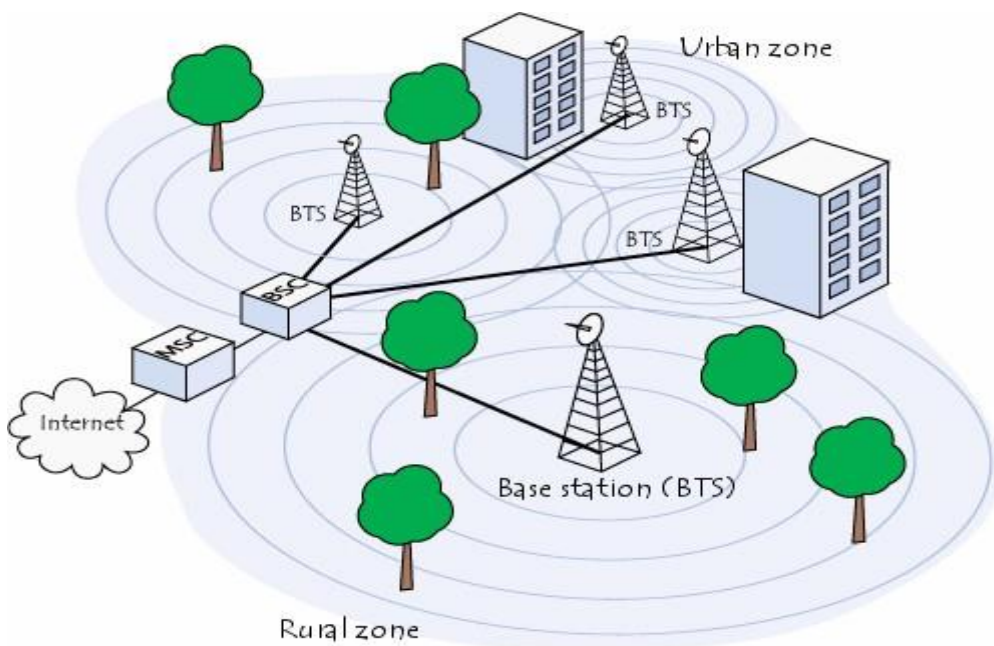


Fig:4.1.2 GSM Network

All the base stations of a cellular network are connected to a **base station controller** (**BSC**) which is responsible for managing distribution of the resources. The system consisting of the base station controller and its connected base stations is called the **Base Station Subsystem** (**BSS**).

Finally, the base station controllers are themselves physically connected to the **Mobile Switching Centre** (**MSC**), managed by the telephone network operator, which connects them to the public telephone network and the Internet. The MSC belongs to a **Network Station Subsystem** (**NSS**), which is responsible for managing user identities, their location and establishment of communications with other subscribers. The MSC is generally connected to databases that provide additional functions:

1. The **Home Location Register** (**HLR**) is a database containing information (geographic position, administrative information etc.) of the subscribers registered in the area of the switch (MSC).
2. The **Visitor Location Register** (**VLR**) is a database containing information of users other than the local subscribers. The VLR retrieves the data of a new user from the HLR of the user's subscriber zone. The data is maintained as long as the user is in the zone and is deleted when the user leaves or after a long period of inactivity (terminal off).
3. The **Equipment Identify Register** (**EIR**) is a database listing the mobile terminals.
4. The **Authentication Centre** (**AUC**) is responsible for verifying user identities.
5. The cellular network formed in this way is designed to support mobility via management of *handovers* (movements from one cell to another).

Finally, GSM networks support the concept of **roaming** i.e., movement from one operator network to another.

Introduction to Modem:

Modem stands for *modulator-demodulator.*

A modem is a device or program that enables a computer to transmit data over telephone or cable lines. Computer information is stored digitally, whereas information transmitted over telephone lines is transmitted in the form of analog waves. A modem converts between these two forms.

Fortunately, there is one standard interface for connecting external modems to computers called *RS-232*. Consequently, any external modem can be attached to any computer that has an RS-232 port, which almost all personal computers have. There are also modems that come as an expansion board that can be inserted into a vacant expansion slot. These are sometimes called *onboard* or *internal modems*.

While the modem interfaces are standardized, a number of different protocols for formatting data to be transmitted over telephone lines exist. Some, like CCITT V.34 are official standards, while others have been developed by private companies. Most modems have built-in support for the more common protocols at slow data transmission speeds at least, most modems can communicate with each other. At high transmission speeds, however, the protocols are less standardized.

Apart from the transmission protocols that they support, the following characteristics distinguish one modem from another:

- **Bps:** How fast the modem can transmit and receive data. At slow rates, modems are measured in terms of baud rates. The slowest rate is 300 baud (about 25 cps). At higher speeds, modems are measured in terms of bits per second (bps). The fastest modems run at 57,600 bps, although they can achieve even higher data transfer rates by compressing the data. Obviously, the faster the transmission rate, the faster the data can be sent and received. It should be noted that the data cannot be received at a faster rate than it is being sent.
- **Voice/data:** Many modems support a switch to change between voice and data modes. In data mode, the modem acts like a regular modem. In voice mode, the modem acts like a regular telephone. Modems that support a voice/data switch have a built-in loudspeaker and microphone for voice communication.
- **Auto-answer:** An auto-answer modem enables the computer to receive calls in the absence of the operator.
- **Data compression:** Some modems perform data compression, which enables them to send data at faster rates. However, the modem at the receiving end must be able to decompress the data using the same compression technique.
- **Flash memory:** Some modems come with *flash memory* rather than conventional ROM which means that the communications protocols can be easily updated if necessary.

- **Fax capability:** Most modern modems are fax modems, which mean that they can send and receive faxes.

GSM Modem:

A GSM modem is a wireless modem that works with a GSM wireless network. A wireless modem behaves like a dial-up modem. The main difference between them is that a dial-up modem sends and receives data through a fixed telephone line while a wireless modem sends and receives data through radio waves.

Fig:4.1.3 GSM Modem

A GSM modem can be an external device or a PC Card / PCMCIA Card. Typically, an external GSM modem is connected to a computer through a serial cable or a USB cable. A GSM modem in the form of a PC Card / PCMCIA Card is designed for use with a laptop computer. It should be inserted into one of the PC Card / PCMCIA Card slots of a laptop computer. Like a GSM mobile phone, a GSM modem requires a SIM card from a wireless carrier in order to operate.
A SIM card contains the following information:

- Subscriber telephone number (MSISDN)
- International subscriber number (**IMSI, International Mobile Subscriber Identity)**
- State of the SIM card

- Service code (operator)
- Authentication key
- PIN (***Personal Identification Code***)
- PUK (***Personal Unlock Code***)

Computers use AT commands to control modems. Both GSM modems and dial-up modems support a common set of standard AT commands. In addition to the standard AT commands, GSM modems support an extended set of AT commands. These extended AT commands are defined in the GSM standards. With the extended AT commands, the following operations can be performed:

- Reading, writing and deleting SMS messages.
- Sending SMS messages.
- Monitoring the signal strength.
- Monitoring the charging status and charge level of the battery.
- Reading, writing and searching phone book entries.

The number of SMS messages that can be processed by a GSM modem per minute is very low i.e., about 6 to 10 SMS messages per minute.

Introduction to AT Commands

AT commands are instructions used to control a modem. AT is the abbreviation of ATtention. Every command line starts with "AT" or "at". That's the reason, modem commands are called AT commands. Many of the commands that are used to control wired dial-up modems, such as ATD (Dial), ATA (Answer), ATH (Hook control) and ATO (Return to online data state) are also supported by GSM modems and mobile phones.

Besides this common AT command set, GSM modems and mobile phones support an AT command set that is specific to the GSM technology, which includes SMS-related commands like AT+CMGS (Send SMS message), AT+CMSS (Send SMS message from storage), AT+CMGL (List SMS messages) and AT+CMGR (Read SMS messages).

It should be noted that the starting "AT" is the prefix that informs the modem about the start of a command line. It is not part of the AT command name. For example, D is the actual AT command name in ATD and +CMGS is the actual AT command name in AT+CMGS.

Some of the tasks that can be done using AT commands with a GSM modem or mobile phone are listed below:

- Get basic information about the mobile phone or GSM modem. For example, name of manufacturer (AT+CGMI), model number (AT+CGMM), IMEI number (International Mobile Equipment Identity) (AT+CGSN) and software version (AT+CGMR).
- Get basic information about the subscriber. For example, MSISDN (AT+CNUM) and IMSI number (International Mobile Subscriber Identity) (AT+CIMI).
- Get the current status of the mobile phone or GSM/GPRS modem. For example, mobile phone activity status (AT+CPAS), mobile network registration status (AT+CREG), radio signal strength (AT+CSQ), battery charge level and battery charging status (AT+CBC).
- Establish a data connection or voice connection to a remote modem (ATD, ATA, etc).
- Send and receive fax (ATD, ATA, AT+F*).
- Send (AT+CMGS, AT+CMSS), read (AT+CMGR, AT+CMGL), write (AT+CMGW) or delete (AT+CMGD) SMS messages and obtain notifications of newly received SMS messages (AT+CNMI).
- Read (AT+CPBR), write (AT+CPBW) or search (AT+CPBF) phonebook entries.
- Perform security-related tasks, such as opening or closing facility locks (AT+CLCK), checking whether a facility is locked (AT+CLCK) and changing passwords(AT+CPWD). (Facility lock examples: SIM lock [a password must be given to the SIM card every time the mobile phone is switched on] and PH-SIM lock [a certain SIM card is associated with the mobile phone. To use other SIM cards with the mobile phone, a password must be entered.])
- Control the presentation of result codes / error messages of AT commands. For example, the user can control whether to enable certain error messages (AT+CMEE) and whether error messages should be displayed in numeric format or verbose format (AT+CMEE=1 or AT+CMEE=2).

- Get or change the configurations of the mobile phone or GSM/GPRS modem. For example, change the GSM network (AT+COPS), bearer service type (AT+CBST), radio link protocol parameters (AT+CRLP), SMS center address (AT+CSCA) and storage of SMS messages (AT+CPMS).
- Save and restore configurations of the mobile phone or GSM/GPRS modem. For example, save (AT+CSAS) and restore (AT+CRES) settings related to SMS messaging such as the SMS center address.
- It should be noted that the mobile phone manufacturers usually do not implement all AT commands, command parameters and parameter values in their mobile phones. Also, the behavior of the implemented AT commands may be different from that defined in the standard. In general, GSM modems, designed for wireless applications, have better support of AT commands than ordinary mobile phones.

Basic concepts of SMS technology

1. Validity Period of an SMS Message

An SMS message is stored temporarily in the SMS center if the recipient mobile phone is offline. It is possible to specify the period after which the SMS message will be deleted from the SMS center so that the SMS message will not be forwarded to the recipient mobile phone when it becomes online. This period is called the validity period. A mobile phone should have a menu option that can be used to set the validity period. After setting it, the mobile phone will include the validity period in the outbound SMS messages automatically.

2. Message Status Reports

Sometimes the user may want to know whether an SMS message has reached the recipient mobile phone successfully. To get this information, you need to set a flag in the SMS message to notify the SMS center that a status report is required about the delivery of this SMS message. The status report is sent to the user mobile in the form of an SMS message.

A mobile phone should have a menu option that can be used to set whether the status report feature is on or off. After setting it, the mobile phone will set the corresponding flag in the outbound SMS messages for you automatically. The status report feature is turned off by default on most mobile phones and GSM modems.

3. Message Submission Reports

After leaving the mobile phone, an SMS message goes to the SMS center. When it reaches the SMS center, the SMS center will send back a message submission report to the mobile phone to inform whether there are any errors or failures (e.g. incorrect SMS message format, busy SMS center, etc). If there is no error or failure, the SMS center sends back a positive submission report to the mobile phone. Otherwise it sends back a negative submission report to the mobile phone. The mobile phone may then notify the user that the message submission was failed and what caused the failure.

If the mobile phone does not receive the message submission report after a period of time, it concludes that the message submission report has been lost. The mobile phone may then send the SMS message again to the SMS center. A flag will be set in the new SMS message to inform the SMS center that this SMS message has been sent before. If the previous message submission was successful, the SMS center will ignore the new SMS message but send back a message submission report to the mobile phone. This mechanism prevents the sending of the same SMS message to the recipient multiple times.

Sometimes the message submission report mechanism is not used and the acknowledgement of message submission is done in a lower layer.

4 .Message Delivery Reports

After receiving an SMS message, the recipient mobile phone will send back a message delivery report to the SMS center to inform whether there are any errors or failures (example causes: unsupported SMS message format, not enough storage space, etc). This process is transparent to the mobile user. If there is no error or failure, the recipient mobile phone sends back a positive delivery report to the SMS center. Otherwise it sends back a negative delivery report to the SMS center.

If the sender requested a status report earlier, the SMS center sends a status report to the sender when it receives the message delivery report from the recipient. If the SMS center does not receive the message delivery report after a period of time, it concludes that the message delivery report has been lost. The SMS center then ends the SMS message to the recipient for the second time.

Sometimes the message delivery report mechanism is not used and the acknowledgement of message delivery is done in a lower layer.

GAS SENSOR

- A sensor is a technological device that detects / senses a signal, physical condition and chemical compounds.
- It is also defined as any device that converts a signal from one form to another.

Sensors are mostly electrical or electronic.

- Gas sensor is a subclass of chemical sensors.
- Gas sensor measures the concentration of gas in its vicinity. Gas sensor interacts with a gas to measure its concentration. Each gas has a unique breakdown voltage i.e. the electric field at which it is ionized. Sensor identifies gases by measuring these voltages. The concentration of the gas can be determined by measuring the current discharge in the device.

applications

- Process control industries
- Environmental monitoring
- Boiler control
- Fire detection
- Alcohol breath tests
- Detection of harmful gases in mines
- Home safety
- Grading of agro-products like coffee and spices

Gas sensing technologies:

- Metal Oxide Based Gas Sensors
- Capacitance Based Gas Sensors

- Acoustic Wave Based Gas Sensors
- Calorimetric Gas Sensors
- Optical gas sensors
- Electrochemical gas sensors

types

1. **Metal Oxide Based Gas Sensors**

- Metal oxide sensors are also known as chemiresistors.
- The detection principle of resistive sensors is based on change of the resistance of a thin film upon adsorption of the gas molecules on the surface of a semiconductor.
- The gas-solid interactions affect the resistance of the film because of the density of electronic
- species in the film.

Capacitance Based Gas Sensors

- They measure the change in dielectric constant of films between the electrodes as a function of the gas concentration.
- The capacitive sensor relies on inter-digitated electrode structures, which correspond to the two plates of a standard capacitor, to monitor changes of the dielectric coefficient of the film.
- The simple theory behind it is if the dielectric constant of the film is lower than that of the analyte, the capacitance will increase and vice versa.

Acoustic Wave Based Gas Sensors

- Sound based gas sensors are known as acoustic wave based gas sensors.

- To launch the acoustic waves, this type of sensor use piezoelectric material either in the thin film form or in bulk form which has one or more transducers on its surface.

Carbon monoxide gas sensor

- It can either be battery-operated or AC powered.
- Mostly the sensor will not sound an alarm at lower concentrations (e.g. 100 ppm). The alarm will sound within a few minutes at 400 ppm. So the function is specific to concentration-time. Figure shows simple carbon monoxide sensor.

Carbon monoxide gas sensor (Contd.)

Carbon monoxide sensor can be of different types such as:

- Semiconductor sensor
- Electrochemical sensor
- Digital sensor
- Biomimetic sensor (chem-optical or gel cell sensor)

BUZZER

1. Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

2. Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

Specifications:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Direct Current Resistance: The direct current resistance is measured by ammeter directly.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp. : Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self drive type to choose. Because of the internal set drive circuit, the self drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

Introduction of Piezo Buzzer

Specifications:

Rated Voltage: A piezo buzzer is driven by square waves (V p-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AZ-xxxxS-x series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current. Besides, there are different tone nature for you to choose, such as continuous, fast pulse, and slow pulse.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Driven by square waves (V p-p), the higher voltage results in the higher SPL.Pin Pitch: The numerous spec. for the piezo buzzers lead to the difficulty in finding a spec. in facsimile, therefore we suggest that you can firstly choose a spec. with the same pitch and similar frequency. Introduction of Micro Speaker

How to choose:

The factors which affect the SPL: the square measure of diaphragm, the amplitude of vibration, magnetic field intensity, power, impedance, resonant chamber, the pattern and the thickness of diaphragm, and the holes.

Power vs. SPL: Suppose all the conditions are the same, increasing the power dose not mean the SPL will increase as well. We need to revise the diaphragm and the sound coil to load the higher power, but it leads to lower SPL instead.

Dimension vs. SPL: A larger speaker can vibrate more air, therefore it provides higher SPL. In addition, the thicker speaker can give wider amplitude of vibration which also leads to higher SPL.

Acoustics: What we request most is how much SPL a micro speaker can output.

Matching: It will be better to provide the power slight higher than the rated power for the enlarged circuit.

Question for mechanism:

The volume of the resonant chamber: The general problem of the consuming products is that the resonant chambers are not big enough. We can only try to find space to enlarge the volume of the resonant chamber.

Airtight: The front and back sound fields of the speaker should be separated to avoid neutralization.

Shock absorber: When a speaker works the vibration will also happen at the same time. In order to reduce interference, it will do good to have some material between speaker and case to absorb the shock.

Mounting: The speakers are usually fixed on the case. Firmly fixed is important especially for the iron housing or the large size to avoid separating in the drop test.

How to choose the speaker

Dimension: To the micro speaker, size has decisive influence on its volume. 5mm difference of diameter might result in double or half area of diaphragm, therefore the SPL is quite different. Besides, the thicker speaker has more space to vibrate the air, and usually has bigger magnet, so it will be more powerful to push the air and emit louder sound.

Power: Mainly refer to how much power can a speaker bear, there is no direct relation to the SPL. The speaker with larger power needs to use thicker diaphragm and sound coil to bear larger power, which will lead to lower efficiency (SPL). Therefore, according to the mechanical design, try to select a larger speaker which matches the outputting power from the amplified circuit, then the best SPL would be emitted.

Impedance: Higher impedance can save more electricity, however, the SPL and the loaded power will go down. The reason is that we have to use thinner wire or to coil more, the front makes the power lower, and the after leads to heaviness and low efficiency.

The material of diaphragm: Most speakers (diameter less than 50mm) use mylar diaphragms, which are easily finished, cheaper and waterproof. However, mylar diaphragm is not good at heatproof and the sound is stiff.The patterns of diaphragm: The speaker with concentric circles diaphragm is good for the speech sounds. Generally, the SPL is good at the frequency before 5-6 KHz, but will dramatically decrease after 6 KHz. On the other hand, the speaker with radiate diaphragm has average frequency response. Supposing other conditions are all the same, the SPL of radiate diaphragm will lower than the concentric circles one at the frequency before 6 KHz.

POWER SUPPLY UNIT

INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

BLOCK DIAGRAM OF POWER SUPPLY:

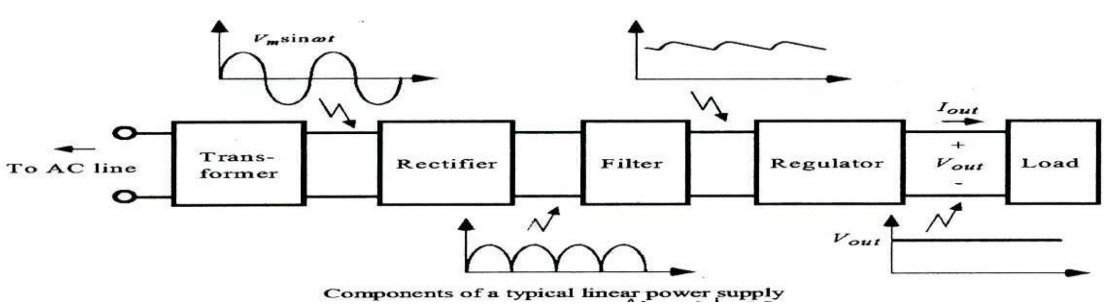

Fig.4.2.1: Block Diagram of Power Supply

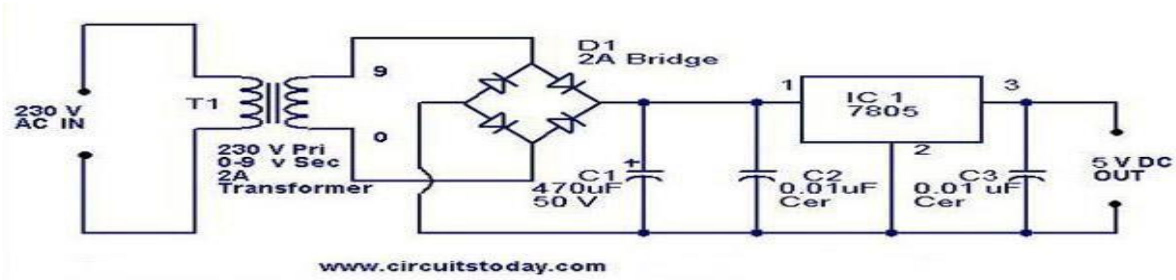

Fig.4.2.2: Schematic Diagram of Power Supply

DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

SOFTWARE EXPLANATION:

Software Requirements

- Proteus simulation
- Arduino software
- Programming language

Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use forbeginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino

products:- Install the Arduino Software (IDE) on

Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software(IDE)

✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

To open an existing project example, select File → Example → Basics → Blink.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

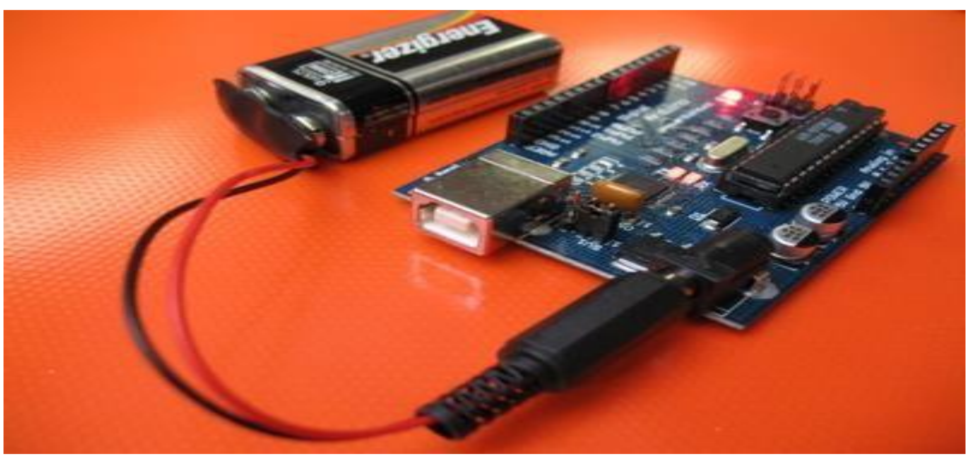

Fig.4.3.: Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

Proteus:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

CHAPTER-5

PROJECT TESTING

SOFTWARE TESTING

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

TESTING LEVELS

There are various testing levels based on the specificity of test.

- Unit testing: Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.
- Integration Testing: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.
- System Testing: System testing tests a completely integrated system to verify that the system meets its requirements.

Acceptance testing: Acceptance testing tests the readiness of application, satisfying all requirements.

Performance testing: Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed fora test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

CODE IMPLEMENTATION

```
#include <LiquidCrystal.h> //LCD
#include <SoftwareSerial.h> //COMMINCATION GSM MODULE

LiquidCrystal lcd(13,12,11,10,9,8);  //RS 13,EN 12, D4 11 ,D5 10,D6 9,D7 8
SoftwareSerial mySerial(2,3);//rx , tx  //GSM

int gas = A5;
int buz=7;
void serialFlush(){
while(Serial.available() > 0) {
char tt = Serial.read();
}
}
void sendmsg(char *num,char * msg)
{
Serial.print("AT+CMGS=\"");
Serial.print(num);
Serial.println("\"");delay(800);
Serial.println(msg);delay(800);
Serial.write(0x1a);delay(2000);
}
const char* number = "8885522598\0";  /*Give the required mobile num to send the msg*/

void setup(void)
```

```
{

Serial.begin(9600);
mySerial.begin(9600);
lcd.begin(16,2);
lcd.clear();lcd.setCursor(0, 0);lcd.print("WELCOME");     // 1st romw 0th colom
delay(1000);
pinMode(gas, INPUT);
pinMode(buz, OUTPUT);

digitalWrite(buz,HIGH);//OFF STATE
Serial.println("AT");delay(1000);
Serial.println("AT+CMGF=1");delay(1000);
Serial.println("AT+CNMI=1,2,0,0");delay(1000);
Serial.println("AT+CSMP=17,167,0,16");delay(1000);
delay(1000);

lcd.clear();lcd.setCursor(0, 0);lcd.print("READY");

}

void loop()
{
int gas_data = digitalRead(gas);
Serial.println(gas_data);
lcd.clear();
lcd.setCursor(0, 0); lcd.print("GASDETECTION GSM ");
delay(2000);
lcd.clear();
lcd.setCursor(0, 1); lcd.print("G:");lcd.print(gas_data);lcd.print("     ");
delay(2000);
```

```
if(gas_data == LOW)
{
lcd.clear();lcd.setCursor(0, 1);lcd.print("GAS DETECTED");
mySerial.println("GAS DETECTED"); delay(500);
lcd.clear();lcd.setCursor(0, 0);lcd.print("GSM INIT");
Serial.println("GSM CONN ... ");
Serial.println("AT");delay(1000);
Serial.println("AT+CMGF=1");delay(1000);
Serial.println("AT+CNMI=1,2,0,0");delay(1000);
Serial.println("AT+CSMP=17,167,0,0");delay(1000);
lcd.clear();lcd.setCursor(0, 0);lcd.print("READY");
Serial.println("GSM DONE");
sendmsg(number,"GAS DETECTED");
delay(3000);
lcd.clear();lcd.setCursor(0, 0);lcd.print("MESSAGE SENT");
digitalWrite(buz,LOW);
delay(1000);
}
else
{
digitalWrite(buz,HIGH);
delay(500);
}
}
```

CHAPTER 6

RESULT ANALYSIS

RESULTS

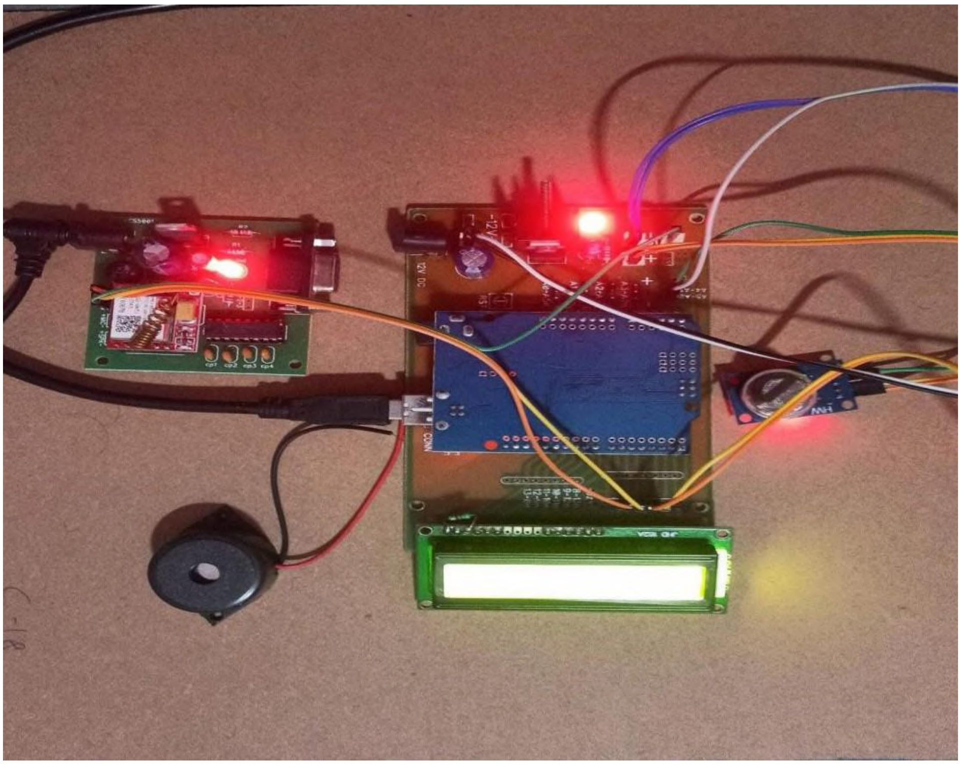

Fig:6.1 The Hardware setup of the proposed system

DISPLAYING NORMAL READING VALUES ON THE LCD

Gas sensor and Buzzer senses the concentration of the harmful gases and the level of concentrated gas in the Environment continuously to the Arduino Uno. Now the Arduino Uno which is brain of this project takes the information from sensors and transmit that values to the LCD for displaying them. The below r represents LCD display that displaying the normal ridings of the sensor and normal range of concentrated harmful gases.

Fig:6.2 Danger gas uploading

DISPLAYING OF WARNING MESSAGES

Here the Gas Sensor and Buzzer consists of potentiometer using this we can set the threshold. When the readings from gas sensor exceeds the set threshold it will display warning messages on the LCD.

Fig:6.3 Gas Detected

Fig:6.4 Displaying Warning message sent to the user

APPLICATIONS AND ADVANTAGES

6.2.1APPLICATION OF THE PROJECT

- Used in Gas Industries, Houses, Labs, Hospitals etc
- It is used when mining of coal and other materials to detect.
- Used in municipal gas distribution.
- Used in nuclear power stations.

ADVANTAGES OF THE PROJECT

- Low cost
- Low power consumption
- High accuracy
- It also detects alcohol so it is used as liquor tester.
- The sensor has excellent sensitivity combined with a quick response time.

CHAPTER 7

CONCLUSION AND FUTURE SCOPE

Future scope

- Additional features include call will initiated to telephone number.
- Temperature display during periods times.
- Another very interesting and significant improvement would be to accommodate multiple receiver MODEMS.
- Multilingual display can be another added variation in the project.

Conclusion

- Hence, **Gas leakage detection** is essential to prevent accidents and to save human lives. This project presented Gas leakage detection and alert system.
- This system triggers LED and buzzer to alert people when **Gas leakage** is detected.
- This system is very simple yet reliable.The gas leakage detector we used can detect the **Gas leakage** in **2 seconds**.

DECLARATION

We, the students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2017-2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project work entitled '**Design and Implementation of Smart Mitten For Deaf and Dumb People**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Y.Lokesh Reddy	Vedvikas Reddy Magam	P.Pravalika	Vure Supriya

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Kumar, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mrs. A. Soumya,** Department of ECE and our project **Internal guide, Ms.Vidadala Srija, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. Y.Lokesh Reddy

ABSTRACT

Communication is the only way by which we are able to express our thoughts among the people. Normalpeople can convey their thoughts effectively by establishing the conversation between them. But in our society there are lot of people who are physically disable that means (deaf and dumb) are not able to communicate effectively. Because of their disability they are not able to stand in race with the normal people. Some of the people have problem regarding hearing and some are not able to talk so they lag behind the normal people. Generally these persons use the sign language for the communication but they find some problem in communication with those is not able to understand sign language. So there is problem between normal people and physically disable people. This system has main purpose to reduce the communication gap between two communities. The main aim of our proposed project is to developed the cost effective system where disable people can communicate with normal people by using hand glove. This means that communication is not barrierbetween two communities by using smart glove. So disable can also able to grow in their respective field. Usingsuch system by disable people can make nation grow.

CHAPTER 1

INTRODUCTION

1.1 INTRODUCTION:

One of the important problems that our society faces is that people with disabilities are finding it hard to come up with the fast-growing technology. The access to communication technologies has become essential for the handicapped people. Deaf and dumb people use sign language for communication but they find difficulty in communicating with others who don't understand sign language. Sign language is an expressive and natural way for communication between normal and dumb people. In this project Force Sensor Plays the major role, which are placed on fingers and it changes resistance depending on the amount of force on the sensor. The proposed algorithm states that four force sensors for four fingers that each sensor has range of voltage and each range indicates one message, the respective message will be displayed on LCD board and vocalized by speaker. Force sensor is load cells, transducers that convert force into measurable electrical outputs. Sensors convert the known applied load into voltage and Arduino microcontroller will receive this sensed data and show output message on the LCD board and vocalized by speaker. The message that has been used is Hungry, Need Water.

This decreasing ratio of Literate and Employed Deaf and Dumb population is a result of the physical disability of hearing for deaf people and disability of speaking for dumb people so it yields to lack of communication between normal person and Deaf and Dumb Person. It actually becomes the same problem of two persons which knows two different language, no one of them knows any common language so it becomes a problem to talk with each other and so they require a translator physically which may not be always convenient to arrange and this same kind of problem occurs in between the Normal Person and the Deaf person or the Normal Person and the Dumb person [2-4]. To overcome this problem, we introduce a unique application. Our application model is a desirable Interpreter which translates. Natural English Sentences as, a text input by Normal Person for Deaf Person and Sign Language, in form of Gesture by a Dumb Person to Synthesized English Words which have a corresponding meaning in Sign Language which interprets a particular thing, as an Audio Output for Normal Person. This will help Normal and Deaf and dumb communities by removing the communication gap between them [5-8]. The sign language is an important and only method of communication for deaf-dumb persons. As sign language is a formal language employing a system of hand gesture for communication (by the deaf).

1.2 EMBEDDED SYSTEMS:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

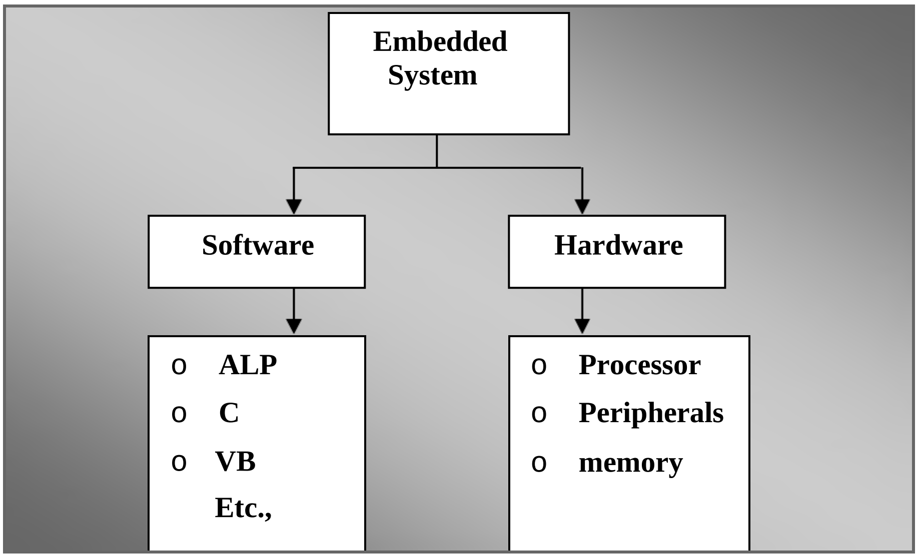

Figure 1.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Medical diagnostics, monitoring and life support

Testing, monitoring and diagnostic systems

Processors are classified into four types like:

Micro Processor (µp)

Micro controller (µc)

Digital Signal Processor (DSP)

Application Specific Integrated Circuits (ASIC)

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

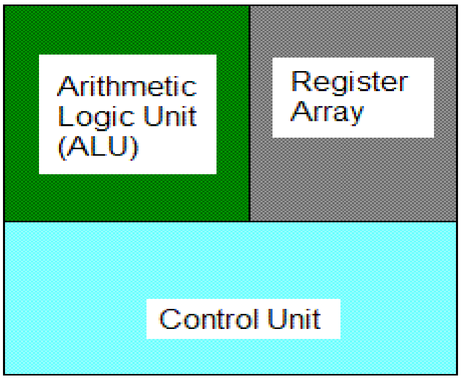
Instruction set: The set of instructions that the microprocessor can execute.

Bandwidth : The number of bits processed in a single instruction.

Clock speed : Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).



Three Basic Elements of a Microprocessor

Micro Controller (µc):

A microcontroller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/output peripherals. Program memory in the form of NOR flash or OTP ROM is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.

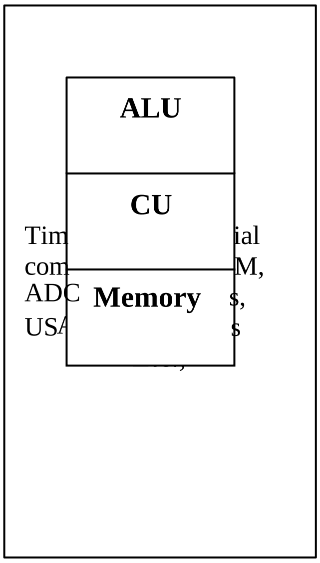


Figure 1.2 Block Diagram of Micro Controller (µc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program
- Analog circuits to provide clocks and interface to the real world which is analog in nature
- I/Os to connect to external components like LEDs, memories, monitors etc.

2.2 Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

2.2.1 Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- Operating system and application programmers who use the

microprocessor's instructions will find it easier to develop code with a smaller instruction set.

- The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.
- Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

2.2.2 RISC characteristics

- **Simple instruction set:**

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- **Same length instructions.**

Each instruction is the same length, so that it may be fetched in a single operation.

- **1machine-cycleinstructions.**

Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

2.2.3 Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively

slow main memory.

- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.
- CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

2.3 Memory Architecture

There two different type’s memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

2.3.1 Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

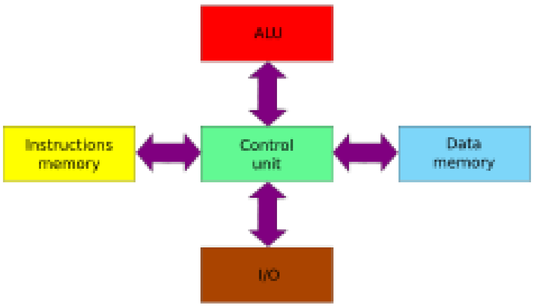

Figure 1.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM

Cortex-M3 processor (not all ARM chips have Harvard architecture).

- Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.3.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

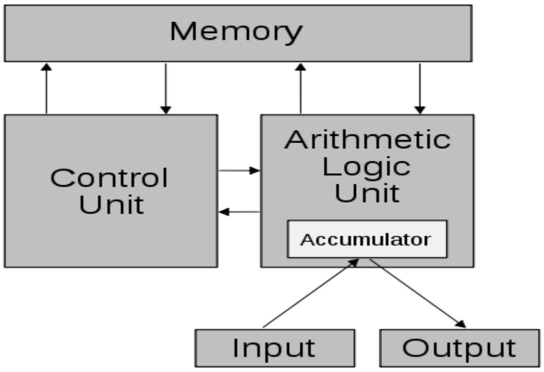

Figure 1.4 Schematic of the Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture

The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.

Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.

In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.

In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.

Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER 2

LITERATURE SURVEY AND EXISTING METHODS

2.1 Literature Survey:

Generally, deaf & dumb people use sign language for the communication. Therefore, it is necessary to have a gesture recognition or sign language detection system to reduce the communication gap between two communities by using glove. The data of force sensor is given to input pin of microcontroller at transmitter side. We get the corresponding voice output of each gesture and display of recognized gesture in form of text on the LCD display at receiver side. As novelty, we are appending home automation. The corresponding home appliances are controlled by using gesture and operated through relay circuit. The main purpose of smart glove an ease of sharing basic ideas, minimize communication gap and an easier collaboration for the hard of hearing people. The main aim of our project is to develop the cost-effective system. So, disable can able to grow in their respective field. Every Normal human being sees, listens and then reacts to the situations by speaking himself out. But there are some human beings those who are not able to speak or listen, but they try to react through actions most of time normal people are not able to understand what they want to say. This application will help for both of them to communicate with each other. It consists of several parts, in part one with the help of hand gestures the signs will be detected by the sensors and the output will be given. Communication between speakers and non-speakers i.e. dumb and deaf people can be problematic, inconvenient etc. This project attempts to bridge the communication gap by designing a portable glove that captures the user’s gestures and outputs the translated text on a device. The glove is equipped with flex sensors, to measure the flexion of the fingers, and the contact between fingers. The glove’s Raspberry Pi microcontroller analyses the sensor readings to identify the gesture from a library of learned gestures. So, we are going to design and built a glove to be worn on the right hand that translate sign language into spoken English. Every person's hand is a unique size and shape, and we aimed to create a device that could provide reliable translations regardless of those differences. Our device uses five Spectra Symbol Flex-Sensors that we use to quantify how much each finger is bent. These sensors are read, averaged, and arranged into packets using a

Raspberry-pi microcontroller. These packets are then sent serially to a Raspberry-pi to be run in conjunction with a Python script. The user creates data sets of information from the glove for each gesture that should eventually be translated, and the algorithm trains over these datasets to predict later at runtime what a user is signing.

2.2 Existing Systems:

Based on Image processing technology, a device that enables Voice for the mute was made. Basically, the gestures are captured using webcam and converted into text using Image processing. This text is then converted to speech using text to speech convertor. But only alphabets were captured in this device, so further research was done to search for better devices.

The system based on "Two Way Wireless Data Communication and American Sign Language Translator Glove for Images Text and Speech Display on Mobile Phone "develops applicative architecture of hand glove. It records the gestures made by a deaf and mute people, converts them into a meaningful text and transmits them to remote areas with help of Bluetooth, GSMCDMA and Internet modules. Then GUI successfully transmits them to an authorized mobile phone and simultaneously displays the responses transmitted by that phone on the same screen . The device "Sign Language Interpreter Using a Smart Glove" uses hand gestures along with the facial expressions and the body language to convey the intended message. The smart glove recognizes the signing gesture and text representation of the signed gesture is created. Then text is converted to audio output.

The system for "Two Way Communication between Deaf and Dumb People and Normal People" uses video processing approach. Video processing involves frame formation from videos, finding region of interest (ROI) and mapping of images with language knowledgebase. Gestures from real-time video and mapping it with human-understandable speech. Then natural language was taken as input and mapped with equivalent Sign Language animated gestures.

Hardware based "Smart Glove with Gesture Recognition Ability for the Hearing and Speech Impaired" design and implements a low cost wired interactive glove. It is interfaced with a computer running MATLAB or Octave, with a high degree of accuracy for gesture recognition. The glove maps the orientation of the hand and fingers with the help of bend sensors, Hall Effect sensors and an accelerometer. The system is modelled for the differently able people to help convert sign language to a more human understandable form such as textual messages.

Authors have utilized of accelerometer glove (which is mounted on each finger) and RBG camera to identify sign language. The entire limb movement is track with the help of additional accelerometer on the limb. The author’s model isolates sign language gestures by using parallel hidden Markov models. Efficiency is much more than video sensors.

SolankiKrunal, has used flex sensor, microcontroller, DC and LCD. Movements in hand’s finger causes voltage drop which is given to the micro controller via ADC. The micro controller identifies the signal and process word to word to be displayed on LCD screen. For example, BOY, each letter is process at a time and it is saved by pressing a button the complete sentence is shown on LCD.

CHAPTER 3

BLOCK DIAGRAM

3.1 Block Diagram:

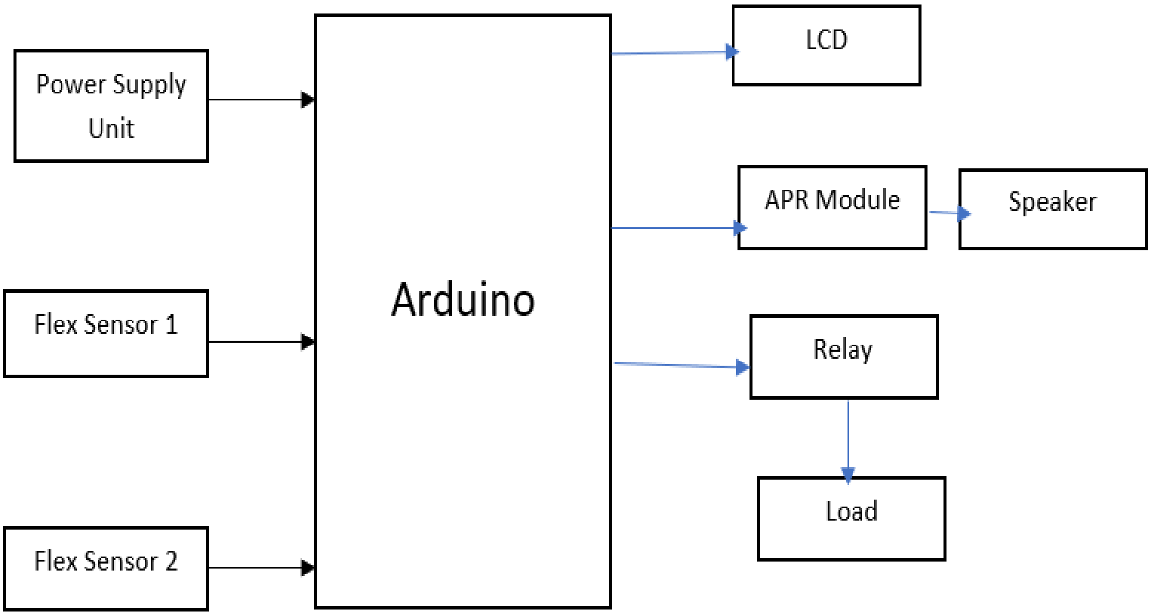

Fig 3.1: Block diagram

The Block Diagram of Smart Mitten for Deaf and Dumb people is shown in the above figure. The Blocks of the circuit are

1. Arduino
2. Power Supply Unit
3. Flex Sensor
4. LCD
5. APR Module
6. Relay
7. Load

- Firstly, the detection of the bending and position of Flex sensors is done and the information is passed to the arduino.
- The Arduino receives the input signals from flex sensors.

- The audio output is given from the speaker.
- The text output is shown in the LCD display.

3.2 COMPONENT DESCRIPTION:

3.2.1 ARDUINO UNO:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

3.2.2 Flex Sensor:

Flex sensors are usually available in two sizes. One is 2.2 inch and another is 4.5 inch. Although the sizes are different the basic function remains the same. They are also divided based on resistance. There are LOW resistance, MEDIUM resistance and HIGH resistance types. Choose the appropriate type depending on requirement. Here we are going to discuss 2.2inch Flex sensor that is FS-L-0055.

3.2.3 LCD

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

3.2.4 APR MODULE

APR9600 is a low-cost high performance sound record/replay IC incorporating flash analogue storage technique. Recorded sound is retained even after power supply is removed from the module. Sampling rate for a 60 second recording period is 4.2 kHz that gives a sound record/replay bandwidth of 20Hz to 2.1 kHz**.**

3.2.5 RELAY

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.

CHAPTER 4

SOFTWARE AND HARDWARE COMPONENTS

4.1 Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.1.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.
ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.
The designer can also develop 2D drawings for the product.

4.1.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through whole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.2 Starting New Design

Step 1: Open ISIS software and select new design in File menu

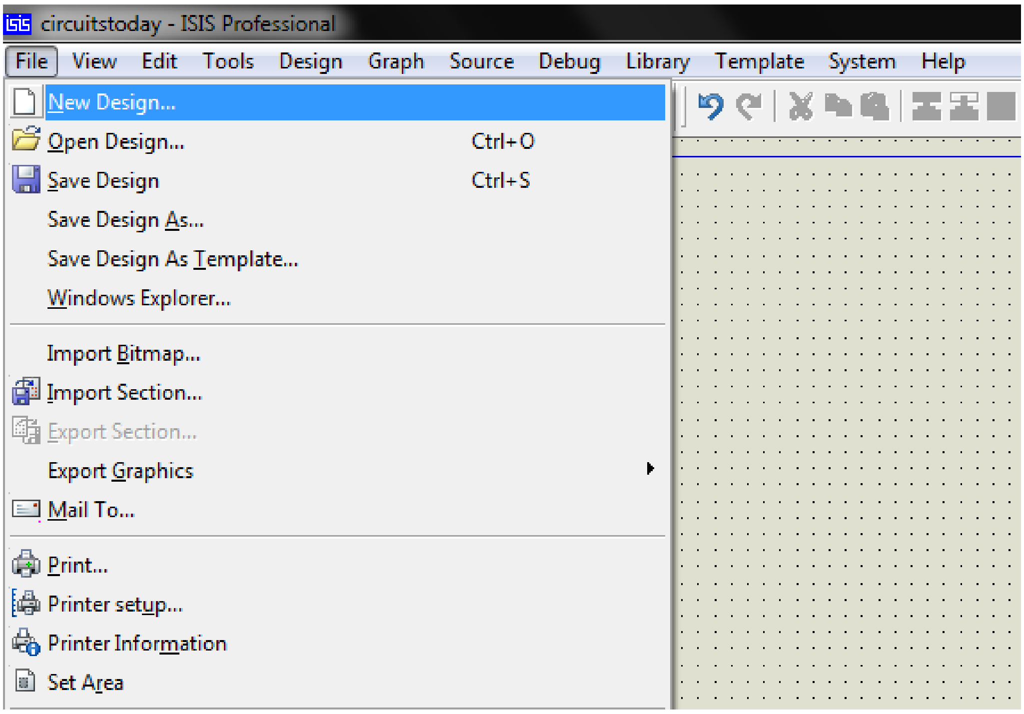

Figure 4.2.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

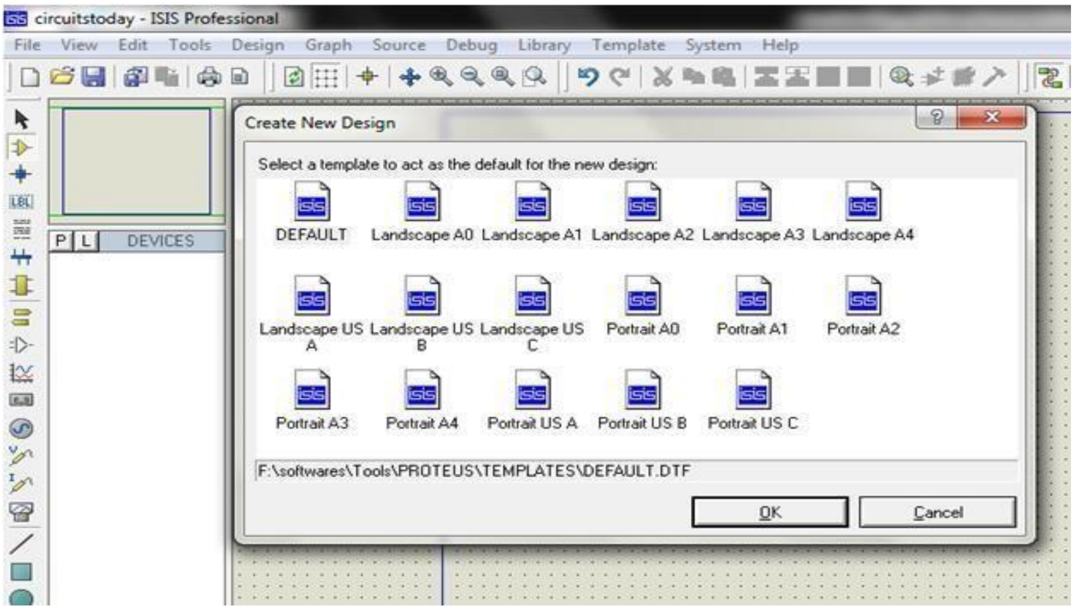

Figure 4.2.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

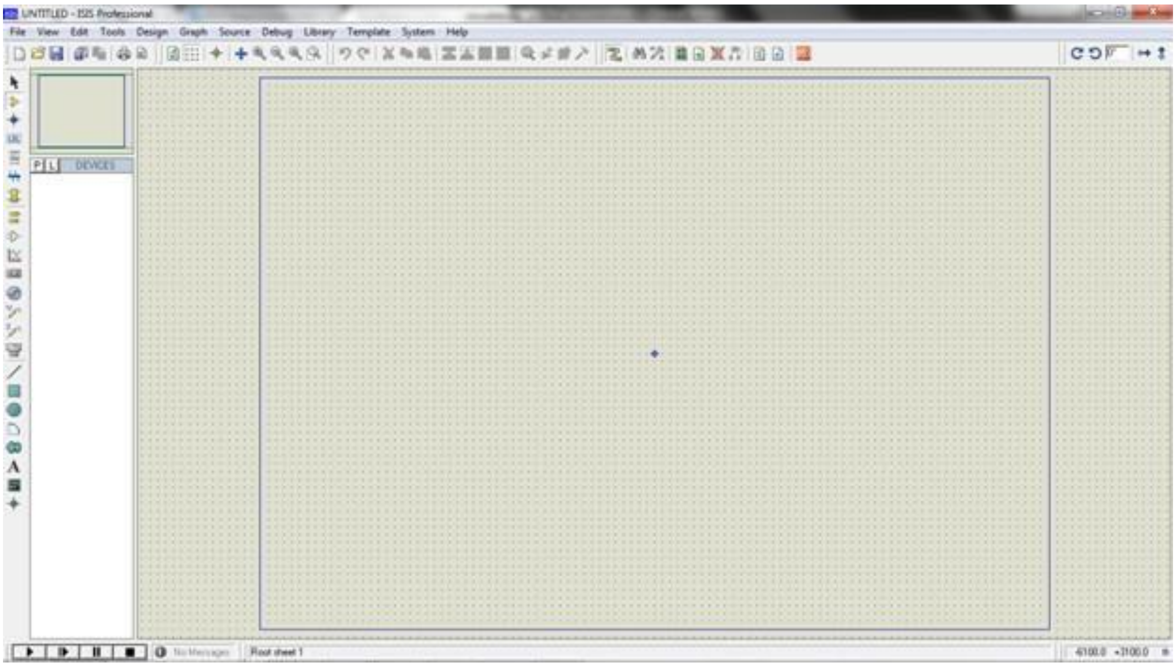

Figure 4.2.3 Proteus Design Sheet Step

4: To select components, Click on the component mode button.

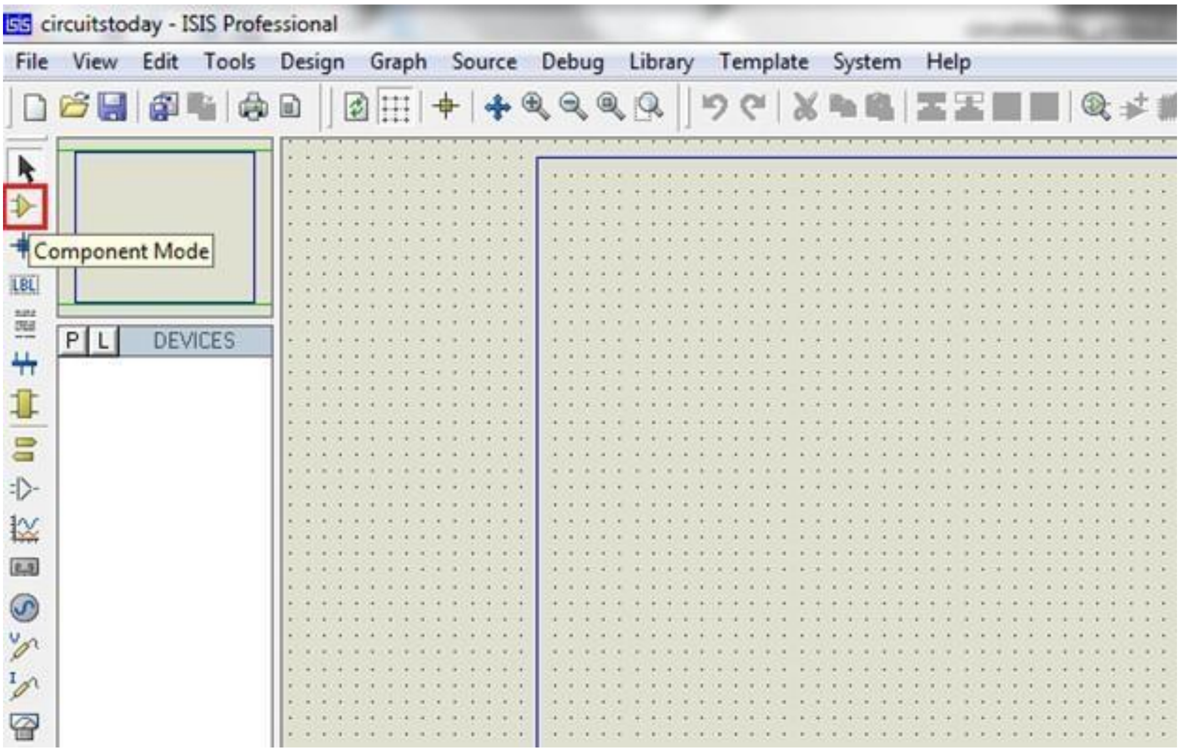

Figure 4.2.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

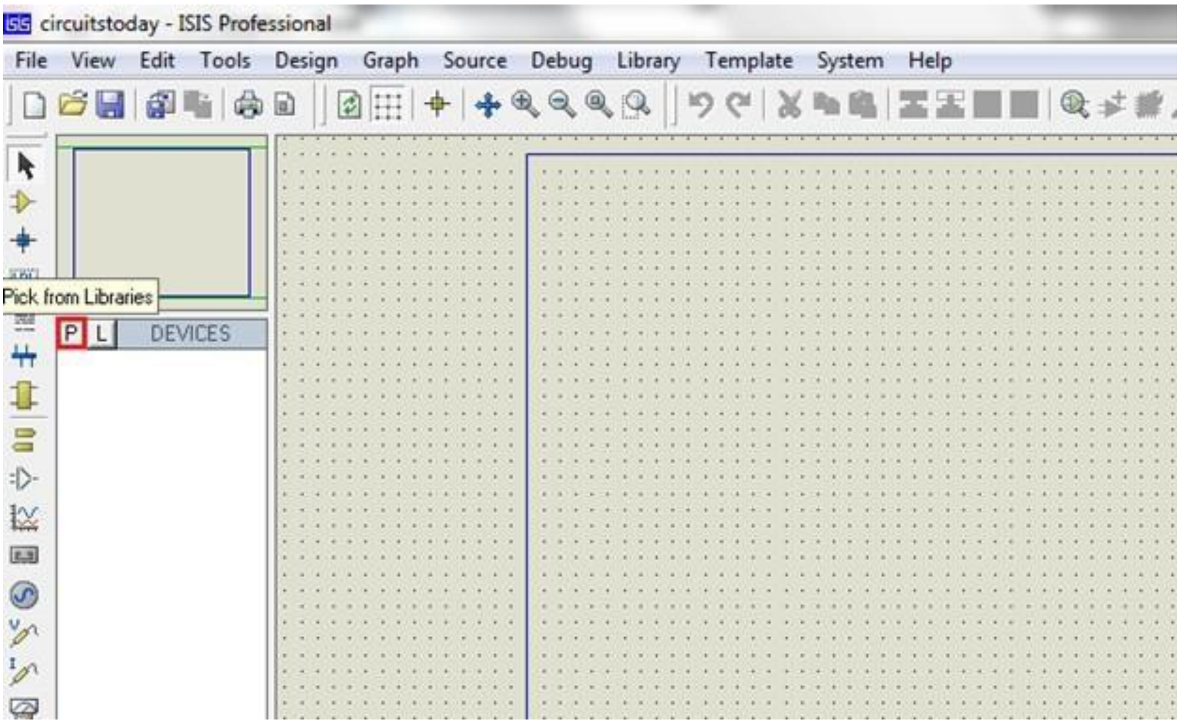

Figure 4.2.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

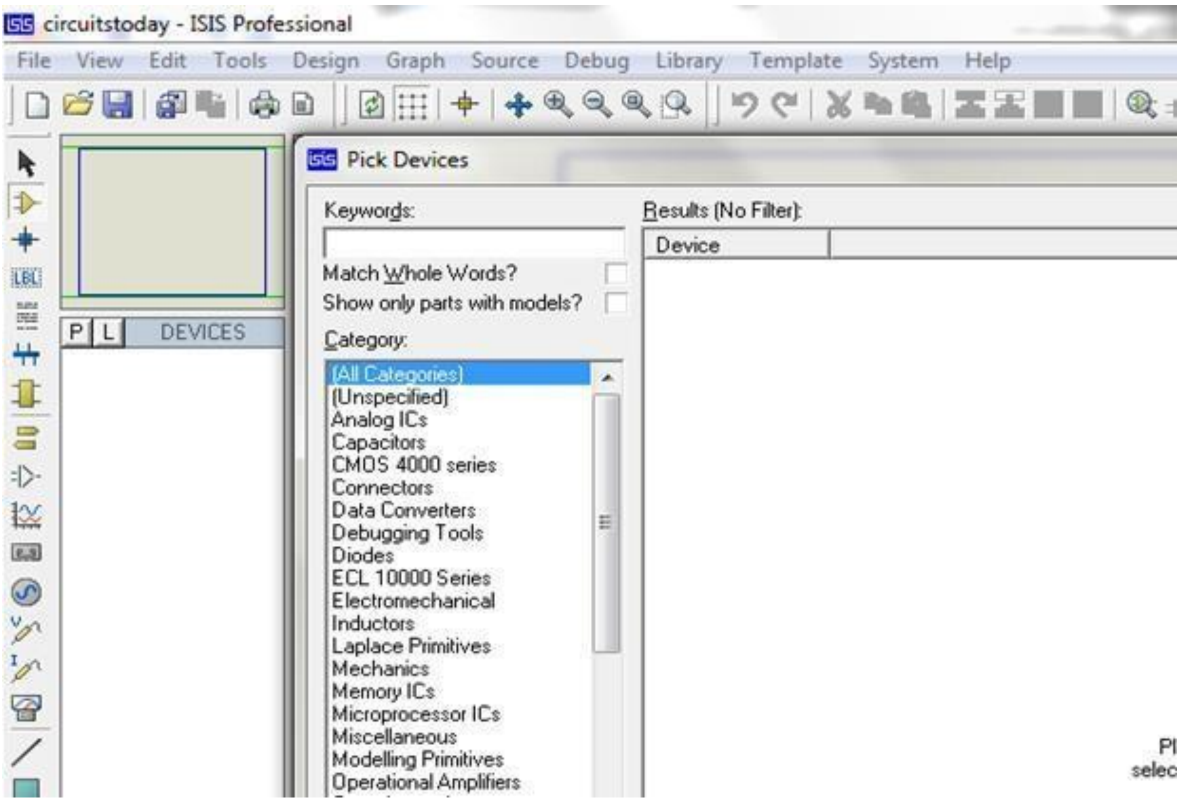

Figure 4.2.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

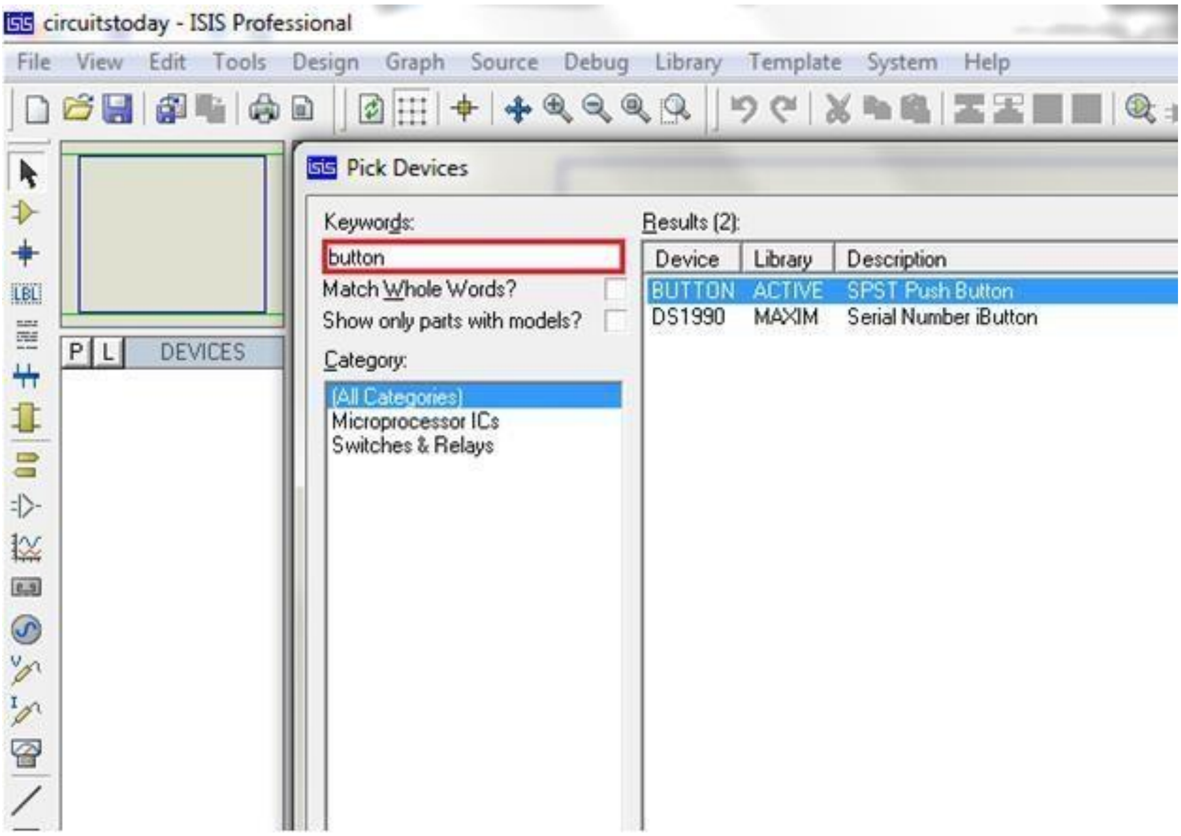

Figure 4.2.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

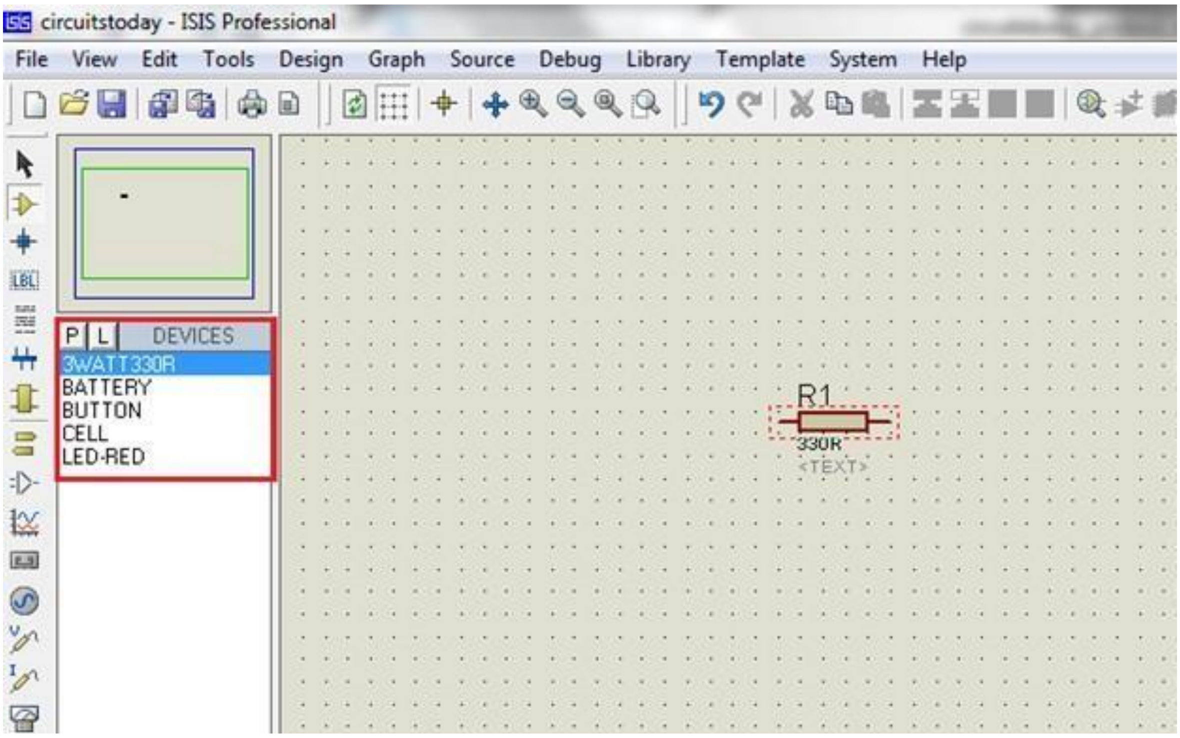

Figure 4.2.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

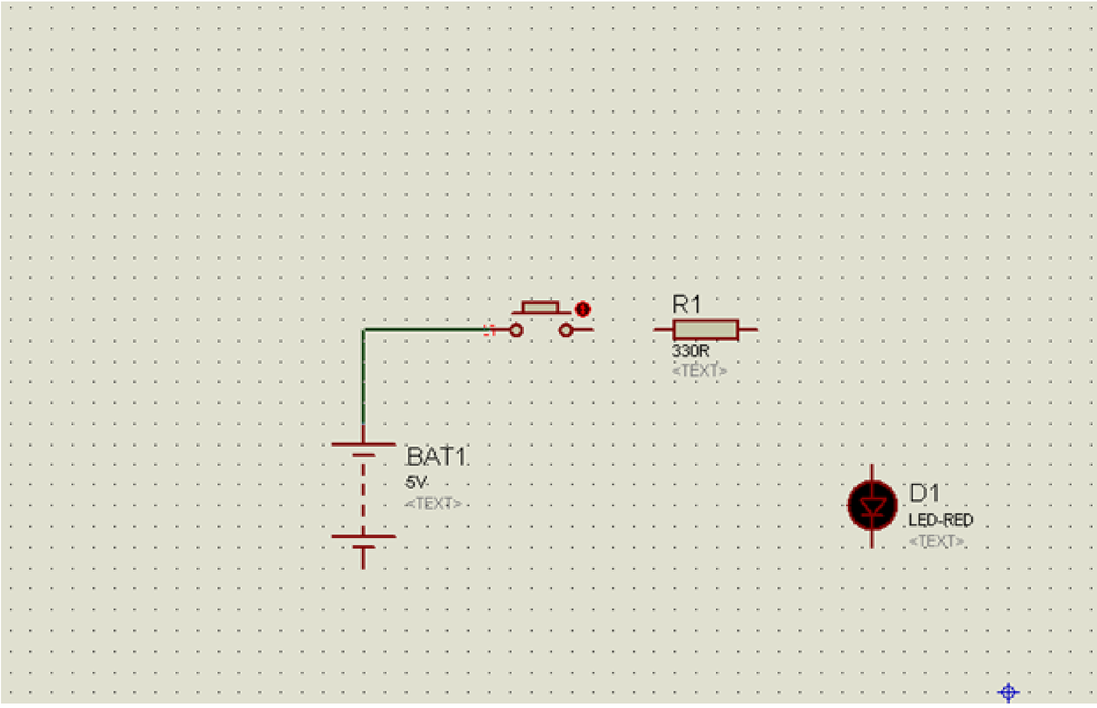

Figure 4.2.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

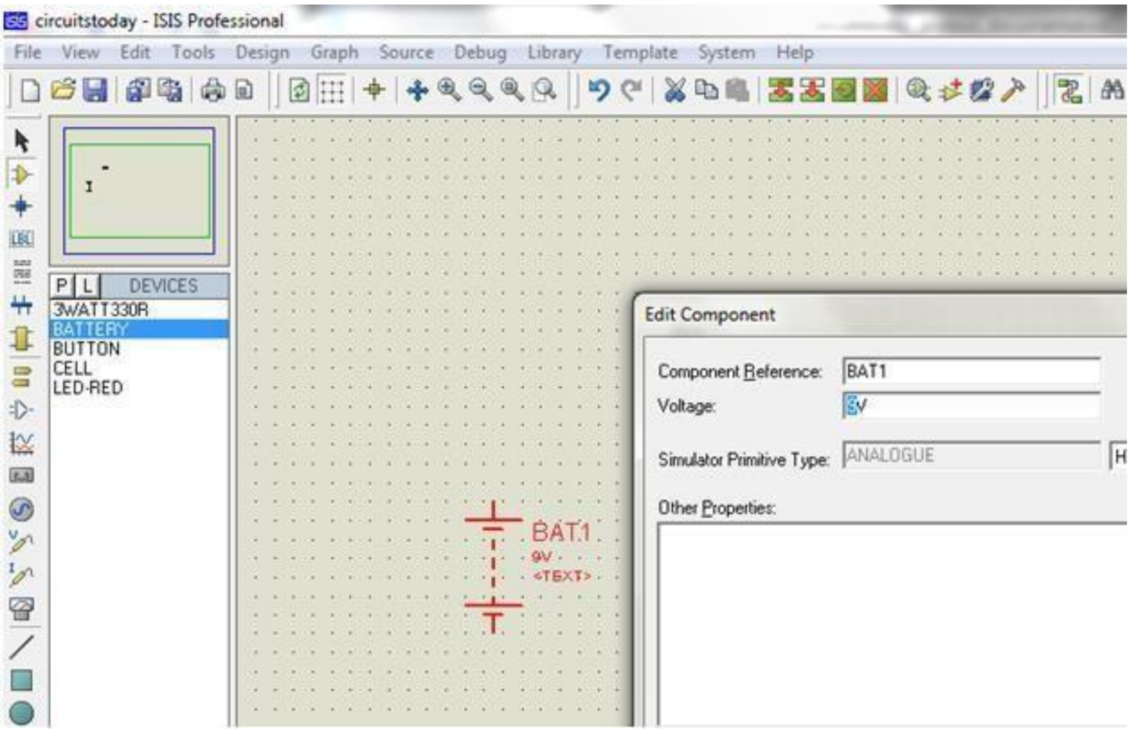

Figure 4.2.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

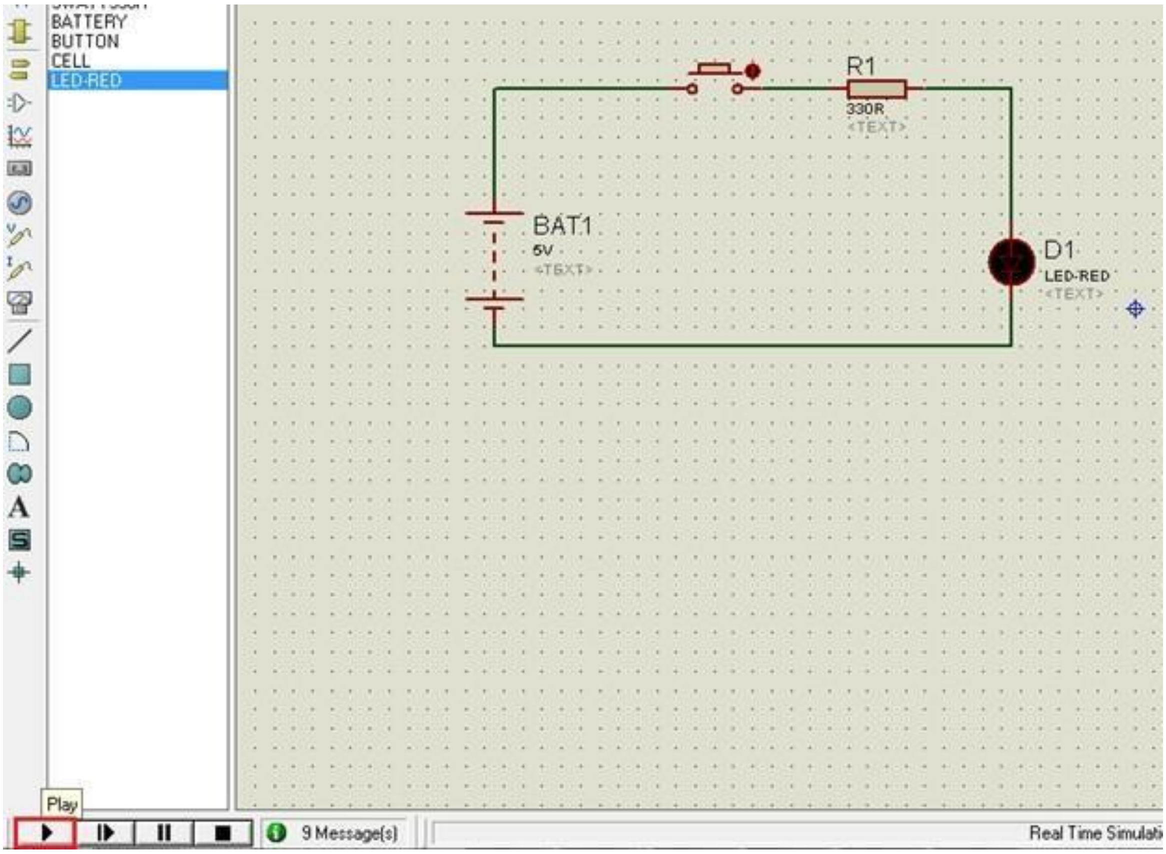

Figure 4.2.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

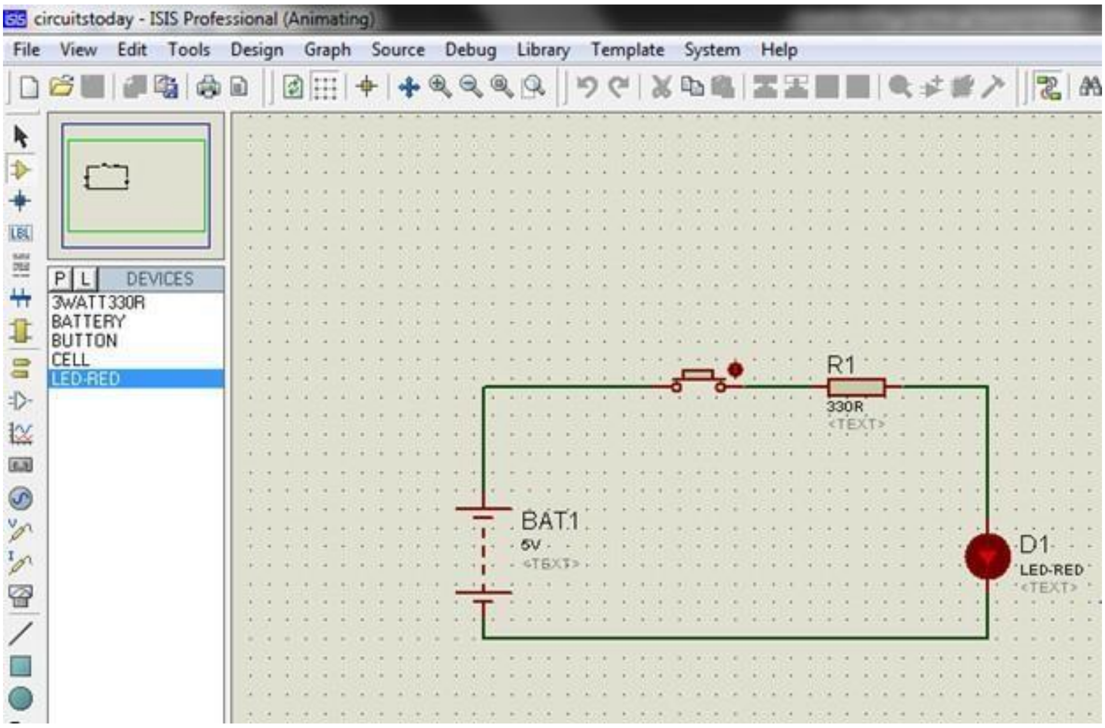

Figure 4.2.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

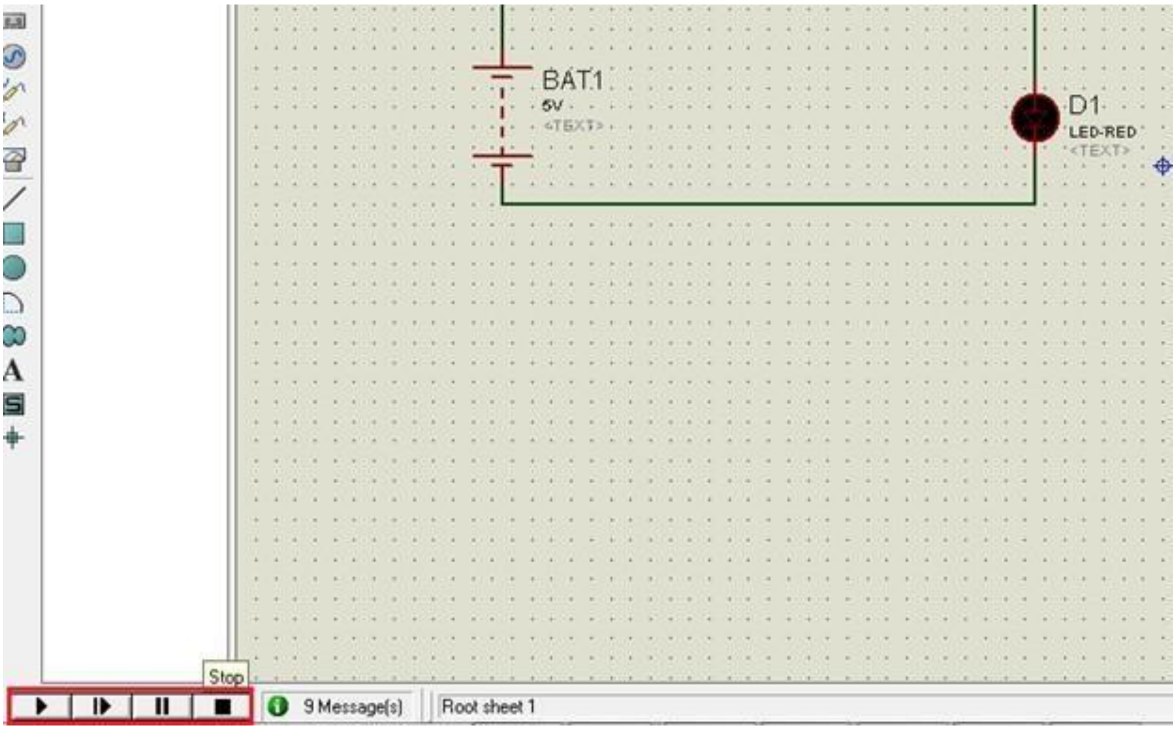

Figure 4.2.13 Simulation Step-Pause-Stop Buttons

4.3 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU tool chain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]

Repository	github.com/arduino/Arduino

Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging [9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

4.3.1 Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Figure 4.3.1 USB Cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

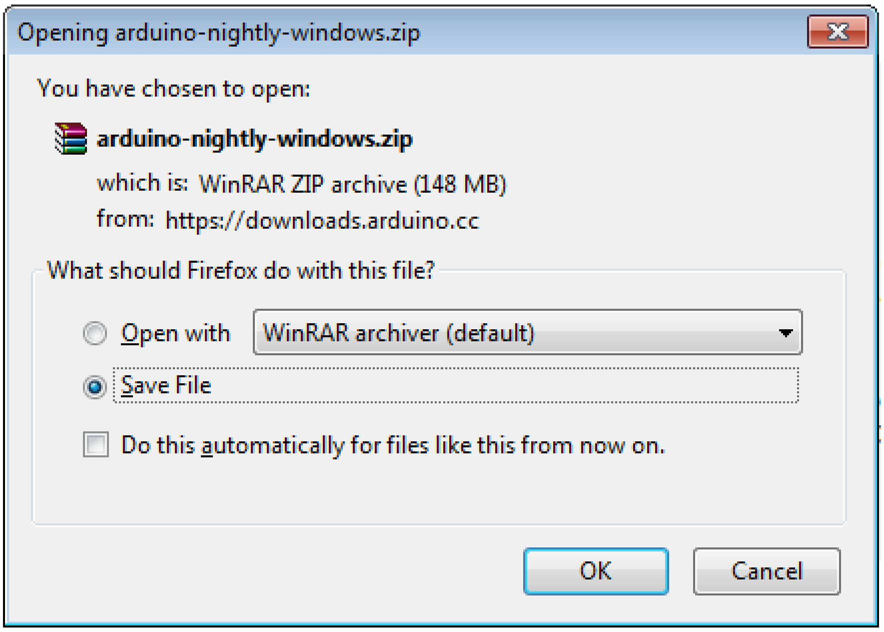

Figure 4.3.2 Downloading Arduino IDE

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labelled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

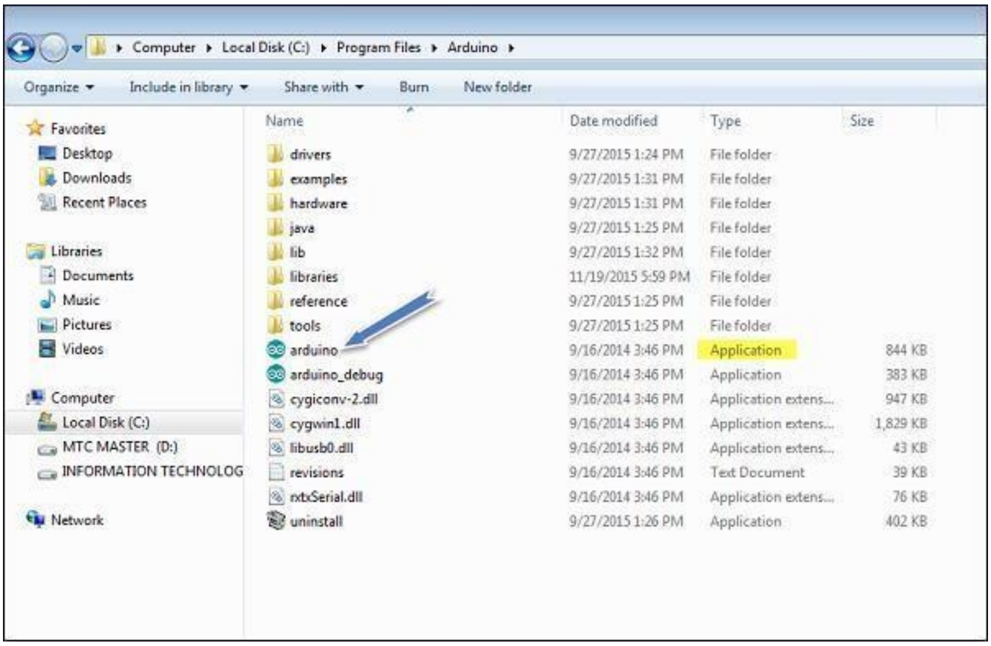

Figure 4.3.3Launching Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

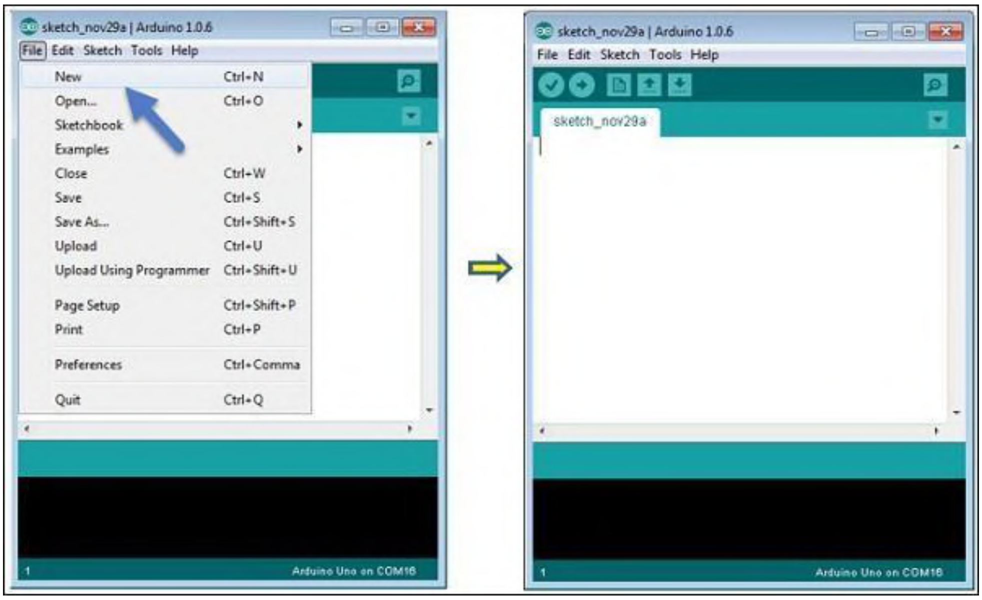

Figure 4.3.4Opening first project

To open an existing project example, select File → Example → Basics → Blink.

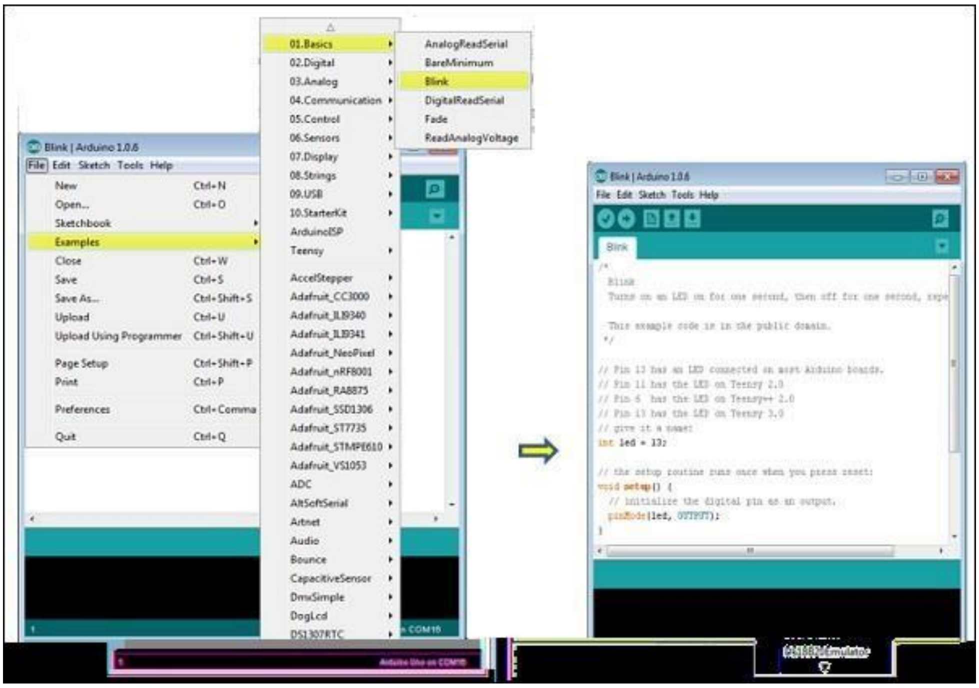

Figure 4.3.4.1Opening first project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

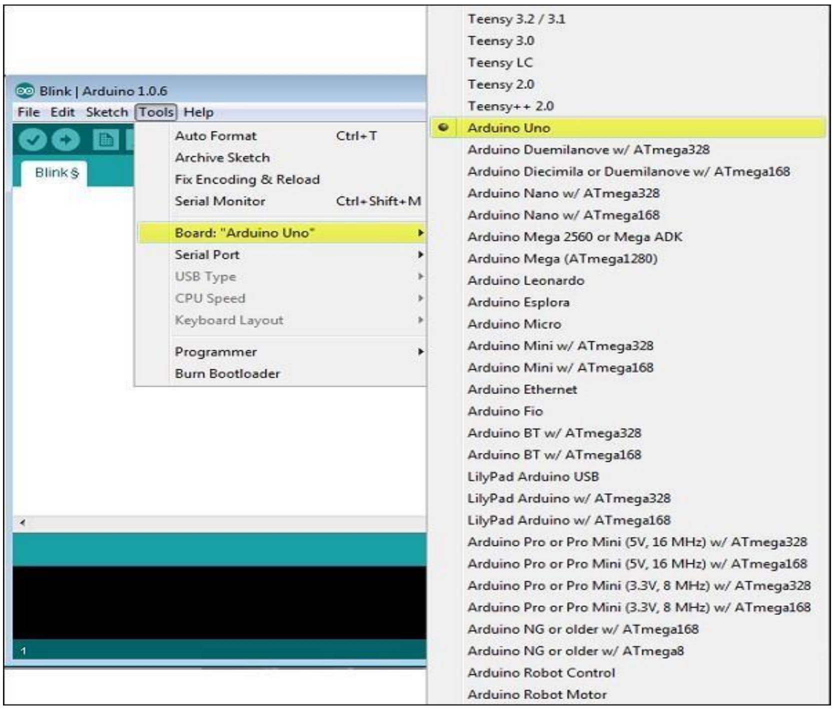

Figure 4.3.5 Selecting Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

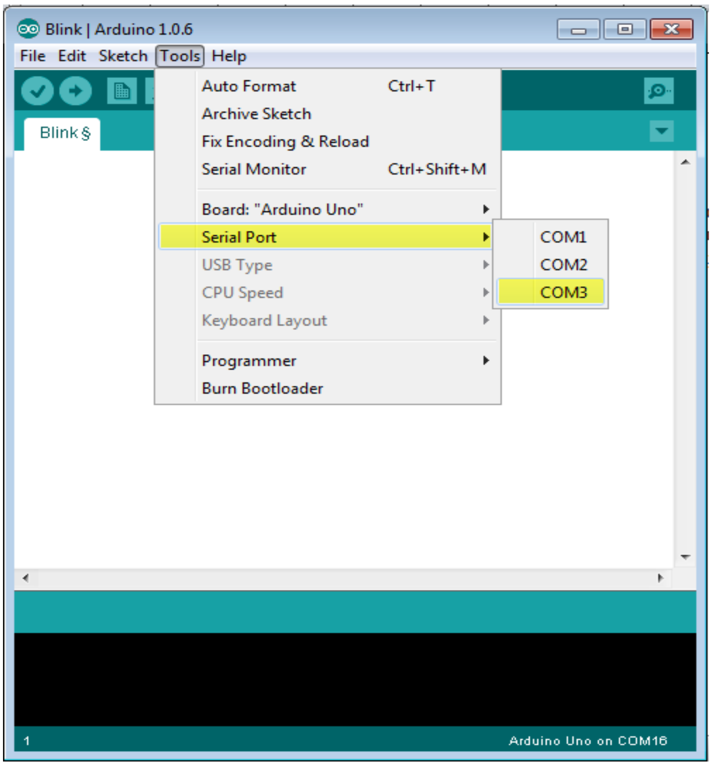

Figure 4.3.6 Selecting serial port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

Figure: 4.3.7 Uploading the program to board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

4.4 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

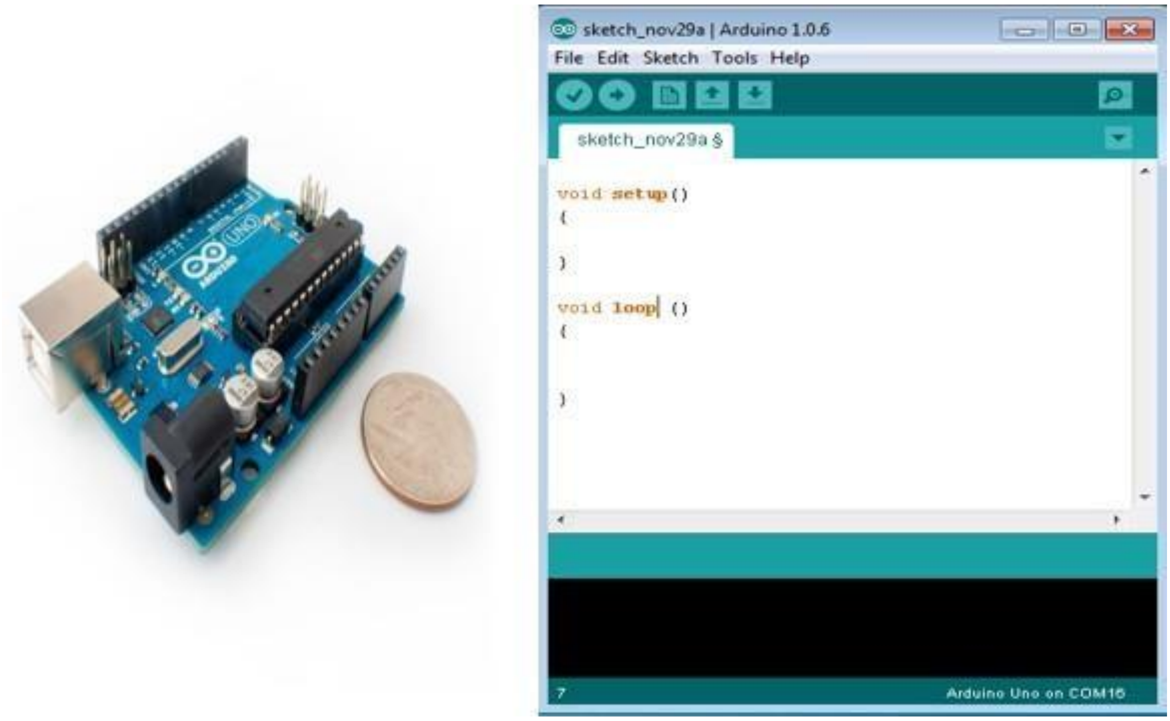

Figure 4.4 Arduino Platform

4.4.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 4.4.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI

Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Lily Pad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Lily Pad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 4.4.2Arduino boards based on ATMEGA32u4 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro	5V	16MHz	14	6	6	1	Native USB

5V/16MHz							
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
Lily Pad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

4.4.3 Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

4.4.4 Arduino boards based on AT91SAM3X8E microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

4.5 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

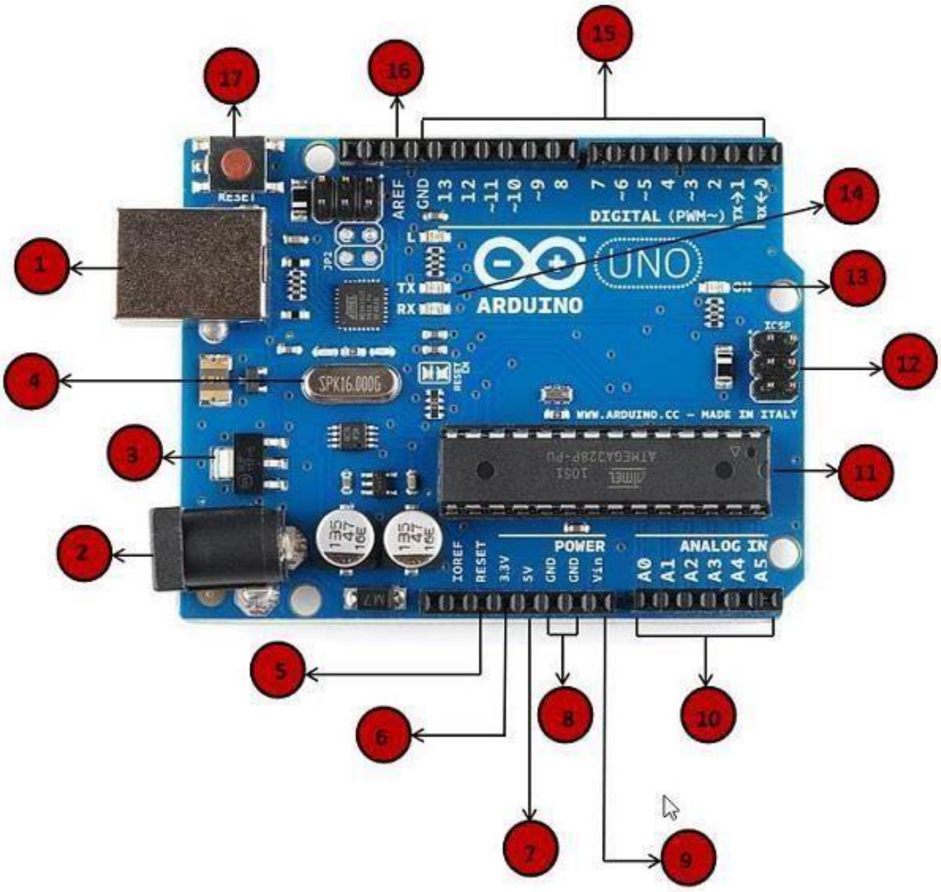

Figure: 4.5 Arduino pins

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz's

5,17	**Arduino Reset** You can reset your Arduino board, i.e., starts your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.

14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labelled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Figure: 4.5.1 Pin description

4.5 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

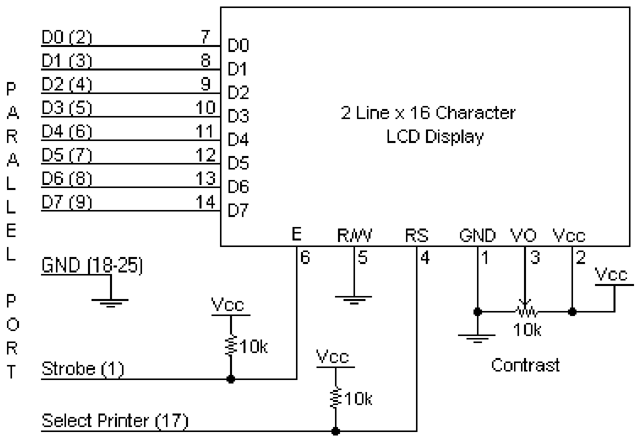
A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

4.5.3 Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram



s

Figure 4.6.1Description Of 16x2

Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there is a few which don't. Thereforeby incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wirethe *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As withall the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you havetrouble with the circuit working properly.

4.5.4 16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

4.5.5 16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

4.5.6 FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

4.6.4.1Figure Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exist. “Super twist” types, for example, offer improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

4.5.7 PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

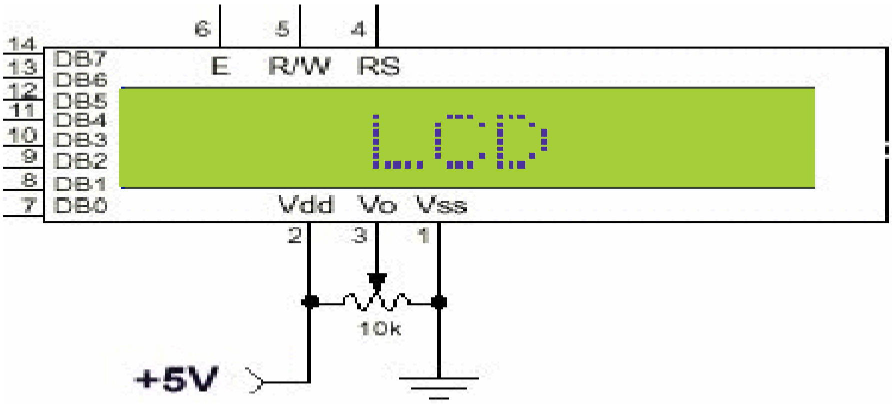


Figure 4.6.5 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 4.6.6 Pin specifications

4.6 CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

4.6.3 LCD Commands:

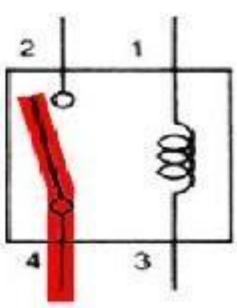
There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

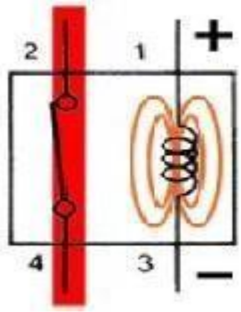
Table 4.7.1 Commands

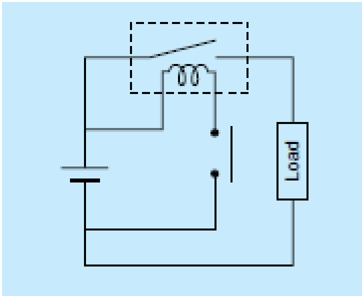
Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

4.7 Relays

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.







4.7.3 Basics on Relay Handling

- To maintain initial performance, care should be taken to avoid dropping or hitting the relay.
- Under normal use, the relay is designed so that the case will not detach. To maintain initial performance, the case should not be removed. Relay characteristics cannot be guaranteed ifthe case is removed.
- Use of the relay in an atmosphere at standard temperature and humidity with minimal amounts of dust, SO 2, H 2 S, or organic gases is recommended.
- Please avoid the use of silicon-based resins near the relay, because doing so may result in contact failure. (This applies to plastic sealed type relays, too.)
- Care should be taken to observe correct coil polarity (+, –) for polarized relays.
- Proper usage requires that the rated voltage be impressed on the coil. Use rectangular wavesfor DC coils and sine waves for AC coils.
- Be sure the coil impressed voltage does not continuously exceed the maximum allowablevoltage.
- Absolutely avoid using switching voltages and currents that exceed the designated values.
- The rated switching power and life are given only as guides. The physical phenomena at the contacts and contact life greatly vary depending on the type of load and the operatingconditions. Therefore, be sure to carefully check the
- Type of load and operating conditions before use.
- Do not exceed the usable ambient temperature values listed in the catalog.
- Use the flux-resistant type or sealed type if automatic soldering is to be used.
- Use alcohol based cleaning solvents when cleaning is to be performed using a sealed type relay.
- Avoid ultrasonic cleaning of all types of relays.
- Avoid bending terminals, because it may cause malfunction.
- As a guide, use a Fasten mounting pressure of 40 to 70N {4 to 7kgf}for relays with tab terminals.

7.1.1 Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current
- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

7.1.2 Applications:

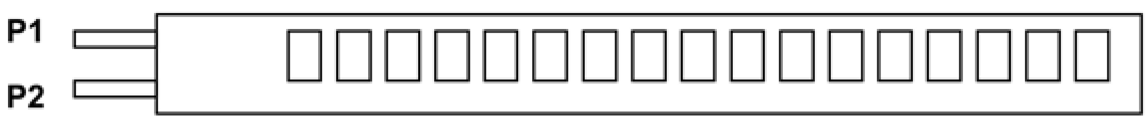
Relays are used:

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems,
- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the Boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.

- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.
- To perform time delay functions. Relays can be used to act as a mechanical time delay device by controlling the release time by using the effect of residual magnetism by means of a inserting copper disk between the armature and moving blade assembly.

Figure 4.8.3 Relay

7.2 Flex Sensor



Flex Sensor   Flex Sensor Pin out

Flex sensors are usually available in two sizes. One is **2.2 inch** and another is **4.5 inch**. Although the sizes are different the basic function remains the same. They are also divided based on resistance. There are LOW resistance, MEDIUM resistance and HIGH resistance types. Choose the appropriate type depending on requirement. Here we are going to discuss 2.2inch Flex sensor that is **FS-L-0055**.

7.1.3 FLEX SENSOR WORKING

This sensor works on the bending strip principle which means whenever the strip is twisted then its resistance will be changed. This can be measured with the help of any controller.

This sensor works similar to a variable resistance because when it twists then the resistance will be changed. The resistance change can depend on the linearity of the surface because the resistance will be dissimilar when it is level.

When the sensor is twisted 450 then the resistance would be dissimilar. Similarly, when this senor is twisted to 900 then the resistance would be dissimilar. These three are the flex sensor's bending conditions.

According to these three cases, the resistance will be normal in the first case, the resistance will be double as contrasted with the first case, and the resistance will be four-time when compared with the first case. So the resistance will be increased when the angle is increased

7.1.4 FLEX SENSOR Pin Configuration

Flex sensor is a two-terminal device. The Flex sensor does not have polarized terminals like diode. So, there is no positive and negative.

Pin Number	**Description**
P1	Usually connected to positive of power source.
P2	Usually connected to ground.

7.1.5 FLEX SENSOR Features and Specifications

- Operating voltage of FLEX SENSOR: 0-5V
- Can operate on LOW voltages
- Power rating: 0.5Watt (continuous), 1 Watt (peak)
- Life: 1 million
- Operating temperature: -45ºC to +80ºC
- Flat Resistance: 25K Ω
- Resistance Tolerance: ±30%
- Bend Resistance Range: 45K to 125K Ohms (depending on bend)

FS-L-0055 Equivalents

FS-L-0095, FS-L-0112, etc

7.1.6Where to Use FLEX SENSOR

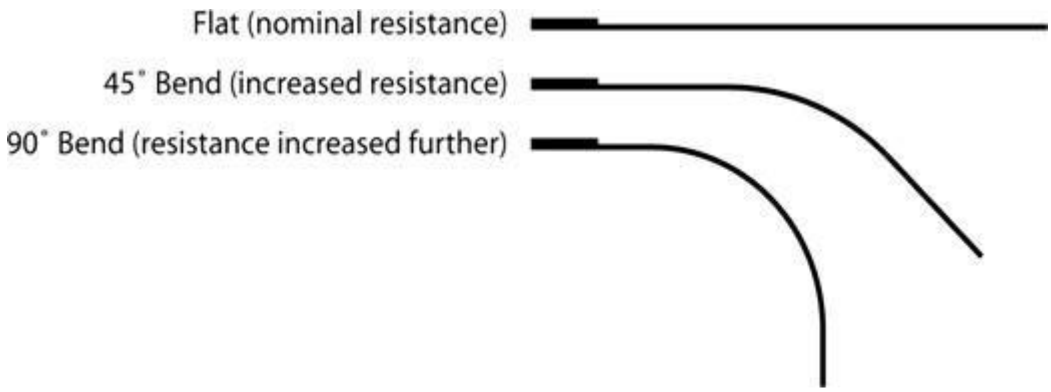
For understanding the use of FLEX SENSOR considers:

Case1: Where you want to check whether the surface of a device or thing is levelled or not. Say you want a device to check whether a window or door is open or not. At that time a Flex sensor could be used. The sensor could be fixed at door edge and when the door opens the Flex sensor gets flexed. With the sensor being flexed its parameters changes which could be designed to provide an alert.

Case2: Where you want to measure the FLEX or BENT or ANGLE change of any instrument or device. The FLEX SENSOR internal resistance changes almost linearly with its flex angle. So by sticking the sensor to the instrument we can have the flex angle in electrical parameter of resistance.

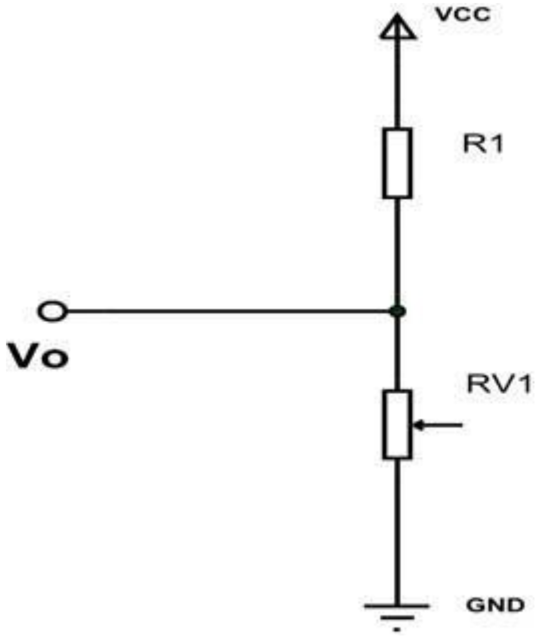
7.1.7 How to Use FLEX SENSOR

As mentioned earlier, **FLEX SENSOR** is basically a **VARIABLE RESISTOR** whose terminal resistance increases when the sensor is bent. So this sensor resistance increases depends on surface linearity. So it is usually used to sense the changes in linearity.



As shown above figure, when the surface of FLEX SENSOR is completely linear it will be having its nominal resistance. When it is bent 45º angle the FLEX SENSOR resistance increases to twice as before. And when the bent is 90º the resistance could go as high as four times the nominal resistance. So the resistance across the terminals rises linearly with bent angle. So in a sense the FLEX sensor converts flex angle to RESISTANCE parameter.

For convenience we convert this RESISTANCE parameter to VOLTAGE parameter. For that we are going to use **VOLTAGE DIVIDER circuit**. A typical VOLTAGE DIVIDER circuit is shown below.



In this resistive network we have two resistances. One is constant resistance (R1) and other is variable resistance (RV1). Vo is the voltage at midpoint of VOLTAGE DIVIDER circuit and is also the output voltage. Vo is also the voltage across the variable resistance (RV1). So when the resistance value of RV1 is changed the output voltage Vo also changes. So we will have resistance change in voltage change with VOLTAGE DIVIDER circuit.

Here we will replace the variable resistance (RV1) with FLEX SENSOR. The circuit will be as below.

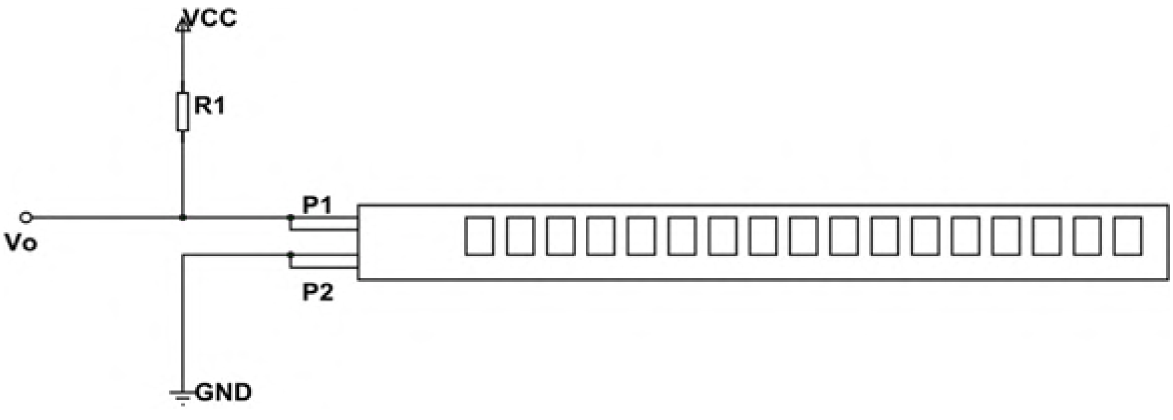


Figure: 4.9.5.1 Flex sensor

As shown in figure, R1 here is a constant resistance and **FLEX SENSOR** which acts as a variable resistance. Vo being output voltage and also the voltage across the FLEX SENSOR.

Here,

Vo = VCC (Rx/ (R1+Rx)).

Rx - FLEX SENSOR resistance

Now, when the FLEX SENSOR is bent the terminal resistance increases. This increase also appears in VOLTAGE DIVIDER circuit. With that the drop across the FLEX SENSOR increases so is Vo. So with increase in bent of FLEX sensor Vo voltage increases linearly. With that we have VOLTAGE parameter representing the flex.

We can take this VOLTAGE parameter and feed it to ADC to get the digital value which can be used conveniently.

7.1.8 Applications

- Robotics
- Gaming (Virtual Motion)
- Medical Devices
- Computer Peripherals
- Musical Instruments
- Physical Therapy

7.2 POWER SUPPLY

7.2.1 Block Diagram

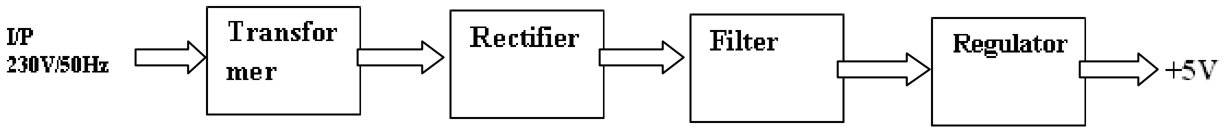

Figure 4.10.1 Power Supply

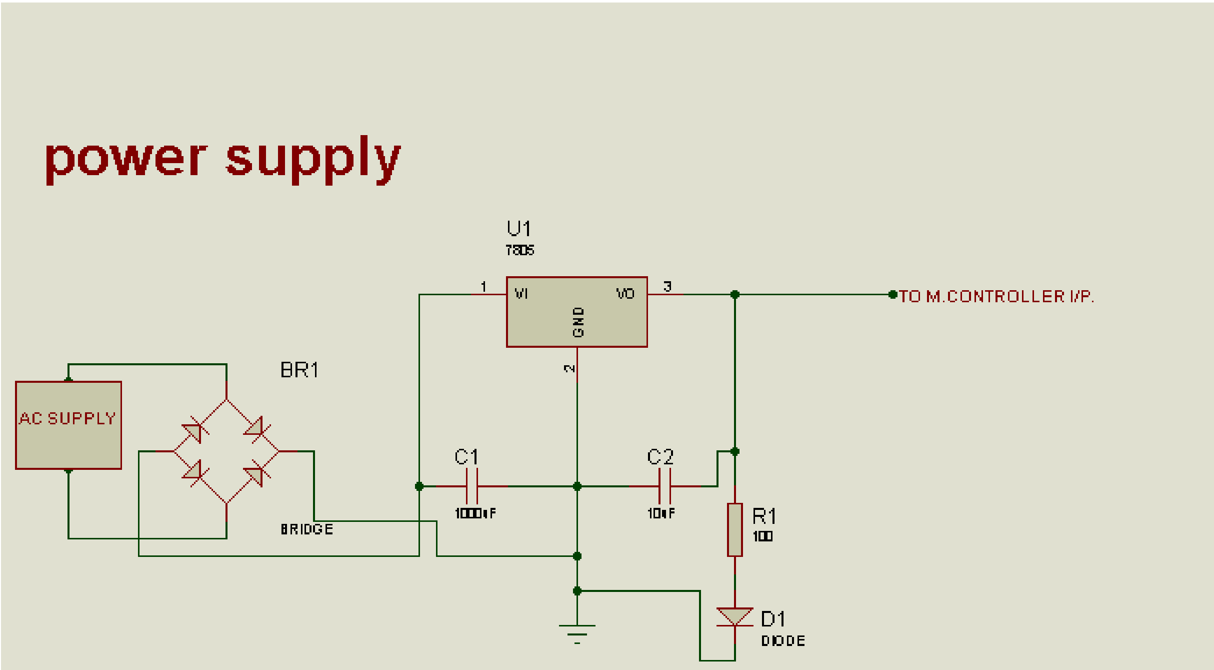
7.2.2 Circuit Diagram



7.2.3 Description

Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

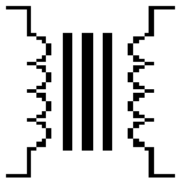


Figure: 4.10.3.1 Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

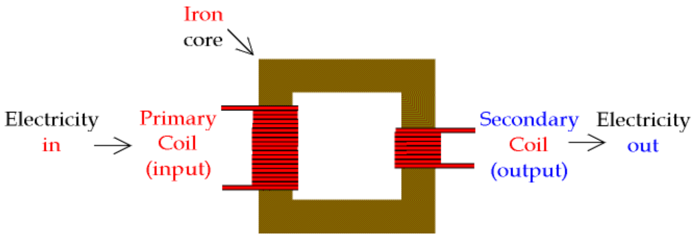

Figure 4.10.3.2 Transformer

7.2.4 Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

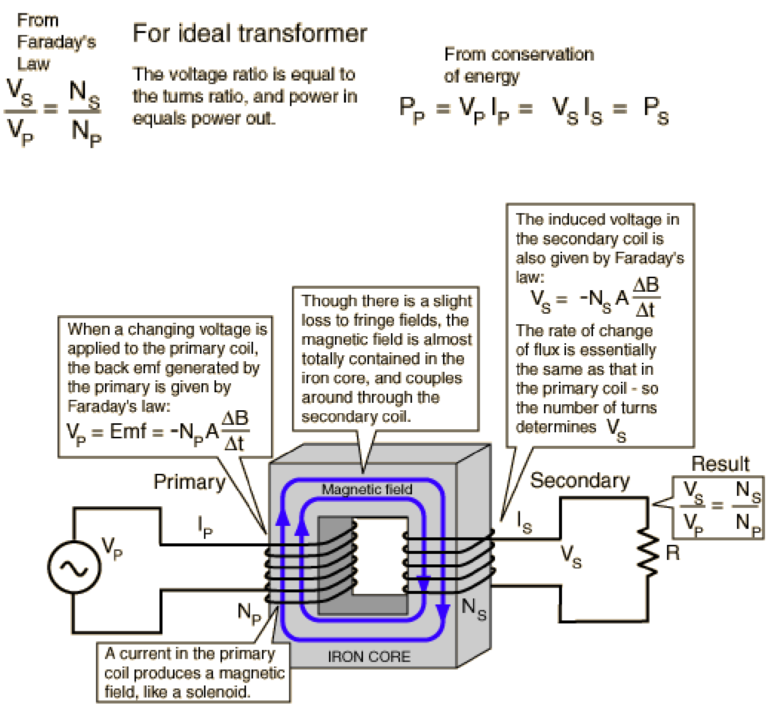

Figure: 4.10.4 Basic Principle

7.2.5 Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

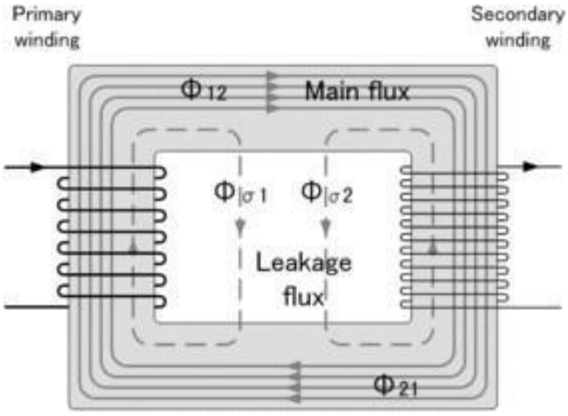

Figure: 4.10.5 Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

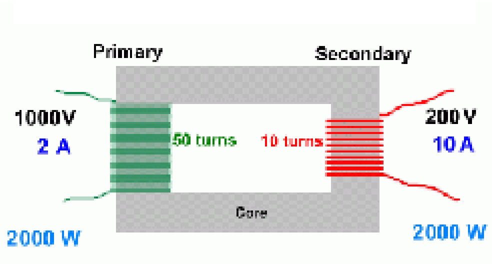

Figure: 4.10.6 Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn’s ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn’s ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

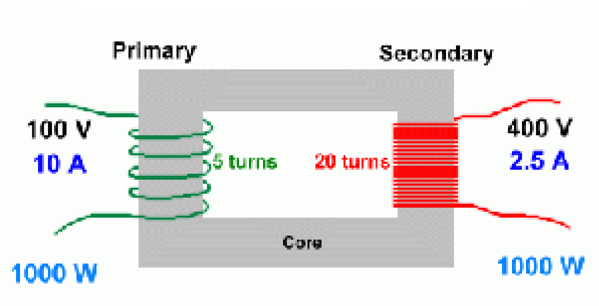

Figure: 4.10.6.1 Step-Up Transformer

7.3 Applications

Generally these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

7.3.1 Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

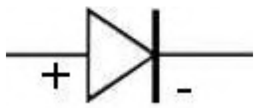

Figure 4.11.1 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

7.3.2 Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-wave Rectifier

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

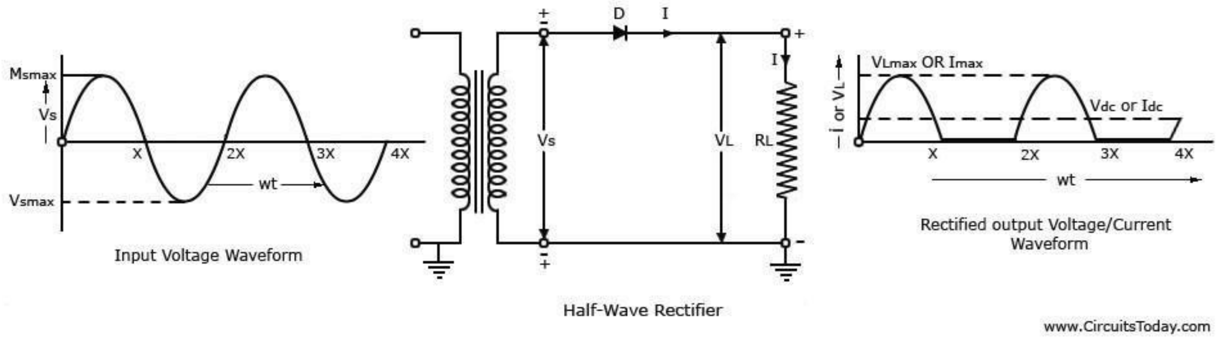

Figure: 4.11.2 Half Wave Rectifier

Figure 4.9.2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

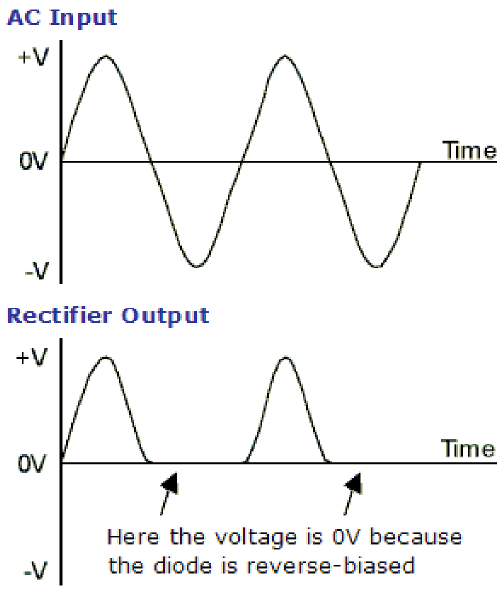

Figure: 4.11.2.1 Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 4.

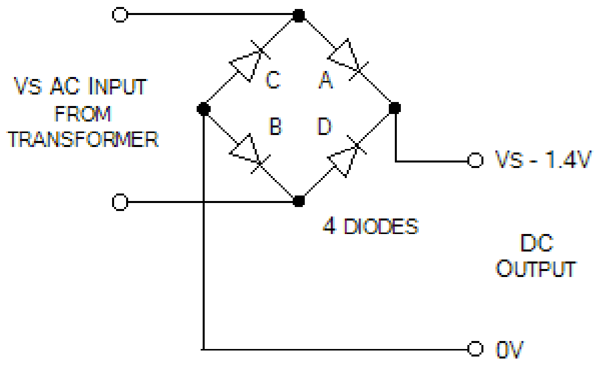

Figure: 4.11.2.2 Full-Wave Rectifier

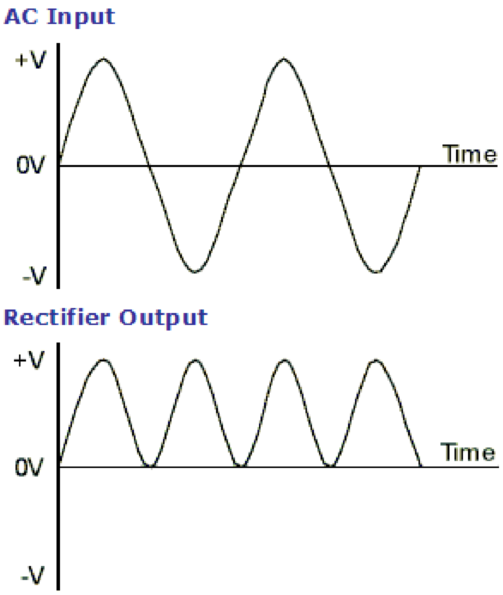

Figure: 4.11.2.3 Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

7.4 Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

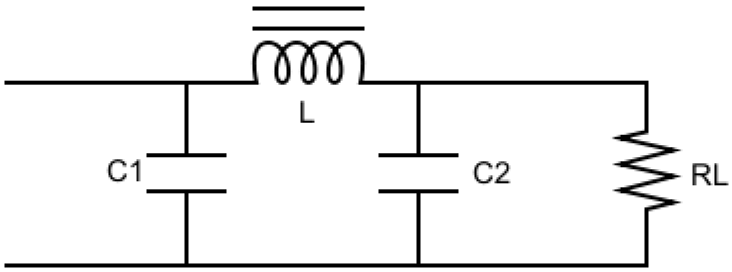

Figure: 4.12.1 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

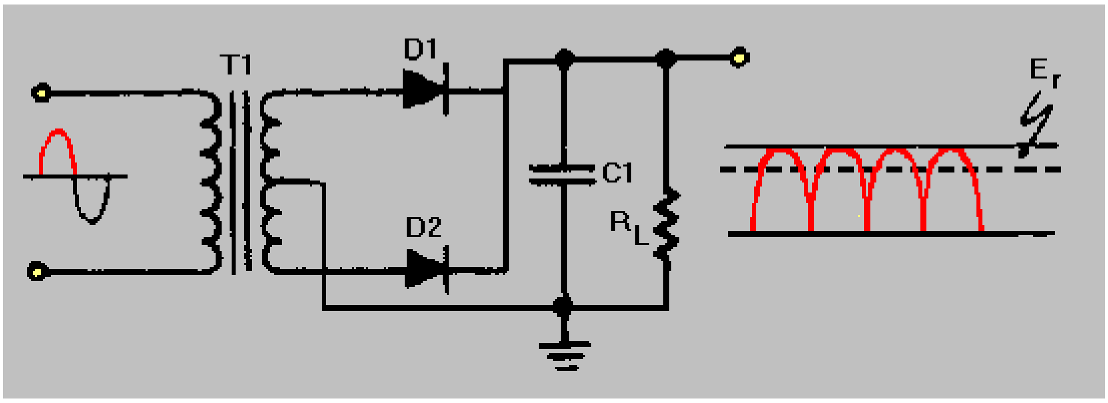

Figure: 4.12.2Centered Tapped Full-Wave Rectifier with a Capacitor Filter

7.5 Voltage Regulator:

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:’78’ indicate the positive series and ‘xx’indicates the voltage rating. Suppose 7805 produces the maximum 5V.’05’indicates the regulator output is 5V.

79xx:’78’ indicate the negative series and ‘xx’indicates the voltage rating. Suppose 7905 produces the maximum -5V.’05’indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

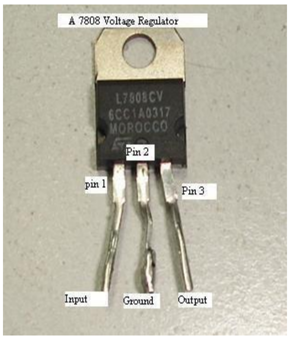

Figure: 4.13 Regulator

CHAPTER

5RESULTS

5.1 RESULTS

The total prototype is shown in the above figure. The microcontroller used in this project is Arduino UNO, it acts as the bridge between the input and the output. The input is taken according to the bend of the flex sensors. The output is seen through the LCD and a audio output is heard through the speaker and the APR module helps to decide which audio should be played according to the digital output given by the Arduino. The relay module which is kept is used for the ON, OFF and the reset the whole circuit.

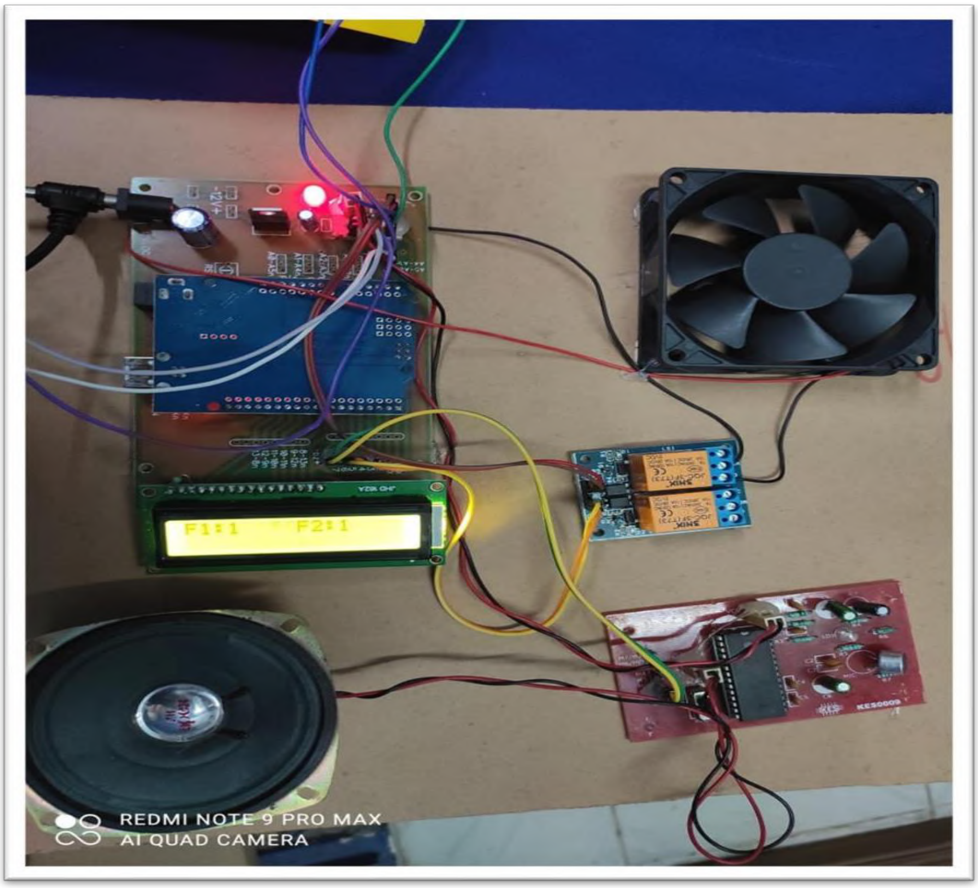

Fig: 5.1 prototype

5.1.1 RESULT

Fig 5.1.1 : Output when flex sensor 1 is bent

5.1.2 RESULT

Now again bring the first sensor to the normal position and check whether the output of both flex sensors are showing 0 as output, now bend the second flex sensor placed on Mitten and now the output changes to 1 at the flex sensor 2 and it shows as TV ON on the LCD and an audio output can be heard from the speaker. The output on the LCD can be seen in the below Figure.

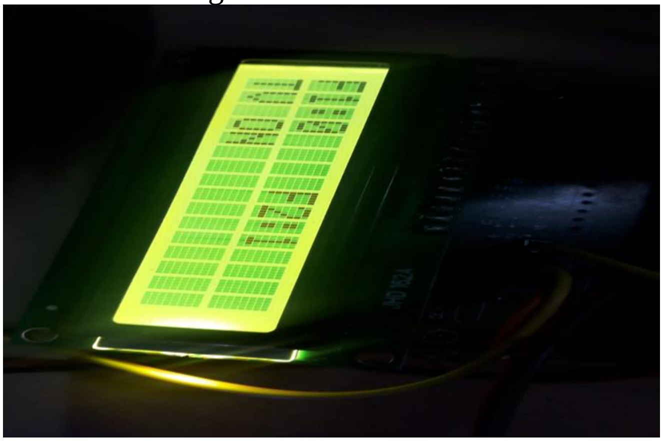

Fig 5.1.2 : Output when flex sensor 1 is bent

CHAPTER 6

ADVANTAGES

- It requires fewer components making the project cost efficient.
- The accuracy of get exact output is comparatively high.
- Easy to carry: As it can be fixed to the person's body who is in need.
- Light in weight.
- Flexible to users.
- Anyone can operate it easily.
- Real time translation.

CHAPTER 7
CONCLUSION

7.1 Conclusion:

Sign language is a method used for communication by disabled person. Here we are converting sign language into text and speech so that communication is not limited between them only, utilizing data gloves communication barrier between two different communities is eliminated. Using data gloves disabled person can also grow in their carrier and makes nation grow as percentage of disabled person are millions in count. Making their future better, making nation better.

ACKKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to Dr.B.Harikrishna, **Head &Professor**, the Dept. of Electronics and communication for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept project coordinator** Dr.A.Anand for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We are highly grateful and obliged to **our college level Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santosh Kumar** , **Associate Professor in CSE** and our project coordinator **N.Vishwanath** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

Finally, I am deeply indebted to our family members for their moral support and continuous encouragement while carrying out this study. I dedicate this thesis to almighty

.

ABSTRACT

Here we propose a smart fingerprint based biometric attendance system that works over IOT so that attendance can be monitored from anywhere in the world. Our system uses a microcontroller based circuit with fingerprint sensor, push buttons, power supply, power supply and WIFI modem to interact with internet based system. We here use IOT Gecko to develop the online attendance display system. Our system allows users/employees/students to first register their fingerprint on the system. After successful registration the print is stored in system with class assigned using push buttons. The system also displays these details over LCD display. Now as soon as the next time a registered user scans the modem, the system checks for authentication and authenticated users data is transferred online to IOT Gecko using the gecko development API codes. Now the online system stores and displays the required data to users as per online login. Thus,our system allows for remote monitoring of biometric based attendance from anywhere over IOT.

CHAPTER 1

INTRODUCTION

1.1 EMBEDDED SYSTEMS

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware. The simplest devices consist of a single microprocessor (often called a "chip"), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware.

1.1.1 Block diagram of embedded system:

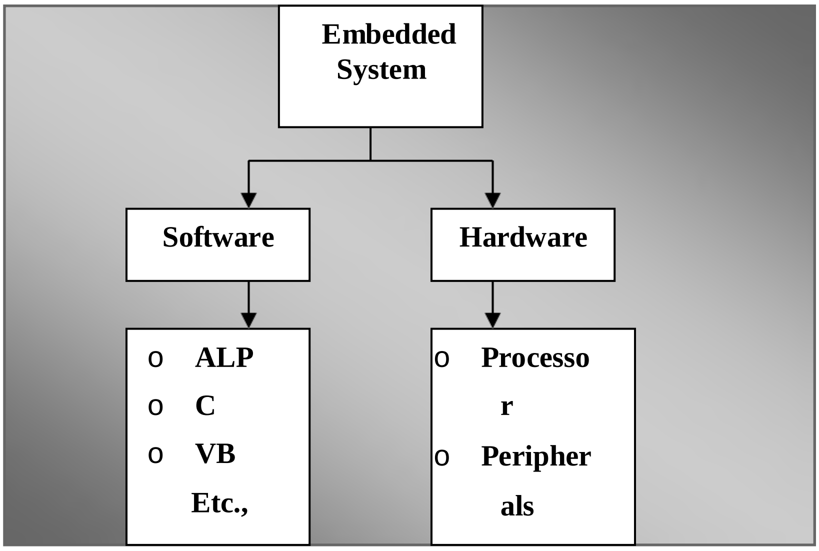

Fig.1.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

1.1.2 Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

1.2 MICRO PROCESSOR (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (μp)
- Micro controller (μc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

1.2.1 Three Basic Elements of a Microprocessor:

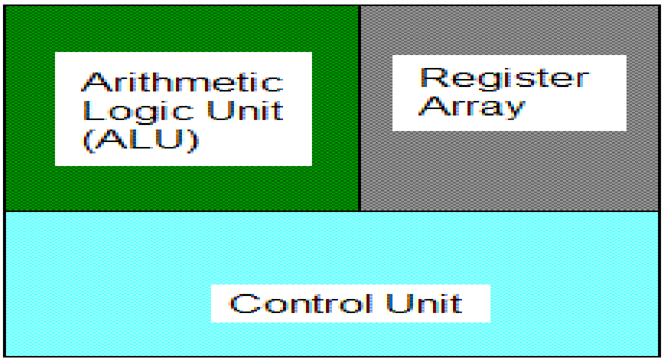

Fig.1.2: Three basic elements of a microprocessor

1.3 HARVARD ARCHITECTURE:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

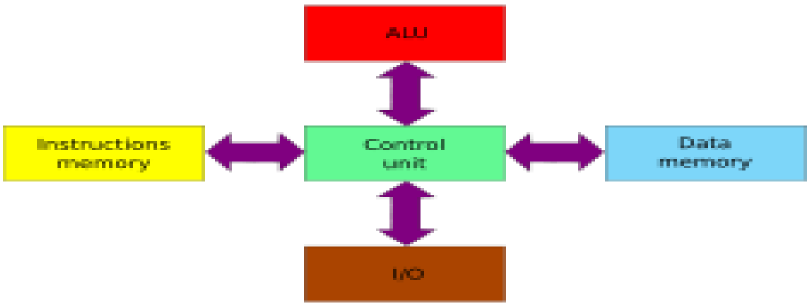

Fig.1.3: Harvard Architecture

1.3.1 Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

1.4 VON-NEUMANN ARCHITECTURE:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

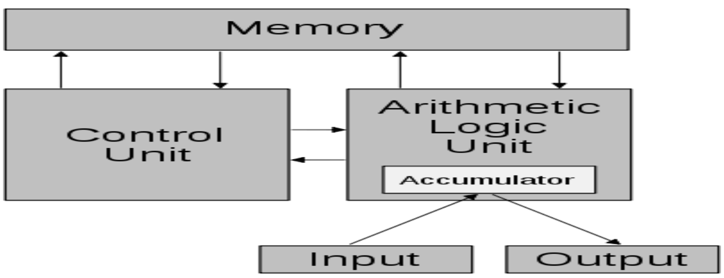

Fig.1.4: Schematic of the Von-Neumann Architecture.

1.5 PROJECT DESCRIPTION:

1.5.1 Objective:

The main aim of this project is to design and implement biometric attendance system over IOT through which the attendance of students is monitored remotely using internet and the data gathered from the fingerprint sensors is stored in the cloud. A portable module is designed which has a capability of recognizing the student via their fingerprints and then sending the ID of student to server, whose fingerprint is recognized. Here we use IOT Gecko Platform in which a person can provide Username and password and can know his/her attendance records, similarly the HOD or teachers can also check the students attendance using their respective username and password.

1.5.2 Aim:

The main reason for preferring this project is to maintain proper record of students or employees for effective functioning of organization. Designing an effective attendance management system for students to maintain the records with ease and accuracy is an important key behind motivating this project. Nowadays attendance is taken on paper and records are maintained where someone keeps all records and does all the calculations at the end of the month due to which it takes time and students have to wait till month end to know their attendance. This system would improve accuracy of attendance records because it will remove all the hassles of roll calling and will save valuable time of the students and teachers and will overcome problems like proxy and provide correct record of attendance.

1.6 COMPONENTS USED :

- WI-FI module(ESP8266 12e)
- Fingerprint Sensor(r-305)
- LCD display(16*2)
- Buzzer
- Push Buttons
- Arduino UNO

1. ARDUINO UNO:

Arduino UNO is a microcontroller which is used to transfer data from Fingerprint sensor to LCD and Wi-fi module. Arduino takes the input from Fingerprint Sensor in Analog form and converts it into digital form. This converted data is sent to the Wi-fi module. The Arduino sends the power required by the Fingerprint Sensors. Arduino gets power from the Wi-fi module to work. The Arduino works according to the code which is dumped into it.

2. ESP-01:

The wi-fi module in the circuit helps in connecting the microcontroller with the wi-fi network. The data received by the Wi-fi module is sent to the server where we can see the student attendance record with their respective username and password.

3. FINGERPRINT SENSOR:

The fingerprint sensor senses the skin on the palms of our hands that have a special pattern called friction ridges that helps us grab things effectively without slipping around it.so, when we place a finger on fingerprint scanner it captures the pattern which is unique to every student.

4 .LCD :

It is an electronic display module that uses liquid crystal to produce a visible image that is used to display 16 characters per line in 2 such lines.it is used in our project to display instructions like enrolling the student fingerprint data ,place the finger and used to display student information.

5. BUZZER:

Buzzer is used here for indication purpose. When an unauthorized student places a finger on fingerprint sensor it indicates that student who placed finger does not have a fingerprint and thus makes a beep sound.

6. PUSH BUTTONS:

Two Push buttons are used in our project.one pushbutton is used for enrolling that is used to store student fingerprint initially and another for checking the fingerprint.

CHAPTER 2

LITERATURE SURVEY AND EXISTING METHODS

2.1 LITERATURE SURVEY

After doing analysis on the recent work done in attendance and performance analysis, we found that many people used different methods to mark attendance And also, this kind of system worked well in all the cases but there were some issues with them, such as the student could mark his/her attendance anything even if he/she is late. Also, certain systems used Arduino and a single board computer with fingerprint biometrics. In such system the idea was to centralized the management system. Some systems used Arduino and raspberry Pi for attendance recording. Such system implemented attendance recording and consolidation with the help of raspberry Pi and Arduino. But, after a certain extent only marking attendance was not a key point as being an engineer no one is happy with doing a small kind of work so there came idea of managing the performance of the student using such kind of data and a new thing came in market known as STUDENT PERFORMANCE ANALYSIS.

2.2 EXISTING METHOD

The existing attendance system requires a teacher to take attendance by roll calling, which has many drawbacks, such as proxy attendance, extra efforts of teacher calculating the attendance percentage, even calculation errors can be made, and students not getting their attendance report till the end of the month. All these problems can be avoided by using this system, as this system uses fingerprint recognition to identify the student, proxy attendance can’t be marked, attendance is sent to server in real time, all the calculations are done by the server and students can check their attendance in real time.

2.3 PROPOSED SYSTEM

We here use IOT to develop the online attendance display system. Our system allows users/employees/students to first register their fingerprint on the system. After successful registration the print is stored in system with class assigned using push buttons. The system also displays these details over LCD display. Now as soon as the next time a registered user scans the modem, the system checks for authentication and authenticated users data is transferred online to IOT. Now the online system stores and displays the required data to users as per online login. Thus our system allows for remote monitoring of biometric based attendance from anywhere over IOT.

3.2 SCHEMATIC EXPLANATION:

3.2.1 INTERFACING BETWEEN ARDUINO AND LCD:

The following circuit diagram shows the liquid crystal display with the Arduino module. From the circuit diagram, we can observe that the RS pin of the LCD is connected to the pin 12 of the Arduino. The LCD of R/W pin is connected to the ground. The pin 11 of the Arduino is connected to the enable signal pin of LCD module. The LCD module & Arduino module are interfaced with the 4-bit mode in this project. Hence there are four input lines which are DB4 to DB7 of the LCD. This process very simple, it requires fewer connection cables and also we can utilize the most potential of the LCD module.

The digital input lines (DB4-DB7) are interfaced with the Arduino pins from 5-2. To adjust the contrast of the display here we are using a 10K potentiometer. The current through the back LED light is from the 560-ohm resistor. The external power jack is provided by the board to the Arduino. Using the PC through the USB port the Arduino can power. Some parts of the circuit can require the +5V power supply it is taken from the 5V source on the Arduino board.

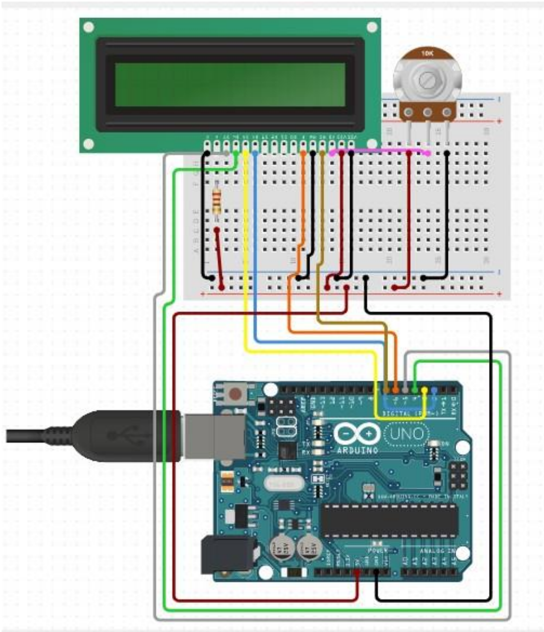

Fig 3.2: Schematic diagram of LCD and Arduino.

3.2.2 INTERFACING BETWEEN ARDUINO AND WI-FI MODULE:

Arduino UNO to configure ESP8266 wi-fi module as TCP Client and Receive/Send data from/to Server using WIFI.

Here, we are using IOT Gecko server for TCP Client demo purpose.

IOT Gecko is an open IOT platform where anyone can visualize and analyze live data from their sensor devices. Also, where data of students attendance can be maintained and stored.

Just sign up and create channel. We have to provide username and password to login to IOT Gecko platform.

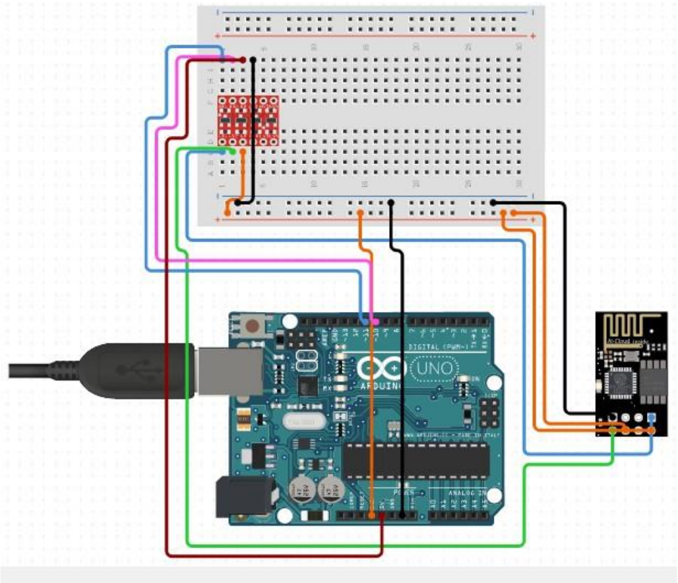

Fig 3.3:Schematic diagram of Wi-fi module and Arduino

3.2.3 INTERFACING BETWEEN ARDUINO AND FINGERPRINT SENSOR:

The +5v for r-305 can be taken from the +5v out pin of arduino uno. Also the ground pin r-305 of can be connected to GND pin of arduino uno. Connect V out (the analog out of r-305) to any of the analog input pin of arduino uno. In this circuit diagram, we have connected Vout of r-305 to A1 of arduino.

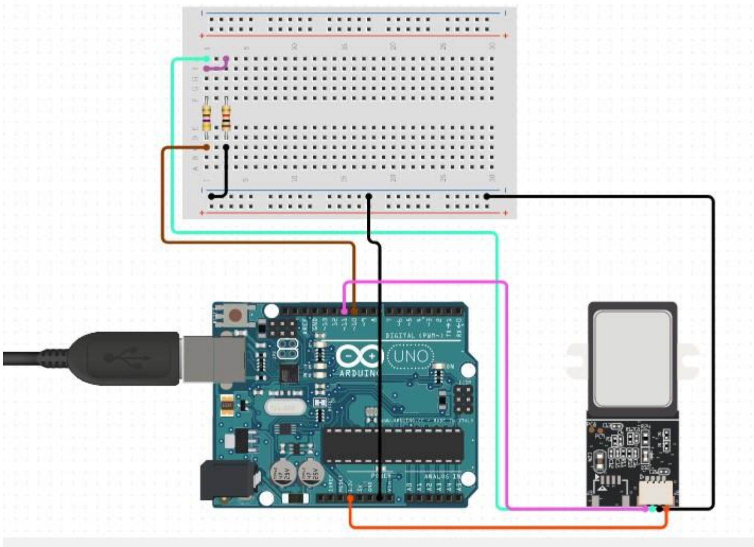

Fig 3.4:Schematic diagram of Temperature Sensor and Arduino.

3.2.4 INTERFACING BETWEEN ARDUINO AND PUSH BUTTONS

The push buttons are used for enrolling and checking of student fingerprints. the two push buttons are connected to 5, 6 pin of Arduino as shown in figure below.

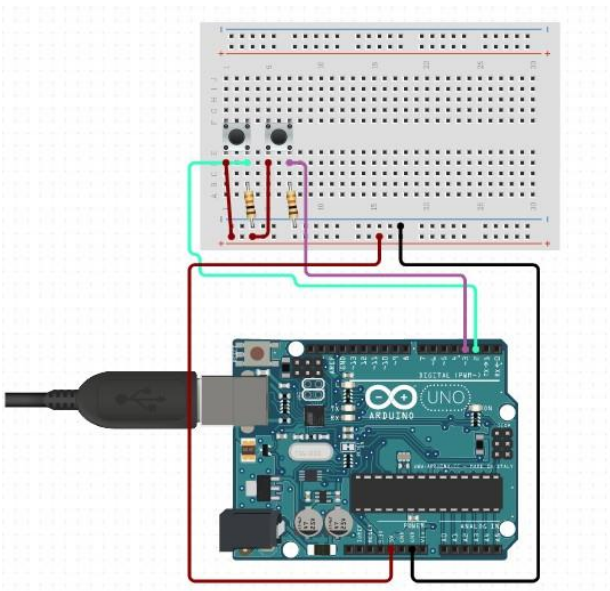

Fig 3.5 Schematic diagram of push buttons and Arduino.

3.2.5 INTERFACING BETWEEN THE COMPONENTS:

The fingerprint sensor output pin is connected to A0 and A1 of arduino analog pins. The Vcc and ground of fingerprint Sensors is connected to 5V and ground of Arduino. The transmitter and receiver of Arduino are connected to the receiver and transmitter of Wi-fi module respectively. The VSS, VEE, RW, D0-D3 pins of LCD are grounded. The RS, E, D4-D7 pins of LCD are connected to 13-8 digital pins of Arduino.

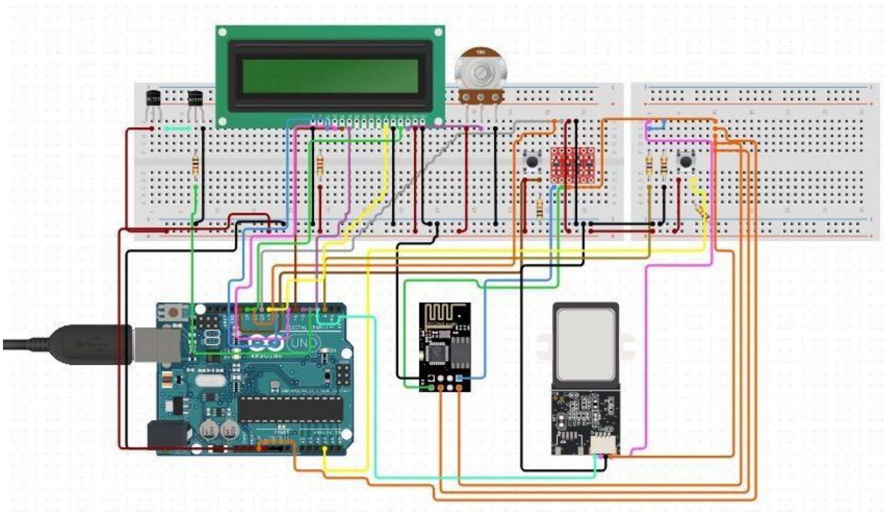

Fig 3.5: Schematic diagram of all components.

3.3 WORKING:

In this system the concept of IOT is applied to attendance system of a classroom. A portable module is designed which has the capability of recognizing the student via their fingerprints and then sending the ID of student to the server, whose fingerprint is recognized. First of all the system requires connectivity to the internet, which can be achieved through Wi-Fi So a system is required which has the capability of Wi-Fi connectivity for which Node mcu (ESP8266 12e) is chosen. Now when the system is powered ON, it first scans all the Wi-Fi networks and any network can be connected by entering the password. Once the connection is established, it scans for the fingerprint via fingerprint module r-305 and recognizes the student, whoever is recognized their fingerprint ID is sent to the server (PC). When the server receives the Fingerprint ID it marks the attendance of the student.

.

CHAPTER-4

HARDWARE AND SOFTWARE COMPONENTS

The hardware and software components used for the implementation of biometric attendance system over IOT are

1. Arduino UNO.
2. Regulated power supply.
3. ESP-01
4. LCD display.
5. Fingerprint Sensor.
6. Buzzer.
7. Push buttons

4.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

4.1.1 SPECIFICATIONS:

Table 4.1: Atmega328 specifications

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V

Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

4.2 ARDUINO:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.

- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

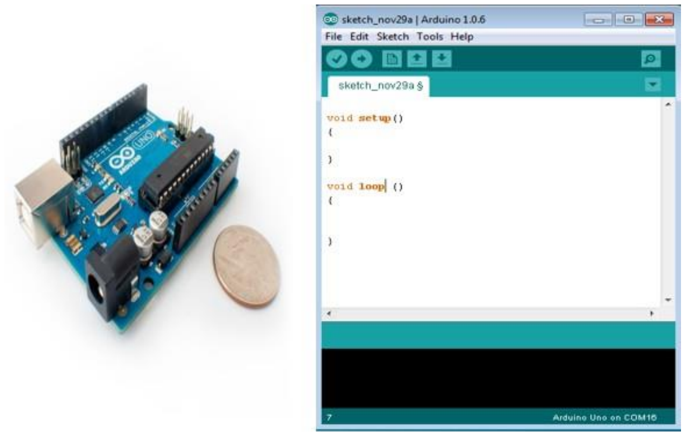

Fig 4.1 Arduino Uno

4.2.1 BOARD TYPES:

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Table 4.2 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16 MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

4.2.2 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

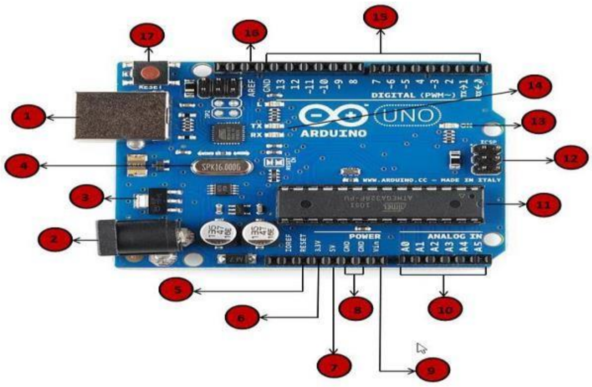

Fig 4.2 Arduino UNO pin description

Table 4.6 Arduino UNO pin description

Pin Category	**Pin Name**	**Details**
Power	Vin, 3.3V, 5V, GND	Vin: Input voltage to Arduino when using an external power source. 5V: Regulated power supply used to power microcontroller and other components on the board. 3.3V: 3.3V supply generated by on-board voltage regulator. Maximum current draw is 50mA. GND: ground pins.
Reset	Reset	Resets the microcontroller.
Analog Pins	A0 – A5	Used to provide analog input in the range of 0-5V

Input/Output Pins	Digital Pins 0 - 13	Can be used as input or output pins.
Serial	0(Rx), 1(Tx)	Used to receive and transmit TTL serial data.
External Interrupts	2, 3	To trigger an interrupt.
PWM	3, 5, 6, 9, 11	Provides 8-bit PWM output.
SPI	10 (SS), 11 (MOSI), 12 (MISO) and 13 (SCK)	Used for SPI communication.
Inbuilt LED	13	To turn on the inbuilt LED.
TWI	A4 (SDA), A5 (SCA)	Used for TWI communication.
AREF	AREF	To provide reference voltage for input voltage.

4.2.3 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

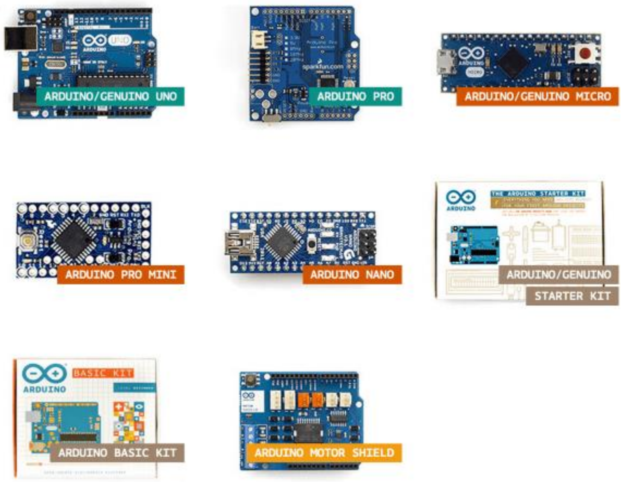

Fig.4.3: Arduino Family

4.2.4 PIN DESCRIPTION OF ATMEGA328

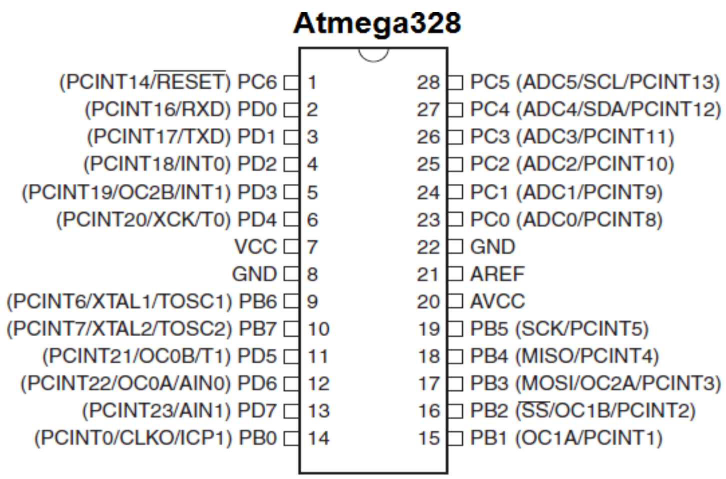

Fig.4.4: Pin description of ATMEGA328

4.2.5 ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.

- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

4.2.6 APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model.

4.3 REGULATED POWER SUPPLY:

4.3.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

4.3.2 BLOCK DIAGRAM OF POWER SUPPLY:

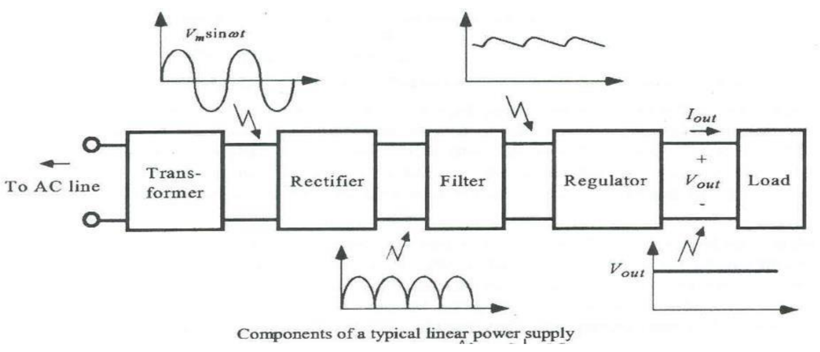

Fig.4.5: Block Diagram of Power Supply

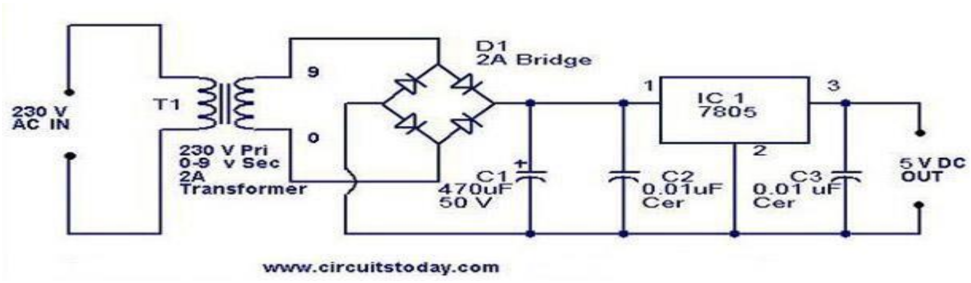

Fig.4.6: Schematic Diagram of Power Supply

4.3.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.3.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

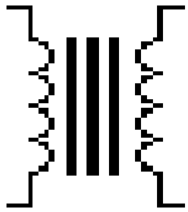

Fig.4.7: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

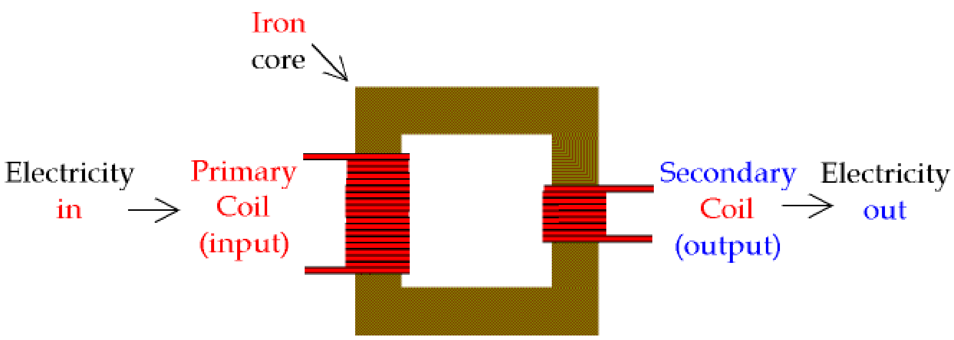

Fig.4.8: Transformer

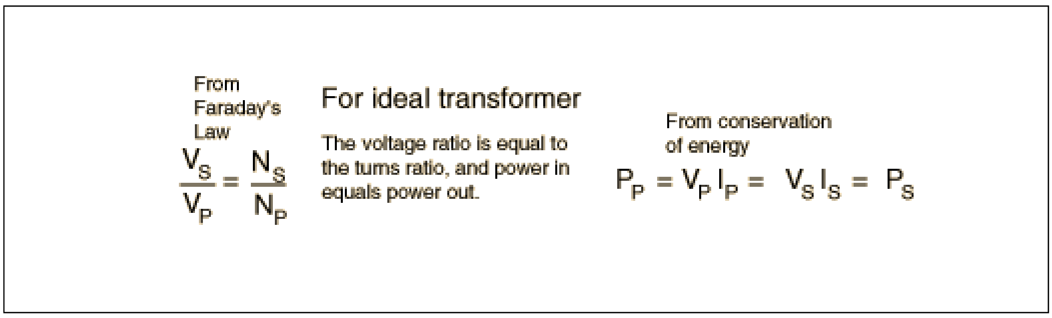
4.3.4.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.



4.3.4.2 Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

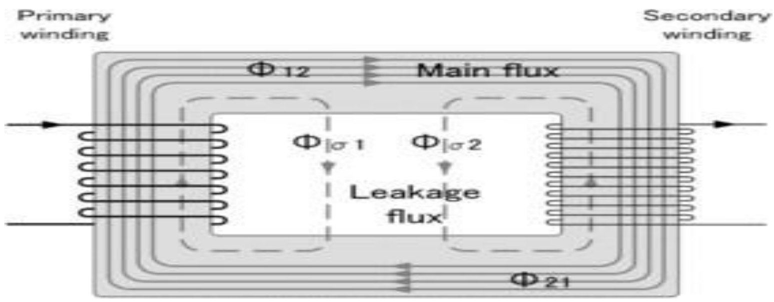


Fig.4.9: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

4.3.4.3 CLASSIFICATION OF TRANSFORMER:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

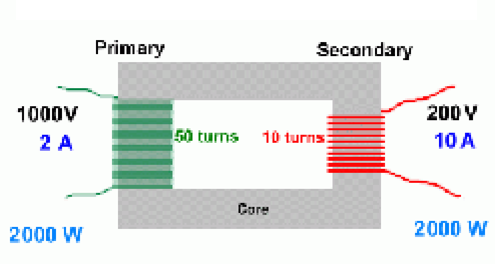

Fig.4.10: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

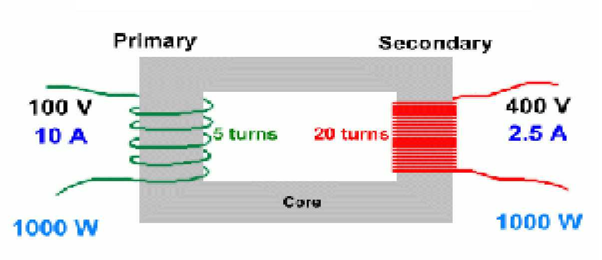

Fig.4.11: Step-Up Transformer

4.3.5 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

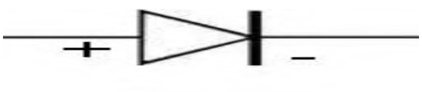

Fig.4.12: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

4.3.6 RECTIFIER:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

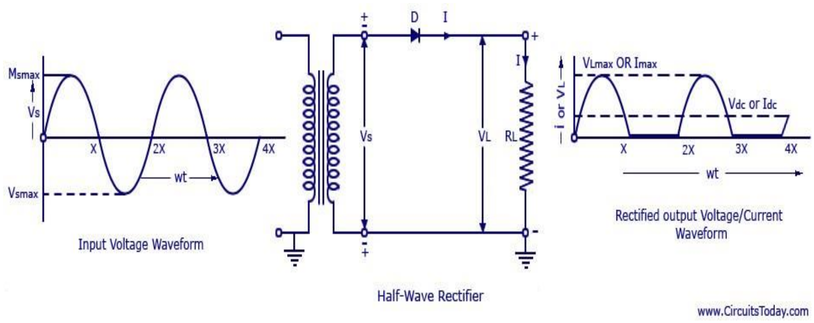

Fig.4.13: Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

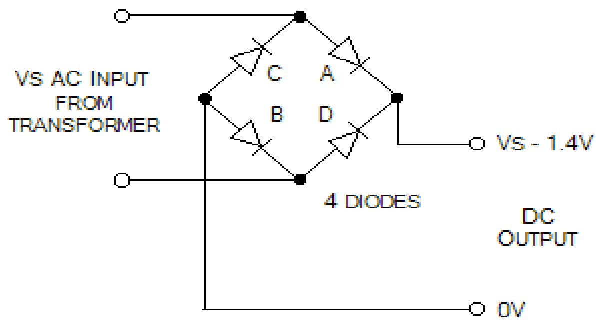

Fig.4.14: Full-Wave Rectifier

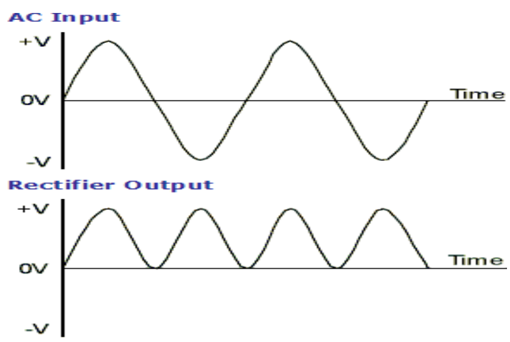

Fig.4.15: Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

4.3.7 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

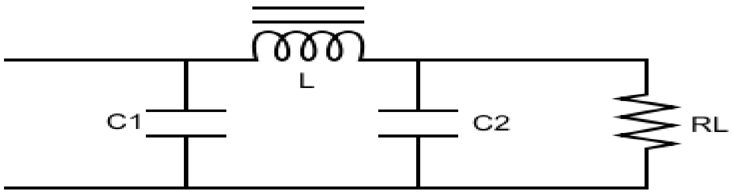

Fig.4.16: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

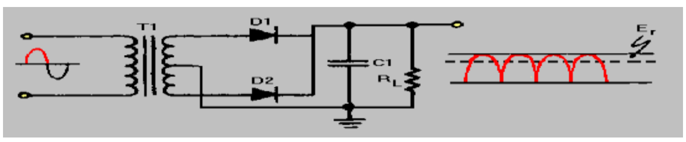

Fig.4.17: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

4.3.8 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin

.Pin2: This is ground pin for regulator.

Pin3: It is used for output pin. Through this pin we get the output.

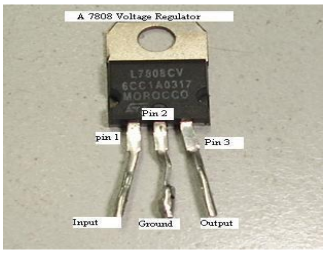

Figure 4.18 Volatge Regulator

4.4 ESP8266 WIFI Module:

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

4.4.1 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I^2C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I^2S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

4.4.2 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring
- Natural Language-based voice assistants.

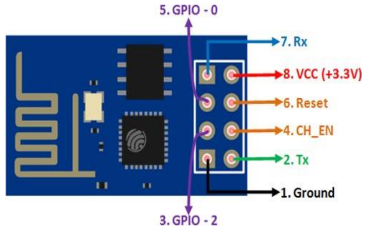

Fig.4.19 ESP8266 wi-fi module pin out

4.5 FINGERPRINT SENSOR :

Finger Print Sensor (R305) -TTL UART is a finger print sensor module with TTL UART interface. The user can store the finger print data in the module and can configure it in 1:1 or 1: N mode for identifying the person. The finger print module can directly interface with 3v3 or 5v Microcontroller. A level converter (like MAX232) is required for interfacing with PC.

Features of Finger Print Sensor (R305) -TTL UART:

- Power DC : 3.6V-6.0V
- Interface : UART (TTL logical level)/ USB 1.1
- Working current : 100mA
- Peak Current : 150mA
- Matching Mode: 1:1 and 1:N
- Baud rate (9600*N)bps, N=1-12 (default N=6 57600bps)
- Character file size: 256 bytes
- Image acquiring time : <0.5s
- Template size : 512 bytes
- Storage capacity: 256
- Security level : 5 (1, 2, 3, 4, 5(highest))
- FAR : <0.001%
- FRR: <0.1%
- Average searching time: < 0.8s (1:880)
- Window dimension : 18mm*22mm

Fig:4.2.1 Fingerprint Scanner r-305

The characteristic of this r-305 sensor is:

- Temp: -10 - +40.
- Storage environment Temp: -40- +85.
- RH: 40%-85% RH: <85%.

4.6 16 x2 ALPHANUMERIC LCD:

4.6.1 DESCRIPTION:

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

4.6.2 BLOCK DIAGRAM:

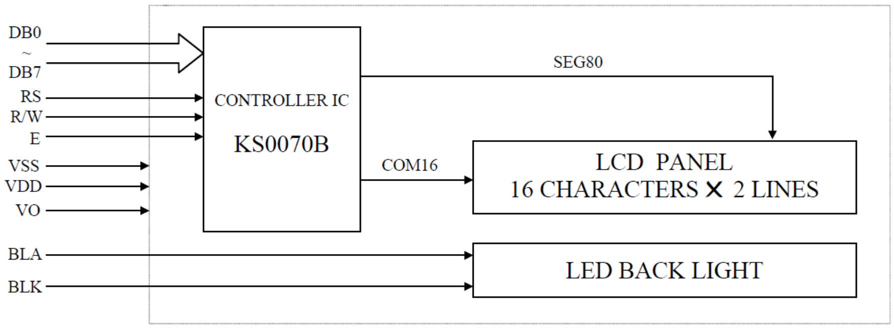

Fig 4.22: Block Diagram

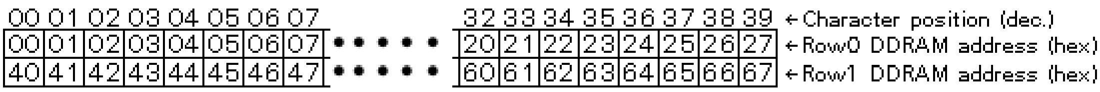
Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. Userdefined character patterns are also available by mask-programmed ROM.

Busy Flag

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact ammount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

Instruction Register(IR) and Data Register(DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and

Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.6.3 16 x 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

4.6.4 SCHEMATIC:

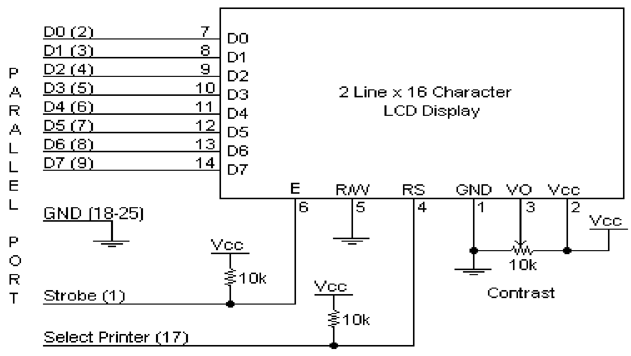


Fig 4.23 Schematic diagram of LCD

4.6.5 SPECIALISATIONS:

Table 4.7: Specifications of LCD

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.

4.6.6 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

4.7 BUZZER

A buzzer or beeper is an audio signaling device, which may be mechanical, electromechanical, or piezoelectric. Typical uses of buzzers and beepers include alarm devices, timers and confirmation of user input such as a mouse click or keystroke.

Mechanical:

A joy buzzer is an example of a purely mechanical buzzer.

Figure 4.24 Mechanical joy buzzer

Electromechanical:

Early devices were based on an electromechanical system identical to an electric bell without the metal going. Similarly, a relay may be connected to interrupt its own actuating current, causing the contacts to buzz. Often these units were anchored to a wall or ceiling to use it as a sounding board. The word "buzzer" comes from the rasping noise that electromechanical buzzers made.

Piezoelectric:

Nowadays, it is more popular to use a ceramic-based piezoelectric sounder like a Son alert which makes a high-pitched tone. Usually these were hooked up to "driver" circuits, which varied the pitch of the sound or pulsedthe sound on and off.

Figure 4.25 Buzzer

A piezoelectric element may be driven by an oscillating electronic circuit or other audio signal source, driven with a piezoelectric audio amplifier. Sounds commonly used to indicate that a button has been pressed are a click, a ring or a beep. Piezo buzzer is an electronic device commonly used to produce sound. Light weight, simple construction and low price make it usable in various applications like car/truck reversing indicator, computers, call bells etc.

Basically, the sound source of a piezoelectric sound component is a piezoelectric diaphragm as shown in fig(1). A piezoelectric diaphragm consists of a piezoelectric ceramic plate which has electrodes on both sides and a metal plate (brass or stainless steel, etc.).

A piezoelectric ceramic plate is attached to a metal plate with adhesives. Applying

D.C. voltage between electrodes of a piezoelectric diaphragm causes mechanical distortion due to the piezoelectric effect. For a misshaped piezoelectric element, the distortion of the piezoelectric element expands in a radial direction. And the piezoelectric diaphragm bends toward the direction. The metal plate bonded to the piezoelectric element does not expand.

Conversely, when the piezoelectric element shrinks, the piezoelectric diaphragm bends in the direction Thus, when AC voltage is applied across electrodes, the bending is repeated, producing sound waves in the air.

Buzzers typically provide a user with an alert when a given condition within the circuit has occurred. Normally man’s audible frequency range is 20Hz to 20kHz , but we can hear up to frequency ranges from 2kHz to 4kHz .

To interface a buzzer the standard transistor interfacing circuit is used(Fig 2). Note that if a different power supply is used for the buzzer, the 0V rails of each power supply must be connected to provide a common reference. If a battery is used as the power supply, it is worth remembering that piezo sounders draw much less current than buzzers. Buzzers also just have one ‘tone’, whereas a piezo sounder is able to create sounds of many different tones. Here transistor acts as a switch.

To switch on buzzer -high 1 To switch off buzzer -low 1

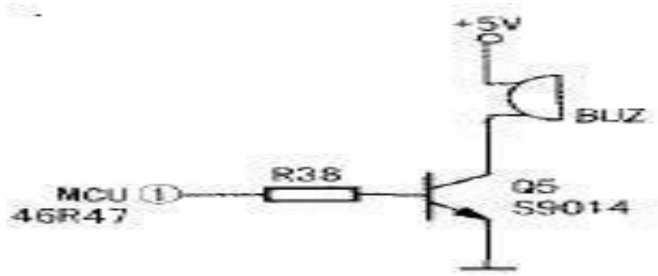

Figure 4.26 Buzzer with transistor interfacing circuit

Notice (Handling) In Using Self Drive Method:

1) When the piezoelectric buzzer is set to produce intermittent sounds, sound may be heard continuously even when the self drive circuit is turned ON / OFF at the "X" point shown in Fig(b). This is because of the failure of turning off the feedback voltage.

2) Build a circuit of the piezoelectric sounder exactly as per the recommended circuit shown in the catalog. Life of the transistor and circuit constants is designed to ensure stable oscillation of the piezoelectric sounder.

3) Design switching which ensures direct power switching.

4) The self drive circuit is already contained in the piezoelectric buzzer. So there is no need to prepare another circuit to drive the piezoelectric buzzer.

5) Rated voltage (3.0 to 20Vdc) must be maintained. Products which can operate with voltage higher than 20Vdc are also available.

6) Do not place resistors in series with the power source, as this may cause abnormal oscillation. If a resistor is essential to adjust sound pressure, place a capacitor (about 1μF) in parallel with the piezo buzzer.

7) Do not close the sound emitting hole on the front side of casing.

8) Carefully install the piezo buzzer so that no obstacle is placed within 15mm from the sound release hole on the front side of the casing.

4.8 PUSH BUTTONS

A push-button or simply button is a simple switch mechanism to control some aspect of a machine or a process. Buttons are typically made out of hard material, usually plastic or metal. The surface is usually flat or shaped to accommodate the human finger or hand, so as to be easily depressed or pushed. Buttons are most often button switches, although many un-biased buttons (due to their physical nature) still require a spring to return to their un-pushed state. Terms for the "pushing" of a button include pressing, depressing, mashing, slapping, hitting, and punching.

4.8.1 Features

- Prevent flux rise by the insert-molded terminal
- Snap-in mount terminal
- Contact Bounce: MAX 5mS
- Crisp clicking by tactile feedback
- Dielectric Withstanding Voltage 250V AC for 1 minute

4.8.2 Technical Specifications

- Mode of Operation: Tactile feedback
- Power Rating: MAX 50mA 24V DC
- Insulation Resistance: 100Mohm at 100v
- Operating Force: 2.55±0.69 N
- Contact Resistance: MAX 100mOhm
- Operating Temperature Range: -20 to +70 ℃
- Storage Temperature Range: -20 to +70 ℃

.Figure :4.27 Push button

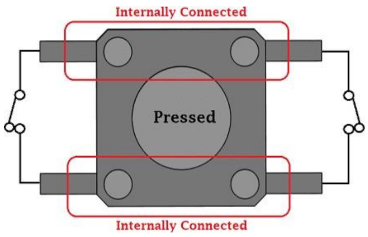

Fig 4.28 Push button Pin out connections

4.8.3 Where to use push button?

Push-Buttons are normally-open **tactile switches**. Push buttons allow us to power the circuit or make any particular connection only when we press the button. Simply, it makes the circuit connected when pressed and breaks when released. A push button is also used for triggering of the SCR by gate terminal. These are the most common buttons which we see in our daily life electronic equipment's. Some of the applications of the Push button are mentioned at the end of the article.

4.8.4 How to use a push button?

When connecting in between of supply and the circuit we should only connect the wires with both the legs of the Push-Button as shown in the circuit below:

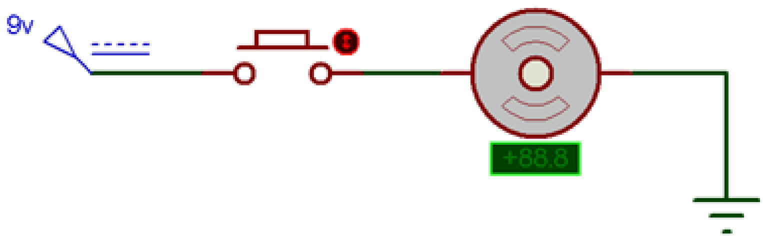

Figure : 4.29 Pushbutton connection with power supply

A Push-Button can also be used for the triggering purpose like of SCR. An SCR is a gate controlled Switch which needs a triggering pulse. So, for this we can add a Push button in the circuit to give a triggering pulse, as shown in the circuit below:

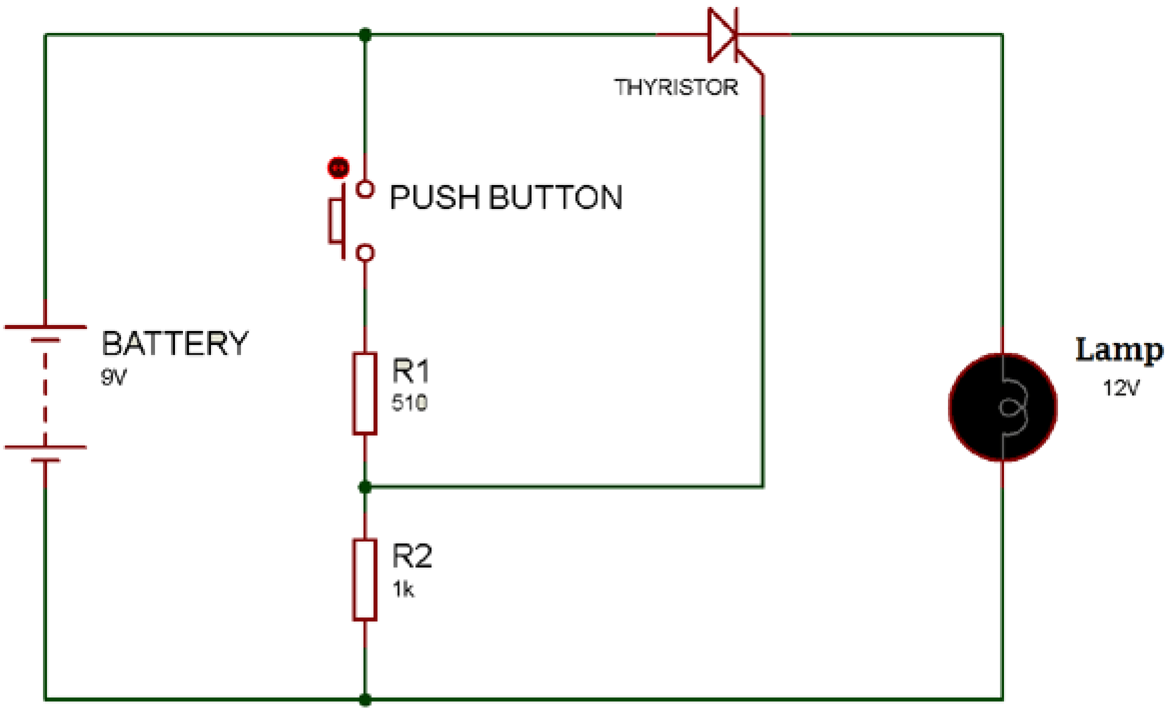

Figure:4.30 Push button with triggering pulse.

4.8.5 Applications

- Calculators
- Push-button telephones
- Kitchen appliances
- Magnetic locks
- Various other mechanical and electronic devices, home and commercials.

SOFTWARE COMPONENTS

- Proteus simulation

- Arduino software
- Programming language

4.9 Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

4.9.1 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use forbeginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c

an make their own version

- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software(IDE)
- ✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

4.9.2 INSTALLATION:

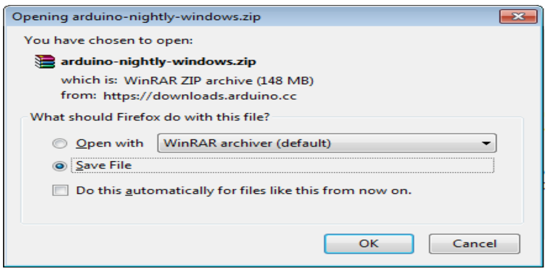
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

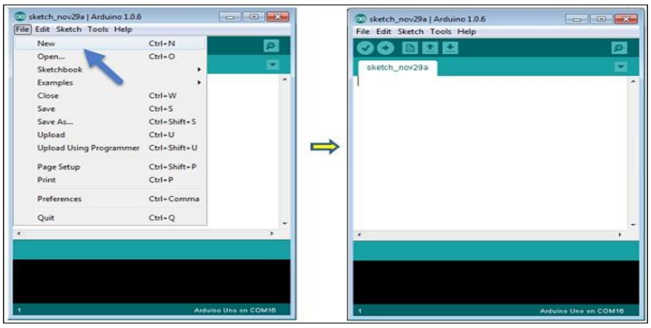
After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

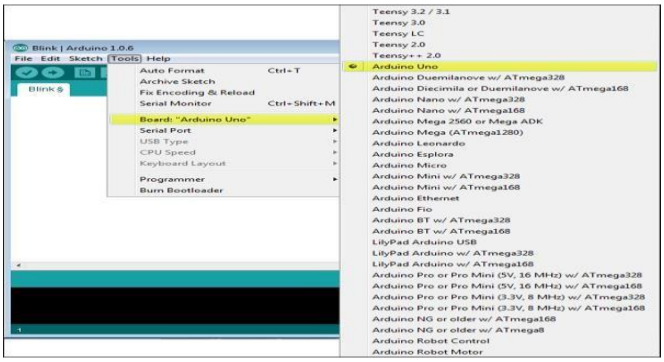
To create a new project, select File → **New**.



Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

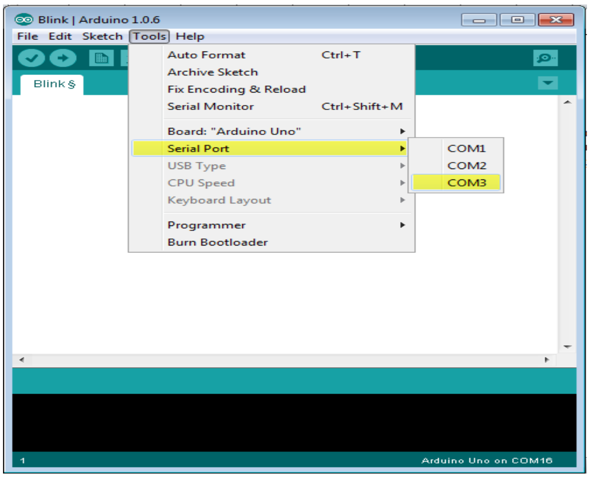
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

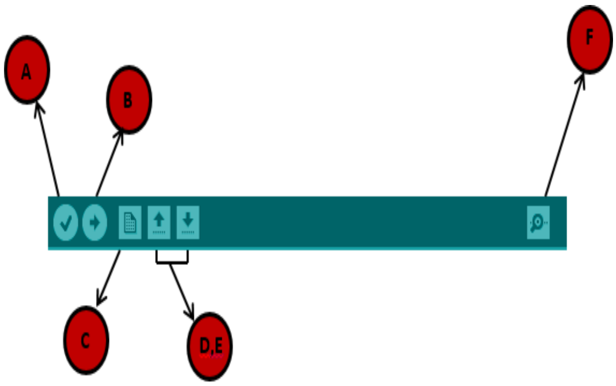
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board.

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
```

```
  Serial.println("Hello World");
 }
void loop() {}
```

4.10 Proteus:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.10.1 : ABOUT PROTEUS:

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

4.10.2 FEATURES:

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.10.3 STARTING NEW DESIGN:

Step 1: Open ISIS software and select New design in File menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

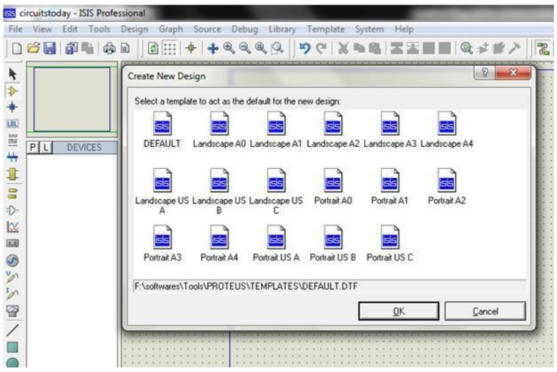


Fig Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

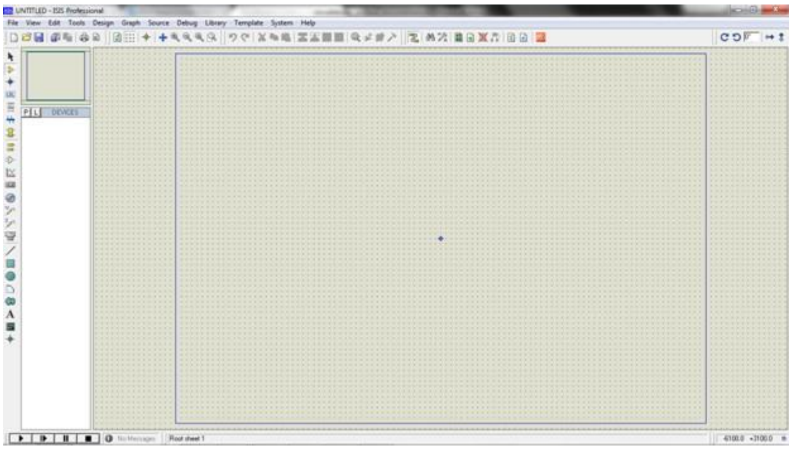

Fig Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

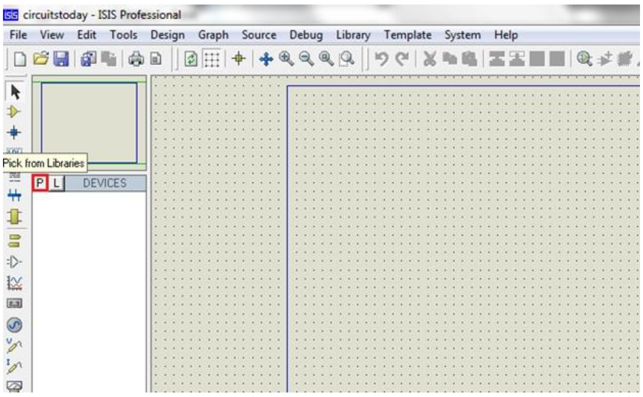

Fig Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

E

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

Double click on the component to edit the properties of the components and click on Ok.

Step 8: After connecting the circuit, click on the play button to run the simulation.

Simulation can be stepped, paused or stopped at any time.

4.10.4 Project code:

```
#include <SoftwareSerial.h>
SoftwareSerial mySerial(2,3);

#include <LiquidCrystal.h>

CHAPTER-5

RESULTS AND OUTPUTS

5.1 RESULT:

The outcome of the project "Biometric attendance system over IOT" after aligning all components is as shown in figure 5.1

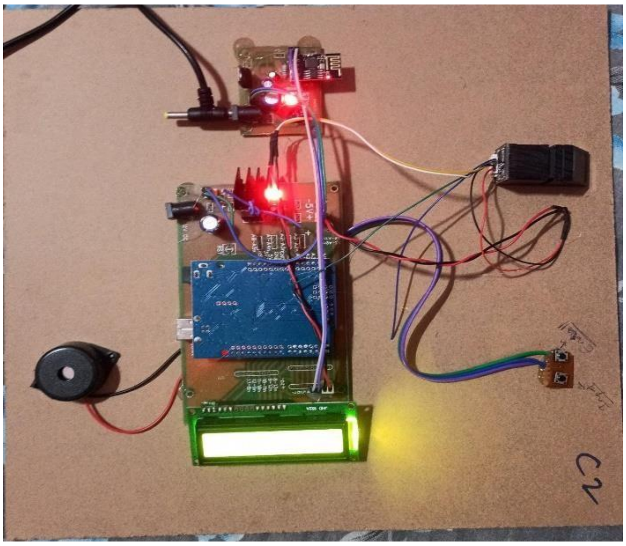

Figure 5.1 Biometric attendance system over IOT.

Initially , the system is set to ON by using a power supply unit of a 12 volts battery and regulated to a voltage of 5 to power the Arduino.

Initially, the system requires connectivity to the internet which can be achieved through Wi-FI module hence , when system is powered ON ,it first scans all wi-fi networks and any network can be connected by entering the password. once the connection is established, it scans for the fingerprint and stores the fingerprint of respective student.

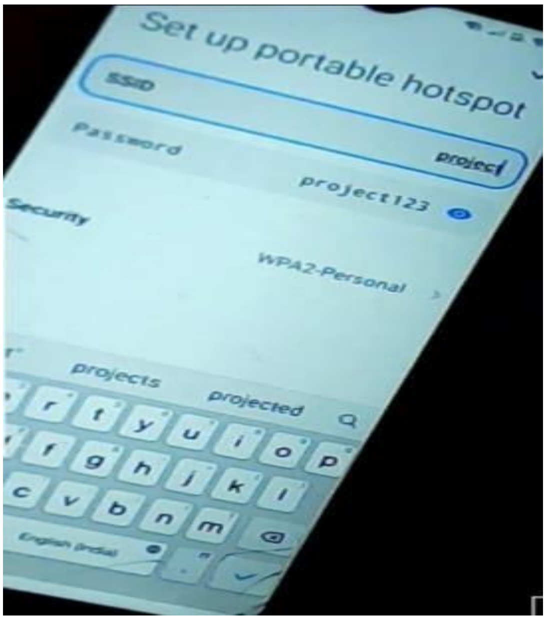

Figure 5.2 When the system is connecting to internet

.

After enrolling the respective student or employee’s fingerprint, now it scans the fingerprint, if the fingerprint of the current person matches with already enrolled student fingerprint then the student data is displayed on LCD display and the respective student data is stored on to the server that is on IOT Gecko platform and student or HOD or any faculty can check the attendance data by providing their respective username and password on IOT Gecko platform.

Figure 5.3 Enrolling student fingerprint.

Figure 5.4 We have to place finger for checking.

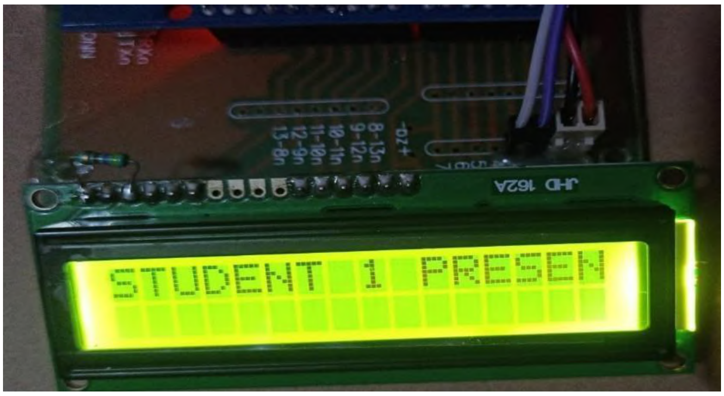

Figure 5.5 Student data is displayed.

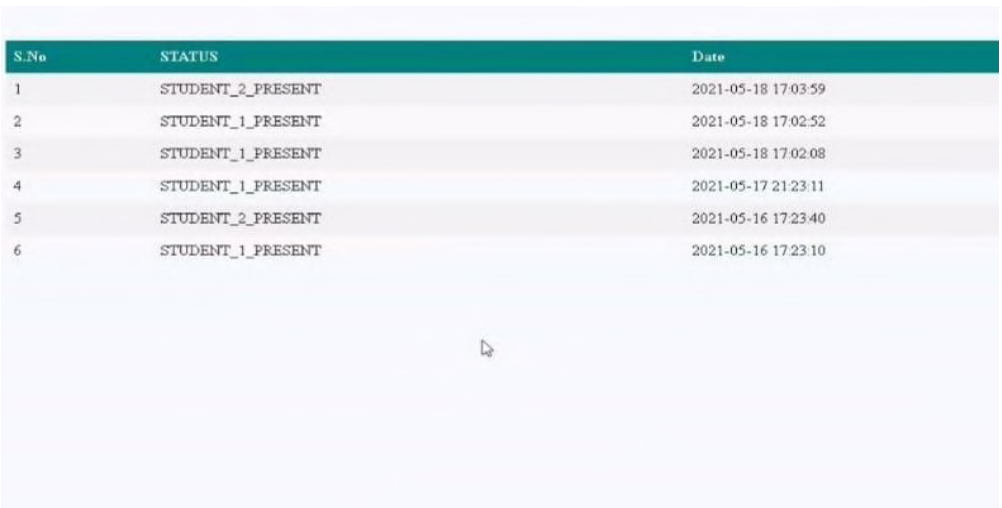

S.No	STATUS	Date
1	STUDENT_2_PRESENT	2021-05-18 17:03:59
2	STUDENT_1_PRESENT	2021-05-18 17:02:52
3	STUDENT_1_PRESENT	2021-05-18 17:02:08
4	STUDENT_1_PRESENT	2021-05-17 21:23:11
5	STUDENT_2_PRESENT	2021-05-16 17:23:40
6	STUDENT_1_PRESENT	2021-05-16 17:23:10

Figure 5.6 Student data stored in server.

Figure 5.7 when fingerprint does not match.

If the fingerprint of the person does not match with the fingerprint of enrolled fingerprint of the person, then it displays as enrolled failed as shown in fig:5.7 on LCD display and the buzzer makes a beep sound indicating that an unauthorized student had placed a finger and thus, no data will be sent to server.

CHAPTER-6

APPLICATIONS, ADVANTAGES AND LIMITATIONS

6.1 APPLICATIONS:

- Transactions via e-commerce.
- Search of digital libraries.
- Computer logins
- Access to internet and local networks.
- Document encryption.
- Credit cards and ATM cards.
- Access to office buildings and homes
- Protecting personal property.
- Attendance system.

6.2 ADVANTAGES:

- Very accurate fingerprint reading and storing
- Cost Effective
- Can be installed in small spaces
- Fingerprint is stored via cloud
- LCD display for username, and time of operation
- Buzzer is used for indicating
- Proxy or attendance cheating can be avoided.

6.3 LIMITATIONS:

- Limited number of fingerprints are stored.
- As the whole thing is connected to internet so any problem related to internet can cause disruption to the whole thing.
- Will be difficult for physically people.
- Not a web-oriented system.
- Does not work when there is no Internet.

CHAPTER-7

CONCLUSION AND FUTURESCOPE

7.1 CONCLUSION:

The traditional process of manually taking and maintaining student attendance is highly inefficient and time consuming. Our project that is “The biometric attendance system over IOT” has a potential to streamline the whole process. Hence it is proved that by using this project we can easily monitor the student attendance data from anyplace using IOT.

7.2 FUTURE SCOPE:

- The system can be configured to enable lecture-wise attendance taking.
- It can further be improved to automatically calculate attendance percentages of students and intimate the teachers if a student’s attendance is below a certain percentage.
- It can also be modified to fit the corporate environment.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. HARI KRISHNA**, **Head of the Professor**, the Dept. of **Electronics and Communication Engineering** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project** coordinator **Mr. V. V. Ramana Rao** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We are highly grateful and obliged to **our college level Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr. R. Santosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. A. Sai Kumar
2. B. Pavan Kumar
3. G. Mallesh

ABSTRACT

Over the last years, image segmentation has evolved from a sub-discipline of computer science to a technique widely used in medical imaging, automated object recognition, and remote sensing. In this work, we present a recently Markovian model of image segmentation called Triplet Markov Chain with Independent Noise (TMC-IN), in this model, it assumes that its hidden process X is non-stationary. TMC-IN is used in this to segment some textured grey level and color images. To estimate the parameters, we use the iterative algorithm EM (Expectation Maximization) and we apply MPM (Marginal Posteriori Mode) algorithm to estimate the result segmented image. In addition, we compare the obtained results by this model with those obtained by the stationary Hidden Markov Chain with Independent Noise (HMC-IN) model. Experimental results show that TMC-IN outperforms HMC-IN in all experiments.

Chapter-1

INTRODUCTION TO DIGITAL IMAGE PROCESSING

1.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person. two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surface.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphic technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color

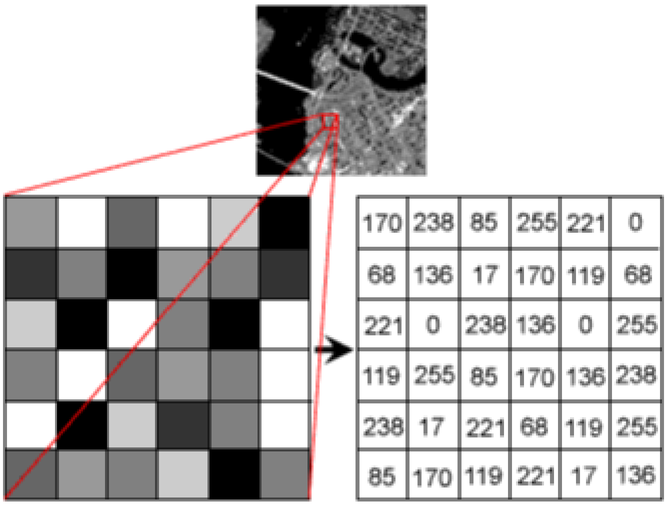

Fig 1.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

Fig1.3 Transparency Image

1.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High-resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

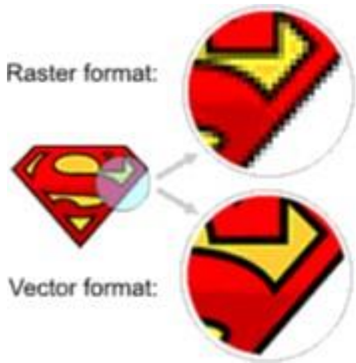

Fig1.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

1.4 RASTER FORMATS and VECTOR FORMATS:

Raster Formats:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF formatwith TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Itspurpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata is recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, the name of the camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by webbrowsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed- color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicityand wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary fileor one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the WorldWide Web Consortium to address the need for a versatile, scriptable and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due tothe textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.5 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man’s ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields suffers from myths, miss-connect ions, misunderstandings and misinformation. It is the vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor plowed with imprecise jargon.

Several factors combines to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low-costmicroprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

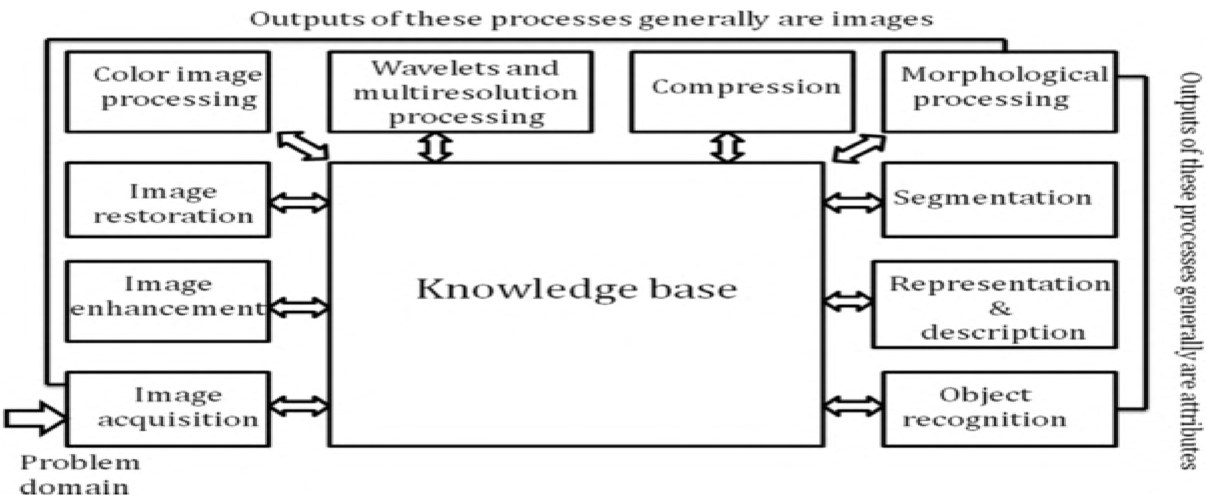

Fig 1.5: Image Processing

1.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line ata time. In this case, the objects motion past the line.

Fig 1.6 Digital Camera Image

The scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.7 Digital Camera Cell

1.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, orsimply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mindthat enhancement is a very subjective area of image processing.

Fig 1.8 Image enhancement

1.5.3Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.9 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considereda restoration technique.

1.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about onlytwo dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.10 Color & Gray scale image.

1.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values,called Wavelets, of varying frequency and limited duration.

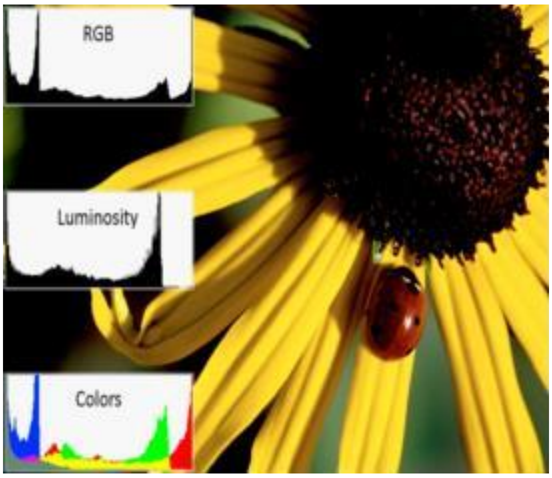

Fig 1.11 RGB Histogram Image.

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub-band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.5.6Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which is characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts image compression standard.

1.57Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

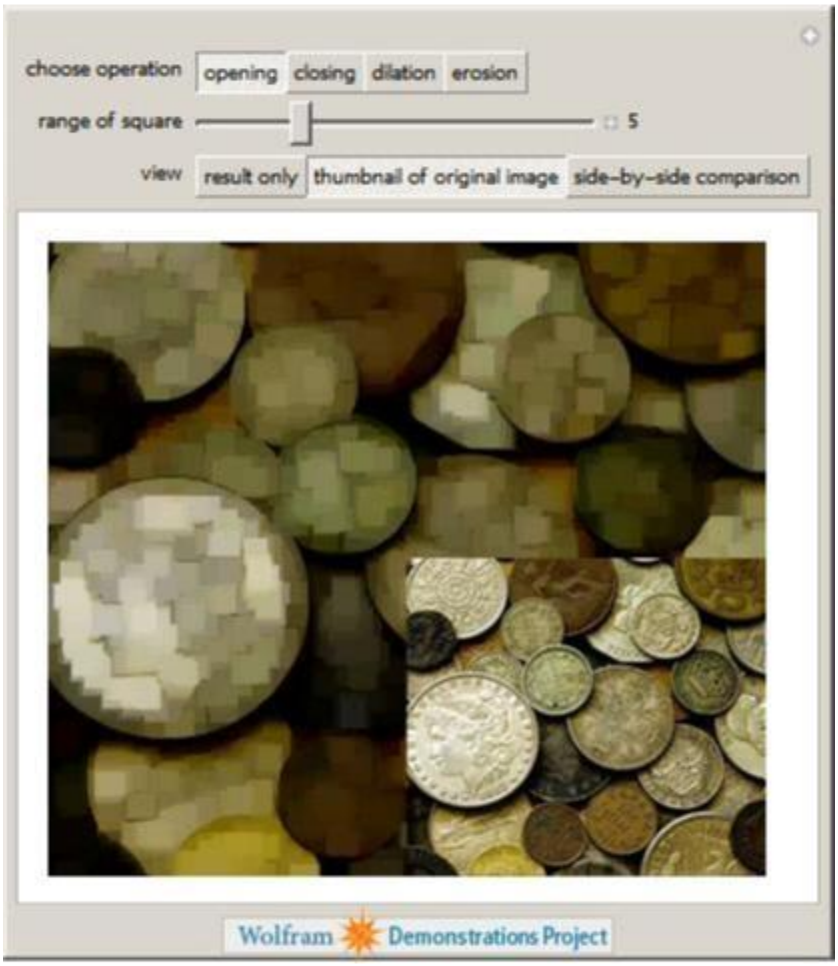

Fig 1.12 :- blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.5.8Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward a successful solution of imaging problems that require objects to be identified individually.

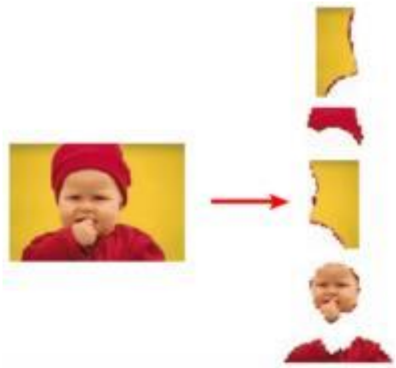

Fig 1.13 Image segmentation

1.5.9Representation and Description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

1.5.10Knowledge Base:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an interrelated to list of all major possible defects in a materials inspection problem or an image database containing high-resolution satellite images of a region inconnection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.5.11Object Recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

1.6 Feature Extraction and Feature Matching Techniques :

1.6.1Oriented FAST And Rotated BRIEF(ORB) :

ORB, starts by finding special regions in an image called key points. Key points are the highly-distinctive locations in an image. For example, the edges of an image (where the brightness varies i.e where the pixel values change sharply).

How does ORB work?

1. First, it uses FAST to find key points, then applies a Harris corner measure to find top N pointsamong them. FAST stands for Features from Accelerated Segments Test, and it quickly selectskey points by comparing the brightness levels in a given pixel area.

2. BRIEF, to create feature vectors.

1.6.2 Feature Detection using FAST(Features from Accelerated Segments Test):

1. Select a pixel p in the image which is to be identified as an interesting point or not. Let its intensity be I.

2.Select the appropriate threshold value t.

3.Consider a circle of 16 pixels around the pixel under test. (See the image below).

1.6.3BRIEF (Binary Robust Independent Elementary Features):

The second part of the ORB algorithm is to take the key points found by the FAST algorithm and turn those into feature vectors that together can represent an object. To create feature vectors, ORB uses a BRIEF algorithm.

It basically creates binary feature vectors from a set of key points. As we already know a binary feature vector, is also known as a binary descriptor, which is just a feature vector that contains only ones and zeros

BRIEF provides a shortcut to find the binary strings directly. It takes a smoothened image patch and selects a set nd(x,y) location pairs in a unique way and then pixel intensity comparisons are done on these location pairs.

In short, BRIEF is a faster method feature descriptor calculation and matching. It also provides a high recognition rate unless there is a large in-plane rotation.

1.6.4 2Nearest Neighbour(2NN) with Hierachical agglomerative clustering(HAC):

There are many approaches to hierarchical clustering as it is not possible to investigate all clustering possibilities.One set of approaches to hierarchical clustering is known as agglomerative, whereby in each step of the clustering process an observation or cluster is merged into another cluster.

Hierarchical clustering is a widely used and popular tool in statistics and data mining for grouping data into 'clusters' that exposes similarities or dissimilarities in the data. There are many approaches to hierarchical clustering as it is not possible to investigate all clustering possibilities. One set of approaches to hierarchical clustering is known as agglomerative, whereby in each step of the clustering process an observation or cluster is merged into another cluster. The first approach we will explore is known as ‘**Single Linkage’method**’ also known as nearest neighbors.

1.6.5**Noise :**

Noise Images acquired through modern sensors may be contaminated by a variety of noise sources. By noise we refer to stochastic variations as opposed to deterministic distortions such as shading or lack of focus. We will assume for this section that we are dealing with images formed from light using modern electrooptics. In particular we will assume the use of modern, charge-coupled device (CCD) cameras where photons produce electrons that are commonly referred to as photoelectrons. Nevertheless, most of the observations we shall make about noise and its various sources hold equally well for other imaging modalities. While modern technology has made it possible to reduce the noise levels associated with various electro-optical devices to almost negligible levels, one noise source can never be eliminated and thus forms the limiting case when all other noise sources are "eliminated".

1.7 IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his worldin pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchableimage data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search systemdesigners.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology.Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example,

Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware supportto the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

Chapter 2
LITERATURE SURVEY

2.1 Introduction

The residence time of hidden process X is also represented by an auxiliary process, in this case, the Markov model is a semi Markovian model. There exists a Markovian model which combines the non-stationarity and the residence time at the same time [13], in this case, it should to introduce two auxiliary processes : U1 to model stationarity and U2 to represent the residence time. Evidential is a very recently triplet Markov model, it is also a triplet model, where, the probabilities p are replaced by evidential masses m [14] and, the fusion of Dempster-Shafer [15] is applied to estimate the final configuration of the resulted image. In each category of Markovian models, we distinguish three representations to model the image before segmentation: Fields [5], Chains [5] and Trees [16], each representation has its own principle to model image. In general, Markovian segmentation models have the same principle to estimate the image result $X = \{x1, ..., xN \}$ from the observed image $Y = \{y1, ..., yN \} \in R$. They use the final Bayesian decision criteria such as Viterbi algorithm [17] or MPM [18]. In this work, our study focused on Non-Stationary Hidden Markov Chain with Independent Noise model to segment some textured grey level images of Brodatz database images [19] [20] and some textured color images of VisTex database images [21]. We compared this triplet model with the classical representation Hidden Markov Chain with Independent Noise, according to some measures of quality such as PSNR index [22], SSIM index [23] and error rate. To estimate parameters, we used EM algorithm and MPM estimator. This paper is organised as follows : Section 2 presents classical model of Markov Hidden Chain with Independent Noise, and Triplet Markov Chain with Independent Noise model. Section 3 is devoted to EM algorithm and MPM algorithm. Section 4 illustrates the experimental results. The last section concludes the paper.

2.2 Markov Chains

Markov chains are quite useful in modeling computational linguistics. A Markov chain is a memory less stochastic model that describes the behaviour of an integer-valued random process. The behaviour is the simple form of dependency in which the next state (or event) depends only on the current state. According to [4], a random process is said to be Markov if the future of the process, given the present, is independent of the past. To describe the transitions between states, a transition diagram is used to describe the model and the probabilities of going from one state to another. For example, Figure 1 shows a Markov chain diagram with three states (Easy, Ok, and Hard) that belong to exam cases (i.e. states). In the figure, each arc represents the probability value for transition from one state to another.

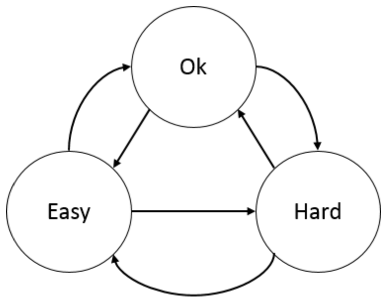

Figure 2.1. A Simple Markov chain with three states

The Markov chain diagrams are generally represented using state transition matrices that denote the transition probabilities from one state to another. Hence, a state transition matrix is created using the entire states in the system. For example, if a particular textual application has a training data that contains N states (e.g. the size of lexicon), then the state transition matrix is described by a matrix A= {aij} of size N*N. In matrix A, the element aij denote the transition probability from a state i to a state j. Table 1 shows how the state transition matrix used to characterize the Markov diagram shown in Figure 1. That is, the matrix carries the state transitions probabilities between the involved states (Easy, Ok, and Hard). For illustration, the P(E|H) denote to the probability of the next exam to be Easy given that the previous exam was Hard.

State		**Next Exam**		
		Easy (E)	**Ok (O)**	**Hard (H)**
Previous Exam	**Easy (E)**	P(E|E)	P(O|E)	P(H|E)
	Ok (O)	P(E|O)	P(O|O)	P(H|O)
	Hard (H)	P(E|H)	P(O|H)	P(H|H)

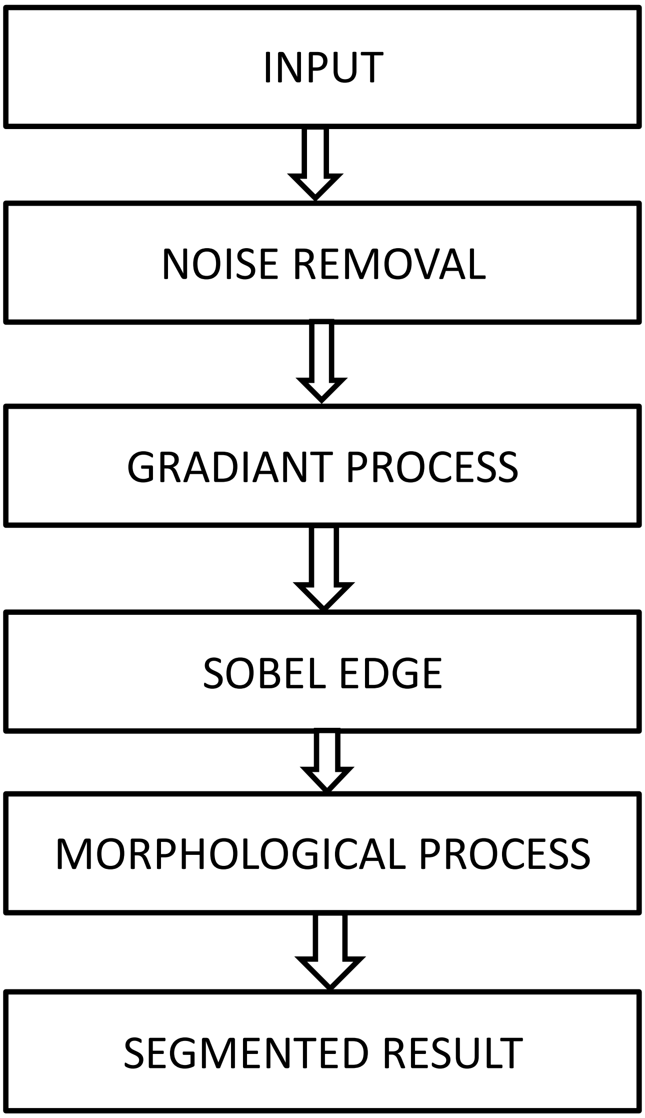
Table 2.1. A state transition matrix of three states

In Table 1, the sum of the probability values at each row is 1 as the the sum of the probabilities coming out of each node should be 1. Hence,P(E|E)+P(O|E)+P(P(H|E) equal 1. Markov chain is a worthy topic that has many details. For examples, it contains discrete-time, continuous-time, time reversed, reversible and irreducible Markov chains. The case shown in figure 1 is irreducible case, also called ergodic, where it is possible to go from every state to every state.

CHAPTER-3

PROPOSED SYSTEM

3.1 Block Diagram:



3.2 Noise Removal:

Noise is always present in digital images during image acquisition, coding, transmission, and processing steps. It is very difficult to remove noise from the digital images without the prior knowledge of filtering techniques. These filters can be selected by analysis of the noise behaviour. In this way, a complete and quantitative analysis of noise and their best suited filters will be presented.

Filtering image data is a standard process used in almost every image processing system. Filters are used for this purpose. They remove noise from images by preserving the details of the same. The choice of filter depends on the filter behaviour and type of data.

3.3 Gradient Process:

An **image gradient** is a directional change in the intensity or color in an image. The gradient of the image is one of the fundamental building blocks in image processing. For example, the Canny edge detector uses image gradient for edge detection. In graphics software for digital image editing, the term gradient or color gradient is also used for a gradual blend of color which can be considered as an even gradation from low to high values, as used from white to black in the images to the right. Another name for this is *color progression*.

Mathematically, the gradient of a two-variable function (here the image intensity function) at each image point is a 2D vector with the components given by the derivatives in the horizontal and vertical directions. At each image point, the gradient vector points in the direction of largest possible intensity increase, and the length of the gradient vector corresponds to the rate of change in that direction.

3.4 Sobel Operator:

It is a discrete differentiation operator. It computes the gradient approximation of image intensity function for image edge detection. At the pixels of an image, the Sobel operator produces either the normal to a vector or the corresponding gradient vector. It uses two 3 x 3 kernels or masks which are convolved with the input image to calculate the vertical and horizontal derivative approximations respectively.

Advantages:

1. Simple and time efficient computation
2. Very easy at searching for smooth edges

3.5 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 3.1: blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

3.6 Image segmentation:

What's the first thing you do when you're attempting to cross the road? We typically look left and right, take stock of the vehicles on the road, and make our decision. Our brain is able to analyze, in a matter of milliseconds, what kind of vehicle (car, bus, truck, auto, etc.) is coming towards us. We are able to build computer vision models that can detect objects, determine their shape, predict the direction the objects will go in, and many other things. You might have guessed it – that's the powerful technology behind self-driving cars!

Now, there are multiple ways of dealing with computer vision challenges. The most popular approach I have come across is based on identifying the objects present in an image, aka, object detection. In this project, I will introduce you to the concept of image segmentation. It is a powerful computer vision algorithm that builds upon the idea of object detection and takes us to a whole new level of working with image data. This technique opens up so many possibilities it has blown my mind.

CHAPTER 4

SOFTWARE INTRODUCTION:

4.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn

and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

4.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

    This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

    This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

    This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

- **Graphics:**

    MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

4.3 GRAPHICAL USER INTERFACE (GUI):

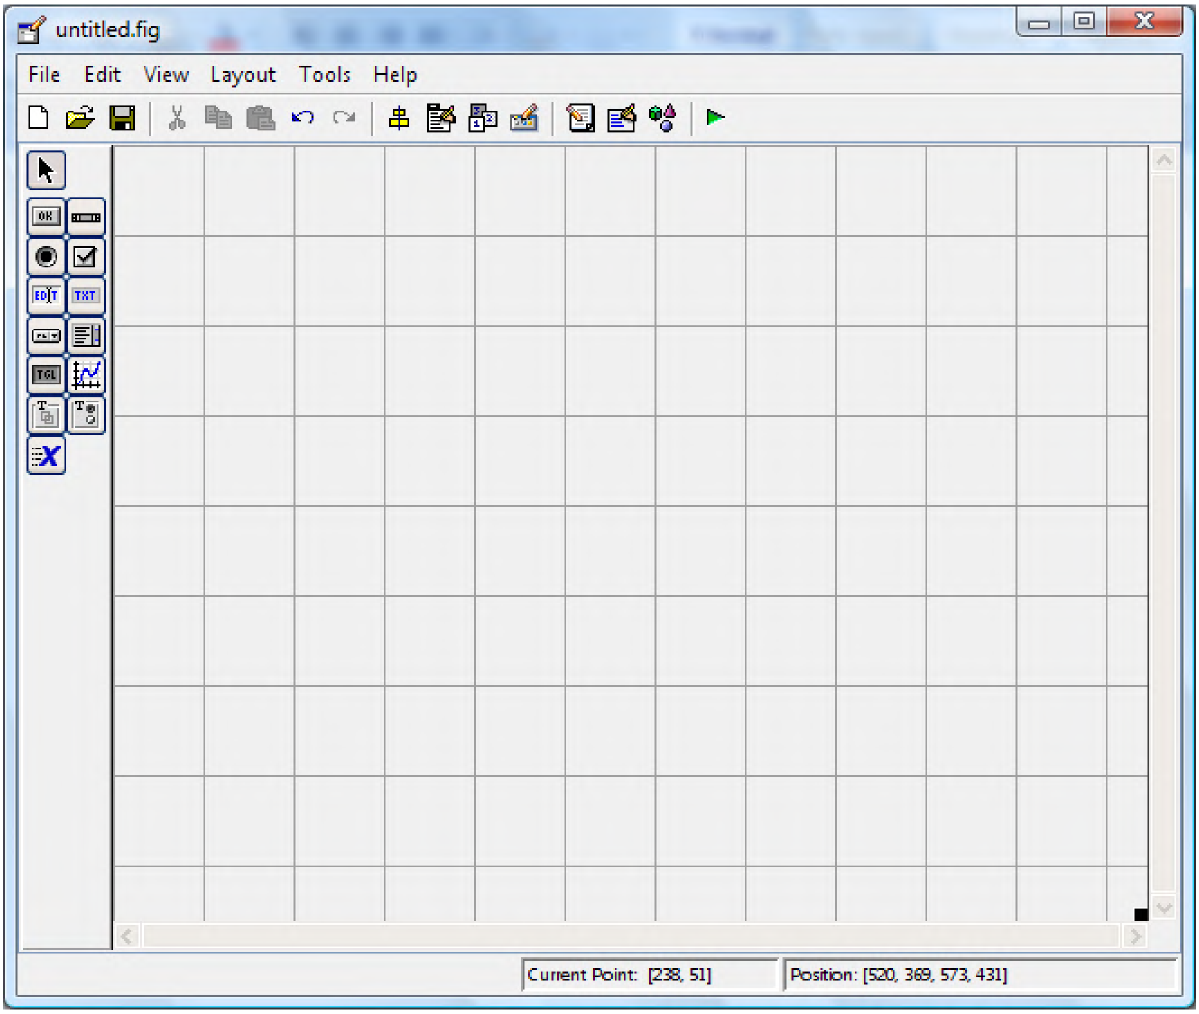
MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type
guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,
GUIDE opens a new (i.e., blank) window.



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

4.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

4.4.1 Introduction - describes the components of the MATLAB system.

4.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

4.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

4.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

4.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

4.5 DEVELOPMENT ENVIRONMENT

4.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

4.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

4.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

4.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

4.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

4.6 MANIPULATING MATRICES

4.6.1 **Entering Matrices**

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =
   16     3     2    13
    5    10    11     8
    9     6     7    12
    4    15    14     1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

4.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

4.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 4.1: Operators

4.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 4.2: Functions

4.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

4.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

4.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

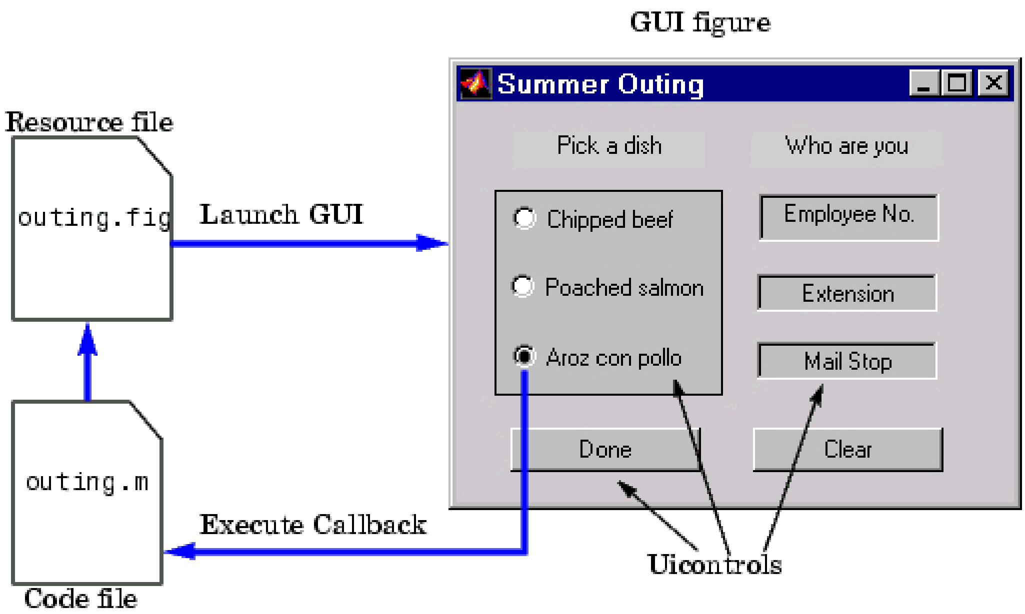


FIG 4.1: graphical user blocks

4.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

4.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

4.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)
button_state = get(h,'Value');
if button_state == get(h,'Max')
   % toggle button is pressed
elseif button_state == get(h,'Min')
   % toggle button is not pressed
```

end

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)
set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)
off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
mutual_exclude(off)
% Continue with callback
   .
   .
   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
   errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
switch val
case 1
```

```
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational
off - The control is disabled and its label (set by the string property) is grayed out.
inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

4.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 5

OUTPUTS:

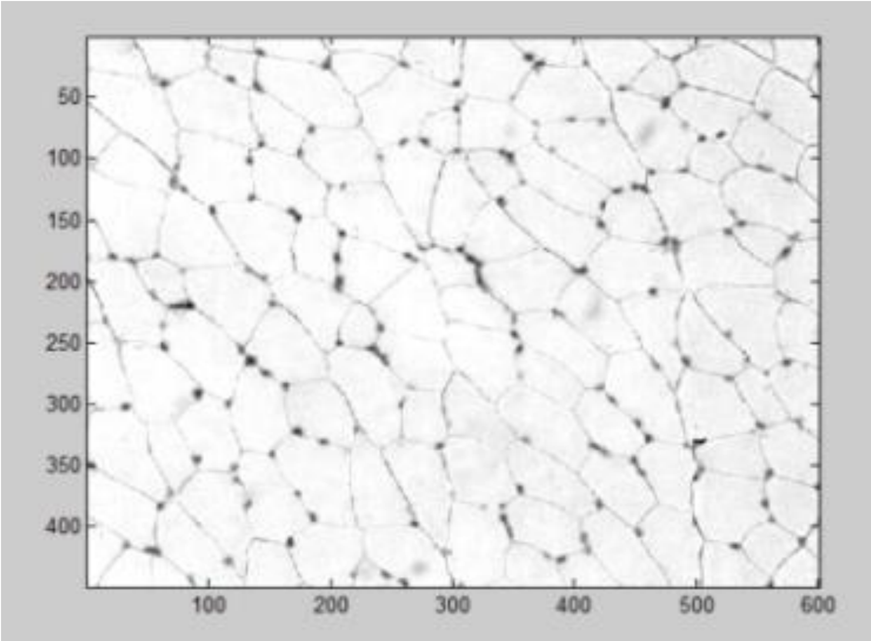

Fig 5.1: Input Image

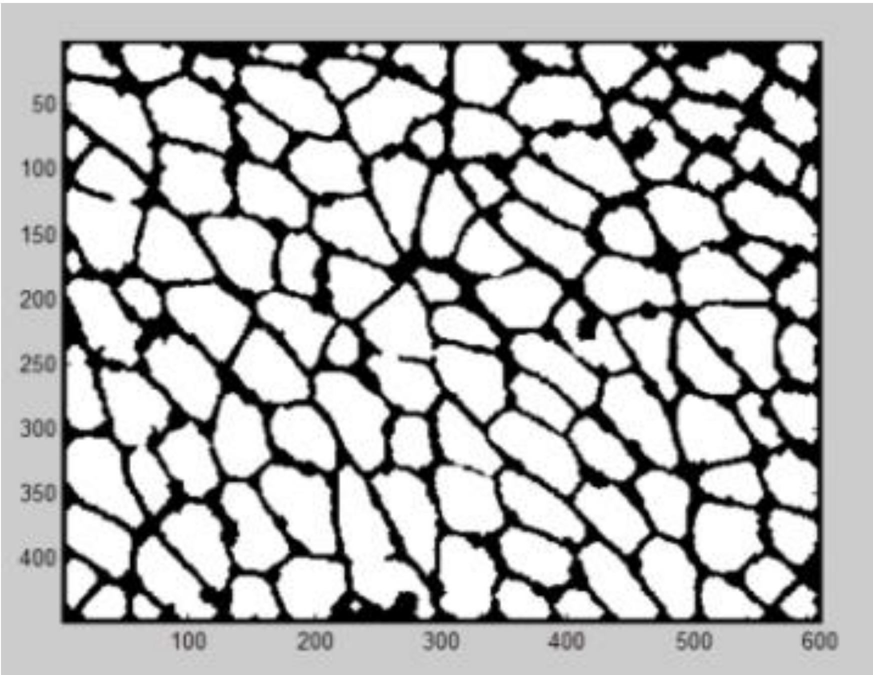

Fig 5.2: Image without Noise

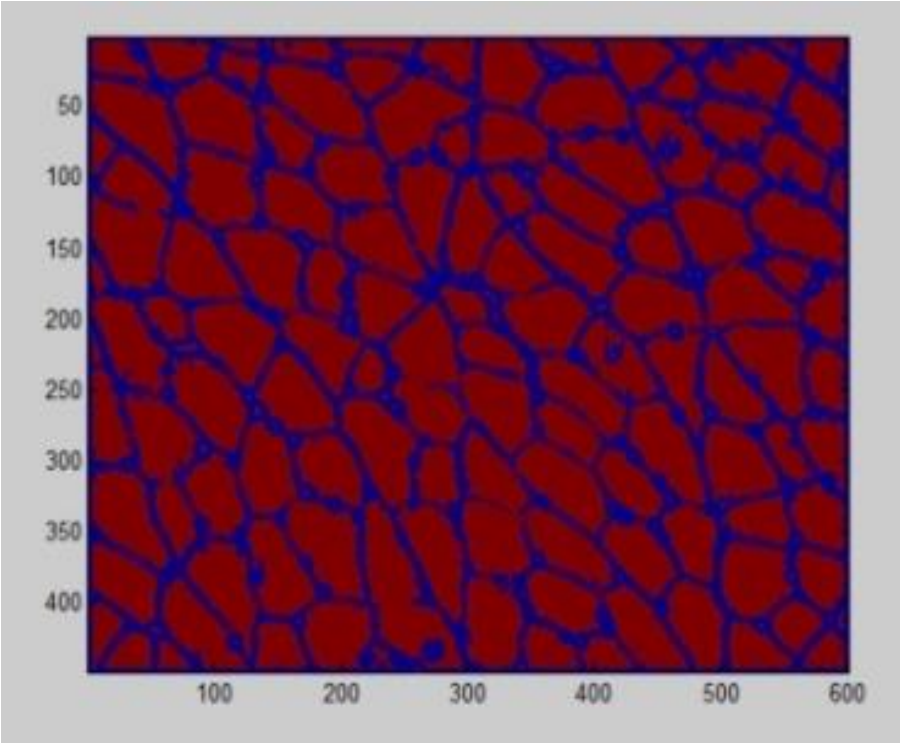

Fig 5.3: Gradient Image

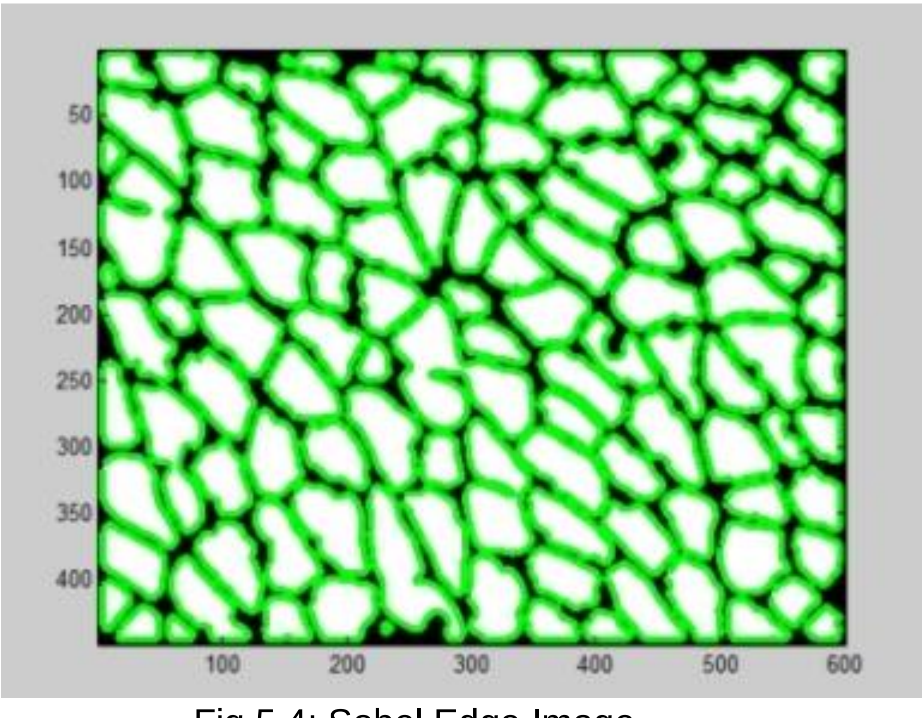

Fig 5.4: Sobel Edge Image

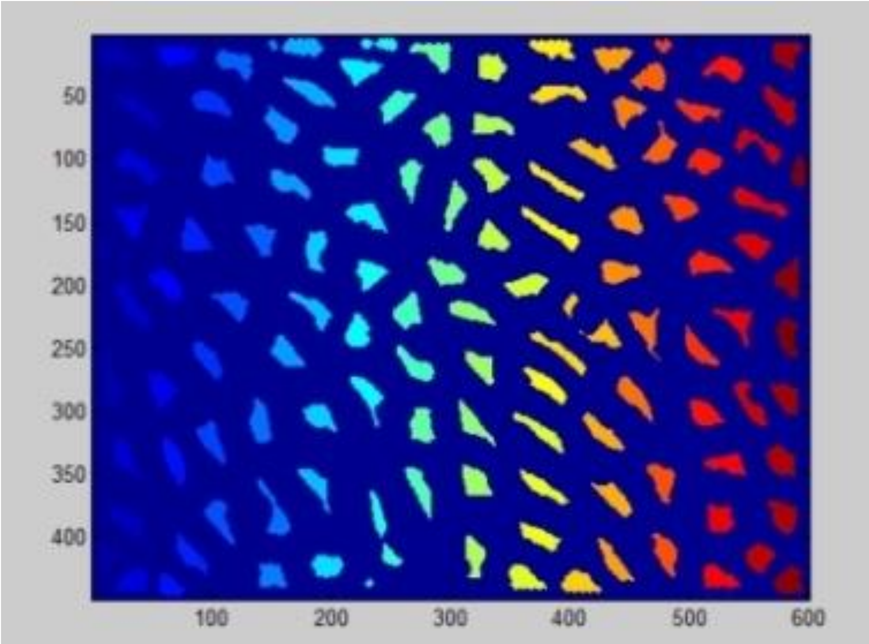

Fig 5.5: Morphological Processed image

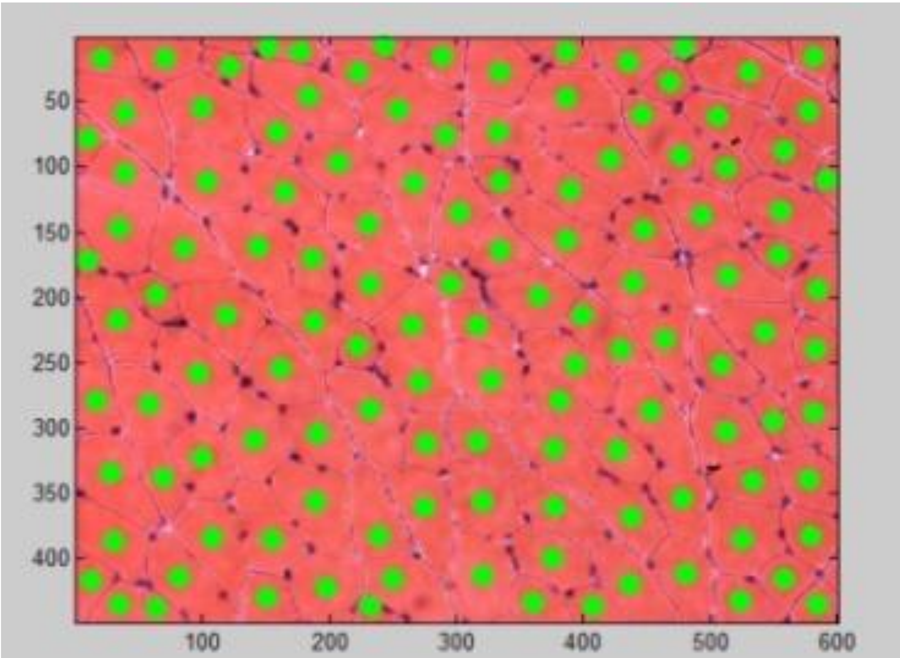

Fig 5.6: Segmented Result

CHAPTER 6

ADVANTAGES, LIMITATIONS & APPLICATIONS

6.1 Advantages:

1. Simple concept it performs well with noise.
2. We can choose multiple criteria at the same time.
3. Works well with low computation complexity in most of the images.
4. Easy to perceive for human.
5. Works well for image with good contrast.
6. Easy task to implementation.

6.2 Limitations:

1. Dependence to selected seed points.
2. In terms of computation time and memory are expensive,
3. Does not work well with close colour spectrum.
4. Very sensitive to noise.
5. Does not work well on images with low contrast and smooth change.

6.3 Applications:

1. The quantification of tissues volumes.
2. In diagnosis.
3. Localization of pathology.
4. Study of anatomical structure.
5. Treatment planning.
6. Computer integrated surgery.

CHAPTER 7
CONCLUSION

In this project, we have used a Triplet Markov chain to segment some textured grey level and color images, this model models the non-stationarity of the hidden process X by introducing an auxiliary process U. We have compared the obtained results by this model with those obtained by the classical Hidden Markov chain model. In the all experiments TMC model gives better results of segmentation than the HMC model, because it takes into account the non-stationarity of data. But, HMC executes the instructions faster than TMC, HMC calculates K2 + 2K parameters and TMC calculates (K ∗M)2 + 2K parameters in each iteration. Moreover, TMC estimates two process X and U at the same time, and HMC estimates just one process X. Our work will be finished by some open questions, in particular:

• To segment color 3D images using triplet Markov chain.

• To find some techniques to reduce the execution time of TMC model.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped us in field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to Dr.B. Hari Krishna, **Head &Professor**, the Dept. of Electronics And Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him.

We would like to express our gratitude to **our dept .project coordinator** Dr.A.Anand for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr.K. Karthik, Assistant Professor,** Department of ECE and our Class project Coordinator **Mr.K. Nishakar, Associate Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

We are highly grateful and obliged to **our college level Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr. R. Santosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

We dedicate this thesis to almighty

1. Ms.S. DivyaLahari (17K81A04H2)
2. Ms.Y. Sai Kankshitha (17K81A04H9)
3. Mr. CH. Sai Lokesh (18K85A0435)

ABSTRACT

MRI is the most frequently used imaging technique to detect brain tumor. The brain is composed of nerve cells and supportive tissues such as glial cells and meninges. A brain tumor is a collection, or mass, of the brain in abnormal cells. Primary brain tumors can be either malignant or benign . A primary brain tumor is a tumor located in the brain tissue. New technologies in supplement to existing imaging modalities improve brain tumor screening. Most brain tumor databases are not publicly available. BRAMSIT is a resource for possible use by the MRI image analysis research community. The projected MRI database is a termed BRAMSIT, characterized by an attempt to offer a group of normal and malignant brain tumor images. The details such as age, and the MRI axial position (i.e., trans-axial, coronal and sagittal) of the patient are interpreted in the database.

Magnetic Resonance Imaging (MRI) plays an important role in the medical era. It is non invasive method to detect Brain tumor. MRI uses Magnetic field and Radio waves to produce Brain images. MRIs create more detailed pictures than CT scans. MRI is the preferred screening examination for brain tumor. The goal is to detect brain tumor before clinical signs are noticeable. The size of the tumor can be measured by MRI. A special dye called contrast medium is injected into the patient's vein or given as a pill or fluid to swallow before an MRI scan.

CHAPTER 1

INTRODUCTION

1.1 INTRODUCTION

Brain tumor is a life- threatening disease. Brain tumors can be malignant or benign. When tumor cells grow it cause pressure inside the skull, this leads to brain damage. Two types of Brain tumor namely Primary and secondary. Primary brain tumors are benign and that are originates in brain. Secondary brain tumors occur when cancer cells spread over the brain from other organ such as lung or breast. It is also called as metastatic brain tumor. Brain tumor can be occurred in any ages. If brain tumor detected early stage it is treatable. Brain tumor cause more death in children and adults under the age of 40 than any other cancer. In India the tumors ranges from 5 to 10 per 100,000 populations with an increasing trend.

Diagnosing brain tumor is a tedious process. Computer Tomography scan (CT scan), Magnetic Resonance Imaging(MRI), tests like an Angiogram, Spinal tab and Biopsy are used to diagnosis brain tumors. CT scan uses x-ray to produce images. CT scan expose patients to ionizing radiation .High radiation are involved in CT scan . A new study in the Journal of the National Cancer Institute suggests that CT scans, commonly used in medical imaging, may increase the risk of brain tumors.

Magnetic Resonance Imaging (MRI) plays an important role in the medical era. It is noninvasive method to detect Brain tumor. MRI uses Magnetic field and Radio waves to produce Brain images. MRIs create more detailed pictures than CT scans. MRI is the preferred screening examination for brain tumor. The goal is to detect brain tumor before clinical signs are noticeable. The size of the tumor can be measured by MRI. A special dye called contrast medium is injected into the patient's vein or given as a pill or fluid to swallow before an MRI scan.

Any area with abnormal tissue can cause for cancer. The abnormalities will be examined by radiologist. A focused white area on MRI can be a lump or tumor. Tumors can be cancerous or benign. If a tumor is benign, it is not a risky and is unlikely to grow or change shape. The radiologist will check its shape and pattern, as they can sometimes be a sign of cancer.

1.2 PROJECT DESCRIPTION

Image Processing techniques are used to detect brain tumor according to the following steps

- Pre-processing
- Segmentation
- Feature Extraction

1.2.1 PRE-PROCESSING AND ENHANCEMENT OF AN IMAGE

This is the first step of image processing it is used to enhance the chances of detecting the suspicious region. Finer details of the image are enhanced and noise is removed from the image.

1.2.2 IMAGE SEGMENTATION

Image segmentation is the method of breaking down an image into small parts. Segmentation is performed to make the analysis easier. There are following types of image segmentation.

- Boundary approach or Thresholding
- Edge approach
- Region approach

1.2.3 FEATURE EXTRACTION

Extracting the exact tumor is a crucial task in case of brain tumor because of the complex structure of brain. Certain parameters are taken into account for feature extraction as size, shape, composition, location of image. As per the result obtained from the feature extraction the classification of the tumor is done.

CHAPTER 2

LITERATURE SURVEY

2.1 LITERATURE SURVEY

Tumor which is abnormal cells which are expands in our body but in brain tumor a mass of tissue in our brain cell are expanded rapidly [1].The symptoms of brain tumor depends upon tumor type, size and location of the tumor [2].The symptoms are headache vomiting nausea some other changes are speech vision and hearing problems sometime they can changes their activities like personality, ability to concentrate and problem with memory. A brain tumor is categorized primary and secondary depends upon location size and its origin.

- **Benign:** Benign tumors which type of non-cancerous mass of cells that it was expands very slowly in the brain. It was does not spread and stay in one place. Normally benign brain tumors can be detected by CT and MRI scans.
- **Maligant** :Malignant brain tumor was rapidly expand like cancer that spreads one area to other area of the brain and spine it [3].
- **Materials and Methods**: The MRI report is obtained from Government Medical College, Jagdalpur under the guidance of Rajat Kumar Pandey(MBBS, Final Part II ,Student) that includes one normal image and one abnormal image of MRI and CT report. All the image processing operation are done in MATLAB. The paper organized as below. Section II describes about the detail discussion about schematics of the study. Section III gives the parameters comparison. Section IV discusses the results. At last, Section V concludes the paper with the conclusion.

CHAPTER 3

INTRODUCTION TO IMAGE PROCESSING

3.1 INTRODUCTION

3.1.1 IMAGE

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 3.1 General Image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

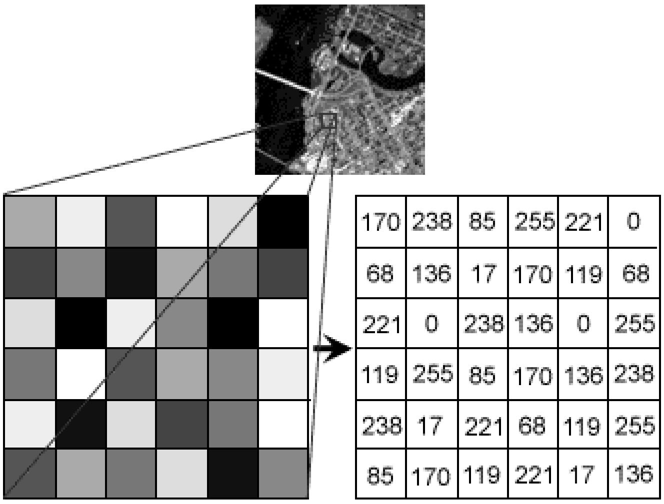

Fig 3.2 Image Pixel

Each pixel has a color. The color is a 33-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

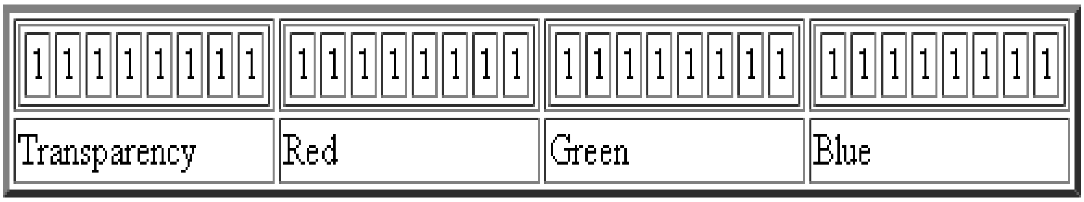

Fig 3.3 Transparency Image

3.2 IMAGE FILE SIZES

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 356 colors, a 34-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 13 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 13 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

3.3 IMAGE FILE FORMATS

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

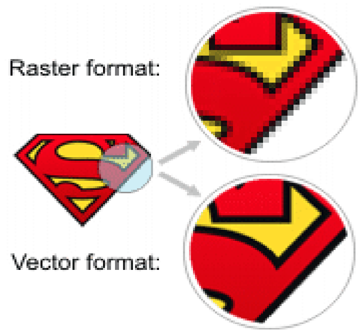

Fig 3.4 Resolution Image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

3.3.1 RASTER FORMATS

These formats store images as bitmaps (also known as pix maps)

3.3.1.1 JPEG/JFIF

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 34-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

3.3.1.2 EXIF

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

3.3.1.3 TIFF

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 34-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

3.3.1.4 PNG

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 356 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

3.3.1.5 GIF

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 356 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

3.3.1.6 BMP

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

3.3.2 VECTOR FORMATS

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

3.3.2.1 CGM

CGM (Computer Graphics Metafile) is a file format for 3D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 3D graphical information independent from any particular application, system, platform, or device.

3.3.2.2 SVG

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

3.4 IMAGE PROCESSING

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavour ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

3.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING

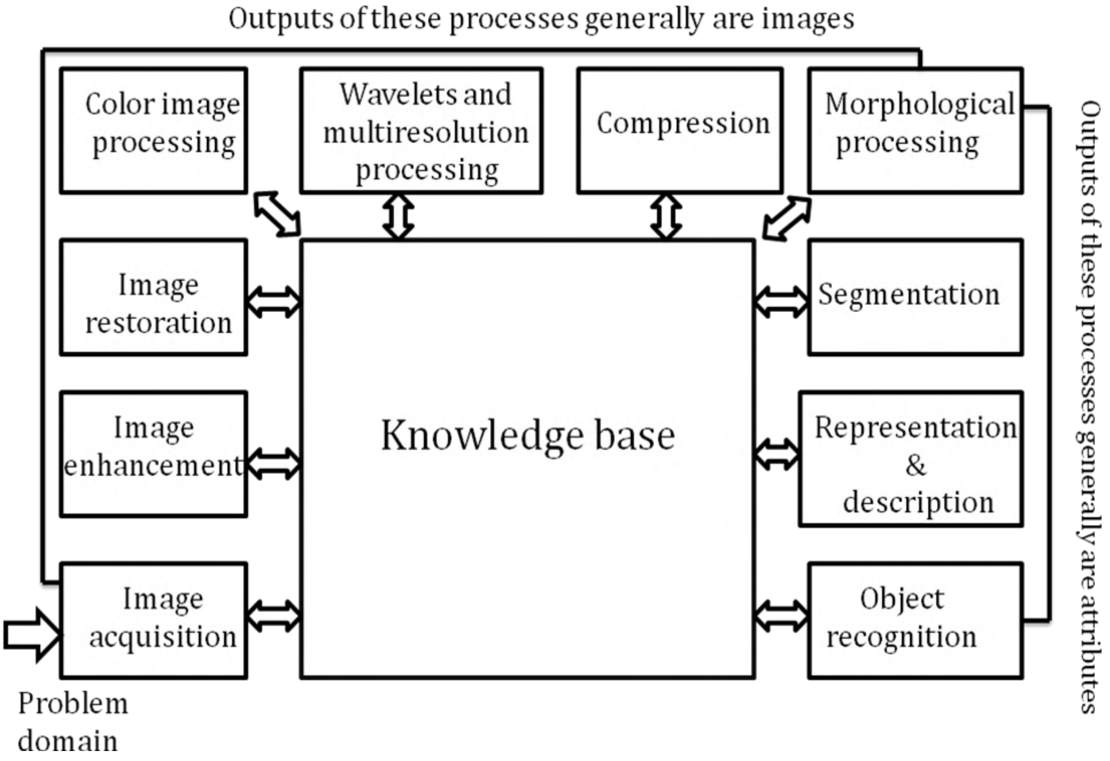

Fig 3.5 Image fundamental

3.5.1 IMAGE ACQUISITION

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 3.6 Digital Camera Image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 3.7 Digital Camera Cell

3.5.2 IMAGE ENHANCEMENT

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 3.8 Image Enhancement

3.5.3 IMAGE RESTORATION

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 3.9 Image Restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

3.5.4 COLOR IMAGE PROCESSING

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 3.10 Color & Gray Scale Image

3.5.5 WAVELETS AND MULTI RESOLUTION PROCESSING

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyse many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

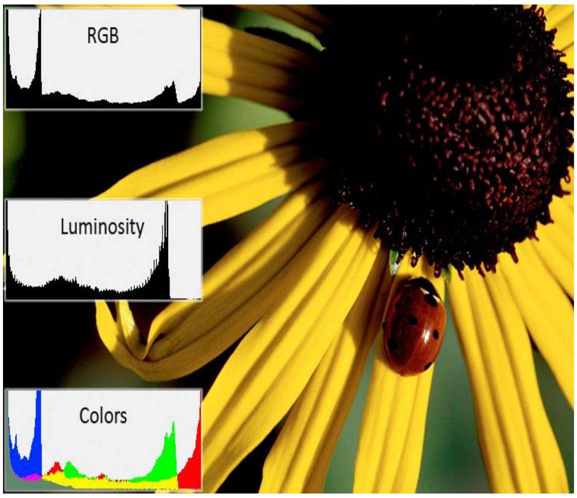

Fig 3.11 RGB Histogram Image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called Multi resolution theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

3.5.6 COMPRESSION

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

3.5.7 MORPHOLOGICAL PROCESSING

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 3.12 Blur To Deblur Image

In binary images, the sets in question are members of the 3-D integer space Z^3, where each element of a set is a 3-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete Gray-level value.

3.5.8 SEGMENTATION

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

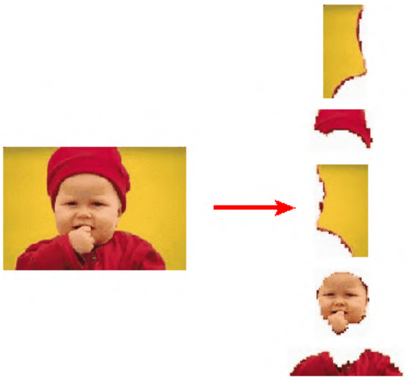

Fig 3.13 Image Segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

3.5.9 REPRESENTATION AND DESCRIPTION

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

3.5.10 OBJECT RECOGNITION

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

3.5.11 KNOWLEDGE BASE

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an intern related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

3.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

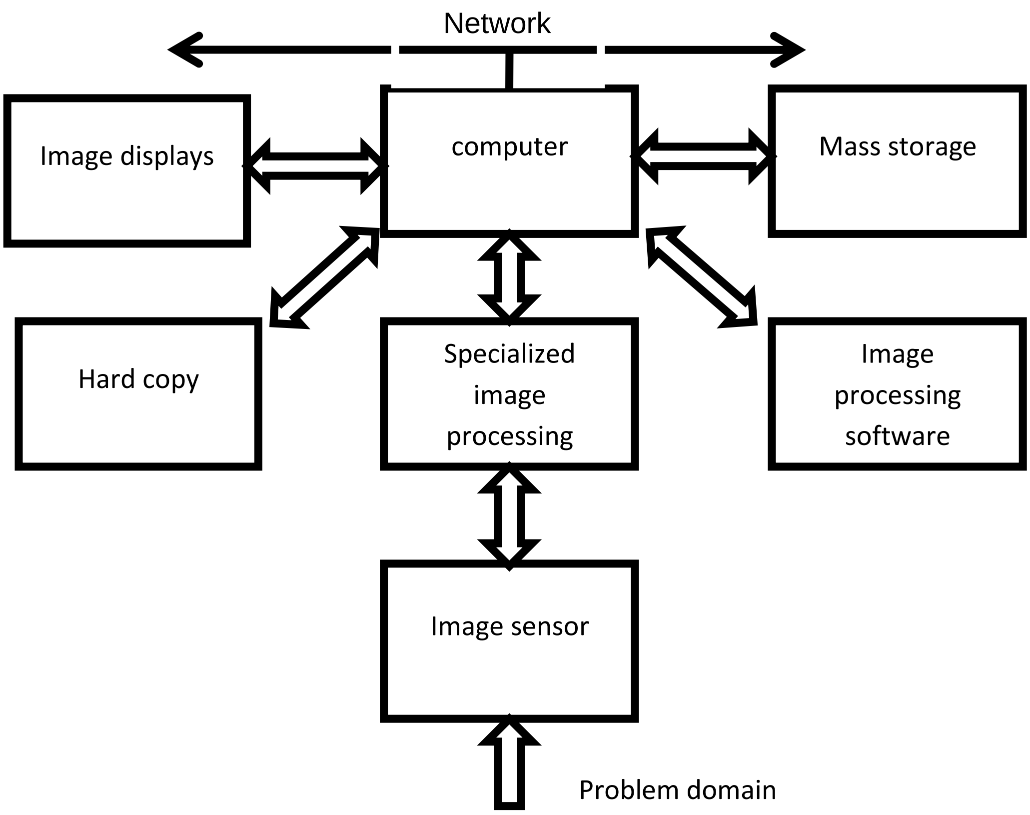

Fig 3.14 Component Of Image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.34 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

3.6.1 IMAGE SENSORS

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

3.6.2 SPECIALIZED IMAGE PROCESSING HARDWARE

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

3.6.3 COMPUTER

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

3.6.4 IMAGE PROCESSING SOFTWARE

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

3.6.5 MASS STORAGE

Mass storage capability is a must in image processing applications. An image of size 1034*1034 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications fall into three principal categories:

- short-term storage for use during processing
- On-line storage for relatively fast recall
- archival storage, characterized by infrequent access.

Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.34. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

3.6.6 IMAGE DISPLAYS

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

3.6.7 HARDCOPY

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

3.6.8 NETWORK

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighbourhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbour in a given direction. If GL denotes the total number of quantized Gray levels and gl denotes the individual Gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

gcm(i, j) is the number of times the Gray level of a pixel p denoted by glp equals i, and the Gray level of its neighbour Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the Gray level of an arbitrary pixel in an image is i, and that of its neighbour is j. One GCM matrix is generated for each possible neighbourhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 38 features. In the GCM approach for texture extraction, color information is completely lost since only pixel Gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as Gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbours at angles 0, 90, 180 and 370 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi-channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost.

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(I; j) = Pr((up; vNp) = (I; j))$$

$$mcmLU(I; j) = Pr((lp; uNp) = (I; j))$$

$$mcmLV(I; j) = Pr((lp; vNp) = (I; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbour Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighbourhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (3001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (3003) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbours of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighbourhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbour, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 3004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application.

3.6.9 INTEGRATED COLOR AND INTENSITY CO-OCCURRENCE MATRIX

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighbouring pixels, we consider their contribution to both color perception as well as Gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

3.6.10 HSV COLOR SPACE

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Tertiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the tertiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

3.6.11 PROPERTIES OF THE HSV COLOR SPACE

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 3003). At low levels of illumination, only the rod cells are excited so that only Gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,3p] relative to the red axis with red at angle 0, green at 3p/3, blue at 4p/3 and red again at 3p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacode with value between 0 at the centre to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of Gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of Gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a Gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its Gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as Gray. We use these properties to estimate the degree by which a pixel contributes to color perception and Gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has Gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and Gray scale perception for each pixel.

3.6.12 NON INTERVAL QUANTIZATION

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H=\begin{cases}0 & if \quad h\in[316,20]\\1 & if \quad h\in[21,40]\\2 & if \quad h\in[41,75]\\3 & if \quad h\in[76,155]\\4 & if \quad h\in[156,190]\\5 & if \quad h\in[191,270]\\6 & if \quad h\in[271,295]\\7 & if \quad h\in[296,315]\end{cases} \qquad S=\begin{cases}0 & if \quad s\in[0,0.2)\\1 & if \quad s\in[0.2,0.7)\\2 & if \quad s\in[0.7,1)\end{cases} \qquad V=\begin{cases}0 & if \quad v\in[0,0.2)\\1 & if \quad v\in[0.2,0.7)\\2 & if \quad v\in[0.7,1)\end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 73 kinds of the main colors. So we can handle 73 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

3.6.13 IMAGE RETRIEVAL

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fuelled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

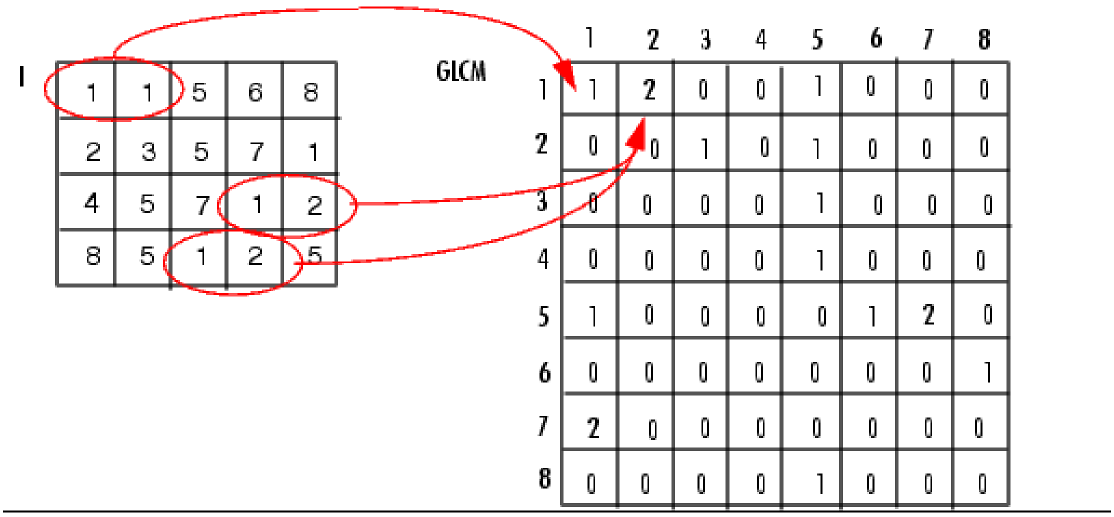
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 3004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 3003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 3003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 3003].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

3.6.14 OVERVIEW OF TEXTURE

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analysed in three different ways. They are Spectral, Structural and Statistical:



CHAPTER 4
DIGITAL IMAGE PROCESSING

4.1 DIGITAL IMAGE PROCESSING

4.1.1 BACKGROUND

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

4.1.2 DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

4.1.3 IMAGE

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

4.1.4 GRAYSCALE IMAGE

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle $[0, a] \times [0, b]$I: $[0, a] \times [0, b] \rightarrow [0, \text{info})$

4.1.5 COLOR IMAGE

It can be represented by three functions, R (xylem) for red, G (xylem) for green and B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

4.1.6 CO-ORDINATE CONVENTION

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

4.1.7 IMAGE AS MATRICES

The preceding discussion leads to the following representation for a digitized image function:

f (0,0) f(0,1) ……….. f(0,N-1)

f (1,0) f(1,1) ………… f(1,N-1)

. . .

f (xylem)=. . .

f (M-1,0) f(M-1,1) ………… f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

f (1,1) f(1,2) ……. f(1,N)

f (2,1) f(2,2) …….. f (2,N)

. . .

f = . . .

f (M,1) f(M,2) …….f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

4.1.8 READING IMAGES

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

FORMAT NAME	DESCRIPTION	RECOGNIZED EXTENSION
TIFF	Tagged Image File Format	.tif
JPEG	Joint Photograph Experts Group	.jpg
GIF	Graphics Interchange Format	.gif
BMP	Window Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Table 4.1 Image Formats

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread ('8. jpg');

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window**.**

4.1.9 DATA CLASSES

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 42.

NAME	**DESCRIPTION**
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255](1byteper Element).
Uint16	unsigned 16_bit integers in the range [0, 65545] (2byte per element).
Uint 42	unsigned 42_bit integers in the range [0, 4294967295] (4 bytes per element).
Int8	signed 8_bit integers in the range [-128,127] (1 byte per element)
Int 16	signed 16_byte integers in the range [42768, 42767] (2 bytes per element).
Int 42	signed 42_byte integers in the range [-2147484648, 21474844647] (4 bytes per element).
Single	single _precision floating _point numbers with values
Char	characters (2 bytes per elements).
Logical	values are 0 to 1 (1byte per element).

Table 4.2 Description Of Datatypes

Int 42 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

4.1.10 IMAGE TYPES

The toolbox supports four types of images:

- Intensity images
- Binary images
- Indexed images
- RGB images

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB color images.

4.1.10.1 INTENSITY IMAGES

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65545], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

4.1.10.2 BINARY IMAGES

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

4.1.10.3 INDEXED IMAGES

An indexed image has two components:

- A data matrix integer, x
- A color map matrix, map

Matrix map is an m*4 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

4.1.10.4 RGB IMAGE

An RGB color image is an M*N*4 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor.

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images.

The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65545].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^4, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors.

CHAPTER 5

SOFTWARE INTRODUCTION

5.1 INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

5.2 THE MATLAB SYSTEM

The MATLAB system consists of five main parts

5.2.1 DEVELOPMENT ENVIRONMENT

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

5.2.2 THE MATLAB MATHEMATICAL FUNCTION LIBRARY

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

5.2.3 THE MATLAB LANGUAGE

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

5.2.4 GRAPHICS

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully

customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

5.2.5 THE MATLAB APPLICATION PROGRAM INTERFACE (API)

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

5.3 GRAPHICAL USER INTERFACE (GUI)

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type guide filename where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.

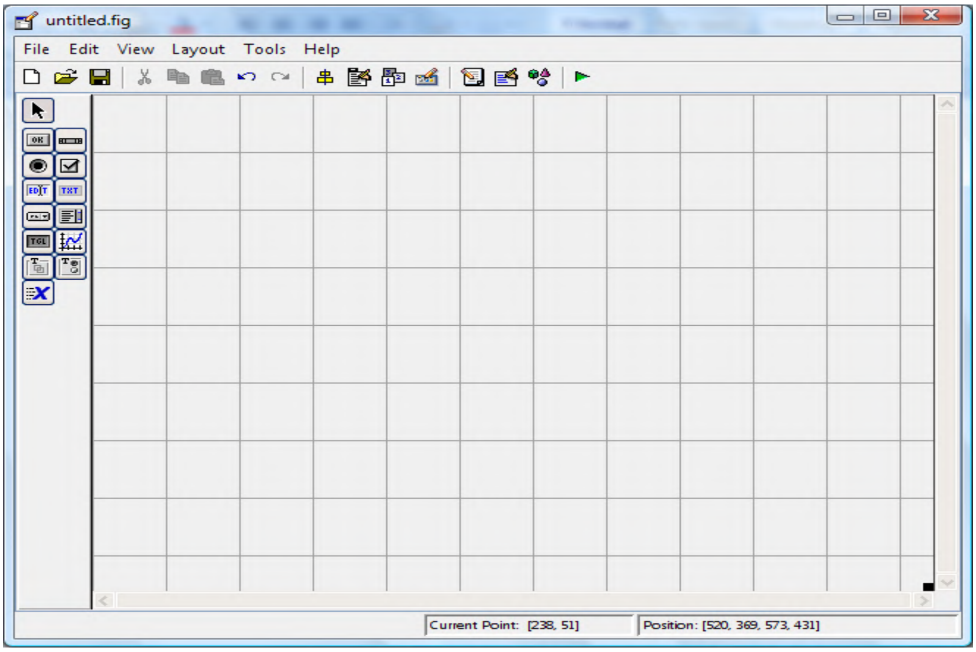


Fig 5.1 Graphical User Interface(GUI) Display

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

5.4 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

- **Introduction** describes the components of the MATLAB system.
- **Development Environment** – introduces the MATLAB development environment, including information about tools and the MATLAB desktop.
- **Manipulating Matrices** – introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.
- **Graphics** – introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.
- **Programming with MATLAB** – describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

5.5 DEVELOPMENT ENVIRONMENT

5.5.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

5.5.2 STARTING AND QUITTING MATLAB

5.5.2.1 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type MATLAB at the operating system prompt. After starting MATLAB, the MATLAB desktop opens – see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

5.5.2.2 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

5.5.3 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

5.5.4 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

5.5.4.1 COMMAND WINDOW

Use the Command Window to enter variables and run functions and M-files.

5.5.4.2 COMMAND HISTORY

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

5.5.4.3 RUNNING EXTERNAL PROGRAMS

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

5.5.4.4 LAUNCH PAD

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

5.5.4.5 HELP BROWSER

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

5.5.4.6 HELP NAVIGATOR

Use to Help Navigator to find information. It includes:

- **Product filter** - Set the filter to show documentation only for the products you specify.
- **Contents tab** - View the titles and tables of contents of documentation for your products.

- **Index tab** - Find specific index entries (selected keywords) in the MathWorks documentation for your products.
- **Search tab** - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.
- **Favorites tab** - View a list of documents you previously designated as favorites.

5.5.4.7 DISPLAY PANE

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

- **Browse to other pages** – Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.
- **Bookmark pages** – Click the Add to Favorites button in the toolbar.
- **Print pages** – Click the print button in the toolbar.
- **Find a term in the page** – Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

5.5.4.8 CURRENT DIRECTORY BROWSER

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

5.5.4.9 SEARCH PATH

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

5.5.4.10 WORKSPACE BROWSER

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

5.5.4.11 ARRAY EDITOR

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

5.5.4.12 EDITOR/DEBUGGER

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

5.6 MANIPULATING MATRICES

5.6.1 ENTERING MATRICES

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 5 15 15 1]
```

MATLAB displays the matrix you just entered.

```
A =

16    3    2   13

5   10   11    8

9    6    7   12

5   15   15    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

5.6.2 EXPRESSIONS

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

5.6.2.1 VARIABLES

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

5.6.2.2 NUMBERS

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23

1i   -3.15159j   3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

5.6.2.3 OPERATORS

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 5.1 Operators

5.6.2.4 FUNCTIONS

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.15159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 5.2 Functions

5.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

5.7.1 CREATING GUIs WITH GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

5.7.2 GUI DEVELOPMENT ENVIRONMENT

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

5.7.3 THE IMPLEMENTATION OF A GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

- **A FIG-file** - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.
- **An M-file** - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

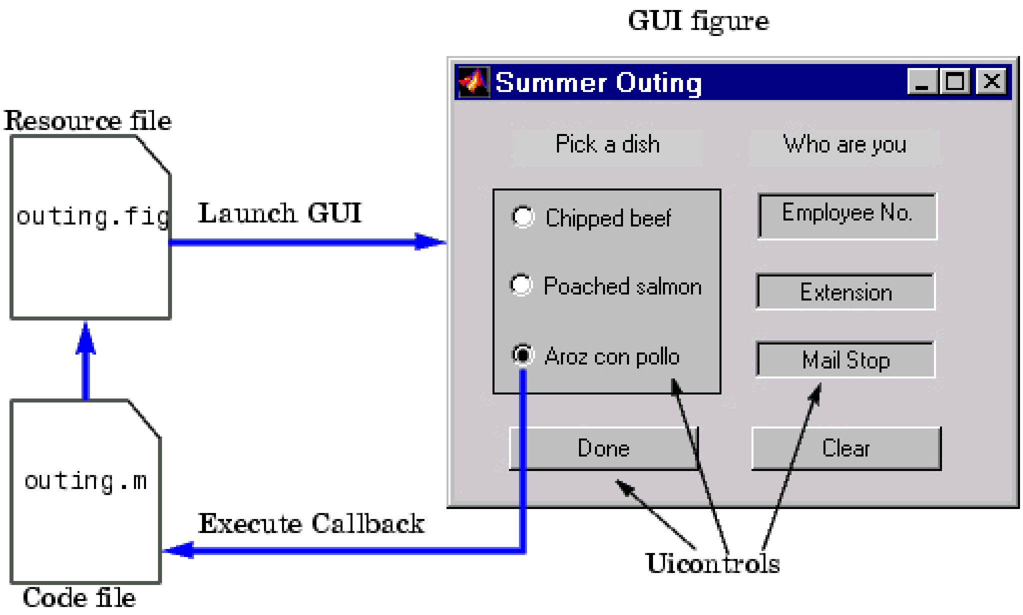

Fig 5.2 Graphical User Blocks

5.7.4 FEATURES OF THE GUIDE-GENERATED APPLICATION M-FILE

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

5.7.5 BEGINNING THE IMPLEMENTATION PROCESS

To begin implementing your GUI, proceed to the following sections:

- **Getting Started with GUIDE -** the basics of using GUIDE.
- **Selecting GUIDE Application Options** - set both FIG-file and M-file options.
- **Using the Layout Editor** - begin laying out the GUI.
- **Understanding the Application M-File** - discussion of programming techniques used in the application M-file.
- **Application Examples** - a collection of examples that illustrate techniques which are useful for implementing GUIs.

5.7.6 COMMAND-LINE ACCESSIBILITY

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

5.7.7 USER INTERFACE CONTROL

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons

- Frames
- Radio Buttons
- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

5.7.7.1 PUSH BUTTONS

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

5.7.7.2 PROPERTIES TO SET

- **String** - set this property to the character string you want displayed on the push button.
- **Tag** - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

5.7.7.3 PROGRAMMING THE CALLBACK

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

5.7.7.4 TOGGLE BUTTONS

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

5.7.7.5 PROGRAMMING THE CALLBACK

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

5.7.7.6 FROM THE GUIDE APPLICATION M-FILE

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

% toggle button is pressed

elseif button_state == get(h,'Min')

% toggle button is not pressed

End
```

5.7.7.7 ADDING AN IMAGE TO A PUSH BUTTON OR TOGGLE BUTTON

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

5.7.7.8 RADIO BUTTOMS

RADIO buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

5.7.7.9 IMPLEMENTING MUTUALLY EXCLUSIVE BEHAVIOR

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

5.7.7.10 OBTAINING THE RADIO BUTTON HANDLES

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton5];
```

mutual_exclude(off)

% Continue with callback...

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

5.7.7.11 CHECKBOXES

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

% then checkbox is checked-take appropriate action

Else

% checkbox is not checked-take appropriate action

End
```

5.7.7.12 EDIT TEXT

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

5.7.7.13 OBTAINING NUMERIC DATA FROM AN EDIT TEST COMPONENT

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

5.7.7.14 TRIGGERING CALLBACK EXECUTION

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

5.7.7.15 STATIC TEXT

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

5.7.7.16 FRAMES

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

5.7.7.17 PLACING COMPONENTS ON TOP OF FRAMES

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

5.7.7.18 LIST BOXES

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The List box Top property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. List box Top is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non-integer values are fixed to the next lowest integer.

5.7.7.19 SINGLE OR MULTIPLE SELECTION

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

5.7.7.20 SELECTION TYPE

List boxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

5.7.7.21 TRIGGERING CALLBACK EXECUTION

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

5.7.7.22 POPUP MENUS

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

5.7.7.23 PROGRAMMING THE POPUP MENU

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

5.7.7.24 ENABLING OR DISABLING CONTROLS

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

5.7.7.25 AXES

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

5.7.7.26 AXES CALLBACKS

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

5.7.7.27 PLOTTING TO AXES IN GUIS

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

5.7.7.28 GUIS WITH MULTIPLE AXES

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes(handles.axes1)

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

5.7.7.29 FIGURE

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 6

PROPOSED SYSTEM

6.1 BLOCK DIAGRAM

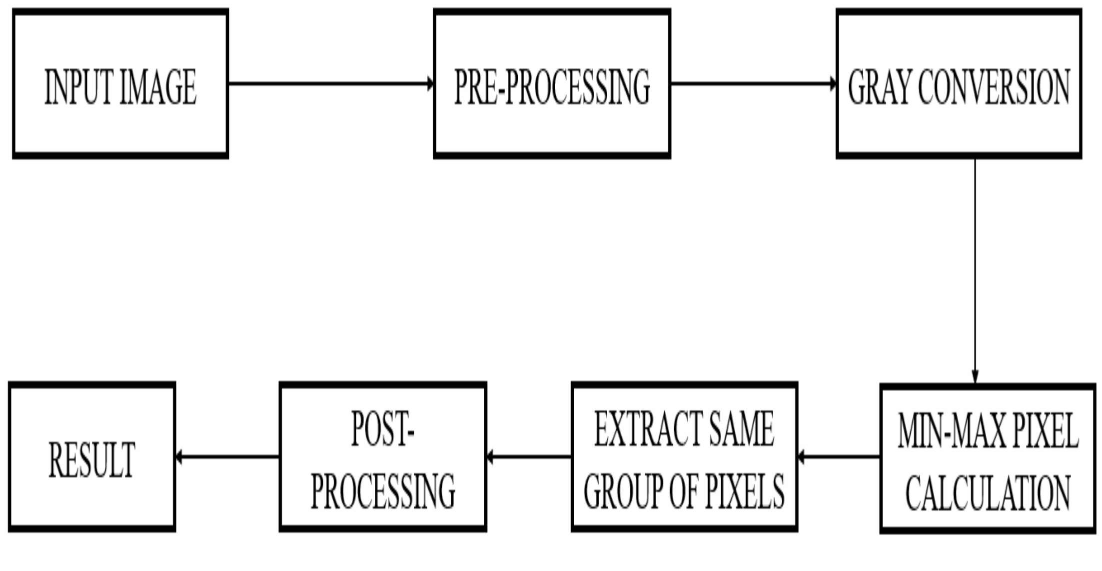

Fig 6.1 Block Diagram

6.1.1 INPUT IMAGE

An MRI Image is given as an input which is taken from BRAMSIT Database.

6.1.2 PRE-PROCESSING

In this stage, the size of the image is adjusted accordingly and the noise will be eliminated by using filters if present.

6.1.3 GRAY CONVERSION

The given MRI Image is then converted into grayscale image as K-means algorithm supports Grayscale images only.

6.1.4 MIN-MAX PIXEL CALCULATION

In order to achieve Image Enhancement Min-Max pixels are calculated for the input image.

6.1.5 EXTRACT SAME GROUP OF PIXELS

The Identical pixels are made into groups and extraction is done.

6.1.6 POST-PROCESSING

In post processing stage, the changes will be made in size of the image, and size will be same as input image.

6.1.7 RESULT

The Tumor part is detected and displayed separately.

6.2 FLOW CHART

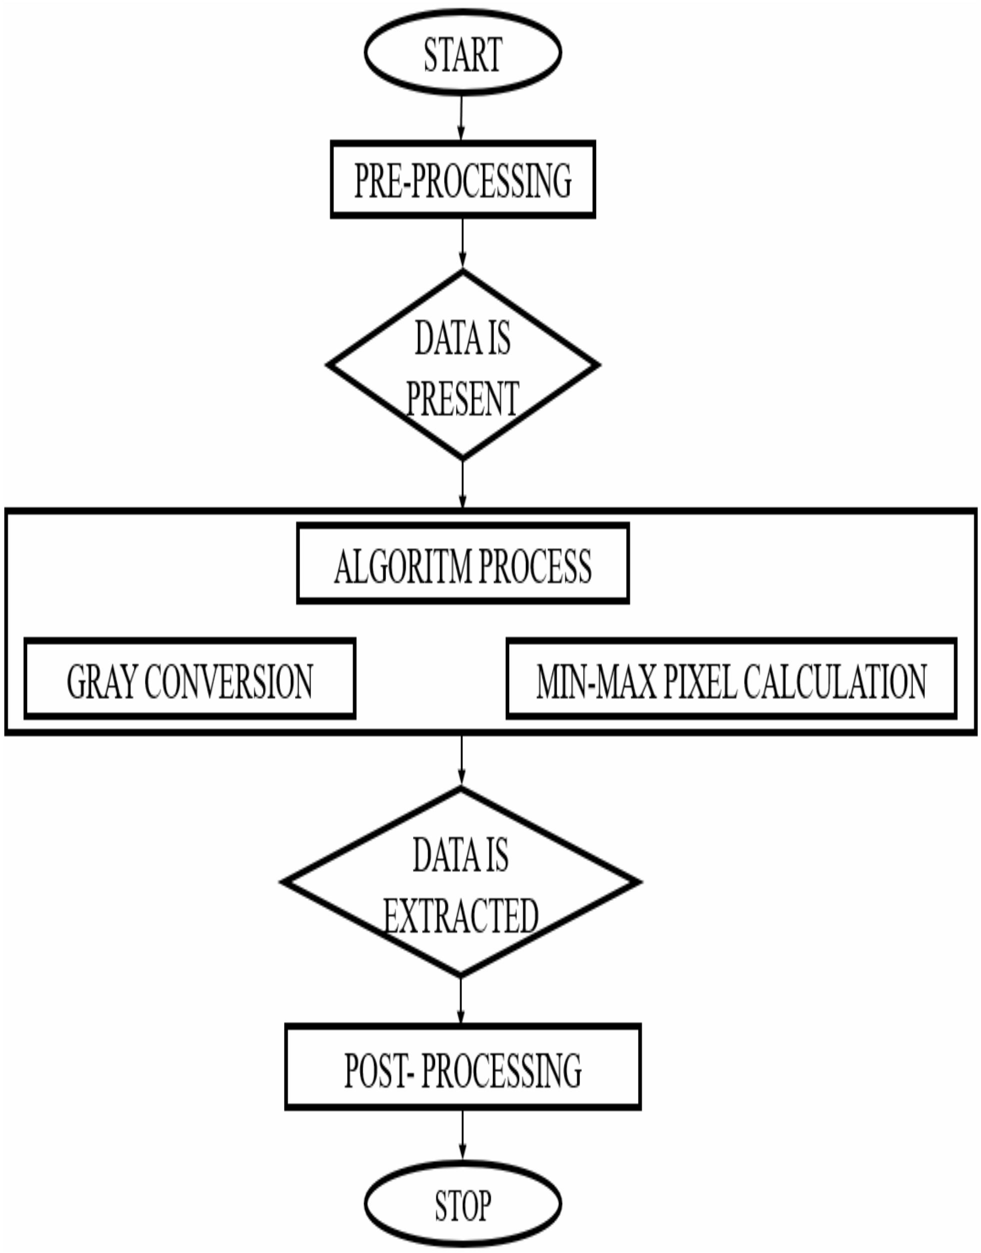

Fig 6.2 Flow Chart

At initial stage, an input MRI Image is given. Later in the pre-processing stage the size of the image is changed accordingly and the noise is eliminated by using filters if present. If the data is present then it will be further processed or the process stops. In the algorithm process, the input image is converted into grayscale image as K-means algorithm only supports grayscale images. Further, the min-max pixels are calculated for the image enhancement. Later these pixels are extracted. In the post-processing, the size of the image which is enhanced, is again converted into the size of original image and divided into clusters. With the help of these clusters, the tumor part is detected and is shown as output.

CHAPTER 7

METHODOLOGY

7.1 METHODOLOGY

In order to detect tumors and validate the results, a few databases available publicly and help the research community to come up with better algorithms. Among those BRATS dataset, Fig share and Kaggle plays a major role with huge image dataset. Fig share[5] consisting of 3064 T1-weighted contrast-enhanced images with three kinds of brain tumor such as normal, benign and malignant. The images can be down loaded along with their ground truth images in BLACK &WHITE (BW) format. The dataset consists of tumor mask, tumor border, and original image in .MAT file. The space occupied by the database is more. Some of the sample dataset images are shown in Figure 7.1.

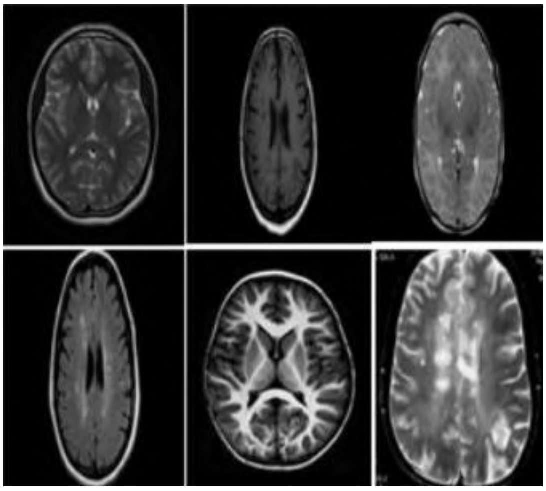

Fig 7.1 Sample Figures Hare Dataset Images Along With Its Ground Truth Images

Brats dataset[6] is a dataset used for many researchers for their work. The numbers of images along with their ground truth are . The images consist of normal benign and malignant images. Lot of versions exist in Brats dataset. All the proposed algorithms for tumor detection in various survey papers are normally validated in BRATS dataset only. Figure 7.2 shows the Kaggle dataset [7]involves the images for brain tumor detection.

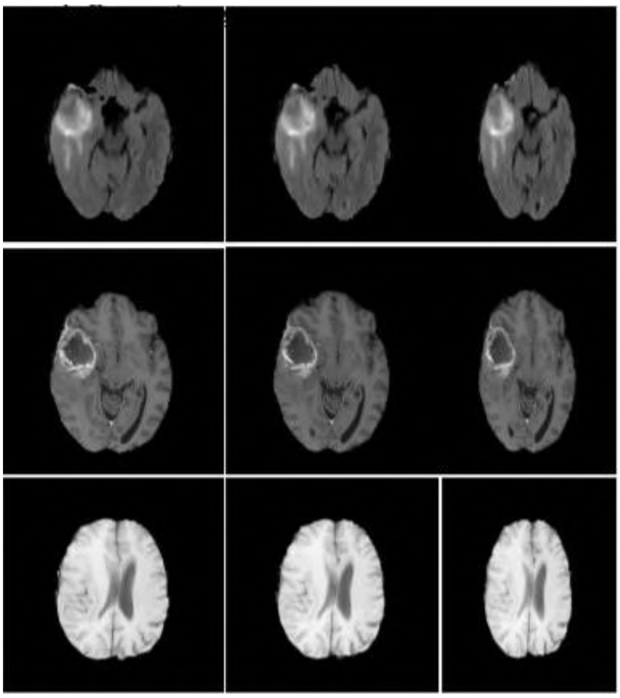

Fig 7.2. Sample Brats Dataset Images And Its Ground Truth Images

It is developed by Navoneel Chakrabarty in the year 2019. These datasets involves original images only. Few images are available for analysis. samples are An example of images from Kaggle dataset are shown in Figure 7.3.

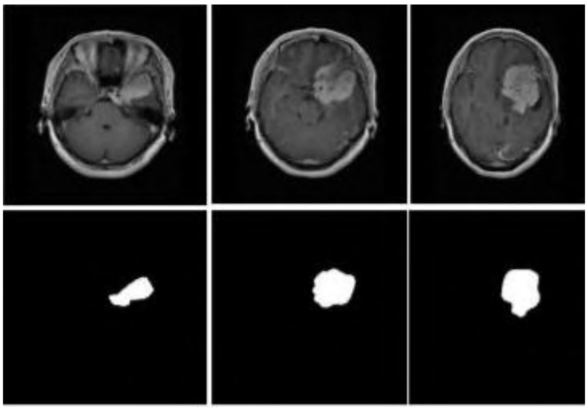

Fig 7.3 Sample Kaggle Dataset Images[7]

In [1], the authors discussed about the method to produce local volumes of the tumor databases. The authors analyzed numerical and quality parameter of the images using changes in morphological variations. In [2], the authors discussed a new method with a large number of CNNs with the information in overlapping regions. The authors used the OASIS dataset for validation of the results. V.P.Gladis Pushpa Rathi et al[3] proposed a tumor classification method based on feature extraction, features selection, PCA analysis and LDA analysis. The classification accuracy for the proposed method is 98.87%. The authors Amit Kumar Rohit et al.,[4], discussed a single query system based on Content Based Image Retrieval System(CBIR).The proposed system involves preprocessing, feature extraction and detection of tumors. The accuracy of the proposed method is 98.33%. Based on above said survey, many of the works still didn't follow a simple user friendly and accessible database. In this work, we proposed to create a database of MRI scan images, which we named as 'BRAMSIT Database' for the benefit of the biomedical engineering research community. An important risk in the research and development of this community is the lack of medical explanation and the plane for the tumor identification. Although some relevant papers have discussed localization issues, they do not provide such databases friendly to researchers.

Thus motivated by these factors, our main contributions in this work are:

• Create a new BRAMSIT database which involves 319 MRI scan images along with its ground truth images.

• Present the annotation of all the 319 subject's biological data along with their axial position.

CHAPTER 8

BRAMSIT DATABASE

The BRAMSIT database is deliberated through subsequent stages:

- Structure Details along with their axial position
- Labelling the Images
- Manual Annotation

8.1 STRUCTURE DETAILS

This dataset involves of 319 MRI scan images collected from various subjects. BRAMSIT consist of 319 images of different subjects. Each subjects includes reference number, age and their axial. The samples of BRAMSIT normal scan images of some subjects are shown in Figure 4. Similarly, the samples MRI abnormal and ground truth images of 5 subjects are shown in Figure 5

The salient features of the database are:

• Creation of database along with its clinic statistics for better use of images for research.

• Abnormal Images with the Ground truth for easy classification. The sample images along with the ground truth images are used for better segmentation and classification. All the ground truth images are developed from the experts opinion.

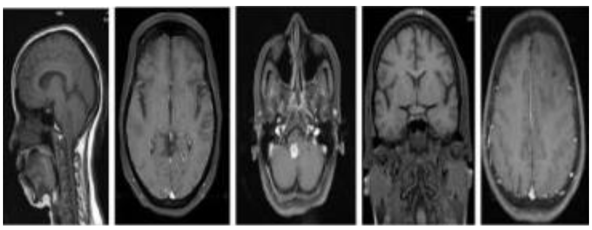

Fig 8.1 Sample Of MRI Normal Scan Images

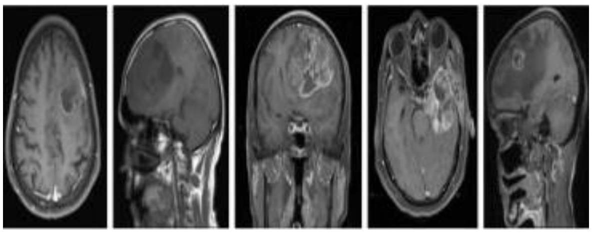

Fig 8.2 Sample Of MRI Abnormal Scan Images

8.2 LABELLING THE IMAGES

In the proposed database all the images are labeled perfectly for the purpose of understanding and interpreting. From the label itself one can easily identify the Subject ID, age and axial position. For example for a image with any abnormality suspect, the images are taken in three planes such as Sagittal ,Transaxial, and coronal View or Transaxial, Coronal and Sagittal View or Coronal ,Sagittal View and Transaxial view. Based on that, some abnormal suspected images are three in number based on their plane. Some normal images are single image with single view. Considering these factors, if Sub1 has three view images then it is labelled as Sub_1_STC, Sub_1_TCS, Sub_1_CST. This indicates subject1's STC means Sagittal, Transaxial, and coronal View, Sub_1_TCS means subject1's Transaxial, Coronal and Sagittal View and Sub_1_CST means subject1's Coronal ,Sagittal View and Transaxial view. In normal cases, the images are labelled as Sub_2_N_TCS, Sub_2_N_STC and Sub_2_N_CST view. TABLE 1. DETAILS OF THE SUBJECT IN THE DATABASE.

8.3 MANUAL ANNOTATION

BRAMSIT provides a detailed analysis of each and every MRI scan image. Each MRI scan images for the following attributes we manually annotated.

- Unique ID of the subject- Based on the axial Position
- Age
- Axial position –Transaxial, Sagittal and Coronal
- Gender- Male or Female

From the database, the table 1 shows the details of the images. The manual annotation is represented below: The age of the subject, gender, subject Id and the axial position is annotated. A sample subject shown in the annotation box below. Sample

MRI images and the ground truth images are shown in Figure.8. Ref.No Age Gender Axial Sub_1_TCS 40 Male Trans axial Sub_2_STC 51 Male Sagittal Sub_2_CTS 51 Male Coronal Sub_3_TCS 55 Female Trans axial Sub_4_STC 58 Female Sagittal Authorized licensed use limited to: Cornell University Library.

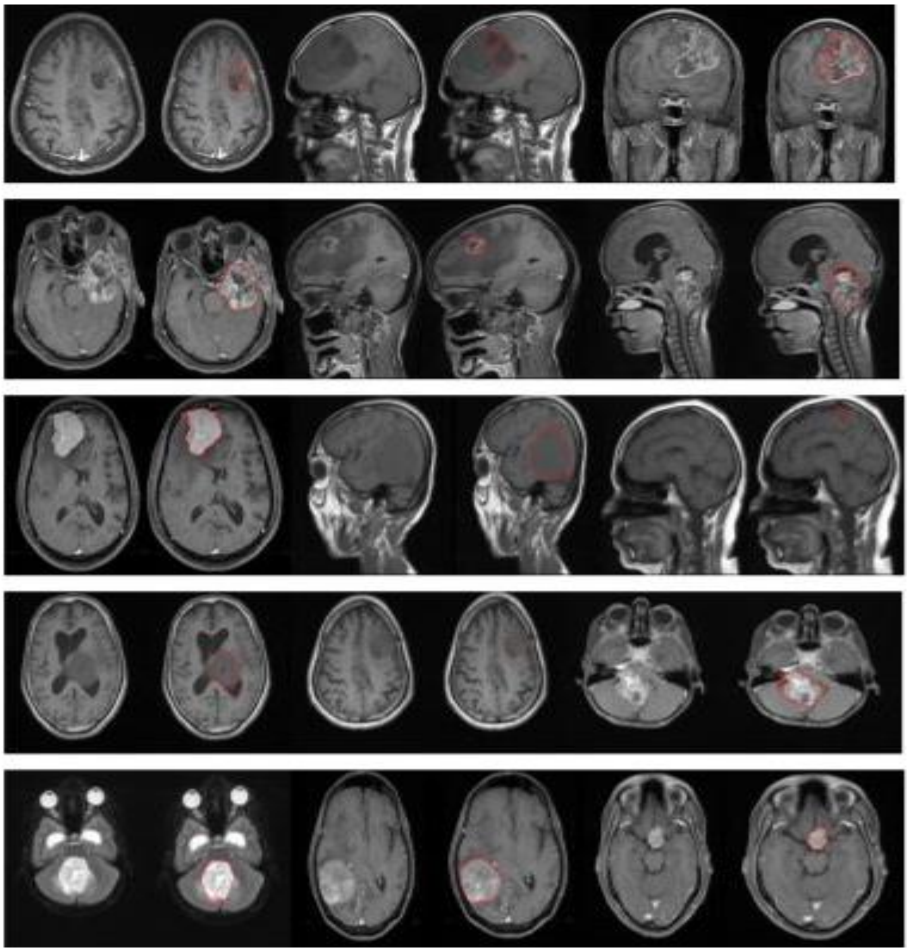

Fig 8.3 Sample Of MRI Abnormal Scan Images And Their Ground Truth Images

CHAPTER 9

COMPLEXITY OF THE DATABASE

9.1 COMPLEXITY OF THE DATABASE

As said earlier, many databases are there for analysis of brain tumor in MRI imaging modality. As this dataset is also created for the same research outcome when compared with the other databases, one main feature of the proposed dataset is the ease of access and the speed in processing or analysis of the images. When compared with the BRATS dataset, Fig share and Kaggle, the proposed BRAMSIT processing time and accessing time is very less during some bench mark image processing algorithms.

S.NO	DATASET	ACCESS TIME	PROCESSING TIME	EFFICIENCY IN(%)
1	BRATS	2.35ms	4.2ms	65
2	Fig share	2.01ms	3.52ms	78
3	Kaggle	2.45ms	3.87ns	84
4	BRAMSIT	0.2ns	1.5ns	95

Table 9.1 Performance Evaluation Of Various Databases

As shown in table 9.1, the access time and processing time for the proposed dataset is very less when compared with other datasets.

CHAPTER 10

RESULTS

CHAPTER 11

CONCLUSION

11.1 CONCLUSION

The project describes Screening Brain Tumor for the most recent database. Investigating brain tumor image analysis by using it as a resource. The "abnormal" and "ground truth" images. The main characteristics of this BRAMSIT database are

a) 319 MRI images.

b) Marking the entire subjects biological data.

The biomedical research community provides the brain tumor of many uncertain research problems.

11.2 FUTURE SCOPE

- The detection of brain tumor can be more easier and effective when coloured MRI images are used.
- Different algorithms may come into existence by which the process of detecting and diagnosing the brain tumor becomes more faster.
- Different databases may come into existence by which the processing time and accessing time becomes very less during some bench mark image processing algorithms.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped us in field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to Dr.B.Hari Krishna ,**Head &Professor**, the Dept. of Electronics And Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him.

We would like to express our gratitude to **our dept .project coordinator** Dr.A.Anand for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We are highly grateful and obliged to **our college level Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santosh Kumar** , **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

We dedicate this thesis to almighty

1. Ms.K.Kalpana(17K81A04F3)
2. Ms.L.Harshitha(17K81A04F4)
3. Ms.D.Suchithra(18K85A0430)

ABSTRACT

- In Magnetic Resonance Imaging (MRI), the poor images quality, particularly the artifacts inherent to this type of images as well as the low contrast between tissues and interindividual variability, could make difficult the image analysis and affect the accuracy of clinical diagnosis.
- Therefore, the needs for image enhancement techniques arise to improve the relevant image contents through reducing the noise while preserving the actual details features. Various MRI images denoising techniques have been proposed in literature where each technique has its advantages and limitations.
- Among them, the Histogram modifications-based approaches arise as the most employed, by many researchers, for MRI contrast enhancement.
- This project presents a comparative study of the most histogram-based techniques, mainly AHE, CLAHE, BPDHE and AIR-AHE techniques, dealing with denoising and contrast enhancement MRI images.
- Experimental study, using real-world databases, is performed based on evaluation of quality measurement metrics: absolute mean brightness error (AMBE), peak signal to noise ratio (PSNR) and Entropy.

TABLE OF CONTENTS

Chapter 1 INTRODUCTION TO DIGITAL IMAGE PROCESSING

Chapter 2 LITERATURE SURVEY

Chapter-1

INTRODUCTION TO DIGITAL IMAGE PROCESSING

1.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person. two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surface.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphic technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color

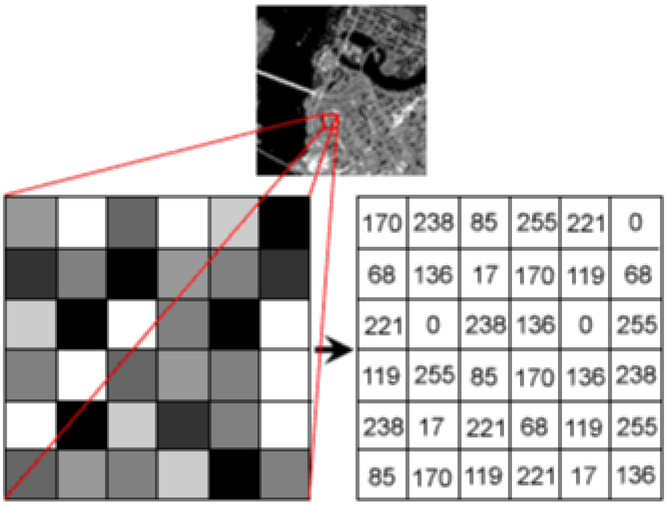

Fig 1.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

Fig1.3 Transparency Image

1.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High-resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

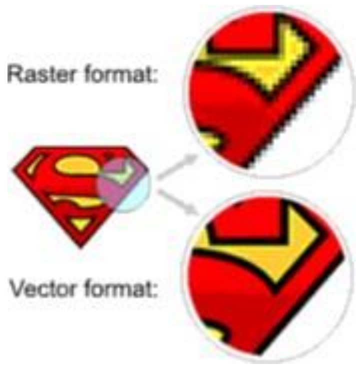

Fig1.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

1.4 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata is recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, the name of the camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

1.5 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

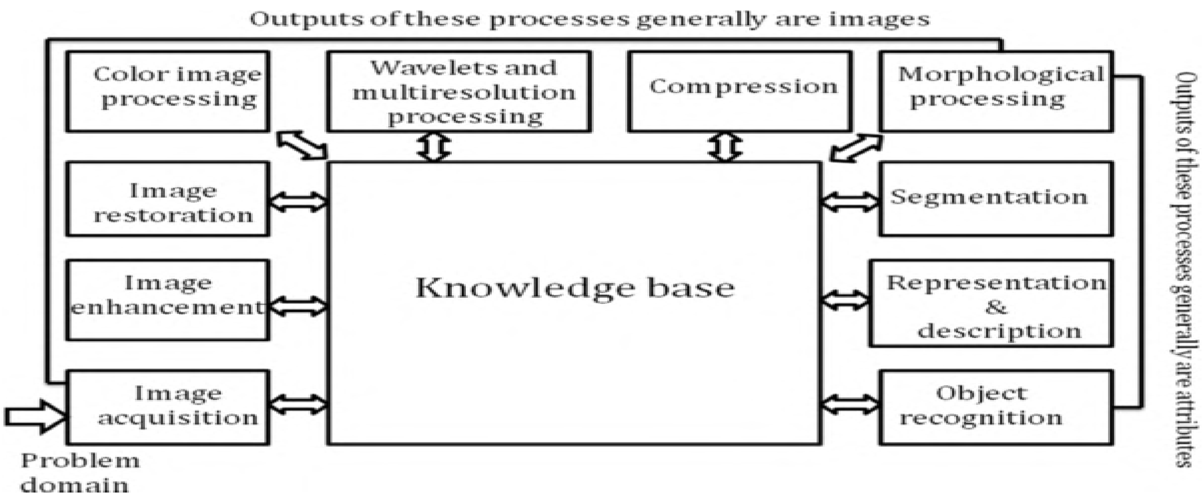
- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.6 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields suffers from myths, miss-connect ions, misunderstandings and misinformation. It is the vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor plowed with imprecise jargon.

Several factors combines to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low-cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.



1.6.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.6 Digital Camera Image

The scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.7 Digital Camera Cell

1.6.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.8 Image enhancement

1.6.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.9 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

1.6.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.10 Color & Gray scale image.

1.6.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

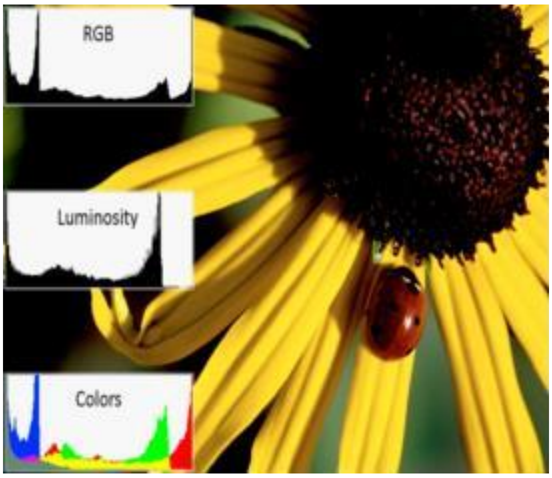


Fig 1.11 RGB Histogram Image.

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub-band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.6.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which is characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts image compression standard.

1.6.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

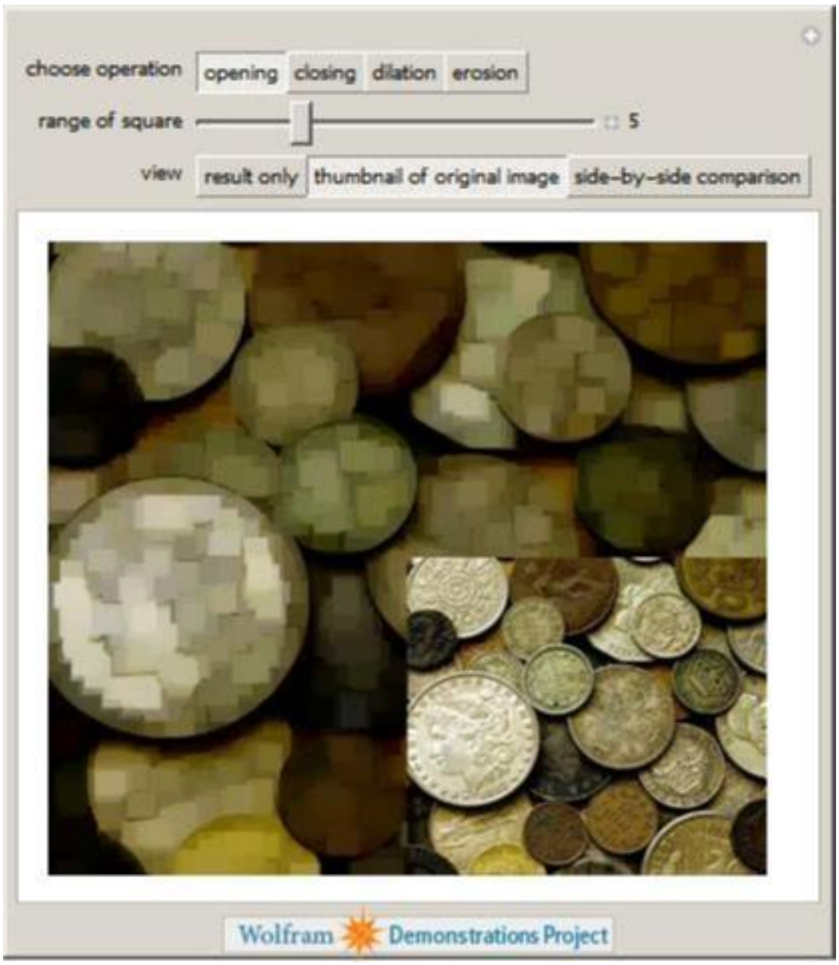

Fig 1.12 :- blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.6.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward a successful solution of imaging problems that require objects to be identified individually.

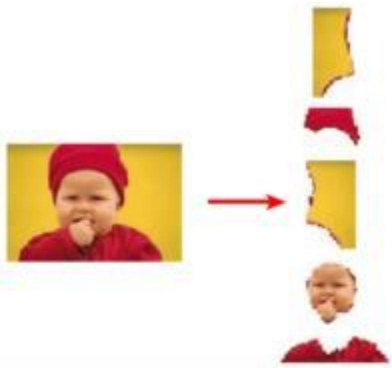

Fig 1.12 Image segmentation

9. Representation and Description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

10. Knowledge Base:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an interrelated to list of all major possible defects in a materials inspection problem or an image database containing high-resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.6.11 Object Recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

7. Feature Extraction and Feature Matching Techniques :

1. Oriented FAST And Rotated BRIEF(ORB) :

ORB, starts by finding special regions in an image called key points. Key points are the highly-distinctive locations in an image. For example, the edges of an image (where the brightness varies i.e where the pixel values change sharply).

How does ORB work?

1. First, it uses FAST to find key points, then applies a Harris corner measure to find top N points among them. FAST stands for Features from Accelerated Segments Test, and it quickly selects key points by comparing the brightness levels in a given pixel area.

2. BRIEF, to create feature vectors.

2. Feature Detection using FAST(Features from Accelerated Segments Test):

1. Select a pixel p in the image which is to be identified as an interesting point or not. Let its intensity be I.

2. Select the appropriate threshold value t.

3. Consider a circle of 16 pixels around the pixel under test. (See the image below).

3. **BRIEF (Binary Robust Independent Elementary Features):**

The second part of the ORB algorithm is to take the key points found by the FAST algorithm and turn those into feature vectors that together can represent an object. To create feature vectors, ORB uses a BRIEF algorithm.

It basically creates binary feature vectors from a set of key points. As we already know a binary feature vector, is also known as a binary descriptor, which is just a feature vector that contains only ones and zeros

BRIEF provides a shortcut to find the binary strings directly. It takes a smoothened image patch and selects a set nd(x,y) location pairs in a unique way and then pixel intensity comparisons are done on these location pairs.

In short, BRIEF is a faster method feature descriptor calculation and matching. It also provides a high recognition rate unless there is a large in-plane rotation.

4. **2 Nearest Neighbour(2NN) with Hierachical agglomerative clustering(HAC):**

There are many approaches to hierarchical clustering as it is not possible to investigate all clustering possibilities.One set of approaches to hierarchical clustering is known as agglomerative, whereby in each step of the clustering process an observation or cluster is merged into another cluster.

Hierarchical clustering is a widely used and popular tool in statistics and data mining for grouping data into 'clusters' that exposes similarities or dissimilarities in the data. There are many approaches to hierarchical clustering as it is not possible to investigate all clustering possibilities. One set of approaches to hierarchical clustering is known as agglomerative, whereby in each step of the clustering process an observation or cluster is merged into another cluster. The first approach we will explore is known as ‘**Single Linkage’method**’ also known as nearest neighbors.

5. Noise :

Noise Images acquired through modern sensors may be contaminated by a variety of noise sources. By noise we refer to stochastic variations as opposed to deterministic distortions such as shading or lack of focus. We will assume for this section that we are dealing with images formed from light using modern electrooptics. In particular we will assume the use of modern, charge-coupled device (CCD) cameras where photons produce electrons that are commonly referred to as photoelectrons. Nevertheless, most of the observations we shall make about noise and its various sources hold equally well for other imaging modalities. While modern technology has made it possible to reduce the noise levels associated with various electro-optical devices to almost negligible levels, one noise source can never be eliminated and thus forms the limiting case when all other noise sources are “eliminated”.

1.8 IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

CHAPTER-2

LITERATURE SURVEY

Over the past several years, numerous MRI contrast enhancement and denoising approaches have been reported in the literature. This step of image preprocessing is very crucial for the efficiency of the subsequent image processing steps, for instance segmentation, classification and reconstruction. Among these approaches, one could report the linear filtering (spatial and temporal [2]) and nonlinear filtering approaches, e.g. anisotropic diffusion filter (ADF), bilateral filtering [3].

There are also the transform-based approaches, e.g. wavelet and curvelet transforms [4] as well as statistical-based approaches e.g. maximum likelihood (ML), random forest and Markov Random Field (MRF), etc. For MRI contrast enhancement, the histogram modifications based approaches have gained a great research interest by scientists due to their advantages: simplicity and ease of use, higher SNR as well as its low computational complexity.

In fact, the most employed classical images contrast enhancement technique is the Histogram Equalization (HE), which provides good performance for ordinary images, such as human portraits or natural images.

However, in MRI brain images, there are often more complex situations where the brain tumor White matter hyper intensities (WMH) signal is high but it may mistakenly be considered as other brain tissues such as Cerebrospinal fluid (CSF). In this paper, we will focus on the study of the major histogram modifications based approaches when applied to brain MRI images for contrast enhancement. Sazanita et al. [5] proposed a new approach applied for FLAIR MRI images, known as the Average Intensity Replacement–Adaptive Histogram Equalization (AIR-AHE), which enhances the contrast without over amplifying the entire image.

It improves the contrast of WMH relying on the intensity adjustment and contrast mapping techniques, more details of this method are explained in this paper. In [6], the authors proposed a Hierarchical Correlation Histogram Analysis algorithm (HCHA) which provides an automatic contrast enhancement of images during the examination of atrophic cell areas of Parkinson Disease (PD) patients.

This algorithm is based on the grayscale distribution degree of pixel intensity by constructing a correlation histogram.

This method has as objective to provide the best segmentation accuracy result and facilitates subsequently CAD processes. SENTHILKUMARAN et al. in [7] performed a comparative study of different histogram-based techniques, mainly the histogram equalization (HE), BHE, modified BHE, AHE and CLAHE, in order to enhance the contrast of general MRI brain images.

They used different evaluation metrics as Michelson contrast, RMS contrast, absolute mean brightness error (AMBE) and Pixel Distance.

While the major comparative studies of histogram-based techniques are performed on general MRI brain images, to the best our knowledge, there is no comparative study performed on MRI glioma brain tumors. In fact, the main objective of the present comparative study is to find, over the existing recent contrast-enhancement methods, the most preferment and effective techniques for the MRI Glioma brain tumors images, specifically glioblastoma. Since glioblastomas are infiltrative tumors, their borders are often fuzzy and hard to distinguish from healthy tissues [1]. Furthermore in some cases, the tumor region might share the same intensity profile with other normal regions within the image [14].

These characteristics make the localization of tumor core edges a very difficult task for radiologists.

Thus, the MRI contrast-enhancement is important on the one hand, it is a clinical necessity that facilitate, for radiologists and neurologists, the tumor detection and distinguish it from other tissues (edema and necrosis), and on the other hand, it makes easier for the CAD to have more efficiency and accuracy in different tasks such as automatic segmentation and even the classification task.

Gliomas are the most common and aggressive type of brain tumors due to their infiltrative nature and rapid progression. The process of distinguishing tumor boundaries from healthy cells is still a challenging task in the clinical routine. Fluid-attenuated inversion recovery (FLAIR) MRI modality can provide the physician with information about tumor infiltration. Therefore, this paper proposes a new generic deep learning architecture, namely DeepSeg, for fully automated detection and segmentation of the brain lesion using FLAIR MRI data.

The developed DeepSeg is a modular decoupling framework. It consists of two connected coreparts based on an encoding and decoding relationship. The encoder part is a convolutional neural network (CNN) responsible for spatial information extraction. The resulting semantic map is inserted into the decoder part to get the full-resolution probability map. Based on modified U-Net architecture, different CNN models such as residual neural network (ResNet), dense convolutional network (DenseNet), and NASNet have been utilized in this study.

This study showed successful feasibility and comparative performance of applying different deep learning models in a new DeepSeg framework for automated brain tumor segmentation in FLAIR MR images.

CHAPTER-3

PROPOSED SYSTEM

3.1 BLOCK DIAGRAM :-

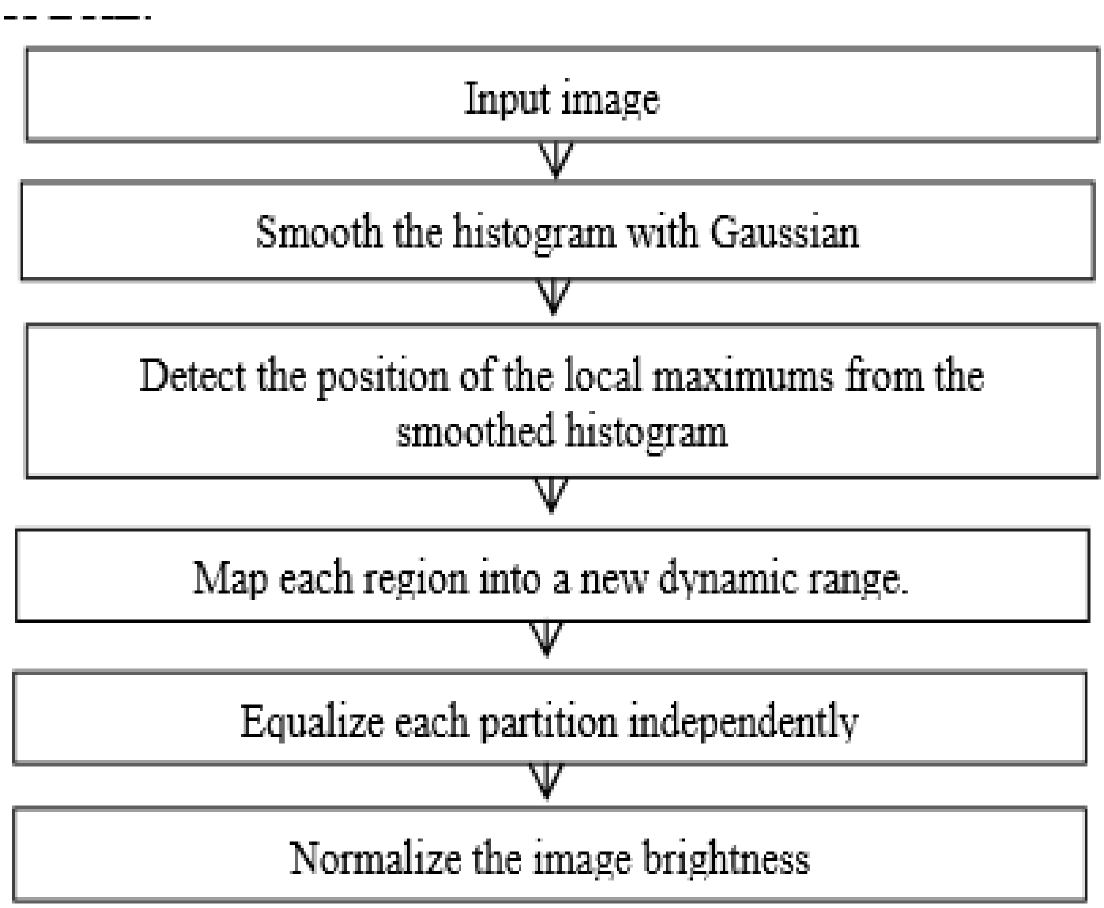

Fig 3.1 Block diagram

Unlike other contrast enhancement techniques, BPDHE divides the input image into sub-regions based on the position of the local maximums of input histogram. The next step is to equalize each partition separately . Before the equalized histogram taking place, BPDHE first map each sub image to a new dynamic range. This change in the dynamic range will cause modification in the mean brightness of the output image, thus the final step of this method is the normalization of the output intensity.

It is very difficult to find the exact location of local maximums due to histogram fluctuation without smoothing the histogram and also the probability that there is some brightness levels are missing. Thus the first step of BPDHE is to apply Gaussian filter to the input histogram [14]. To keep the mean brightness of the input image, BPDHE apply the brightness normalization process, as define by: (5) Where Mi is the mean brightness of the input image, Mf is the mean brightness after the equalization process and f(x, y) is the output image after the equalization process. D. Average Intensity Replacement based on Adaptive Histogram Equalization (AIR-AHE) AIR-AHE is a recent contrast enhancement technique for brain MRI images proposed by Iza et al. [5]. This technique, composed of four processing steps, combines several established enhancement algorithms:

• Step1: Contrast stretching process where the principal purpose is increasing the contrast of the enhanced image.

• Step2: Apply the CLAHE technique with clipping limits in the range of 0-1, in order to improve the contrast of the potential regions;

• Step3: Region of maximum intensity where the higher intensity location in the potential regions is determined. It could be further improved by including the regional maxima function.

• Step4: Window sliding neighborhood operation for intensity measurement. A sliding neighborhood operation is used to determine the average intensity value of the pixel's neighborhood. It is performed by sliding a set of pixels relative to the center of the pixel [4].

CHAPTER-4

SOFTWARE AND ITS FUNCTIONS

1. Introduction To MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation.
- Algorithm development.
- Data acquisition.
- Modeling, simulation, and prototyping.
- Data analysis, exploration, and visualization.
- Scientific and engineering graphics.
- Application development, including graphical user interface building.

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high- productivity research, development, and analysis.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high- productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

2. The MATLAB system:

The MATLAB system consists of five main parts

Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

The MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3. GRAPHICAL USER INTERFACE (GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

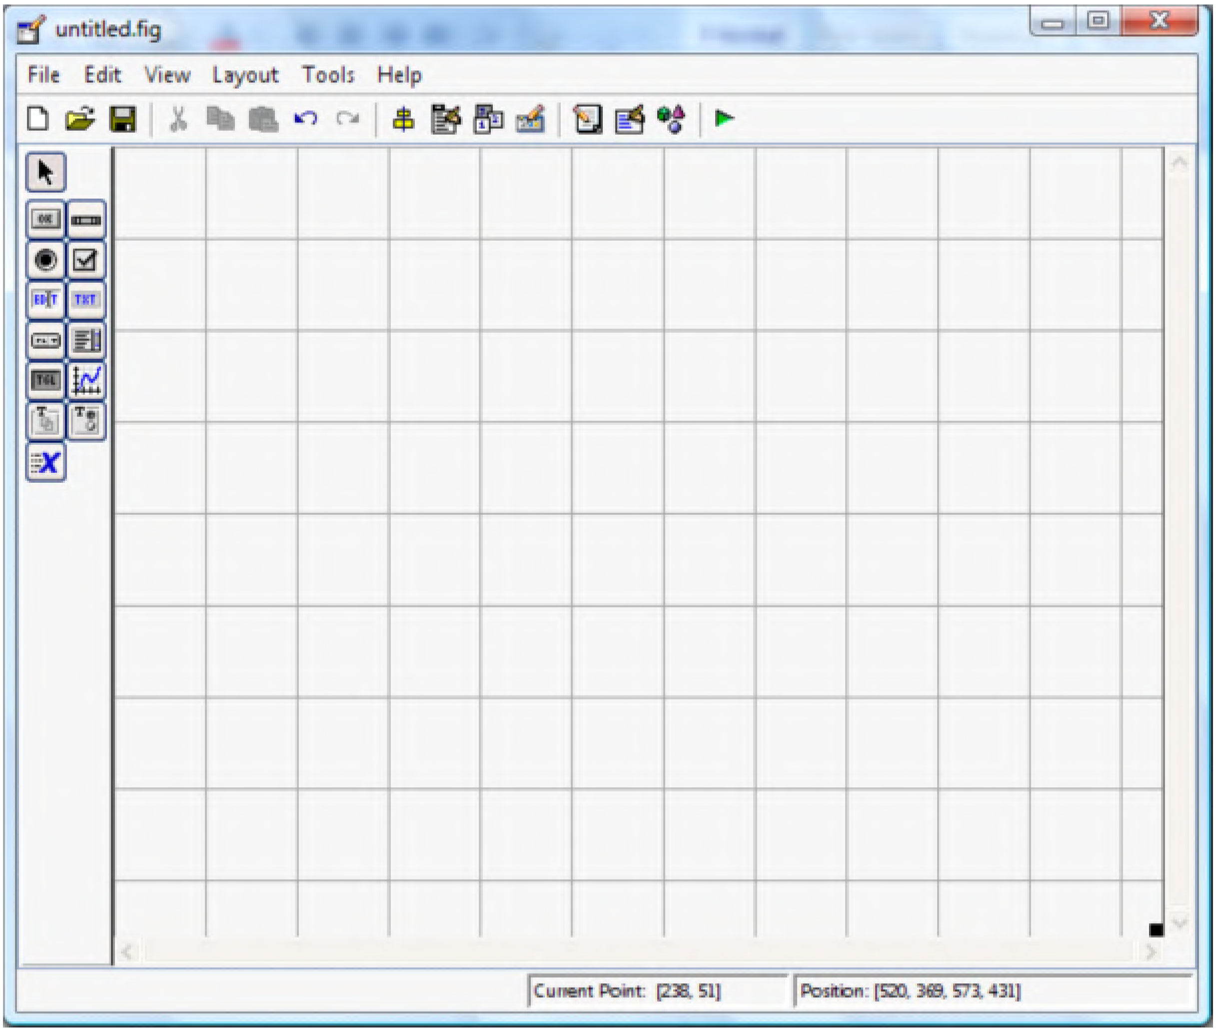
A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

1. **Introduction** - describes the components of the MATLAB system.

2. **Development Environment** - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3. **Manipulating Matrices** - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

4. **Graphics** - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5. **Programming with MATLAB** - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

4. DEVELOPMENT ENVIRONMENT

1. Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

2. Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3. Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

4. MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

4.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad

- Help Browser

1. Command Window

Use the Command Window to enter variables and run functions and M-files.

2. Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

3. Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

4. Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

5. Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

6. Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

4.5.7 Display Panel

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

4.6 Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

4..6.1 Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

4.6.2 Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

3. Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

4. Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function

4.7 MANIPULATING MATRICES

4.7.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

Separate the elements of a row with blanks or commas.

Use a semicolon, ; , to indicate the end of each row.Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =

   16    3    2   13

    5   10   11    8

    9    6    7   12

    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

4.7.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

4.7.3 Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

4.7.4 Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

4.7.5 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

4.7.6 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

4.8 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

1. Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

2. GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

4.8.3 The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

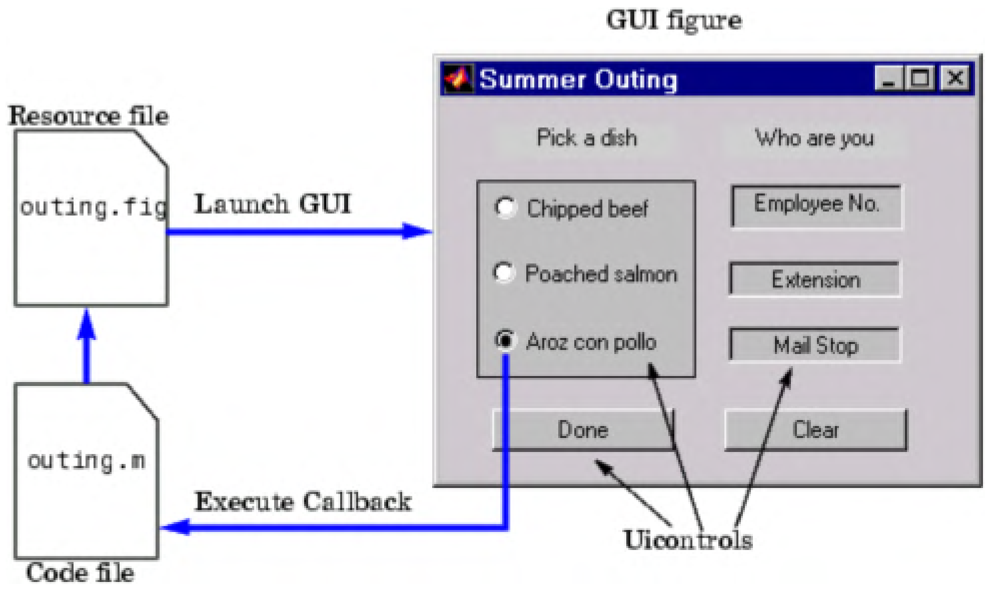


FIG 4.2 graphical user blocks

Features of the GUIDE-Generated Application M-File

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

4.8.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

9. Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

1. User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

4.9.2 From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

function varargout = togglebutton1_Callback**5 User Interface Control**

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames

- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback:

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons:

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)
button_state = get(h,'Value');
if button_state == get(h,'Max')
   % toggle button is pressed
elseif button_state == get(h,'Min')
   % toggle button is not pressed
end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

   .

   .

   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
```

```
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function  edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
   errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback…
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute.

This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes(handles.axes1)

4.10 Software Functions:

- **imread function**:- The **imread function** supports four general syntaxes, described below. ... See Special Case Syntax for information about these syntaxes

  A = **imread**(filename, fmt)

  reads a greyscale or color image from the file specified by the string filename ,where the string fmt specifies the format of the file.

- **imshow function :-** The **imshow function** displays the value low (and any value less than low) as black, and it displays the value high (and any value greater than high) as white. Values between low and high are displayed as intermediate shades of gray, using the default number of gray levels.

B = **imshow**(A);

- **Imwrite function :- imwrite** function converts indexed images to RGB before writing data to JPEG files, because the JPEG format does not support indexed images. The **imwrite function** does not support writing of indexed PNG files that have insufficient colormap entries.

  A = **imwrite**(variable,"Newfilename.Newfileformat');

- **Uigetfile :- uigetfile** displays a dialog box used to retrieve one or more files. The dialog box lists the files and directories in the current directory.

  uigetfile(' FilterSpec ')

  It displays a dialog box that lists files in the current directory.

- **Imresize :-** B = **imresize**(A , scale)

  returns image B that is scale times the size of A . The input image A can be a grayscale, RGB, or binary image. If A has more than two dimensions, **imresize** only resizes the first two dimensions.

CHAPTER-6

CONCLUSION :

The main objective of this paper is to provide a comparative study of some existing techniques of contrast enhancement based on histogram equalization for MRI Glioblastoma brain tumour. Particularly the AHE, CLAHE, AIR-AHE and BPDHE methods are explained and then compared. Each studied method is evaluated relying on image quality measurement mainly AMBE, PSNR and entropy. For the evaluation process, we selected the most relevant slices where the tumour core appears clearly, then we computed the average value (with a standard deviation) of the quality evaluation metrics which makes the evaluation to be more precise. Through this study one could notice that, Adaptative Histogram Equalization (AHE) technique provides efficient performances for MRI contrast enhancement compared to other studied techniques. For future works, we will focus on enhancing the AHE techniques by introducing filtering approaches that could improve the results in terms of accuracy and treatment efficiency.

CERTIFICATE

This is to certify that the major-project work entitled **"Automatic Railway Train Safety System"** is a Bonafide work carried out by **Y.Suresh Kumar (18K85A0424), G.Ruchitha (18K85A0426), DV.Harish (18K85A0434)** in partial fulfilment of the requirements for the degree of **Bachelor of Technology in Electronics & Communication Engineering** by the Jawaharlal Nehru Technological University, Hyderabad during the academic year 2020-21.

The results embodied in this report have not been submitted to any other University or Institution for the award of any degree.

INTERNAL GUIDE	HEAD of THE DEPARTMENT, ECE
Mrs.T.Sri Lakshmi Assistant Professor, Department of ECE.	Dr.B. Hari Krishna, Professor

EXTERNAL EXAMINER

// ACKNOWLEDGEMENT

We sincerely thank the management of our college **St. MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work.

We derive our great pleasure in expressing our sincere gratitude to our principal **Dr.P. Santosh Kumar Patra** for his timely suggestions, which helped us to complete the project work successfully.

It is the very auspicious moment to express our gratitude to **Dr. B. Hari Krishna**, Head of the Department, ECE for his consistent encouragement during the progress of this project.

We take it as a privilege to thank our project coordinator **Mr.M.Nishakar** Associate Professor, department of ECE for the ideas that led to complete the project work and we also thank them for their continuous guidance, support and unfailing patience, throughout the course of this work.

We sincerely thank our project Internal guide **Mrs.T.Sri Lakshmi,** Assistant Professor**,** Department of ECE for guidance and encouragement in carrying out this project work.

DECLARATION

We, the students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2018 – 2021, **St. Martin's Engineering College**, hereby declare that the project work entitled '**Automatic Railway Train Safety System**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

ABSTRACT

Automatic Railway Safety System can sense the presence of fire and smoke and generate a series of alarm driven events after it. When the fire is detected it turns on a motor which is depicted in the project as breaking system or chain pulling mechanism. Thus by this the train can be stopped and the passengers and other payloads can be safeguarded thereafter. Along with breaking, the system sounds a buzzer that would alert nearby people around it so that they can be cautious about the presence of fire in the Train. Also, an SMS is sent to the Railway Authorities which will help them to take quick decisions to take control of the fire and in evacuating the Train. Hence this project offers a very robust mechanism for safety in the Railways which works automatically with the help of microcontrollers and sensors.

CHAPTER-1

INTRODUCTION

1.1 INTRODUCTION ABOUT EMBEDDED SYSTEMS:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.
The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.
The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

1.1.1 Block Diagram of Embedded System:

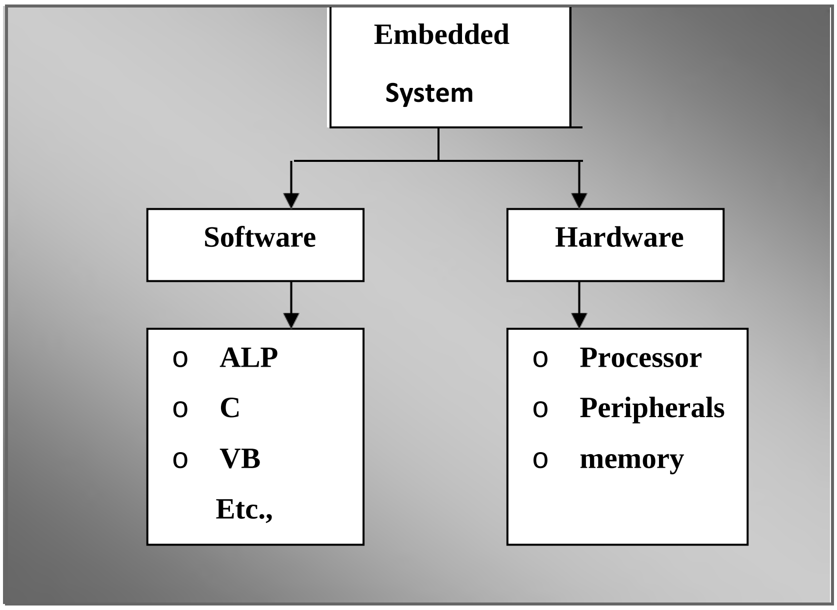

Fig.1.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

1.1.2 Applications of Embedded Systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

1.2 MICRO PROCESSOR (µP):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

1.2.1 Three Basic Elements Of A Microprocessor:

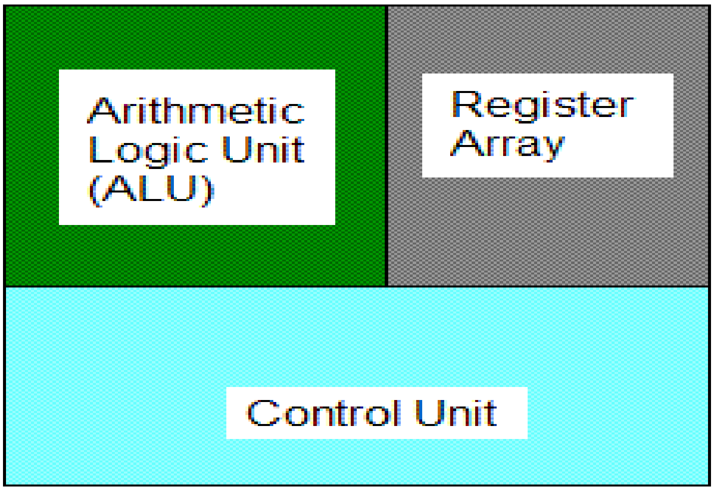

Fig.1.2: Three basic elements of a microprocessor

1.3 HARVARD ARCHITECTURE:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data.

The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

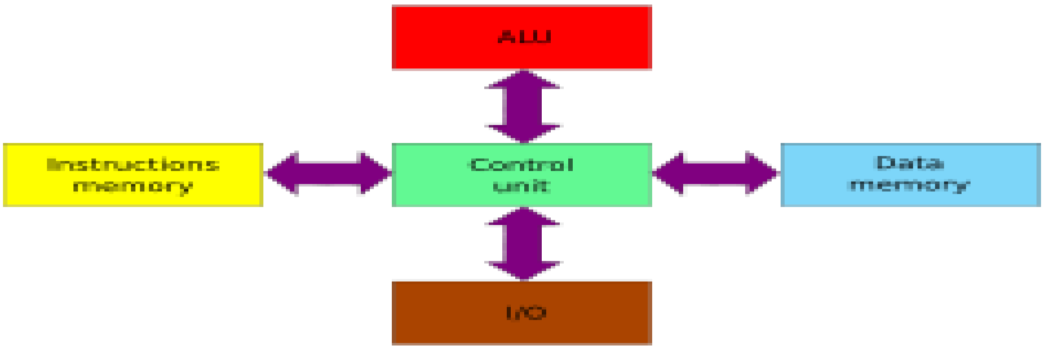

Fig.1.3: Harvard Architecture

1.3.1 Uses of The Harvard Architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access.
- The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

1.4 VON-NEUMANN ARCHITECTURE

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

Astored-programdigit computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

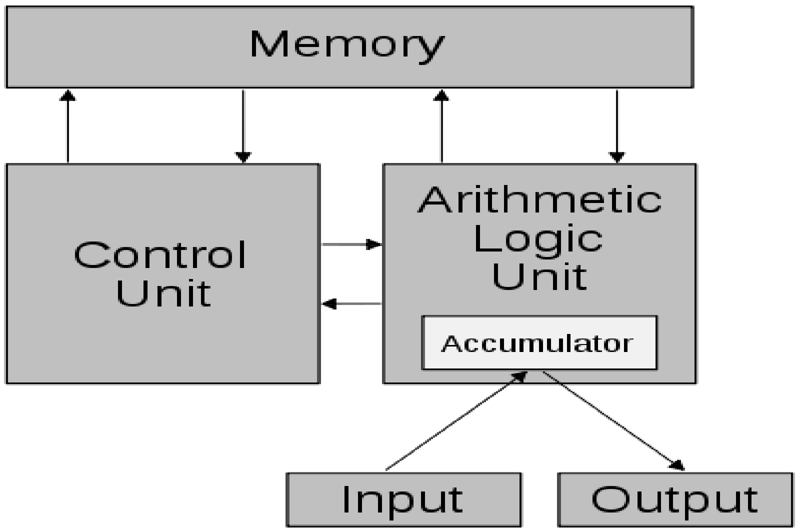

Fig.1.4: Schematic of the Von-Neumann Architecture.

1.5 PROJECT DESCRIPTION

1.5.1 Objective:

The aim and objective of the proposed project is to improve the safety of the railway system and to save human life. The key objective of this application is public safety. To automatic pull the chain when fire is accurs.To detect fire attack in train and control using buzzer.

1.5.2 Components Used:

- Arduino Uno
- Power supply
- LCD
- GSM
- L293D
- Motor
- Temperature sensor
- Gas sensor

CHAPTER-2

LITERATURE SURVEY AND EXISTING METHODS

2.1 LITERATURE SURVEY

Now days, the usage of fire alarm is become popular in office and homes. So, market will be up because of the request. But, users are no longer satisfied with a simple fire alarm detector that just senses and sounds the alarm. Many would like to have a fire alarm system that monitors and alerts them in case of emergency especially when they are away. Price for this system is usually expensive and its installation is complicated. However, user always suspected the cost of that system is cheap and easy to install. Traditional fire alarm systems are classified in a hardwired. So it will use many cables to connect one another. User's find it's untidy and inconvenience to

A sensor is an electronic device used to measure a physical quantity and convert into an electrical signal, which can be read by an observer. The common types of automatic fire detectors are thermal and flame detectors. The thermal detectors are ability to identify high temperature, smoke detectors replicate the sense of smell , and flame detectors are electronic eyes. The properly selected and installed automatic fire detector can be a highly reliable sensor. Unfortunately, a person can also be an unrel

ghly reliable sensor. Unfortunately, a person can also be an unreliable detection method since they may not be present when a fire starts, may not be in perfect health to recognize fire signatures. The advantage of manual alarm stations is that, upon discovering the fire, they provide occupants with a readily identifiable means to activate the building fire alarm system. The alarm system can serve in life of the shouting person's voice. They are simple devices, and can be highly reliable when the building occupied

2.2 EXISTING METHODS

In The existing conventional signaling system most of the times relay on the oral communication through telephonic and telegraphic conversations as input for the decision making in track allocation for trains.There is large scope for miscommunication of the information or communication gap due to the higher human interface in the system.This miscommunication may lead to wrong allocation of the track for trains , which ultimately leads to the train collision.

2.3 PROPOSED SYSTEM

In This proposed system have to developed an automatic fire detection and rescue system based on GSM. In order to provide an early extinguishing of fire, large numbers of detectors, which measure temperature and gas concentrations are deployed in train. When there is a detection of fire, an alarm sounds and the same time, the information reports their organization via GSM

3.2 SCHEMATIC EXPLANATION

3.2.1 Interfacing Between LCD and Arduino

The following circuit diagram shoes the liquid crystal display with Arduino module. From the circuit diagram, we can observe that the RS pin of the LCD is connected to the pin 7 of the Arduino. The LCD of R/W pin is connected to the ground. The pin 6 of the Arduino is connected to the enable signal pin of LCD module. The LCD module & Arduino module are interfaced with the 4-bit mode in this project. Hence there are four input lines which are DB4 to DB7 of the LCD. This process very simple, it requires fewer connection cables and also we can utilize the most potential of the LCD module.

The digital input lines (DB4-DB7) are interfaced with the Arduino pins from 2-5. To adjust the contrast of the display here we are using a 10K potentiometer. The current through the back LED light is from the 560-ohm resistor. The external power jack is provided by the board to the Arduino. Using the PC through the USB port the Arduino can power. Some parts of the circuit can require the +5V power supply it is taken from the 5V source on the Arduino board.

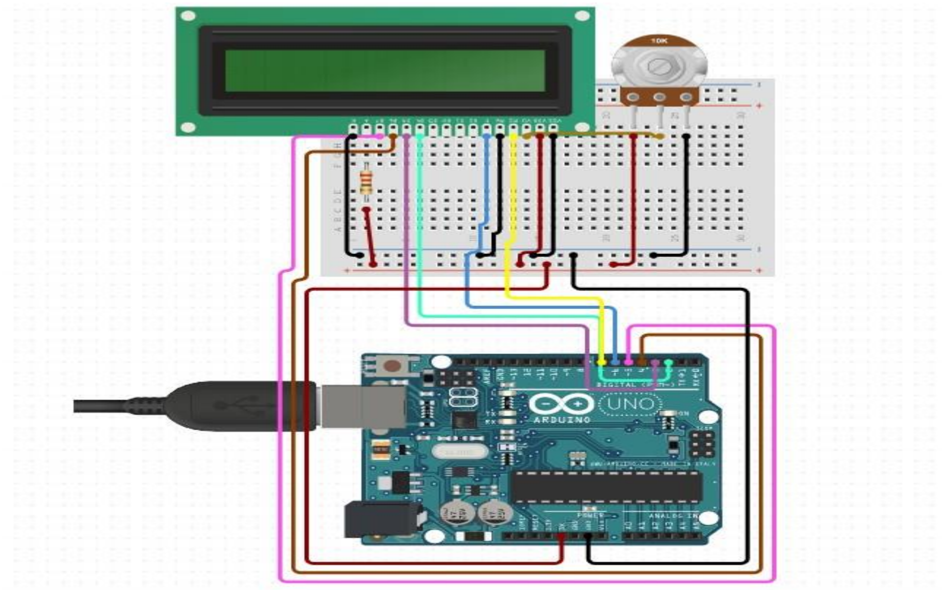

Fig.3.2: Interfacing Between LCD and Arduino

3.2.2 Interfacing Between Temperature Sensor and Arduino

4 The +5v for LM35 can be taken from the +5v out pin of arduino uno. Also the ground pin of LM35 can be connected to GND pin of arduino uno. Connect Vout (the analog out of LM35) to any of the analog input pin of arduino uno. In this circuit diagram, we have connected Vout of LM35 to A1 of arduino.

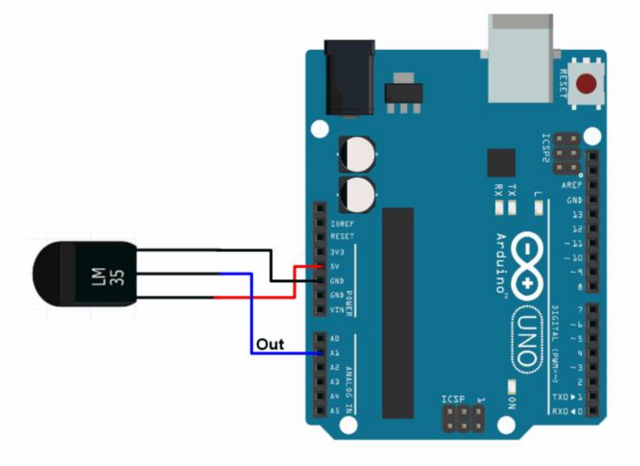

Fig.3.3: Schematic diagram of Temperature Sensor and Arduino

3.2.3 Interfacing between PC and GSM Module:

A GSM modem can be an external device or a PC Card / PCMCIA Card. Typically, an external GSM modem is connected to a computer through a serial cable or a USB cable. A GSM modem in the form of a PC Card / PCMCIA Card is designed for use with a laptop computer. It should be inserted into one of the PC Card / PCMCIA Card slots of a laptop computer. Like a GSM mobile phone, a GSM modem requires a SIM card from a wireless carrier in order to operate.

A SIM card contains the following information:

- Subscriber telephone number (MSISDN)
- International subscriber number (**IMSI, International Mobile Subscriber Identity)**
- State of the SIM card
- Service code (operator)
- Authentication key
- PIN (***Personal Identification Code***)
- PUK (***Personal Unlock Code***)

Computers use AT commands to control modems. Both GSM modems and dial-up modems support a common set of standard AT commands. In addition to the standard AT commands, GSM modems support an extended set of AT commands. These extended AT commands are defined in the GSM standards. With the extended AT commands, the following operations can be performed:

- Reading, writing and deleting SMS messages.
- Sending SMS messages.
- Monitoring the signal strength.
- Monitoring the charging status and charge level of the battery.
- Reading, writing and searching phone book entries.

The number of SMS messages that can be processed by a GSM modem per minute is very low i.e., about 6 to 10 SMS messages per minute.

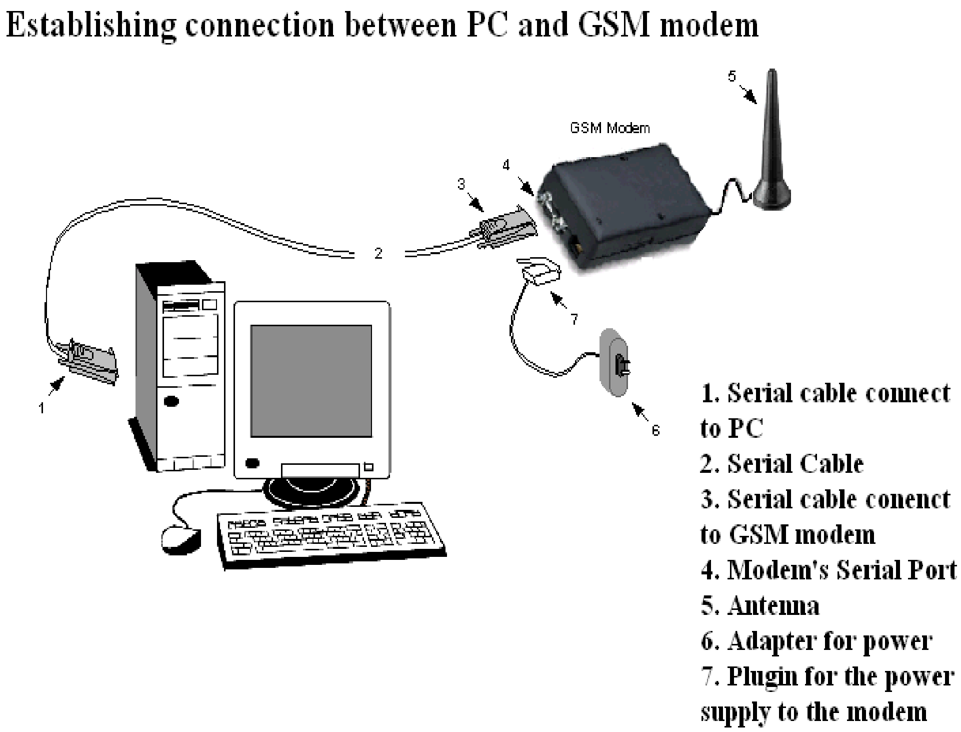

Fig.3.4 Interferance between the PC and GSM

3.2.4 Interfacing between Arduino and L293D

4-7 numbered digital pins act as output pins from Arduino are connected to the motor driver module i.e L293D as input and output of the module is connected to motors for forward or backward movements,

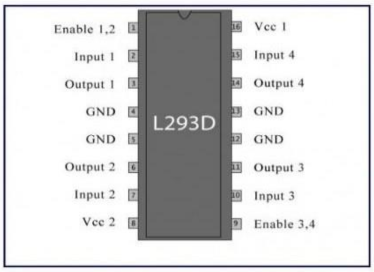

Fig.3.5. L293D Motor Driver

All the Ground pins should be grounded. There are two power pins for this IC, one is the Vss (Vcc1) which provides the voltage for the IC to work, this must be connected to +5V. The other is Vs (Vcc2) which provides voltage for the motors to run, based on the specification of your motor you can connect this pin to anywhere between 4.5V to 36V, here I have connected to +12V.

From the figure Enable pins (Enable 1, 2 and Enable 3, 4) are used to Enable Input pins for Motor 1 and Motor 2 respectively. Since in most cases we will be using both the motors both the pins are held high by default by connecting to +5V supply. The input pins Input 1, 2 which are digital pins 4,5 from Arduino are used to control the motor 1 and Input pins 3, 4 which are digital pins 6,7 from Arduino are used to control the Motor 2. The input pins are connected to the any Digital circuit or microcontroller to control the speed and direction of the motor. You can toggle the input pins based on the following table to control your motor.

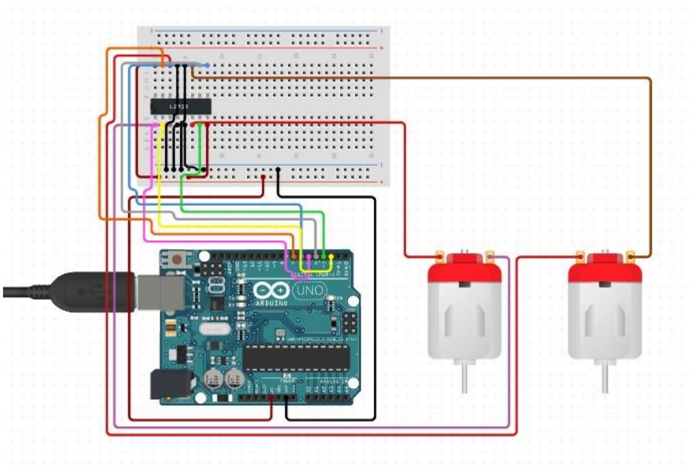

Fig.3.6. Interfacing between Arduino and L293D

3.2.5 Interfacing between Components

we used 8-13 numbered digital pins of Arduino to connect to LCD to display acknowledgment messages, 4-7 numbered digital pins act as output pins from Arduino are connected to the motor driver module i.e L293D as input and output of the module is connected to motors for forward or backward movements, A4 and A5 Analog pins of Arduino act as input and is connected to two Sensors. A one is temperature sensor And Gas Sensor.And it sense the temperature And the GSM is used to send the message to the railway Authorities.

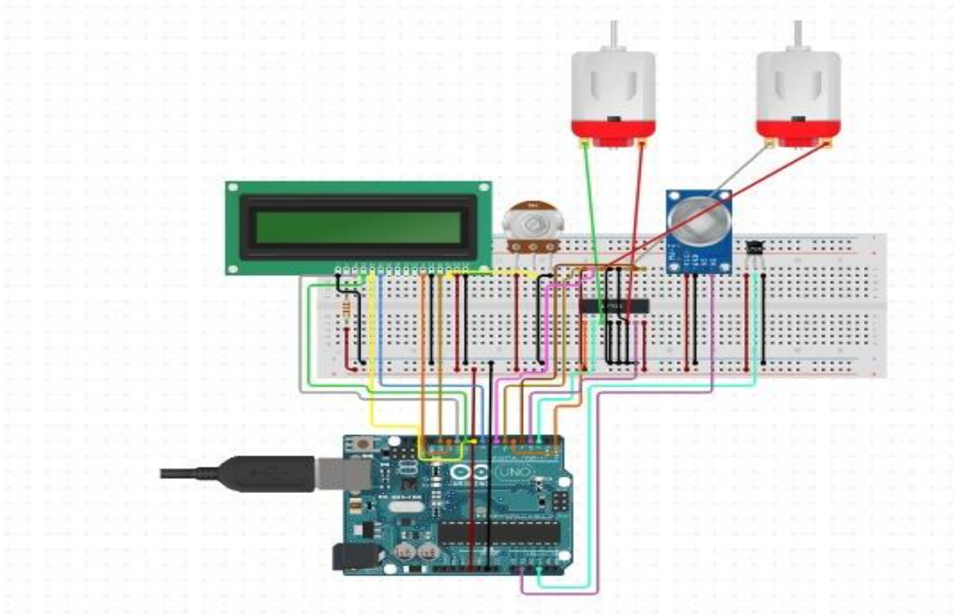

Fig: 3.7 Schematic Diagram of All Components

3.2.6 WORKING:

The whole circuit is designed and implemented on the PCB (Printed Circuit Board). The connections are made as shown in the figure. The 12v supply from the mainline is converted into 5v Dc using a 7805 voltage regulator and capacitors(1000uf and 10uf). There are 2 sensors one is temperature sensor and gas sensor. Thise two sensors are detect the temperature and gas. In this situation the motor turns on . this motor helps to pull the chain to stop the train. The sensed temperature is transmitted to the arduino and displayed on the LCD. The lcd is display the output. The GSM module can be used to send the message to railway authorities .which helP them to take quick decions to take control of fire and evaluting the train. This system works on the microcontrollers and sensors.

CHAPTER-4

HARDWARE AND SOFTWARE COMPONENTS

MICRO CONTROLLER UNIT

4.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 Analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Table 4.1: Atmega328 specifications

4.1.1 Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

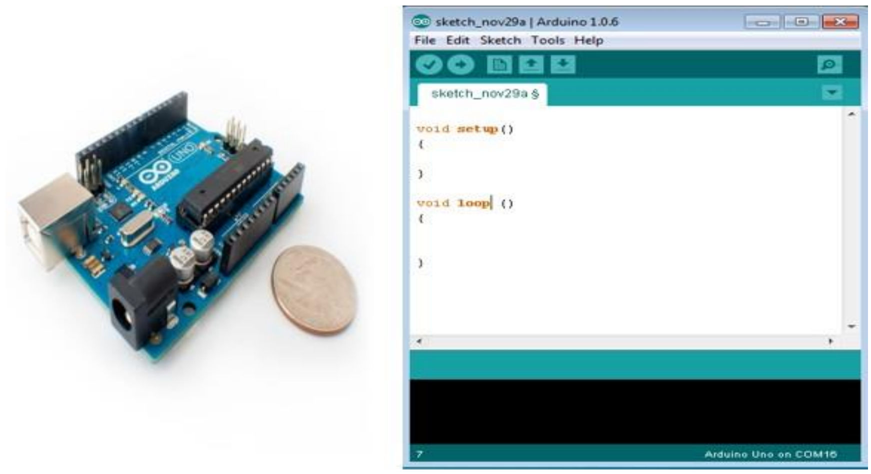

Fig 4.1 Arduino Uno

4.1.2 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

ATMEGA328:

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16 U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16 U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati

LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

4.1.3 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

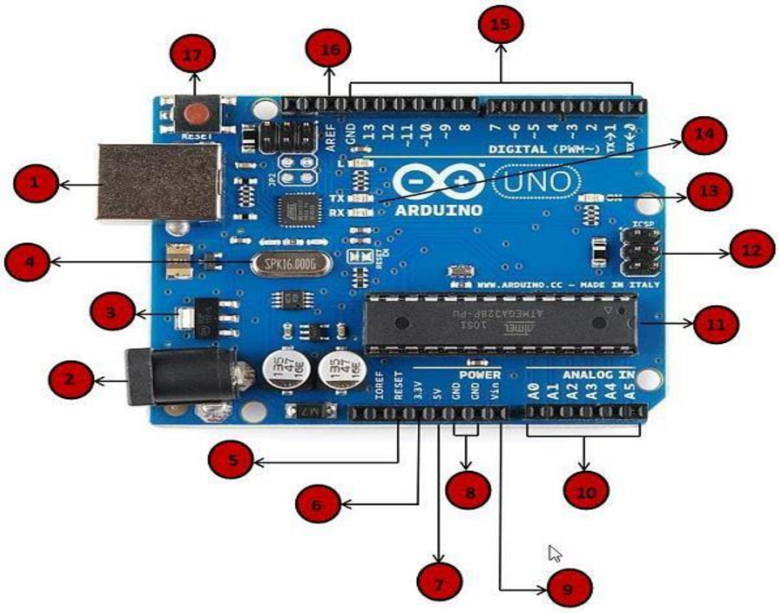

Fig 4.2 Arduino Uno board pins

Pin number and Pin Use

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.

4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.

12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 4.6 Pin Explanation of Arduino

4.1.4 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

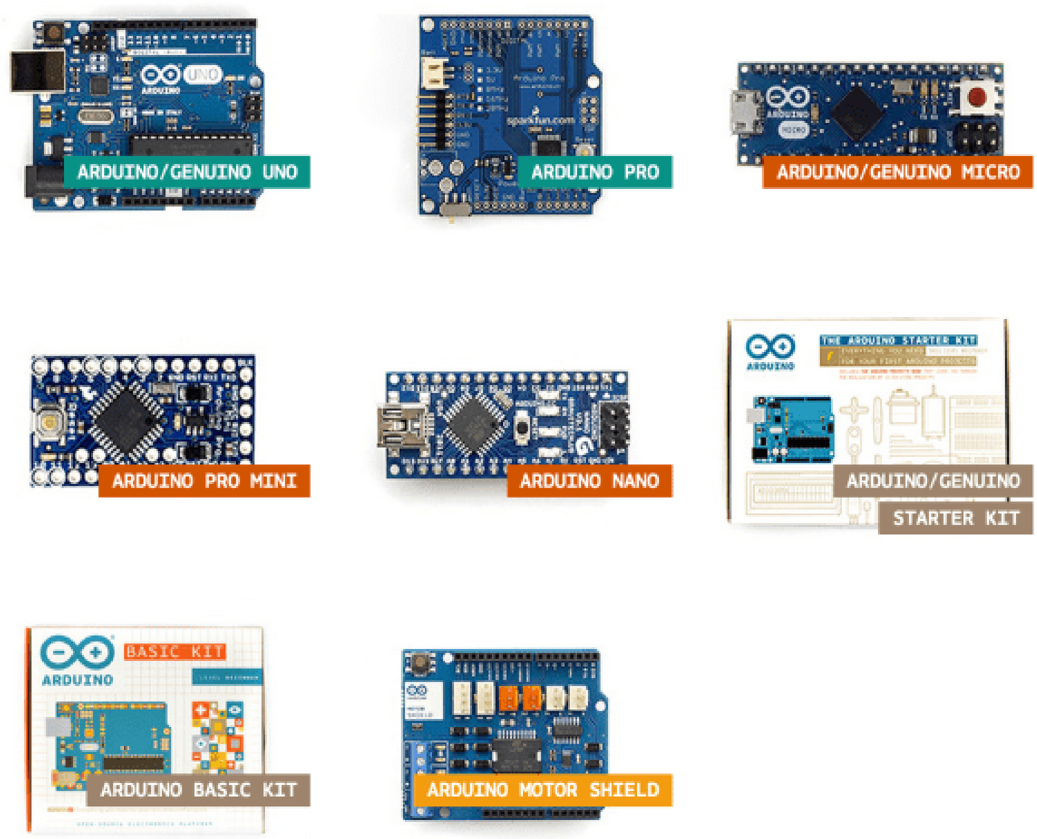

Fig.4.3 Arduino Family

4.1.5 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

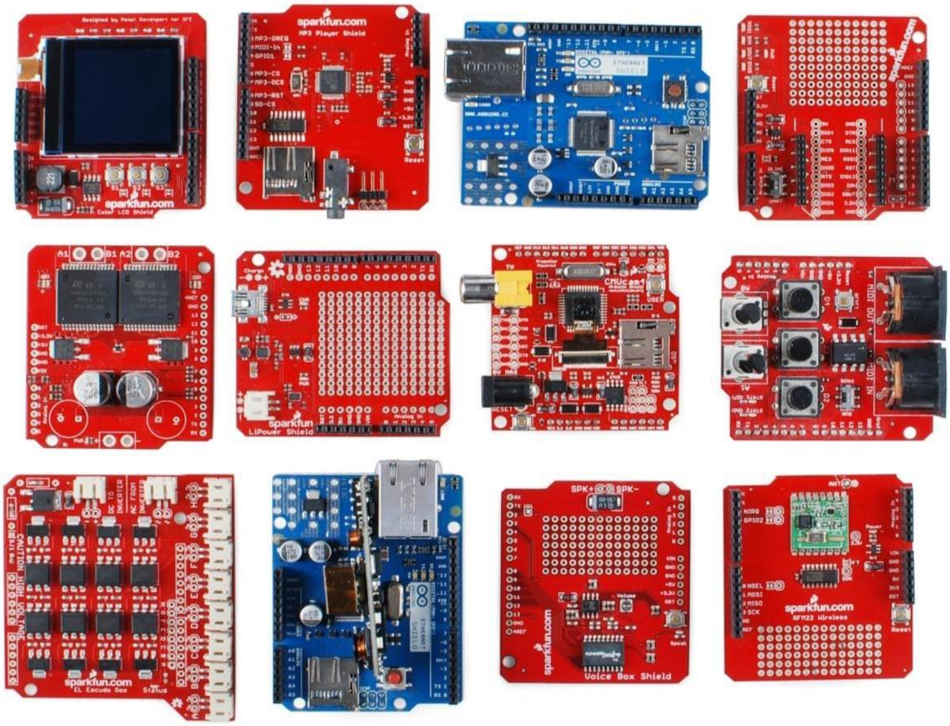

Fig.4.4 Arduino Shields

4.1.6 Pin Description Of Atmega328

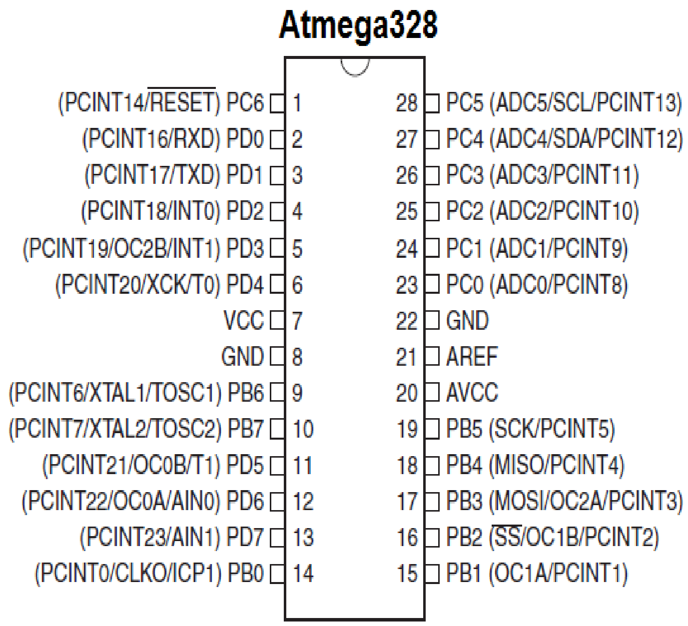

Fig.4.5 Pin description of ATMEGA328

4.1.7 Advantages Of Arduino

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

4.1.8 Applications

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

4.2 POWER SUPPLY UNIT

4.2.1 Introduction:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices.

A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

- **Block Diagram Of Power Supply:**

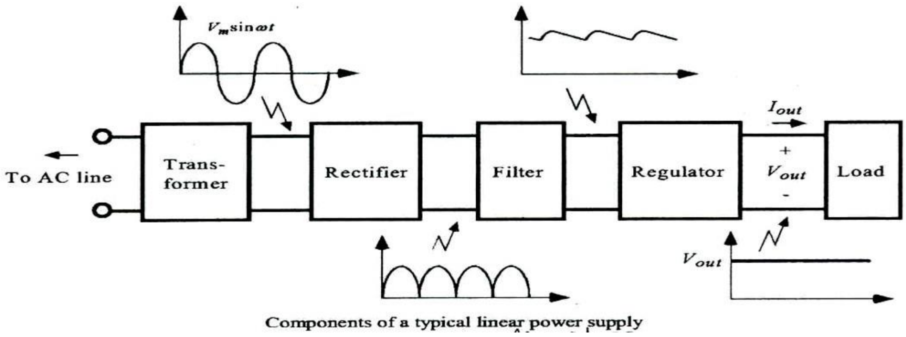

Fig.4.6 (a) Block Diagram of Power Supply

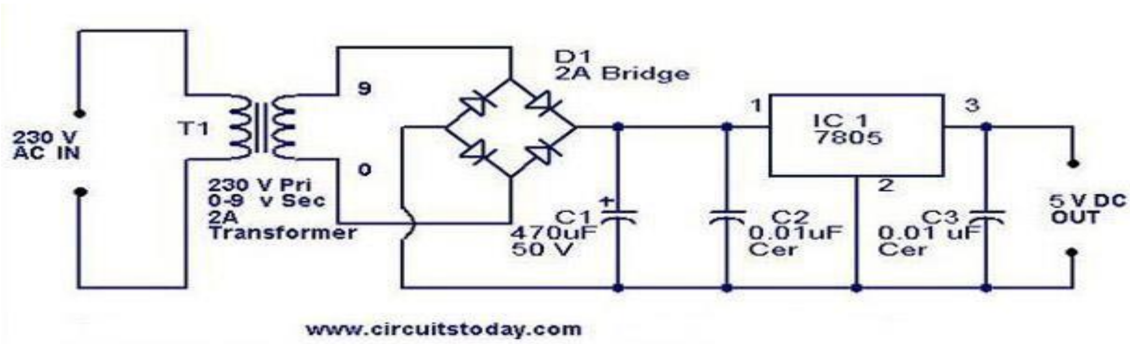

Fig.4.6 (b) Schematic Diagram of Power Supply

- **Description Of Power Supply:**

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered.

For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.2.2 Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

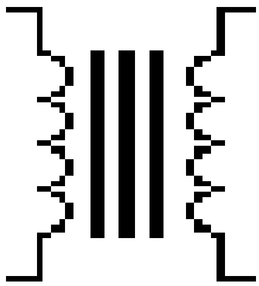

Fig.4.7 (a) Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

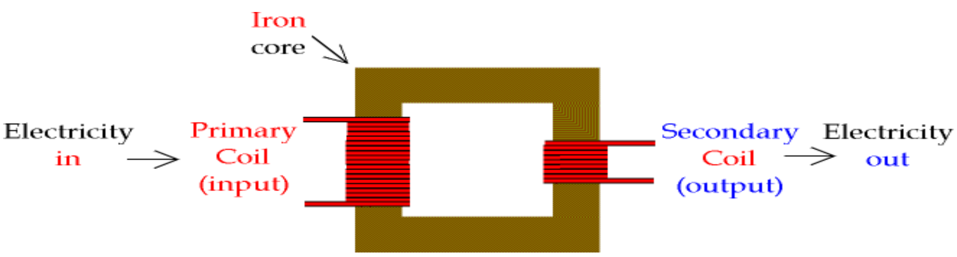

Fig.4.7 (b)Transformer

- **Basic Principle Of Transformer:**

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

- **Working Of Transformer:**

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below.

There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

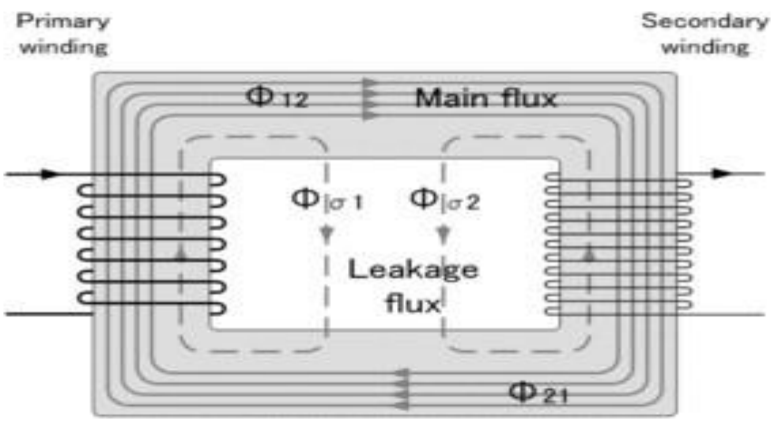

Fig.4.8 Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced EMF. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

- ## Classification Of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage

applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

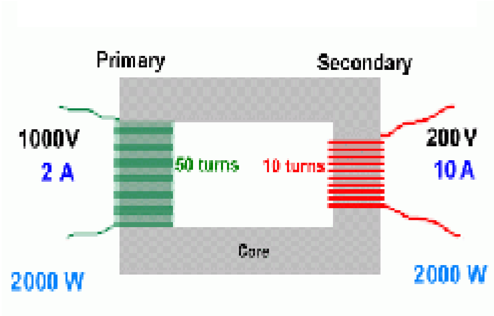

Fig.4.9 (a) Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.**Step down transformers can be considered nothing more than a voltage ratio device.**

With step down transformers the voltage ratio between primary and secondary will mirror the "turn’s ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn’s ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated.

Because of this it is possible to do some non-standard applications using standard transformers.Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.

- **Step-Up Transformer:**

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

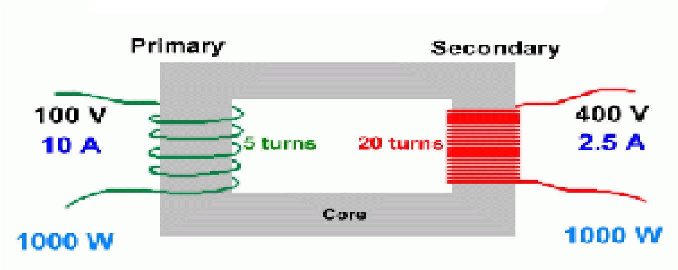

Fig.4.9 (b) Step-Up Transformer

- **Diodes:**

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

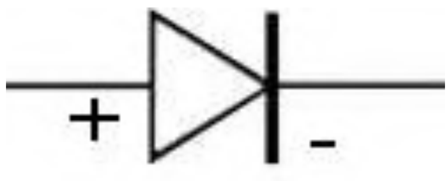

Fig.4.10 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

- **Rectifier:**

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

  - **The Half-Wave Rectifier:**

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

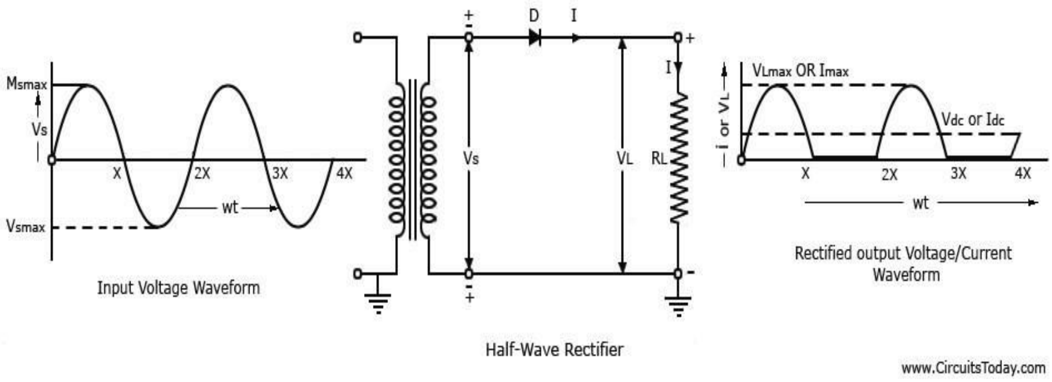

Fig.4.11 (a) Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

- ## The Full-Wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

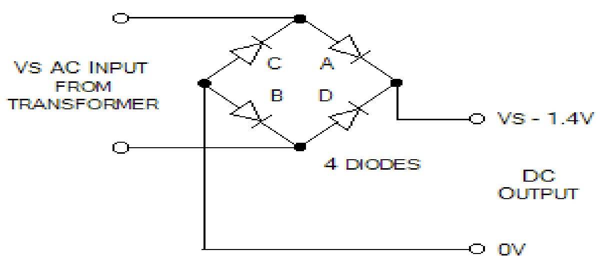

Fig.4.11 (b) Full-Wave Rectifier

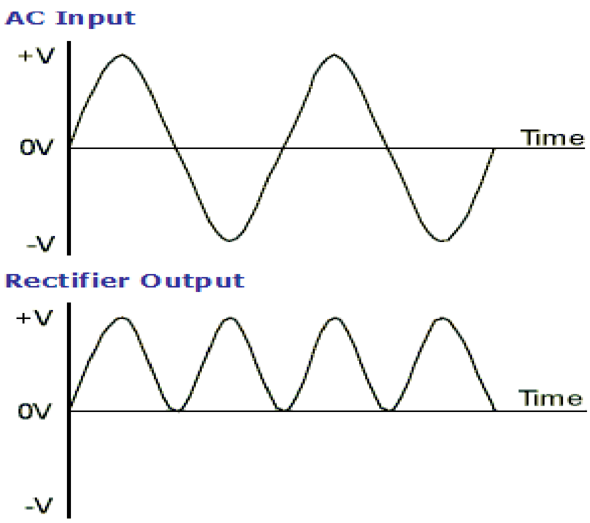

Fig.4.11 (c) Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

- **Capacitor Filter:**

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

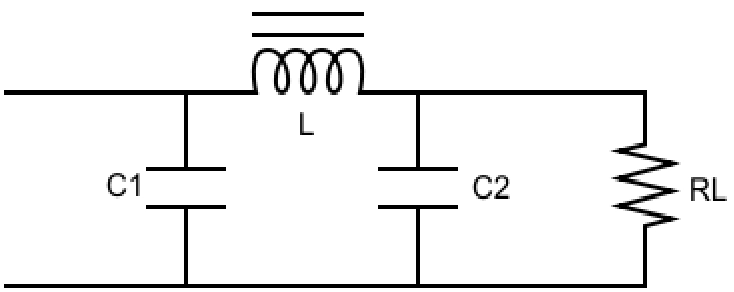

Fig.4.12 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

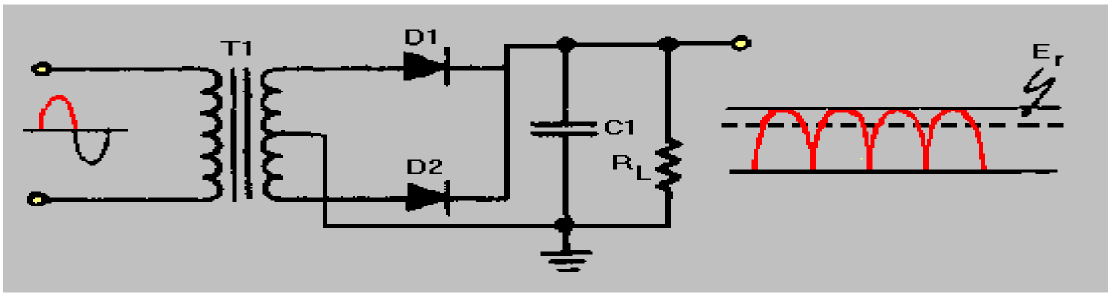

Fig.4.13 Centered Tapped Full-Wave Rectifier with a Capacitor Filter

- **Voltage Regulator:**

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages.

There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

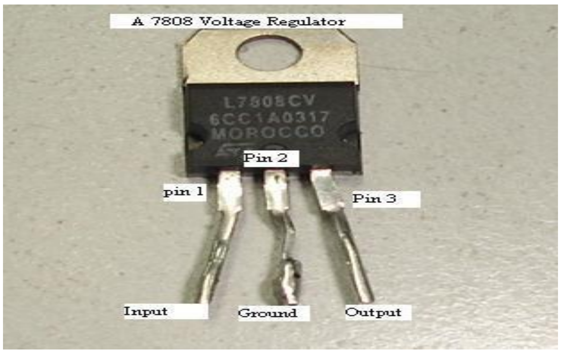

Fig.4.14 Regulator

4.3 TEMPERATURE SENSOR:

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. . The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range.

The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 μA from its supply, it has very low self-heating, less than 0.1°C in still air.

4.31 Features

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60 μA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

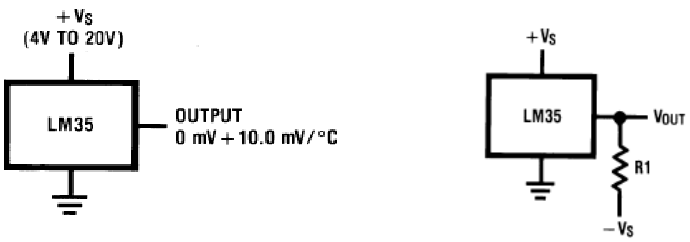

Fig.4.15. Temperature Sensor

The characteristic of this LM35 sensor is:

For each degree of centigrade temperature it outputs 10milli volts.ADC accepts the output from LM35 and converts that data into digital form which is sent to microcontroller for further processing.

Temperature sensing circuit:

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact.

In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

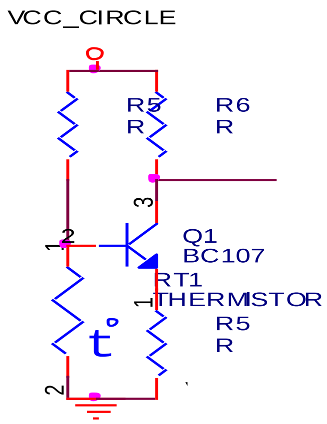

Fig.4.16. Temperature Sensing Circuit

4.4 16 * 2 ALPHANUMERIC LCD

4.4.1 Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

4.4.2 Block diagram

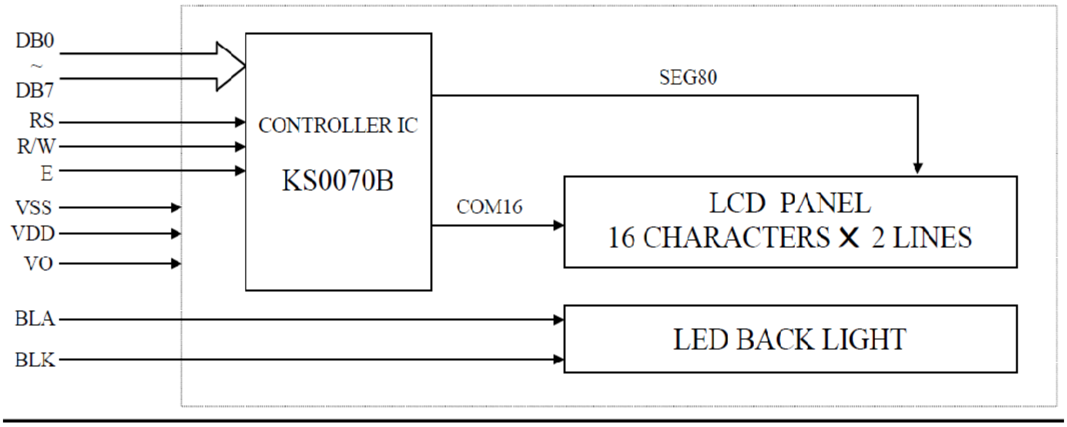

Fig.4.17 Block diagram of LCD display

- **Diplay Data Ram**

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD.

For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

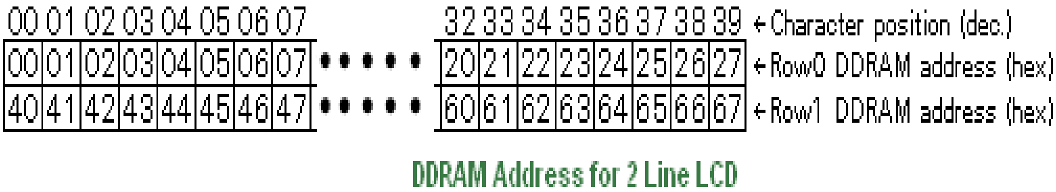

Fig.4.18 DDRAM Address of 2 Line LCD

- **Character Generator Rom**

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

- **Busy Flag**

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

- **Instruction Register (IR) And Data Register (DR)**

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD.

When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.4.3 16 x 2 Alphanumeric LCD Module

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

- **Schematic**

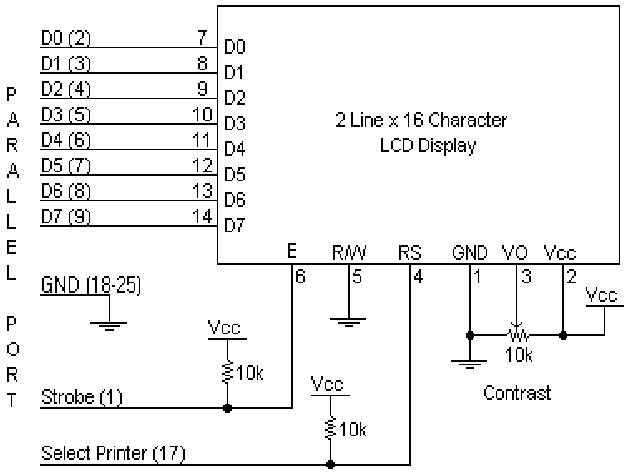

Fig.4.19 Schematic of 2 x16 Character LCD Display

- ## Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.

Note2: Pin 14 is marked with a "1" on the back of the PCB. Do not get confused by this.

Table.4.19 Connector pin Assignment

- ## Circuit Description

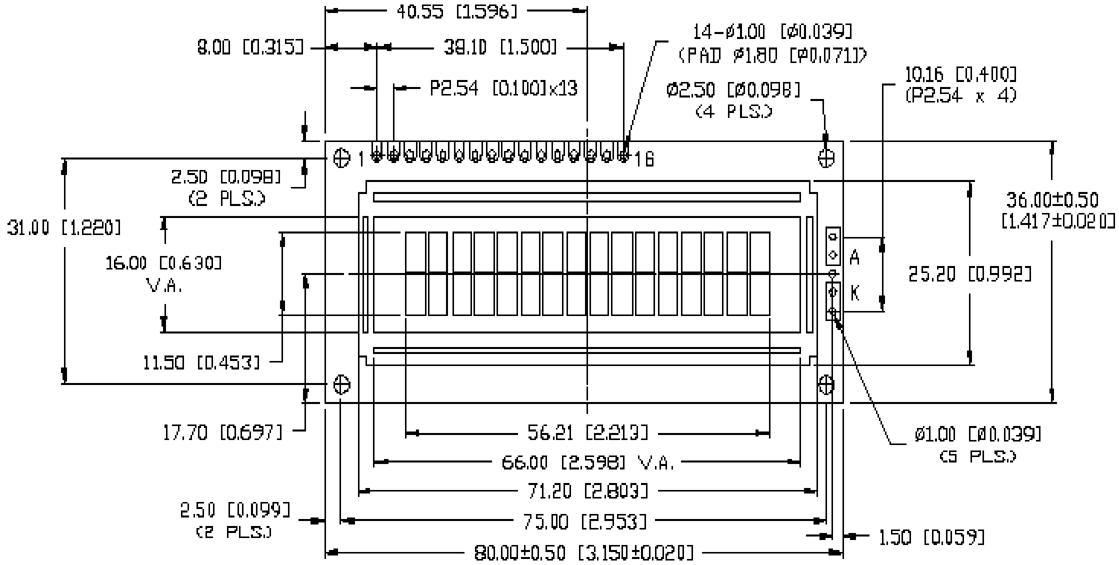

Fig.4.20 Internal Voltage and Current Distribution

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output.

While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

4.5 GSM

Definition of GSM:

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services.

GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. It supports voice calls and data transfer speeds of up to 9.6 kbit/s, together with the transmission of SMS (Short Message Service).

4.5.1 History

In 1982, the European Conference of Postal and Telecommunications Administrations (CEPT) created the Group Special Mobile (GSM) to develop a standard for a mobile telephone system that could be used across Europe. In 1987, a memorandum of understanding was signed by 13 countries to develop a common cellular telephone system across Europe. Finally the system created by SINTEF lead by Torleiv Maseng was selected.

In 1989, GSM responsibility was transferred to the European Telecommunications Standards Institute (ETSI) and phase I of the GSM specifications were published in 1990. The first GSM network was launched in 1991 by Radiolinja in Finland with joint technical infrastructure maintenance from Ericsson.

By the end of 1993, over a million subscribers were using GSM phone networks being operated by 70 carriers across 48 countries. As of the end of 1997, GSM service was available in more than 100 countries and has become the *de facto* standard in Europe and Asia.

GSM Frequencies

GSM networks operate in a number of different frequency ranges (separated into GSM frequency ranges for 2G and UMTS frequency bands for 3G). Most 2G GSM networks operate in the 900 MHz or 1800 MHz bands. Some countries in the Americas (including Canada and the United States) use the 850 MHz and 1900 MHz bands because the 900 and 1800 MHz frequency bands were already allocated. Most 3G GSM networks in Europe operate in the 2100 MHz frequency band. The rarer 400 and 450 MHz frequency bands are assigned in some countries where these frequencies were previously used for first-generation systems.

GSM-900 uses 890–915 MHz to send information from the mobile station to the base station (uplink) and 935–960 MHz for the other direction (downlink), providing 124 RF channels (channel numbers 1 to 124) spaced at 200 kHz. Duplex spacing of 45 MHz is used. In some countries the GSM-900 band has been extended to cover a larger frequency range. This 'extended GSM', E-GSM, uses 880–915 MHz (uplink) and 925–960 MHz (downlink), adding 50 channels (channel numbers 975 to 1023 and 0) to the original GSM-900 band.

Time division multiplexing is used to allow eight full-rate or sixteen half-rate speech channels per radio frequency channel. There are eight radio timeslots (giving eight burst periods) grouped into what is called a TDMA frame. Half rate channels use alternate frames in the same timeslot. The channel data rate for all 8 channels is 270.833 Kbit/s, and the frame duration is 4.615 ms.

The transmission power in the handset is limited to a maximum of 2 watts in GSM850/900 and 1 watt in GSM1800/1900. GSM operates in the 900MHz and 1.8GHz bands in Europe and the 1.9GHz and 850MHz bands in the US. The 850MHz band is also used for GSM and 3G in Australia, Canada and many South American countries. By having harmonized spectrum across most of the globe, GSM's international roaming capability allows users to access the same services when travelling abroad as at home. This gives consumers seamless and same number connectivity in more than 218 countries.

Terrestrial GSM networks now cover more than 80% of the world's population. GSM satellite roaming has also extended service access to areas where terrestrial coverage is not available.

Mobile Telephony Standards

Standard	Generation	Frequency band	Throughput	
GSM	2G	Allows transfer of voice or low-volume digital data.	9.6 kbps	9.6 kbps
GPRS	2.5G	Allows transfer of voice or moderate-volume digital data.	21.4-171.2 kbps	48 kbps
EDGE	2.75G	Allows simultaneous transfer of voice and digital data.	43.2-345.6 kbps	171 kbps
UMTS	3G	Allows simultaneous transfer of voice and high-speed digital data.	0.144-2 Mbps	384 kbps

1G

The first generation of mobile telephony (written **1G**) operated using analogue communications and portable devices that were relatively large. It used primarily the following standards:

- **AMPS** (Advanced Mobile Phone System), which appeared in 1976 in the United States, was the first cellular network standard. It was used primarily in the Americas, Russia and Asia. This first-generation analogue network had weak security mechanisms which allowed hacking of telephones lines.
- **TACS** (Total Access Communication System) is the European version of the AMPS model. Using the 900 MHz frequency band, this system was largely used in England and then in Asia (Hong-Kong and Japan).
- **ETACS** (Extended Total Access Communication System) is an improved version of the TACS standard developed in the United Kingdom that uses a larger number of communication channels.

The first-generation cellular networks were made obsolete by the appearance of an entirely digital second generation.

Second Generation of Mobile Networks (2G)

The second generation of mobile networks marked a break with the first generation of cellular telephones by switching from analogue to digital. The main 2G mobile telephony standards are:

- GSM (*Global System for Mobile communications*) is the most commonly used standard in Europe at the end of the 20th century and supported in the United States. This standard uses the 900 MHz and 1800 MHz frequency bands in Europe. In the United States, however, the frequency band used is the 1900 MHz band. Portable telephones that are able to operate in Europe and the United States are therefore called **tri-band**.

- **CDMA** (*Code Division Multiple Access*) uses a spread spectrum technique that allows a radio signal to be broadcast over a large frequency range.
- **TDMA** (*Time Division Multiple Access*) uses a technique of time division of communication channels to increase the volume of data transmitted simultaneously. TDMA technology is primarily used on the American continent, in New Zealand and in the Asia-Pacific region.

With the 2G networks, it is possible to transmit voice and low volume digital data, for example text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*). The GSM standard allows a maximum data rate of 9.6 kbps.

Extensions have been made to the GSM standard to improve throughput. One of these is the **GPRS** (*General Packet Radio System*) service which allows theoretical data rates on the order of 114 Kbit/s but with throughput closer to 40 Kbit/s in practice. As this technology does not fit within the "3G" category, it is often referred to as **2.5G**

The **EDGE** (*Enhanced Data Rates for Global Evolution*) standard, billed as **2.75G**, quadruples the throughput improvements of GPRS with its theoretical data rate of 384 Kbps, thereby allowing the access for multimedia applications. In reality, the EDGE standard allows maximum theoretical data rates of 473 Kbit/s, but it has been limited in order to comply with the IMT-2000 (*International Mobile Telecommunications-2000*) specifications from the ITU (*International Telecommunications Union*).

3G

The IMT-2000 (*International Mobile Telecommunications for the year 2000*) specifications from the International Telecommunications Union (ITU) defined the characteristics of **3G** (third generation of mobile telephony). The most important of these characteristics are:

1. High transmission data rate.
2. 144 Kbps with total coverage for mobile use.
3. 384 Kbps with medium coverage for pedestrian use.
4. 2 Mbps with reduced coverage area for stationary use.
5. World compatibility.
6. Compatibility of 3rd generation mobile services with second generation networks.

3G offers data rates of more than 144 Kbit/s, thereby allowing the access to multimedia uses such as video transmission, video-conferencing or high-speed internet access. 3G networks use different frequency bands than the previous networks: 1885-2025 MHz and 2110-2200 MHz.

The main 3G standard used in Europe is called **UMTS** (*Universal Mobile Telecommunications System*) and uses **WCDMA** (*Wideband Code Division Multiple Access*) encoding. UMTS technology uses 5 MHz bands for transferring voice and data, with data rates that can range from 384 Kbps to 2 Mbps. **HSDPA** (*High Speed Downlink Packet Access*) is a third generation mobile telephony protocol, (considered as "3.5G"), which is able to reach data rates on the order of 8 to 10 Mbps. HSDPA technology uses the 5 GHz frequency band and uses WCDMA encoding.

Introduction to the GSM Standard

The **GSM** (*Global System for Mobile communications*) network is at the start of the 21st century, the most commonly used mobile telephony standard in Europe. It is called as Second Generation (2G) standard because communications occur in an entirely digital mode, unlike the first generation of portable telephones. When it was first standardized in 1982, it was called as **Group Special Mobile** and later, it became an international standard called **"Global System for Mobile communications"** in 1991.

In Europe, the GSM standard uses the 900 MHz and 1800 MHz frequency bands. In the United States, however, the frequency band used is the 1900 MHz band. For this reason, portable telephones that are able to operate in both Europe and the United States are called **tri-band** while those that operate only in Europe are called **bi-band**.

The GSM standard allows a maximum throughput of 9.6 kbps which allows transmission of voice and low-volume digital data like text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*).

GSM Standards:

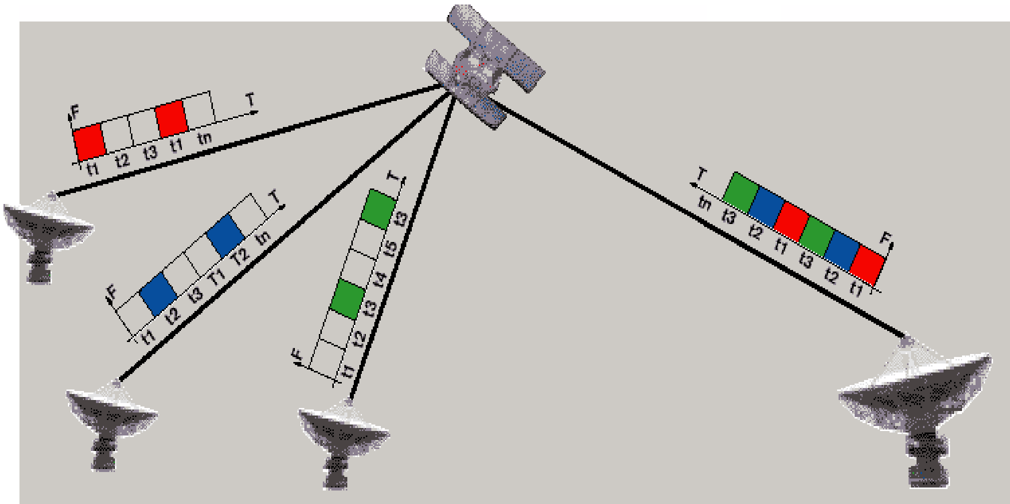
GSM uses narrowband TDMA, which allows eight simultaneous calls on the same radio frequency. There are three basic principles in multiple access, FDMA (Frequency Division Multiple Access), TDMA (Time Division Multiple Access), and CDMA (Code Division Multiple Access). All three principles allow multiple users to share the same physical channel. But the two competing technologies differ in the way user sharing the common resource.

TDMA allows the users to share the same frequency channel by dividing the signal into different time slots. Each user takes turn in a round robin fashion for transmitting and receiving over the channel. Here, users can only transmit in their respective time slot.

CDMA uses a spread spectrum technology that is it spreads the information contained in a particular signal of interest over a much greater bandwidth than the original signal. Unlike TDMA, in CDMA several users can transmit over the channel at the same time.

TDMA in brief:

In late1980’s, as a search to convert the existing analog network to digital as a means to improve capacity, the cellular telecommunications industry association chose TDMA over FDMA. Time Division Multiplex Access is a type of multiplexing where two or more channels of information are transmitted over the same link by allocating a different time interval for the transmission of each channel. The most complex implementation using TDMA principle is of GSM’s (Global System for Mobile communication). To reduce the effect of co-channel interference, fading and multipath, the GSM technology can use frequency hopping, where a call jumps from one channel to another channel in a short interval.



Time Division Multiple Access

TDMA systems still rely on switch to determine when to perform a handoff. Handoff occurs when a call is switched from one cell site to another while travelling. The TDMA handset constantly monitors the signals coming from other sites and reports it to the switch without caller’s awareness. The switch then uses this information for making better choices for handoff at appropriate times. TDMA handset performs hard handoff, i.e., whenever the user moves from one site to another, it breaks the connection and then provides a new connection with the new site.

Advantages of TDMA:

There are lots of advantages of TDMA in cellular technologies.

1. It can easily adapt to transmission of data as well as voice communication.
2. It has an ability to carry 64 kbps to 120 Mbps of data rates. This allows the operator to do services like fax, voice band data and SMS as well as bandwidth intensive application such as multimedia and video conferencing.
3. Since TDMA technology separates users according to time, it ensures that there will be no interference from simultaneous transmissions.
4. It provides users with an extended battery life, since it transmits only portion of the time during conversations. Since the cell size grows smaller, it proves to save base station equipment, space and maintenance.

TDMA is the most cost effective technology to convert an analog system to digital.

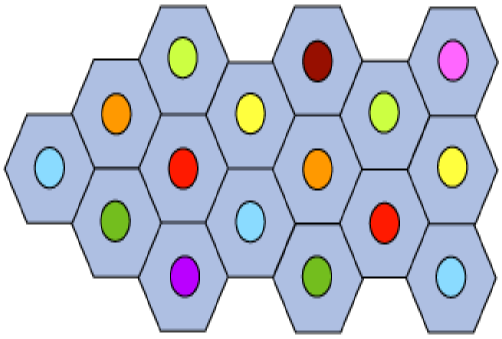
Disadvantages of TDMA:

One major disadvantage using TDMA technology is that the users has a predefined time slot. When moving from one cell site to other, if all the time slots in this cell are full the user might be disconnected. Likewise, if all the time slots in the cell in which the user is currently in are already occupied, the user will not receive a dial tone.

The second problem in TDMA is that it is subjected to multipath distortion. To overcome this distortion, a time limit can be used on the system. Once the time limit is expired, the signal is ignored.

The concept of cellular network

Mobile telephone networks are based on the concept of **cells**, circular zones that overlap to cover a geographical area.



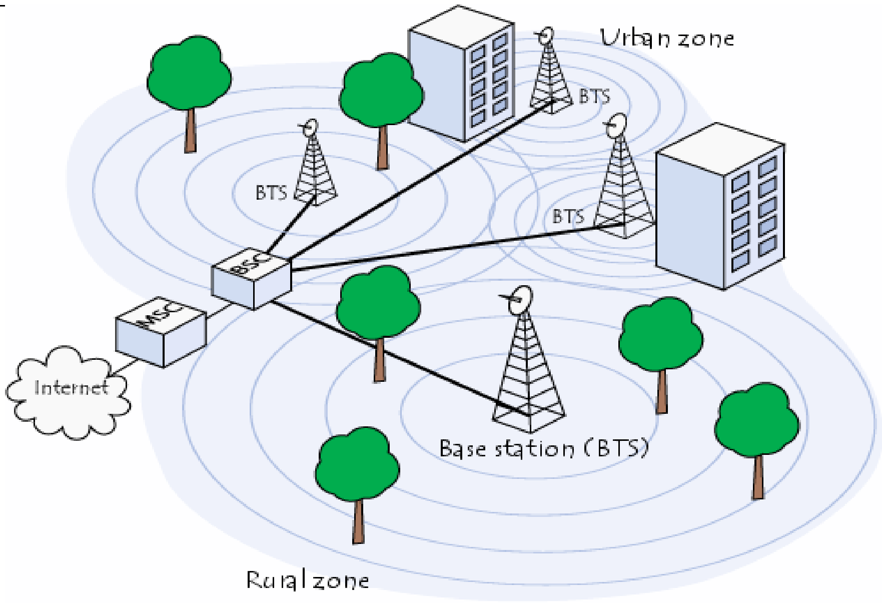
Cellular networks are based on the use of a central transmitter-receiver in each cell, called a "**base station**" (or *Base Transceiver Station*, written **BTS**). The smaller the radius of a cell, the higher is the available bandwidth. So, in highly populated urban areas, there are cells with a radius of a few hundred meters, while huge cells of up to 30 kilometers provide coverage in rural areas.

In a cellular network, each cell is surrounded by 6 neighbouring cells (thus a cell is generally drawn as a hexagon). To avoid interference, adjacent cells cannot use the same frequency. In practice, two cells using the same frequency range must be separated by a distance of two to three times the diameter of the cell.

Architecture of the GSM Network

In a GSM network, the user terminal is called a **mobile station**. A mobile station is made up of a **SIM** (*Subscriber Identity Module*) card allowing the user to be uniquely identified and a mobile terminal. The terminals (devices) are identified by a unique 15-digit identification number called **IMEI** (*International Mobile Equipment Identity*). Each SIM card also has a unique (and secret) identification number called **IMSI** (*International Mobile Subscriber Identity*). This code can be protected using a 4-digit key called a *PIN code*.

The SIM card therefore allows each user to be identified independently of the terminal used during communication with a base station. Communications occur through a radio link (air interface) between a mobile station and a base station.



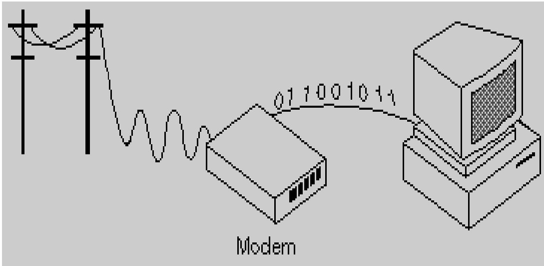
All the base stations of a cellular network are connected to a **base station controller** (**BSC**) which is responsible for managing distribution of the resources. The system consisting of the base station controller and its connected base stations is called the **Base Station Subsystem** (**BSS**).

Finally, the base station controllers are themselves physically connected to the **Mobile Switching Centre** (**MSC**), managed by the telephone network operator, which connects them to the public telephone network and the Internet. The MSC belongs to a **Network Station Subsystem** (**NSS**), which is responsible for managing user identities, their location and establishment of communications with other subscribers. The MSC is generally connected to databases that provide additional functions:

1. The **Home Location Register** (**HLR**) is a database containing information (geographic position, administrative information etc.) of the subscribers registered in the area of the switch (MSC).
2. The **Visitor Location Register** (**VLR**) is a database containing information of users other than the local subscribers. The VLR retrieves the data of a new user from the HLR of the user's subscriber zone. The data is maintained as long as the user is in the zone and is deleted when the user leaves or after a long period of inactivity (terminal off).
3. The **Equipment Identify Register** (**EIR**) is a database listing the mobile terminals.
4. The **Authentication Centre** (**AUC**) is responsible for verifying user identities.
5. The cellular network formed in this way is designed to support mobility via management of *handovers* (movements from one cell to another).

Finally, GSM networks support the concept of **roaming** i.e., movement from one operator network to another.

Introduction to Modem:



Modem stands for *modulator-demodulator.*

A modem is a device or program that enables a computer to transmit data over telephone or cable lines. Computer information is stored digitally, whereas information transmitted over telephone lines is transmitted in the form of analog waves. A modem converts between these two forms.

Fortunately, there is one standard interface for connecting external modems to computers called *RS-232*. Consequently, any external modem can be attached to any computer that has an RS-232 port, which almost all personal computers have. There are also modems that come as an expansion board that can be inserted into a vacant expansion slot. These are sometimes called *onboard* or *internal modems*.

While the modem interfaces are standardized, a number of different protocols for formatting data to be transmitted over telephone lines exist. Some, like CCITT V.34 are official standards, while others have been developed by private companies. Most modems have built-in support for the more common protocols at slow data transmission speeds at least, most modems can communicate with each other. At high transmission speeds, however, the protocols are less standardized.

Apart from the transmission protocols that they support, the following characteristics distinguish one modem from another:

- **Bps:** How fast the modem can transmit and receive data. At slow rates, modems are measured in terms of baud rates. The slowest rate is 300 baud (about 25 cps). At higher speeds, modems are measured in terms of bits per second (bps). The fastest modems run at 57,600 bps, although they can achieve even higher data transfer rates by compressing the data. Obviously, the faster the transmission rate, the faster the data can be sent and received. It should be noted that the data cannot be received at a faster rate than it is being sent.
- **Voice/data:** Many modems support a switch to change between voice and data modes. In data mode, the modem acts like a regular modem. In voice mode, the modem acts like a regular telephone. Modems that support a voice/data switch have a built-in loudspeaker and microphone for voice communication.
- **Auto-answer:** An auto-answer modem enables the computer to receive calls in the absence of the operator.

- **Data compression:** Some modems perform data compression, which enables them to send data at faster rates. However, the modem at the receiving end must be able to decompress the data using the same compression technique.
- **Flash memory:** Some modems come with *flash memory* rather than conventional ROM which means that the communications protocols can be easily updated if necessary.
- **Fax capability:** Most modern modems are fax modems, which mean that they can send and receive faxes.

GSM Modem:

A GSM modem is a wireless modem that works with a GSM wireless network. A wireless modem behaves like a dial-up modem. The main difference between them is that a dial-up modem sends and receives data through a fixed telephone line while a wireless modem sends and receives data through radio waves.

A GSM modem can be an external device or a PC Card / PCMCIA Card. Typically, an external GSM modem is connected to a computer through a serial cable or a USB cable. A GSM modem in the form of a PC Card / PCMCIA Card is designed for use with a laptop computer. It should be inserted into one of the PC Card / PCMCIA Card slots of a laptop computer. Like

4.6 L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to Built in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

4.6.1 Introduction to L293D

L293D is basically a motor driver or controller. It has two built in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc.

Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

Fig.4.20 L293D

1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	V_{CC2}
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	V_{CC1}

4.7MOTORS

4.7.1Definition

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
  - AC motor, an electric motor that is driven by alternating current
    - Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
    - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction
  - DC motor, an electric motor that runs on direct current electricity
    - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
    - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
  - Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
  - Servo motor, an electric motor that operates a servo, commonly used in robotics

- Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

4.7.2 Types of Motors

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

1. **AC Motors**

The most common and simple industrial motor is the three phase AC induction motor, sometimes known as the "squirrel cage" motor. Substantial information can be found about any motor by checking its (nameplate).

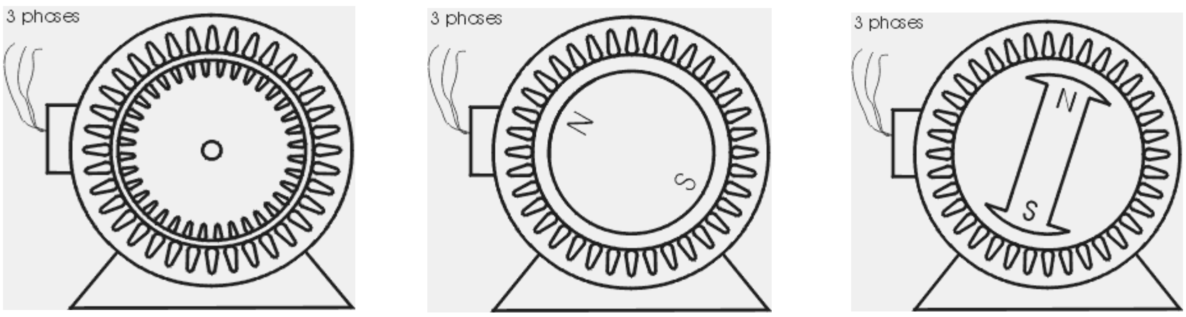

Fig.4.22. 3 Phase AC Induction Motor

Advantages

- Simple Design
- Low Cost
- Reliable Operation
- Easily Found Replacements
- Variety of Mounting Styles
- Many Different Environmental Enclosures

Simple Design

The simple design of the AC motor -- simply a series of three windings in the exterior (stator) section with a simple rotating section (rotor). The changing field caused by the 50 or 60 Hertz AC line voltage causes the rotor to rotate around the axis of the motor.

The speed of the AC motor depends only on three variables:

1. The fixed number of winding sets (known as poles) built into the motor, which determines the motor's base speed.
2. The frequency of the AC line voltage. Variable speed drives change this frequency to change the speed of the motor.
3. The amount of torque loading on the motor, which causes slip.

Low Cost

The AC motor has the advantage of being the lowest cost motor for applications requiring more than about 1/2 hp (325 watts) of power. This is due to the simple design of the motor. For this reason, AC motors are overwhelmingly preferred for fixed speed applications in industrial applications and for commercial and domestic applications where AC line power can be easily attached. Over 90% of all motors are AC induction motors. They are found in air conditioners, washers, dryers, industrial machinery, fans, blowers, vacuum cleaners, and many, many other applications.

- **Reliable Operation**

The simple design of the AC motor results in extremely reliable, low maintenance operation. Unlike the DC motor, there are no brushes to replace. If run in the appropriate environment for its enclosure, the AC motor can expect to need new bearings after several years of operation. If the application is well designed, an AC motor may not need new bearings for more than a decade.

- **Easily Found Replacements**

The wide use of the AC motor has resulted in easily found replacements. Many manufacturers adhere to either European (metric) or American (NEMA) standards. (For Replacement Motors) Variety of Mounting Styles

AC Motors are available in many different mounting styles such as:

- Foot Mount
- C-Face
- Large Flange
- Vertical
- Specialty

2. DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

- **Advantages**

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

- **Easy to understand design**

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings.

Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

- **Easy to control speed**

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjunction with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparable AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

- **Easy to control torque**

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

- **Simple, cheap drive design**

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance trade offs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

- **Disadvantages**
  - Expensive to produce
  - Can't reliably control at lowest speeds
  - Physically larger
  - High maintenance
  - Dust

4.7.3 WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.

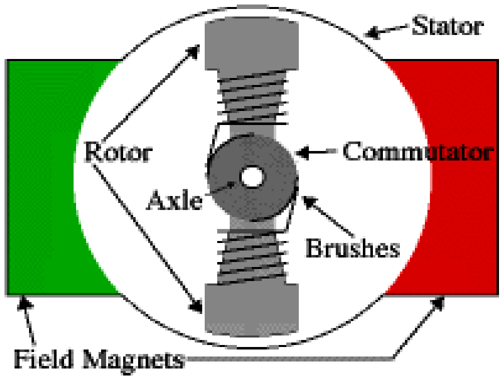

Fig.4.23 Internal Components of Motor

Principle

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously. When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout-- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator.

You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).

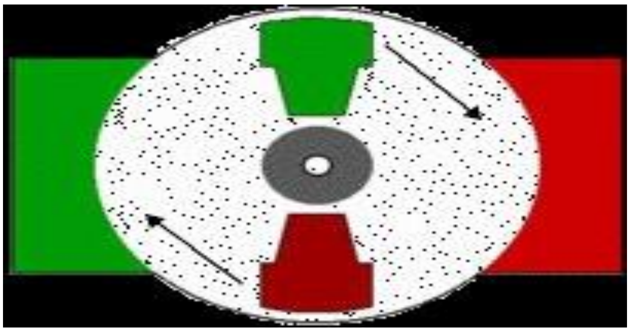

Fig.4.24 Rotation of two polar Motor

- **Construction and Working**

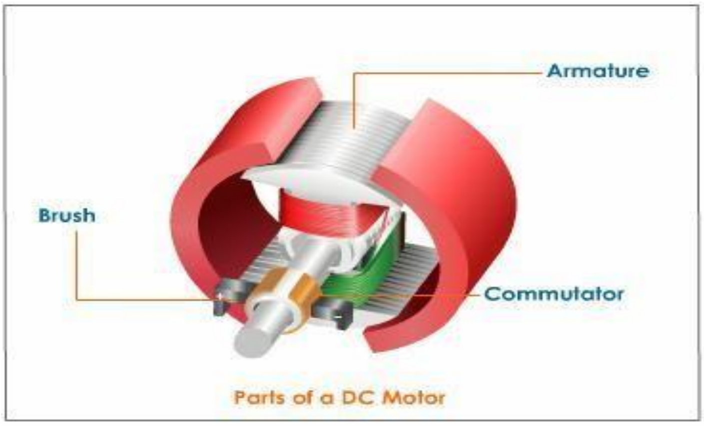

Fig.4.25 Parts of DC Motor

4.7.4 Parts of a DC Motor

- **Armature**

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

- **Commutator**

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.

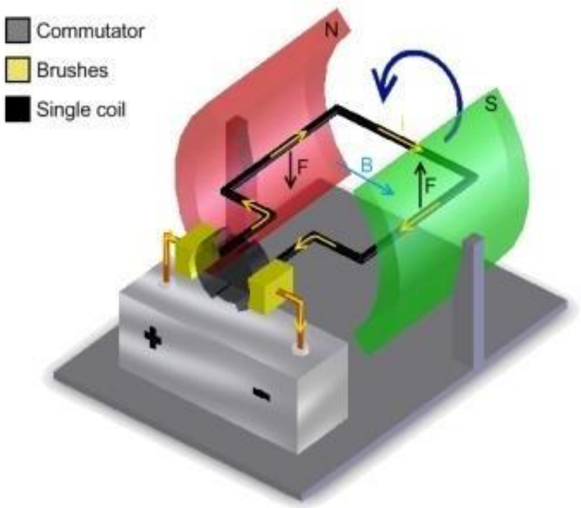

Fig.4.26 Commutator

- **Brushes**

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

- **Working of a DC Motor**

When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.

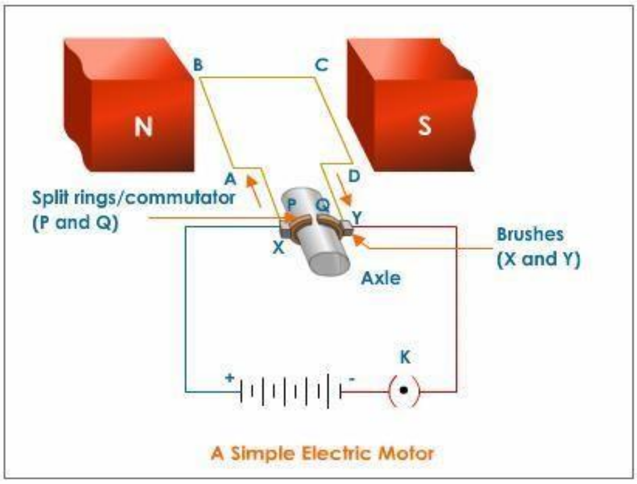

Fig.4.27 Simple Electric Motor

When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

However the coil keeps turning because of its own momentum. Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.

4.6.4 Parameters of the Dc Motors

- Direction of rotation
- Motor Speed
- Motor Torque
- Motor Start and Stop

▪ Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.

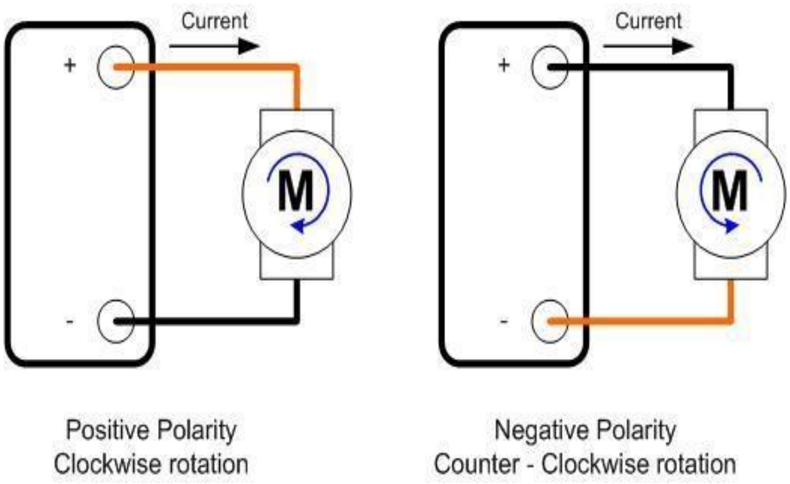

Fig.4.28Motor rotation with Polarity

▪ DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.

- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

DC Motor Speed

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as attract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attraction will try to take place. As a result, motor speed is directly proportional to applied voltage.

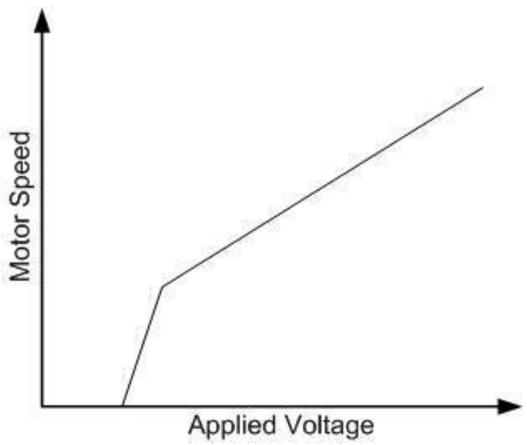

Fig.4.29 Motor Speed Vs Applied Voltage

Motor Speed Curve

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will supply not move. This is because the magnetic field strength is not enough to overcome friction.

Once friction is overcome, motor speed will start to increase as voltage increase. The following video shows the concept of speed control and offers some ideas on how this can be achieved.

- ## Motor Torque

In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.

Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy cannot be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

$$\mathbf{P = IV}$$

Where P is power, I is motor current and V is motor voltage. Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current.As you increase load (or torque requirements) current must also increase.

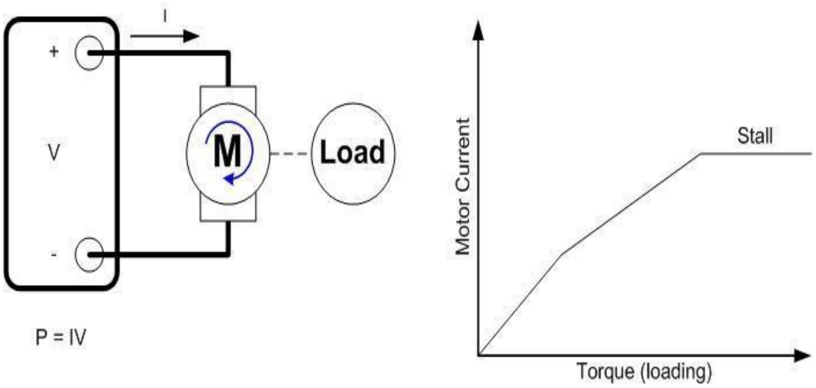

Fig.4.30 Torque Vs Motor Current

- **Motor Loading**

One aspect about DC motors which we must not forget is that loading or increase of torque cannot be infinite as there is a point in which the motor simply cannot move. When this happens, we call this loading “Stalling Torque”. At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

- **Motor Start and Stop**

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current cannot change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.

Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.

Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs.

The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back EMF is directly proportional to speed, making Back EMF = 0, also means making speed = 0.

4.6.5 MOTOR DRIVER CIRCUIT

The name "H-Bridge" is derived from the actual shape of the switching circuit which control the motion of the motor. It is also known as "Full Bridge". Basically there are four switching elements in the H-Bridge as shown in the figure below.

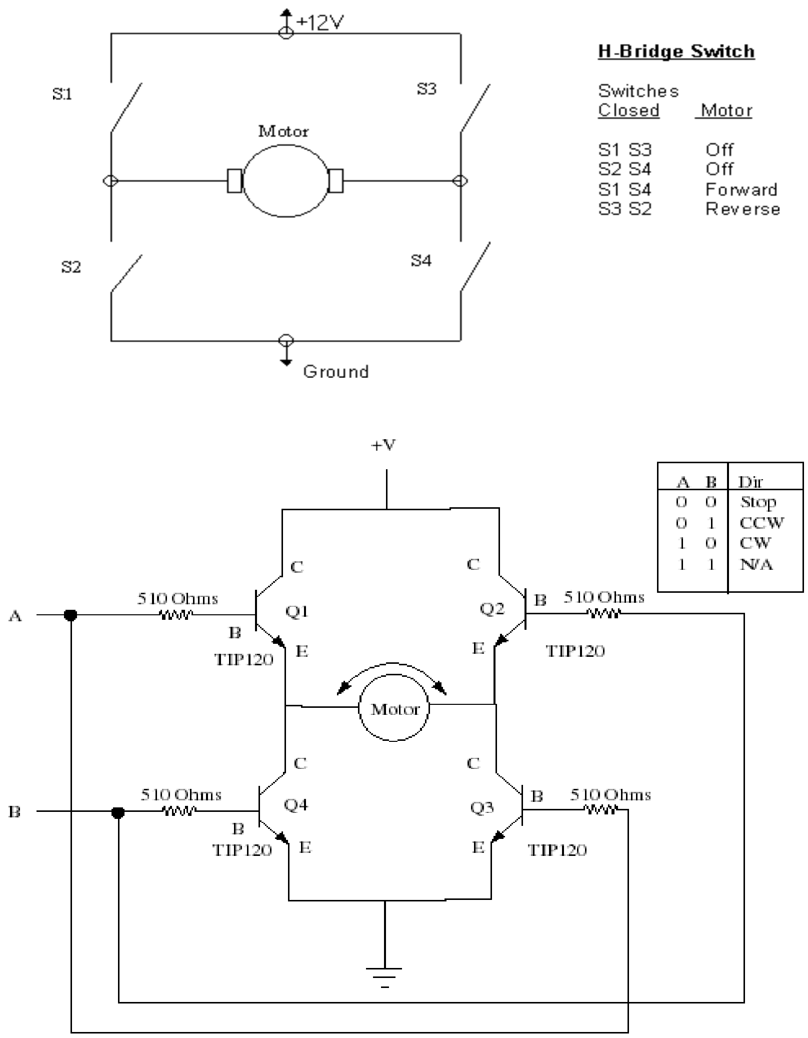

Fig.4.30 Motor driver Circuit

As you can see in the figure above there are four switching elements named as "High side left", "High side right", "Low side right", "Low side left". When these switches are turned on in pairs motor changes its direction accordingly. Like, if we switch on High side left and Low side right then motor rotate in forward direction, as current flows from Power supply

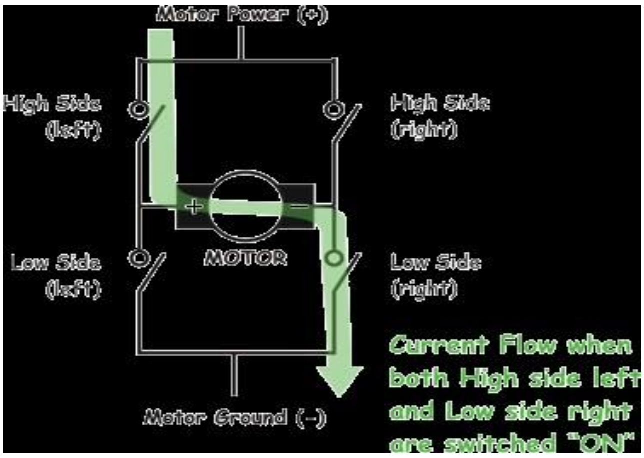

Fig.4.31 Current in Motor Circuit

Similarly, when you switch on low side left and high side right, the current flows in opposite direction and motor rotates in backward direction. This is the basic working of H-Bridge. We can also make a small truth table according to the switching of H-Bridge explained above.

Truth Table

High Left	High Right	Low Left	Low Right	Description
On	Off	Off	On	Motor runs clockwise
Off	On	On	Off	Motor runs anti-clockwise
On	On	Off	Off	Motor stops or decelerates
Off	Off	On	On	Motor stops or decelerates

Table.4.9 Truth Tables

As already said, H-bridge can be made with the help of transistors as well as MOSFETs, the only thing is the power handling capacity of the circuit. If motors are needed to run with high current then lot of dissipation is there. So head sinks are needed to cool the circuit.

Now you might be thinking why I did not discuss the cases like High side left on and Low side left on or high side right on and low side right on. Clearly seen in the diagram, you don't want to burn your power supply by shorting them. So that is why those combinations are not discussed in the truth table.

4.8 GAS SENSOR

Fig.4.32 Gas Sensor

4.8.1 Description

A gas detector is a device that detects the presence of gases in an area , often as part of a safety system .A gas detector can should an alarm to operators in the area where the leak is occurring, giving them the opportunity to leave.This type of device is important because there are many gases that can be harmful to organic life, such as humans or animals.A temperature sensor is an electronic device that measures c the temperature of its environment and converts the input data into electric data to record ,monitor temperature changes.

4.9 SOFTWARE EXPLINATION

Software Requirements

- Proteus simulation
- Arduino software
- Programming language

4.9.1 Arduino software

Arduino is an open-s4ource prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike.

Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IOT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

4.9.2 Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux.

Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments.

Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand thectechnical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version

- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- Download the Arduino Software(IDE)
- Proceed with board specific instructions.

4.9.3 How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1

First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.33 (a) Standard USB Cable

Fig.4.34 (b) USB cable Mini-B

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

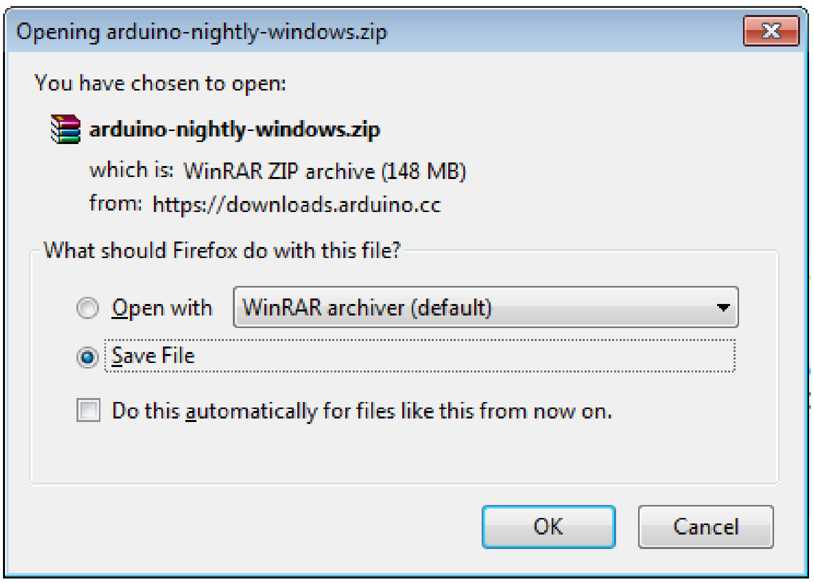

Fig.4.35 Process of Downloading the Arduino

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply.

If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe).

Double-click the icon to start the IDE.

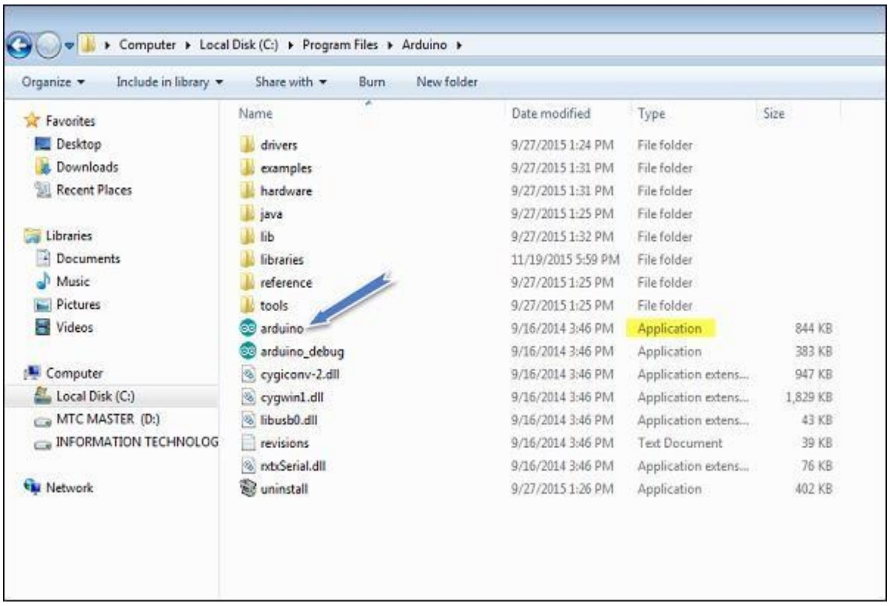

Fig.4.36 Launching Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

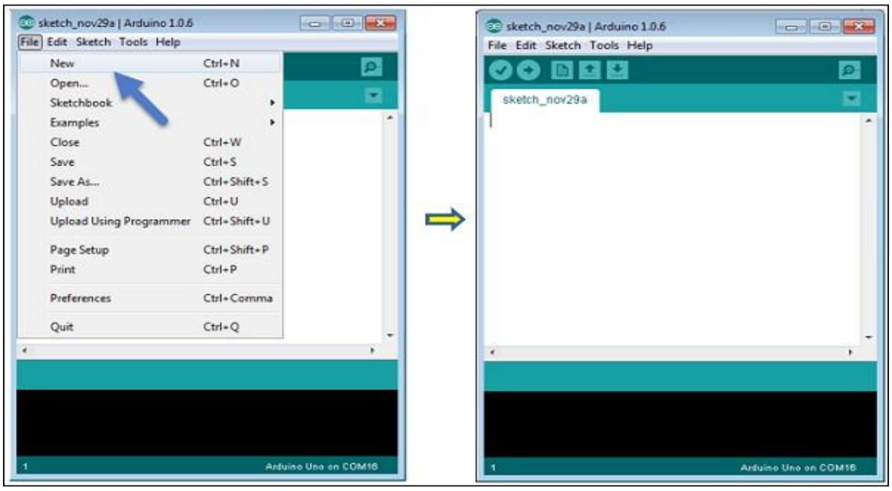

Fig.4.37 Opening Editor Window in IDE

To open an existing project example, select File → Example → Basics → Blink.

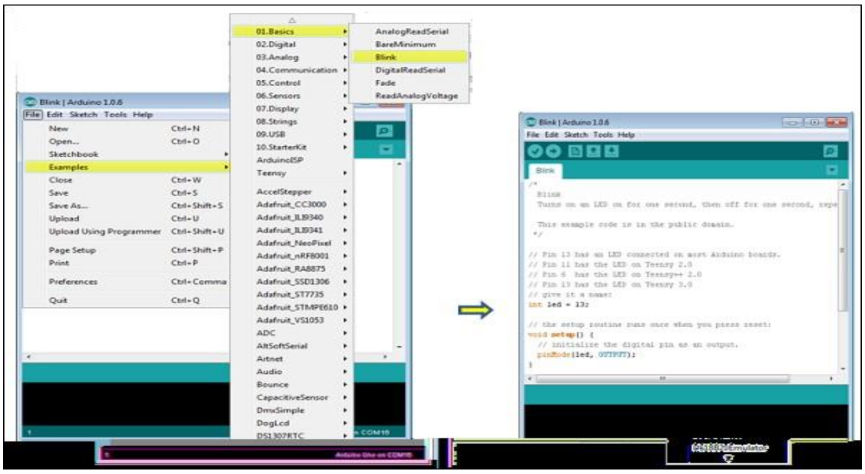

Fig.4.38 Opening Existing File in IDE

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

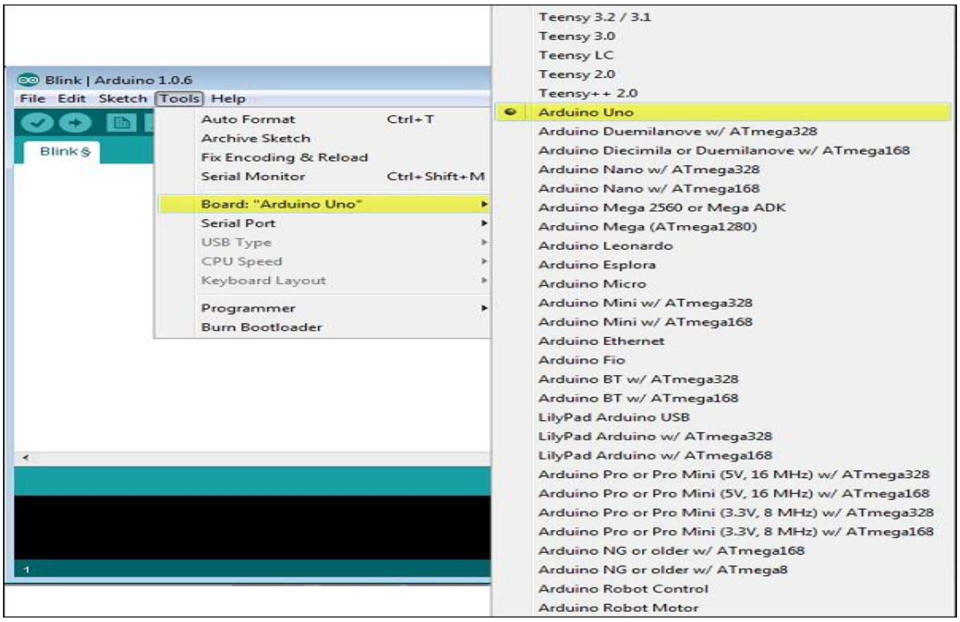

Fig.4.39 Selecting Arduino Board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports).

To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

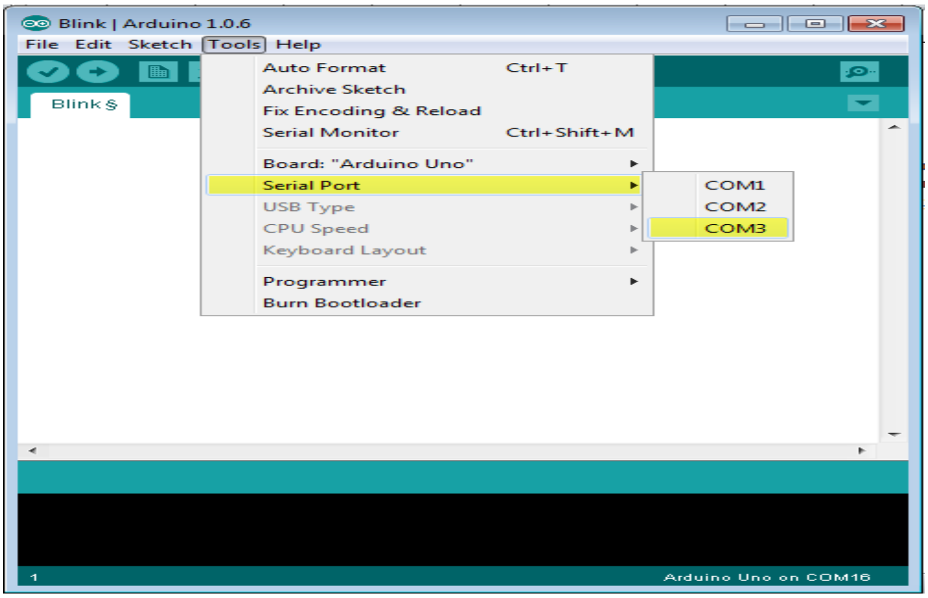

Fig.4.40 Selecting Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

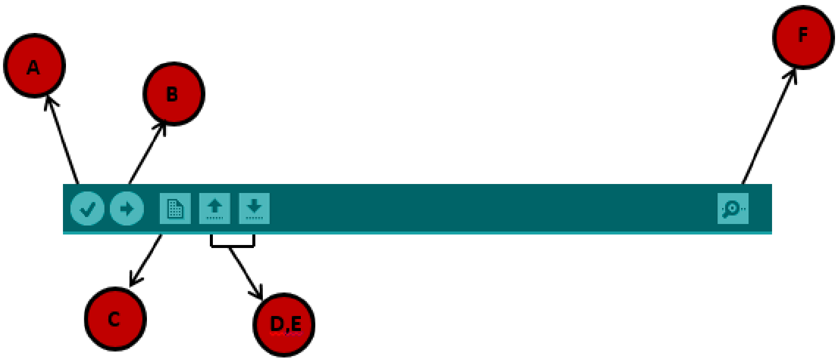

Fig.4.41 IDE Tool Bar

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

4.9.4 Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

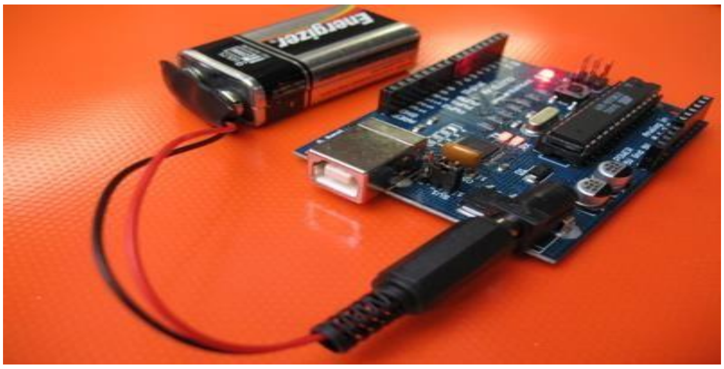

Fig.4.42 Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program show in Figure:4.66, paying attention to where semi-colons appear at the end of command lines.

Fig.4.43 Writing the Program in IDE

4.10 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems.

There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

4.11 Proteus:

Proteus is a simulation and design software tool developed by Lab Centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.11.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.
ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

4.11.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components.

It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.11.3 Starting New Design

Step 1: Open ISIS software and select new design in File menu

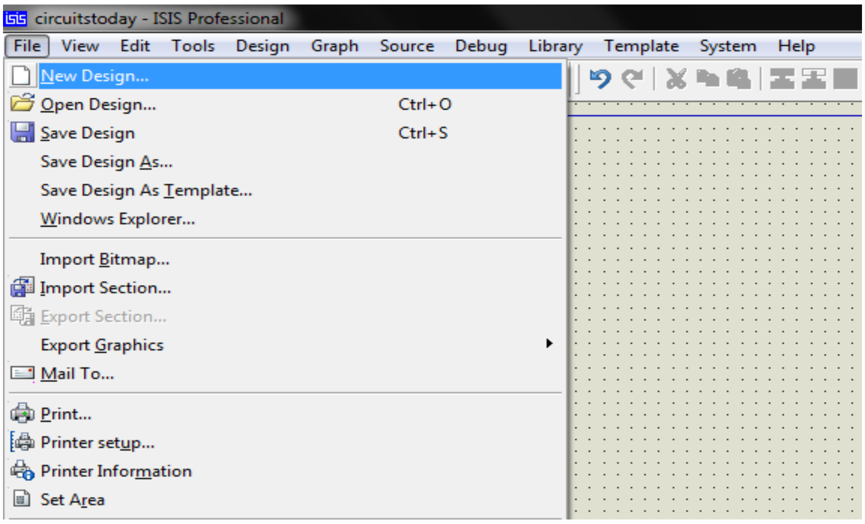

Fig .4.44 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

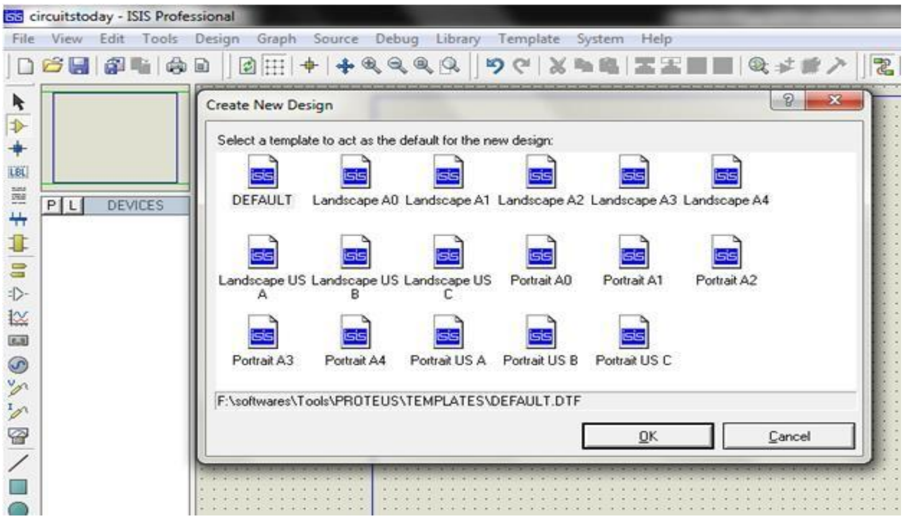

Fig.4.45 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

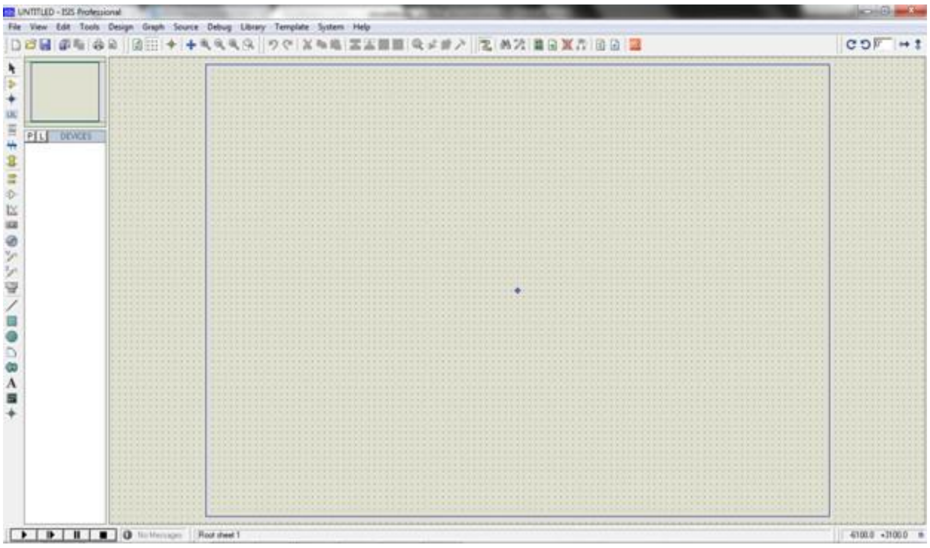

Fig 4.46 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

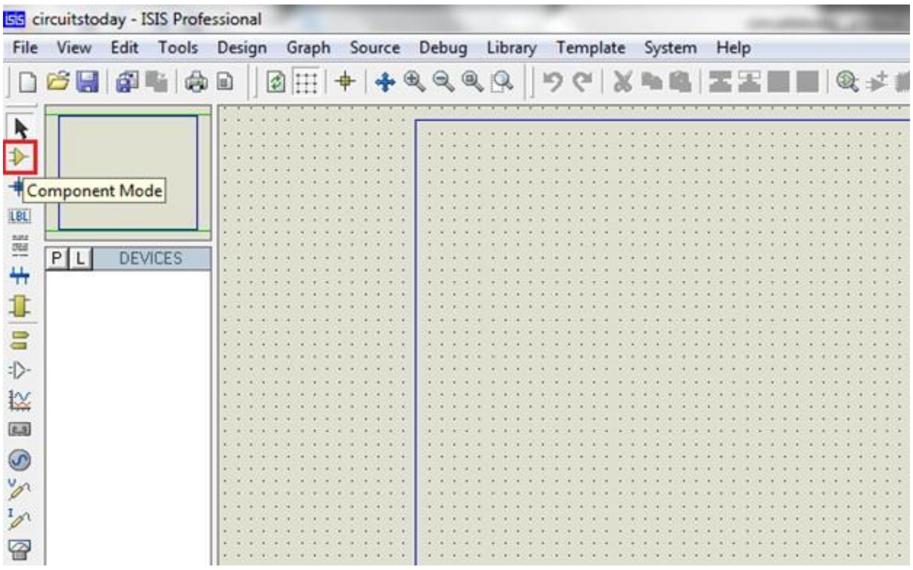

Fig.4.47 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

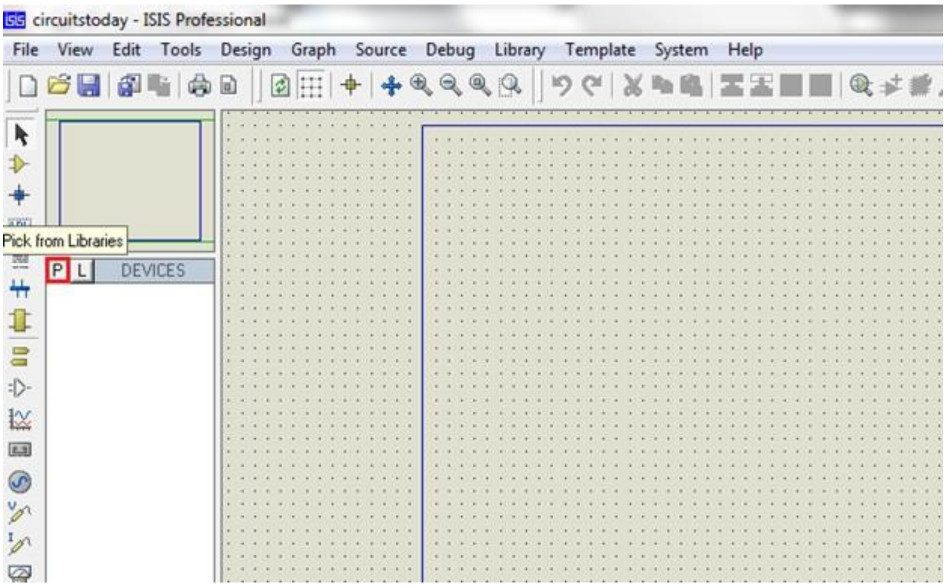

Fig4.47 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

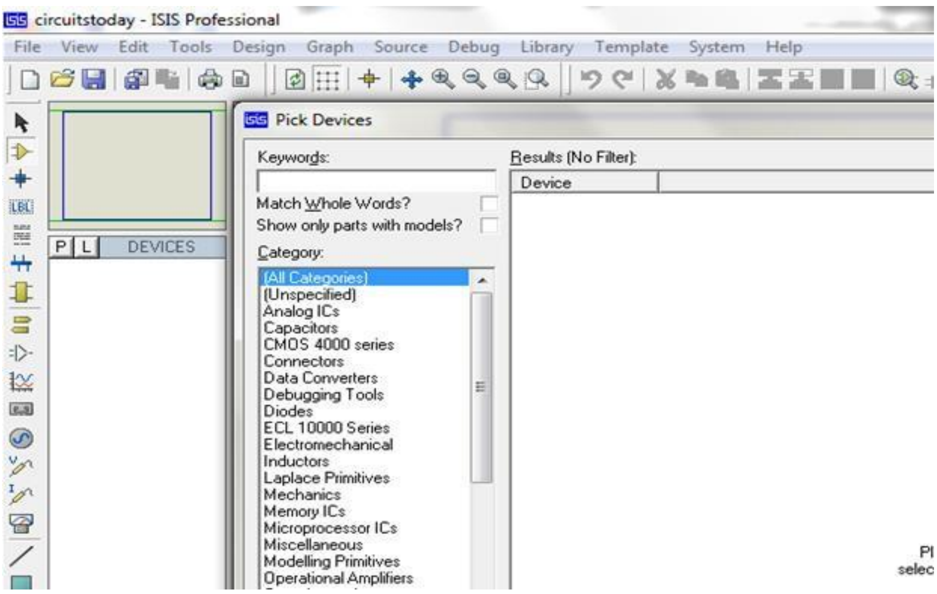

Fig 4.48 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

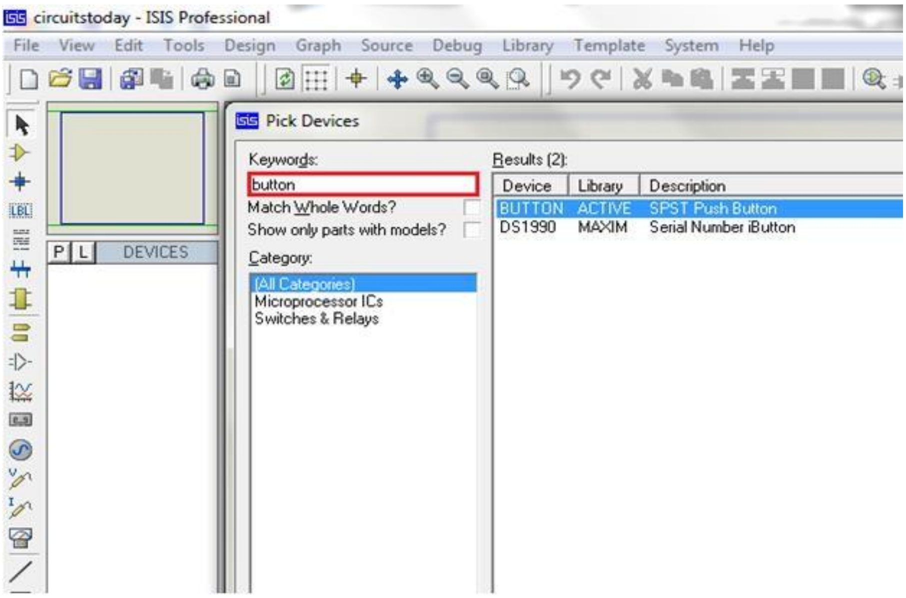

Fig4.49 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

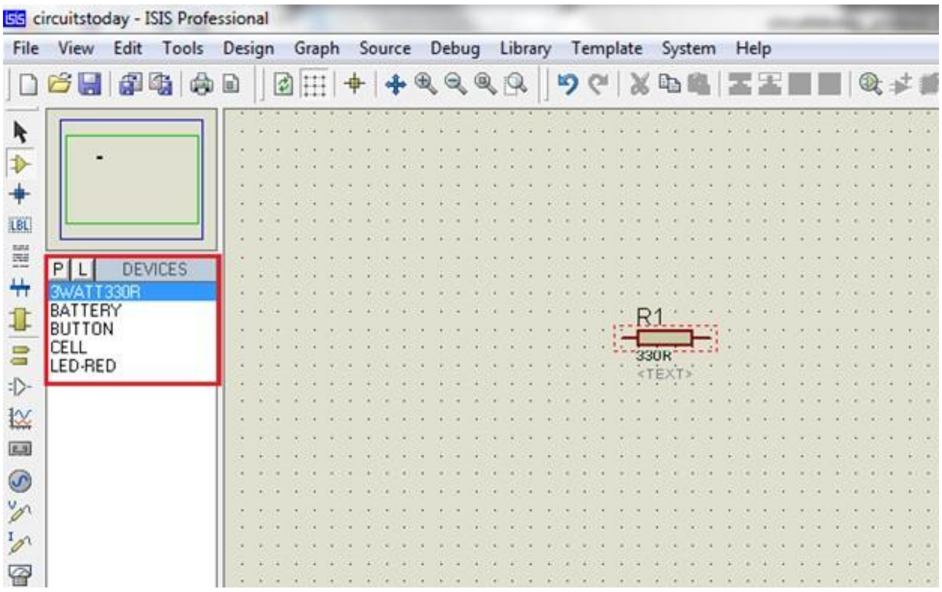

Fig4.50 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

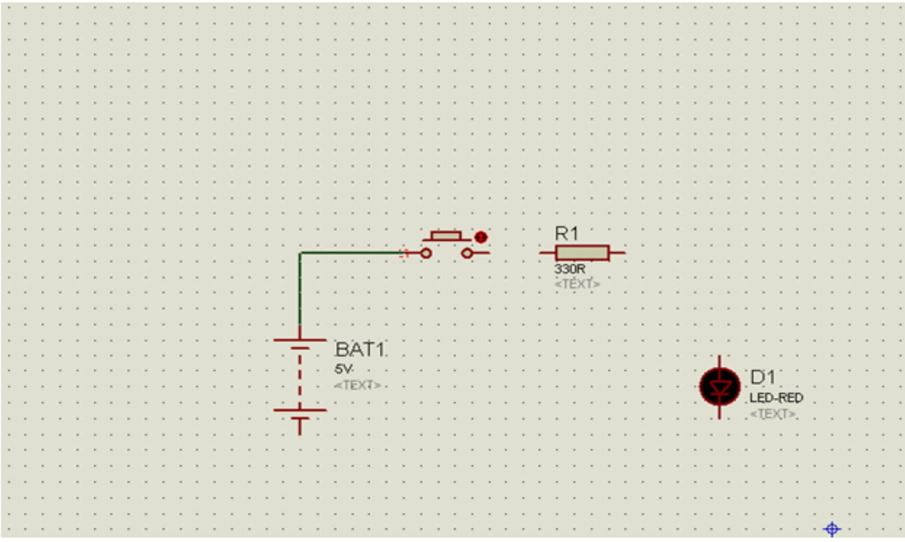

Fig4.51 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

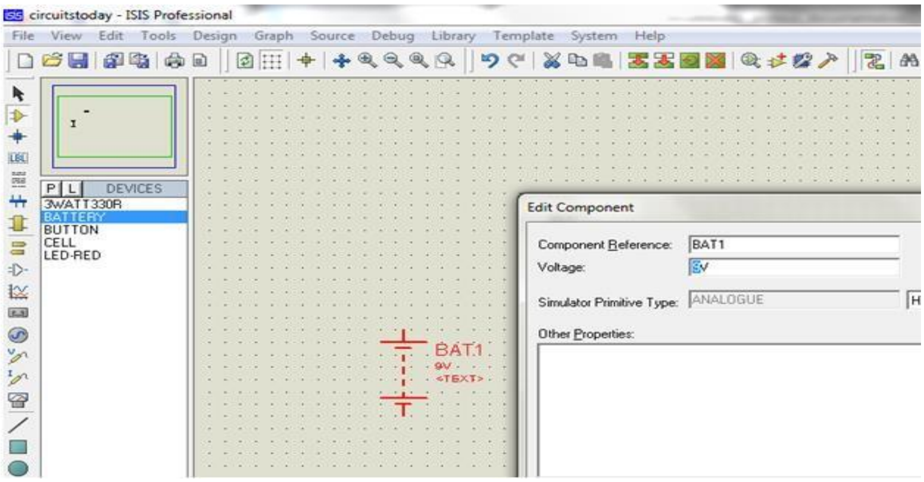

Fig4.52 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

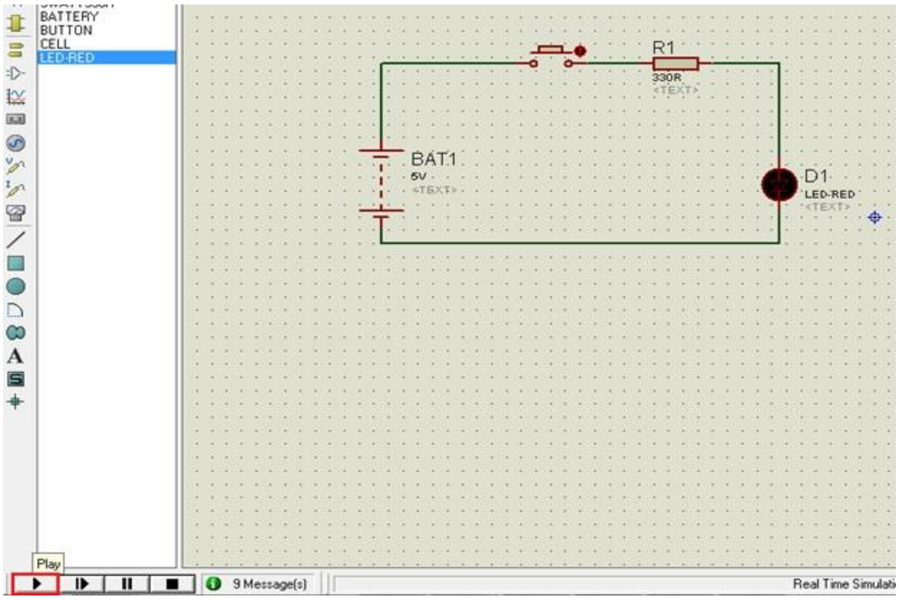

Fig 4.53 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

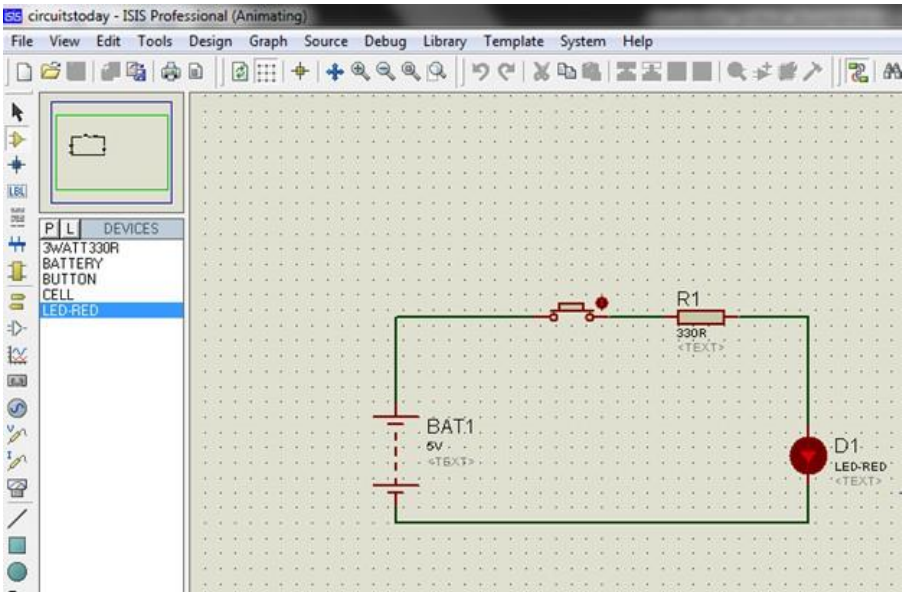

Fig4.54 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

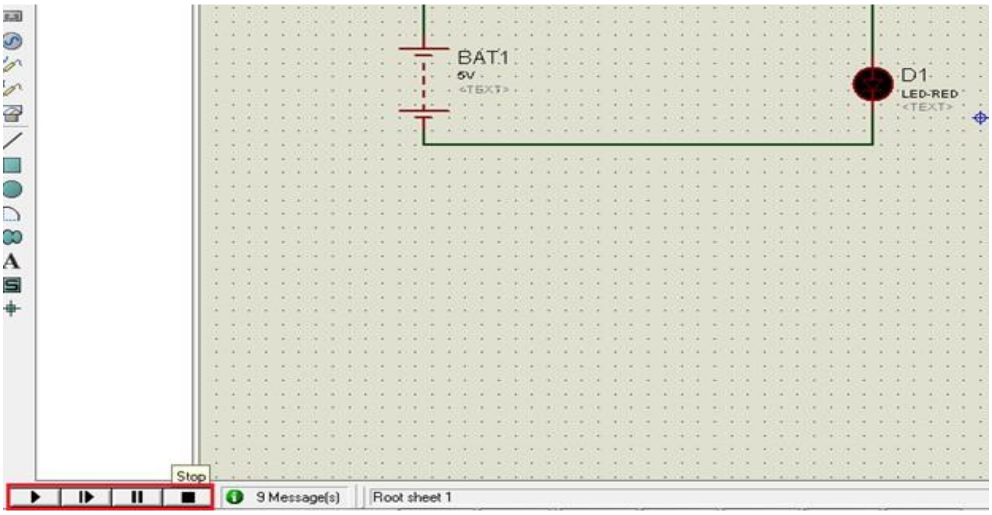

Fig4.55 Simulation Step-Pause-Stop Buttons

4.11.4 Project Code:

```
#include <LiquidCrystal.h>
 LiquidCrystal
lcd(13,12,11,10,9,8);//rs//en///d7//d6//d5//d4//
char res[130];

```

CHAPTER-5

RESULTS & OUTPUTS

5.1 RESULT:

The outcome of the project "Automatic railway train safety system " after aligning all components is shown in figure.5.1 and figure.5.2, all the components are placed over the comfortable movements in any directions.

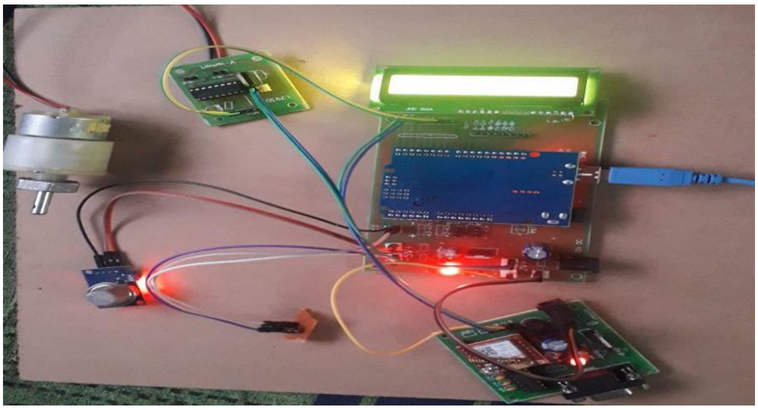

Fig.5.1 Automatic railway train safety system

The design of automation the system is used to stop the train whenever smoke and fire is accur. In these the input as LM35 we can use to sense the temperature and gas detection.in this situation temperature is high our motor will be turned on and it helps to pull the chain to stop the train. Along with breaking, the system sounds a buzzer that would alert nearby people. we get the output on LCD In that LCD we can found that smoke.in this situation GSM will be used to send the message to railway authority. These authority makes quick decisions to take control of fire.

Fig.5.2 :Smoke is found

Whenever smoke is found the GSM is send the message to railway authorities.and motor will be used to pull the chain and train will be stoped.the passangers are safe together.

CHAPTER-6

APPLICATIONS, ADVANTAGES AND LIMITATIONS

6.1 APPLICATIONS OF THE PROJECT:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic services
- Communications
- Office systems and mobile equipment
- Banking finance and commercial

6.2 ADVANTAGES OF THE PROJECT:

- Automatic operation prevents errors due to manual operation.
- Lastly, no human resource is required . This makes its running cost very low compared to manned gates.
- We can avoid accident which sometimes happen.
- Power supply for the motor operation and signal lights is required.

6.3 LIMITATIONS:

- To establish the entire network is quite costly task.
- Energy requirements are high.
- Involves complex network of connections and require skilled workforce to build it in a good manner.

CHAPTER-7

CONCLUSION AND FUTURE SCOPE

7.1 CONCLUSION:

- It is a challenge to save the human life and vehicles from miserable train accidents in the area of modern science and technology.The obstacle detection system is very helpful to avoid accidents while the train is moving through the forest it will save the life of wild animals and also reduce the accidents in track.

.

7.2 FUTURE SCOPE:

- By using this project ,we can save man power.
- Hare,there is no need of man. The circuit is self sense the alarm. Once we switch on the circuit,it automacially performs all those actions without man handling.
- And we can implement a few more sensors and connect it to the satellite as a global feature of this system.
- It is the most advantages of the project.For this reason,in future, this project may be used in railways and also in aparments,military,hospitals , etc.

ACKNOWLEDGEMENT

We sincerely thank the management of our college **ST. MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work.

We derive our great pleasure in expressing our sincere gratitude to our principal **Dr.P. Santosh Kumar Patra** for his timely suggestions, which helped us to complete the project work successfully.

It is the very auspicious moment to express our gratitude to **Dr. B. Hari Krishna**, Head of the Department, ECE for his consistent encouragement during the progress of this project. We take it as a privilege to thank our project coordinator **Dr. A. Anand**, Professor, department of ECE for the ideas that led to complete the project work and we also thank them for their continuous guidance, support and unfailing patience, throughout the course of this work.

We sincerely thank our project Internal guide **Mr. G. Ramesh Reddy** M.Tech(Ph.D)**,** Department of ECE for guidance and encouragement in carrying out this project work.

M. Bhargav Prasad	17K81A04F5
K. Vijay Kumar	17K81A04F7
P. Anand	17K81A04G3

DECLARATION

We, the students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2017 – 2021, **St. Martin's Engineering College**, hereby declare that the project work entitled '**UNDERWATER IMAGE RESTORATION USING SCENE DEPTH ESTIMATION TECHNIQUE**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

M. Bhargav Prasad	**K. Vijay Kumar**	**P. Anand**

ABSTRACT

Underwater image restoration is a difficult task due to the shortage of reference image and changing underwater environment. The images are distorted by absorption and scattering eff ect of light. In deep water, light undergoes wavelength-dependent attenuation. Thus, red color light that has a large wavelength attenuates more than blue light and any other color. As depth increases, light attenuates most of the red content and image appears in bluish-green color. These images also have low contrast, color cast and hazy appearance. Existing methods may need specialized hardware or it may be based on multiple images of the same scene. Thus they cannot be used in real-time or video acquisition task. So, it's better to form an effective method for color enhancement and image restoration of images. Here depth map estimation along with image blurriness is proposed. As light travels deeper into the water, the image gets blurred and this is used to obtain depth map. The backlight is also obtained. These factors are substituted in the IFM (Image Formation Model) to restore the image. Keywords—IFM, Image restoration, image enhancement

TABLE OF CONTENTS

Chapter 1

INTRODUCTION

In oceanic engineering, underwater imaging has a significant role. Underwater images have large scope in various research work. Nowadays several technologies are available to record underwater images and videos like waterproof cameras. But underwater images suff er from various demerits in case of visibility, contrast, illumination. This is because light rays on its path from the object to the camera get reflected by the organic particles dispersed in water. The major problem in image restoration is lack of reference image and underwater environment. In underwater, light propagation suffers from absorption and scattering. Scattering is because of collision with suspended particles and causes light rays to reflect in different directions, which can add a hazy layer to the image. Absorption causes energy loss of light rays and it depends upon the water medium properties such as density and turbidity. As turbidity increases absorption rate increases. Colors degrade gradually depending on wavelength as it moves deeper. Red light with large wavelength value attenuates more than shorter wavelength blue color light. Thus blue and green light reaches depth compared to red and orange. Thus, underwater images have appeared in bluish-green.

The methods used to increase the underwater image quality falls under two categories restoration and enhancement. Enhancement involves unsharp masking, histogram equalization, etc. for visually better results. The enhanced image is not necessarily to be exactly similar to the original image. But restoration can improve the image as same as the original image by modeling degradation. It restores an image by estimating underwater image formation model parameters. It can be modeled as a linear combination of the direct component and backscattered component. Direct component is the amount of light reflected from the object surface, only a portion of it reaches the camera and remaining gets scattered or absorbed. Scattering is of two types: forward and backward scattering. Backward scattering is responsible for low contrast thus it is included in the image formation model and the forward scattering component is neglected. Image formation model is given by

$$I(x) = S(x)\, t(x) + B\,(1-t(x)) \qquad (1)$$

I(x) is observed intensity at pixel x. J(x) is scene radiance, a fraction of light reflected from the scene into the camera. t(x) is a transmission map, a portion of the light that is not scattered or absorbed. B is a backlight, portion of light scattered into the camera by the suspended particles, it may add a hazy layer to the image. The main steps in this paper include image blurriness estimation, backlight estimation, depth map estimation, transmission map estimation, and scene radiance recovery. Finally, non-reference image quality assessment methods such as BRISQUE, entropy are used to measure the restored image quality.

Autonomous Underwater Vehicle (AUV) is an underwater unmanned vehicle for ocean exploration. It is suitable for detecting unknown environment and has the functions of autonomous decision-making, planning and obstacle avoidance in complex environment. Autonomous localization is of great significance to realize safe and efficient work of AUV. There are two main localization methods of AUV: dead reckoning and acoustic beacon positioning, but their complexity and the expensive instrumentation restrict the promotion of AUV. Compared with inertial navigation and acoustic beacon positioning, SLAM is a method with small-sized and affordable instrument. Simultaneous location and mapping (SLAM) refers to estimating a robot's pose (position and orientation) in unknown environment through repeated observation of environmental characteristics. Based on this foundation, an incremental map of the surrounding environment is constructed. Through the efforts of researchers, the SLAM technology has been widely used in fields such as unmanned aerial vehicle, sweeping robot, unmanned driving and intelligent wearing equipment. Compared with the SLAM of land and aerial unmanned system, the application of the SLAM in AUV positioning and navigation is just beginning. The research on AUV SLAM was mainly based on extended Kalman Filter and Particle Filter. Sonar is used as environment sensing sensor [1-2].

The earth is associate aquatic planet and the maximum amount as eightieth of its surface is roofed by water.. Moreover, there is a strong interest in knowing what lies in underwater. Present days, an image of deep waters has a scope to large investigation to explore the underwater for sea floor expedition and navigation. Enthusiasm of underwater imaging includes the inspection of plants, seabed exploration, the search for wrecks up and to the exploration of natural resources. There were several issues faced by the human in the underwater, if he dives deep into the ocean and stay there for a long time to perform experimentation. [1]. Due to the above reasons, unmanned remote vehicles are used to sea floor exploration.

A. Historical Development

Underwater image quality improvement approaches present a path to magnify the object recognition in underwater surrounding. A heap of research started for the upgradation of image visual quality, but a little amount of work has been carried out in this area. In the deep waters, image quality is degrades due to poor illumination conditions and the light properties differ in water compared to air.[2]. There were several parameters which decreases the quality of an image in underground waters. So in order to remove all these effects

there are several techniques has been implemented and practiced.

B. Need for Pre process

Initially processing is necessary for deep water images due to their poor quality during acquisition. Necessity for pre-processing of deep water images[1] are discussed below:

(i) Quality of images taken from deep water is deteriorated due to light ray attributes like scattering and absorption of light.

(ii) Specificity of surroundings such as lighting inequalities, water torridness, and blue complexion is more or less influential when vehicles move.

(iii) Video or image captured from deep waters like unknown rigid scene, and the depth of the scene and low light sensitivity due to Marine snow etc.

1.1 TRADITIONAL TECHNIQUES FOR IMAGE ENHANCEMENT

There are several techniques which are used very frequently for processing the image to improve the visual quality. Some of them are as follows:

(i) Contrast Stretching

(ii) Adaptive Histogram Equalization

A. Contrast stretching

The contrast stretching is a method to transform high intense region of image into brighter and less intense region into more darker by using a predefined transformation function T(r) [2]. Generally, the underwater images will have less grey values. There are 256 grey values. ‘0’ indicates black and ‘255’ indicates white. In this method the current grey value of the image is stretched towards 255 i.e., from black to white, pixel by pixel. That means the contrast of the image is stretched, so that the quality of the image is improved for better vision.

For example:

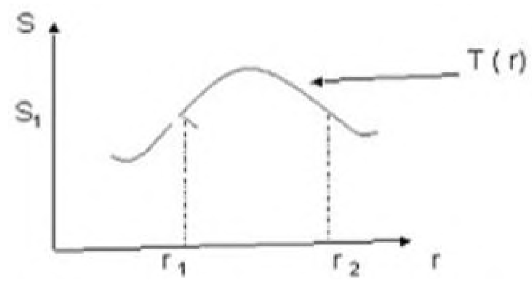

Fig.1. Two different gray levels look same

Here two different thresholds are considered for the entire image and the values between them are stretched to the maximum extent, so that the contrast increases. And more over by this method the entire global image contrast is enhanced.

Fig.2. (a) Raw image (b) Enhanced image

But the disadvantage here is that the transformation function is not unique. Depending on the application the suitable transformation function is chosen

B. Adaptive histogram equalization

Adaptive histogram equalization is a PC based image processing technique which is used to improve the quality of image properties like contrast. It is similar to contrast stretching method but with a slight difference. It computes several intensities of specific gray value, each corresponding to a distinct portion of an image, and with the help of them intensities are rearranged by applying a suitable transformation function. For example, a simple transformation function such as each pixel transformed based on the histogram of a square surrounding the pixel [3]. Existing values will be mapped to new values keeping actual number of intensities in the resulting image equal or less than the original number of intensities. The transformation function applied on the histogram is proportional to the cumulative distributive function (CDF) of pixel values in the neighborhood. Therefore it suits for enhancing the local details and enhancing the edge information of each region of an image.

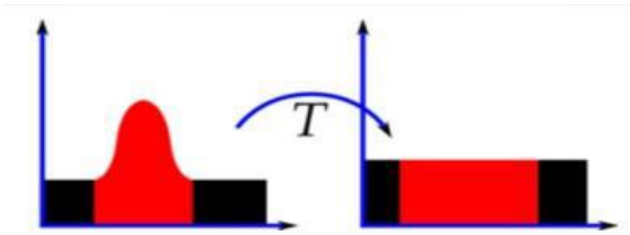

Fig.3. Histograms of an image before and after histogram equalization

Histogram equalization is a technique for changing the overall pixel intensities based on transformation function and contrast of an image. Histogram equalization is an effective technique which will benefit for the images with extreme contrast values. The limitation of this technique highlights the unwanted noise present in the background of an image and lead to loss in the information signal. It results in undesired effects in the resultant images [4].

Fig.4. (a) Raw image **(b) Enhanced image**

Here the noise in relatively homogeneous regions of the image are amplified which results in poor SNR. And also only the local objects of the image are enhanced and the background is left unenhanced.

CHAPTER 2

INTRODUCTION TO IMAGE PROCESSING

INTRODUCTION

2.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

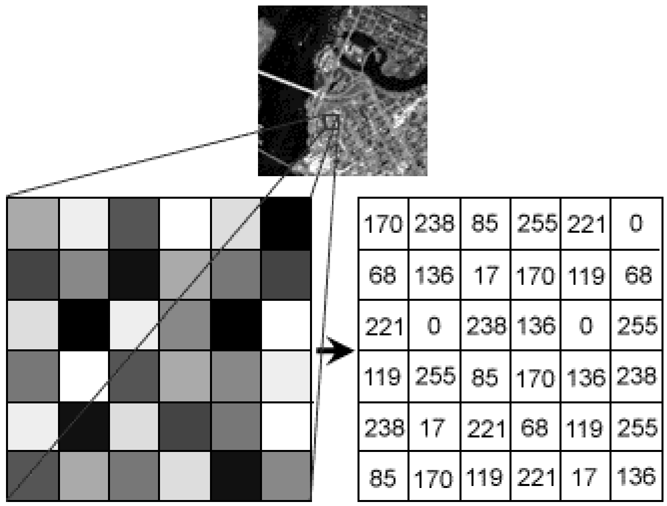

Fig 2.1 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

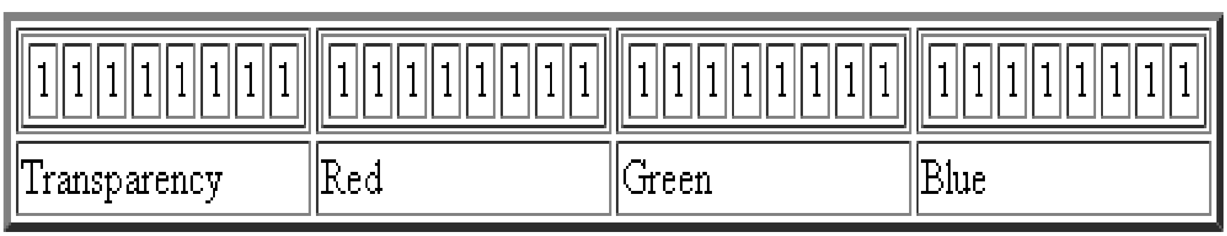

Fig2.2 Transparency image

2.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

2.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

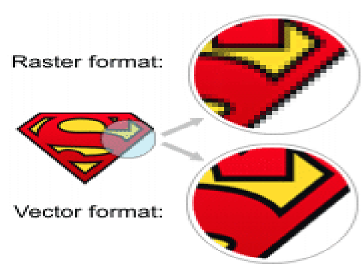

Fig2.3 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

2.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

2.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

2.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

2.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

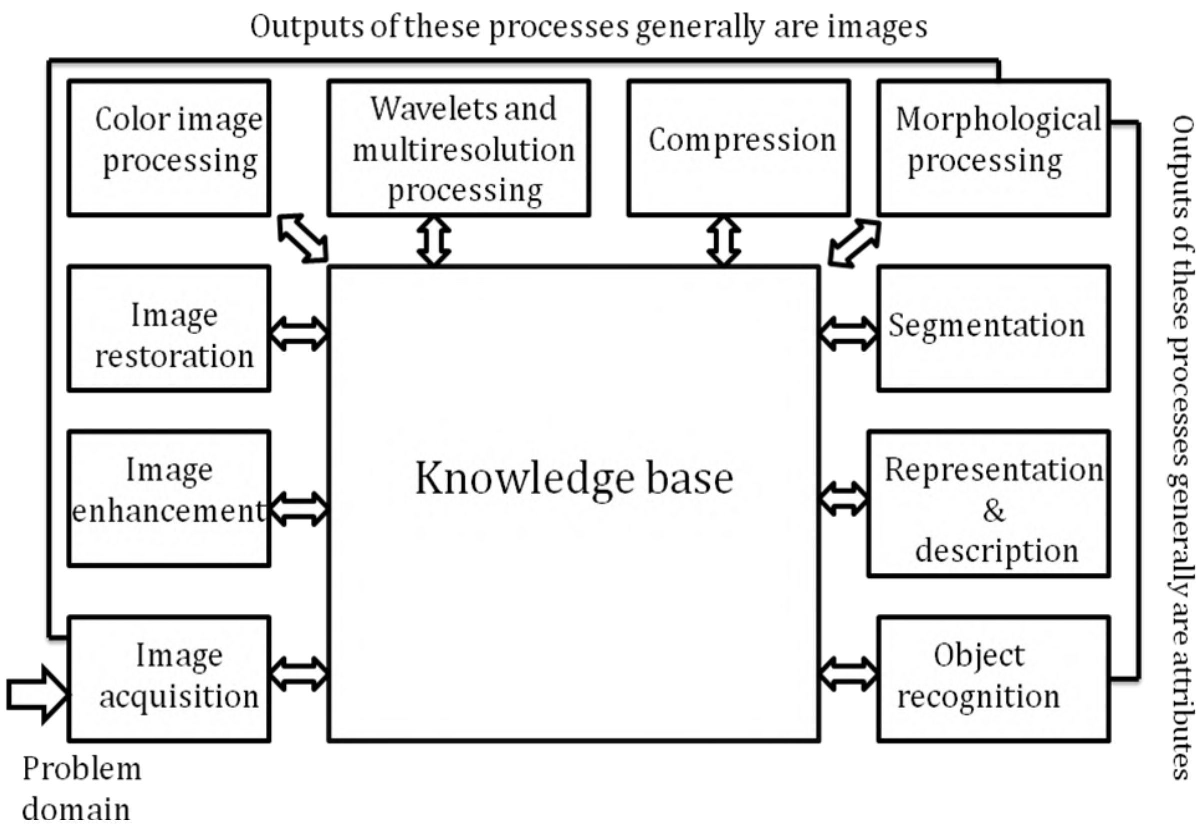

Fig 2.5 Image fundamental

2.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 2.5.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 2.5.2 digital camera cell

2.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 2.5.3 Image enhancement

2.5.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 2.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

2.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 2.5.5 Color & Gray scale image

2.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

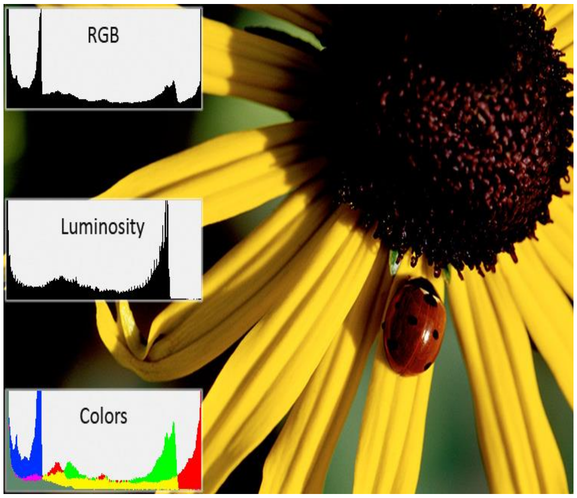

Fig 2.5.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

2.5.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

2.5.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 2.5.7 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

2.5.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

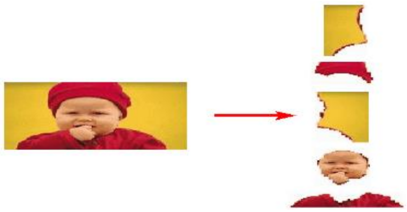

Fig 2.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

2.5.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

2.5.10 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

2.5.11 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

2.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

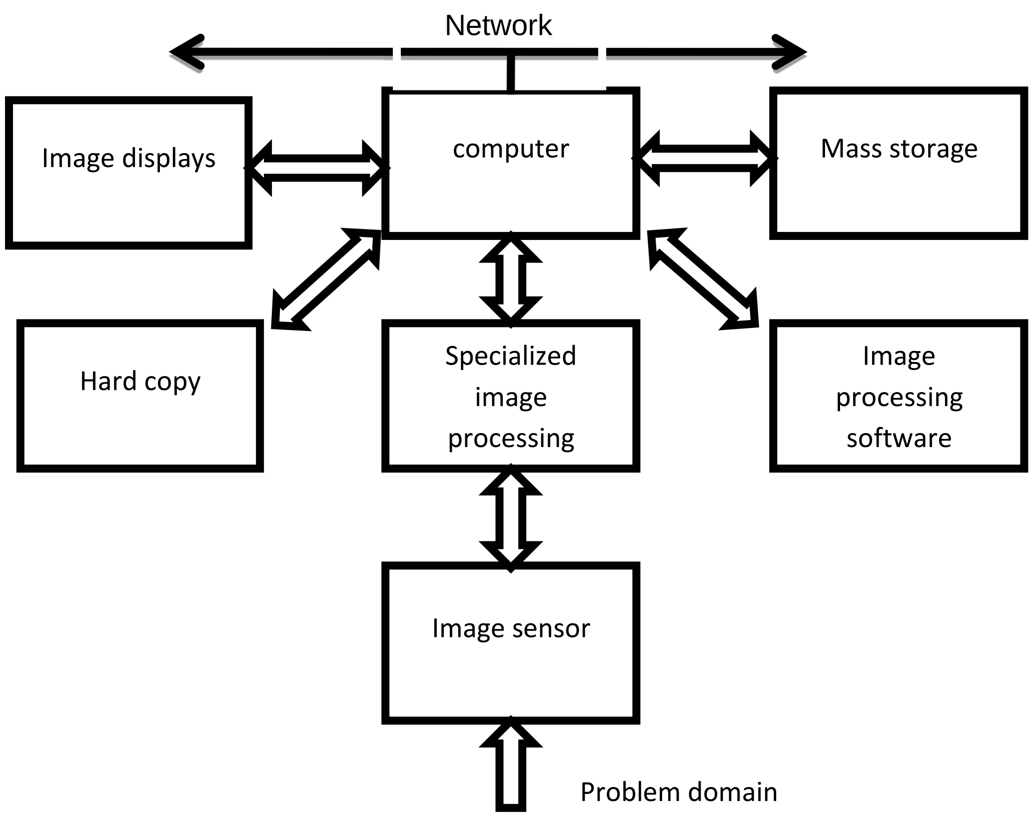

Fig 2.6 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram-based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance 'd' apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance 'd' apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance 'd' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(i; j) = Pr((up; vNp) = (i; j))$$

$$mcmLU(i; j) = Pr((lp; uNp) = (i; j))$$

$$mcmLV(i; j) = Pr((lp; vNp) = (i; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the

properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexacone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V).

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 \ \ if \ \ h \in [316,20] \\ 1 \ \ if \ \ h \in [21,40] \\ 2 \ \ if \ \ h \in [41,75] \\ 3 \ \ if \ \ h \in [76,155] \\ 4 \ \ if \ \ h \in [156,190] \\ 5 \ \ if \ \ h \in [191,270] \\ 6 \ \ if \ \ h \in [271,295] \\ 7 \ \ if \ \ h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \ \ if \ \ s \in [0,0.2) \\ 1 \ \ if \ \ s \in [0.2,0.7) \\ 2 \ \ if \ \ s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \ \ if \ \ v \in [0,0.2) \\ 1 \ \ if \ \ v \in [0.2,0.7) \\ 2 \ \ if \ \ v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented to differentiate between already segmented regions or to classify them. we can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:

I

1	1	5	6	8

CHAPTER-3

DIGITAL IMAGE PROCESSING

Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of ‘f’ at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

$$f\ (\text{xylem}) = \begin{matrix} f(0,0) & f(0,1) & \dots\dots\dots.. & f(0,N-1) \\ f(1,0) & f(1,1) & \dots\dots\dots\dots & f(1,N-1) \\ . & . & & . \\ . & . & & . \\ f(M-1,0) & f(M-1,1) & \dots\dots\dots\dots & f(M-1,N-1) \end{matrix}$$

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

$$f = \begin{matrix} f(1,1) & f(1,2) & \dots\dots. & f(1,N) \\ f(2,1) & f(2,2) & \dots\dots.. & f(2,N) \\ f(M,1) & f(M,2) & \dots\dots. & f(M,N) \end{matrix}$$

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Format name	**Description**	**recognized extension**
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

```
>> f   = imread ('8. jpg');
```

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name	**Description**
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255] (1byte per Element).
Uint16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).

Uint 32 unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element). Int8 signed 8_bit integers in the range [-128,127] 1 byte per element)

Int 16 signed 16_byte integers in the range [32768, 32767] (2 bytes per element).

Int 32 Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions.

When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as "stack" of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER 4

SOFTWARE INTRODUTION:

4.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

4.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

4.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

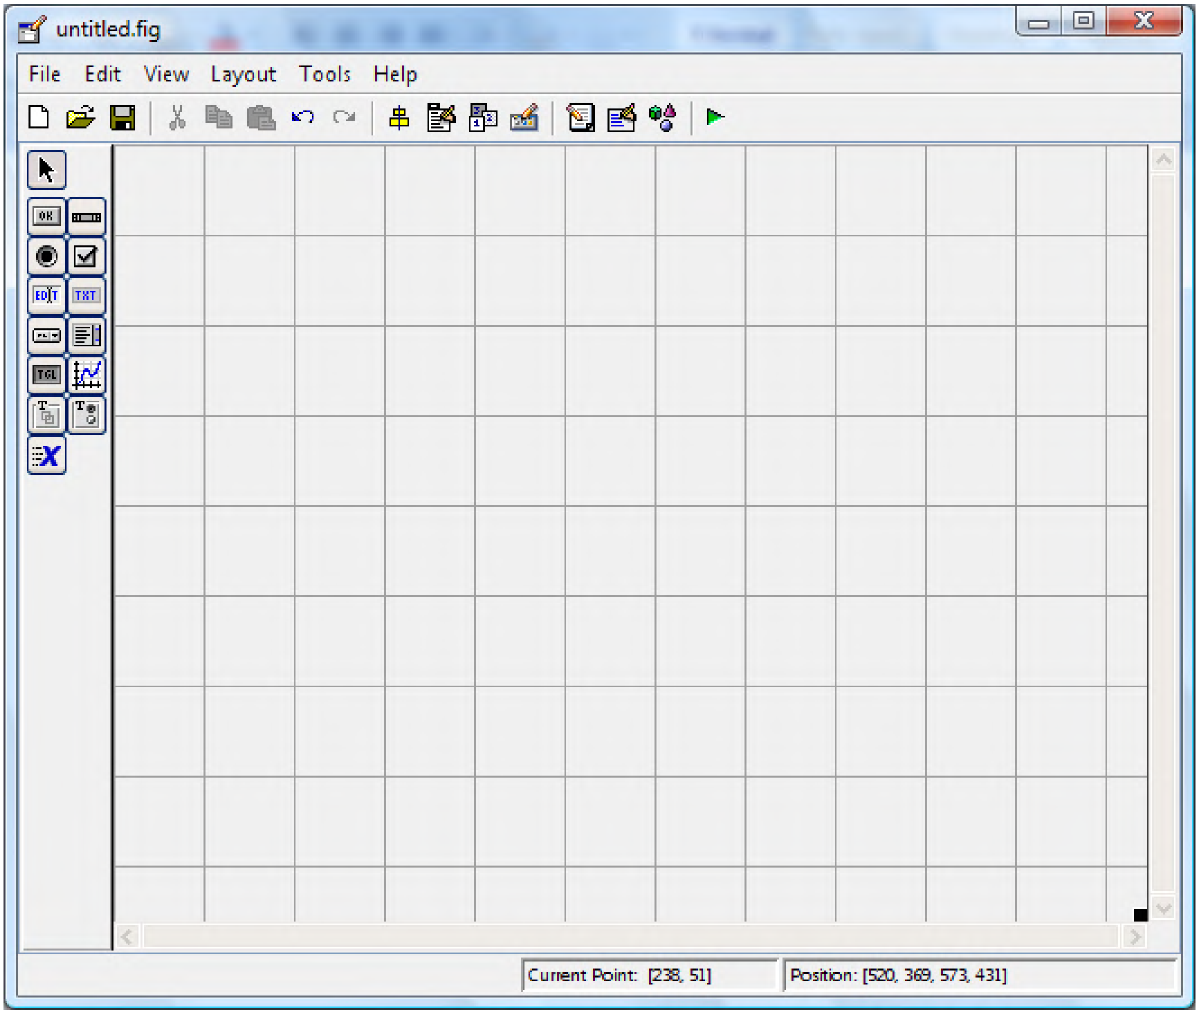
- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

4.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

4.4.1 Introduction - describes the components of the MATLAB system.

4.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

4.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

4.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

4.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

4.5 DEVELOPMENT ENVIRONMENT

4.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

4.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

4.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

4.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

4.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

4.6 MANIPULATING MATRICES

4.6.1 **Entering Matrices**

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

   16     3     2    13

    5    10    11     8

    9     6     7    12

    4    15    14     1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

4.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

4.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

4.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

4.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

4.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects.

You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

4.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

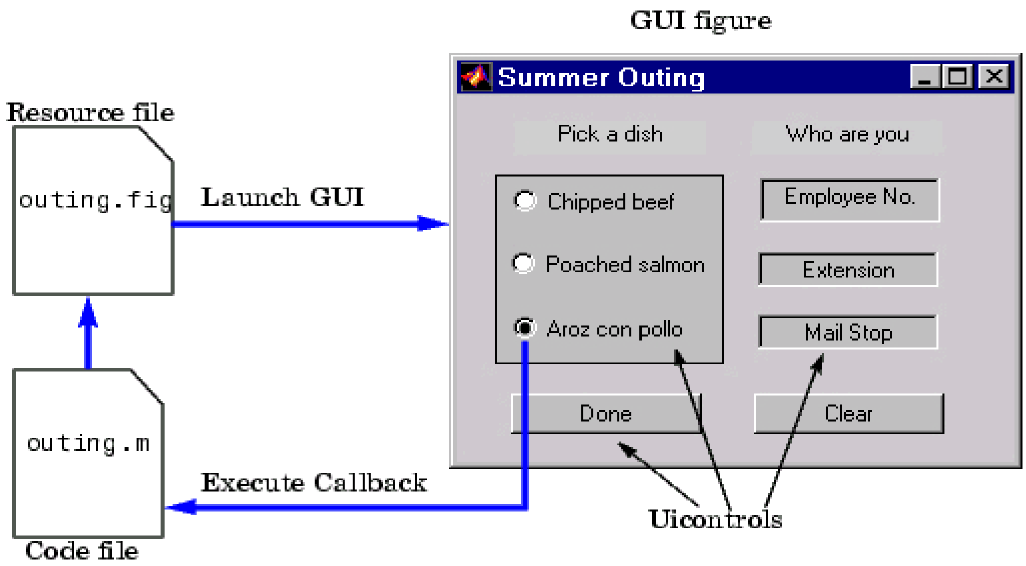


FIG 3.7.2 graphical user blocks

4.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

4.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

4.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders

- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
```

```
mutual_exclude(off)

% Continue with callback

    .

    .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

   % then checkbox is checked-take approriate action

else

   % checkbox is not checked-take approriate action

end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non integer values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

4.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

Chapter 5

PROPOSED METHOD

underwater image restoration using depth map estimation. Image blurriness is used as a before acquiring a depth map. As depth increases, image blurriness also gets increased. Here backlight is retrieved from the largest blurriness region and lowest variance region. A backlight is estimated from the top brightest pixel. If artificial lighting is used for illumination, foreground objects appear to be brighter than background objects. So, selecting the brightest pixels may lead to erroneous results. Then substituting backlight and depth map in IFM scene radiance is restored. Fig.1 shows the block diagram of the proposed method.

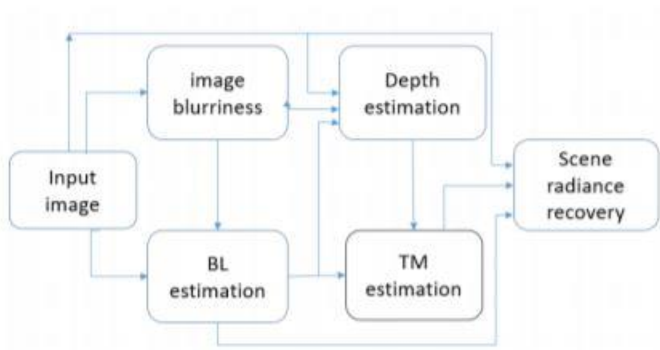

Fig.1. Block Diagram

A. Image Blurriness Estimation:

Image blurriness is due to scattering by suspended particles, minerals, rocks in the water. There is a linear relationship between blurriness and depth. Thus estimating blurriness in the image gives depth information. There are 5 types of image blurriness measuring techniques. In the first category, image blurriness is found by measuring the energy of the image. Blurring can smooth edges of the image and thus decreases high-frequency coefficients energy, thus a comparison of the energy of original and degraded image gives blurriness metric. The second category considers the edge of the image since blurriness may convert the sharp edges in the image into a smooth one. The edges and its width are obtained from vertical/horizontal gradients. The third category involves pixel intensity distribution. This method considers, a sharper image has a greater value of entropy and variance. The fourth category blurriness evaluation includes local gradient measures. Singular value decomposition is a local gradient measure used for blurriness estimation.

The fifth category uses a combination of the other 4 categories. But these methods are susceptible to noise since noise may increase high-frequency content in an image. In underwater image restoration, a reference image is not available thus above mentioned methods for blurriness calculation cannot be used. First, the input image is converted into YCbCr color space Y represents luminance and Cb, Cr represents chrominance values. Blurriness is calculated using the luminance component only, rather than considering chrominance values. Since it is perceptually more representative, it easy to tell blurry and sharp areas based on Y. Sharp edges in the image indicate blurriness is less. Then calculates the difference between the luminance component and Gaussian filtered version of that component. Gaussian filtering is a lowpass filter it removes high-frequency content such as edges or noise and retains low frequency information. This Difference contains sharp objects and fine details. Then a maximum filter is applied to this difference. This filter calculates the maximum value within the window and this window is slid over. A window size of 7 to 31 is suitable for any image size. Here window size equal to 7 is used. The output image is reconstructed by hole filling. The output image contains only sharp details and the blurred regions are removed. Thus in the blurriness map, small value means the corresponding pixels in the image are blurry, large value means they are not blurry. So sharp edges would have large values and a smooth region would have small values. However, a smooth region encompassed by sharp edges would be considered not blurry since they all belong to a single object. Fig.2 shows the image blurriness

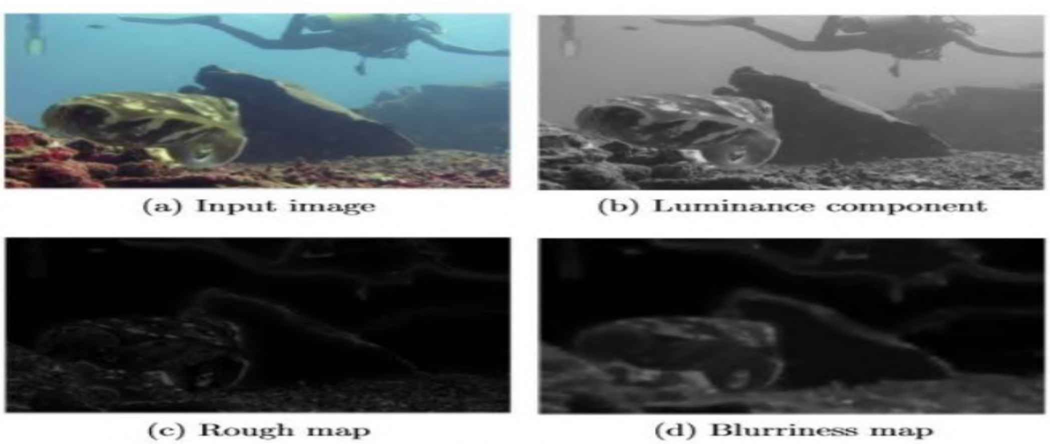

Fig.2. Image Blurriness Estimation

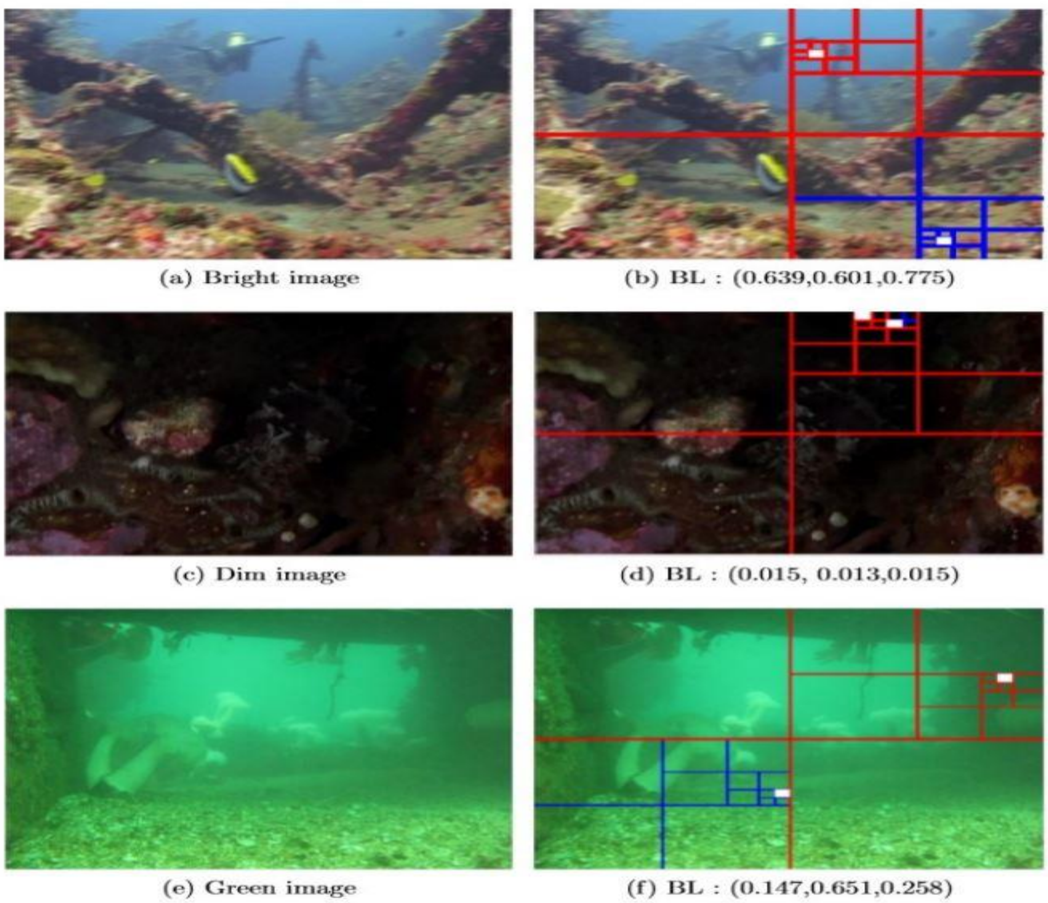
B. Backlight Estimation:

The backlight is due to the scattering of light by the particles in water. It adds a hazy layer and reduces image contrast. To overcome the drawbacks of backlight estimation methods (in the case of artificial lighting or brighter foreground object) this method considers variance and blurriness in addition to 1 percentage of top brightest pixels. Here largest blurriness and lowest variance regions are considered, these regions are obtained using quadtree subdivision. In low variance region pixel values do not change dramatically. Thus it is more likely to find backlight. Blur regions always have low variance but low variance does not always infer a region is blurry. Thus low variance and largest blurriness criteria are not interchangeable. The backlight has a dependence on depth because the scattering of ambient light increases as goes deeper into water. To take this dependence, backlight estimation considers the largest blurriness region.



(a) Bright image

(b) BL : (0.639,0.601,0.775)

(c) Dim image

(d) BL : (0.015, 0.013,0.015)

(e) Green image

(f) BL : (0.147,0.651,0.258)

Fig.3. Backlight Estimation

The image is first divided into four quadrants equally according to blurriness or variance. Then the quadrant with the lowest variance (in the case of blurriness region with the largest value is chosen.

Variance within a quadrant is obtained by the averaging variance of individual pixels. The quadrant with the lowest variance is further divided into four. This process is repeated until the quadrant size got lesser than a predefined threshold. The threshold value must lie between 0 and 1. From the largest blurriness region, lowest variance region, and top brightest pixels, the maximum, and minimum of the backlight are obtained. It is not able to find backlight anywhere in the image so maximum and minimum values are separately obtained for each color channel. Then calculates the ratio of pixels with intensity greater than a threshold (here chosen 0.5) to the total number of pixel values. If the image is taken under sufficient lighting this ratio would have larger value otherwise it would be a smaller value. When the percentage of bright pixels is high then the estimated backlight is bright is more suitable thus the maximum value of backlight is chosen as estimated backlight. If the image is taken without sufficient lighting (smaller ratio) then the minimum value of backlight is chosen as estimated backlight. In between these extreme conditions, the backlight is calculated as the combination of these maximum and minimum values. The figure shows backlight estimation where the blue line indicates variance and the red line indicates blurriness. The white portion indicates the lowest variance and largest blurriness region. Fig3.shows backlight estimation of bright, dim, and green input image. A bright image has larger backlight values in all color channels (RGB), the obtained BL for fig.3. a,b is [0.639,0.601,0.775]. For the dim input image, all three channels have lower backlight values and obtained backlight for fig.3. c,d is [0.015, 0.013,0.015]. Green input image has larger backlight value in the green channel only other channels have smaller values. Obtained backlight for fig.3. e,f is [0.147, 0.651,0.258].

C. Depth Estimation:

Attenuation of light in underwater depends upon light wavelength and distance it travels. Here depth is estimated by combining 3 methods. The first two methods are based on different wavelength have different attenuation rates and the third method is based on image blurriness. 1) Using red channel content: Red light has the longest wavelength in the visible spectrum hence it attenuates at a higher rate than other colors. As the light reaches greater depth most of the red channel content may be lost. Thus a measure of red channel content is used to obtain an estimate of depth. If the image has a considerable amount of red channel value it indicates that an image is captured at a lower depth. When the image I c (y) is captured at a larger depth the red channel information is almost lost.

Red channel content is,

$$R(x) = \max y \varepsilon \omega(x) I\ c\ (y) \qquad (2)$$

where ω(x) is a window of size 7,centered about x and c ε{r,g,b}. Then depth map is,

$$dR = 1 - K(R) \qquad (3)$$

Since three diff erent depth maps are combined, for them to be in the same range [0, 1] stretching function K is used. It is given by

$$K(L) = L - Lmin \,/\, Lmax - Lmin \qquad (4)$$

2)Using 3color channel: Difference between attenuation of different color channels (red, green, blue) can be used as a prior to calculate depth map since light undergoes attenuation which depends on color. Red light has a larger attenuation constant than green and blue light. For this depth estimation method, the difference between the maximum value of green and blue channels and that of the red channel is calculated. When the difference is larger it indicates that red channel intensity is low, the image is distorted badly and depth value is high. If this blue-green channel has a smaller value the red channel is less attenuated and depth is low. The prior value is,

$$BGR = \max y\varepsilon\omega(x),c\varepsilon(g,b)\ I\ c\ (y) - \max y\varepsilon\omega(x),c\varepsilon r\ I\ c\ (y) \ (5)$$

When the prior value increases depth also increases. Then the depth map is:

$$dBGR = K(BGR) \qquad (6)$$

3) Using image blurriness: As the image is more blurred, indicates that the image is from more depth and vice-versa. If image blurriness value is small, it's blurry and large value indicates the image is sharp. Thus, the depth map is; dB = 1 – K(Blurriness map) (7) When there is insufficient lighting, method of using red channel content is used. If there is an intense backlight, red content in the image is retained and this method is failed. In this case, the second method using 3 color channels is proposed. If there is a brighter backlight, all the 3 channels have larger values. Whether the backlight is dim or bright, when image lacks red content, the third method alone is used. As a combination of these three depth maps, the final depth map is processed. Fig.4 and Fig.5 show the depth map estimation.

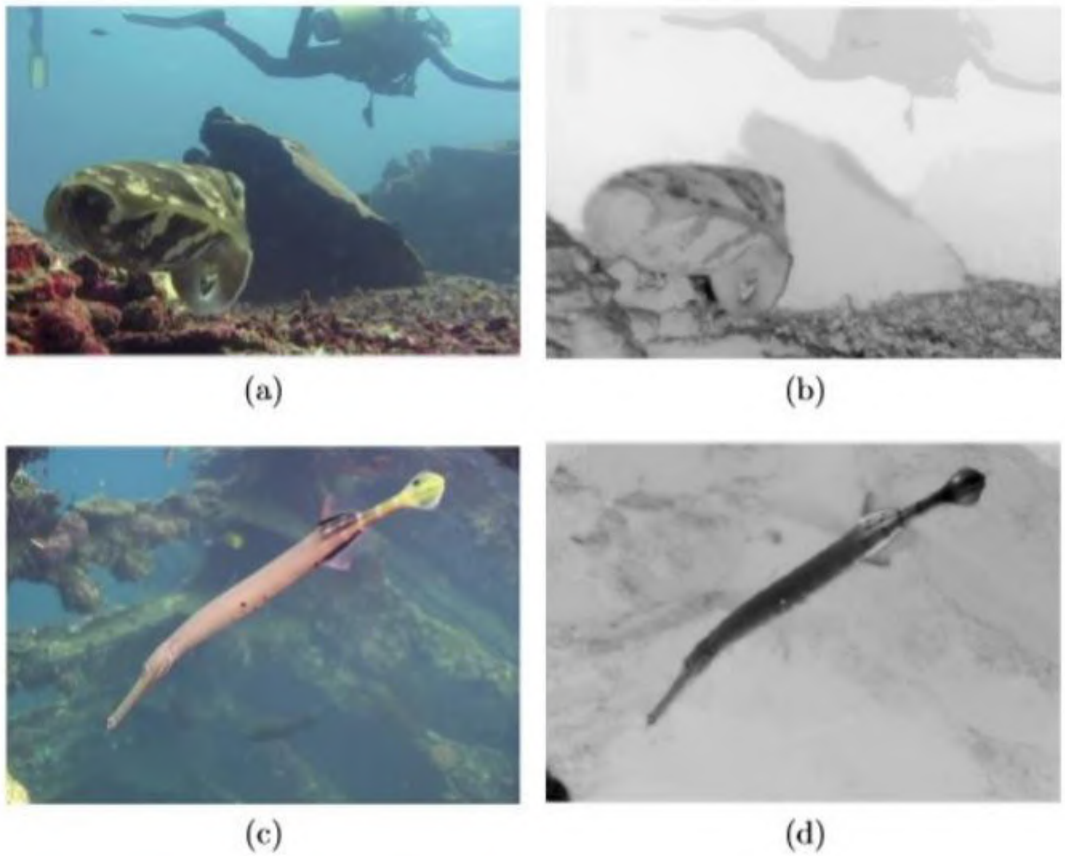


Fig.4. Depth Map Estimation

D. Transmission Map Estimation:

Transmission map is the part of the light that is not scattered or absorbed and finally reaches the camera. According to Beer-Lambert law light is exponentially attenuated with distance when it travels through a medium. $t_c(x) = \exp(-\beta_c\, d(x))$ (8) where $d(x)$ is scene depth and β is attenuation coefficient c represent RGB color channels. Transmission map is separately obtained for each color channel. Underwater image restoration using a single image makes use of the assumption that attenuation is wavelength independent (or color independent). But in underwater red light decays faster than green light and blue light. In this method wavelength-dependent attenuation is considered. The standard wavelength of red, green and blue are 620 nm, 540 nm, 450 nm respectively. Attenuation constant is proportional to wavelength and inversely proportional to the backlight. Using this relation the attenuation coefficient is:

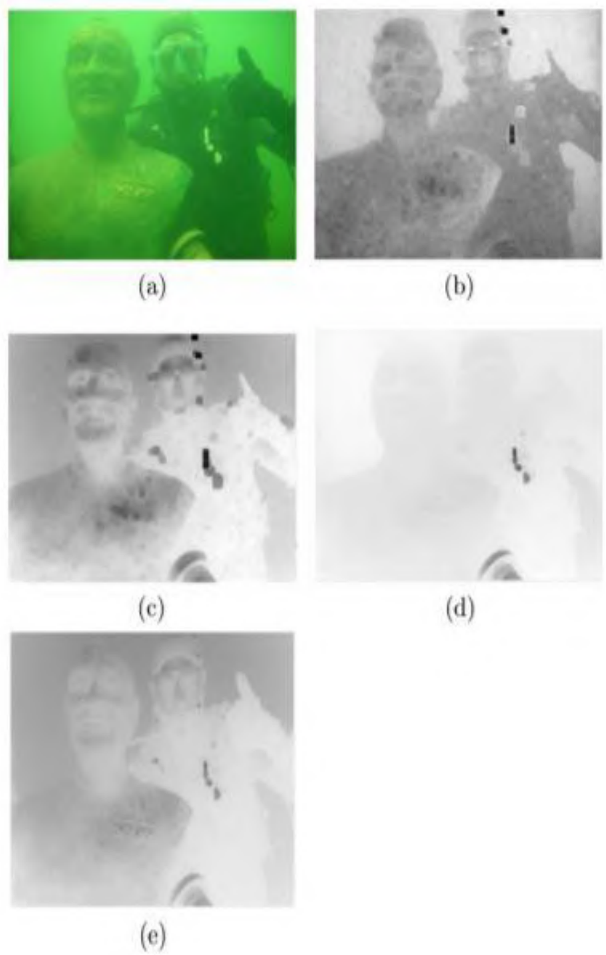

Fig.5: Depth map estimation (a) Input image (b) Depth map using red content (c) Depth map using 3 color channels (d) Depth map using image blurriness (e) Final depth map

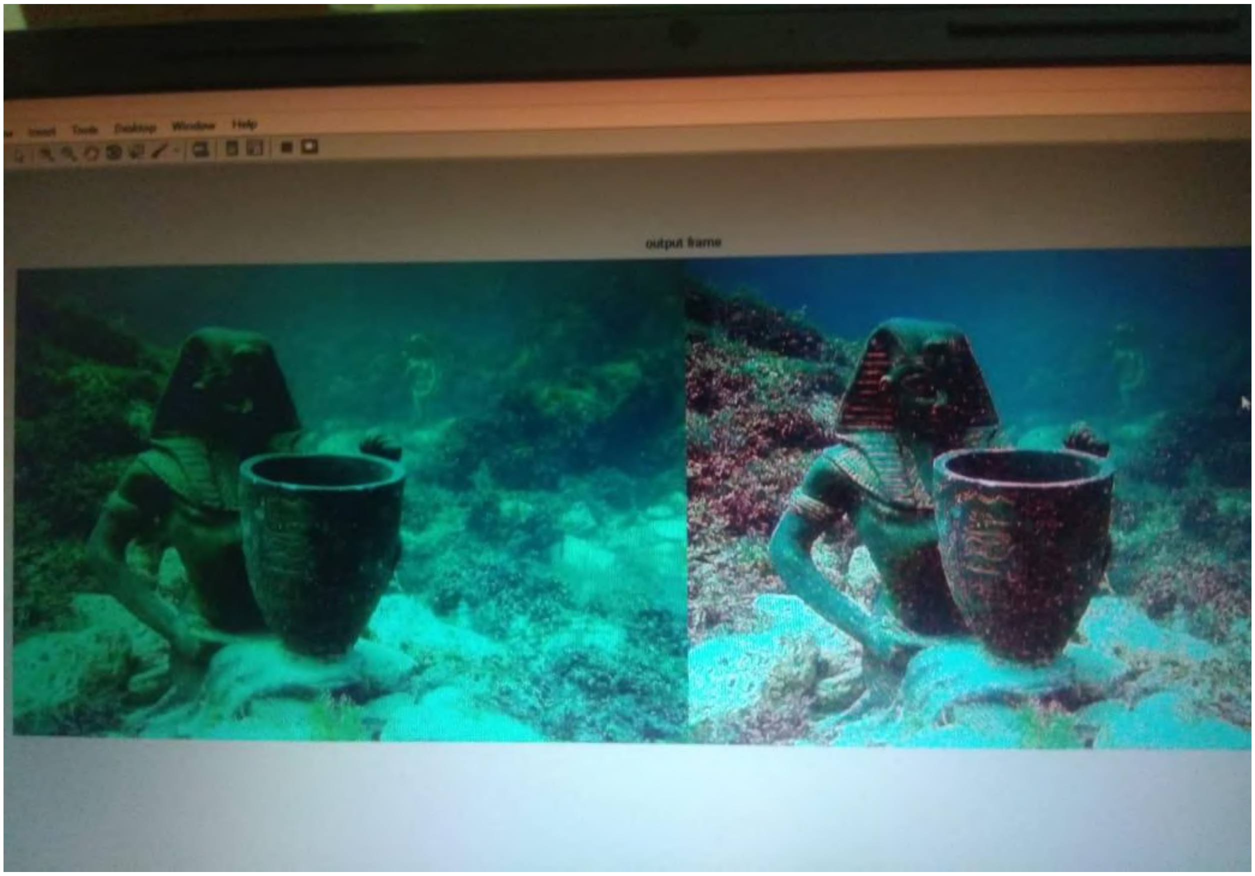
Chapter 6

Experiment results



Chapter 7

CONCLUSIONS

Underwater image restoration is a difficult task as there is a shortage of reference images and a changing underwater environment. Existing methods need specialized hardware or multiple images of the same scene, and is inadequate for real time and video applications. Algorithms using a single image also deals with several problems due to the wavelength dependency of light and its attenuation. Here images are restored using depth estimation based on image blurriness and light absorption. Image blurriness is linearly dependent on depth. Thus image blurriness is obtained to provide a measure of a depth map. This technique utilizes the largest blurriness and lowest variance region to estimate backlight and thus avoids faults of bright foreground objects. Finally, the image is restored by providing estimated parameters in the image formation model. It requires only a single image of a scene. Quality of restored images is evaluated using non-reference image quality measures and works well with many underwater images without numerous images dataset of one scene itself. Therefore, this technique provides better restoration results compared to other existing methods.

ACKNOWLEDGEMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to Dr. B. Hari Krishna **Head &Professor**, the Dept. of electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator** Dr. A. Anand for his involvement with originality has nourished my intellectual maturity that will help me for a long time to come. We are highly grateful and obliged to **our class Project Coordinator** Mr. K. Nishakar, **Professor in ECE** and our **project guide** Mr. S. P. Manikanta, **Associate Professor in ECE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

Finally, I am deeply indebted to my mother, my father, my siblings and to my family members for their moral support and continuous encouragement while carrying out this study. I dedicate this thesis to almighty.

.

ABSTRACT

The recent upsurge of diversified mobile applications, especially those supported by AI, is spurring heated discussions on the future evolution of wireless communications. While 5G is being deployed around the world, efforts from industry and academia have started to look beyond 5G and conceptualize 6G. We envision 6G to undergo an unprecedented transformation that will make it substantially different from the previous generations of wireless cellular systems. In particular, 6G will go beyond mobile Internet and will be required to support ubiquitous AI services from the core to the end devices of the network. Meanwhile, AI will play a critical role in designing and optimizing 6G architectures, protocols, and operations. In this article, we discuss potential technologies for 6G to enable mobile AI applications, as well as AI-enabled methodologies for 6G network design and optimization. Key trends in the evolution to 6G will also be discussed.

CHAPTER 1

INTRODUCTION

1.1 INTRODUCTION TO THE PROJECT:

The wireless communications industry is one of the few industry sectors that have kept a fast growing trend with creative features for a number of decades. The current 4G LTE networks have led to the thriving of mobile Internet, enabling various innovative applications, such as mobile shopping and payment, smart home/city, mobile gaming, and so on. The great success of mobile Internet has in turn been a driving force behind the evolution of wireless technologies. The upcoming 5G network will support a wide range of services, including eMBB (enhanced mobile broadband), uRLLC (ultra-reliable and low-latency communications), and mMTC (massive machinetype communications).

While 5G is still at an initial stage, to maintain the sustainability and competitiveness of wireless communication systems, it is time for both the industry and academia to think about what 6G will be. There are already initiatives describing the roadmap toward 6G along with the emerging trends and requirements, as well as various enabling techniques and architectures. In contrast to previous generations, 6G will be transformative and will revolutionize the wireless evolution from "connected things" to "connected intelligence" with more stringent requirements specified as follows:

- Very high data rates, up to 1 Tb/s;
- Very high energy efficiency, with the ability to support battery-free IoT devices;
- Massive low-latency control (less than 1 msec end-to-end latency);
- Very broad frequency bands (e.g., 73GHz140GHz and 1THz-3THz [4]);
- Ubiquitous always-on broadband global network coverage by integrating terrestrial wireless with satellite systems;

• Connected intelligence with machine learning capability. 6G will also require the support of three new service types beyond the eMBB, uRLLC, and mMTC services, as described below. Computation Oriented Communications (COC): New smart devices call for distributed computation to enable the key functionalities, such as federated learning.

Instead of targeting classical quality of service (QoS) provisioning, CoC will flexibly choose an operating point in the rate-latency-reliability space depending on the availability of various communications resources to achieve a certain computational accuracy. Contextually Agile eMBB Communications (CAeC): The provision of 6G eMBB services is expected to be more agile and adaptive to the network context, including the communication network context such as link congestion and network topology; the physical environment context such as surrounding location and mobility; and the social network context such as social neighborhood and sentiments. Event Defined uRLLC (EDuRLLC): In contrast to the 5G uRLLC application scenario where redundant resources are in place to offset many uncertainties, 6G will need to support uRLLC in extreme or emergency events with spatially and temporally changing device densities, traffic patterns, and spectrum and infrastructure availability. The above service types represent emerging driving applications of 6G. They can hardly be offered by 5G, not only because of their stringent requirements for higher data rates, lower latency, denser connection, and so on, but also due to their extreme demand for new performance metrics that have never been considered in 5G, for example, delay jitter, context awareness, UAV/ satellite compatibility, and so on. Inspired by these trends, in this article, we attempt to conceptualize 6G as an intelligent information system that is both driven by and a driver of the modern AI technologies. A roadmap for 6G is depicted in Fig. 1, which is plotted based on the strategic plans of various standards bodies and is also projected based on the 5G status. Key performance indicators (KPIs) and service types are also illustrated. Meanwhile, a potential network architecture for 6G is shown in Fig. 2. We envision that AI will greatly enhance the situational awareness of the network operators, and enable closed-loop optimization to support the new service types as mentioned above. As such, 6G will unleash the full potential of mobile communications, computing, and control in a host of exciting applications, including smart cities, autonomous driving, UAVs , seamless virtual and augmented reality, Internet of Vehicles, space-air-ground integrated networks and much more.

Wireless Sensor Networks (WSN) consists of a large number of miniature size, low-power, smart sensor nodes interfacing with one another and deployed over a certain inaccessible geographical locale having inadequate power and storage space. Energy efficiency is a foremost concern in WSN.To maximize the network lifetime, one possible solution is to harvest energy from the ambient boundless accessible energy sources in the environment nearby to the sensor nodes. The use of energy harvesting (EH) nodes as cooperative relays is a promising and budding solution in WSN. Energy harvest from one source is not sufficient to congregate the power requirement of sensor nodes. In this work, in order to improve the network lifetime electromagnetic radiation energy harvesting (EMR EH) method has been proposed. Communication is carried out by signal cooperation through relays in order to assist the sources to exchange their data for longer time periods. The current slot's transmission is based on transmitter knowledge about the present channel signal to noise ratio (SNR), past harvested energy and present energy stored in the battery. In order to solve the low power problem while maximizing the lifetime of wireless sensor nodes power management schemes like water filling energy harvesting strategies is included. The network performance metrics such as the probability of successful data exchange and the network lifetime gain has been derived and simulated using MATLAB.Simulations results illustrate that proposed technique afford enhanced result compared to existing energy harvesting schemes.A WSN is capable of gathering, data processing and communicating through nodes which have fascinated much interest during the previous decade in forming the notion of smart spaces. It consists of spatially sprinkled autonomous sensors to examine physical or environmental conditions, and to cooperatively overtake their data through the network to a main location. The swift development of wireless networks devices comprise their own batteries to deliver energy. For each message sent or else received, every communication and computation performed in the operation drains the battery, unique concern is mandatory in the utilization of power.

Accomplishing sensor lifetime of numerous years signifies one of the utmost challenges for designers. Hence the project present research guidelines for alleviating the energy problems in growth of WSN, including wireless sensor architecture power management techniques, and environmental energy harvesting approaches. The rest of the manuscript is organised as follows. Section II gives the system model adopted. Section III introduces a brief overview of techniques used to improve the network lifetime.

The latter technique exploits the low power modes of wireless transceivers, whose components can be switched off for energy saving. When the node is in a low power (or “sleep”) mode its consumption is significantly lower than when the transceiver is on.

However, when asleep the node cannot transmit or receive packets. The duty cycle expresses the ratio between the time when the node is on and the sum of the times when the node is on and asleep. Adopting protocols that operate at very low duty cycles is the leading type of solution for enabling long lasting WSNs.

However, this approach suffers from two main drawbacks.

1) There is an inherent tradeoff between energy efficiency (i.e., low duty cycling) and data latency.

2) Battery operated WSNs fail to provide the needed answer to the requirements of many emerging applications that demand network lifetimes of decades or more.

Battery leakage depletes batteries within a few years even if they are seldom used For these reasons recent research on long-lasting WSNs is taking a different approach, proposing energy harvesters combined with the use of rechargeable batteries and super capacitors (for energy storage) as the key enabler to “perpetual” WSN operations. Energy Harvesting-based WSNs (EHWSNs) are the result of endowing WSN nodes with the capability of extracting energy from the surrounding environment. Energy harvesting can exploit different sources of energy, such as solar power, wind, mechanical vibrations, temperature variations, magnetic fields, etc.

Continuously providing energy, and storing it for future use, energy harvesting subsystems enable WSN nodes to last potentially forever. This chapter explores the opportunities and challenges of EHWSNs, explaining why the design of protocol stacks for traditional WSNs has to be radically revisited. We start by describing the architecture of a EHWSN node, and especially that of its energy subsystem . We then present the various forms of energy that are available and ways for harvesting them , Models for predicting availability of wind and solar energy are described in Section 1.4. We then survey task allocation, MAC and routing protocols proposed so far for EHWSNs.

A Wireless Sensor Network (WSN) is composed of a large number of small dispersed devices known as sensor nodes that are closely deployed in the environment sense changes. The location of nodes in a sensor network may not be predetermined and usually have a unique sensor node called Base Station (BS). All member nodes will forward data to BS either directly or through multi hop transmission. A base station may be either static or dynamic sensor node and provides wireless connectivity to its users. It is usually more capable than other sensor nodes in the WSN . When sensor nodes in a WSN run out of energy, they stop working which causes the whole sensor network to fail. Therefore, the main issue of WSN is energy conservation. Hence, such protocols should be designed which use minimum energy and should be utilized during sensing, processing and transmission.

In Wireless Sensor Network, energy consumption is a vital challenge for sensor node for sensing and transmitting the data to the closest SN or the base station. The key requirement of a WSN is to minimize energy consumption and prolong network lifetime. Communication among sensor nodes stops when these sensor nodes lose their battery power.

A Challenges to Wireless Sensor Network Several challenges still need to be faced by WSNs. The main challenges and essential design limitation which affect the performance of Wireless Sensor Network are discussed here :

1) Resource limitations: Sensing nodes are bounded by energy, data processing abilities, memory and the data transmission rate to be gained.

2) Security: The Wireless Sensor Network must be secure to control illegal entities spreading false data to the sensor node or giving wrong information to the other sensor nodes and possibly causing significant damage to the sensor nodes.

3) Self-Management: After deployment of the sensor nodes, the user has less interaction with these sensor nodes with no infrastructure support or the capability to keep and repair itself. Therefore, the sensor nodes must be self-organised in a way that must be configured, work together with other sensor nodes.

4) Heterogeneity: It is a group of sensor nodes which are not identical and do not have similar capabilities, i.e. some sensor nodes are more powerful than others. Heterogeneity arises when two different sensor networks need to communicate with each other. There will be some mechanism which is required to enable efficient information exchange among these networks.

These sensor nodes are able to sense the information from one end transmitter side and process it and send it to the selected destinations. Wireless sensors have characteristics behaviors such as macro dimension, very low cost, highly reliable, flexibility to install anywhere and low energy consumption. Because of these energy saving behaviors, they could be deployed in various fields such as oil fields, military, defense, agricultural, industrial, and biomedical and many more real and non real time application domains. The sensor they could easily be used in different environments such as unmanned and critical regions.

So the cost of network is less, complicated configuration and installation for these sensors in the network connects each other, we could use them with lesser cost in comparison with traditional or commercial networks. Our research efforts focused on establishing efficient routing paths for transmitting packets from a sensor node to a sensor destination. Routes to find the best and well selected profitable way for data transmission from source node to the destination node in the network by considering different parameters (e.g. flexibility, reliability overhead, throughput, stability, consumed and wasted power, data speed, etc). Our proposed sensor parameters to increase the wireless sensor networks Lifetime. Life time is one of the most important factors of deployed wireless sensor networks. Finding the best shortest route length to reduce the transmission overhead and reduced delay time. To increase the ratio of packets in packet delivery fraction, these wireless sensor networks must be designed and used in an efficient way to optimize the sensor to reduced power consumption and increased life time of the sensor network player.

Our idea to proposed work, using probability selection Game Theory approach for WSN, optimal discovery of route in WSN is discovered. Our approach towards this proposed project, we developed network to select route based on routing and sensor nodes the same things are assumed to be the game and players of the networks respectively. Each and every node in the network we considered wants to increase their benefit in the present network. So we use a different mixed strategy model as well as network profit and loss calculation for each player that alive in the networks. In this proposed method, the destination node player node pays a recognition to the source player node for each data packet successfully reception from the source player to destination player.

Moreover, the source player pays attention of this credit to each intermediate player node or relay player node that participates in sending data packet transaction. Yet to decide, each node sustains a transmission cost for each data packet transaction to other intermediate or destination receiving node. The cost is called networks Transmission Cost or path loss and related to different type of parameters.

Each player transmits the received data packet to the next or intermediate hop with the selected player game probability, calculated by the reliability of the multiple player that playing in the network. Our enhanced parameter checked on player characteristics or behavior, e.g. link error checking, probability, duty cycle, etc. ehwsns are composed of individual nodes that in addition to sensing and wireless communications are capable of extracting energy from multiple sources and converting it into usable electrical power. In this section we describe in details the architecture of a wireless sensor node with energy harvesting capabilities, including models for the harvesting hardware and for batteries.

The system architecture of a wireless sensor node includes the following components

1) The energy harvester(s), in charge of converting external ambient or human-generated energy to electricity;

2) a power management module, that collects electrical energy from the harvester and either stores it or delivers it to the other system components for immediate usage;

3) energy storage, for conserving the harvested energy for future usage;

4) a microcontroller;

5) a radio transceiver, for transmitting and receiving information;

6) sensory equipment;

7) an A/D converter to digitize the analog signal generated by the sensors and makes it available to the microcontroller for further processing, and

8) memory to store sensed information, application related data, and code. In the next section we focus on the energy harvesting components (the energy subsystem) of a EHWSN node, describing abstractions that have been proposed for modeling them.

The general architecture of the energy subsystem of a wireless sensor node with energy harvesting capabilities is shown. The energy subsystem includes one or multiple harvesters that convert energy available from the environment to electrical energy. The energy obtained by the harvester may be used to directly supply energy to the node or it may be stored for later use. Although in some application it is possible to directly power the sensor node using the harvested energy, with no energy storage (harvest-use architecture)in general this is not a viable solution.

A more reasonable architecture enables the node to directly use the harvested energy, but also includes a storage component that acts as an energy buffer for the system, with the main purpose of accumulating and preserving the harvested energy. When the harvesting rate is greater than the current usage, the buffer component can store excess energy for later use (e.g., when harvesting opportunities do not exist), thus supporting variations in the power level emitted by the environmental source. The two alternatives commonly used for energy storage are secondary rechargeable batteries and super capacitors (also known as ultra capacitors). Super capacitors are similar to regular capacitors, but they offer very high capacitance in a small size.

They offer several advantages with respect to rechargeable batteries . First of all, super capacitors can be recharged and discharged virtually an unlimited number of times, while typical lifetimes of an electrochemical battery is less than 1000 cycles. Second, they can be charged quickly using simple charging circuits, thus reducing system complexity, and do not need full-charge or deep-discharge protection circuits. They also have higher charging and discharging efficiency than electrochemical batteries. Another additional benefit is the reduction of environmental issues related to battery disposal. Thanks to these characteristics, many platforms with harvesting capabilities use super capacitors as energy storage, either by themselves or in combination with batteries.

Other systems, instead, focus on platforms using only rechargeable batteries. Both types of storage devices deviate from ideal energy buffers in a number of ways: They have a finite size BMax and can hold a finite amount of energy; they have a charging efficiency $\eta c < 1$ and a discharging efficiency $\eta d < 1$, i.e., some energy is lost while charging and discharging the buffer, and they suffer from leakage and self-discharge, i.e., some stored energy is lost even if the buffer is not in use. Leakage and self-discharge are phenomena that affect both batteries and super capacitors. All batteries suffer from self-discharge: A cell that simply sits on the shelf, without any connection between the electrodes, experiences a reduction in its stored charge due to internal chemical reactions, at a rate depending on the cell chemistry and the temperature.

A similar phenomenon affects electrochemical super-capacitors in charged state. They suffer gradual loss of energy and reduction of the inter-plate voltage. In order to reduce the energy lost trough buffer inefficiencies, many platforms allow the node to directly use the energy harvested. In particular, if the current energy consumption is greater or equal than the energy currently harvested, then the node can use the harvested energy for its operations.

This is the most efficient way of using the environmental energy, because it is used directly and there is no energy loss. Otherwise, if the amount of energy harvested is greater than the current energy consumption, some energy is directly used to sustain the node operations, while excess energy is stored in the buffer for later use.

A super capacitor leakage is strongly variable and depends on several factors, including the capacitance value of the super capacitor, the amount of energy stored, the operating temperature, the charge duration, etc. For this reason, the leakage pattern of a particular super capacitor must often be determined experimentally .Additionally, the leakage current varies with time: It is considerably higher immediately after the super capacitor has been charged, then it decreases to a plateau. Several model for the leakage from a charged super capacitor have been proposed in the literature, modeling the leakage as a constant current, or as an exponential function of the current super capacitor voltage , or by using a polynomial approximation of its empirical leakage pattern , or, finally, by using a piecewise linear approximation of its empirical leakage pattern.

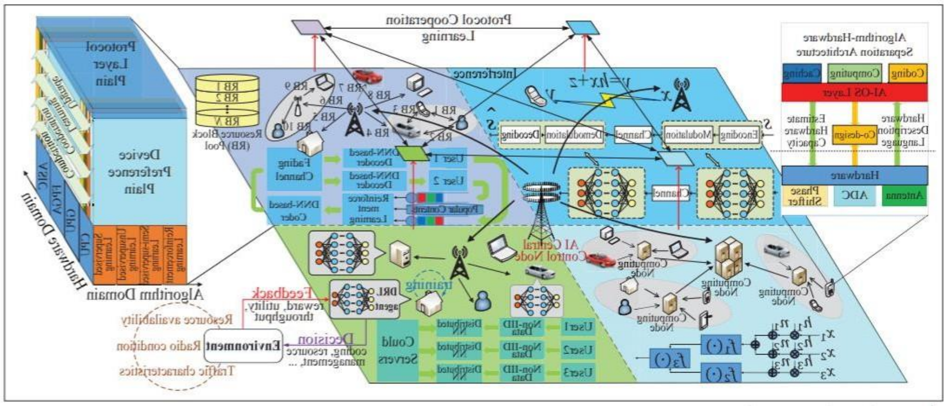

Fig: Architecture of 6G network

These models have been proposed after experimental observations of actual super capacitor leakage, such as those shown in Figure showing the self-discharge experienced by a charged 25F super capacitor over a two-weeks period. Another aspect to consider in the super capacitors vs. battery comparison is that in many application scenarios it is not possible to use the full energy stored in the super capacitor. The voltage of a super capacitor drops from full voltage to zero linearly, without the flat curve that is typical of most electrochemical batteries. The fraction of the charge available to the sensor node depends on the voltage requirements of the platform. For example, a Telos B mote requires a minimal voltage ranging from 1.8 V to 2.1 V. When the super capacitor voltage drops below this threshold, its residual energy can no longer be used to power the node.

This aspect may be partially mitigated by using a DC-DC converter to increase the voltage range, at the cost of introducing inefficiencies and an additional source of power consumption.

Wireless sensor network (WSN) refers to a group of spatially dispersed and dedicated sensors for monitoring and recording the physical conditions of the environment and organizing the collected data at a central location. WSNs measure environmental conditions like temperature, sound, pollution levels, humidity, wind, and so on.

These are similar to wireless ad hoc networks in the sense that they rely on wireless connectivity and spontaneous formation of networks so that sensor data can be transported wirelessly. WSNs are spatially distributed autonomous sensors to monitor physical or environmental conditions, such as temperature, sound, pressure, etc. And to cooperatively pass their data through the network to a main location. The more modern networks are bi-directional, also enabling control of sensor activity. The development of wireless sensor networks was motivated by military applications such as battlefield surveillance; today such networks are used in many industrial and consumer applications, such as industrial process monitoring and control, machine health monitoring, and so on.

The WSN is built of "nodes" – from a few to several hundreds or even thousands, where each node is connected to one (or sometimes several) sensors. Each such sensor network node has typically several parts: a radio transceiver with an internal antenna or connection to an external antenna, a microcontroller, an electronic circuit for interfacing with the sensors and an energy source, usually a battery or an embedded form of energy harvesting. A sensor node might vary in size from that of a shoebox down to the size of a grain of dust, although functioning "motes" of genuine microscopic dimensions have yet to be created.

The cost of sensor nodes is similarly variable, ranging from a few to hundreds of dollars, depending on the complexity of the individual sensor nodes. Size and cost constraints on sensor nodes result in corresponding constraints on resources such as energy, memory, computational speed and communications bandwidth. The topology of the WSNs can vary from a simple star network to an advanced multi-hop wireless mesh network. The propagation technique between the hops of the network can be routing or flooding.

Energy harvesting (also known as power harvesting or energy scavenging or ambient power) is the process by which energy is derived from external sources (e.g., solar power, thermal energy, wind energy, salinity gradients, and kinetic energy, also known as ambient energy), captured, and stored for small, wireless autonomous devices, like those used in wearable electronics and wireless sensor networks.

Energy harvesters provide a very small amount of power for low-energy electronics. While the input fuel to some large-scale generation costs resources (oil, coal, etc.), the energy source for energy harvesters is present as ambient background. For example, temperature gradients exist from the operation of a combustion engine and in urban areas, there is a large amount of electromagnetic energy in the environment because of radio and television broadcasting.

One of the earliest applications of ambient power collected from ambient electromagnetic radiation (EMR) is the crystal radio.

The principles of energy harvesting from ambient EMR can be demonstrated with basic components

Energy can also be harvested to power small autonomous sensors such as those developed using MEMS technology. These systems are often very small and require little power, but their applications are limited by the reliance on battery power. Scavenging energy from ambient vibrations, wind, heat or light could enable smart sensors to be functional indefinitely. Several academic and commercial groups have been involved in the analysis and development of vibration-powered energy harvesting technology, including the Control and Power Group and Optical and Semiconductor Devices Group at Imperial College London, IMEC and the partnering Holst Centre, Adaptive Energy, LLC, ARVENI, MIT Boston, Victoria University of Wellington, Georgia Tech, UC Berkeley, Southampton University, University of Bristol, Micro Energy System Lab at The University of Tokyo, Nanyang Technological University, PMG Perpetuum, ReVibe Energy, Vest fold University College, National University of Singapore, NiPS Laboratory at the University of Perugia, Columbia University, Universidad Autónoma de Barcelona and USN & Renewable Energy Lab at the University of Ulsan (Ulsan, South Korea). The National Science Foundation also supports an Industry/University Cooperative Research Center led by Virginia Tech and The University of Texas at Dallas called the Center for Energy Harvesting Materials and Systems.

Typical power densities available from energy harvesting devices are highly dependent upon the specific application (affecting the generator's size) and the design itself of the harvesting generator. In general, for motion powered devices, typical values are a few $\mu W/cm^3$ for human body powered applications and hundreds of $\mu W/cm^3$ for generators powered from machinery. Most energy scavenging devices for wearable electronics generate very little power.

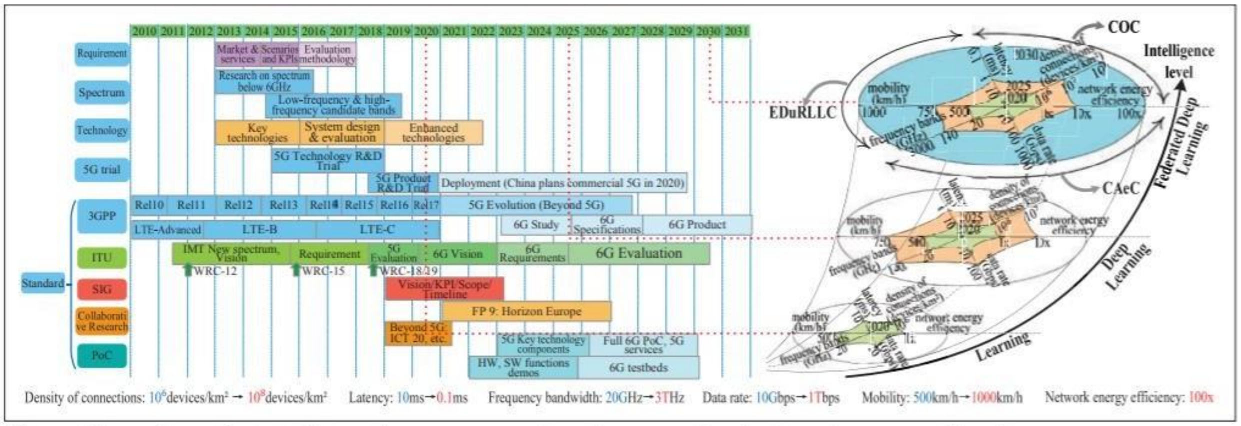

Fig: Spectrum Explanation of learning, Deep learning, federated deep learning

1.2 The Architecture of 6G Networks :

In this section, we introduce a potential architecture for 6G as shown in Fig.2, in which network intelligentization, subnetwork evolution, and intelligent radio are embraced. From Network Softwarization to Network Intelligentization We envision that 6G will take network softwarization to a new level, namely toward network intelligentization. In 5G, the “non-radio” aspect has become more and more important, and has been the key driver behind the recent efforts on “softwarization”. More specifically, two key 5G technologies are Software-Defined Networking (SDN) and Network Functions Virtualization (NFV), which have moved modern communications networks toward software-based virtual networks. They also enable network slicing, which can provide a powerful virtualization capability to allow multiple virtual networks to be created atop a shared physical infrastructure. Nevertheless, as the network is becoming more complex and more heterogeneous, softwarization is not going to be sufficient for 6G. In particular, to support AI-based applications, the network entities have to support diverse capabilities, including communications, content caching, computing, and even wireless power transfer. Furthermore, 6G will embrace new radio access interfaces such as THz communications and intel ligent surfaces. It will also need to support more advanced IoT functionalities including sensing, data collection, analytics, and storage. All of the aforementioned challenges call for an architecture that is flexible, adaptive, and more importantly, intelligent. Existing technologies, such as SDN, NFV, and network slicing will need to be further improved to meet these challenges. By enabling fast learning and adaptation, AI-based methods will render network slicing much more versatile in 6G.

The design of the 6G architecture shall follow an “AI native” approach where intelligentization will allow the network to be smart, agile, and able to learn and adapt itself according to the changing network dynamics. It will evolve into a “network of subnetworks,” allowing more efficient and flexible upgrades, and a new framework based on intelligent radio and algorithm-hardware separation to cope with the heterogeneous and upgradable hardware capabilities. Both of these two features will exploit AI techniques, as further illustrated in the following subsections. A Network of Subnetworks: Local vs Global Evolution Given its expected ultra-high heterogeneity, one key feature of 6G will be its capability to exploit a flexible subnetwork-wide evolution to effectively adapt to the local environments and user demands, thereby resulting in a “network of subnetworks.” In particular, local subnetworks in 6G may evolve individually to upgrade themselves. The local evolution may happen in a few neighboring cells in order to flexibly apply cutting-edge developments on new waveforms, coding, and multi-access protocols in subnetworks without extensive time-consuming tests. In contrast to the global evolution from 1G to 5G, in which both hardware and software of all the cells are upgraded simultaneously, there is no need to find a onesize-fit-all solution for all the cells and rebuild the whole system when local evolution is exploited. To achieve this goal, we need to address the following three challenges:

• Each subnetwork should collect and analyze its local data, which may include the wireless environments, user requests, mobility patterns, and so on, and then exploit AI methods to upgrade itself locally and dynamically.

• When the local PHY or MAC protocols are changed, the inter-subnetwork interaction is expected to maintain new inter-subnetwork coordination. One possible solution is to adopt game and learning approaches, which can assure the convergence of the sub networks upgrades.

• The local evolution of 6G requires a relatively stable control plane to support the evolution in the “network of subnetworks” level. One possible solution relies on the “learning from scratch” method developed in Alpha Zero.

CHAPTER 2

INTRODUCTION TO MATLAB

2.1 Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

2.2 THE MATLAB SYSTEM:

The MATLAB system consists of five main parts

- Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- The MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

- Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for twodimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

2.3. GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based Mfunction is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.

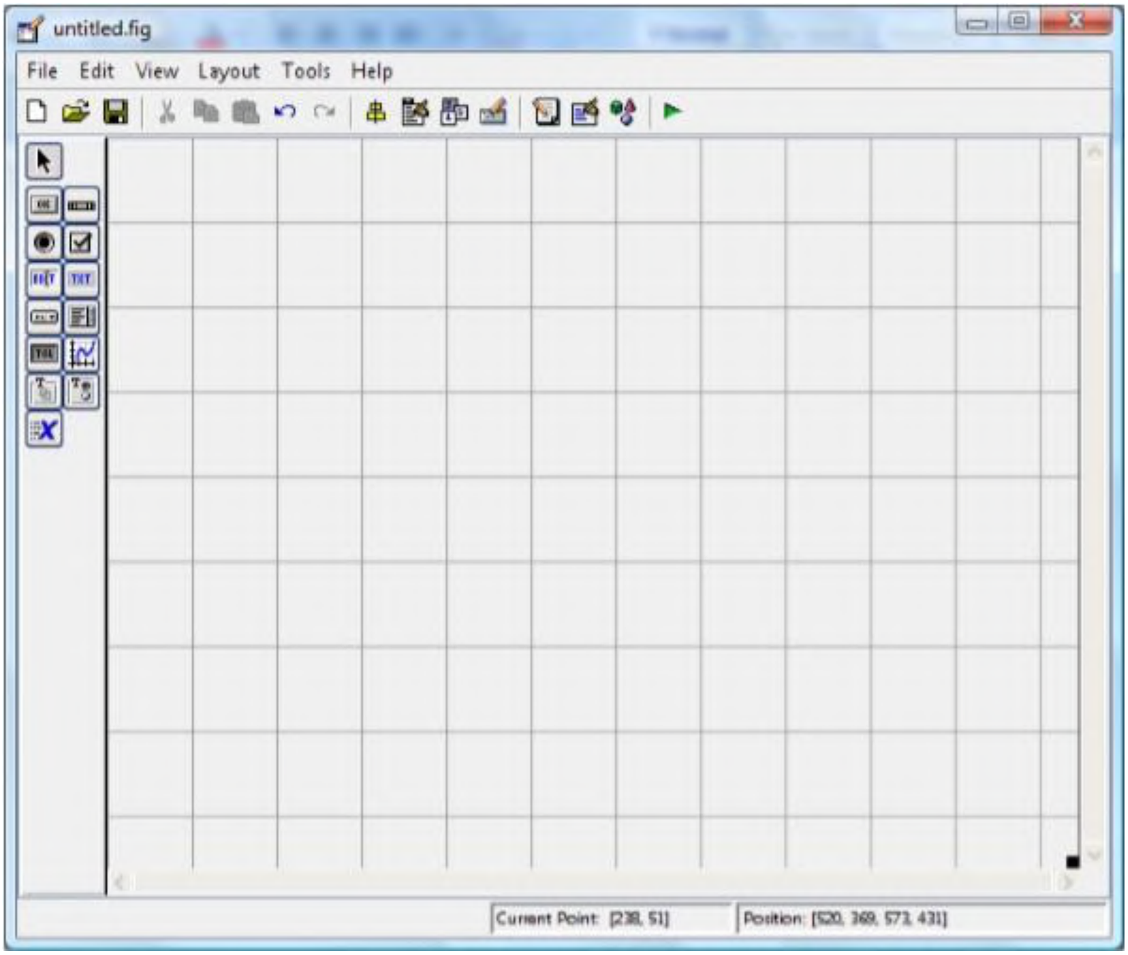

Figure : Matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

2.4 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

2.4.1 INTRODUCTION - describes the components of the MATLAB system.

2.4.2 DEVELOPMENT ENVIRONMENT - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

2.4.3 MANIPULATING MATRICES - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

2.4.4 GRAPHICS - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images. 2.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

2.4.5 DEVELOPMENT ENVIRONMENT – A Development environment is a collection of procedures and tools for developing ,testing and debugging an application or program

2.5.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

2.5.2 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab

At the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

2.5.3 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

2.5.4 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

2.5.5 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

- Running External Programs - You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.
- Launch Pad - MATLAB's Launch Pad provides easy access to tools, demos, and documentation.
- Help Browser - Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in theCommand Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.
- Help Navigator - Use to Help Navigator to find information. It includes:
- Product filter - Set the filter to show documentation only for the products you specify.
- Contents tab - View the titles and tables of contents of documentation for your products.
- Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.
- Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.
- Favorites tab - View a list of documents you previously designated as favorites.
- Display Pane - After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:
- Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.
- Bookmark pages - Click the Add to Favorites button in the toolbar.
- Print pages - Click the print button in the toolbar.
- Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

- Current Directory Browser - MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.
- Search Path - To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.
- Workspace Browser - The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

- Array Editor - Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

- Editor and debugger- MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

CHAPTER 3

3.1 ENERGY HARVESTING

The generation of electrical energy involves an energy-to-energy conversion process such as mechanical-to-electrical (ME), chemical-to-electrical (CE), solar-to-electrical (SE), radio frequency-to-electrical (RFE), and thermal-to-electrical (TE). ME conversion is used in hydroelectric and wind turbines for large-scale generation to meet the demands of cities. CE conversion is used in batteries to provide portable electrical energy. TE conversion is a technology under development.

SE conversion uses solar energy to generate electrical energy. Solar farms provide electrical generation on a large industrial scale as well as for individual home owners. RFE converts electromagnetic energy in the millimeter (mm)-to-micron-wavelength range of the electromagnetic spectrum to electrical energy. Currently, energy harvesting refers to the nonchemical generation of small amounts of electrical energy on a local scale using one of the above energy conversion principles. Among the above energy conversion processes for electrical energy harvesting, even under very low light levels, SE conversion has generally been found to be the best choice and is widely used in consumer goods and many other products.

For example, SE conversion is used to power wrist watches, calculators, road signs, and in practically any other application where solar illumination is available and its space and power requirements can be met. The energy output of SE-based energy harvesters is limited by the size of the solar cell. However, in many energy-harvesting applications, a few microwatts of power may suffice and can be obtained. For 24/7 operation, storage devices such as rechargeable batteries and super-capacitors have been used. It is, however, important to note that in many applications, the use of SE conversion is not practical, such as in enclosed environments where enough light is never available.

The use of SE conversion may also be impractical due to the required size of the solar collector and its collection and storage components. Examples of such cases include self-powered and networked sensors used on machinery to monitor vibration and health in industrial plants; sensors for use inside an enclosed space such as in vehicle tires or inside a machine body; or self-powering of encapsulated microelectromechanical systems (MEMS)-type sensors of various types.

In many applications, the energy that has been made available for harvesting is in the form of mechanical kinetic and/or potential energy, or even impulsive loading of some form. As a result, in many applications, energy harvesters based on converting kinetic and/or potential energy to electrical energy become the only viable option. Certain ME-based energy-harvesting devices, such as those employing piezoelectric transducers, also have the unique capability of being used as sensors,

for example, for detecting and measuring acceleration or force generated due to a specific emergency event. Today, energy harvesters may be designed to provide perpetual power for autonomous wireless sensor nodes, or pulse power for short-lived one-time use, as in initiation or emergency systems. Design of energy harvesters is determined by both the local energy source (host system) and by the interfacing mechanism, particularly for motion-based energy-harvesting systems. Available sources of energy for harvesters can be grouped into either ambient or man-made.

The former category includes natural sources such as solar radiation, thermal gradients, wind, and ocean waves. Man-made sources may arise as by-products of various activities and processes, for example, background energy from radio-frequency signals generated primarily for use in telecommunication systems, or vibrational energy resulting from vehicles or large industrial systems, such as production machinery.

The choice of a particular energy source is determined by the operational environment, available energy density, and the required energy level to power the intended device. Figure 1.1 shows some of the popular energy sources and the corresponding energy density. It should be noted that, while the solar

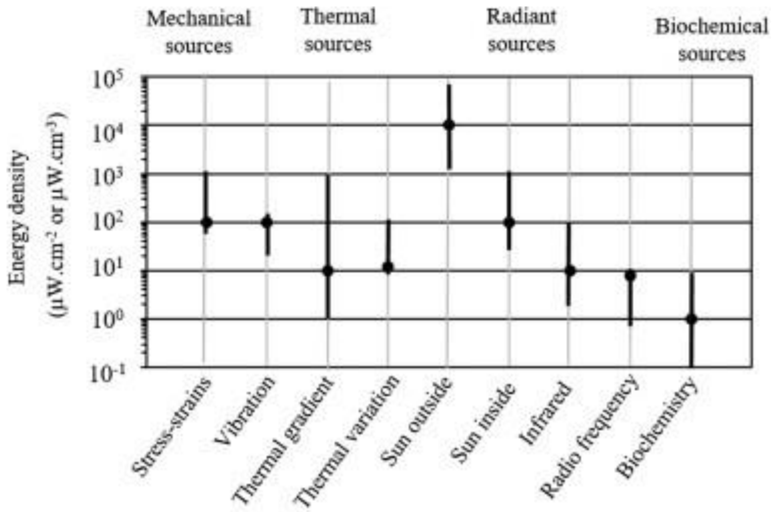

Figure 1.1 Energy densities of typical ambient energy sources.[1]

luminance has the highest available power density, it cannot be changed, and its availability is not always guaranteed. The primary focus of this book is on harnessing mechanical potential and/or kintic energy. Other sources of energy are also available, such as thermal gradient and radiated electromagnetic energy. The latter sources of energy are briefly described below. A brief description of the application of energy harvesting for self-powering implantable devices and sensors in the human body is also provided. The reader is referred to available literature for an in-depth treatment of the subject and for other sources of available energy for harvesting.

3.2 Thermal-to-Electrical-based Energy Harvesting:

The thermoelectric effect2 is used to convert temperature difference into voltage. An implementation of the effect in a loop constructed of two dissimilar conductors generates an electromotive force Vemf when a constant temperature gradient exists between the two common points. The generated voltage is given where a1 and a2 are the Seebeck coefficients for the two dissimilar conductors. The value of a may range from –100 mV/K to 1000 mV/K for common conductors.3 Very large temperature differences are needed to produce useful operating voltages compatible with electronic integrated circuits.

In order to make a useful generator, conductors are typically replaced by n- and p-type semiconductors, as illustrated in Fig. 1.2. This configuration allows heat transfer in the same direction, while the voltage difference across the n- and p-type materials is additive. The power output of an n-p-based thermoelectric generator is proportional to the square of the temperature difference between the hot and cold surfaces and is proportional to the physical cross-sectional area of the n-p legs. For example, the generated power density at a temperature difference of 200 °C is on the order of 100 mW/cm2.

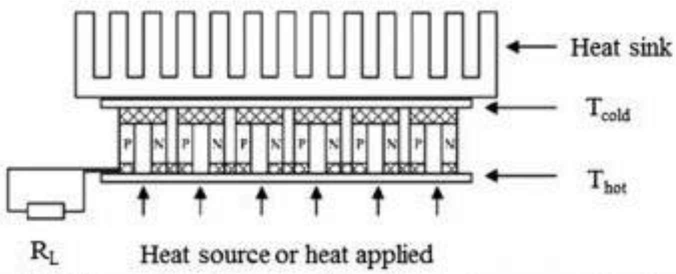

Figure 1.2 Thermoelectric-generating cell n- and p-type semiconductors.[4]

3.3 Solar-to-Electrical-based Energy Harvesting:

The most dominant source of radiated electromagnetic energy is solar energy, which illuminates the surface of the earth at a nominal value of 1 kW · m2 . Solar energy may be harvested indoors and outdoors using photovoltaic devices. This makes solar energy the first choice for harvesting, as long as it satisfies the constraints of the devices or systems to be powered. For example, the device to be powered may not have direct solar radiation or may require uninterrupted power during daytime as well as during the night without the use of a storage device due to size or weight limitations. Photovoltaics technology primarily targets the visible-to-near infrared part of the electromagnetic spectrum.

The transducers, commonly referred to as photovoltaics or photocells, are quantum devices that directly generate electron–hole pairs from the absorption of incident photons within the depletion region of a p-n junction device. These devices are generally modeled as a current source shunted by an ideal p-n junction diode. For indoor applications, electrical energy generated will also depend on the spatial characteristics of the light source as well as the distance of the transducer from the source. For example, a 100-W incandescent bulb is expected to generate a few microwatts at the output of a 2-mm diameter photovoltaic cell placed at a distance of 2 m.

3.4 Radio-Frequency-to-Electrical-based Energy Harvesting:

RFE technology harvests electromagnetic energy in the radio-frequency band from megahertz to microwave. RFE devices typically have a tuned receiving antenna for converting the received RF energy into electrical energy. The power generated by RFE harvesters is extremely low unless the receiver is in close proximity to the source and/or the receiver is very large. Some of these energy-harvesting devices use the ambient electromagnetic energy emitted by nearby sources and are finding use in autonomous sensor nodes. However, these types of harvesters cannot be placed inside conductive enclosures. Directed radiofrequency emissions have also been used for collection by matched receiving antennas (the so-called rectenna). For example, active and passive radio-frequency identification (RFID) systems use such technologies.

3.5 Sources of Energy from Human Activity:

Due to the recent proliferation of wearable health monitoring devices and portable electronics, considerable effort is being devoted to harnessing power from voluntary and involuntary human activities, for example, from the pulsating motion of the heart. Table compares nominal values of power available from human activity and the corresponding power needs of some typical applications. In addition to harnessing energy from human locomotion, devices to convert body heat to electrical energy through thermoelectric conversion and flexible piezoelectric materials embedded into fabrics may soon be coming to the market. In addition to harnessing energy from human activity, there is considerable interest in attaching self-powered health-monitoring sensors directly to organs, such as the heart. The sensors may also assist the organ’s function by providing electrical stimulus, as is the case with heart pacemakers. Figure shows an example of an autonomous device mounted on a bovine heart. This heart-assist device uses a flexible piezoelectric energy harvester. On another note, the hidden cost of attaching an energy-harvesting device to a system such as the heart, which is optimized for a particular function, should not be underestimated or overlooked. For instance, the heart, which is a pulsating oscillator with a life cycle of over 5 billion beats has taken nature over 65 million years to perfect. It pumps blood through a circulatory system

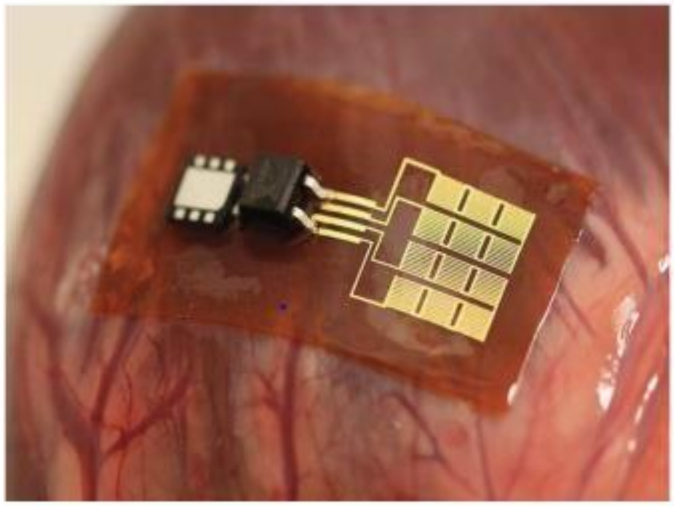

Figure 1.3 A piezoelectric energy harvester, with rectifier and microbattery, mounted on a bovine heart. (Reprinted with permission from Ref. 12.)

of vessels to deliver oxygen and nutrients to individual cells and removes metabolic waste.13 Attaching an external device, no matter how small, may produce a reactive chain of events from the cardiovascular system. The longterm effects of loading the cardiovascular system are difficult to predict and will require the accumulation of clinical data over many years.

3.6 Mechanical-to-Electrical-based Energy Harvesting:

The design of energy harvesters intended for converting mechanical kinetic and/or potential energy from a host system to electrical energy for direct consumption or storage for later use. The process of converting mechanical energy to electrical energy may be described in three distinct phases, as shown in Fig. 1.4. In the first phase, an interfacing mechanism properly transfers the mechanical energy to the transducer. In the second phase, the transducer generates electrical energy. In the third phase, the generated electrical energy is collected and conditioned to be either stored in an energy storage device such as a rechargeable battery or a capacitor or to be delivered directly to the intended electrical energy consuming device (load). The remainder of this book is divided into four chapters. Chapter 2 describes the three primary types of transducers typically used for converting mechanical energy to electrical energy, that is, piezoelectric, electromagnetic, and electrostatic transducers. Magnetostrictive-based transducers are also briefly introduced. Chapter 3 presents an in-depth analysis of the interfacing mechanisms used for coupling mechanical kinetic and/or potential energy to the transducer for effective energy transfer. Chapter

4 addresses coupling and conditioning circuits needed to extract the generated electrical energy for delivery to the load. The theme of these chapters shows the connection between the three components of an energy-harvesting system, namely, the interfacing mechanism, the transducer, and the collection and conditioning circuit. Chapter presents case studies of some available energy harvesting system solutions.

Energy harvesting (also known as power harvesting or energy scavenging or ambient power) is the process by which energy is derived from external sources (e.g., solar power, thermal energy, wind energy, salinity gradients, and kinetic energy, also known as ambient energy), captured, and stored for small, wireless autonomous devices, like those used in wearable electronics and wireless sensor networks.

Energy harvesters provide a very small amount of power for low-energy electronics. While the input fuel to some large-scale generation costs resources (oil, coal, etc.), the energy source for energy harvesters is present as ambient background. For example, temperature gradients exist from the operation of a combustion engine and in urban areas, there is a large amount of electromagnetic energy in the environment because of radio and television broadcasting.

One of the earliest applications of ambient power collected from ambient electromagnetic radiation (EMR) is the crystal radio.

The principles of energy harvesting from ambient EMR can be demonstrated with basic components

3.6.1 OPERATION:

Energy harvesting devices converting ambient energy into electrical energy have attracted much interest in both the military and commercial sectors. Some systems convert motion, such as that of ocean waves, into electricity to be used by oceanographic monitoring sensors for autonomous operation. Future applications may include high power output devices (or arrays of such devices) deployed at remote locations to serve as reliable power stations for large systems. Another application is in wearable electronics, where energy harvesting devices can power or recharge cellphones, mobile computers, radio communication equipment, etc. All of these devices must be sufficiently robust to endure long-term exposure to hostile environments and have a broad range of dynamic sensitivity to exploit the entire spectrum of wave motions.

3.7 Accumulating energy:

Energy can also be harvested to power small autonomous sensors such as those developed using MEMS technology. These systems are often very small and require little power, but their applications are limited by the reliance on battery power. Scavenging energy from ambient vibrations, wind, heat or light could enable smart sensors to be functional indefinitely. Several academic and commercial groups have been involved in the analysis and development of vibration-powered energy harvesting technology, including the Control and Power Group and Optical and Semiconductor Devices Group at Imperial College London, IMEC and the partnering Holst Centre, Adaptiv Energy, LLC, ARVENI, MIT Boston, Victoria University of Wellington, Georgia Tech, UC Berkeley, Southampton University, University of Bristol, Micro Energy System Lab at The University of Tokyo, Nanyang Technological University, PMG Perpetuum, ReVibe Energy, Vestfold University College, National University of Singapore, NiPS Laboratory at the University of Perugia,] Columbia University, Universidad Autonoma de Barcelona and USN & Renewable Energy Lab at the University of Ulsan (Ulsan, South Korea). The National Science Foundation also supports an Industry/University Cooperative Research Center led by Virginia Tech and The University of Texas at Dallas called the Center for Energy Harvesting Materials and Systems.

Typical power densities available from energy harvesting devices are highly dependent upon the specific application (affecting the generator's size) and the design itself of the harvesting generator. In general, for motion powered devices, typical values are a few $\mu W/cm^3$ for human body powered applications and hundreds of $\mu W/cm^3$ for generators powered from machinery. Most energy scavenging devices for wearable electronics generate very little power.

3.8 Storage of power:

In general, energy can be stored in a capacitor, super capacitor, or battery. Capacitors are used when the application needs to provide huge energy spikes. Batteries leak less energy and are therefore used when the device needs to provide a steady flow of energy. Compared to batteries, super capacitors have virtually unlimited charge-discharge cycles and can therefore operate forever enabling a maintenance-free operation in IoT and wireless sensor devices.

3.9 Use of the power:

Current interest in low power energy harvesting is for independent sensor networks. In these applications an energy harvesting scheme puts power stored into a capacitor then boosted/regulated to a second storage capacitor or battery for the use in the microprocessor or in the data transmission. The power is usually used in a sensor application and the data stored or is transmitted possibly through a wireless method.

The history of energy harvesting dates back to the windmill and the waterwheel. People have searched for ways to store the energy from heat and vibrations for many decades. One driving force behind the search for new energy harvesting devices is the desire to power sensor networks and mobile devices without batteries. Energy harvesting is also motivated by a desire to address the issue of climate change and global warming.

There are many small-scale energy sources that generally cannot be scaled up to industrial size:

- Some wristwatches are powered by kinetic energy (called automatic watches), in this case movement of the arm is used. The arm movement causes winding of its mainspring. A newer design introduced by Seiko ("Kinetic") uses movement of a magnet in the electromagnetic generator instead to power the quartz movement. The motion provides a rate of change of flux, which results in some induced emf on the coils. The concept is related to Faraday's Law.
- Photovoltaics is a method of generating electrical power by converting solar radiation (both indoors and outdoors) into direct current electricity using semiconductors that exhibit the photovoltaic effect. Photovoltaic power generation employs solar panels composed of a number of cells containing a photovoltaic material. Note that photovoltaics have been scaled up to industrial size and that large solar farms exist.
- Thermoelectric generators (TEGs) consist of the junction of two dissimilar materials and the presence of a thermal gradient. Large voltage outputs are possible by connecting many junctions electrically in series and thermally in parallel. Typical performance is 100-300 μV/K per junction. These can be utilized to capture mW.s of energy from industrial equipment,

structures, and even the human body. They are typically coupled with heat sinks to improve temperature gradient.

- Micro wind turbine are used to harvest wind energy readily available in the environment in the form of kinetic energy to power the low power electronic devices such as wireless sensor nodes. When air flows across the blades of the turbine, a net pressure difference is developed between the wind speeds above and below the blades. This will result in a lift force generated which in turn rotate the blades. Similar to photovoltaics, wind farms have been constructed on an industrial scale and are being used to generate substantial amounts of electrical energy.
- Piezoelectric crystals or fibers generate a small voltage whenever they are mechanically deformed. Vibration from engines can stimulate piezoelectric materials, as can the heel of a shoe, or the pushing of a button.
- Special antennas can collect energy from stray radio waves. this can also be done with a Rectenna and theoretically at even higher frequency EM radiation with a Nantenna.
- Power from keys pressed during use of a portable electronic device or remote controller, using magnet and coil or piezoelectric energy converters, may be used to help power the device.

3.9.1 Ambient-radiation sources:

A possible source of energy comes from ubiquitous radio transmitters. Historically, either a large collection area or close proximity to the radiating wireless energy source is needed to get useful power levels from this source. The n antenna is one proposed development which would overcome this limitation by making use of the abundant natural radiation (such as solar radiation).

One idea is to deliberately broadcast RF energy to power and collect information from remote devices:[14] This is now commonplace in passive radio-frequency identification (RFID) systems, but the Safety and US Federal Communications Commission (and equivalent bodies worldwide) limit the maximum power that can be transmitted this way to civilian use. This method has been used to power individual nodes in a wireless sensor network

3.9.2 Fluid flow

Airflow can be harvested by various turbine and non-turbine generator technologies. For example, Zephyr Energy Corporation's patented Windbeam micro generator captures energy from airflow to recharge batteries and power electronic devices. The Windbeam's novel design allows it to operate silently in wind speeds as low as 2 mph. The generator consists of a lightweight beam suspended by durable long-lasting springs within an outer frame. The beam oscillates rapidly when exposed to airflow due to the effects of multiple fluid flow phenomena. A linear alternator assembly converts the oscillating beam motion into usable electrical energy. A lack of bearings and gears eliminates frictional inefficiencies and noise. The generator can operate in low-light environments unsuitable for solar panels (e.g. HVAC ducts) and is inexpensive due to low cost components and simple construction. The scalable technology can be optimized to satisfy the energy requirements and design constraints of a given application.

The flow of blood can also be used to power devices. For instance, the pacemaker developed at the University of Bern, uses blood flow to wind up a spring which in turn drives an electrical micro-generator

3.9.3 Photovoltaic

Photovoltaic (PV) energy harvesting wireless technology offers significant advantages over wired or solely battery-powered sensor solutions: virtually inexhaustible sources of power with little or no adverse environmental effects. Indoor PV harvesting solutions have to date been powered by specially tuned amorphous silicon (aSi)a technology most used in Solar Calculators. In recent years new PV technologies have come to the forefront in Energy Harvesting such as Dye Sensitized Solar Cells (DSSC). The dyes absorbs light much like chlorophyll does in plants. Electrons released on impact escape to the layer of TiO_2 and from there diffuse, through the electrolyte, as the dye can be tuned to the visible spectrum much higher power can be produced. At 200 lux a DSSC can provide over 10 µW per cm².

3.9.4 Piezoelectric

The piezoelectric effect converts mechanical strain into electric current or voltage. This strain can come from many different sources. Human motion, low-frequency seismic vibrations, and acoustic noise are everyday examples. Except in rare instances the piezoelectric effect operates in AC requiring time-varying inputs at mechanical resonance to be efficient.

Most piezoelectric electricity sources produce power on the order of milliwatts, too small for system application, but enough for hand-held devices such as some commercially available self-winding wristwatches. One proposal is that they are used for micro-scale devices, such as in a device harvesting micro-hydraulic energy. In this device, the flow of pressurized hydraulic fluid drives a reciprocating piston supported by three piezoelectric elements which convert the pressure fluctuations into an alternating current.

As piezo energy harvesting has been investigated only since the late 1990s, it remains an emerging technology. Nevertheless, some interesting improvements were made with the self-powered electronic switch at INSA school of engineering, implemented by the spin-off Arveni. In 2006, the proof of concept of a battery-less wireless doorbell push button was created, and recently, a product showed that classical wireless wallswitch can be powered by a piezo harvester. Other industrial applications appeared between 2000 and 2005 to harvest energy from vibration and supply sensors for example, or to harvest energy from shock.

Piezoelectric systems can convert motion from the human body into electrical power. DARPA has funded efforts to harness energy from leg and arm motion, shoe impacts, and blood pressure for low level power to implantable or wearable sensors. The nanobrushes are another example of a piezoelectric energy harvester. They can be integrated into clothing. Multiple other nanostructures have been exploited to build an energy-harvesting device, for example, a single crystal PMN-PT nanobelt was fabricated and assembled into a piezoelectric energy harvester in 2016. Careful design is needed to minimise user discomfort. These energy harvesting sources by association affect the body.

The Vibration Energy Scavenging Project is another project that is set up to try to scavenge electrical energy from environmental vibrations and movements. Microbelt can be used to gather electricity from respiration. Besides, as the vibration of motion from human comes in three directions, a single piezoelectric cantilever based omni-directional energy harvester is created by using 1:2 internal resonance. Finally, a millimeter-scale piezoelectric energy harvester has also already been created.

The use of piezoelectric materials to harvest power has already become popular. Piezoelectric materials have the ability to transform mechanical strain energy into electrical charge. Piezo elements are being embedded in walkways to recover the "people energy" of footsteps. They can also be embedded in shoes to recover "walking energy". Researchers at MIT developed the first micro-scale piezoelectric energy harvester using thin film PZT in 2005. Arman Hajati and Sang-Gook Kim invented the Ultra Wide-Bandwidth micro-scale piezoelectric energy harvesting device by exploiting the nonlinear stiffness of a doubly clamped microelectromechanical systems (MEMSs) resonator. The stretching strain in a doubly clamped beam shows a nonlinear stiffness, which provides a passive feedback and results in amplitude-stiffened Duffing mode resonance.

Typically, piezoelectric cantilevers are adopted for the above-mentioned energy harvesting system. One drawback is that the piezoelectric cantilever has gradient strain distribution, i.e., the piezoelectric transducer is not fully utilized. To address this issue, triangle shaped and L-shaped cantilever are proposed for uniform strain distribution.

In 2018, Soochow University researchers reported hybridizing a triboelectric nanogenerator and a silicon solar cell by sharing a mutual electrode. This device can collect solar energy *or* convert the mechanical energy of falling raindrops into electricity

Energy from smart roads and piezoelectricity

Brothers Pierre Curie and Jacques Curie gave the concept of piezoelectric effect in 1880. Piezoelectric effect converts mechanical strain into voltage or electric current and generates electric energy from motion, weight, vibration and temperature changes as shown in the figure.

Considering piezoelectric effect in thin film lead zirconate titanate PZT, microelectromechanical systems (MEMS) power generating device has been developed. During recent improvement in piezoelectric technology, Aqsa Abbasi (also known as Aqsa Aitbar, General secretory at IMS, IEEE MUET Chapter and Director Media at HYD MUN) diffentiated two modes called and in vibration converters and re-designed to resonate at specific frequencies from an external vibration energy source, thereby creating electrical energy via the piezoelectric effect using electromechanical damped mass.

However, Aqsa further developed beam-structured electrostatic devices that are more difficult to fabricate than PZT MEMS devices versus a similar because general silicon processing involves many more mask steps that do not require PZT film. Piezoelectric type sensors and actuators have a cantilever beam structure that consists of a membrane bottom electrode, film, piezoelectric film, and top electrode. More than (3-5 masks) mask steps are required for patterning of each layer while have very low induced voltage. Pyroelectric crystals that have a unique polar axis and have spontaneous polarization, along which the spontaneous polarization exists. These are the crystals of classes 6mm, 4mm, mm2, 6, 4, 3m, 3,2, m. The special polar axis crystallo physical axis X3 coincides with the axes L6,L4, L3, and L2 of the crystals or lies in the unique straight plane P (class “m”). Consequently, the electric centers of positive and negative charges are displaced of an elementary cell from equilibrium positions, i.e., the spontaneous polarization of the crystal changes. Therefore, all considered crystals have spontaneous polarization .

Since piezoelectric effect in pyroelectric crystals arises as a result of changes in their spontaneous polarization under external effects (electric fields, mechanical stresses). As a result of displacement, Aqsa Abbasi introduced change in the components along all three axes . Suppose that is proportional to the mechanical stresses causing in a first approximation, which results where Tkl represents the mechanical stress and dikl represents the piezoelectric modules.

PZT thin films have attracted attention for applications such as force sensors, accelerometers, gyroscopes actuators, tunable optics, micro pumps, ferroelectric RAM, display systems and smart roads, when energy sources are limited, energy harvesting plays an important role in the environment. Smart roads have the potential to play an important role in power generation. Embedding piezoelectric material in the road can convert pressure exerted by moving vehicles into voltage and current.

3.9.5 Smart transportation intelligent system

Piezoelectric sensors are most useful in Smart-road technologies that can be used to create systems that are intelligent and improve productivity in the long run. Imagine highways that alert motorists of a traffic jam before it forms. Or bridges that report when they are at risk of collapse, or an electric grid that fixes itself when blackouts hit. For many decades, scientists and experts have argued that the best way to fight congestion is intelligent transportation systems, such as roadside sensors to measure traffic and synchronized traffic lights to control the flow of vehicles. But the spread of these technologies has been limited by cost. There are also some other smart-technology shovel ready projects which could be deployed fairly quickly, but most of the technologies are still at the development stage and might not be practically available for five years or more.

Energy and global warming are two subjects that recently drew lots of attention in different sections of the society. Among all energy dependent units, automobiles are in fact one of the biggest consumers. Some considerable amount of the energy that an automobile produces for motion is wasted through heat and vibrations. Although different parts of

automobiles are subjected to vibrations (engine, passenger seats, and the body of the vehicle) and constant deformations (tires), no significant research has been done on recycling those wastes. Some early attempts show feasibility of energy harvesting using piezoelectric energy harvester in cars. Kim et al. investigated the capability of piezoelectric transducer to scavenge electric power from automobile engine vibrations. Furthermore, hybrid cars are other examples of energy harvesting in automobiles but they are not in the scope of this research topic. Ambient deflection energy of pneumatic tire which is normally lost could be utilized to develop fully self-powered electronics.

In this study, we propose a solution to harvest tire deflection energy by using devices which are independent from tire structure. This research facilitates the application of smart tires where reliable and sustainable power sources are essentially vital for different wired and wireless sensor. Some of the low power components such as tire pressure sensors are already utilized in the new automobiles. Those sensors are not communicating with the Engine Control Unit (ECU) continually (every 10-30 sec) so the battery can live longer. Other important features regarding to the tire condition that are needed for better isolation and preventing roll over are not implemented due to serious power issues. The appropriate sensors for those applications require reliable and unlimited life power sources because of being in constant communication with ECU and the actuators.

So far, only a few patents are available in the literature about tire energy harvesting. Their fundamental problem is the dependency of the proposed energy harvesting devices on the tire structure. As a result, replacing the tire, they are throwing away their energy harvesting devices as well. In addition, there is no analytical study conducted over the feasibility and the amount of energy which can be harvested from tires. The lack of this information in addition to the design shortcomings makes all those solutions not appealing for the automotive and tire industries for commercialization.

Among different candidates that can potentially be utilized for tire energy harvesting applications, piezoelectric is an ideal material. In fact, this material converts mechanical strain (tire deflection) directly to electrical current and as a result can be used to generate power from tire flexure. Many research has been done on the applications of piezoelectric for power harvesting systems as well as the estimation of electric charge output for piezoelectric energy harvesting devices , and the techniques to increase the efficiency of the charging the batteries by improving the circuits. Similar studies performed on the efficiency of battery recharging. Such research is still in progress and needs more improvement. One early study performed by Sodano et al. investigates the power harvesting from vibration using piezoelectric materials.

The results indicate the feasibility of using the piezoelectric material to power the portable electronics and wireless sensors. Consequently, Sodano et al estimated the electric charge output for piezoelectric energy harvesting. The constitutive equations of a bimorph PZT cantilever beam with base excitation are derived by authors. Later on, Sodano et al. compared the performance of different piezoelectric materials for recharging batteries. This study was done on PZT, QP and MFC.

The conclusion was that PZT is the most effective device for power harvesting applications. The objectives of the research described here are calculations of the wasted tire deformation energy, analytical study on the feasibility of the tire energy harvesting, and the amount of energy using the piezoelectric materials. The paper initially presents the concept of tire deflection and the amount of energy wasted in a car because of tire deflections. The paper then introduces piezoelectric transducer and a model for PZT from literature which is tailored for tire application. Finally, the paper presents the amount of energy which can be captured from tires using PZT.

3.10 ESTIMATION OF WASTED DEFLECTION ENERGY FROM ROAD LOADS:

Investigation of the energy harvesting of the tires is the main goal of this research. However a basic background of the forces which cause the deflection as well as evaluation of the energy used for the deflection is required for better understanding of the problem. Although all the energy of the WLUH GHIOHFWLRQ FDQ W EH UHFRYHUHG it justifies the significance of further studies in this area. It also gives a measure to calculate the efficiency of the power harvesting process which later on can be used as a metric for comparing different methods of harvesting and the appropriate materials for this application. There are three forces and one torque dominantly acting on an automobile tire. These forces as shown in Fig. 1, are the result of different characteristics of a car. The vertical force is due to the sprung mass of the vehicle, aligning torque is caused by the steering torque on the tire, longitudinal force is originated by the traction/acceleration or braking/deceleration, and the lateral force is the reaction of the forces to turn the vehicle.

All these forces contribute to the deformation of the tire (sidewall 13%, shoulder region, 12%, and the beads 2%); however the share of the vertical component is dominant (tread region 73%).

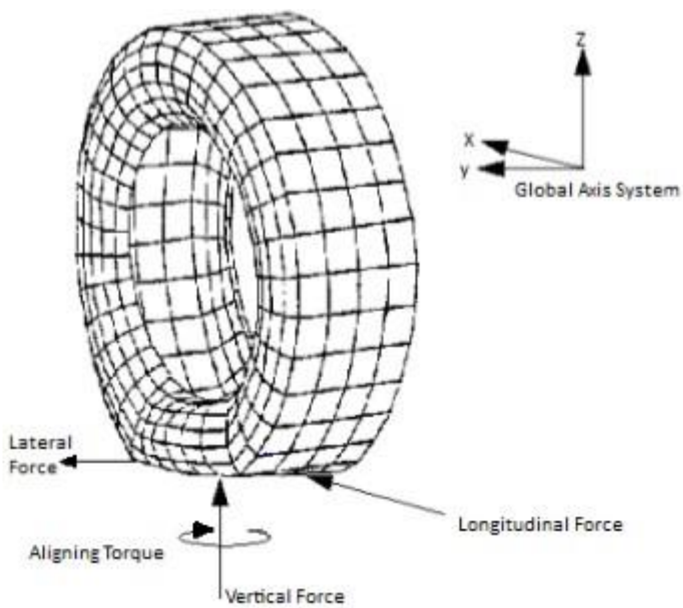

Fig. 1   Forces and Torque at the Center of the Tire-Road Surface Contact Patch

Calculation of the tire deflection in real world is difficult and there is no accurate model to relate different important factors to the energy loss in tire deflection. However, the relation between the tire deflection energy loss and the rolling resistance is well established in the vehicle textbooks. To understand the rolling resistance and its relevance to the tire deflection, It should be noted that when the tire is rolling, the tire carcass is deflected due to the vertical component of the forces on the tire. When tire deformed, the normal pressure distribution in the whole contact patch is not similar. In fact, the normal pressure in the leading half is higher than in the trailing half. Consequently, the center of normal pressure is transferred in the rolling direction. As a result of this transfer, a moment is produced about the tire rotation axis. This moment is the rolling resistance. Although other factors such as tire-road friction (2±10%), and circulation of air inside the tire and the tire fan effect (1.5±3.5%), contribute to the rolling resistance, it is evident that the tire deflection has a dominating effect (90± 95%). As a result, about 65-69% of the rolling resistance is from the tire deflection caused by vertical forces. Considering the whole vehicle wheel, the total rolling resistance is the sum of the resistances from all the wheels which can be presented as:

Where R is the rolling resistance force, fr is the coefficient of rolling resistance, and W is weight of the wheel. The coefficient of rolling resistance, fr, is a dimensionless factor that expresses the effects of the complicated and interdependent physical properties of tire and ground. Several equations for estimating rolling resistance have been developed over the years. To estimate fr, the studies on the rolling loss characteristics of solid rubber tires suggest an equation

Where C is a Constant reflecting loss and elastic characteristics of the tire material, D is the Outside diameter, ht is the tire section height, and w is the tire section width. Over broader speed ranges, the coefficient rises in a manner that is closer to a speed-squared relationship. Another study by the institute of technology in Stuttgart suggests the following equation for rolling on a concrete surface Where V is the speed in mph, fo is the basic coefficient, and fs is the speed effect coefficient. The two coefficients, fo and fs, depend on inflation pressure and are determined from the graph shown in Fig. 2

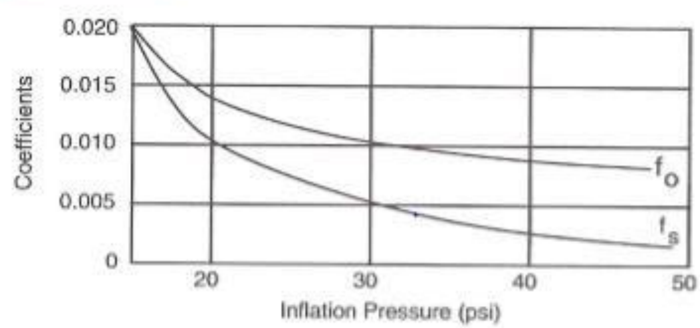

Fig. 2 tire deflection coefficients versus inflation pressure

The road load horsepower is computed by multiplying Eq. (1) by the vehicle velocity and applying the appropriate conversion factor to obtain horsepower.

Where V is in mph. These equations are used to estimate the energy of tire deflection. For instance, in a car weighing 1361kg rolls along a road at a speed of 50mph, the air temperature is 55°F and the inflation pressure is 30 psi, with radial-ply tires,the rolling resistance coefficient is:

3.10.1 PIEZOELECTRIC TRANSDUCER:

Piezoelectric transducers are classified as devices which can convert mechanical energy to electricity and vice versa. Given an electrical voltage, the piezoelectric transducers generate large forces in a small displacement. This characteristic makes the piezoelectric material a good candidate for actuation and micro position application. As a mechanical to electrical transducer, piezoelectric material can be used to convert small displacements to electricity. In fact, change of stress in the element of piezoelectric provides a transient potential difference across the electrodes. This electricity can then be stored or used to extend the life of the power supply of electronic devices. In fact, using piezoelectric material is ideal for the situations where continuous source of deflections exists; for instance mechanical vibrations. It can provide energy for the wireless devices which are hard to reach for battery replacement and their life span are mainly limited to the capacity of their power supply. In addition, piezoelectric devices are inexpensive and reliable to the environmental factors such as electromagnetic fields and humidity. Being robust to damage and environment factors are two desirable characteristics for energy harvesting applications. For using piezoelectric devices to capture energy from tire deflections, some concepts may exist. Here the idea is to have arrays of piezoelectric stacks connected together by small springs and makes a flexible ring. As soon as the tire is inflated the piezoelectric stacks are connected to the tire. The coil springs restore the tension and produce the required distance for the two adjacent piezoelectric stacks. The advantage of this arrangement is the simplicity of installation and replacement. If something goes wrong with the tire, flat tire for instance, the energy harvesting system can be pulled off and replaced in the new tire. Consider piezoelectric energy harvester model PEH (Mide´ Technology Corporation, Medford, MA, USA) which includes 1 stack of 2 PZT active elements. The size of this device is 9.20 x 4.38 x 0.99 cm. By the concept of having PZT arrays as the energy harvesting unit, inside a 195/60-15 tire structure which has the perimeter of 193 cm, about 14 stacks of piezo with a small spring with a half length of stack size between each two stacks can be mounted. The schematic view of this design and the connection among different sections of the power harvesting system is illustrated in Fig. 3. In this configuration, electrical energy is transferred by the wires to the battery charger. There are different strategies and circuits available for this purpose. The efficiency of the harvesting highly depends on the recharging technique. It seems the method purposed by Sodano achieves an acceptable efficiency with less complexity. It can be easily implemented in automotive application where the simplicity and low cost is always required. The energy can then be used to power the electronics and sensors which are hard to reach inside the tire.

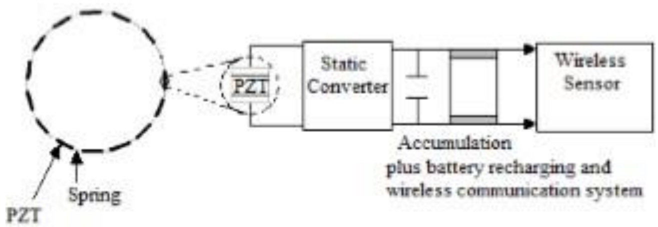

Fig. 3 System for harvesting energy from tire

3.10.2 AMOUNT OF HARVESTED ENERGY USING PZT:

One of the main objectives in this paper is giving an estimate of the amount of energy which can be harvested from tire deflections using piezoelectric materials. This study will help the researchers and manufacturers to have a better picture about the feasibility of the subject. To estimate this energy a realistic model is required. For this application, the model should combine constitutive equations of piezoelectric and the equation of motion of the cantilever beam including bimorph PZT components (Fig. 4). Sodano et al. got an accurate model of the power harvesting system for a bimorph PZT cantilever stack displacement of the beam as the summation of product of the modes and the temporal coordinates (RayleighRitz method) 2- Euiler-Bernolli beam model for The PZT stack vibrations 3- Constant electric energy across the PZT Eqs.(5) and (6) are derived for all vibration modes of a cantilever beam. For the tire energy harvesting applications, the PZT inside the tire only experiences the first mode. Other modes of vibration will not happen due to the physical constraints inside the tire. For the cantilever beam the first mode of vibration can be written.

CHAPTER 4

ELECTROMAGNETIC RADIATION

Electromagnetic radiation (EM radiation or EMR) refers to the waves (or their quanta, photons) of the electromagnetic field, propagating (radiating) through space, carrying electromagnetic radiant energy. It includes radio waves, microwaves, infrared, (visible) light, ultraviolet, X-rays, and gamma rays

Classically, electromagnetic radiation consists of electromagnetic waves, which are synchronized oscillations of electric and magnetic fields that propagate at the speed of light, which, in a vacuum, is commonly denoted c. In homogeneous, isotropic media, the oscillations of the two fields are perpendicular to each other and perpendicular to the direction of energy and wave propagation, forming a transverse wave. The wavefront of electromagnetic waves emitted from a point source (such as a light bulb) is a sphere. The position of an electromagnetic wave within the electromagnetic spectrum can be characterized by either its frequency of oscillation or its wavelength. Electromagnetic waves of different frequency are called by different names since they have different sources and effects on matter. In order of increasing frequency and decreasing wavelength these are: radio waves, microwaves, infrared radiation, visible light, ultraviolet radiation, X-rays and gamma rays.

Electromagnetic waves are emitted by electrically charged particles undergoing acceleration, and these waves can subsequently interact with other charged particles, exerting force on them. EM waves carry energy, momentum and angular momentum away from their source particle and can impart those quantities to matter with which they interact. Electromagnetic radiation is associated with those EM waves that are free to propagate themselves ("radiate") without the continuing influence of the moving charges that produced them, because they have achieved sufficient distance from those charges. Thus, EMR is sometimes referred to as the far field. In this language, the near field refers to EM fields near the charges and current that directly produced them specifically, electromagnetic induction and electrostatic induction phenomena.

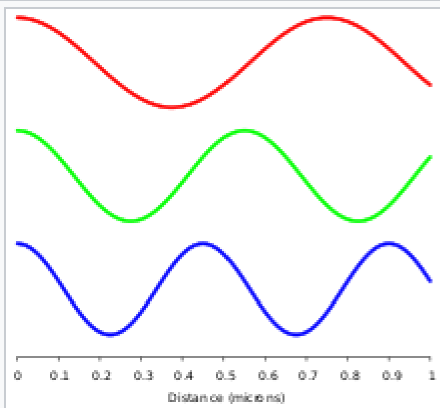
In quantum mechanics, an alternate way of viewing EMR is that it consists of photons, uncharged elementary particles with zero rest mass which are the quanta of the electromagnetic force, responsible for all electromagnetic interactions. Quantum electrodynamics is the theory of how EMR interacts with matter on an atomic level. Quantum effects provide additional sources of EMR, such as the transition of electrons to lower energy levels in an atom and black-body radiation. The energy of an individual photon is quantized and is greater for photons of higher frequency. This relationship is given by Planck's equation $E = h\nu$, where E is the energy per photon, ν is the frequency of the photon, and h is Planck's constant. A single gamma ray photon, for example, might carry 100,000 times the energy of a single photon of visible light.

The effects of EMR upon chemical compounds and biological organisms depend both upon the radiation's power and its frequency. EMR of visible or lower frequencies (i.e., visible light, infrared, microwaves, and radio waves) is called non-ionizing radiation, because its photons do not individually have enough energy to ionize atoms or molecules or break chemical bonds. The effects of these radiations on chemical systems and living tissue are caused primarily by heating effects from the combined energy transfer of many photons. In contrast, high frequency ultraviolet, X-rays and gamma rays are called ionizing radiation, since individual photons of such high frequency have enough energy to ionize molecules or break chemical bonds. These radiations have the ability to cause chemical reactions and damage living cells beyond that resulting from simple heating, and can be a health hazard.

4.1 Maxwell’s equations:

James Clerk Maxwell derived a wave form of the electric and magnetic equations, thus uncovering the wave-like nature of electric and magnetic fields and their symmetry. Because the speed of EM waves predicted by the wave equation coincided with the measured speed of light, Maxwell concluded that light itself is an EM wave. Maxwell's equations were confirmed by Heinrich Hertz through experiments with radio waves.

According to Maxwell's equations, a spatially varying electric field is always associated with a magnetic field that changes over time. Likewise, a spatially varying magnetic field is associated with specific changes over time in the electric field. In an electromagnetic wave, the changes in the electric field are always accompanied by a wave in the magnetic field in one direction, and vice versa. This relationship between the two occurs without either type of field causing the other; rather, they occur together in the same way that time and space changes occur together and are interlinked in special relativity. In fact, magnetic fields can be viewed as electric fields in another frame of reference, and electric fields can be viewed as magnetic fields in another frame of reference, but they have equal significance as physics is the same in all frames of reference, so the close relationship between space and time changes here is more than an analogy. Together, these fields form a propagating electromagnetic wave, which moves out into space and need never again interact with the source. The distant EM field formed in this way by the acceleration of a charge carries energy with it that "radiates" away through space, hence the term.



Shows the relative wavelengths of the electromagnetic waves of three different colours of light (blue, green, and red) with a distance scale in micrometers along the x-axis.

Fig: Relation Between Wavelengths

4.2 Near and far fields:

Maxwell's equations established that some charges and currents ("sources") produce a local type of electromagnetic field near them that does not have the behaviour of EMR. Currents directly produce a magnetic field, but it is of a magnetic dipole type that dies out with distance from the current. In a similar manner, moving charges pushed apart in a conductor by a changing electrical potential (such as in an antenna) produce an electric dipole type electrical field, but this also declines with distance. These fields make up the near-field near the EMR source. Neither of these behaviours are responsible for EM radiation. Instead, they cause electromagnetic field behaviour that only efficiently transfers power to a receiver very close to the source, such as the magnetic induction inside a transformer, or the feedback behaviour that happens close to the coil of a metal detector. Typically, near-fields have a powerful effect on their own sources, causing an increased “load” (decreased electrical reactance) in the source or transmitter, whenever energy is withdrawn from the EM field by a receiver. Otherwise, these fields do not “propagate” freely out into space, carrying their energy away without distance-limit, but rather oscillate, returning their energy to the transmitter if it is not received by a receiver.

By contrast, the EM far-field is composed of radiation that is free of the transmitter in the sense that (unlike the case in an electrical transformer) the transmitter requires the same power to send these changes in the fields out, whether the signal is immediately picked up or not. This distant part of the electromagnetic field is "electromagnetic radiation" (also called the far-field). The far-fields propagate (radiate) without allowing the transmitter to affect them. This causes them to be independent in the sense that their existence and their energy, after they have left the transmitter, is completely independent of both transmitter and receiver. Due to conservation of energy, the amount of power passing through any spherical surface drawn around the source is the same. Because such a surface has an area proportional to the square of its distance from the source, the power density of EM radiation always decreases with the inverse square of distance from the source; this is called the inverse-square law.

This is in contrast to dipole parts of the EM field close to the source (the near-field), which varies in power according to an inverse cube power law, and thus does not transport a conserved amount of energy over distances, but instead fades with distance, with its energy (as noted) rapidly returning to the transmitter or absorbed by a nearby receiver (such as a transformer secondary coil).

The far-field (EMR) depends on a different mechanism for its production than the near-field, and upon different terms in Maxwell's equations. Whereas the magnetic part of the near-field is due to currents in the source, the magnetic field in EMR is due only to the local change in the electric field. In a similar way, while the electric field in the near-field is due directly to the charges and charge-separation in the source, the electric field in EMR is due to a change in the local magnetic field. Both processes for producing electric and magnetic EMR fields have a different dependence on distance than do near-field dipole electric and magnetic fields. That is why the EMR type of EM field becomes dominant in power “far” from sources. The term “far from sources” refers to how far from the source (moving at the speed of light) any portion of the outward-moving EM field is located, by the time that source currents are changed by the varying source potential, and the source has therefore begun to generate an outwardly moving EM field of a different phase.

A more compact view of EMR is that the far-field that composes EMR is generally that part of the EM field that has traveled sufficient distance from the source, that it has become completely disconnected from any feedback to the charges and currents that were originally responsible for it. Now independent of the source charges, the EM field, as it moves farther away, is dependent only upon the accelerations of the charges that produced it. It no longer has a strong connection to the direct fields of the charges, or to the velocity of the charges (currents).

In the Lienard–Wiechert potential formulation of the electric and magnetic fields due to motion of a single particle (according to Maxwell's equations), the terms associated with acceleration of the particle are those that are responsible for the part of the field that is regarded as electromagnetic radiation. By contrast, the term associated with the changing static electric field of the particle and the magnetic term that results from the particle's uniform velocity, are both associated with the electromagnetic near-field, and do not comprise EM radiation.

4.3 Properties:

Electrodynamics is the physics of electromagnetic radiation, and electromagnetism is the physical phenomenon associated with the theory of electrodynamics. Electric and magnetic fields obey the properties of superposition. Thus, a field due to any particular particle or time-varying electric or magnetic field contributes to the fields present in the same space due to other causes. Further, as they are vector fields, all magnetic and electric field vectors add together according to vector addition. For example, in optics two or more coherent lightwaves may interact and by constructive or destructive interference yield a resultant irradiance deviating from the sum of the component irradiances of the individual lightwaves.

Since light is an oscillation it is not affected by traveling through static electric or magnetic fields in a linear medium such as a vacuum. However, in nonlinear media, such as some crystals, interactions can occur between light and static electric and magnetic fields — these interactions include the Faraday effect and the Kerr effect.

In refraction, a wave crossing from one medium to another of different density alters its speed and direction upon entering the new medium. The ratio of the refractive indices of the media determines the degree of refraction, and is summarized by Snell's law. Light of composite wavelengths (natural sunlight) disperses into a visible spectrum passing through a prism, because of the wavelength-dependent refractive index of the prism material (dispersion); that is, each component wave within the composite light is bent a different amount.

EM radiation exhibits both wave properties and particle properties at the same time (see wave-particle duality). Both wave and particle characteristics have been confirmed in many experiments. Wave characteristics are more apparent when EM radiation is measured over relatively large timescales and over large distances while particle characteristics are more evident when measuring small timescales and distances. For example, when electromagnetic radiation is absorbed by matter, particle-like properties will be more obvious when the average number of photons in the cube of the relevant wavelength is much smaller than 1. It is not too difficult to experimentally observe non-uniform deposition of energy when light is absorbed, however this alone is not evidence of "particulate" behavior. Rather, it reflects the quantum nature of matter. Demonstrating that the light itself is quantized, not merely its interaction with matter, is a more subtle affair.

Some experiments display both the wave and particle natures of electromagnetic waves, such as the self-interference of a single photon. When a single photon is sent through an interferometer, it passes through both paths, interfering with itself, as waves do, yet is detected by a photomultiplier or other sensitive detector only once.

A quantum theory of the interaction between electromagnetic radiation and matter such as electrons is described by the theory of quantum electrodynamics.

Electromagnetic waves can be polarized, reflected, refracted, diffracted or interfere with each other.

4.4 Wave model:

In homogeneous, isotropic media, electromagnetic radiation is a transverse wave, meaning that its oscillations are perpendicular to the direction of energy transfer and travel. The electric and magnetic parts of the field stand in a fixed ratio of strengths in order to satisfy the two Maxwell equations that specify how one is produced from the other. In dissipation less (lossless) media, these E and B fields are also in phase, with both reaching maxima and minima at the same points in space (see illustrations). A common misconception is that the E and Bfields in electromagnetic radiation are out of phase because a change in one produces the other, and this would produce a phase difference between them as sinusoidal functions (as indeed happens in electromagnetic induction, and in the near-field close to antennas). However, in the far-field EM radiation which is described by the two source-free Maxwell curl operator equations, a more correct description is that a time-change in one type of field is proportional to a space-change in the other. These derivatives require that the E and B fields in EMR are in-phase (see math section below).

An important aspect of light's nature is its frequency. The frequency of a wave is its rate of oscillation and is measured in hertz, the SI unit of frequency, where one hertz is equal to one oscillation per second. Light usually has multiple frequencies that sum to form the resultant wave. Different frequencies undergo different angles of refraction, a phenomenon known as dispersion.

A wave consists of successive troughs and crests, and the distance between two adjacent crests or troughs is called the wavelength. Waves of the electromagnetic spectrum vary in size, from very long radio waves the size of buildings to very short gamma rays smaller than atom nuclei. Frequency is inversely proportional to wavelength, according to the equation:

Electromagnetic waves in free space must be solutions of Maxwell's electromagnetic wave equation. Two main classes of solutions are known, namely plane waves and spherical waves. The plane waves may be viewed as the limiting case of spherical waves at a very large (ideally infinite) distance from the source. Both types of waves can have a waveform which is an arbitrary time function (so long as it is sufficiently differentiable to conform to the wave equation). As with any time function, this can be decomposed by means of Fourier analysis into its frequency spectrum, or individual sinusoidal components, each of which contains a single frequency, amplitude and phase. Such a component wave is said to be monochromatic. A monochromatic electromagnetic wave can be characterized by its frequency or wavelength, its peak amplitude, its phase relative to some reference phase, its direction of propagation and its polarization.

Interference is the superposition of two or more waves resulting in a new wave pattern. If the fields have components in the same direction, they constructively interfere, while opposite directions cause destructive interference. An example of interference caused by EMR is electromagnetic interference (EMI) or as it is more commonly known as, radio-frequency interference (RFI). Additionally, multiple polarization signals can be combined (i.e. interfered) to form new states of polarization, which is known as parallel polarization state generation.

The energy in electromagnetic waves is sometimes called radiant energy.

An anomaly arose in the late 19th century involving a contradiction between the wave theory of light and measurements of the electromagnetic spectra that were being emitted by thermal radiators known as black bodies. Physicists struggled with this problem, which later became known as the ultraviolet catastrophe, unsuccessfully for many years. In 1900, Max Planck developed a new theory of black-body radiation that explained the observed spectrum. Planck's theory was based on the idea that black bodies emit light (and other electromagnetic radiation) only as discrete bundles or packets of energy. These packets were called quanta. Later, Albert Einstein proposed that light quanta be regarded as real particles. Later the particle of light was given the name photon, to correspond with other particles being described around this time, such as the electron and proton. A photon has an energy, E, proportional to its frequency, f.

4.5 Wave and particle effects of electromagnetic radiation:

Together, wave and particle effects fully explain the emission and absorption spectra of EM radiation. The matter-composition of the medium through which the light travels determines the nature of the absorption and emission spectrum. These bands correspond to the allowed energy levels in the atoms. Dark bands in the absorption spectrum are due to the atoms in an intervening medium between source and observer. The atoms absorb certain frequencies of the light between emitter and detector/eye, then emit them in all directions. A dark band appears to the detector, due to the radiation scattered out of the beam. For instance, dark bands in the light emitted by a distant star are due to the atoms in the star's atmosphere. A similar phenomenon occurs for emission, which is seen when an emitting gas glows due to excitation of the atoms from any mechanism, including heat. As electrons descend to lower energy levels, a spectrum is emitted that represents the jumps between the energy levels of the electrons, but lines are seen because again emission happens only at particular energies after excitation. An example is the emission spectrum of nebulae. Rapidly moving electrons are most sharply accelerated when they encounter a region of force, so they are responsible for producing much of the highest frequency electromagnetic radiation observed in nature.

These phenomena can aid various chemical determinations for the composition of gases lit from behind (absorption spectra) and for glowing gases (emission spectra). Spectroscopy (for example) determines what chemical elements comprise a particular star. Spectroscopy is also used in the determination of the distance of a star, using the red shift.

CHAPTER 5

WIRELESS SENSOR NETWORKS

Wireless Sensor Networks (WSNs) can be defined as a self-configured and infrastructureless wireless networks to monitor physical or environmental conditions, such as temperature, sound, vibration, pressure, motion or pollutants and to cooperatively pass their data through the network to a main location or sink where the data can be observed and analysed. A sink or base station acts like an interface between users and the network. One can retrieve required information from the network by injecting queries and gathering results from the sink. Typically a wireless sensor network contains hundreds of thousands of sensor nodes. The sensor nodes can communicate among themselves using radio signals. A wireless sensor node is equipped with sensing and computing devices, radio transceivers and power components. The individual nodes in a wireless sensor network (WSN) are inherently resource constrained: they have limited processing speed, storage capacity, and communication bandwidth. After the sensor nodes are deployed, they are responsible for self-organizing an appropriate network infrastructure often with multi-hop communication with them. Then the onboard sensors start collecting information of interest. Wireless sensor devices also respond to queries sent from a “control site” to perform specific instructions or provide sensing samples. The working mode of the sensor nodes may be either continuous or event driven. Global Positioning System (GPS) and local positioning algorithms can be used to obtain location and positioning information. Wireless sensor devices can be equipped with actuators to “act” upon certain conditions. These networks are sometimes more specifically referred as Wireless Sensor and Actuator Networks as described in (Akkaya et al., 2005). Wireless sensor networks (WSNs) enable new applications and require non-conventional paradigms for protocol design due to several constraints. Owing to the requirement for low device complexity together with low energy consumption (i.e. long network lifetime), a proper balance between communication and signal/data processing capabilities must be found. This motivates a huge effort in research activities, standardization process, and industrial investments on this field since the last decade (Chiara et. al. 2009). At present time, most of the research on WSNs has concentrated on the design of energy- and computationally efficient algorithms and protocols, and the application domain has been restricted to simple data-oriented monitoring and reporting applications (Labrador et. al. 2009). The authors in (Chen et al., 2011) propose a Cable Mode Transition (CMT) algorithm, which determines the minimal number of active sensors to maintain K-coverage of a terrain as well as K-connectivity of the network. Specifically, it allocates periods of inactivity for cable sensors without affecting the coverage and connectivity requirements of the network based only on local information. In (Cheng et al., 2011), a delay-aware data collection network structure for wireless sensor networks is proposed. The objective of the proposed network structure is to minimize delays in the data collection processes of wireless sensor networks which extends the lifetime of the network. In (Matin et al., 2011), the authors have considered relay nodes to mitigate the network geometric deficiencies and used Particle Swarm Optimization (PSO) based algorithms to locate the optimal sink location with respect to those relay nodes to overcome the lifetime challenge. Energy efficient communication has also been addressed in (Paul et al., 2011; Fabbri et al. 2009). In (Paul et al., 2011), the authors proposed a geometrical solution for locating the optimum sink placement for maximizing the network lifetime. Most of the time, the research on wireless sensor networks have considered homogeneous sensor nodes. But nowadays researchers have focused on heterogeneous sensor networks where the sensor nodes are unlike to each other in terms of their energy. In (Han et al., 2010), the authors addresses the problem of deploying relay nodes to provide fault tolerance with higher network connectivity in heterogeneous wireless sensor networks, where sensor nodes possess different transmission radii. New network architectures with heterogeneous devices and the recent advancement in this technology eliminate the current limitations and expand the spectrum of possible applications for WSNs considerably and all these are changing very rapidly.

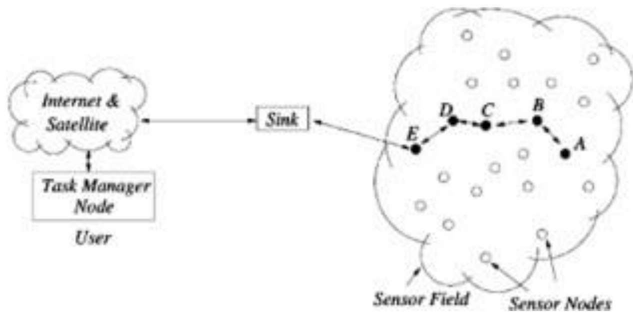


Figure: A typical Wireless Sensor Network

5.1 Applications of wireless sensor network:

Wireless sensor networks have gained considerable popularity due to their flexibility in solving problems in different application domains and have the potential to change our lives in many different ways. WSNs have been successfully applied in various application domains (Akyildiz et al. 2002; Bharathidasan et al., 2001), (Yick et al., 2008; Boukerche, 2009), (Sohraby et al., 2007), and (Chiara et al., 2009; Verdone et al., 2008), such as: Military applications: Wireless sensor networks be likely an integral part of military command, control, communications, computing, intelligence, battlefield surveillance, reconnaissance and targeting systems. Area monitoring: In area monitoring, the sensor nodes are deployed over a region where some phenomenon is to be monitored. When the sensors detect the event being monitored (heat, pressure etc), the event is reported to one of the base stations, which then takes appropriate action. Transportation: Real-time traffic information is being collected by WSNs to later feed transportation models and alert drivers of congestion and traffic problems. Health applications: Some of the health applications for sensor networks are supporting interfaces for the disabled, integrated patient monitoring, diagnostics, and drug administration in hospitals, tele-monitoring of human physiological data, and tracking & monitoring doctors or patients inside a hospital. Environmental sensing: The term Environmental Sensor Networks has developed to cover many applications of WSNs to earth science research. This includes sensing volcanoes, oceans, glaciers, forests etc. Some other major areas are listed below:

Air pollution monitoring Forest fires detection

- Greenhouse monitoring

- Landslide detection

- Structural monitoring: Wireless sensors can be utilized to monitor the movement within buildings and infrastructure such as bridges, flyovers, embankments, tunnels etc enabling Engineering practices to monitor assets remotely with out the need for costly sitevisits. Industrial monitoring: Wireless sensor networks have been developed for machinery condition-based maintenance (CBM) as they offer significant cost savings and enable new functionalities. In wired systems, the installation of enough sensors is often limited by the cost of wiring. Agricultural sector: using a wireless network frees the farmer from the maintenance of wiring in a difficult environment. Irrigation automation enables more efficient water use and reduces waste.

5.2 Design issues of a wireless sensor network:

There are a lot of challenges placed by the deployment of sensor networks which are a superset of those found in wireless ad hoc networks. Sensor nodes communicate over wireless, lossy lines with no infrastructure. An additional challenge is related to the limited, usually non-renewable energy supply of the sensor nodes. In order to maximize the lifetime of the network, the protocols need to be designed from the beginning with the objective of efficient management of the energy resources (Akyildiz et al., 2002). Wireless Sensor Network Design issues are mentioned in (Akkaya et al., 2005), (Akyildizet al., 2002), (SensorSim; Tossim, Younis et al., 2004), (Pan et al., 2003) and different possible platforms for simulation and testing of routing protocols for WSNs are discussed in (NS-2, Zeng et al., 1998, SensorSim, Tossiim). Let us now discuss the individual design issues in greater detail. Fault Tolerance: Sensor nodes are vulnerable and frequently deployed in dangerous environment. Nodes can fail due to hardware problems or physical damage or by exhausting their energy supply. We expect the node failures to be much higher than the one normally considered in wired or infrastructure-based wireless networks. The protocols deployed in a sensor network should be able to detect these failures as soon as possible and be robust enough to handle a relatively large number of failures while maintaining the overall functionality of the network. This is especially relevant to the routing protocol design, which has to ensure that alternate paths are available for rerouting of the packets. Different deployment environments pose different fault tolerance requirements. Scalability: Sensor networks vary in scale from several nodes to potentially several hundred thousand. In addition, the deployment density is also variable.

For collecting high resolution data, the node density might reach the level where a node has several thousand neighbours in their transmission range. The protocols deployed in sensor networks need to be scalable to these levels and be able to maintain adequate performance. Production Costs: Because many deployment models consider the sensor nodes to be disposable devices, sensor networks can compete with traditional information gathering approaches only if the individual sensor nodes can be produced very cheaply. The target price envisioned for a sensor node should ideally be less than $1. Hardware Constraints: At minimum, every sensor node needs to have a sensing unit, a processing unit, a transmission unit, and a power supply. Optionally, the nodes may have several built-in sensors or additional devices such as a localization system to enable location-aware routing. However, every additional functionality comes with additional cost and increases the power consumption and physical size of the node. Thus, additional functionality needs to be always balanced against cost and low-power requirements. Sensor Network Topology: Although WSNs have evolved in many aspects, they continue to be networks with constrained resources in terms of energy, computing power, memory, and communications capabilities. Of these constraints, energy consumption is of paramount importance, which is demonstrated by the large number of algorithms, techniques, and protocols that have been developed to save energy, and thereby extend the lifetime of the network. Topology Maintenance is one of the most important issues researched to reduce energy consumption in wireless sensor networks. Transmission Media: The communication between the nodes is normally implemented using radio communication over the popular ISM bands. However, some sensor networks use optical or infrared communication, with the latter having the advantage of being robust and virtually interference free. Power Consumption: As we have already seen, many of the challenges of sensor networks revolve around the limited power resources. The size of the nodes limits the size of the battery. The software and hardware design needs to carefully consider the issues of efficient energy use. For instance, data compression might reduce the amount of energy used for radio transmission, but uses additional energy for computation and/or filtering. The energy policy also depends on the application; in some applications, it might be acceptable to turn off a subset of nodes in order to conserve energy while other applications require all nodes operating simultaneously.

5.3 Structure of a wireless sensor network:

Structure of a Wireless Sensor Network includes different topologies for radio communications networks. A short discussion of the network topologies that apply to wireless sensor networks are outlined below:

Star network (single point-to-multipoint) (Wilson, 2005) A star network is a communications topology where a single base station can send and/or receive a message to a number of remote nodes. The remote nodes are not permitted to send messages to each other. The advantage of this type of network for wireless sensor networks includes simplicity, ability to keep the remote node's power consumption to a minimum. It also allows low latency communications between the remote node and the base station. The disadvantage of such a network is that the base station must be within radio transmission range of all the individual nodes and is not as robust as other networks due to its dependency on a single node to manage the network.

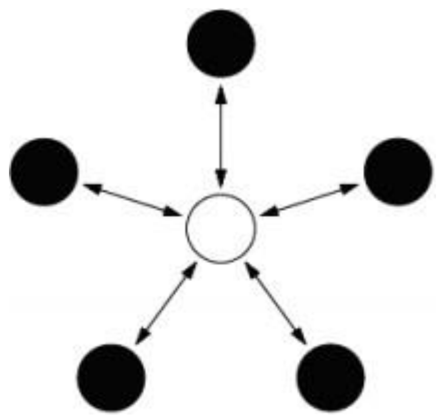

Figure : A Star network topology

5.4 Mesh network:

A mesh network allows transmitting data to one node to other node in the network that is within its radio transmission range. This allows for what is known as multi-hop communications, that is, if a node wants to send a message to another node that is out of radio communications range, it can use an intermediate node to forward the message to the desired node. This network topology has the advantage of redundancy and scalability. If an individual node fails, a remote node still can communicate to any other node in its range, which in turn, can forward the message to the desired location. In addition, the range of the network is not necessarily limited by the range in between single nodes; it can simply be extended by adding more nodes to the system. The disadvantage of this type of network is in power consumption for the nodes that implement the multi-hop communications are generally higher than for the nodes that don't have this capability, often limiting the battery life. Additionally, as the number of communication hops to a destination increases, the time to deliver the message also increases, especially if low power operation of the nodes is a requirement.

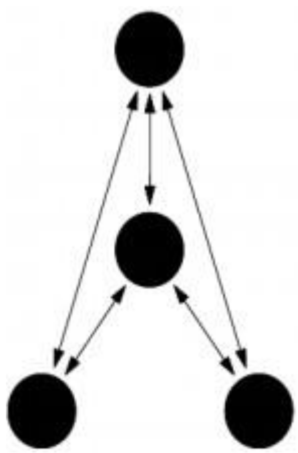

Figure: A Mesh network topology

5.5 Hybrid star – Mesh network:

A hybrid between the star and mesh network provides a robust and versatile communications network, while maintaining the ability to keep the wireless sensor nodes power consumption to a minimum. In this network topology, the sensor nodes with lowest power are not enabled with the ability to forward messages. This allows for minimal power consumption to be maintained. However, other nodes on the network are enabled with multi-hop capability, allowing them to forward messages from the low power nodes to other nodes on the network. Generally, the nodes with the multi-hop capability are higher power, and if possible, are often plugged into the electrical mains line. This is the topology implemented by the up and coming mesh networking standard known as ZigBee.

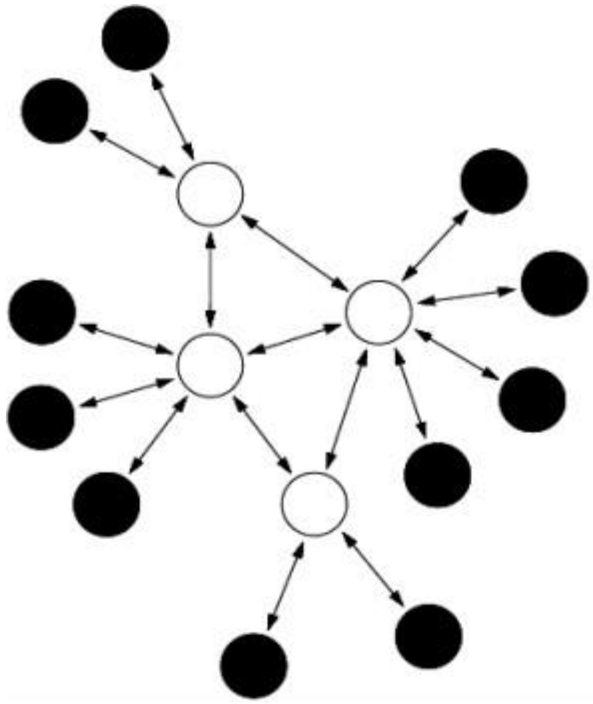

Figure: A Hybrid Star – Mesh network topology

Structure of a wireless sensor node: A sensor node is made up of four basic components such as sensing unit, processing unit, transceiver unit and a power unit which is shown in Fig. 5. It also has application dependent additional components such as a location finding system, a power generator and a mobilizer. Sensing units are usually composed of two subunits: sensors and analogue to digital converters (ADCs) (Akyildiz et al., 2002). The analogue signals produced by the sensors are converted to digital signals by the ADC, and then fed into the processing unit. The processing unit is generally associated with a small storage unit and it can manage the procedures that make the sensor node collaborate with the other nodes to carry out the assigned sensing tasks. A transceiver unit connects the node to the network. One of the most important components of a sensor node is the power unit. Power units can be supported by a power scavenging unit such as solar cells. The other subunits, of the node are application dependent. A functional block diagram of a versatile wireless sensing node is provided in Fig. 6. Modular design approach provides a flexible and versatile platform to address the needs of a wide variety of applications. For example, depending on the sensors to be deployed, the signal conditioning block can be re-programmed or replaced. This allows for a wide variety of different sensors to be used with the wireless sensing node. Similarly, the radio link may be swapped out as required for a given applications' wireless range requirement and the need for bidirectional communications.

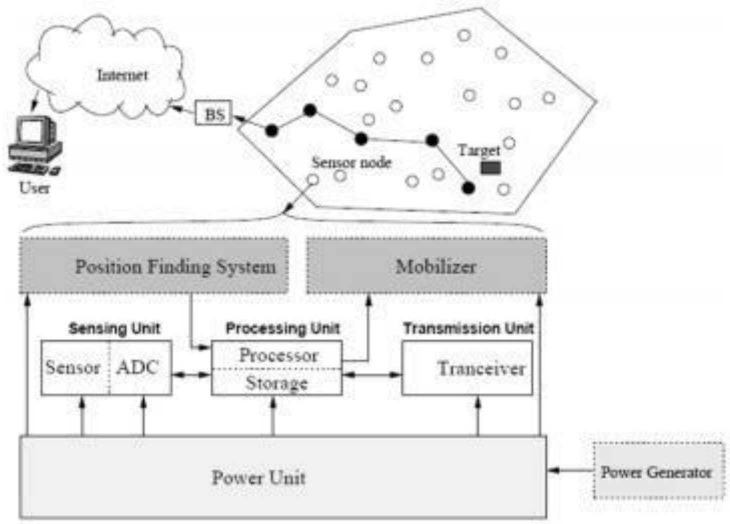

Figure: The components of a sensor node

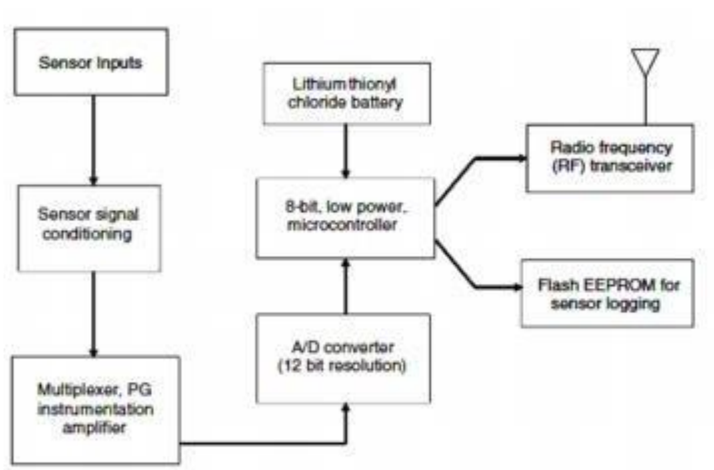

Figure: Functional block diagram of a sensor node

Using flash memory, the remote nodes acquire data on command from a base station, or by an event sensed by one or more inputs to the node. Moreover, the embedded firmware can be upgraded through the wireless network in the field. The microprocessor has a number of functions including:

- Managing data collection from the sensors

- performing power management functions

- interfacing the sensor data to the physical radio layer

- managing the radio network protocol

- A key aspect of any wireless sensing node is to minimize the power consumed by the system.

Usually, the radio subsystem requires the largest amount of power. Therefore, data is sent over the radio network only when it is required. An algorithm is to be loaded into the node to determine when to send data based on the sensed event. Furthermore, it is important to minimize the power consumed by the sensor itself. Therefore, the hardware should be designed to allow the microprocessor to judiciously control power to the radio, sensor, and sensor signal conditioner (Akyildiz et al., 2002). 6. Communication structure of a wireless sensor network The sensor nodes are usually scattered in a sensor field as shown in Fig. 1. Each of these scattered sensor nodes has the capabilities to collect data and route data back to the sink and the end users. Data are routed back to the end user by a multi-hop infrastructure-less architecture through the sink as shown in Fig. 1. The sink may communicate with the task manager node via Internet or Satellite.

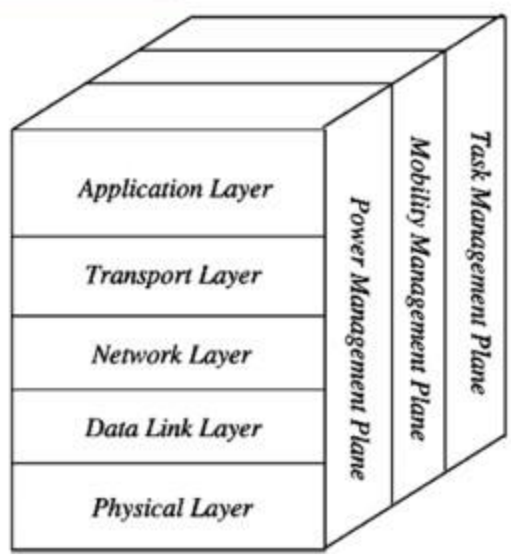

Figure: Wireless Sensor Network protocol stack

The protocol stack used by the sink and the sensor nodes is given in Fig. 7. This protocol stack combines power and routing awareness, integrates data with networking protocols, communicates power efficiently through the wireless medium and promotes cooperative efforts of sensor nodes. The protocol stack consists of the application layer, transport layer network layer, data link layer, physical layer, power management plane, mobility management plane, and task management plane (Akyildiz et al., 2002). Different types of application software can be built and used on the application layer depending on the sensing tasks. This layer makes hardware and software of the lowest layer transparent to the end-user. The transport layer helps to maintain the flow of data if the sensor networks application requires it. The network layer takes care of routing the data supplied by the transport layer, specific multi-hop wireless routing protocols between sensor nodes and sink. The data link layer is responsible for multiplexing of data streams, frame detection, Media Access Control (MAC) and error control. Since the environment is noisy and sensor nodes can be mobile, the MAC protocol must be power aware and able to minimize collision with neighbours' broadcast. The physical layer addresses the needs of a simple but robust modulation, frequency selection, data encryption, transmission and receiving techniques. In addition, the power, mobility, and task management planes monitor the power, movement, and task distribution among the sensor nodes. These planes help the sensor nodes coordinate the sensing task and lower the overall energy consumption.

Energy consumption issues in wireless sensor network Energy consumption is the most important factor to determine the life of a se ensor network because usually sensor nodes are driven by battery. Sometimes energy optimization is more complicated in sensor networks because it involved not only reduction of energy consumption but also prolonging the life of the network as much as possible. The optimization can be done by having energy awareness in every aspect of design and operation. This ensures that energy awareness is also incorporated into groups of communicating sensor nodes and the entire network and not only in the individual nodes (Bharathidasan et al. 2001). A sensor node usually consists of four sub-systems (Bharathidasan et al. 2001): a computing subsystem : It consists of a microprocessor(microcontroller unit, MCU)

- which is responsible for the control of the sensors and implementation of communication protocols. MCUs usually operate under various modes for power management purposes. As these operating modes involves consumption of power, the energy consumption levels of the various modes should be considered while looking at the battery lifetime of each node. a communication subsystem: It consists of a short range radio which communicate with

• neighboring nodes and the outside world. Radios can operate under the different modes. It is important to completely shut down the radio rather than putting it in the Idle mode when it is not transmitting or receiving for saving power. a sensing subsystem : It consists of a group of sensors and actuators and link the node

• to the outside world. Energy consumption can be reduced by using low power components and saving power at the cost of performance which is not required. a power supply subsystem : It consists of a battery which supplies power to the node.

It should be seen that the amount of power drawn from a battery is checked because if high current is drawn from a battery for a long time, the battery will die faster even though it could have gone on for a longer time. Usually the rated current capacity of a battery being used for a sensor node is less than the minimum energy consumption. The lifetime of a battery can be increased by reducing the current drastically or even turning it off often. To minimize the overall energy consumption of the sensor network, different types of protocols and algorithms have been studied so far all over the world. The lifetime of a sensor network can be increased significantly if the operating system, the application layer and the network protocols are designed to be energy aware.

These protocols and algorithms have to be aware of the hardware and able to use special features of the micro-processors and transceivers to minimize the sensor node's energy consumption. This may push toward a custom solution for different types of sensor node design. Different types of sensor nodes deployed also lead to different types of sensor networks. This may also lead to the different types of collaborative algorithms in wireless sensor networks arena. 8. Protocols & algorithms of wireless sensor network In WSN, the main task of a sensor node is to sense data and sends it to the base station in multi hop environment for which routing path is essential. For computing the routing path from the source node to the base station there is huge numbers of proposed routing protocols exist (Sharma et al., 2011).

The design of routing protocols for WSNs must consider the power and resource limitations of the network nodes, the time-varying quality of the wireless channel, and the possibility for packet loss and delay. To address these design requirements, several routing strategies for WSNs have been proposed in (Labrador et al., 2009), (Akkaya et al., 2005), (Akyildiz et al. 2002), (Boukerche, 2009, Al-karaki et al., 2004, Pan et al., 2003) and (Waharte et al., 2006). The first class of routing protocols adopts a flat network architecture in which all nodes are considered peers. Flat network architecture has several advantages, including minimal overhead to maintain the infrastructure and the potential for the discovery of multiple routes between communicating nodes for fault tolerance.

A second class of routing protocols imposes a structure on the network to achieve energy efficiency, stability, and scalability. In this class of protocols, network nodes are organized in clusters in which a node with higher residual energy, for example, assumes the role of a cluster head. The cluster head is responsible for coordinating activities within the cluster and forwarding information between clusters. Clustering has potential to reduce energy consumption and extend the lifetime of the network. A third class of routing protocols uses a data-centric approach to disseminate interest within the network. The approach uses attribute-based naming, whereby a source node queries an attribute for the phenomenon rather than an individual sensor node. The interest dissemination is achieved by assigning tasks to sensor nodes and expressing queries to relative to specific attributes. Different strategies can be used to communicate interests to the sensor nodes, including broadcasting, attribute-based multicasting, geo-casting, and any casting.

A fourth class of routing protocols uses location to address a sensor node. Location-based routing is useful in applications where the position of the node within the geographical coverage of the network is relevant to the query issued by the source node. Such a query may specify a specific area where a phenomenon of interest may occur or the vicinity to a specific point in the network environment. In the rest of this section we discuss some of the major routing protocols and algorithms to deal with the energy conservation issue in the literatures.

5.6 Flooding:

Flooding is a common technique frequently used for path discovery and information dissemination in wired and wireless ad hoc networks which has been discussed in (Akyildiz et al., 2002). The routing strategy of flooding is simple and does not rely on costly network topology maintenance and complex route discovery algorithms. Flooding uses a reactive approach whereby each node receiving a data or control packet sends the packet to all its neighbors. After transmission, a packet follows all possible paths. Unless the network is disconnected, the packet will eventually reach its destination. Furthermore, as the network topology changes, the packet transmitted follows the new routes. Fig. 8 illustrates the concept of flooding in data communications network. As shown in the figure, flooding in its simplest form may cause packets to be replicated indefinitely by network nodes.

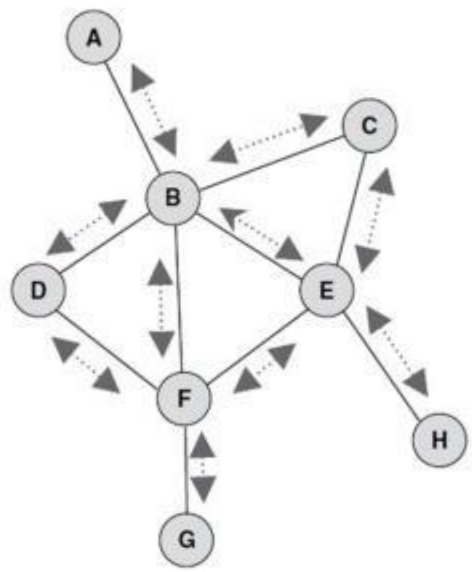

Figure : Flooding in data communication networks

5.7 Gossiping:

To address the shortcomings of flooding, a derivative approach, referred to as gossiping, has been proposed in (Braginsky et al., 2002). Similar to flooding, gossiping uses a simple forwarding rule and does not require costly topology maintenance or complex route discovery algorithms. Contrary to flooding, where a data packet is broadcast to all neighbors, gossiping requires that each node sends the incoming packet to a randomly selected neighbor. Upon receiving the packet, the neighbor selected randomly chooses one of its own neighbors and forwards the packet to the neighbor chosen. This process continues iteratively until the packet reaches its intended destination or the maximum hop count is exceeded. 2. Protocols for Information via Negotiation (SPIN): Sensor protocols for information via negotiation (SPIN), is a data-centric negotiation-based family of information dissemination protocols for WSNs (Kulik et al., 2002). The main objective of these protocols is to efficiently disseminate observations gathered by individual sensor nodes to all the sensor nodes in the network. Simple protocols such as flooding and gossiping are commonly proposed to achieve information dissemination in WSNs. Flooding requires that each node sends a copy of the data packet to all its neighbors until the information reaches all nodes in the network. Gossiping, on the other hand, uses randomization to reduce the number of duplicate packets and requires only that a node receiving a data packet forward it to a randomly selected neighbor.

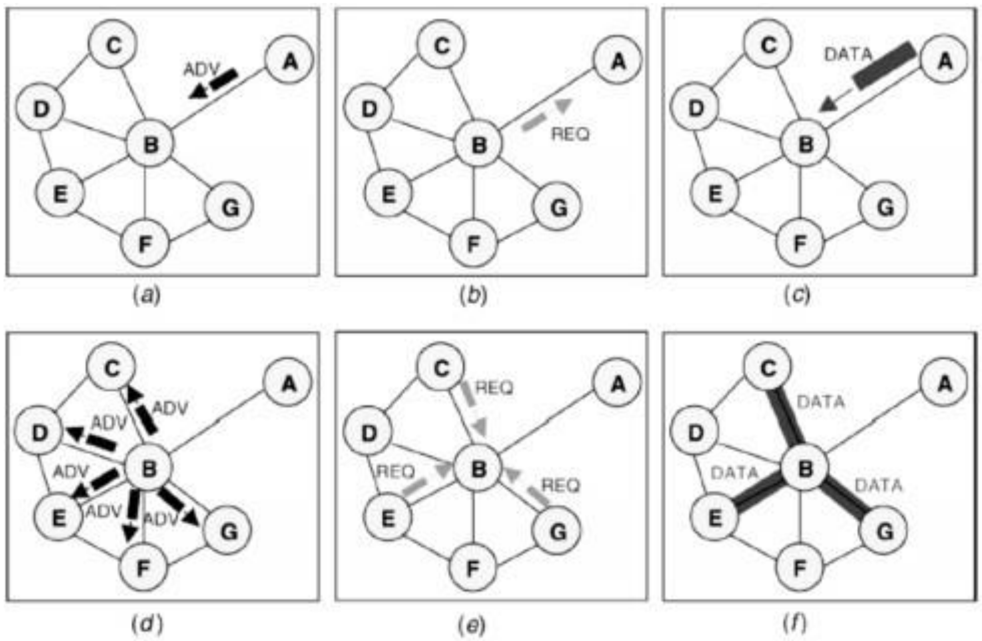

Figure. SPIN basic protocol operation

5.8 Low-Energy Adaptive Clustering Hierarchy (LEACH)

Low-energy adaptive clustering hierarchy (LEACH) is a routing algorithm designed to collect and deliver data to the data sink, typically a base station (Heinzelman et. al. 2000).

The main objectives of LEACH are:

- Extension of the network lifetime
- Reduced energy consumption by each network sensor node
- Use of data aggregation to reduce the number of communication messages

To achieve these objectives, LEACH adopts a hierarchical approach to organize the network into a set of clusters. Each cluster is managed by a selected cluster head. The cluster head assumes the responsibility to carry out multiple tasks. The first task consists of periodic collection of data from the members of the cluster. Upon gathering the data, the cluster head aggregates it in an effort to remove redundancy among correlated values. The second main task of a cluster head is to transmit the aggregated data directly to the base station over single hop. The third main task of the cluster head is to create a TDMA-based schedule whereby each node of the cluster is assigned a time slot that it can use for transmission. The cluster head announces the schedule to its cluster members through broadcasting.

To reduce the likelihood of collisions among sensors within and outside the cluster, LEACH nodes use a code-division multiple access–based scheme for communication. The basic operations of LEACH are organized in two distinct phases. The first phase, the setup phase, consists of two steps, cluster-head selection and cluster formation. The second phase, the steady-state phase, focuses on data collection, aggregation, and delivery to the base station. The duration of the setup is assumed to be relatively shorter than the steadystate phase to minimize the protocol overhead. At the beginning of the setup phase, a round of cluster-head selection starts. To decide whether a node to become cluster head or not a threshold T(s) is addressed in (Heinzelman et. al. 2000) which is as follows:

$$T(s) = \begin{cases} \dfrac{p_{opt}}{1 - p_{opt}.(r.\mathrm{mod}.\dfrac{1}{p_{opt}})}, ifs \in G' \\ 0, otherwise \end{cases}$$

Where r is the current round number and G is the set of nodes that have not become cluster head within the last 1/popt rounds. At the beginning of each round, each node which belongs to the set

G selects a random number 0 or 1. If the random number is less than the threshold T(s) then the node becomes a cluster head in the current round.

5.9 Threshold-sensitive Energy Efficient Protocols (TEEN and APTEEN):

Two hierarchical routing protocols called TEEN (Threshold-sensitive Energy Efficient sensor Network protocol), and APTEEN (Adaptive Periodic Threshold-sensitive Energy Efficient sensor Network protocol) are proposed in (Manjeshwar et al., 2001) and (Manjeshwar et al., 2002) , respectively. These protocols were proposed for time-critical applications. In TEEN, sensor nodes sense the medium continuously, but the data transmission is done less frequently. A cluster head sensor sends its members a hard threshold, which is the threshold value of the sensed attribute and a soft threshold, which is a small change in the value of the sensed attribute that triggers the node to switch on its transmitter and transmit. Thus the hard threshold tries to reduce the number of transmissions by allowing the nodes to transmit only when the sensed attribute is in the range of interest. The soft threshold further reduces the number of transmissions that might have otherwise occurred when there is little or no change in the sensed attribute. A smaller value of the soft threshold gives a more accurate picture of the network, at the expense of increased energy consumption. Thus, the user can control the trade-off between energy efficiency and data accuracy. When cluster-heads are to change, new values for the above parameters are broadcast. The main drawback of this scheme is that, if the thresholds are not received, the nodes will never communicate, and the user will not get any data from the network at all.

5.10 Power-Efficient Gathering in Sensor Information Systems (PEGASIS):

Power-efficient gathering in sensor information systems (PEGASIS) (Lindsey et al., 2002) and its extension, hierarchical PEGASIS, are a family of routing and information-gathering protocols for WSNs. The main objectives of PEGASIS are twofold. First, the protocol aims at extending the lifetime of a network by achieving a high level of energy efficiency and uniform energy consumption across all network nodes. Second, the protocol strives to reduce the delay that data incur on their way to the sink. The network model considered by PEGASIS assumes a homogeneous set of nodes deployed across a geographical area. Nodes are assumed to have global knowledge about other sensors' positions. Furthermore, they have the ability to control their power to cover arbitrary ranges. The nodes may also be equipped with CDMA-capable radio transceivers. The nodes' responsibility is to gather and deliver data to a sink, typically a wireless base station. The goal is to develop a routing structure and an aggregation scheme to reduce energy consumption and deliver the aggregated data to the base station with minimal delay while balancing energy consumption among the sensor nodes. Contrary to other protocols, which rely on a tree structure or a cluster-based hierarchical organization of the network for data gathering and dissemination, PEGASIS uses a chain structure.

5.11 Directed Diffusion:

Directed diffusion (Intanagonwiwat et al., 2000) is a data-centric routing protocol for information gathering and dissemination in WSNs. The main objective of the protocol is to achieve substantial energy savings in order to extend the lifetime of the network. To achieve this objective, directed diffusion keeps interactions between nodes, in terms of message exchanges, localized within limited network vicinity. Using localized interaction, direct diffusion can still realize robust multi-path delivery and adapt to a minimal subset of network paths. This unique feature of the protocol, combined with the ability of the nodes to aggregate response to queries, results into significant energy savings.

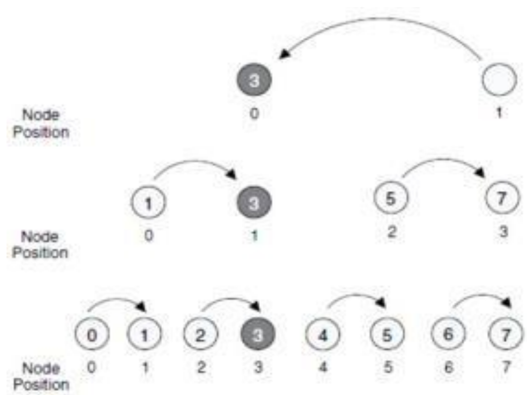

Figure 10. Chain-based data gathering and aggregation scheme

The main elements of direct diffusion include interests, data messages, gradients, and reinforcements. Directed diffusion uses a publish-and-subscribe information model in which an inquirer expresses an interest using attribute–value pairs. An interest can be viewed as a query or an interrogation that specifies what the inquirer wants.

5.12 Geographic Adaptive Fidelity (GAF):

GAF (Xu et al., 2001) is an energy-aware location-based routing algorithm designed mainly for mobile ad hoc networks, but may be applicable to sensor networks as well. The network area is first divided into fixed zones and forms a virtual grid. Inside each zone, nodes collaborate with each other to play different roles. For example, nodes will elect one sensor node to stay awake for a certain period of time and then they go to sleep. This node is responsible for monitoring and reporting data to the BS on behalf of the nodes in the zone. Hence, GAF conserves energy by turning off unnecessary nodes in the network without affecting the level of routing fidelity.

5.13 Security issues in wireless sensor network :

Security issues in sensor networks depend on the need to know what we are going to protect. In (Zia et al., 2006), the authors defined four security goals in sensor networks which are Confidentiality, Integrity, Authentication and Availability. Another security goal in sensor network is introduced in (Sharma et al., 2011).Confidentiality is the ability to conceal message from a passive attacker, where the message communicated on sensor networks remain confidential. Integrity refers to the ability to confirm the message has not been tampered, altered or changed while it was on the network. Authentication Need to know if the messages are from the node it claims to be from, determining the reliability of message's origin. Availability is to determine if a node has the ability to use the resources and the network is available for the messages to move on.

Freshness implies that receiver receives the recent and fresh data and ensures that no adversary can replay the old data. This requirement is especially important when the WSN nodes use shared-keys for message communication, where a potential adversary can launch a replay attack using the old key as the new key is being refreshed and propagated to all the nodes in the WSN (Sen, 2009). To achieve the freshness the mechanism like nonce or time stamp should add to each data packet. Having built a foundation of security goals in sensor network, the major possible security attacks in sensor networks are identified in (Undercoffer et al., 2002) . Routing loops attacks target the information exchanged between nodes. False error messages are generated when an attacker alters and replays the routing information. Routing loops attract or repel the network traffic and increases node to node latency.

Selective forwarding attack influences the network traffic by believing that all the participating nodes in network are reliable to forward the message. In selective forwarding attack malicious nodes simply drop certain messages instead of forwarding every message. Once a malicious node cherry picks on the messages, it reduces the latency and deceives the neighboring nodes that they are on a shorter route. Effectiveness of this attack depends on two factors. First the location of the malicious node, the closer it is to the base stations the more traffic it will attract. Second is the percentage of messages it drops. When selective forwarder drops more messages and forwards less, it retains its energy level thus remaining powerful to trick the neighboring nodes. In sinkhole attacks, adversary attracts the traffic to a compromised node. The simplest way of creating sinkhole is to place a malicious node where it can attract most of the traffic, possibly closer to the base station or malicious node itself deceiving as a base station. One reason for sinkhole attacks is to make selective forwarding possible to attract the traffic towards a compromised node.

The nature of sensor networks where all the traffic flows towards one base station makes this type of attacks more susceptible. Sybil attacks are a type of attacks where a node creates multiple illegitimate identities in sensor networks either by fabricating or stealing the identities of legitimate nodes. Sybil attacks can be used against routing algorithms and topology maintenance; it reduces the effectiveness of fault tolerant schemes such as distributed storage and disparity. Another malicious factor is geographic routing where a Sybil node can appear at more than one place simultaneously. In wormhole attacks an adversary positioned closer to the base station can completely disrupt the traffic by tunneling messages over a low latency link. Here an adversary convinces the nodes which are multi hop away that they are closer to the base station. This creates a sinkhole because adversary on the other side of the sinkhole provides a better route to the base station.

In Hello flood attacks a Broadcasted message with stronger transmission power is pretending that the HELLO message is coming from the base station. Message receiving nodes assume that the HELLO message sending node is the closest one and they try to send all their messages through this node. In this type of attacks all nodes will be responding to HELLO floods and wasting the energies. The real base station will also be broadcasting the similar messages but will have only few nodes responding to it. Denial of service (DoS) attacks occur at physical level causing radio jamming, interfering with the network protocol, battery exhaustion etc. An specific type of DoS attack, Denial-of-service attack has been explored in (Raymond et al., 2009), in which a sensor node's power supply is targeted. Attacks of this type can reduce the sensor lifetime from years to days and have a devastating impact on a sensor network.

5.14 Layering based security approach

5.14.1 Application layer:

Data is collected and managed at application layer therefore it is important to ensure the reliability of data. Wagner (Wanger, 2004) has presented a resilient aggregation scheme which is applicable to a cluster based network where a cluster leader acts as an aggregator in sensor networks. However this technique is applicable if the aggregating node is in the range with all the source nodes and there is no intervening aggregator between the aggregator and source nodes. To prove the validity of the aggregation, cluster leaders use the cryptographic techniques to ensure the data reliability.

5.14.2 Network layer:

Network layer is responsible for routing of messages from node to node, node to cluster leader, cluster leaders to cluster leaders, cluster leaders to the base station and vice versa.

5.15.2 Data link layer:

Data link layer does the error detection and correction, and encoding of data. Link layer is vulnerable to jamming and DoS attacks. TinySec (Karlof et al., 2004) has introduced link layer encryption which depends on a key management scheme. However, an attacker having better energy efficiency can still rage an attack. Protocols like LMAC (Hoesel et al., 2004) have better anti-jamming properties which are viable countermeasure at this layer.

5.15.3 Physical Layer:

The physical layer emphasizes on the transmission media between sending and receiving nodes, the data rate, signal strength, frequency types are also addressed in this layer. Ideally FHSS frequency hopping spread spectrum is used in sensor networks.

CHAPTER 6

RESULT AND CONCLUSION:

6.1 RESULTS:

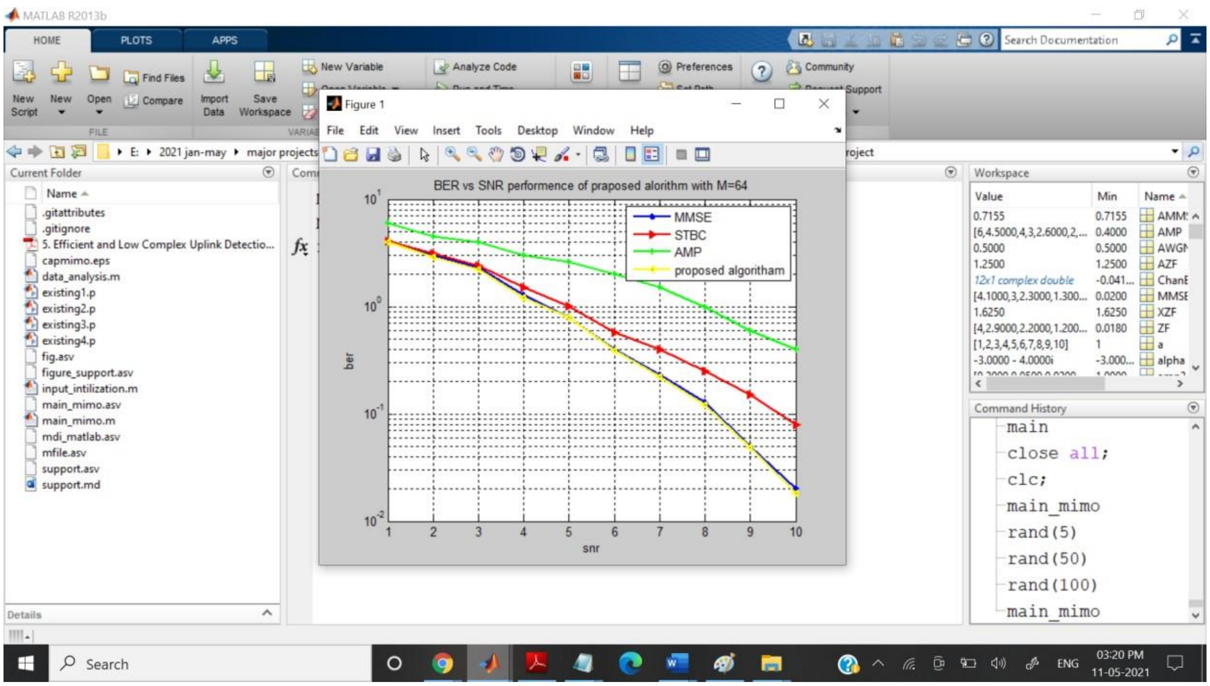

Fig:BER vs SNR performance of proposed algorithm with M=64

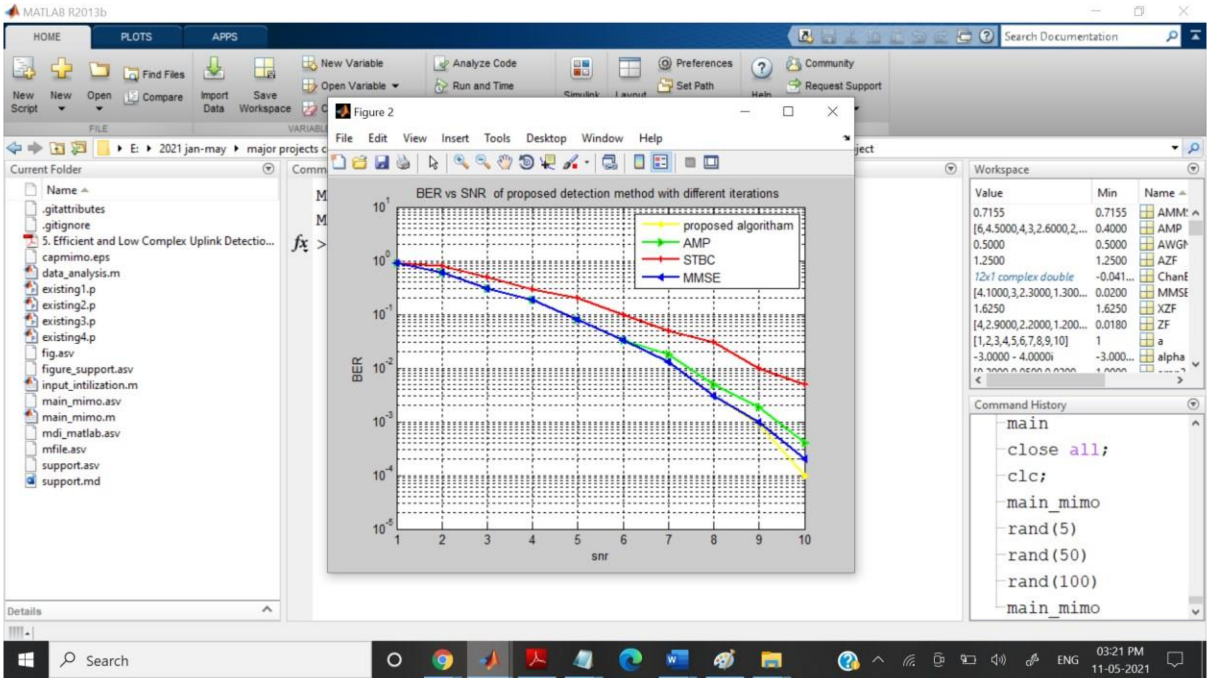

Fig: BER vs SNR of proposed detection method with different iterations

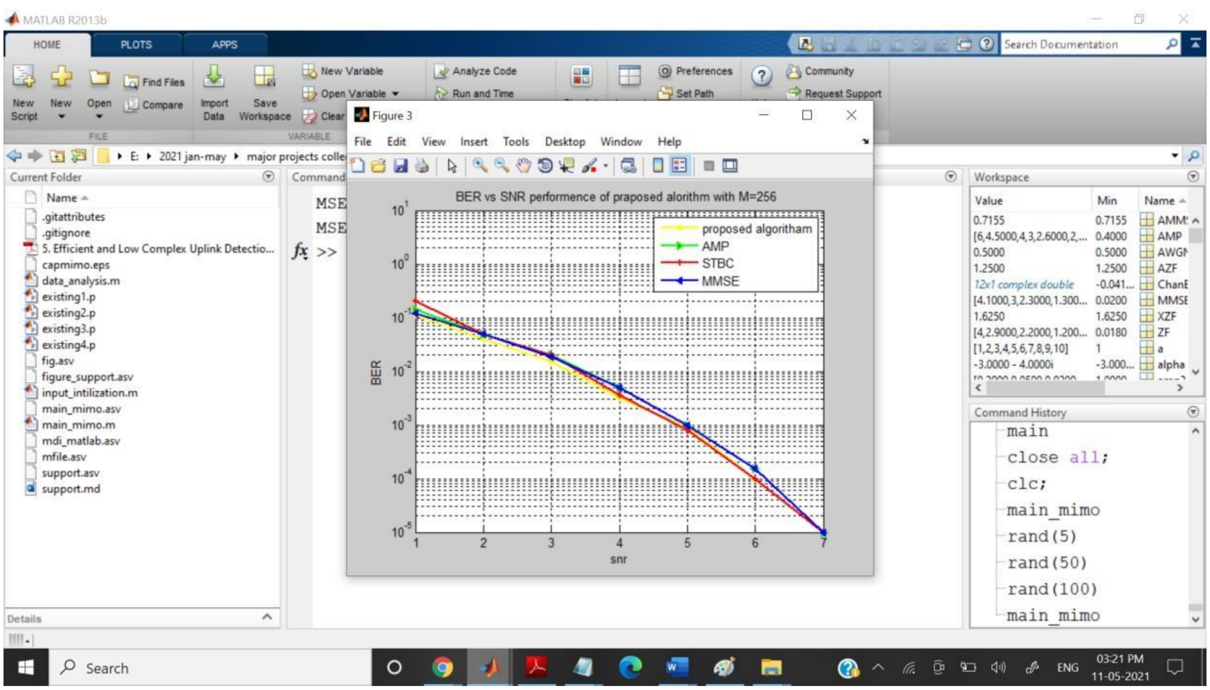

Fig: BER vs SNR performance of proposed algorithm with M=256

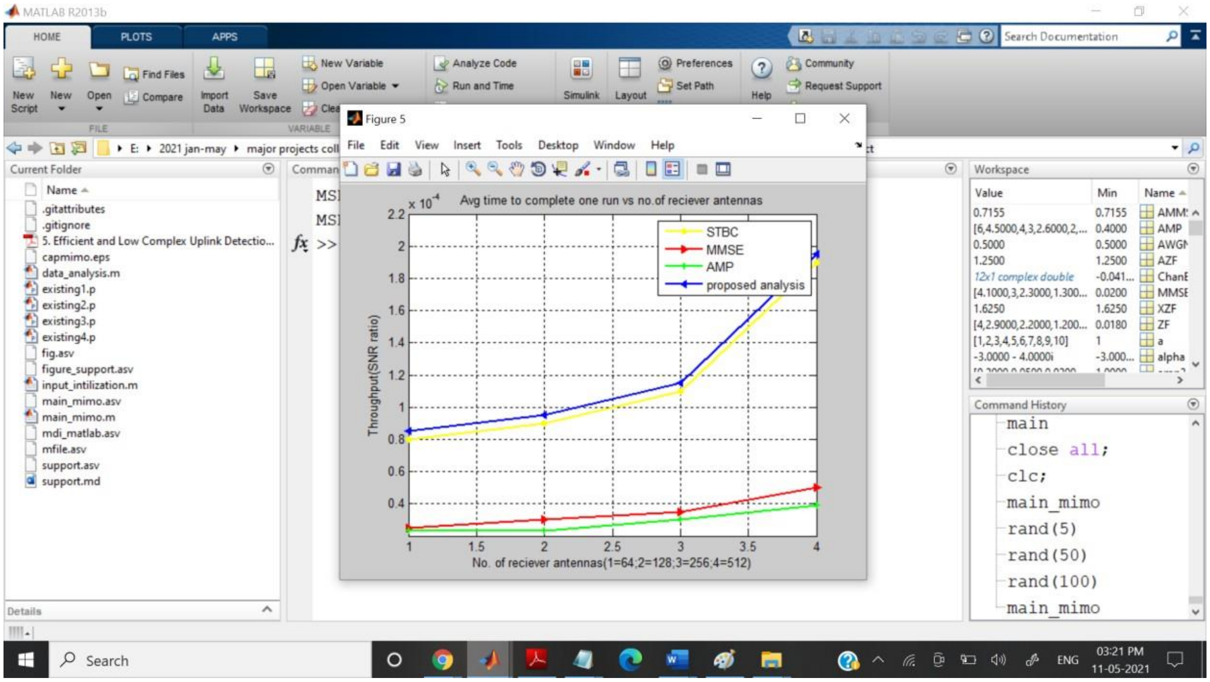

Fig: Aug time to complete one run vs no of receiver antennas

CONCLUSION:

This article is a humble attempt to provide a forward looking research roadmap for 6G. New features of the 6G evolution were identified, and enabling technologies were discussed. While a partial picture was presented, we hope our discussion will spur interests and further investigations on the future evolution of cellular networks.

DECLARATION

We declare that this project report titled **Minimum Time Delay and More Efficient Image Filtering Brain Tumor Detection With The Help Of MATLAB** submitted in partial fulfillment of the degree of B. Tech in Electronics And Communication Engineering record of original work carried out by us under the guidance and supervision of Mr. K. Nishakar, and has not formed the name basis for the award of any other degree or diploma, in this or any other Institution or University. In keeping with the ethical practice in reporting scientific information, due acknowledgements have been made wherever the findings of others have been cited.

.

G. Vishwas	A.Mary Sophia	B.Srinish Kumar
(17KA81A0E7)	(17K81A04C3)	(17K81A04D5)

Place: Secunderabad

Date: 25-06-2021

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

We extended our deep sense of gratitude to Principal, **Dr. P. SANTOSH KUMAR PATRA**, St. Martin's Engineering College, Dhulapally, for permitting us to undertake this project.

We are also thankful to **Dr.B.Hari Krishna** Head of the Department, Electronics And Communications, St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project and as well as our project coordinator **Dr.A.Anand**, Professor in Electronics And Communication Engineering, for his valuable support.

We would like to express our sincere gratitude and indebtedness to our project supervisor **Mr.K.Nishakar**, Associate Professor, Electronics And Communications St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project.

Finally, we express thanks to all those who have helped us successfully to completing this project. Furthermore, we would like to thank our family and friends for their moral support and encouragement.

We express thanks to all those who have helped us in successfully completing the project.

.

1. G. Vishwas

3. B. Srinish Kumar

ABSTRACT

Brain tumour detection is one of the intriguing task in the medical field still now. Earlier the technologies pneumoencephalography and cerebral angiography were used but they had drawbacks. The next technologies such as CT and MRI scan techniques with the help of surgeons came into use to provide a higher quality result in image processing. However it is difficult in distinguishing between brain tumour tissue and normal tissue because it they are similar in colour. Hence Brain tumour must be analysed more precisely in order to cure it. In this paper Tumour Detection with help of MATLAB image processing catches three stages Pre-processing, Processing and Post-Postprocessing in morphological detection. After the getting MRI report first stage is pre-processing which is converting the original RGB image to gray-scale image and then using a Gaussian high pass filter for noise reduction. In the second stage processing for pixel enhancement we use Median filter and in third stage i.e. the post-processing where different filters such as Entropy Filter., Standard Deviation Filter (SDF), Weiner Filter, Gradient Magnitude, Regional Maxima are used for various different-different results. In this post processing which is followed by algorithm not only creates the report automatically, but has very less delay time and gives the output more efficiently.

LIST OF TABLES

CHAPTER-1
INTRODUCTION

Brain tumor is a life- threatening disease. Brain tumors can be malignant or benign. When tumor cells grow it cause pressure inside the skull, this leads to brain damage. Two types of Brain tumor namely Primary and secondary. Primary brain tumors are benign and that are originates in brain. Secondary brain tumors occur when cancer cells spread over the brain from other organ such as lung or breast. It is also called as metastatic brain tumor. Brain tumor can be occurred in any ages. If brain tumor detected early stage it is treatable. Brain tumor cause more death in children and adults under the age of 40 than any other cancer. In India the tumors ranges from 5 to 10 per 100,000 populations with an increasing trend.

Diagnosing brain tumor is a tedious process. Computer Tomography scan (CT scan), Magnetic Resonance Imaging(MRI), tests like an Angiogram, Spinal tab and Biopsy are used to diagnosis brain tumors. CT scan uses x-ray to produce images. CT scan expose patients to ionizing radiation. High radiation are involved in CT scan . A new study in the Journal of the National Cancer Institute suggests that CT scans, commonly used in medical imaging, may increase the risk of brain tumors.

Magnetic Resonance Imaging (MRI) plays an important role in the medical era. It is noninvasive method to detect Brain tumor. MRI uses Magnetic field and Radio waves to produce Brain images. MRIs create more detailed pictures than CT scans. MRI is the preferred screening examination for brain tumor. The goal is to detect brain tumor before clinical signs are noticeable. The size of the tumor can be measured by MRI. A special dye called contrast medium is injected into the patient's vein or given as a pill or fluid to swallow before an MRI scan.

Any area with abnormal tissue can cause for cancer. The abnormalities will be examined by radiologist. A focused white area on MRI can be a lump or tumor. Tumors can be cancerous or benign. If a tumor is benign, it is not a risky and is unlikely to grow or change shape. The radiologist will check its shape and pattern,as they can sometimes be a sign of cancer.

1.1 Project Overview

Brain tumour detection is one of the intriguing task in the medical field still now. Earlier the technologies pneumoencephalography and cerebral angiography were used but they had drawbacks. The next technologies such as CT and MRI scan techniques with the help of surgeons came into use to provide a higher quality result in image processing. However it is difficult in distinguishing between brain tumour tissue and normal tissue because it they are similar in colour. Hence Brain tumour must be analyzed more precisely in order to cure it. In this project Tumor Detection with help of MATLAB image processing catches three stages Pre-processing, Processing and Post-Postprocessing in morphological detection. After the getting MRI report first stage is pre-processing which is converting the original RGB image to gray-scale image and then using a Weiner filter for noise reduction. In the second stage processing for pixel enhancement we use Median filter Entropy Filter., Standard Deviation Filter (SDF), Gradient Magnitude, Regional Maxima are used for various different-different results and in third stage we do image fusion and add some standard no. of pixels to the resultant image. We then compare the input image and resultant image and find some parameters which tells about the efficiency and noise present.

1.2 Project Objective

The Objective of our project is to

- Study the literature that is based on image processing.
- Identify the major areas of image processing in medicine and in particularly on brain tumor detection.
- Identify the current issues in brain tumor identification.
- Propose future directions and improvements that can be made in this area.
- Critically analyze and review identification of brain tumor using image processing.
- To detect the brain tumour with very less time delay and more efficiently.

1.3 Organisation Of Chapters

1.3.1 Introduction

1.3.2 Literature Survey

1.3.3 Software Introduction

1.3.4 Introduction to Image Processing

1.3.5 Digital Image Processing

1.3.6 Methodology

1.3.7 Results

1.3.8 Conclusion and Future Scope

CHAPTER-2
LITERATURE SURVEY

Tumors are abnormal cells which expands in our body but in brain tumor a mass of tissue in our brain cell are expanded rapidly. The symptoms of brain tumor depends upon tumor type, size and location of the tumor. The symptoms are headache vomiting nausea some other changes are speech vision and hearing problems sometime they can changes their activities like personality, ability to concentrate and problem with memory. A brain tumor is categorized primary and secondary depends upon location size and its origin.

A. Benign: Benign tumors which type of non-cancerous mass of cells that it was expands very slowly in the brain. It was does not spread and stay in one place. Normally benign brain tumors can be detected by CT and MRI scans.

B. Maligant: Malignant brain tumor was rapidly expand like cancer that spreads one area to other area of the brain and spine it [3].

C. Materials and Methods: The MRI report is obtained from Government Medical College, Jagdalpur under the guidance of Rajat Kumar Pandey(MBBS, Final Part II ,Student) that includes one normal image and one abnormal image of MRI and CT report. All the image processing operation are done in MATLAB.

2.1 Existing Method:-

- The existing method first employed the wavelet transform to extract features from images, followed by applying principle component analysis (PCA) to reduce the dimensions of features. The reduced features were submitted to a kernel support vector machine (KSVM).
- Another method employed a discrete wavelet transform to extract features from images, and then applied the technique of principle component analysis (PCA) to reduce the size of the features. The reduced features were sent to an FNN, of which the parameters were optimized via an improved artificial bee colony (ABC) algorithm based on both fitness scaling and chaotic theory.

2.2 Proposed Method:-

- Now in our project we proposed some new types of filtering method which may perform the tumor detection more efficiently than the previous methods and give us a detailed output of the tumor cells.
- These filtering techniques such as Weiner filter, Gaussian filter reduce the time in giving us the required output and the output formed is more clear with less amount of noise present in it. Thus, our system lays an emphasis in detecting tumor in an easier manner than the previous ones.

CHAPTER-3
SOFTWARE INTRODUCTION

3.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn

and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 The MATLAB System:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3.3 Graphical User Interface (GUI)

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .Figure, called a FIGURE-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIGURE-file contains binary data that does not need to be parsed whenhe associated GUI-based M-function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIGURE-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

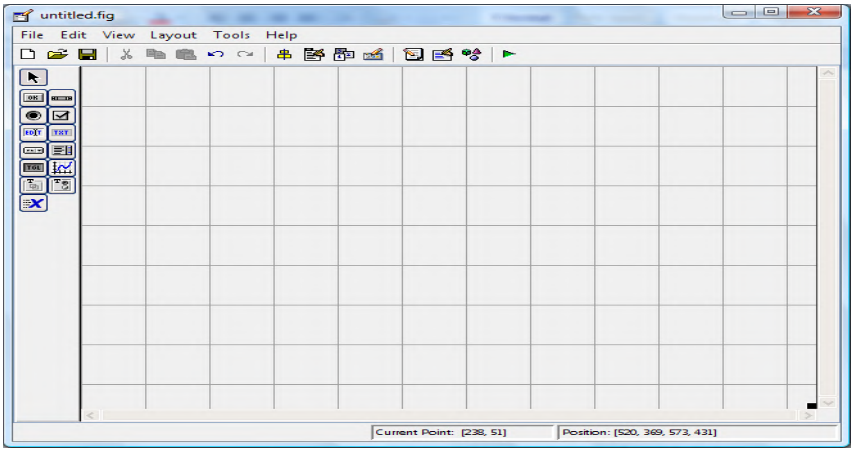

Figure 3. 1 Graphical User Interface

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

[1] Introduction - describes the components of the MATLAB system.

[2] Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

[3] Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

[4] Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

[5] Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cellarrays and multidimensional arrays.

3.5- Development Environment

3.5.1 Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

3.5.2 Starting and Quitting MATLAB

- **Starting MATLAB**

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type MATLAB at the operating system prompt. After starting MATLAB,the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

- **Quitting MATLAB**

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.6 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in thefollowing illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.6.1 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- **Current Directory Browser**
- **Workspace Browser**
- **Array Editor**
- **Editor/Debugger**
- **Command Window**
- **Command History**
- **Launch Pad**
- **Help Browser**

  - **Command Window**

Use the Command Window to enter variables and run functions and M-files.

- **Command History**

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

- **Running External Programs**

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

- **Launch Pad**

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

- **Help Browser**

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, whereyou view the information.

- **Help Navigator**

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

3.6.2 Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

3.6.3 Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

3.6.4 Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select SaveWorkspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There areoptions for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

3.6.5 Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

3.6.6 Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

3.7 Manipulating Matrices

3.7.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow afew basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ]. To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =

16    3    2   13

 5   10   11    8

 9    6    7   12

 4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can referto it simply as A.

3.8 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

3.8.1 Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

3.8.2 Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.8.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

Table 3.8. 1 Operators

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose

3.8.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Table 3.8. 2 Functions

I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

3.9 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

3.9.1 Creating GUIs with GUIDE

MATLAB implements GUIs as Figureure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.9.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

3.9.3 The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIGURE-file - contains a complete description of the GUI Figureure and all of its children (uicontrols and axes), as well as the values of all object properties. **An M-file** - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as theapplication M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIGURE-file.

The following diagram illustrates the parts of a GUI implementation.

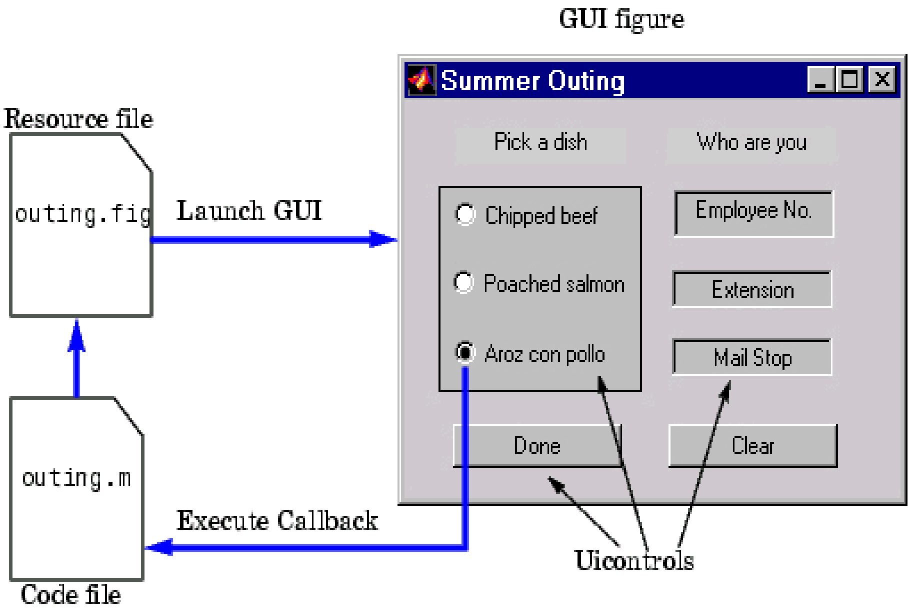

Figure 3. 2 Graphical user blocks

3.9.4 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see ConFigureuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIGURE-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIGURE-file generated by the Layout Editor.

3.9.5 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIGURE-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

3.9.6 Command-Line Accessibility

When MATLAB creates a graph, the Figureure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current Figureure and axes.

GUIs are also created in Figureure windows. Generally, you do not want GUI Figureures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI Figureure, resulting in the graph appearingin the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.9.7User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides informationon these components.

- Push Buttons

- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figureures

- **Push Buttons**

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

- **Programming the Callback**

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

- **Toggle Buttons**

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

- **Programming the Callback**

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

- **Radio Buttons**

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

- **Checkboxes**

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function  checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

   % then checkbox is checked-take approriate action
else

   % checkbox is not checked-take approriate action

end
```

- **Edit Text**

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function  edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the Figureure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

- **Static Text**

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it.

- **Frames**

Frames are boxes that enclose regions of a Figureure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

- **List Boxes**

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the Figureure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the Figureure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

- **Popup Menus**

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then youcan use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

- **Enabling or Disabling Controls**

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the Figureure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.9.8 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example, axes(handles.axes1) makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you wantto target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figure are the windows that contain the GUI you design with the Layout Editor. See the description of Figure properties for information on what Figure characteristics you can control.

CHAPTER-4
INTRODUCTION TO IMAGE PROCESSING

Introduction

4.1. Image

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and naturalobjects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional Figureure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Figure 4.1. 1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display.However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each

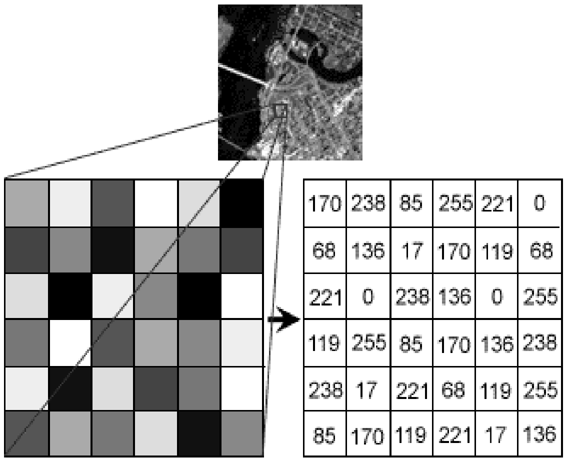

Figure 4.1. 2 Image pixel

pixelconsists of numbers representing magnitudes of brightness and color.

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

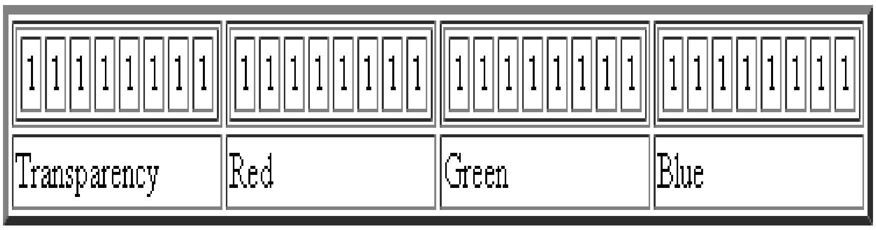

Figure 4.1. 3 Pixel Transparency

4.2 Image File Sizes

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color.

For example, an image recorded by a 12 MPcamera; since each pixel uses 3 bytes to record true color, the uncompressed imagewould occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

4.3 Image File Formats

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

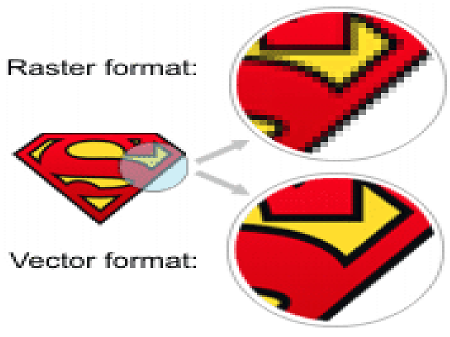

Figure 4.3. 1 Resolution Image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

JPEG/JFIF:

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

EXIF:

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

TIFF:

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

PNG:

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

GIF:

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

BMP:

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

CGM:

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

SVG:

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

4.4 Image Processing

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man’s ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

4.4.1 Fundamental Steps In Digital Image Processing

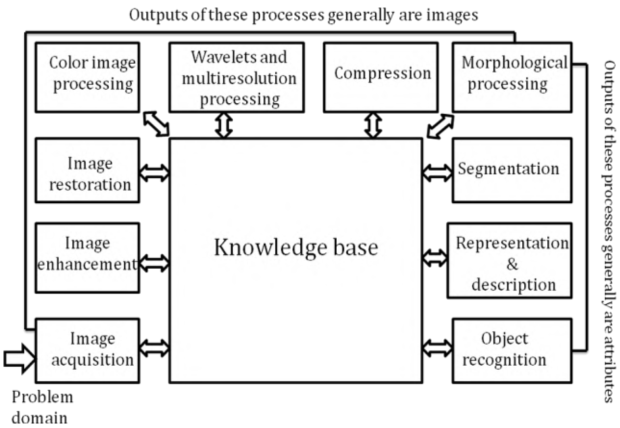

Figure 4.4. 1 Image Segmentation

4.4.2 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Figure 4.4. 2 Digital Camera Image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

4.4.3 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Figure 4.4. 3 Image Enhancement

4.4.4 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Figure 4.4. 4 Image Restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

4.4.5 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Figure 4.4. 5 Colour Image Processing

4.4.6 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

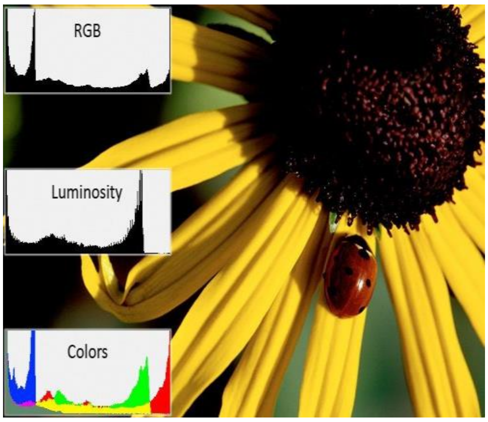

Figure 4.4. 6 RGB Histogram Image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

4.4.7 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

4.4.8 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Figure 4.4. 7 Blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

4.4.9 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

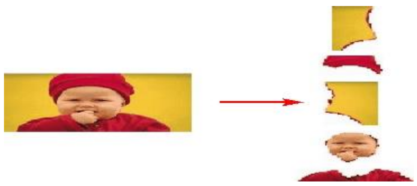

Figure 4.4. 8 Image Segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

4.4.10 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region.

Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

4.4.11 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

4.4.12 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

4.5 Components Of An Image Processing System

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

- Image sensors:

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- Specialized image processing hardware:

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- Computer:

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- Image processing software:

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- Mass storage:

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Figure. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- Image displays:

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- Hardcopy:

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- Network:

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient.

CHAPTER-5
DIGITAL IMAGE PROCESSING

5.1 Digital image processing

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

5.2 An overview of Digital Image Processing

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

5.3 The definition of an Image

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of ‘f’ at any pair of coordinates (x, y) is called the intensity of the image at that point.

5.4 Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

5.5 Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

5.6 Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following Figureure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

5.7 Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0)   f(0,1)   ………..   f(0,N-1)

f (1,0)   f(1,1)   …………   f(1,N-1)

f (xylem)=   .   . .

.   .

f (M-1,0)   f(M-1,1) .... f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f(1,2)...........f(1,N)

f (2,1)   f(2,2)...........f (2,N)

.   .   .

f= f (M,1) f(M,2) …….f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

5.8 Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Table 5. 1 Classification of Different Formats

Format name	**Description Extension**	**Recognized**
TIFF	Tagged Image File Format	.tif
JPEG	Joint Photograph Experts Group	.jpg
GIF	Graphics Interchange Format	gif
BMP	Windows Bitmap	.bmp

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

5.9 Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Table 5. 2 Data Classes

Name	Description
Double	Double _ precision, floating_ point numbers the
Unit 8	unsigned 8_bit integers in the range[0,255](1byte per Element).
Unit 16	unsigned 16_bit integers in the range[0,65535](2byteper element)

5.10 Image Types:

The toolbox supports four types of images:

1. Intensity images
2. Binary images;
3. Indexed images;
4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

- Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

- Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

- Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

- RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER-6
METHODOLOGY

6.1 Pre-Processing:

I. Pre-processing: The aim of pre-processing is to convert the RGB image into gray image using Gray-Scale conversion. The converted image is then processed to reduce noise and implement the contrast enhancement [4,5] to improve the quality of the image.

The working process of pre-processing is as follows:

1. Gray-scale conversion
2. Addition of Poisson Noise

Gray Scale Conversion*:* The Gray scale image includes only gray-scale values, but MRI report consist of primary colors (RGB) [6]. Gray scale is a type of monochrome image where each pixel of any image consists some information of the intensity of light hence it is similar to that of conventional black and white image. By converting the image into gray it becomes easier for further processing. Here we take the help of 'RGB2gray' or 'binarize' the commands which converts the three dimensional image into two dimensional or gray scale image.

Poisson noise addition and applying a high pass filter *:* Filtering is a technique in image processing where we try to reduce the effect of noise as minimum as possible. Let us assume that the image consists of Gaussian noise present in it. After the conversion of image into gray, we try to minimize the noise effect by passing it through a high pass filter known as Gaussian HPF. Median filter is the type of filter provides a median value of the pixels of an image and it is used because the mean values obtained using averaging filters it makes image blur [7]. In MRI, Gaussian noise are more commonly seen or observed. Salt and Pepper noise canbe reduced with the help of median filter, considering that Gaussian noise is reduced by a Gaussian high pass filter (HPF).

Weiner Filtering*:* On comparing and analyzing various filters and their capabilities we came to a conclusion that Weiner filter is the most suitable filter for further stages of processing. Hence the addition of Weiner filter completes the 1st stage i.e. pre-processing.

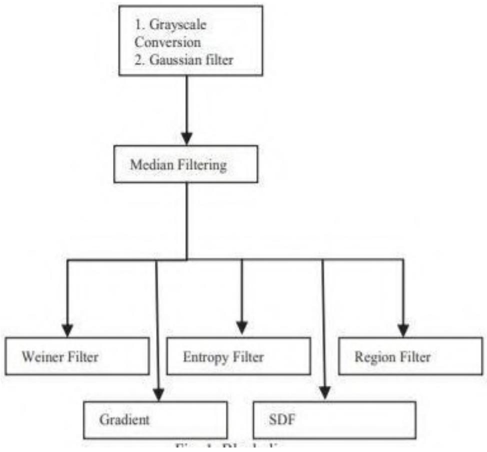

Figure 6. 1 Block Diagram

6.2 Processing:

Processing: The 2nd stage starts with processing of the Weiner filter image. In stage 2 we applied median and gradient filters to reduce the noise at the edges and to improve the intensity of the image at the later stages. Hence Processing stage consists of Median and Gradient filtering.

1. Median Filtering.
2. Gradient Filtering.

Median Filtering*:* The median filter is a type of filter which is used to reduce or minimize the salt and pepper noises present in the image, which are caused by motion artifacts (movement of patient during scan). In-order to reduce these kinds of noise we used this filter in our MATLAB code following the command '**medfilt2**'. We are sub-dividing the images into 4 variants (Low-Low Image Low-High Image, High-Low image High-High Image) using **2-Dimensional Discrete Wavelet Transform**. The command 'Dwt2' subdivides the image based on its intensity values. The image obtained is combination of all the intensities

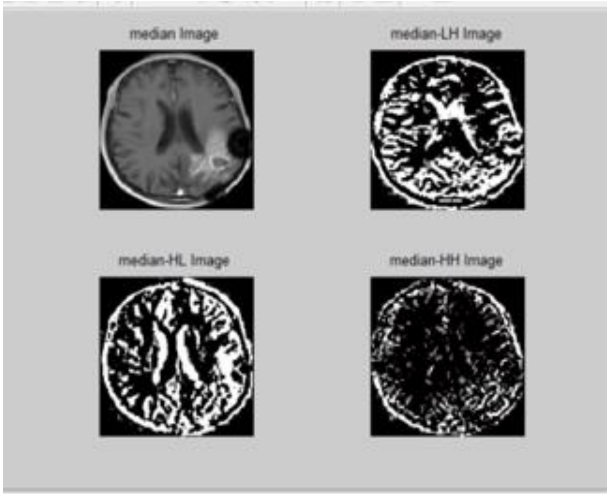

Figure 6. 2 Median Image

Gradient Filtering*:* The gradient of any vector of an image contains the information which can let us know about the change in the intensity of the image at any given point of time. By using the 'imgradient' command present in the MATLAB and converting the matrix values (which are the intensity values) into the same components as we stated in median filtering, we can know the intensities of the image at any given point of time. For our project we've taken the combination of Low-High and High-Low intensity values lying between (90-200). These values are used to produce the combined image and is further processed to stage 3. The processing stage ends here and the following stage is post-processing.

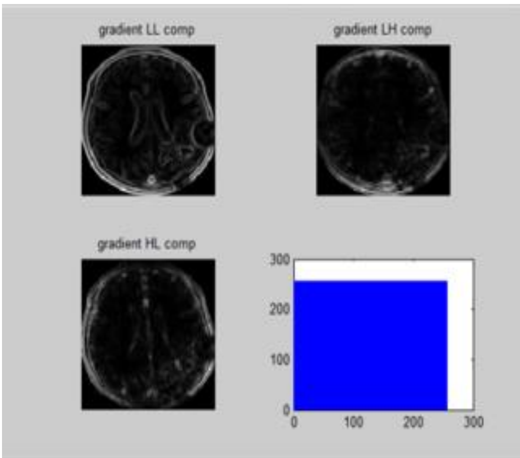

Figure 6. 3 Gradient filter output

6.3 Post-Processing:

Post-Processing: In post processing stage, the obtained gradient output images are combined together to obtain a standard output image. This is done with the help of for loop and having iterations in the program. To obtain the combination of all the pixels into single output we used four for loops and 72 iterations. These commands run and execute the code to give a single result image. For the image obtained we add some standard number of pixels to enhance the image. The addition of standard number of pixels to the image is done using "imadd()" command. The resultant output image is also resized using 'imresize(image_name,[256,256])' command.

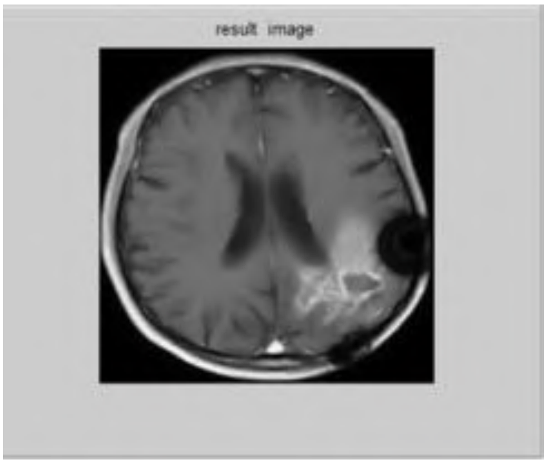

Figure 6. 4 Resultant image

This completes the 3rd stage which is post-processing. The obtained image is then compared with the noise image and gives us the Peak Signal to Noise Ratio, and Mean Square Error. Hence the margin or error and the value of noise reduced can be known.

6.4 Comparison

The following table consists of the comparison between the normal CT and MRI scanned images in tally with the abnormal CT and MRI scanned images. The parameters such as mean. standard deviation, area, entropy, median, moment fifth are been showed. This table gives us the range of values where one can know if the scanned image consists of the tumor or is the person normal.

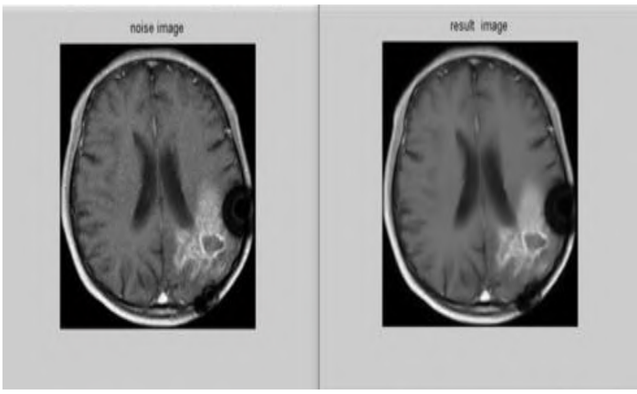

Figure 6. 5 Comparison of noise and result image

The comparison of the result and noise image in the above figure lets us in calculating the PSNR and MSE values so that the robustness of the image obtained can be known when some external disturbances occur.

Table 6. 1 Comparison of Statistical properties of MRI and CT-Scan

S. N O.	**Parameters**	**MRI**		**CT**	
		Normal	**Abnormal**	**Normal**	**Abnormal**
01	**Mean**	63.008	75.916	482.22	78.1154
02	**Standard deviation**	440.578	227.134	8.033	477.3392
03	**Median**	8	7	3	2
04	**Moment fifth**	21.068	35.882	21.536	21.765
05	**Area**	113	36	18	156
06	**Entropy**	5.987	6.9627	4.3295	6.9948

CHAPTER-7
RESULTS

- **Input Image**

The input image is converted from RGB to grey using grey scale conversion

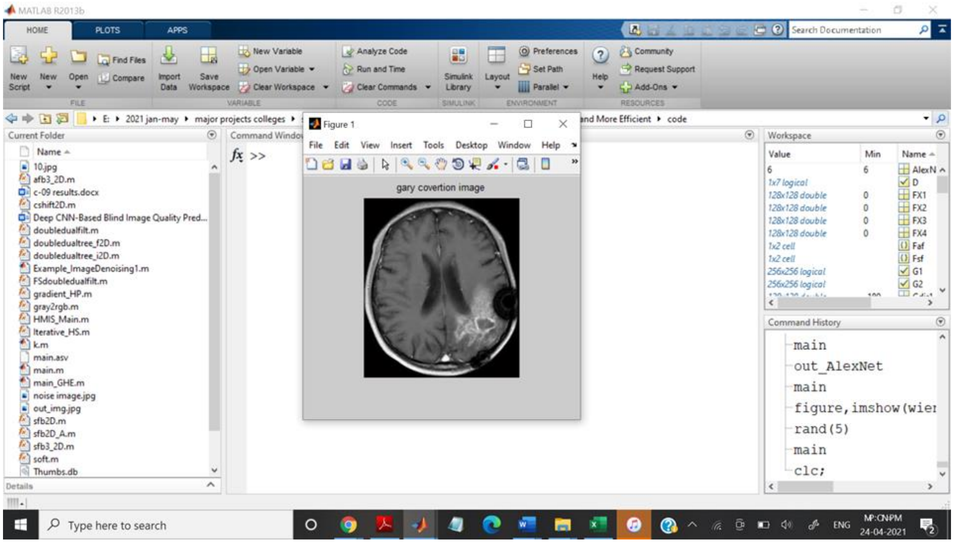

Figure 7.1 Grey Conversion Image

- **Noise Image**

After adding poison noise to the Grey image we get Noise image.

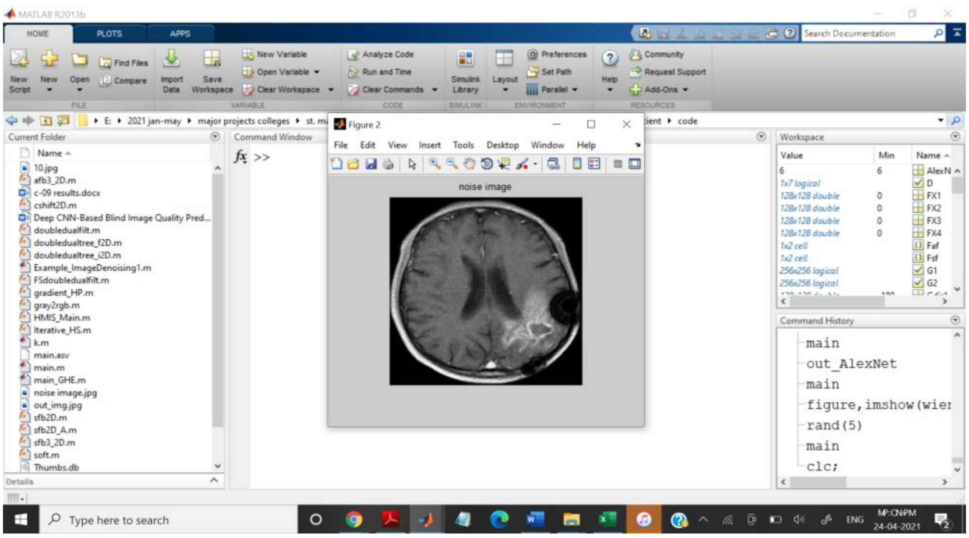

Figure 7.2 Noise Image

- **Weiner Filter Image:**

  This image shows the Weiner filter output where the errors are reduced as minimal as possible and only high frequency parts of the image are visible

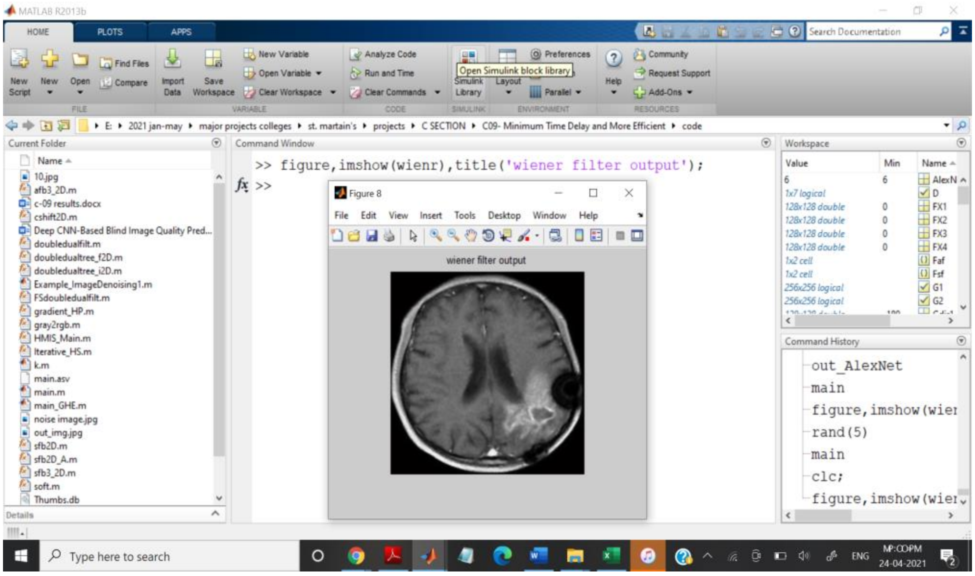

Figure 7.3 Wiener Filter Output Image

- **Region Based Filter:**

  This image shows the region based enhancement where any part of the imagecan be cropped out for having a better analysis of that part.

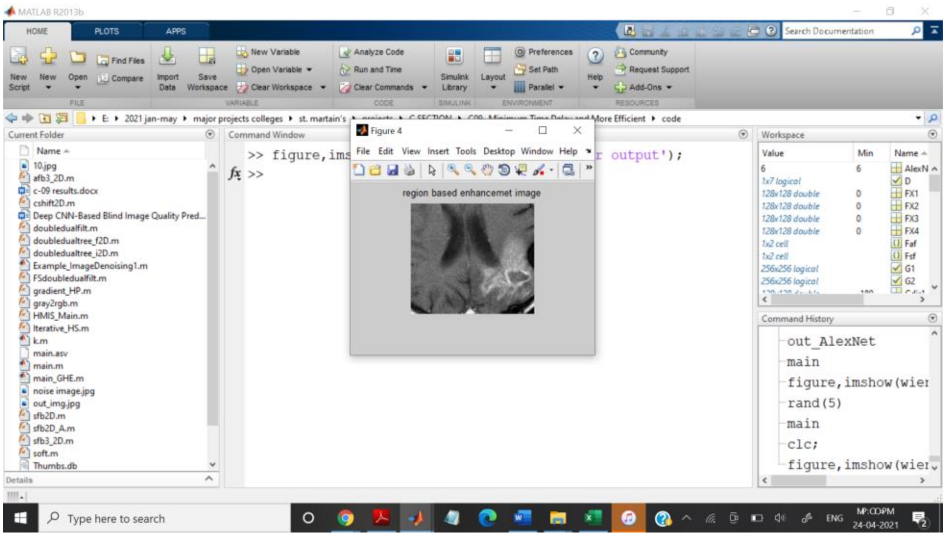

Figure 7.4 Region Based Enhancement Image

- **Median Filter Outputs:**

These images are the outputs of median filter where the image is free from salt and paper noise and divided into median Low-Low image, median High-Low image, median High-High image according to pixels intensity.

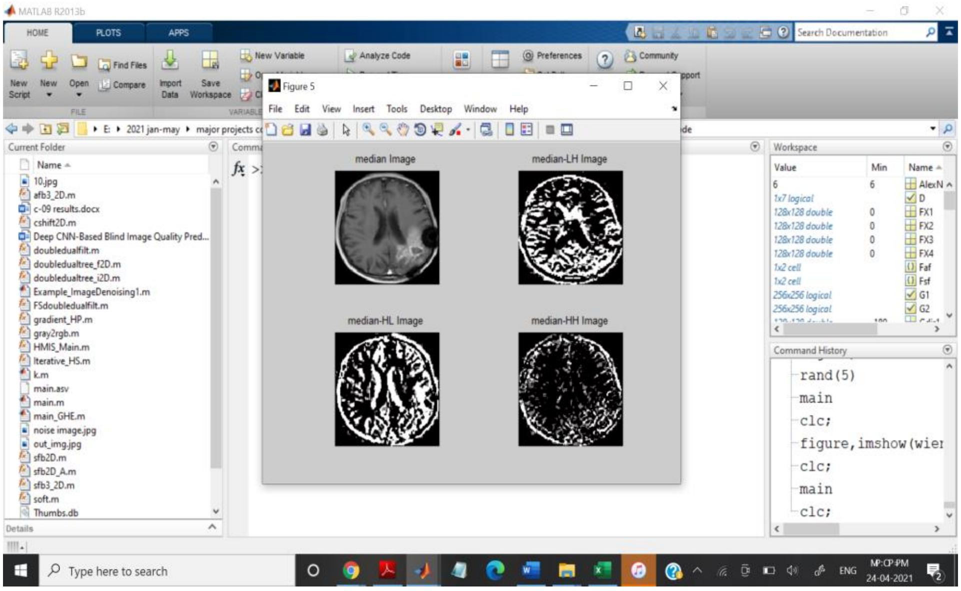

Figure 7.5 Median Images

- **Gradient Filter Outputs:**

These images are the outputs of gradient filter. From this image we can seethe tumor region more efficiently.

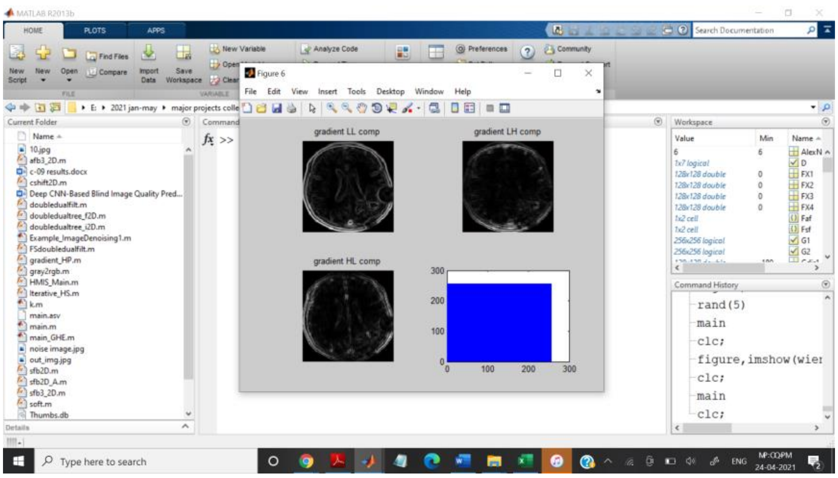

Figure 7.6 Gradient Scale Images

- **Resultant Image:**

  The image shows the obtained result image after applying all the filers.

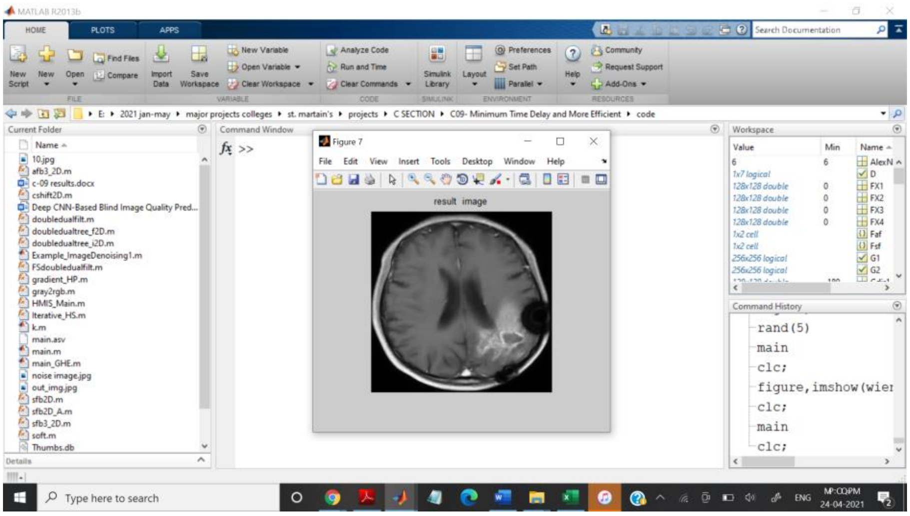

Figure 7.7 Result Image

- **Comparison between Noise and Resultant Image:**

  The image shows the comparison between the noise and the result image. From this image we can see how the noise image is Enhanced.

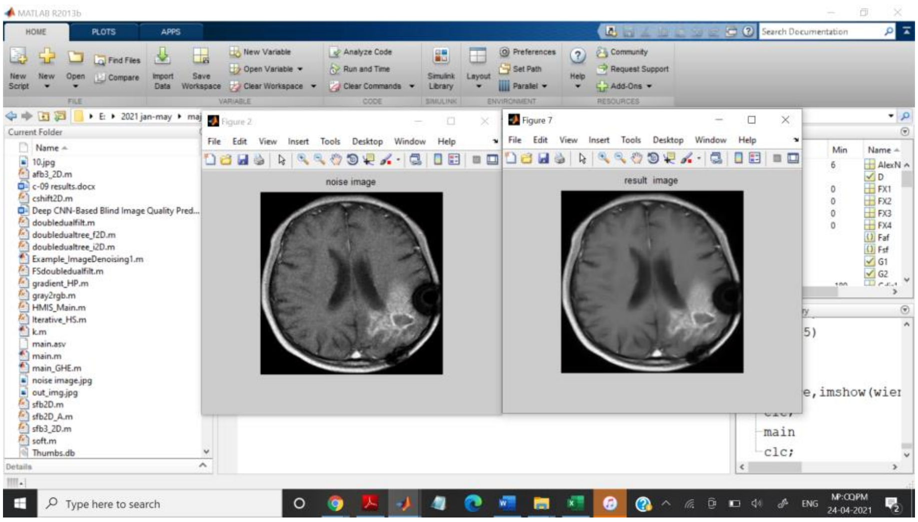

Figure 7.8 Noise vs Result Image

- **Parameters Measured:**

This image shows the calculated PSNR and MSE values which gives us theefficiency of the resultant image i.e., the performance of the filters.

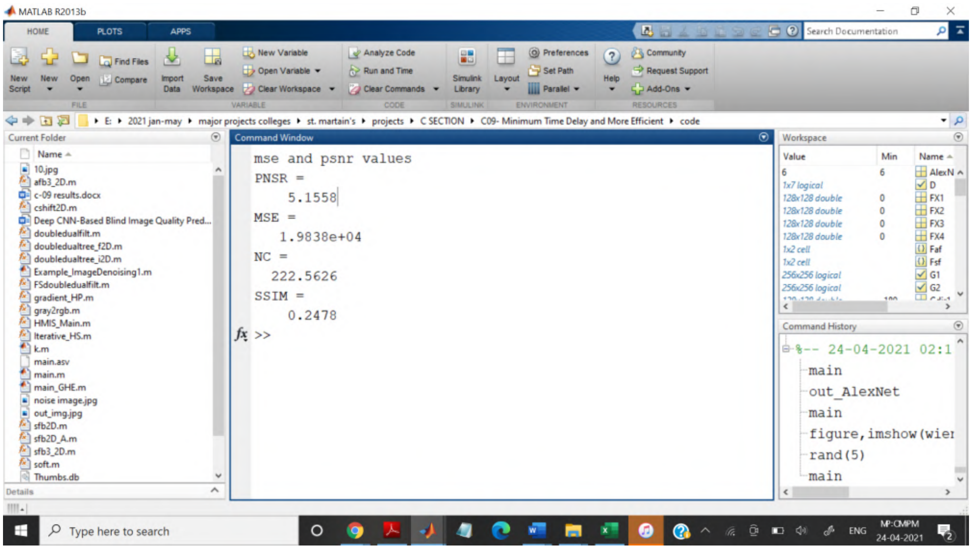

Figure 7.9 PSNR and MSE Values

CHAPTER-8
CONCLUSION AND FUTURE SCOPE

8.1 Conclusion:

All the discussion is aiming to detect the brain Tumor from or the abnormal behavior of the any one's brain through CT and MRI brain images. The brain tumor is detected more accurately using image processing and various type of the morphological operations, image filtering are performed for analysis or to observe and to obtain the various parameters like Mean, Standard deviation, Third moment, Area, Entropy of the image.

8.2 Future Scope:

- In future this method can be enhanced and can be used to detect brain tumor in colored MRI images.

- As we are currently using this method to detect the tumour in brain only, in future this method can be further processed to detect the tumour in various parts of the body with very less time delay and more efficiency.

DECLARATION

We, the student of **'Bachelor of Technology in Department of Electronics and Communication Engineering'**, session: 2017 – 2021, **St. Martin's Engineering College**, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **'SOLAR POWERED AUTOMATED MULTITASKING AGRICULTURE ROBOT USING IOT'** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

A.LAHARIKA	(17K81A04C4)
K.YASHWANTH REDDY	(17K81A04E9)
P.AJAY GOUD	(18K85A0429)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B.Hari Krishna**, **Head &Professor**, the Dept. of Information Technology for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.Maalyadri, Professor** for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Mrs.P.Kiranmayee**, **Assistant Professor in ECE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. A.LAHARIKA

Abstract:

Agriculture plays a vital role in socio-economic development of India. Agriculture is the cultivation of animals, plants, fungi, and other life forms for food, fiber, biofuel, medicinal and other products used to sustain and enhance human life. Agriculture is the most essential and foremost economic activity of all times. Until the Industrial Revolution, the vast majority of the human population laboured in agriculture. Pre-industrial agriculture was typically subsistence agriculture/self- sufficiency in which farmers raised most of their crops for their own consumption instead of cash crops for trade. But now, agriculture is undergoing a structural change leading to a crisis situation. The growth rate of agricultural output is gradually declining in the recent years due to labour scarcity and more expensive.Seed and chemical prices are rising too, creating the need for their efficient use. The recent survey shows that the world should double their agriculture productivity to feed the entire booming population by 2050. At that time with efficient management of natural resources will meet increasing demand by adopting modern technology in farming to improve agricultural productivity. Hence, as the farmers are struggle with higher seed and chemical prices, the prospect of labour shortages and growing world demand for food will drive to think an innovative and more efficient farming method. These problems in agriculture led us to propose an automated design “Agribot” which can perform most of the farming activities.

CHAPTER-1

INTRODUCTION

1.1. Introduction to the project:

The primary occupation in a developing country like India is agriculture. But nowadays the number of people involved in agricultural sector is declining due tovarious reasons. It is essential to improve the efficiency and productivity of agriculture. By using this project, we can perform various tasks for agricultural purposes. Despite large-scale mechanization in agricultural field in some parts of the country, most of the agricultural operations in large number of parts are carried on by humans by using simple tools and implements like wooden plough, sickle, etc. Little or no use of machines is made in ploughing, sowing, irrigating, weeding the crops. This is specially the case with small and marginal farmers. It results in huge wastage of men power and in lower yields per capita labour force. So, we must mechanize the agricultural operations so that wastage of labour force is avoided, and farming is made convenient and efficient. We believe some progress will be madeby applying this vehicle in agricultural field.

Current agricultural practices in India are neither economically nor sustainable and India's yield for many agricultural commodities are low. The main factors are poorly maintained irrigation systems and almost universal lack of good extension services. So, this project is also meant for control the irrigation activities. Through this design the required water supply is automatically monitored and used whenever needed. Some farmers areunaware of the technological developments in farming. Increase the yields which not only alleviated the level of hunger, but simultaneously released the human population from the nutritional obstacle to further growth. So continued growth demands even more agricultural improvements. So, we must find whatever ways to improve the agriculture and make our country a better place to live. India is an agricultural country. Nearly seventy percent of our population depends on agriculture. Agriculture yields one-third of our National income. Our economy is based on agriculture. The development of agriculture has a great impact on the economic welfare of our country. Our agriculture was in underdeveloped condition for a long time. We didn't produce enough food for our people. Our country had to buy vegetables and grains from foreign countries, but the things are changing now. India is producing more foodgrains than its needs. Some food-grains are being sent to other countries. Great improvements have been made in. agriculture through our five-year plans. Green Revolution has been brought in the agricultural sector. Now our country is self-sufficient in food-grains. It is now able to export surplus food-grains and some other agricultural products to other countries. Our country ranks first in the world in the production of tea and groundnuts. It ranks second in the world in the production of rice, sugarcane, jute and oil seed.

CHAPTER-2

LITERATURE SURVEY AND EXISTING METHODS

2.1 Literature survey:

The seeding and fertilizing agriculture robot using microcontroller . The point of composed framework for seeding, treating, moisture level calculation, temperature checking and humidity level detection.The robot system is monitored by remotely. Composed framework includes the route of robot to the goal effectively and does the predetermined functions. The robotic system and the remote framework are associated via networking framework. DC motors are utilized for route of the robotic system. DC motors speed can be managed by utilizing controller. The solenoid is utilized to control the seeding operation and treating.

Seed Sowing Using Robotics Technology. This framework presents a control system which drop the seed at specific location which determined separation in two seeds that is row and column while sowing. They utilizes mechanical autonomy innovation in the cultivating framework to decrease the effort of agriculturists and also to reduce time, energy and required cost for the seeding. The issues of the existing system in seeding operation can be removed completely in this proposed system.

“Multi-purpose agriculture machine”. This paper proposed the concept of usage of solar energy in the agricultural fields. Solar energy is the very power full energy, it plays very significant role in agriculture. This can be used in irrigation purpose for drawing water in the well remotely to the towns without power supply. Mechanism includes the utilization of a hybrid energy device between the power source and the work. project is to develop the cost-effective system. So, disable can able to grow in their respective field. Every Normal human being sees, listens and then reacts to the situations by speaking himself out. But there are some human beings those who are not able to speak or listen, but they try to react through actions most of time normal people are not able to understand what they want to say. This application will help for both of them to communicate with each other. It consists ofseveral parts, in part one This system deals with multi- operational irrigation machine for seeding, fungicides, splashing pesticides & fertilizers and plant cutting. Consequently, it is more efficient, economic and multi-operational equipment for agriculturist.

Mahesh R. Pundkar contemplated the execution of seeding, ploughing and plant cutting machine using algorithm of image processing by flash magic. They also declared the impact in depth of seed, spacing between the seed, ratio of miss seeding and proportion and execution seeding gadget on germination of seed and productivity of yield trim.

2.2 Existing systems:

Agriculture is main stay of many nations across the globe. There are multiple interventions by many scholars to utilize technology and mechanical intervention into agriculture. In the early 1920’s itself there were attempts to implement robotics to help improve agriculture. These were primitive models that required use of cable connection to operate the machine. Revolutionary attempts in the field of applying robots to agriculture continued to develop especially after 1980s as technological advancement in the field of computer science and engineering made machine vision (MV) guidance possible.Machine vision is nothing but integration of many technologies, software, hardware products, systems engineering, applied mechanical engineering actions,methods and expertise. It is integration of these technological advancements to resolve real world issues and problems on hand. Our design and structure of Agricultural Robot is one such attempt to help the farmers reap the benefits of technological advancement and to get benefits.

An “agricultural robot” is a robot deployed for agricultural purposes. It utilizes MV applications to identify required tasks assigned and shall do as per given schema to achieve results. Robots are mainly applied in the field of agriculture in weed control, seeding, and harvesting. Soil analysis and environmental monitoring are other areas where Robotics and AI are helping the farmers.

In the coming years there is an expectation of exponentially increased market for robotics in agricultureMany of the versions that are available in market or are being developed elsewhere globally have one limitation that they all are making robots to work in predefined way of work. So, specific tasks that are often repeatable and can be programmed were only being addressed. Most of these machines require electricity or battery or solar power to operate. Our robot is designed solely to minimize the labor of farmers in addition to increasing the speed and accuracy of the work. It performs the elementary functions involved in farming i.e. ploughing the field, sowing of seeds and covering the seeds with soil, spray fertilizer, sprinkle water etc.

(1) NURSERY

The Agri robot is used in nursery for row to row spacing can be adjusted, Required seed spacing can be achieved as well as variety of seed can be sowing by this robot.

(2) FARM

In farm Agri robot is used for planted seeds in all the rows of the farming plot are watered and fertilizer is sprayed on all the plants. Some crops need fertilizers when the seed germinates and the plant begins to grow

(3) AUTOMATIC GRASS CUTTER

Using the electrical energy without the help of manpower it removes all the unwanted grass in the fields.

(4) AUTOMATIC SEEDLING

To reduce the manpower robots are designed for the purpose of sowing seeds.

(5)SPRINKLING FERTILIZER

Using the robot it sprinkles the fertilizers in the fields it consumes less time saves manpower.

(6) SOLAR POWER OPERATED

Using solar energy it can perform task i.e., sowing seed Solar power operated.

(7) MULTI PURPOSE ROBOT

Using solar energy it can perform wide variety of tasks such as grass cutting ,soil testing, sowing.

(8) AUTOMATED WITH MOBILE PHONE

In this we operated the given tasks using mobile phone technology.

CHAPTER-3

BLOCK DIAGRAM

3.1 Block diagram

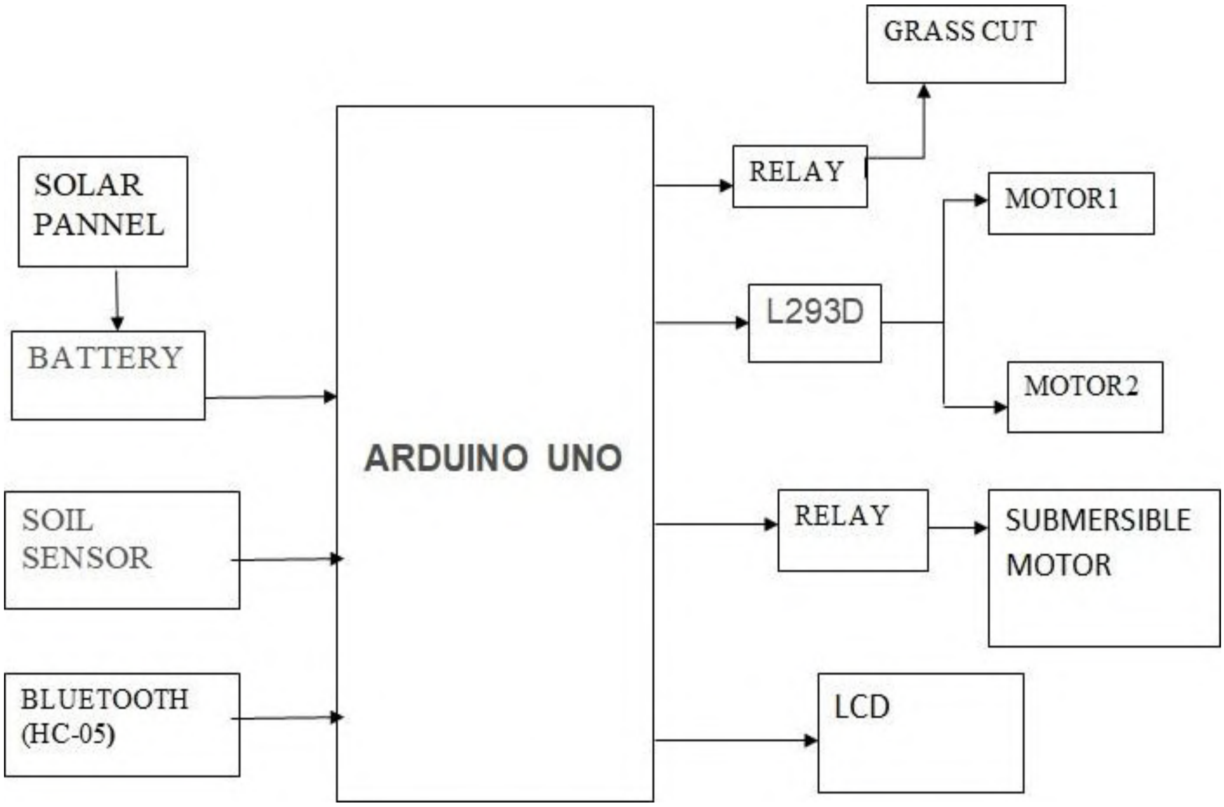

Fig : 3.1 Block diagram

The diagram 3.1 shows the block diagram of solar powered automated multitasking agriculture robot using IOT

The blocks of the circuit are

1. Battery
2. LCD 3.

L293D

4. Motors

5. Soil sensor
6. Arduino UNO
7. 2-Relay
8. Submersible Motor
9. Bluetooth (HC-05)

- Firstly the soil moisture senses whether the soil is in dry or wet condition and the information will be provided to the Arduino.
- The Arduino receives the information from the soil sensor.
- The Arduino output is given to the relay to on/off the submersible motor.
- The command will be displayed in the LCD.

3.2 COMPONENT DESCRIPTION:

3.2.1 ARDUINO UNO:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

3.2.2 Soil Sensor:

Soil moisture sensors measure the volumetric water content in soil. Since the direct gravimetric measurement of free soil moisture requires removing, drying, and weighing of a sample, soil moisture sensors measure the volumetric water content indirectly by using some other property of the soil, such as electrical resistance, dielectric constant, or interaction with neutrons, as a proxy for the moisture content.

3.2.3 LCD:

A liquid crystal display (LCD) is a thin, flat display device made up of any number of colour or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists to allow it to pass through other.

3.2.4 RELAY:

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.

3.2.5 BLUETOOTH:

Bluetooth is a short-range wireless technology standard used for exchanging data between fixed and mobile devices over short distances using UHF radio waves in the ISM bands, from 2.402 GHz to 2.48 GHz, and building personal area networks (PANs). It was originally conceived as a wireless alternative to RS-232 data cables. It is mainly used as an alternative to wire connections, to exchange files between nearby portable devices and connect cell phones and music players with wireless headphones. In the most widely used mode, transmission power is limited to 2.5 milli watts, giving it a very short range of up to 10 meters (30 feet).

3.2.6 L293D:

The L293D is quadruple high-current half-H drivers. It is designed to provide bidirectional drive currents of up to 600-mA at voltages from 4.5 V to 36 V. Both devices are designed to drive inductive loads such as relays, solenoids, dc and bipolar stepping motors, as well as other high-current/high-voltage loads in positive-supply applications. All inputs are TTL compatible. Each output is a complete totem-pole drive circuit, with a Darlington transistor sink and a pseudo- Darlington source. Drivers are enabled in pairs, with drivers 1 and 2 enabled by 1,2EN and drivers 3 and 4 enabled by 3,4EN. When an enable input is high, the associated drivers are enabled, and their outputs are active and in phase with their inputs. When the enable input is low, those drivers are disabled, and their outputs are off and in the high-impedance state. With the proper data inputs, each pair of drivers forms a full-H (or bridge) reversible drive suitable for solenoid or motor applications.

3.2.7 BATTERY:

A rechargeable battery, storage battery, or secondary cell, (or archaically accumulator) is a type of electrical battery which can be charged, discharged into a load, and recharged many times, as opposed to a disposable or primary battery, which is supplied fully charged and discarded after use. It is composed of one or more electrochemical cells. The term "accumulator" is used as it accumulates and stores energy through a reversible electrochemical reaction. Rechargeable batteries are produced in many different shapes and sizes, ranging from button cells to megawatt systems connected to stabilize an electrical distribution network. Several different combinations of electrode materials and electrolytes are used, including lead–acid, zinc–air, nickel– cadmium (NiCd), nickel–metalhydride (NiMH), lithium-ion (Li-ion), lithium connected iron phosphate (LiFePO4), and lithium-ion polymer (Li-ion polymer).

3.2.8 SUBMERSIBLE MOTOR PUMP:

A submersible pump (or sub pump, electric submersible pump (ESP)) is a device which has a hermetically sealed motor close-coupled to the pump body. The whole assemblyis submerged in the fluid to be pumped. The main advantage of this type of pump is that it prevents pump cavitation, a problem associated with a high elevation difference between the pump and the fluid surface. Submersible pumps push fluid to the surface, ratherthan jet pumps, which create a vacuum and rely upon atmospheric pressure. Submersibles use pressurized fluid from the surface to drive a hydraulic motor downwhole, rather than an electric motor, and are used in heavy oil applications with heated water as the motive fluid.

CHAPTER 4

SOFTWARE AND HARDWARE COMPONENTS

4.1 Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.1.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

4.1.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through whole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.2 Starting New Design

Step 1: Open ISIS software and select new design in File menu

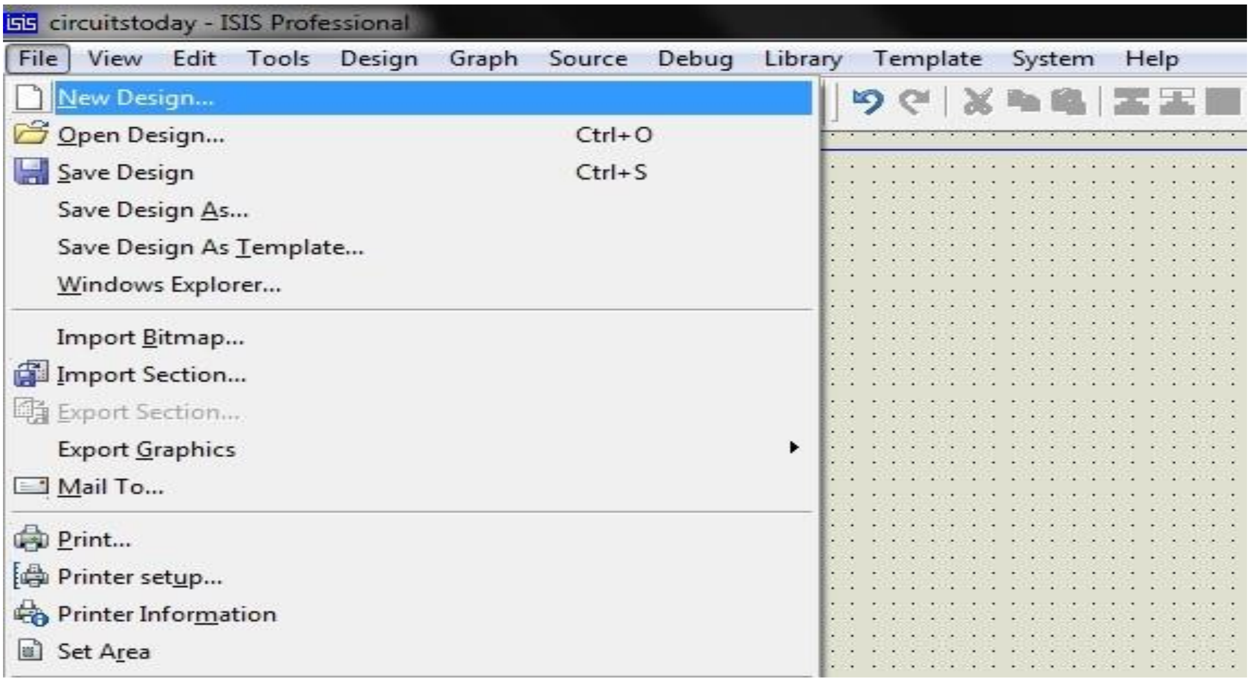

Figure 4.2.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

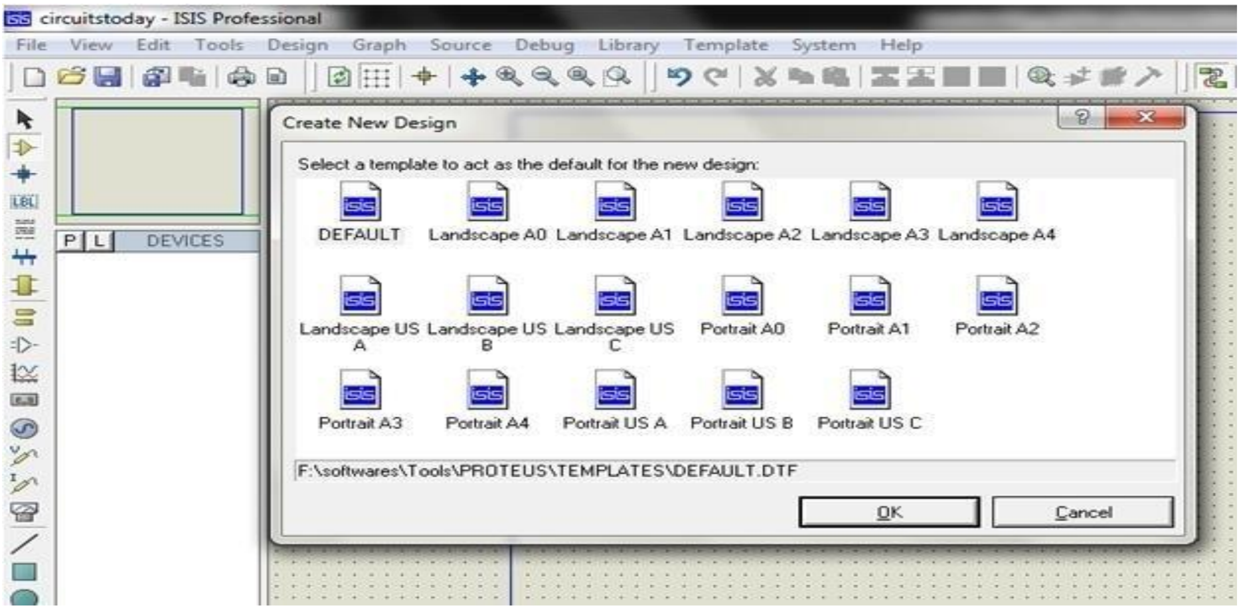

Figure 4.2.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

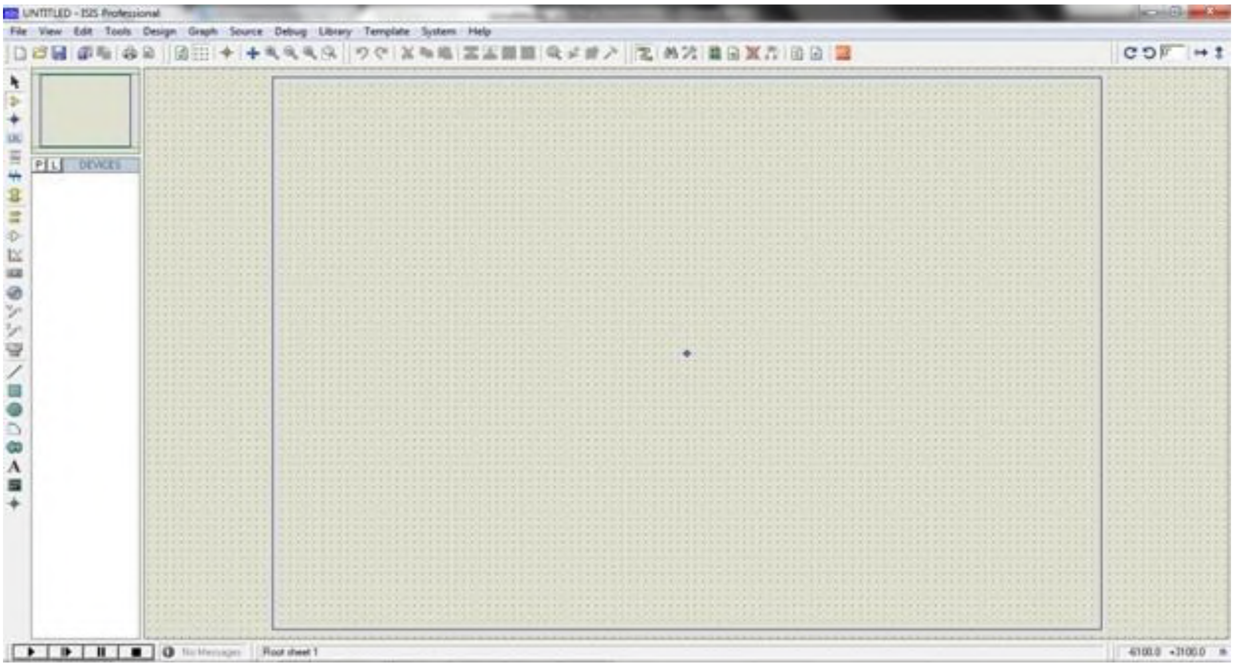

Figure 4.2.3 Proteus Design Sheet

Step 4: To select components, Click on the component mode button.

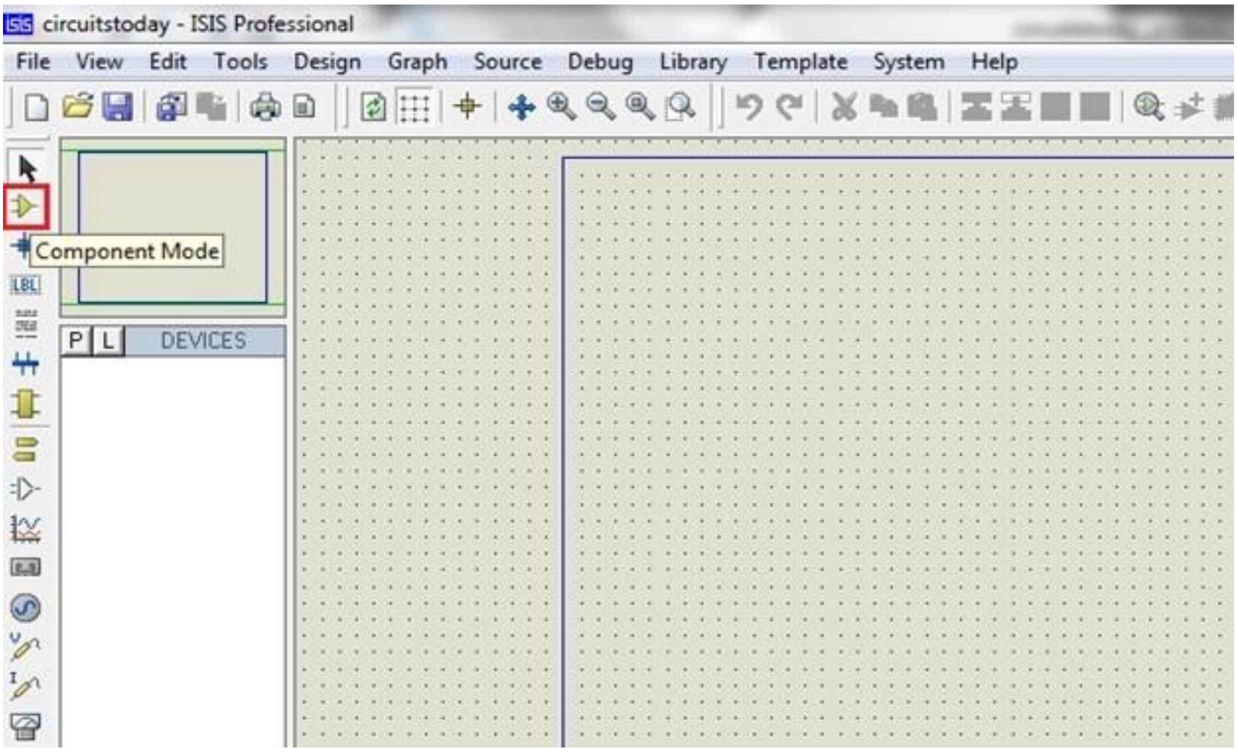

Figure 4.2.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

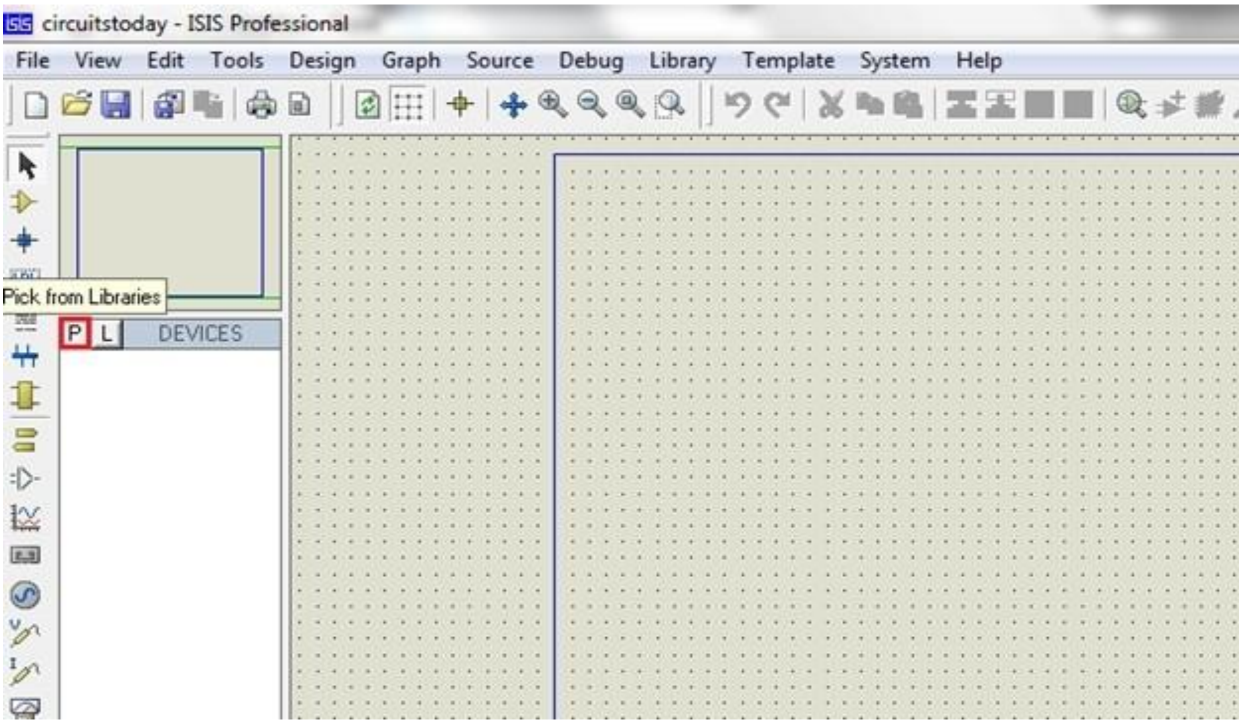

Figure 4.2.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

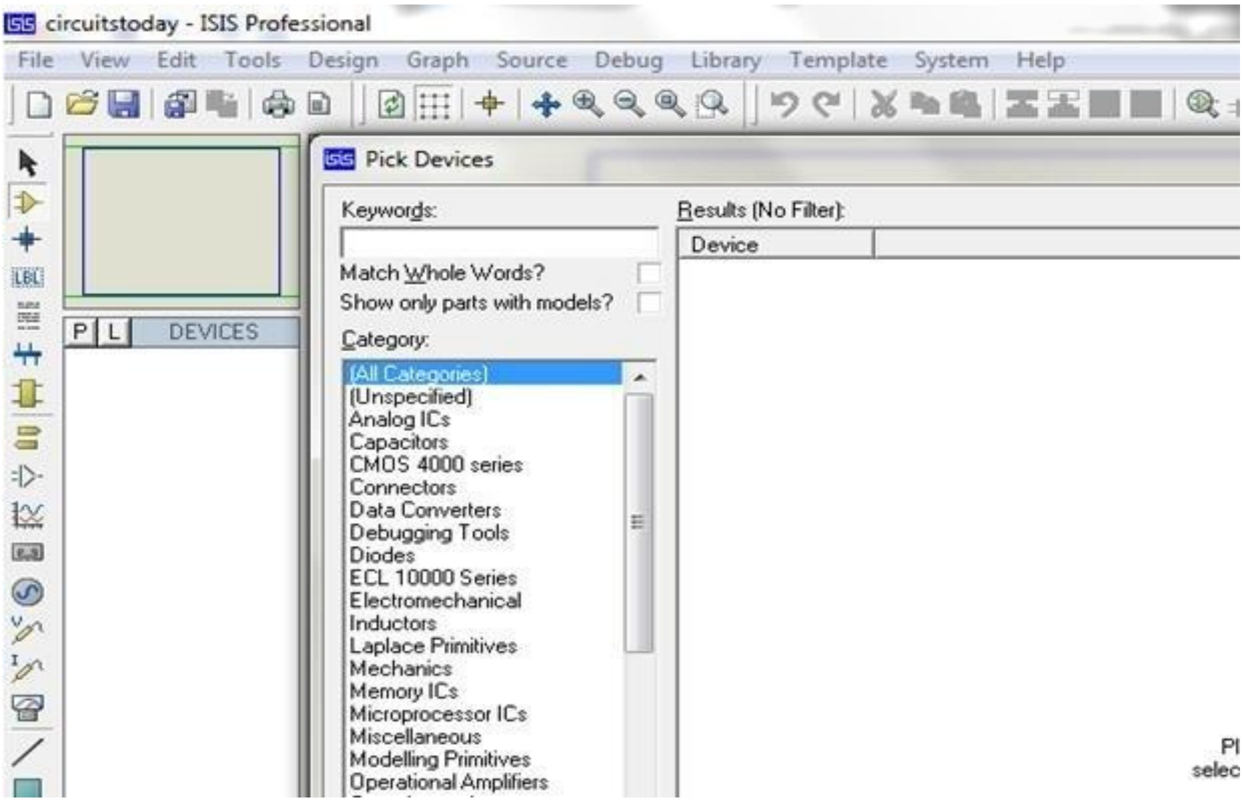

Figure 4.2.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

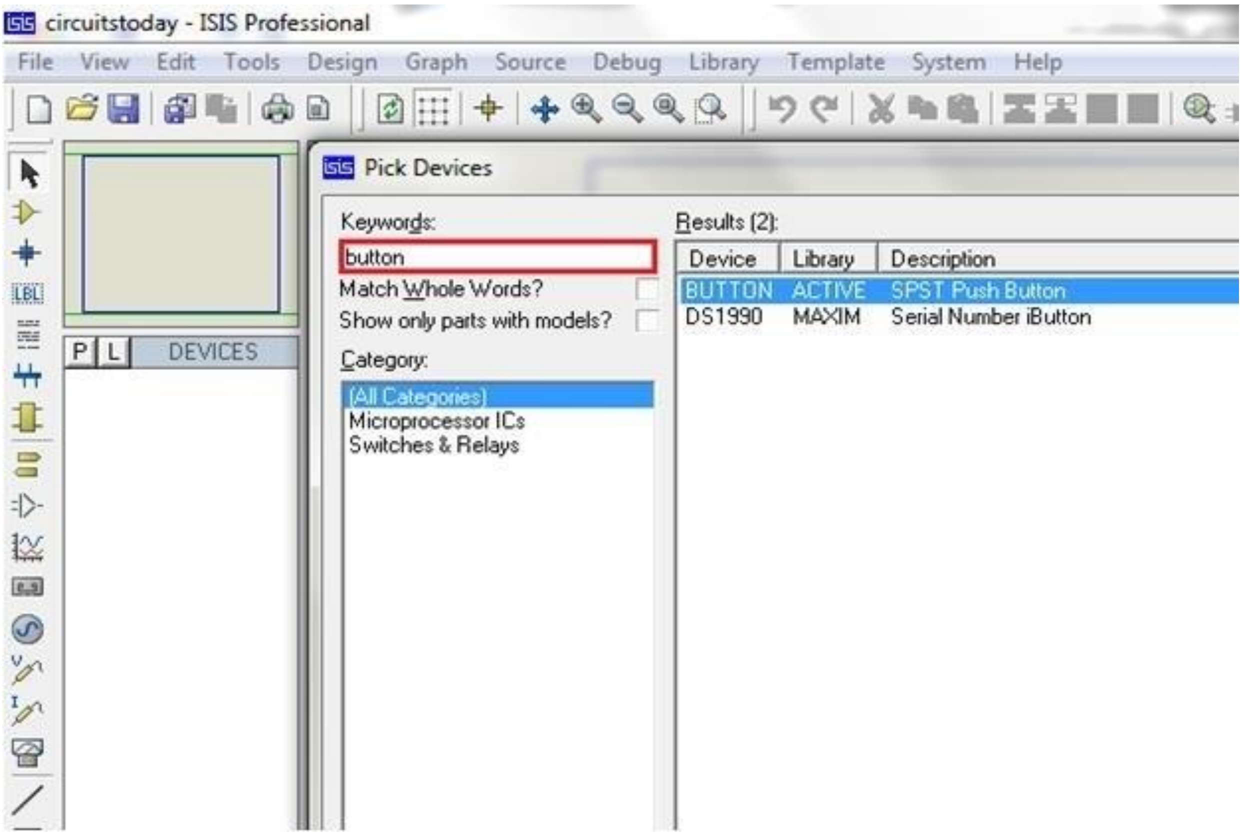

Figure 4.2.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

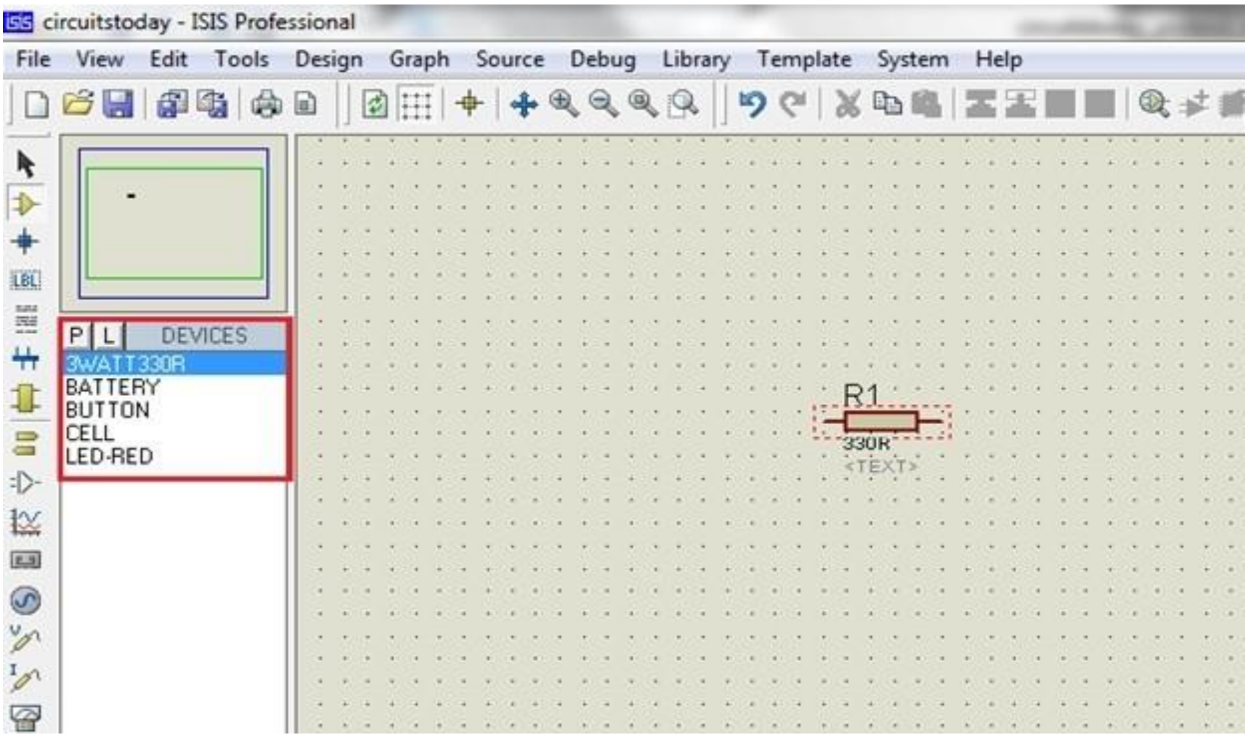

Figure 4.2.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

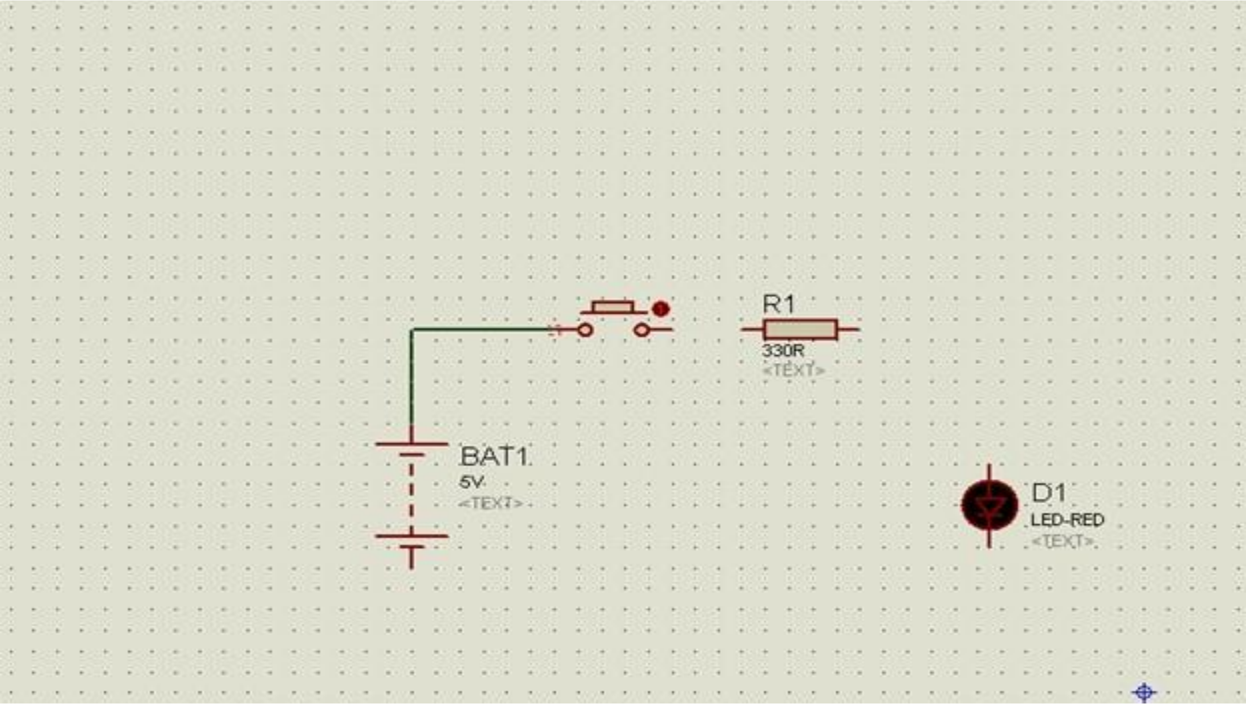

Figure 4.2.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

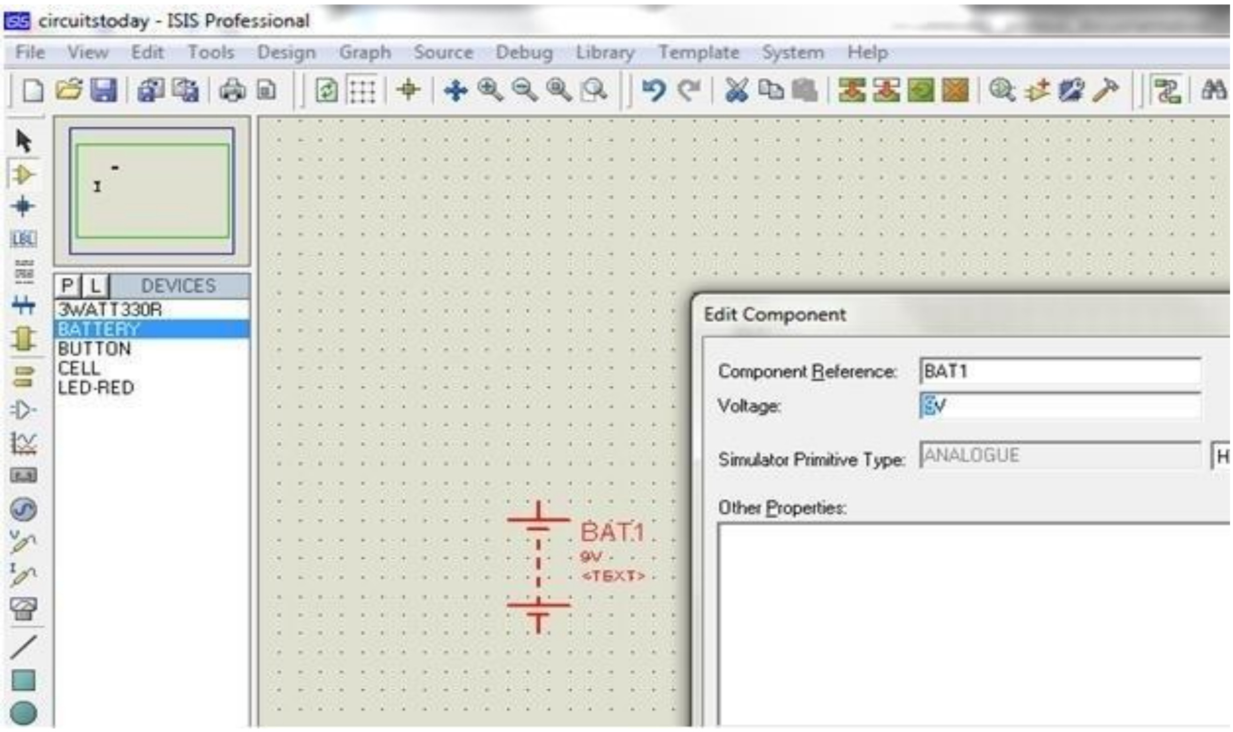

Figure 4.2.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

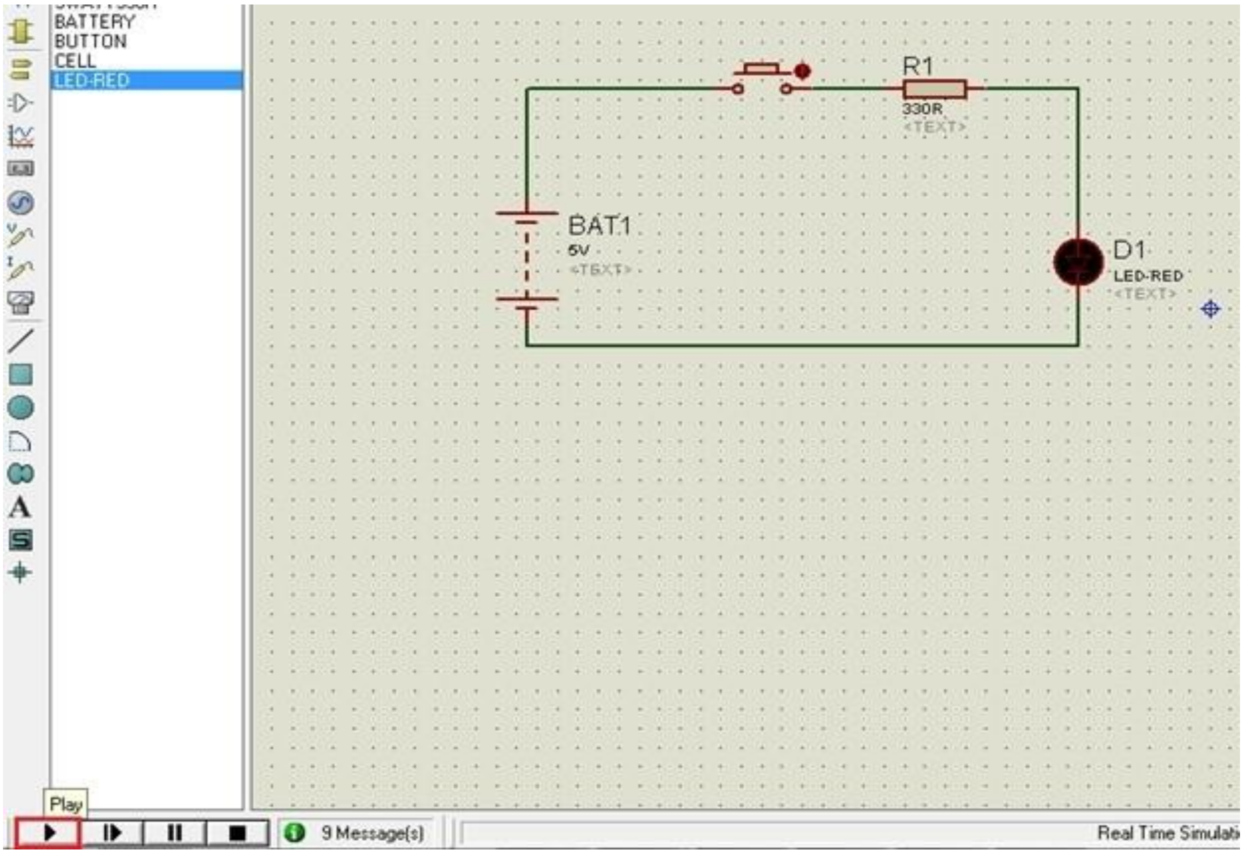

Figure 4.2.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

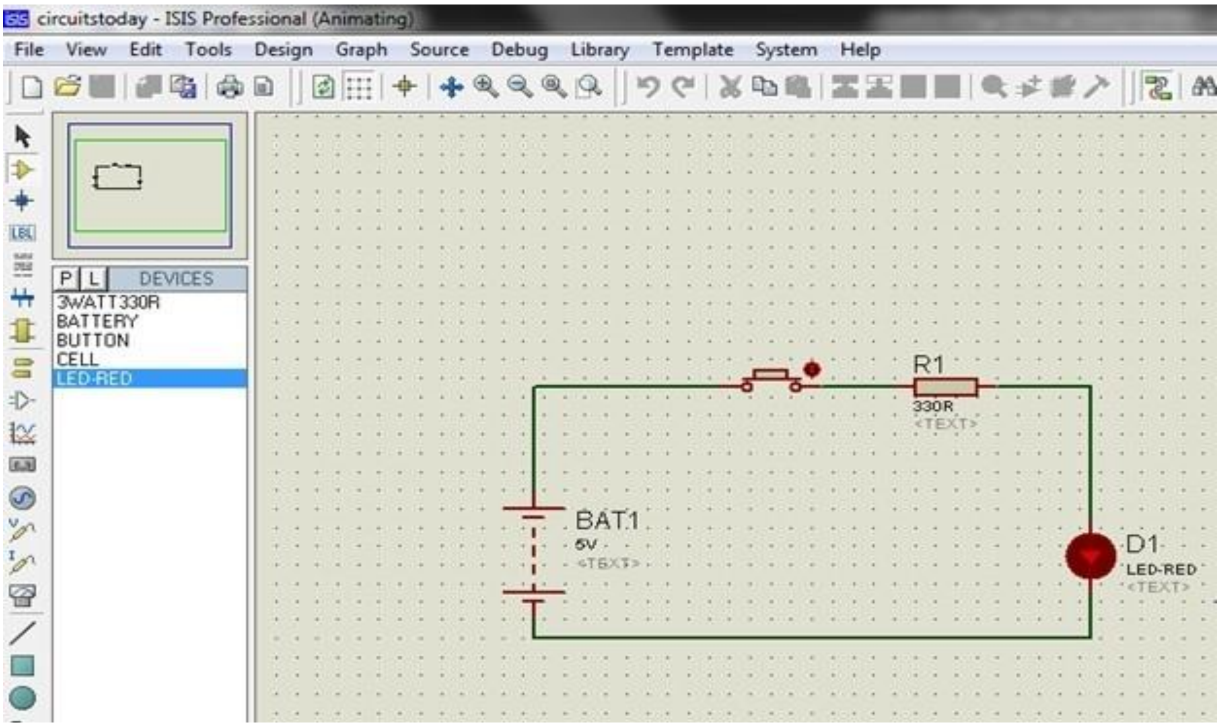

Figure 4.2.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

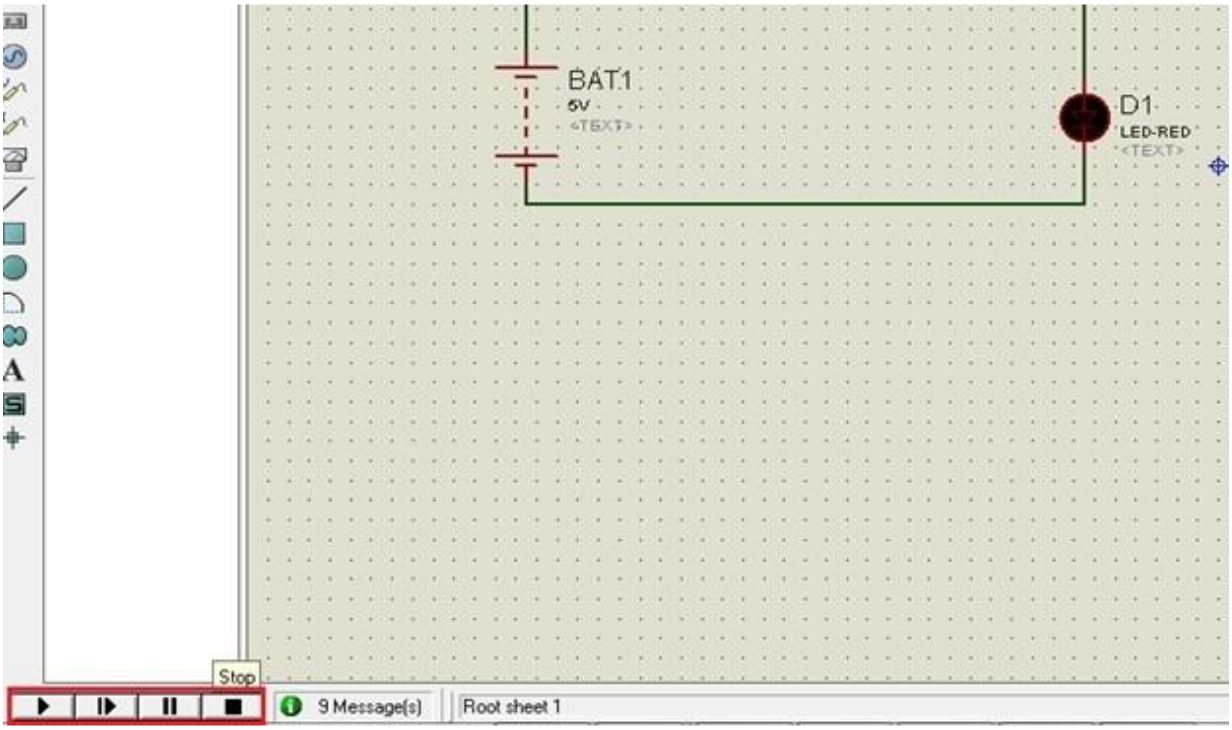

Figure 4.2.13 Simulation Step-Pause-Stop Buttons

4.3 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross- platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU tool chain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]
Repository	github.com/arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux
Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging [9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

4.3.1 Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Figure 4.3.1 USB Cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

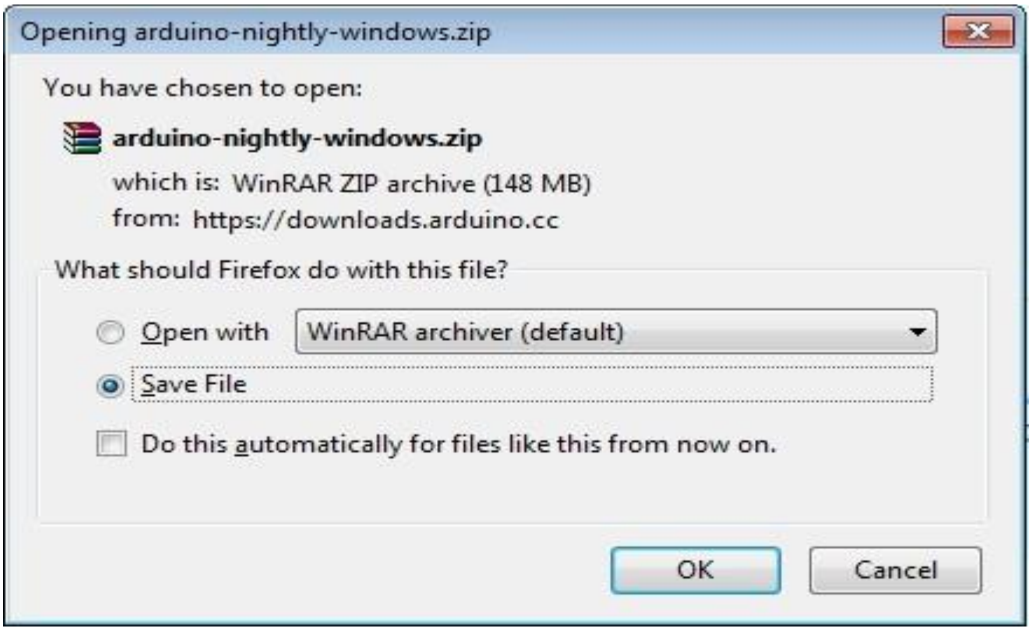

Figure 4.3.2 Downloading Arduino IDE

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece ofplastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labelled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

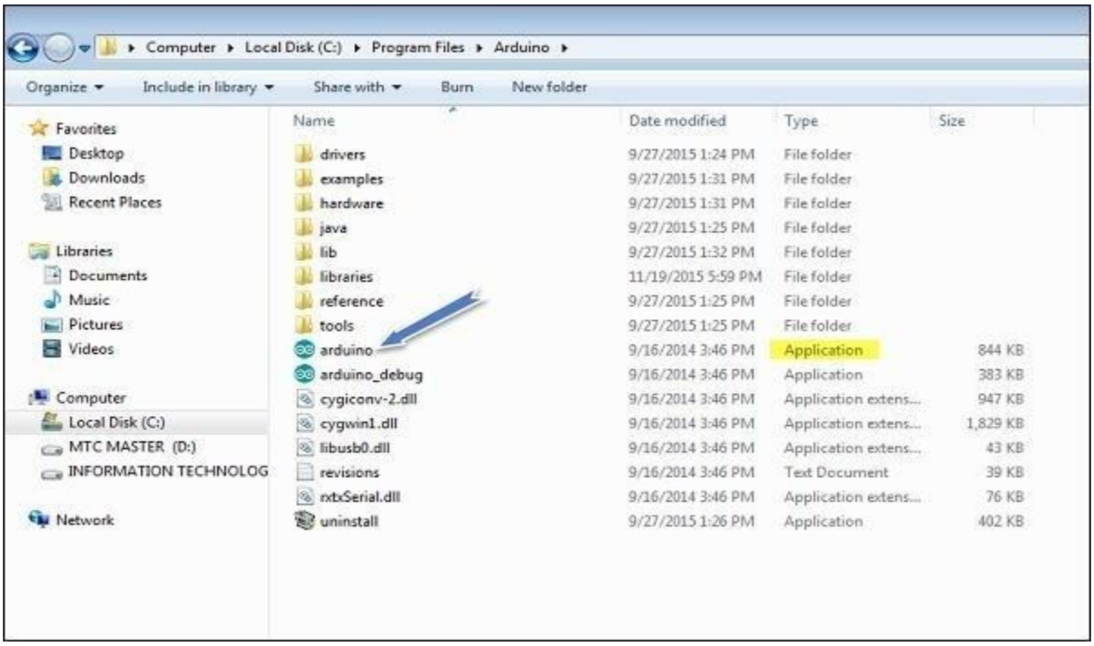

Figure 4.3.3Launching Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

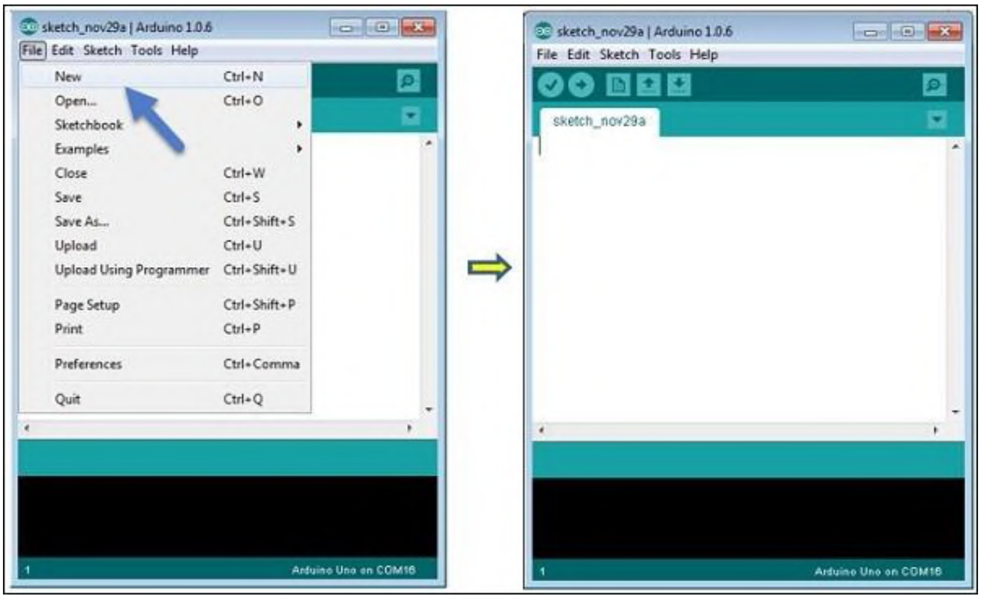

Figure 4.3.4Opening first project

To open an existing project example, select File → Example → Basics → Blink.

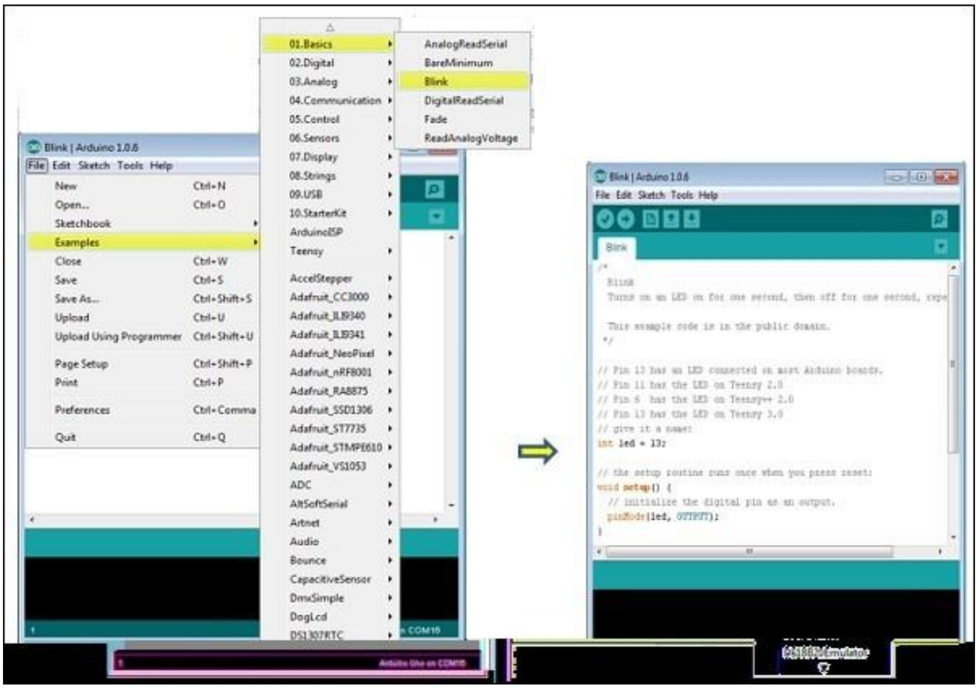

Figure 4.3.4.1Opening first project

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

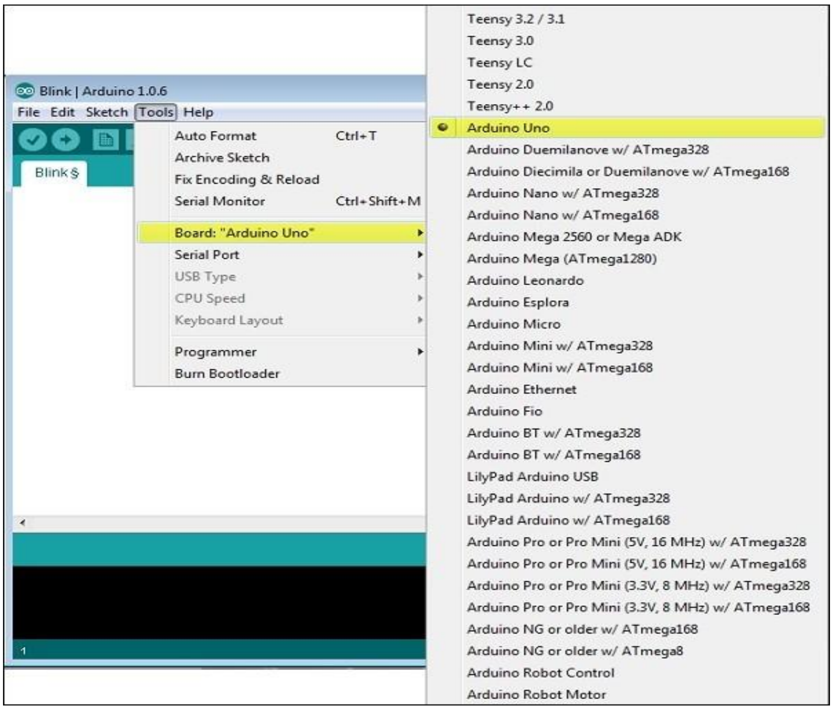

Figure 4.3.5 Selecting Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

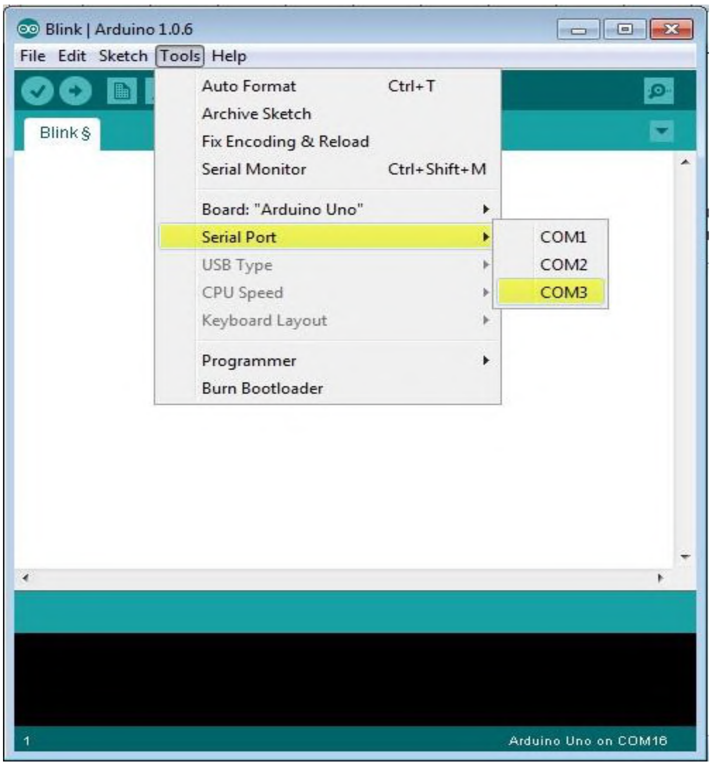

Figure 4.3.6 Selecting serial port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

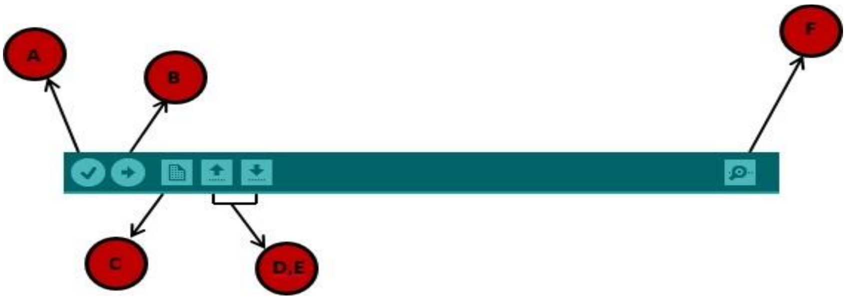

Figure: 4.3.7 Uploading the program to board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

4.4 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board. The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

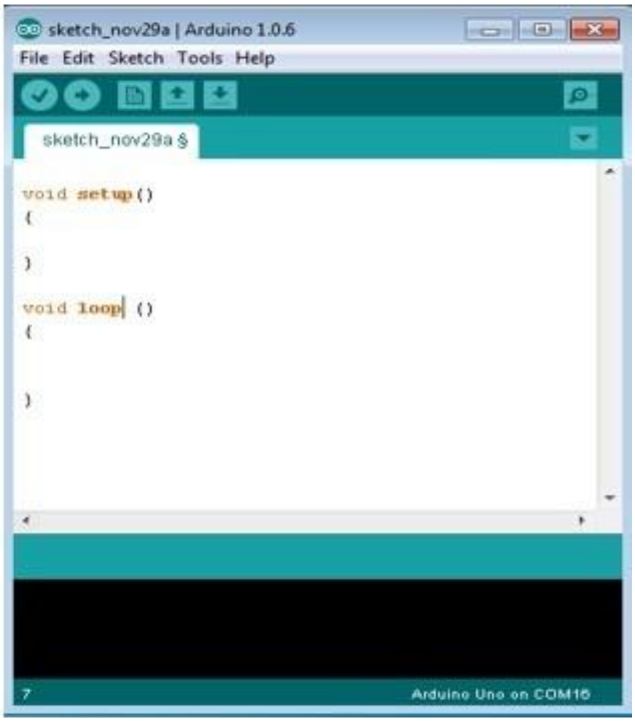

Figure 4.4 Arduino Platform

4.4.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 4.4.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI

Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header

4.5 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

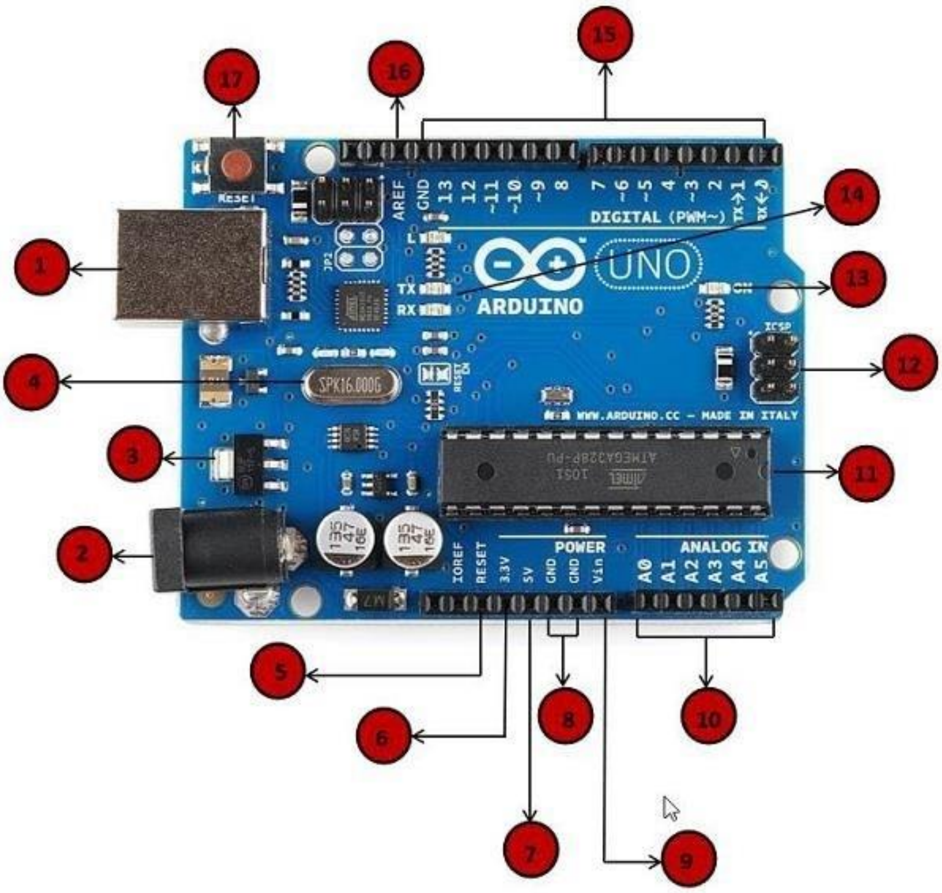

Fig: 4.5 Arduino pins

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz’s

5,17	**Arduino Reset** You can reset your Arduino board, i.e., starts your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.

14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data.The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labelled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Fig: 4.5.1 Pin description

4.6 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

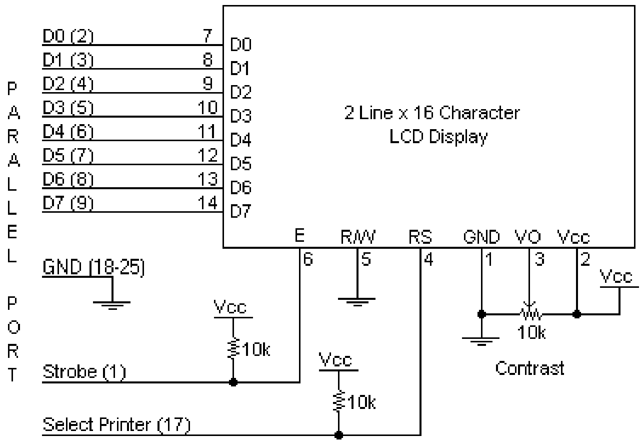
Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5

D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

4.6.1 Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram



s

Figure 4.6.1Description Of 16x2

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there is a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a on board +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

4.6.2 16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM prov
- iding simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

4.6.3 16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

4.6.4 FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

4.6.4.1 Figure Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exist. “Super twist” types, for example, offer improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

4.6.5 PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

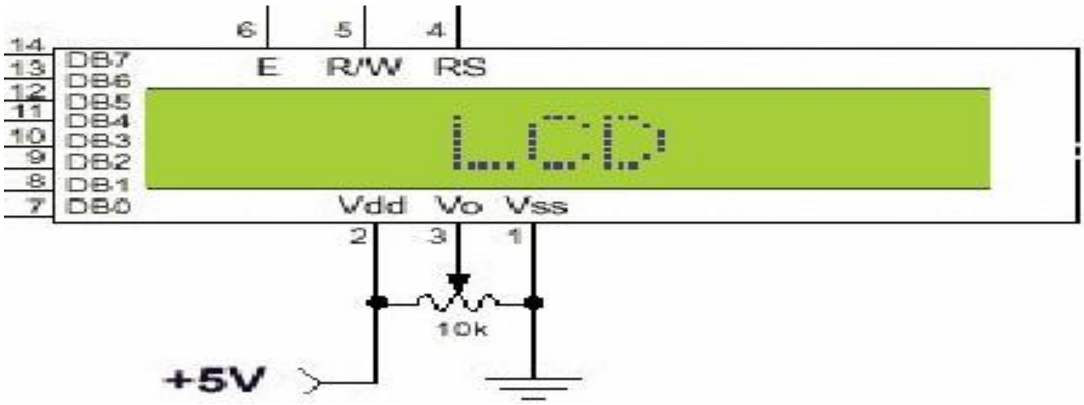


Figure 4.6.5 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 4.6.6 Pin specifications

4.7 CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

4.7.1 LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

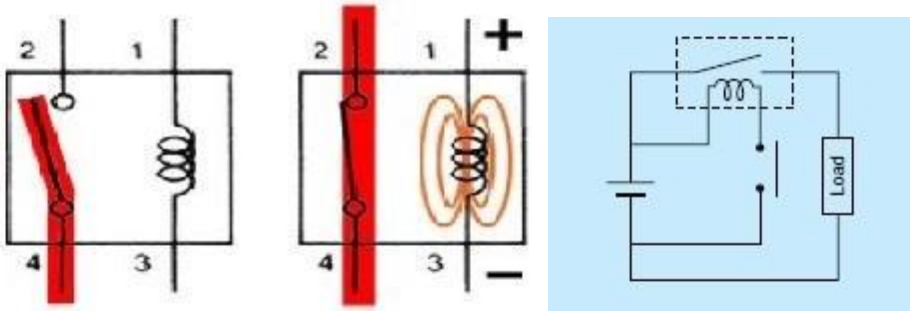
Table 4.7.1 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home

04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

4.8 Relays

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.



4.8.1 Basics on Relay Handling

- To maintain initial performance, care should be taken to avoid dropping or hitting the relay.

- Under normal use, the relay is designed so that the case will not detach. To maintain initial performance, the case should not be removed. Relay characteristics cannot be guaranteed if the case is removed.
- Use of the relay in an atmosphere at standard temperature and humidity with minimal amounts of dust, SO 2, H 2 S, or organic gases is recommended.
- Please avoid the use of silicon-based resins near the relay, because doing so may result in contact failure. (This applies to plastic sealed type relays, too.)
- Care should be taken to observe correct coil polarity (+, –) for polarized relays.
- Proper usage requires that the rated voltage be impressed on the coil. Use rectangular waves for DC coils and sine waves for AC coils.
- Be sure the coil impressed voltage does not continuously exceed the maximum allowable voltage.
- Absolutely avoid using switching voltages and currents that exceed the designated values.
- The rated switching power and life are given only as guides. The physical phenomena at the contacts and contact life greatly vary depending on the type of load and the operating conditions. Therefore, be sure to carefully check the
- Type of load and operating conditions before use.
- Do not exceed the usable ambient temperature values listed in the catalog.
- Use the flux-resistant type or sealed type if automatic soldering is to be used.
- Use alcohol based cleaning solvents when cleaning is to be performed using a
  sealed type relay.
- Avoid ultrasonic cleaning of all types of relays.
- Avoid bending terminals, because it may cause malfunction.
- As a guide, use a Fasten mounting pressure of 40 to 70N {4 to 7kgf} for relays
  with tab terminals.

4.8.2 Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current

- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

4.8.3 Applications:

Relays are used:

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems,
- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the Boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consistsof a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.

- To perform time delay functions. Relays can be used to act as a mechanical time delay device by controlling the release time by using the effect of residual magnetism by means of a inserting copper disk between the armature and moving blade assembly.

Figure 4.8.3 Relay

4.9 PIN DESCRIPTION OF ATMEGA328

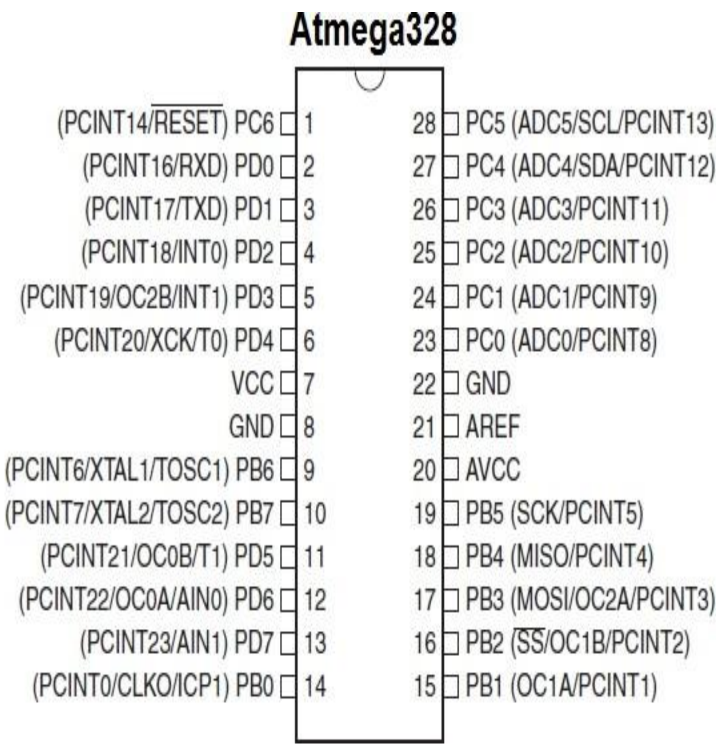


Fig.4.9: Pin description of ATMEGA328

ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

4.10 SOLAR PANNEL

The term solar panel is used colloquially for a photo-voltaic (PV) module.

A PV module is an assembly of photo-voltaic cells mounted in a frame work for installation. Photo-voltaic cells use sunlight as a source of energy and generate direct current electricity. A collection of PV modules is called a PV Panel, and a system of Panels is an Array. Arrays of a photovoltaic system supply solar electricity to electrical equipment.

The most common application of solar energy collection outside agriculture is solar water heating systems.

Fig 4.10 : Solar pannel

Photovoltaic modules use light energy (photons) from the Sun to generate electricity through the photovoltaic effect. Most modules use wafer-based crystalline silicon cells or thin-film cells. The structural (load carrying) member of a module can be either the top layer or the back layer. Cells must be protected from mechanical damage and moisture. Most modules are rigid, but semi-flexible ones based on thin-film cells are alsoavailable. The cells are connected electrically in series, one to another to a desired voltage, and then in parallel to increase amperage. The wattage of the module is the mathematical product of the voltage and the amperage of the module.

A PV junction box is attached to the back of the solar panel and functions as its output interface. External connections for most photovoltaic modules use MC4 connectors to facilitate easy weatherproof connections to the rest of the system. A USB power interface can also be used.

Module electrical connections are made in series to achieve a desired output voltage or in parallel to provide a desired current capability (amperes) of the solar panel or the PV system. The conducting wires that take the current off the modules are sized according to the ampacity and may contain silver, copper or other non-magnetic conductive transition metals. Bypass diodes may be incorporated or used externally, in case of partial module shading, to maximize the output of module sections still illuminated.

Some special solar PV modules include concentrators in which light is focused by lenses or mirrors onto smaller cells. This enables the use of cells with a high cost per unit area (such as gallium arsenide) in a cost-effective way.

Solar panels also use metal frames consisting of racking components, brackets, reflector shapes, and troughs to better support the panel structure.

4.11 BATTERY:

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and some kind of electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place. When the material in the cathode or anode is consumed or no longer able to be used in the reaction, the battery is unable to produce electricity. At that point, your battery is "dead."

Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Fig 4.11(A) : Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

Fig4.11(B) : Batteries come in a variety of shapes, sizes, and chemistries.

4.12 History of battery

The Term Battery

Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Fig 4.12(A) : Battery of Leyden Jar

Battery of Leyden Jar "capacitors" linked together (Image courtesy of Alvinrune of Wikimedia Commons)

4.12.1 Invention of the Battery

One fateful day in 1780, Italian physicist, physician, biologist, and philosopher, Luigi Galvani, was dissecting a frog attached to a brass hook. As he touched the frog's leg with an iron scapel, the leg twitched. Galvani theorized that the energy came from the leg itself, but his fellow scientist, Alessandro Volta, believed otherwise.

Volta hypothesized that the frog's leg impulses were actually caused by different metals soaked in a liquid. He repeated the experiment using cloth soaked in brine instead of a frog corpse, which resulted in a similar voltage. Volta published his findings in 1791 and later created the first battery, the voltaic pile, in 1800.

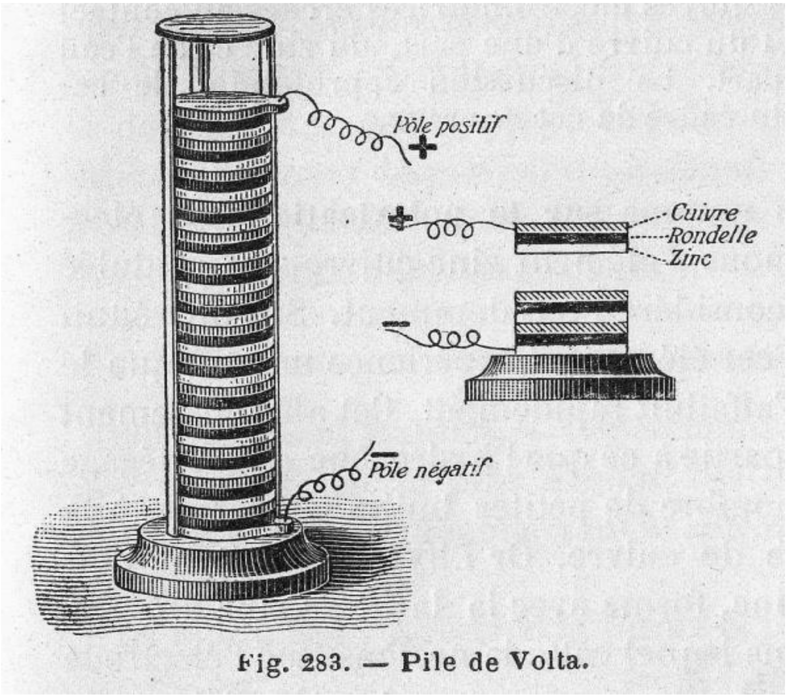

Fig 4.12.1.1: pile de volta

The voltaic pile consisted of a stack of zinc and copper plates separated by cloth soaked in brine. Volta's pile was plagued by two major issues: the weight of the stack caused the electrolyte to leak out of the cloth, and the particular chemical properties of the components resulted in a very short life span (about an hour). The next two hundred years would be spent perfecting Volta's design and solving these issues.

4.12.2 Fixes to the Voltaic Pile

William Cruickshank of Scotland solved the leakage problem by laying the voltaic pile on its side to form the "trough battery."

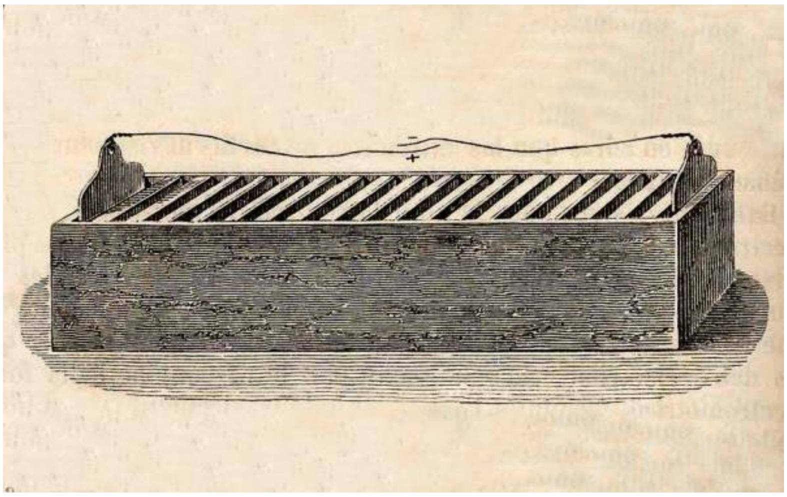

Fig4.12.2.1 : The trough battery solved the leakage problem of the voltaic pile

The second problem, short life span, was caused by the degradation of the zinc due to impurities and a build-up of hydrogen bubbles on the copper. In 1835, William Sturgeon discovered that treating the zinc with mercury would prevent degradation.

The British chemist John Frederic Daniell used a second electrolyte that reacted with the hydrogen, preventing buildup on the copper cathode. Daniell's two-electrolyte battery, known as the "Daniell cell," would become a very popular solution to providing power to the budding telegraph networks.

Fig4.12.2.2 : A collection of Daniell cells from 1836

4.12.3 The First Rechargeable Battery

In 1859, the French physicist Gaston Planté created a battery using two rolled sheets of lead submerged in sulfuric acid. By reversing the electrical current through the battery, the chemistry would return to its original state, thus creating the first rechargeable battery.

Later, in 1881, Camille Alphonse Faure improved Planté's design by forming the lead sheets into plates. This new design made the batteries easier to manufacture, and the lead acid battery saw wide-spread use in automobiles.

Fig 4.12.3.1 : Rechargeable Battery

-> The design for the common "car battery" has been around for more than 100 years (Image courtesy of Emilian Robert Vicol of Wikimedia Commons) <-

4.12.4 The Dry Cell

Up until the late 1800s, the electrolyte in batteries was in a liquid state. This made battery transportation a very careful endeavor, and most batteries were never intended to be moved once attached to the circuit.

In 1866, Georges Leclanché created a battery using a zinc anode, a manganese dioxide cathode, and an ammonium chloride solution for the electrolyte. While the electrolyte in the Leclanché cell was still a liquid, the battery's chemistry proved to be an important step for the invention of the dry cell.

Carl Gassner figured out how to create an electrolyte paste out of ammonium chloride and Plaster of Paris. He patented the new "dry cell" battery in 1886 in Germany. These new dry cells, commonly called "zinc-carbon batteries," were massed produced and proved hugely popular until the late 1950s. While carbon is not used in the chemical reaction, it performs an important role as an electrical conductor in the zinc-carbon battery.

Fig 4.12.4.1: Dry cell

-> 3V zinc-carbon battery from the 1960s (Image courtesy of PhFabre of Wikimedia Commons)

<- In the 1950s, Lewis Urry, Paul Marsal, and Karl Kordesch of the Union Carbide company (later known as "Eveready" and then "Energizer") replaced the ammonium chloride electrolyte with an alkaline substance, based on the battery chemistry formulated by Waldemar Jungner in 1899. Alkaline dry cell batteries could hold more energy than zinc carbon batteries of the same size and had a longer shelf life.

Alkaline batteries rose in popularity in the 1960s, overtook zinc-carbon batteries, and have since become the standard primary cell for consumer use.

Fig 4.12.4.2 batteries

-> Alkaline batteries come in many shapes and sizes (Image courtesy of Aney~commonswiki of Wikimedia Commons) <-

4.12.5 20th Century Rechargeable Batteries

In the 1970s, COMSAT developed the nickel-hydrogen battery for use in communication satellites. These batteries store hydrogen in a pressurized, gaseous form. Many man-made satellites, like the International Space Station, still rely on nickel-hydrogen batteries.

The research of several companies since the late 1960s resulted in the creation of the nickel-metal hydride (NiMH) battery. NiMH batteries were released to the consumer market in 1989, and provided a smaller, cheaper alternative to the rechargeable nickel-hydrogen cells.

Asahi Chemical of Japan built the first lithium-ion battery in 1985, and Sony created the first commercial lithium-ion battery in 1991. In the late 1990s, a soft, flexible casing was created for lithium-ion batteries and gave rise to the "lithium polymer" or "LiPo" battery.

Fig 4.12.5.1 : lithium-ion battery

The chemical reactions in the lithium polymer battery are essentially the same as those in the lithium-ion battery. Obviously, many more battery chemistries have been invented, manufactured, and become obsolete. If you would like to read more about modern, popular battery technologies, check out our Battery Technologies tutorial.

4.12.6 Components

Batteries are made up of three basic components: an **anode**, a **cathode**, and an **electrolyte**. A **separator** is often used to prevent the anode and cathode from touching, if the electrolyte is not sufficient. In order to store these components, batteries usually have some kind of **casing**.

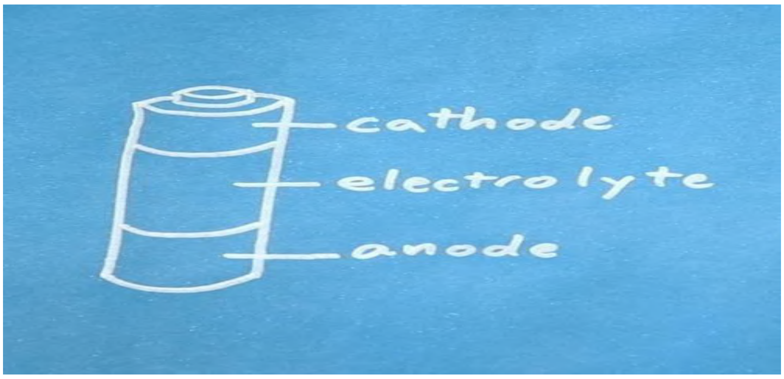

Fig 4.12.6.1 : Electrode

OK, most batteries are not actually divided up in three equal sections, but you get the idea. A better cross-section of an alkaline cell can be found on Wikipedia.

Both the anode and cathode are types of **electrodes**. Electrodes are conductors through which electricity enters or leaves a component in a circuit.

4.12.6(A) Anode

Electrons flow out from the anode in a device connected to a circuit. This means that conventional "current" flows into an anode.

Fig4.12.6(A).1: On batteries, the anode is marked as the negative (-) terminal

In a battery, the chemical reaction between the anode and electrolyte causes a build up of electrons in the anode. These electrons want to move to the cathode, but cannot pass through the electrolyte or separator.

4.12.6(B) Cathode

Electrons flow into the cathode in a device connected to a circuit. This means that conventional "current" flows out from a cathode.

Fig4.12.6(B).1: On batteries, the anode is marked as the negative (+) terminal

In batteries, the chemical reaction in or around the cathode uses the electrons produced in the anode. The only way for the electrons to get to the cathode is through a circuit, external to the battery.

4.12.6(C) Electrolyte

The electrolyte is the substance, often a liquid or gel, that is capable of transporting ions between the chemical reactions that happen at the anode and cathode. The electrolyte also inhibits the flow of electrons between the anode and cathode so that the electrons more easily flow through the external circuit rather than through the electrolyte.

Fig4.12.6(C).1: Alkaline batteries

-> Alkaline batteries can leak their electrolyte, potassium hydroxide, if subjected to high heat or reverse voltage (Image courtesy of Wiliam Davies of Wikimedia Commons)

<- The electrolyte is crucial in the operation of a battery. Because electrons cannot pass through it, they are forced to travel through electrical conductors in the form of a circuit that connect the anode to the cathode.

4.12.6(D) Separator

Separators are porous materials that prevent the anode and cathode from touching, which would cause a short circuit in the battery. Separators can be made from a variety of materials, including cotton, nylon, polyester, cardboard, and synthetic polymer films. Separators do not chemically react with either the anode, cathode, or electrolyte.

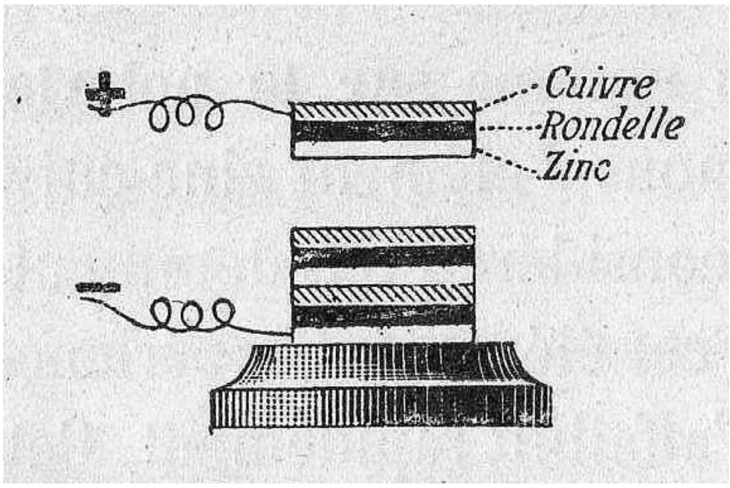

Fig 4.12.6(D).1: separator

The voltaic pile used cloth or cardboard (separator) soaked in brine (electrolyte) to keep the electrodes apart. Ions in the electrolyte can be positively charged, negatively charged, and can come in a variety of sizes. Special separators can be manufactured that allow some ions to pass but not others.

4.12.7 Casing

Most batteries need a way to contain their chemical components. Casings, otherwise known as "housings" or "shells," are simply mechanical structures meant to hold the battery's internals.

Fig4.12.7.1 :This lead-acid battery has a plastic casing

Battery casings can be made of almost anything: plastic, steel, soft polymer laminate pouches, and so on. Some batteries use a conducting steel casing that is electrically connected to one of the electrodes. In the case of the common AA alkaline cell, the steel casing is connected to the cathode.

4.12.8 Operation

Batteries generally require several chemical reactions in order to operate. At least one reaction occurs in or around the anode and one or more reactions occur in or around the cathode. In all cases, the reaction at the anode produces extra electrons in a process called **oxidation**, and the reaction at the cathode uses the extra electrons during a process known as **reduction**.

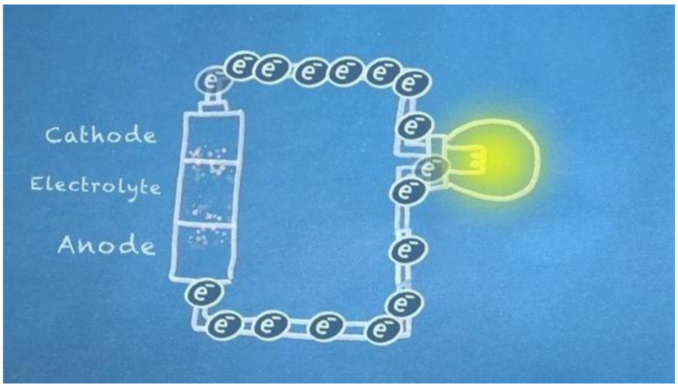

Fig 4.12.8.1: Electron flows

When the switch is closed, the circuit is complete, and electrons can flow from the anode to the cathode. These electrons enable the chemical reations at the anode and cathode.

In essence, we are separating a certain kind of chemical reaction, a reduction-oxidation reaction or redox reaction, into two separate parts. Redox reactions occur when electrons are transferred between chemicals. We can harness the movement of electrons in this reaction to flow outside the battery to power our circuit.

4.13 L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to builtin H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

4.13.1 Introduction to L293D

L293D is basically a motor driver or controller. It has two builtin H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc. Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

Fig 4.13.1(A) : L293D Motor Driver

1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

Fig 4.13.1(B) : L293D Pins

3. L293D Pinout

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.
- L293D pinout diagram is shown in the figure given below.

Fig 4.13.1(C) L293D Pins OUT

4.14 Soil Sensor

Soil moisture sensors measure the volumetric water content in soil. Since the direct gravimetric measurement of free soil moisture requires removing, drying, and weighing of a sample, soil moisture sensors measure the volumetric water content indirectly by using some other property of the soil, such as electrical resistance, dielectric constant, or interaction with neutrons, as a proxy for the moisture content.

The relation between the measured property and soil moisture must be calibrated and may vary depending on environmental factors such as soil type, temperature, or electric conductivity. Reflected microwave radiation is affected by the soil moisture and is used for remote sensing in hydrology and agriculture. Portable probe instruments can be used by farmers or gardeners.

Soil moisture sensors typically refer to sensors that estimate volumetric water content. Another class of sensors measure another property of moisture in soils called water potential; these sensors are usually referred to as soil water potential sensors and include tensiometers and gypsum blocks.

In the waveform analysis a sensor (usually a probe) is placed in the material to be tested. The sensor contains a waveguide consisting of two, three, or more parallel wires which is connected via a coaxial cable to a voltage pulse generator which sends precisely defined voltage pulses into the sensor. As the pulse travels along the wave guide its progress varies depending on the moisture content of the material being examined. When the pulse reaches the end of the wave guide it is reflected. This reflection is visualized in a TDR waveform using an oscilloscope connected to the sensor. The rate of travel of the pulse in the probe is measured and related to moisture content, with slower travel indicating an increase of moisture. By measuring the time from the initial pulse until the reflection is received the average moisture content and relative permitivity of the sample can be calculated by using an equivalent circuit as a reference.

Standard waveform analysis can be used either manually (hand held instruments) or automatically for monitoring moisture content in several areas such as hydrology, agriculture and construction.

Measurement usually involves inserting a sensor into the substance to be tested and then applying either Standard Waveform Analysis to determine the average moisture content along the sensor or Profile Analysis to provide moisture content at discrete points along the sensor. A spatial location can be achieved by appropriate installation of several sensors.

Moisture may be present as adsorbed moisture at internal surfaces and as capillary condensed water in small pores. At low relative humidities, moisture consists mainly of adsorbed water. At higher relative humidities, liquid water becomes more and more important, depending or not depending on the pore size can also be an influence of volume

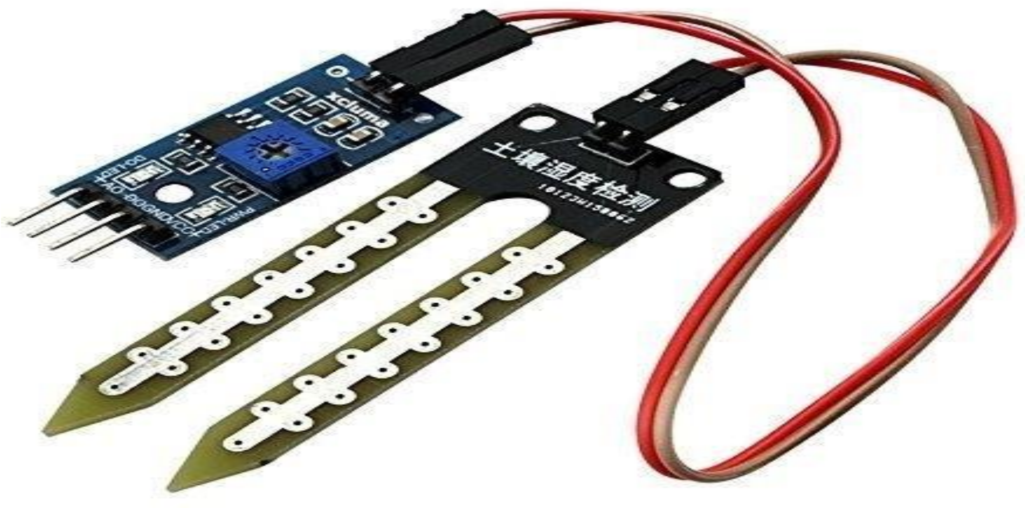

Fig 4.14(A) : Soil Moisture Sensor

4.14.1 Soil Sensor Pin Configuration

Pin Name	Description
VCC	The VCC **pin** powers the module, typically with +5V
GND	Power Supply Ground
DO	Digital Out **Pin** for Digital Output.
AO	Analog Out **Pin** for Analog Output

4.14.2 Moisture Sensor Module Features & Specifications

- Operating Voltage: 3.3V to 5V DC.
- Operating Current: 15mA.
- Output Digital - 0V to 5V, Adjustable trigger level from preset.
- Output Analog - 0V to 5V based on infrared radiation from fire flame falling on the **sensor**.
- LEDs indicating output and power.
- PCB Size: 3.2cm x 1.4cm.

4.15 POWER SUPPLY

4.15.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as "Regulated D.C Power Supply".

4.15.2 BLOCK DIAGRAM OF POWER SUPPLY:

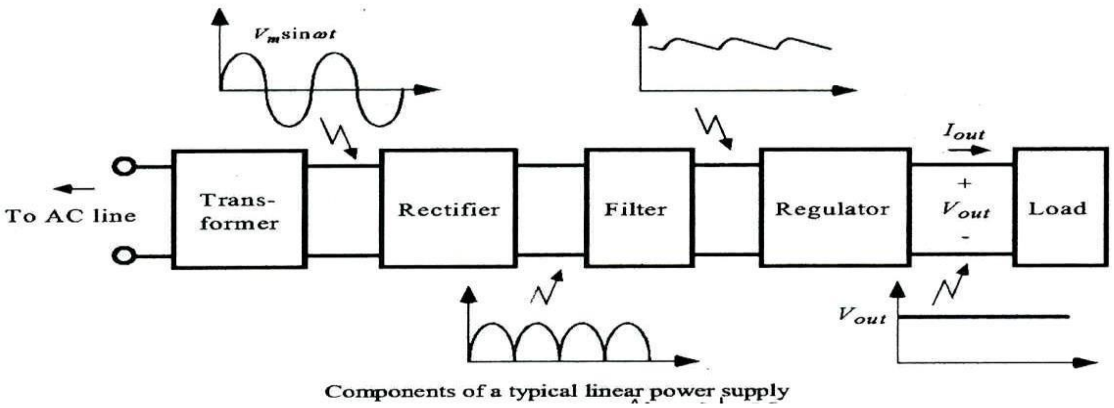

Fig.4.15.2.1: Block Diagram of Power Supply

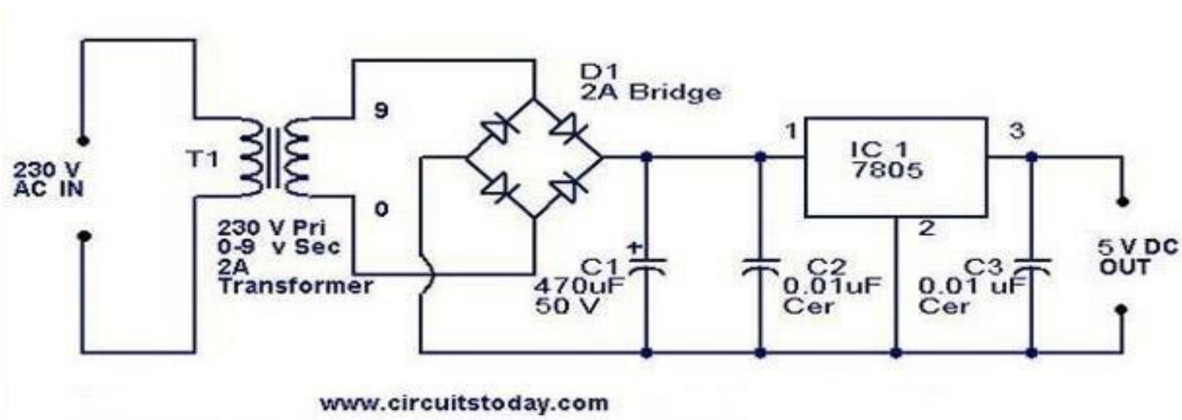

Fig.4.15.2.2: Schematic Diagram of Power Supply

4.15.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.15.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current inthe first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

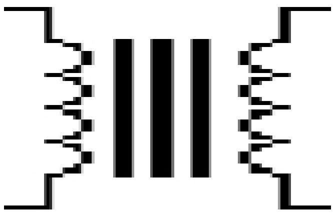

Fig.4.15.4.1: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

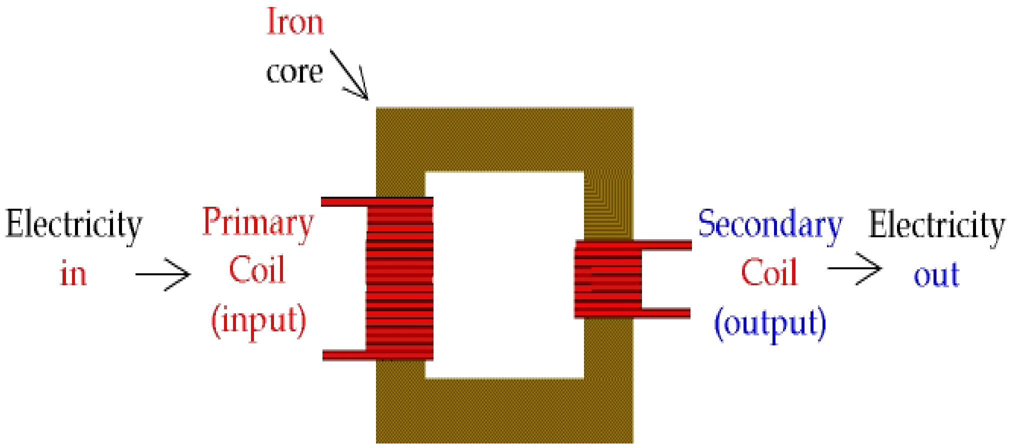

Fig.4.15.4.2: Transformer

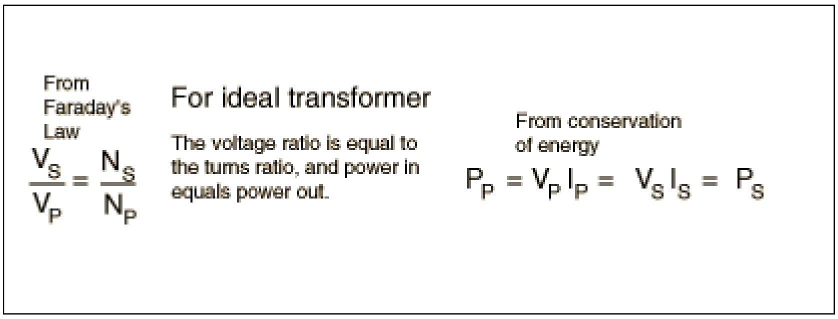
4.15.4(A): Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.



4.15.4(B) Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

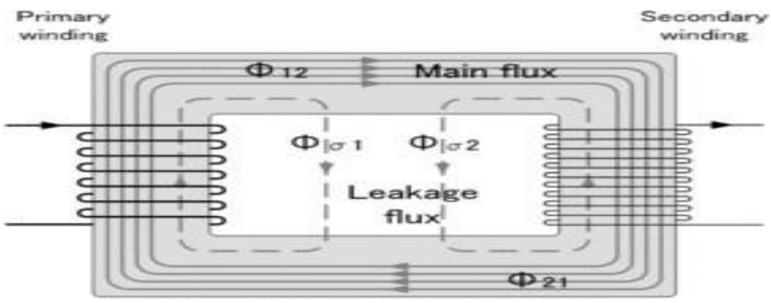


Fig.4.15.4.1(B): Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

4.15.4.1 Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

4.15.4.1(A) Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

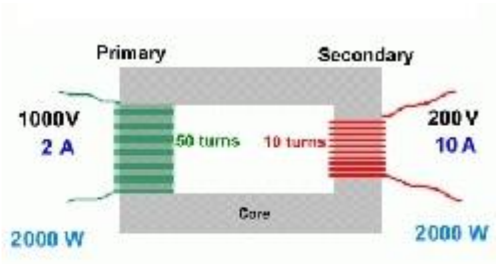

Fig.4.15.4.1(A).1: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn’s ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn’s ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

4.15.4.1(B) Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

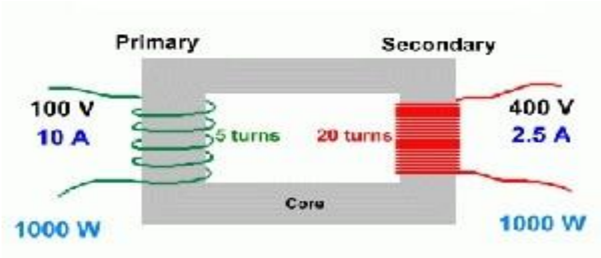

Fig.4.15.4.1(B).1: Step-Up Transformer

4.16 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are:

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

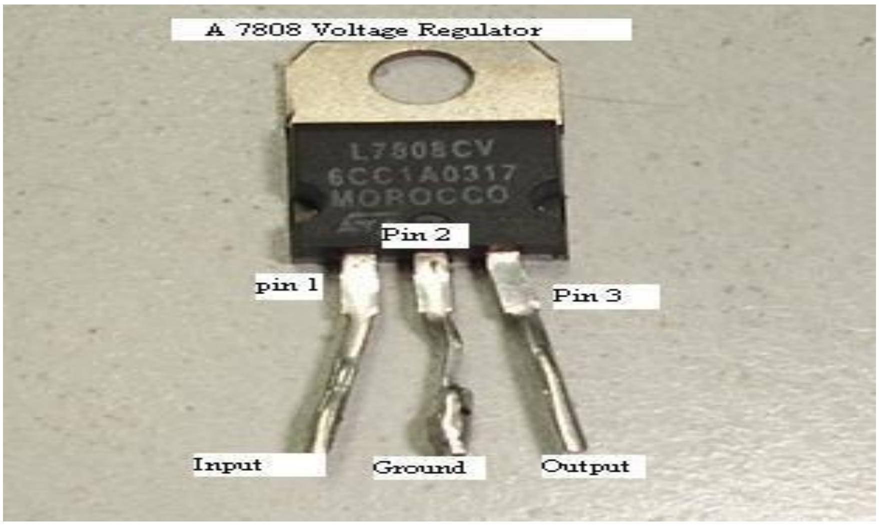

Fig.4.16.1: Regulator

4.17 Bluetooth :

Generally, the HC-05 Bluetooth Module, or the HC-05 Sub Module, to be precise, comes with the BC417 IC along with a flash memory. Such Modules come as surface mount board and several third-party manufacturers use these board to build a more complete system with necessary pins and components.

Bluetooth is a short-range wireless technology standard that is used for exchanging data between fixed and mobile devices over short distances using UHF radio waves in the ISM bands, from 2.402 GHz to 2.48 GHz, and building personal area networks.

Bluetooth is managed by the Bluetooth Special Interest Group (SIG), which has more than 35,000 member companies in the areas of telecommunication, computing, networking, and consumer electronics. The IEEE standardized Bluetooth as IEEE 802.15.1, but no longer maintains the standard. The Bluetooth SIG oversees development of the specification, manages the qualification program, and protects the trademarks. A manufacturer must meet Bluetooth SIG standards to market it as a Bluetooth device.

The following image shows one such HC-05 Bluetooth Sub Module (the green board mounted on the blue board) being used as a part of a complete Bluetooth Module.

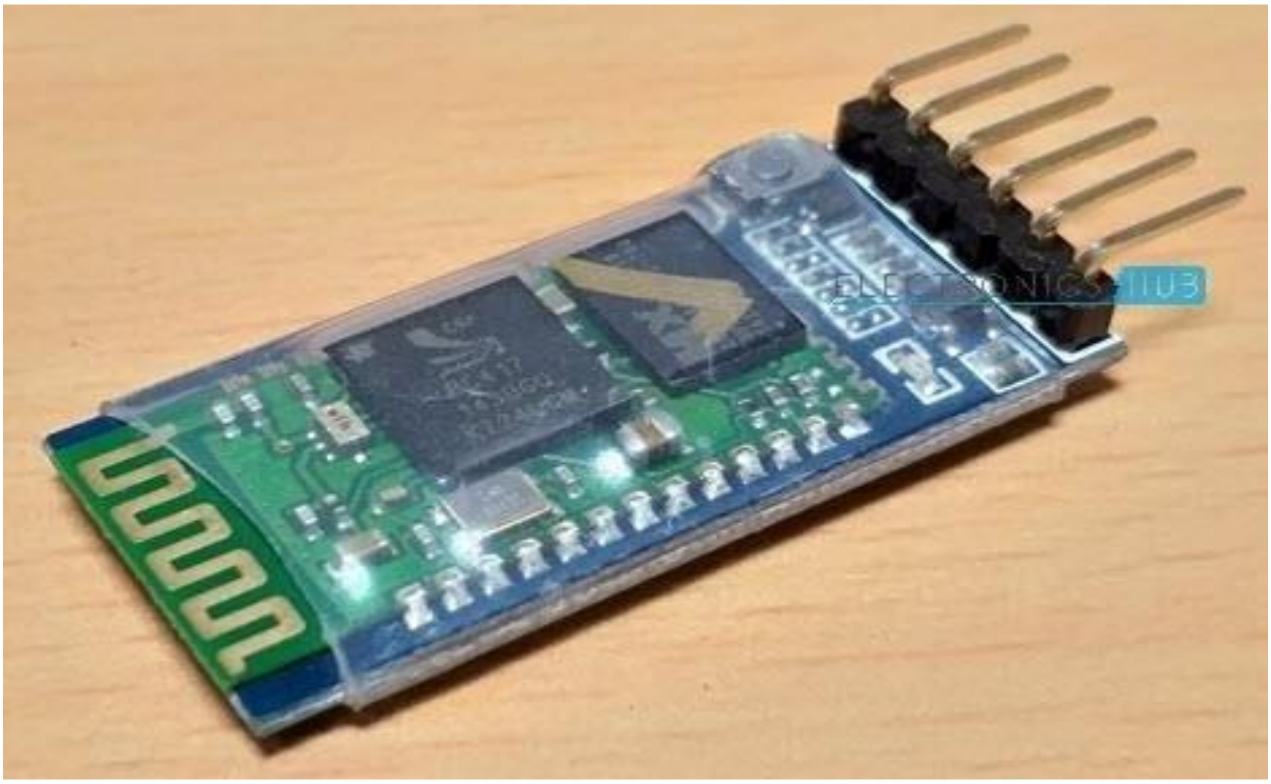

Fig 4.17(A): Bluetooth

4.17.1 Pins of HC-05 Bluetooth Module

The HC-05 Module supports for UART, USB as well as SPI communication and depending on the application, necessary pins can be used. In my case, the board uses the UART communication.

Coming to the pins of the Bluetooth Module, generally, four pins are sufficient for successfully enabling a wireless communication link but the modules produced now-a-days come with six pins namely: VCC, GND, TX, RX, EN and STATE.

Image below shows the pins and other components on a typical HC-05 Bluetooth Module. An important point to remember is the HC-05 Bluetooth Module works on a logic level of 3.3V. Hence, a 3.3V Regulator is used on the board.

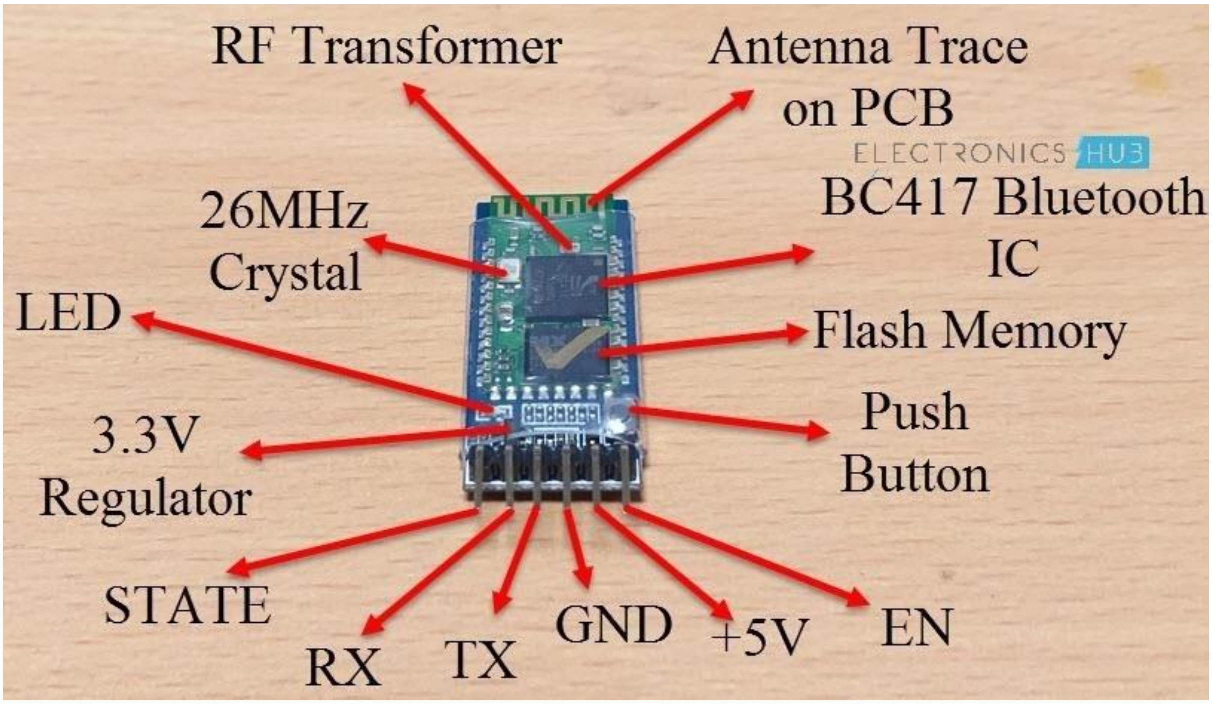

Fig 4.17.1(A) Bluetooth pins.

NOTE: The button present on the board is used to configure the Bluetooth Module in AT Command Mode. This part of the Module is not discussed in this project.

4.17.2 Pin Description

- **EN:** It is the enable pin. When this pin is floating or connected to 3.3V, the module is enabled. If this pin is connected to GND, the module is disabled.
- **+5V:** This is the supply pin for connecting +5V. As the Module has on-board 3.3V regulator, you can provide +5V supply.
- **GND:** It is the ground pin.
- **TX:** It is the Transmitter pin of the UART Communication.
- **RX:** It is the Receive Pin of UART.
- **STATE:** This is a status indicator pin. This pin goes LOW when the module is not connected to any device. When the module is paired with any device, this pin goes HIGH.

NOTE: The on-board LED is used to indicate the status of the connection. When the module is not paired, the LED blinks or flashes repeatedly. Once the module is paired, the LED blinks at a constant delay of 2 seconds.

4.17.3 Modes of Operation

The HC-05 Bluetooth Module can be configured in two modes of operation: Command Mode and Data Mode.

In Command Mode, you can communicate with the Bluetooth module through AT Commands for configuring various settings and parameters of the Module like get the firmware information, change UART Baud Rate, change module name, set it as either Master or slave etc.

An important point about HC-05 Module is that it can be configured as Master or Slave in a communication pair. In order to select either of the modes, you need to activate the Command Mode and sent appropriate AT Commands.

Coming to the Data Mode, in this mode, the module is used for communicating with other Bluetooth device i.e. data transfer happens in this mode.

4.17.4 Default Settings of HC-05 Bluetooth Module

The following is a list of few of the default settings of the HC-05 Bluetooth Module.

- Name: HC-05
- Password: 1234 (or 0000)
- Type: Slave
- Mode: Data
- Baud Rate: 9600 with 8 data bits, no parity and 1 stop bit

4.18 MOTORS

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

4.18.1 AC Motors

The most common and simple industrial motor is the three phase AC induction motor, sometimes known as the "squirrel cage" motor. Substantial information can be found about any motor by checking its (nameplate).

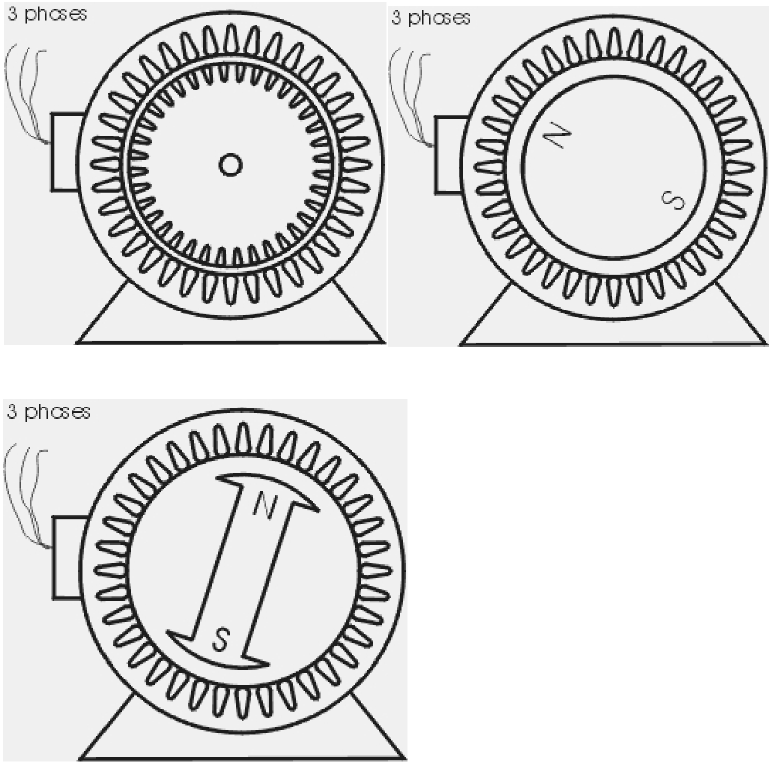

Fig 4.18.1(A) : three figures of AC motor 3 phases

Advantages

- Simple Design
- Low Cost
- Reliable Operation
- Easily Found Replacements
- Variety of Mounting Styles
- Many Different Environmental Enclosures

Simple Design

The simple design of the AC motor -- simply a series of three windings in the exterior (stator) section with a simple rotating section (rotor). The changing field caused by the 50 or 60 Hertz AC line voltage causes the rotor to rotate around the axis of the motor.

The speed of the AC motor depends only on three variables:

1. The fixed number of winding sets (known as poles) built into the motor, which determines the motor's base speed.

2. The frequency of the AC line voltage. Variable speed drives change this frequency to change the speed of the motor.
3. The amount of torque loading on the motor, which causes slip.

Low Cost

The AC motor has the advantage of being the lowest cost motor for applications requiring more than about 1/2 hp (325 watts) of power. This is due to the simple design of the motor. For this reason, AC motors are overwhelmingly preferred for fixed speed applications in industrial applications and for commercial and domestic applications where AC line power can be easily attached. Over 90% of all motors are AC induction motors. They are found in air conditioners, washers, dryers, industrial machinery, fans, blowers, vacuum cleaners, and many, many other applications.

Reliable Operation

The simple design of the AC motor results in extremely reliable, low maintenance operation. Unlike the DC motor, there are no brushes to replace. If run in the appropriate environment for its enclosure, the AC motor can expect to need new bearings after several years of operation. If the application is well designed, an AC motor may not need new bearings for more than a decade.

Easily Found Replacements

The wide use of the AC motor has resulted in easily found replacements. Many manufacturers adhere to either European (metric) or American (NEMA) standards. (For Replacement Motors)

Variety of Mounting Styles

AC Motors are available in many different mounting styles such as:

- Foot Mount
- C-Face
- Large Flange
- Vertical

- Specialty

4.18.2 DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

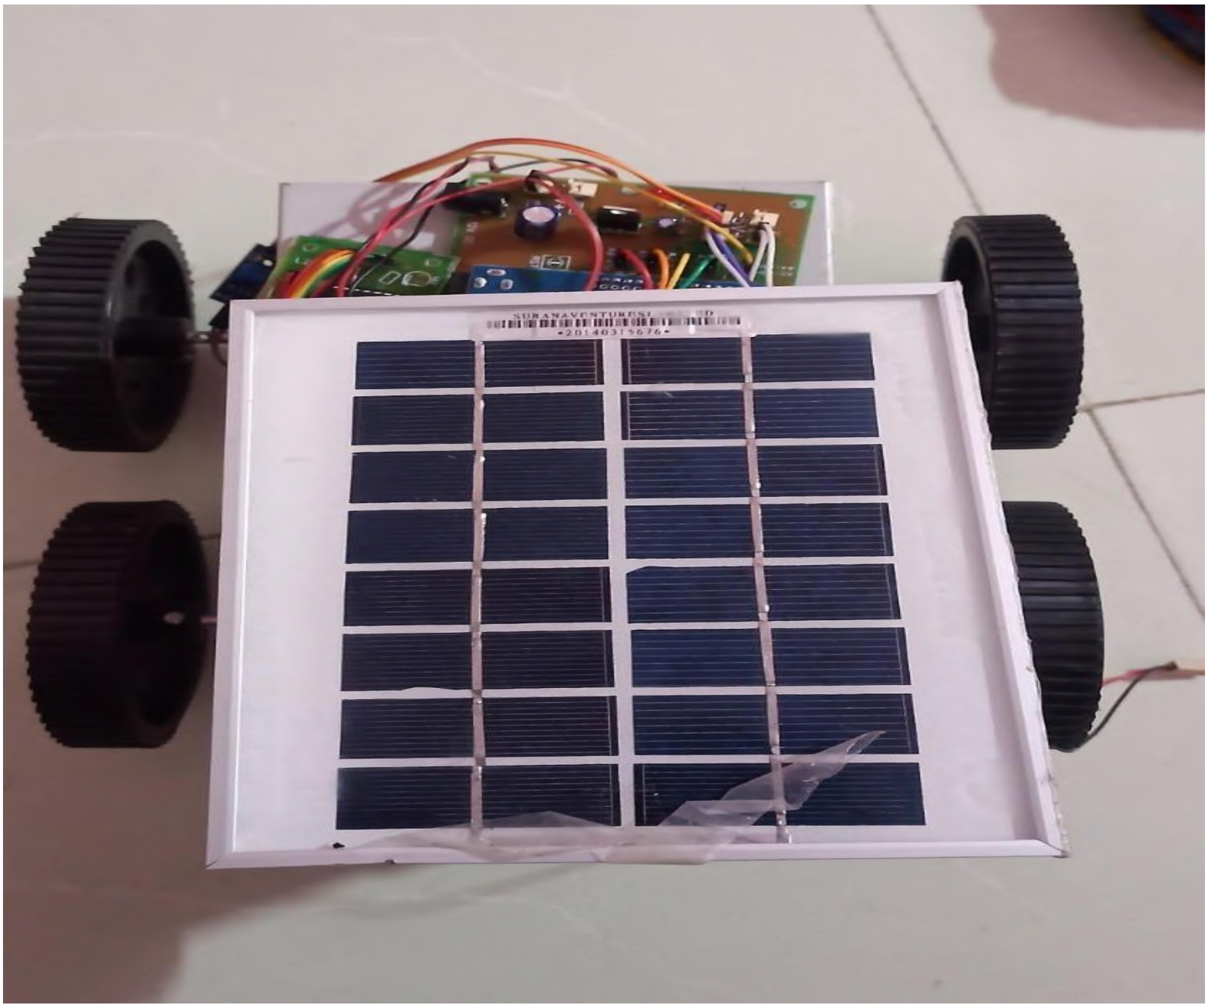
The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjunction with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparible AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

CHAPTER-5

RESULTS



5.1 Results

Fig 5.1.1 : Robot outer view

The outer part of the agriculture robot is covered with a solar pannel. Here solar pannel is generating power supply required to work all the components in the project

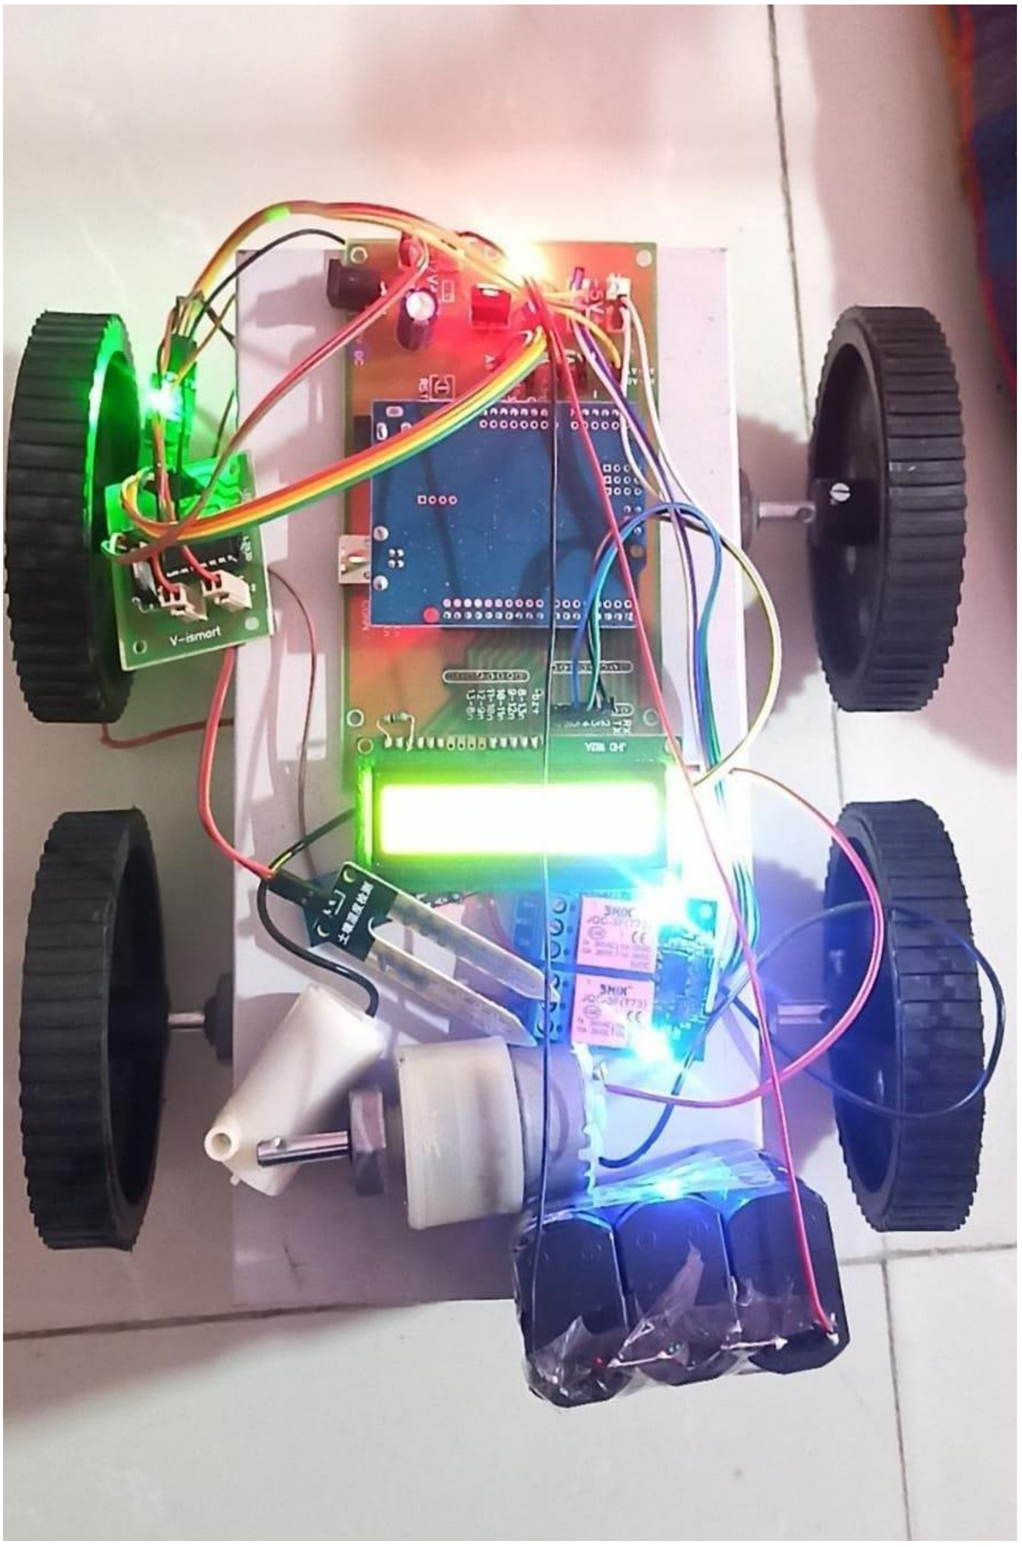


Fig 5.1.2: Internal structure of robot

Fig 5.1.3 : Soil sensor operation

The designed robot gets power from solar panel which converts sunlight into electricity. This electrical energy is given to the charging circuit in order to charge the battery to 12V. This battery gives power to controller, motor driver and other mechanisms. The entire prototype of solar powered multifunction agricultural robot is shown in fig: 5.1.3.

Firstly it paired app with the HC-05 module. The movement of robot controlled by following commands #: Stop, *: Forward movement, @: Backward movement, %: Right turn, &: Left turn, c: Grass cutting

When we send ‘c’ commands the robot starts Grass Cutting . Grass cutting mechanism has a circular cutter provided with sharp edges. Weeds were successfully cut by this cutter. ‘#’ is sent to stop the function of the robot. If the Soil Sensor receive the command dry detector then the Submersible motor turns on and sprinkle water on field.

CHAPTER-6

ADVANTAGES

6.1 ADVANTAGES OF THE PROJECT:

- No extra cost is required for fueling.
- Reduces the labour cost.
- The use of machineries in this field save time.
- Increase efficiency and indirectly increase the production in farms.
- No external power consumption is required.

6.2 Draw backs of the project :

- It can be controlled up to short range itself.

CHAPTER – 7

CONCLUSION & FUTURE SCOPE

7.1 Conclusion:

Multipurpose farming robot has effectively actualized and tried for operations like grass cutting and water sprinkling. An underlying result of this examination shows that the greater part of these frameworks that work with self-governing, are more adaptable than customary frameworks. It was developed for integrating agricultural robot using programming. The advantages of Multi-tasking agricultural robots are reducing human effort, ensuring proper irrigation and efficient utilization of all resources. The upsides of multipurpose horticultural robots are lessening human intercession, guaranteeing appropriate water system and proficient use of assets. the different parameters like soil condition, region secured by the robot and leveling.

7.2 Future scope:

Robots will replace the human labor and, in every aspect, which will make agricultural sector much more efficient than today’s time. Artificial intelligence technologies, especially in machine learning, are expected to play a serious role in most of the above technology areas, and can be essential enablers for agricultural robots. Agricultural environments are subject to changes throughout the lifetime of a robotic system. For example, there could also be new crop varieties, weeds, pests, diseases, treatments, legislation, temperature change, etc., as well as new robotic technologies. In AI terms this suggests managing an open world, so techniques to enable adaptation during operation rather than at the planning phase are going to be crucial. Techniques that allow robots to find out from experience include reinforcement learning, learning from demonstration, and transfer learning to exploit prior knowledge, e.g. from another domain or task. Ongoing research is investigating deep learning methods, especially in perception-related tasks involving the interpretation of sensor data, including recognition and segmentation tasks in automated weeding and fruit picking. Robots also will have to leverage human knowledge, especially when facing situations that weren't foreseen at design time.

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to our **College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra, our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna, Head and Professor, the department of Electronics and Communication** for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **department project coordinator Dr.A.Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

Finally, we are highly grateful and obliged to our **Internal Project Guide Mr. Basava Dhanne** , Assistant Professor in ECE for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

P. NIHAL REDDY.

P. HRITHIK.

S. PRAMODINI.

ABSTRACT

Complex illumination condition is one of the most critical challenging problems for practical face recognition. In this paper, we propose a novel method based on deep learning to solve the adverse impact imposed by illumination variation in the face recognition process. Firstly, illumination preprocessing is applied to improve the adverse effects of intense illumination changes on face images. Secondly, the Log-Gabor filter is used to obtain the Log-Gabor feature images of different scales and directions, then, LBP (Local Binary Pattern) features of images subblock is extracted. Lastly, texture feature histograms are formed and input into the deep belief network (DBN) visual layer, then classification and recognition are completed through deep learning in DBN. Experimental results show that superior performance can be obtained in the developed approach by comparisons with some state-of-the-arts.

CONTENTS

TABLE OF FIGURES

1 INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

Complex illumination condition is one of the most critical challenging problems for practical face recognition. This project presents an effective method to extract the robust deep features of face images under severe illumination conditions. We propose a novel method based on deep learning to solve the adverse impact imposed by illumination variation in the face recognition process. Firstly, illumination preprocessing (analyzing the pixel values, size of images, background, foreground, intensities, contrast and so on of images) is applied to improve the adverse effects of intense illumination changes on face images. Secondly, the Log-Gabor filter (a low pass filter) is used to obtain the Log-Gabor feature images of different scales and directions, then, LBP (Local Binary Pattern) features of image subblocks is extracted. Deep learning simulates the deep organizational structure of brain groups, and it forms more abstract and effective high-level representation by combining low-level features. Deep belief network (DBN) is a typical deep learning method. DBN automatically learns the abstract features of different levels from bottom to top, and finally obtains the nonlinear description of features. An automatic feature extraction process without artificial choice is presented. DBN has been successfully applied to handwritten numeral recognition, dynamic human detection, and many other fields.

However, DBN may ignore the local structure of the image and it is difficult to learn the local features of the face image . At the same time, the network will learn the unfavorable feature expression for the influence of illumination and other factors when the pixel-level face features are used as the input of DBN. It uses LBP feature as the input of the deep learning network. It improves the performance of LBP and deep learning algorithm respectively. The texture feature histograms are formed and input into the deep belief network (DBN) visual layer, then face classification and recognition are completed through deep learning in DBN. Experimental results show that superior performance can be obtained in the developed approach by comparisons with some state-of-the-arts.

1.2 STATEMENT OF THE PROBLEM

Face Recognition has gained much attention due to its wide range of applications, such as biometric, identity authentication, law enforcement, and video surveillance. Even though human eye can detect and identify faces in a scene easily, building an automatic system that accomplishes such a task is still very challenging. Due to the dynamic nature of face images, a face recognition system encounters various problems during the recognition process. It is possible to classify a face recognition system as either "robust" or "weak" based on its recognition performances.

Robust face recognition requires the ability to recognize identity despite many variations in appearance that the face can have in a scene. The face is a object which is illuminated from a variety of light sources and surrounded by arbitrary background data (including other faces). Therefore, the appearance a face has when projected onto a image can vary tremendously. The challenges are mainly from large variations of illumination, expression, pose, corruption, and occlusion which can cause sharp decline in recognition rate.

1.3 AIMS AND OBJECTIVES OF THE STUDY

Face recognition presents a challenging problem in the field of image analysis and computer vision, and as such has received a great deal of attention over the last few years because of its many applications in various domains. Face recognition techniques can be broadly divided into categories based on the face data acquisition methodology: methods that operate on intensity images; In the language of information theory, the objective is to extract the relevant information in a face image, encode it as efficiently as possible, and compare one face encoding with a database of models encoded in the same way.

In mathematical terms, the objective is to find the principal components of the distribution of faces, or the eigenvectors of the covariance matrix of the set of face images or eigen vectors. The set of eigen vectors is termed as eigen faces. The aim of the study is to recognize face images under worst/complex light illumination conditions by extracting robust deep features of the face images for robust Face Recognition.

1.4 SCOPE OF THE STUDY

As an important branch of biometric identification technology, face recognition technology has the characteristics of convenient acquisition and high reliability that has widely used in the fields of information security, national security and traffic monitoring. Face recognition appears to offer several advantages over other biometric methods, a few of which are outlined here. Almost all these technologies require some voluntary action by the user,for examples, the user needs to place his hand on a hand-rest for fingerprinting or hand geometrydetection and has to stand in a fixed position in front of a camera for iris or retina identification. However, face recognition can be done passively without any explicit action or participation on the part of the user since face images can be acquired from a distance by a camera. This is particularly beneficial for security and surveillance purposes.

In security system, many types of passwords are used to access the private and confidential data. Such password can be as insert characters (key in pin) and touch smart card using RFID technology. Passwords and PINs are hard to remember and can be stolen or guessed; cards, tokens, keys and the like can be misplaced, forgotten, purloined or duplicated; magnetic cards can become corrupted and unreadable. By developed face recognition it more secure because facial image had been used as the ID. It also helps to avoid any duplicated identification. Other problem is to identify certain criminals especially in identification technique used by the police. Face recognition helps to recognize the facial image in more efficient and accurate in order to match with the identity stored in the database.

1.5 SYSTEM REQUIREMENTS

MATLAB - A high-performance language for technical computing.

Typical uses of MATLAB include :

-Math and computation.

-Algorithm development.

-Modeling, simulation, and prototyping.

DIGITAL IMAGE PROCESSING - an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing and experimentation that normally is required before arriving at an acceptable solution.

1.6 ORGANIZATION OF CHAPTERS

The paper is organized as follows, Chapter 1 presents Introduction of the project including the overview of the project, the statement of the problem, objective of the project, the scope of study, and the system requirements of the project.

Chapter 2 presents the Literature Survey ,the literature review on research area of related existing methods, review on research of proposed project, and conclusions on reviews.

Chapter 3 presents Research Methodology which includes the system requirements of the project, analyzing the problem of existing methods, defining a solution of the problem through the proposed system, , the architectural design related block diagram of project defining the independent units and explaining their functionalities

Chapter 4 presents the Project Implementation, the implementation stages of project ,the activities involved in implementation, the testing of the project and results of the project.

Chapter 5 presents the Project Testing taking into account two standard databases as training and testing datasets and comparing the efficiency of the recognition rate with various other face recognition methods.

Chapter 6 presents the Conclusion and Future Enhancement of the project.

2 LITERATURE SURVEY

As one of the most visible and challenging problems in computer vision and pattern recognition, face recognition (FR) has been extensively studied in the past two decades and many representative methods, such as Eigenface, Fisher face and SVM, have been proposed. Moreover, to deal with the challenges in practical FR system, active shape model and active appearance model were developed for face alignment; LBP and its variants were used to deal with illumination changes; and Eigenimages and probabilistic local approach were proposed for FR with occlusion.

Although much progress have been made, robust FR to occlusion/corruption is still a challenging issue because of the variations of occlusion, such as disguise, continuous or pixel-wise occlusion, randomness of occlusion position and the intensity of occluded pixels. The recognition of a query face image is usually accomplished by classifying the features extracted from this image. The most popular classifier for FR may be the nearest neighbor (NN) classifier due to its simplicity and efficiency. In order to overcome NN's limitation that only one training sample is used to represent the query face image, Li and Lu proposed the nearest feature line (NFL) classifier, which uses two training samples for each class to represent the query face. Chien and Wu then proposed the nearest feature plane (NSP) classifier, which uses three samples to represent the test image. Lateron, classifiers using more training samples for face representation were proposed, such as the local subspace classifier (LSC) and the nearest subspace (NS) classifiers, which represent the query sample by all the training samples of each class. Though NFL, NSP, LSC and NS achieve better performance than NN, all these methods with holistic face features are not robust to face occlusion.

Generally speaking, these nearest classifiers, including NN, NFL, NFP, LSC and NS, aim to find a suitable representation of the query face image, and classify it by checking which class can give a better representation than other classes. Nonetheless, how to formulate the representation model for classification tasks such as FR is still a challenging problem.

Wright et al. proposed a novel face recognition method called sparse representation classification (SRC). In this method, a test face sample can be represented by the linear combination of part of training face samples from all subjects with sparsity regularization on the representation vector Wright *et al.* applied sparse coding to FR and proposed the sparse coding classification (SRC) scheme. The SRC has close relationship to the nearest classifiers. Like NN, NFL, NFP, LSC and NS classifiers, SRC also represents the query sample as the linear combination of training samples however, it forces the representation coefficients being sparse (instead of presetting the number of non-zero representation be from samples of different classes). SRC could be seen as a more general model than the previous nearest classifiers, and it uses the samples from all classes to collaboratively represent the query sample to overcome the small-sample-size problem in FR. In addition, different from the methods such as which use local region features, color features or gradient information to handle some special occlusion SRC shows interesting results in dealing with occlusion by assuming a sparse coding.

Recently, Hinton and Salakhutdinov proposed a deep learning (DL) method to train a deep neural network, which is also successfully applied for the face recognition task. Since the trained deep network can achieve a better representation of the face data, the DL based face recognition methods obtain very good performances. We propose a regularized robust coding (RRC) model in our project. A special case of RRC, namely robust sparse coding (RSC), has been presented in our previous work by assuming that the coding coefficients are sparse. Our extensive experiments in benchmark face databases show that RRC achieves much better performance than existing sparse representation based FR methods, especially when there are complicated variations, such as face occlusions, corruptions etc. problem involves face detection, feature extraction from the face regions and recognition.

The key procedure in PCA is based on Karhumen-Loeve transformation. If the image elements are considered to be random variables, the image may be seen as a sample of a stochastic process. The focus of the research is to find the accuracy of eigenfaces method in face recognition. Eigenface approach seemed to be an adequate method to be used in face recognition due to its simplicity, speed and learning capability.

3 RESEARCH METHODOLOGY

3.1 SYSTEM REQUIREMENTS

3.1.1 MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems along withsolutions are expressed in familiar mathematical notation. MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for *matrix laboratory*. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high- productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called *toolboxes*. Very important to most users of MATLAB, toolboxes allow you to *learn* and *apply* technology.

Toolboxes are comprehensive collections of MATLAB functions (M-files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

Typical uses of MATLAB include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

The MATLAB system consists of five main parts

Development Environment

This is the set of tools and facilities that help you use MATLAB functions and files. Manyof these tools are graphical user interfaces. It includes the MATLAB desktop and Command Window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

The MATLAB Mathematical Function

This is a vast collection of computational algorithms ranging from elementary functions like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigen values, Bessel functions, and fast Fourier transforms.

The MATLAB Language

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create complete large and complex application programs.

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well asannotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API**)**

This is a library that allows you to write C and Fortran programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

3.1.2 MATLAB WORKING ENVIRONMENT

MATLAB DESKTOP

Matlab Desktop is the main Matlab application window. The desktop contains five sub windows, the command window, the workspace browser, the current directory window, the command history window, and one or more figure windows, which are shown only when the user displays a graphic.

The command window is where the user types MATLAB commands and expressions atthe prompt (>>) and where the output of those commands is displayed. MATLAB defines the workspace as the set of variables that the user creates in a work session. The workspace browser shows these variables and some information about them. Double clicking on a variable in the workspace browser launches the Array Editor, which can be used to obtain information and income instances edit certain properties of the variable.

The current Directory tab above the workspace tab shows the contents of the current directory, whose path is shown in the current directory window. For example, in the windows operating system the path might be as follows: C:\MATLAB\Work, indicating that directory “work” is a subdirectory of the main directory “MATLAB”; WHICH IS INSTALLED IN DRIVE C. clicking on the arrow in the current directory window shows a list of recently used paths. Clicking on the button to the right of the window allows the user to change the current directory.

MATLAB uses a search path to find M-files and other MATLAB related files, which are organize in directories in the computer file system. Any file run in MATLAB must reside in the current directory or in a directory that is on search path. By default, the files supplied with MATLAB and math works toolboxes are included in the search path. The easiest way to see which directories are on the search path. The easiest way to see which directories are soon the search path, or to add or modify a search path, is to select set path from the File menu the desktop, and then use the set path dialog box. It is good practice to add any commonly used directories to the search path to avoid repeatedly having the change the current directory.

The Command History Window contains a record of the commands a user has entered in the command window, including both current and previous MATLAB sessions. Previously entered MATLAB commands can be selected and re-executed from the command history window by right clicking on a command or sequence of commands. This action launches a menu from which to select various options in additionto executing the commands. This is useful to select various options in addition to executing the commands. This is a useful feature when experimenting with various commands in a work session.

Using the MATLAB Editor to create M-Files

The MATLAB editor is both a text editor specialized for creating M-files and a graphical MATLAB debugger. The editor can appear in a window by itself, or it can be a sub window in the desktop. M-files are denoted by the extension .m, as in pixel up.m. The MATLAB editor window has numerous pull-down menus for tasks such as saving, viewing, and debugging files.

Because it performs some simple checks and also uses color to differentiate between various elements of code, this text editor is recommended as the tool of choice for writing and editing M-functions. To open the editor window, type edit at the prompt opens the M-file file name.m in an editor window, ready for editing. As noted earlier, the file must be in the current directory, or in a directory in the search path.

Getting Help from MATLAB

The principal way to get help online is to use the MATLAB help browser, opened as a separate window either by clicking on the question mark symbol (?) on the desktop toolbar, or bytyping help browser at the prompt in the command window. The help Browser is a web browser integrated into the MATLAB desktop that displays a Hypertext Markup language (HTML) documents. The Help Browser consists of two panes, the help navigator pane, used to find information, and the display pane, used to view the information. Self-explanatory tabs other than navigator pane are used to perform a search.

3.2 DIGITAL IMAGE PROCESSING

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing and experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches and quickly prototype candidate solutions generally plays a major role in reducing the cost and time required to arrive at a viable system implementation.

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to thevisual band of the EM spectrum imaging machines cover almost the entire EM spectrum, rangingfrom gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images butits outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end ofthe continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value. An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of theimage at that point.

Gray scale image

A grayscale image is a function I (xylem) of the two spatial coordinates of the image.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I(xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] $\times$[0, b]I:[0, a] $\times$ [0, b] $\rightarrow$ [0, info)

Color image

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue. An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates. In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentationrefers to the coordinates. Less frequently the toolboxalso employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers torows. This is the opposite of our use of variables x and y.

Image as Matrices

The preceding discussion leads to the following representation for a digitized image function:

f (0,0) f(0,1) ……….. f(0,N-1)

f (1,0) f(1,1) ………… f(1,N-1)

f (xylem)=f (M-1,0) f(M-1,1) f(M-1,N-1)

Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

f (1,1) f(1,2)……….f(1,N)

f (2,1) f(2,2)……….f (2,N)

f (M,1) f(M,2)……….f(M,N)

Where f (1,1) = f(0,0), Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q.

For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectivelyto denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar. Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. All MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax

is imread (‘filename’)

Use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the resultsof the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytesto represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1 with each element being stored in memory using function logical or by using relational operators.

Image Types

The toolbox supports four types of images:

- Intensity images.
- Binary images.
- Indexed images.
- R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit 8, or class unit 16, they have integer values in the range [0,255] and [0,65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB. A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0's and 1's, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function is logical(c).

If c is a logical array, this function returns a 1. Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Image

An indexed image has two components

A data matrix integer, xA color map matrix.

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double then all of its components with values less than or equal to 1point to the first row in map, all components with value 2 point to the second row and soon. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image

A RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in tothe red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB colorimage are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535]. For RGB images of class units or unit 16 . The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8-bit image, the corresponding RGB image is said to be 24-bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits

3.3 ANALYSIS OF THE PROBLEM

With the aggravation of social public security problems, the face recognition without occluded parts can no longer meet the needs of modern society. All kinds of face recognitions in complex environment need to be realized in the real situations. Face images are disturbed by occlusion factors, which results in the loss or alienation of the recognized image pixels, thus resulting in the recognition errors of traditional models.

Even though human eye can detect and identify faces in a scene easily, building an automatic system that accomplishes such a task is still very challenging. Due to the dynamic nature of face images, a face recognition system encounters various problems during the recognition process.

Robust face recognition requires the ability to recognize identity despite many variations in appearance that the face can have in a scene.The appearance a face when projected onto image can vary tremendously. The challenges are mainly from large variations of illumination, expression, pose, corruption, and occlusion which can cause sharp decline in recognition rate. At present, researchers have proposed numerous illumination processing algorithms for face images under complex illumination conditions, and achieved relatively good experimental results. attitude and illumination in environmental factors.

The algorithms based on 2-D model are the research hotspots Deep learning algorithm has the characteristics of high recognition rate and strong robustness. The Deep Learning based algorithm uses an effective method of extracting the ROBUST deep features of face images under severe illumination conditions based on the combination of Log-Gabor filter and LBP (an effective local texture descriptor. It is widely used in face recognition because of its advantages in image texture description) with the Deep Belief Network (DBN). The description of LBP (local binary pattern) and combine it with Gabor wavelet to obtain the best representation of face image features under complex illumination conditions The Deep Learning based face recognition methods obtain very good performances and it obtains accurate recognition rate.

3.4 BLOCK DIAGRAM/DESIGN OF PROJECT

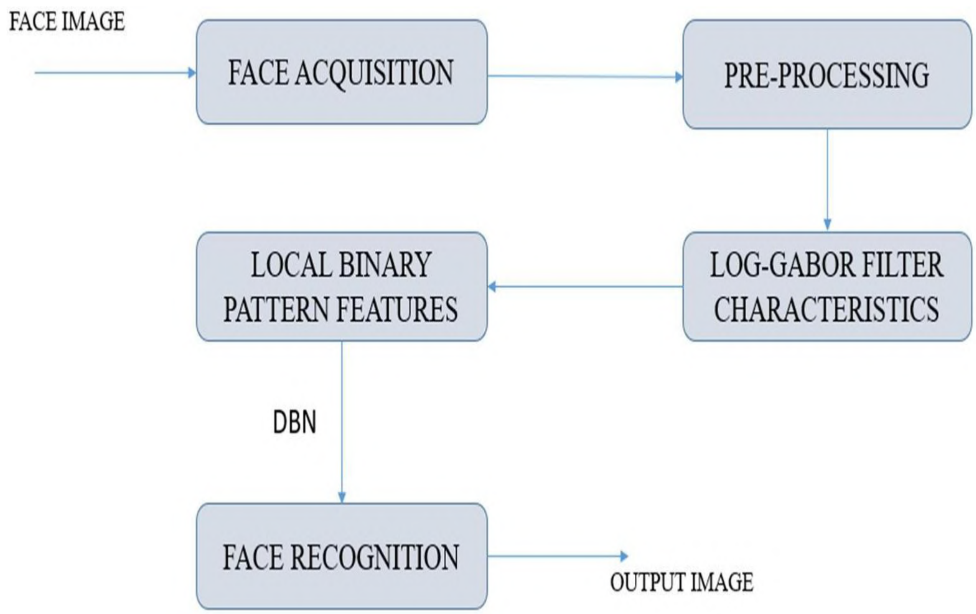

Figure 3-1 Block diagram

3.5 MODULES AND THEIR FUNCTIONALITIES

The project involves the following standard units or blocks for its implementation

PREPROCESSING

Illumination preprocessing is applied to improve the adverse effects of intense illumination changes on face images. The pre-processing is done so as to analyze the face images based on the required needs it involves the resizing of images, minimum pixels , maximum pixels, adjusting the contrast, brightness, the foreground and background of each image for the required algorithm.

LOG-GABOR

Log-Gabor function is an alternative to the Gabor function.log-Gabor functions, by definition, always have no DC component, therefore, the influence of illumination conditions on image processing is relatively small, which can overcome the adverse effects of illumination on face recognition to a certain extent. It acts as a low pass filter to get rid of high frequency components. It is a filter for extracting the log-gabor features of an image.

LOCAL BINARY PATTERN

The local binary pattern operator is used to extract the sub-blocks of the image. LBP has the advantages of gray translation invariance, rotation invariance and simple calculation. The texture features of LBP have been successfully applied in texture classification, face recognition, image analysis, background modeling and other fields. It shows superior performance in texture classification of a 2-D image .

DEEP BELIEF NETWORK

DBN is a typical deep learning network. Its prototype is similar to human brain tissue structure. The DBN extracts the input data features from simple to complex and from low-level to high-level. The DBN does not rely on the manual selection, and it learns the input data actively and digs out rich information hidden in the known data automatically. Using the deep learning and DBN the data is sliced, layered and forms histograms and recognition is done effectively by combining low level features.

4 PROJECT IMPLEMENTATION

4.1 FLOWCHART OF PROPOSED PROJECT

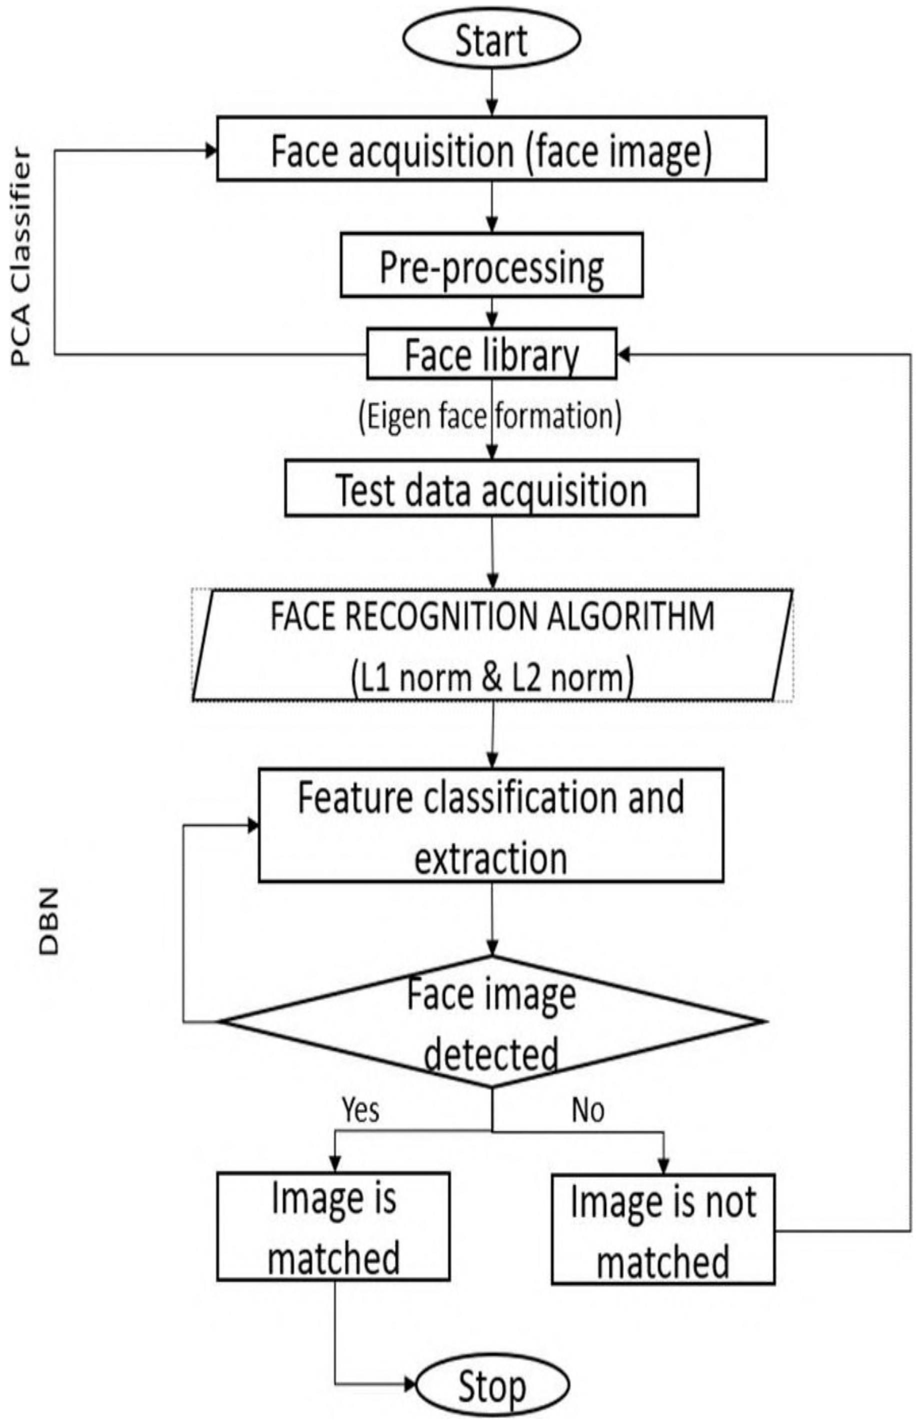

Figure 4-1 Flowchart of project.

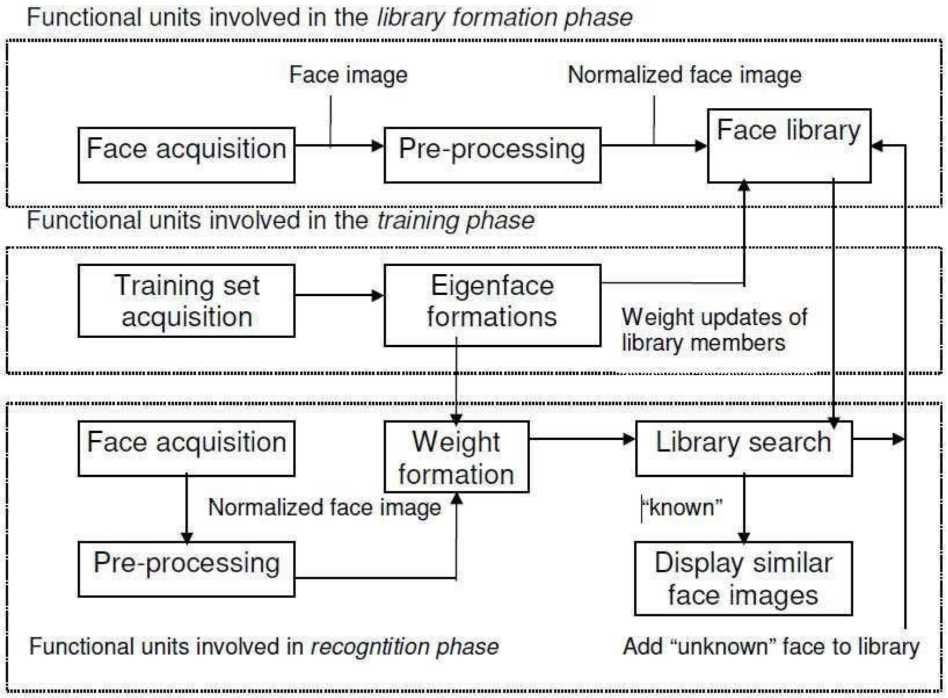

Figure 4-2 Functional block diagram.

The above block diagram represents the functional units involved and the phases involved in the face recognition process

4.2 IMPLEMENTATION STAGES

The proposed face recognition system passes through three main phases/stages during a face recognition process. Three major functional units are involved in these phases and they are defined. The characteristics of these phases in conjunction with the three functional units are given below:

4.2.1 Face Library Formation Phase

In this phase, the acquisition and the preprocessing of the face images that are going to be added to the face library are performed. Face images are stored in a face library in the system. We call this face database a "face library" because at the moment, it does not have the properties of a relational database. Every action such as 8 training set or eigenface formation is performed on this face library. Face library is initially empty. In order to start the face recognition process, this initially empty face library has to be filled with face images. In order to perform image size conversions and enhancements on face images, there exists the "pre-processing" module. This module automatically converts everyface image to necessary size based on user request, it can modify the dynamic range of face images (histogram equalization) in order to improve face recognition performance. After acquisition and pre- processing, face image under consideration is added to the face library. Each face is represented by two entries in the face library: One entry corresponds to the face image itself and the other corresponds to the weight vector associated for that face image. Weight vectors of the face library members are empty until a training set is chosen and eigenfaces are formed.

4.2.2 Training Phase

After adding face images to the initially empty face library, the system is ready to perform training set and eigenface formations. Those face images that are going to be in the training set are chosen from the entire face library. Because that the face library entries are normalized, no further pre-processing is necessary at this step. After choosing the training set, eigenfaces are formed and stored for later use. Eigenfaces arecalculated from the training set, keeping only the M images that correspond to thehighest eigen values. These M eigenfaces define the M-dimensional "face space". As new faces are experienced, the eigen faces can be updated or recalculated. The corresponding distribution in the M-dimensional weight space is calculated for each face library member, by projecting its face image onto 9 the "face space" spanned by the eigen faces. Now the corresponding weight vector of each face library member has been updated which were initially empty. The system is now ready for the recognition process.

4.2.3 Recognition and Learning Phase

Now the corresponding weight vector of each face library member has been updated which were initially empty. The system is now ready for the recognition process. User initiates the recognition process through selecting a face image. Based on the user request and the acquired image size, pre-processing is applied to normalize this acquired image to face library specifications (if necessary). Once the image is normalized, its weight vector is constructed with the help of the eigenfaces that were already stored during the training phase. After obtaining the weight vector, it is compared with the weight vector of every face library member within a user defined "threshold".If there exists at least one face library member that is similar to the acquired image within the threshold then, the face image is classified as "known". Otherwise, a miss has occurred and the face image is classified as "unknown". After being classified as unknown, this new face imagecan be added to the face library with its corresponding weight vector for later use

4.3 EXPERIMENTAL RESULTS

4.3.1 TEST DATA COLLECTED

Figure 4-3 Train Database

4.3.2 TRAIN DATA COLLECTED

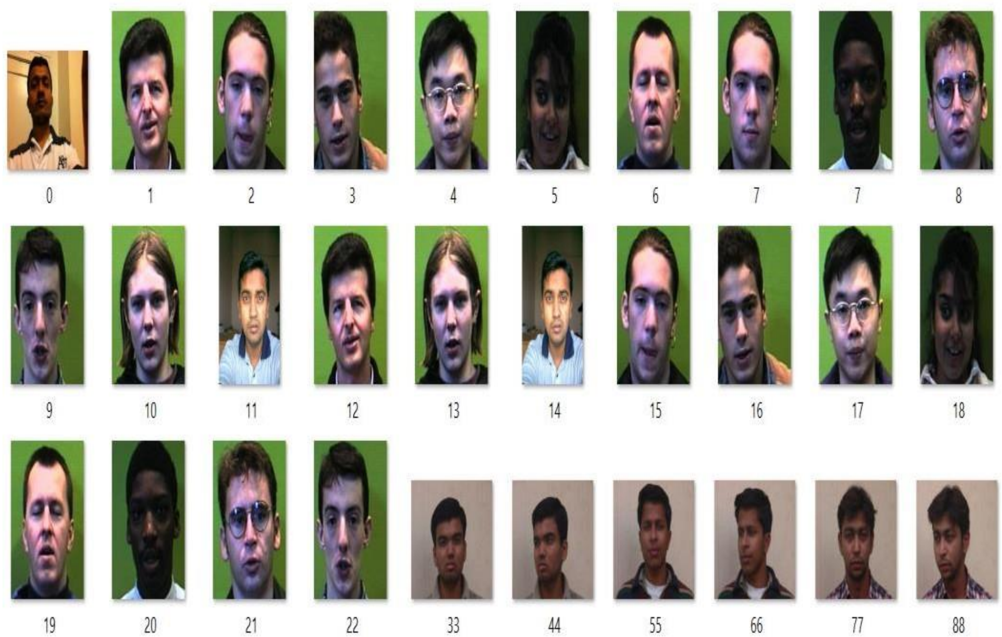

Figure 4-4 Test Database

The database of images shown above are both training dataset and test dataset. These are taken as input images for Robust Face Recognition.

When the program is executed the following is shown , it displays Train and Test data uploading.

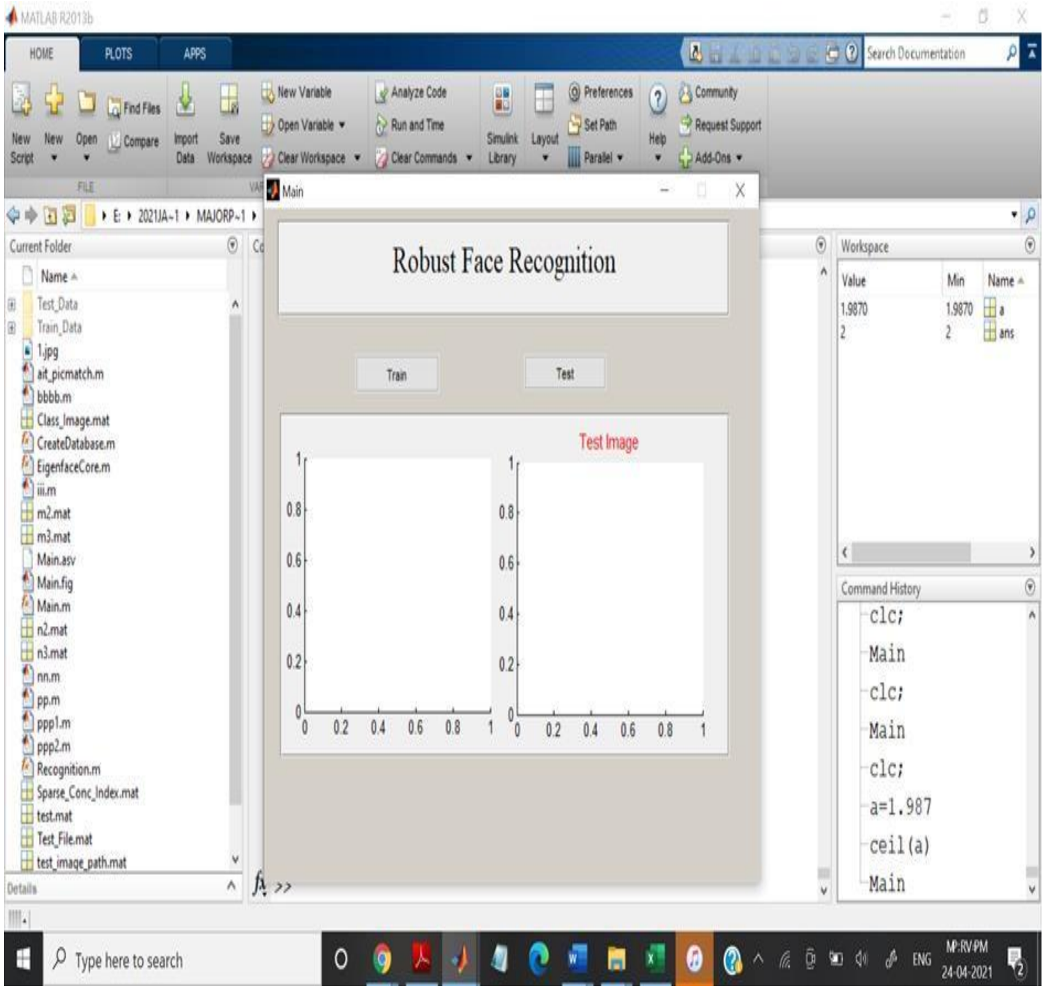

Figure 4-5 Uploading Train and Test database

Use the images above and Upload them into train and test database, select the test image and crop it and upload to test database. The following outputs are displayed.

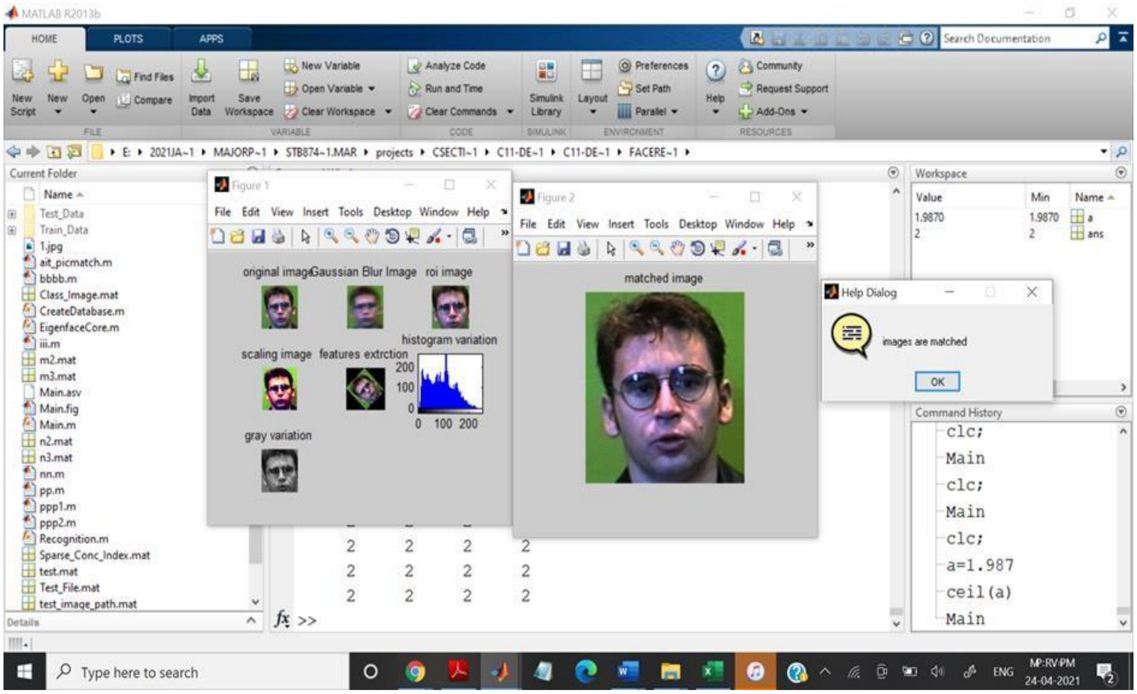

Figure 4-6 Result displaying Images are Matched.

The image shown is a result displaying “**Images are matched**.”

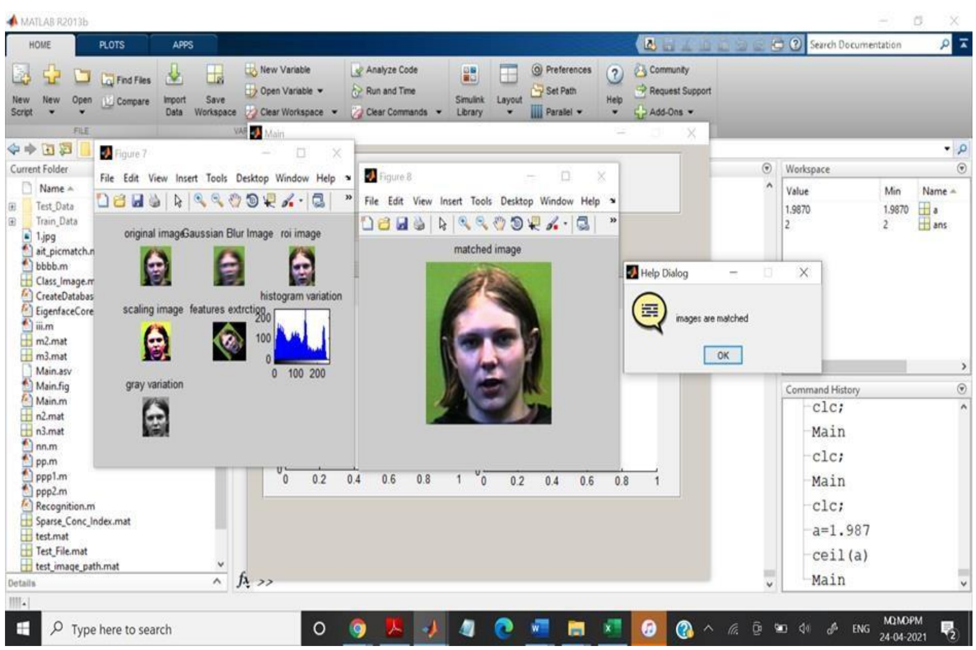

Figure 4-7 Image displaying images are matched.

The following.displays result showing “**Images are not matched.**”

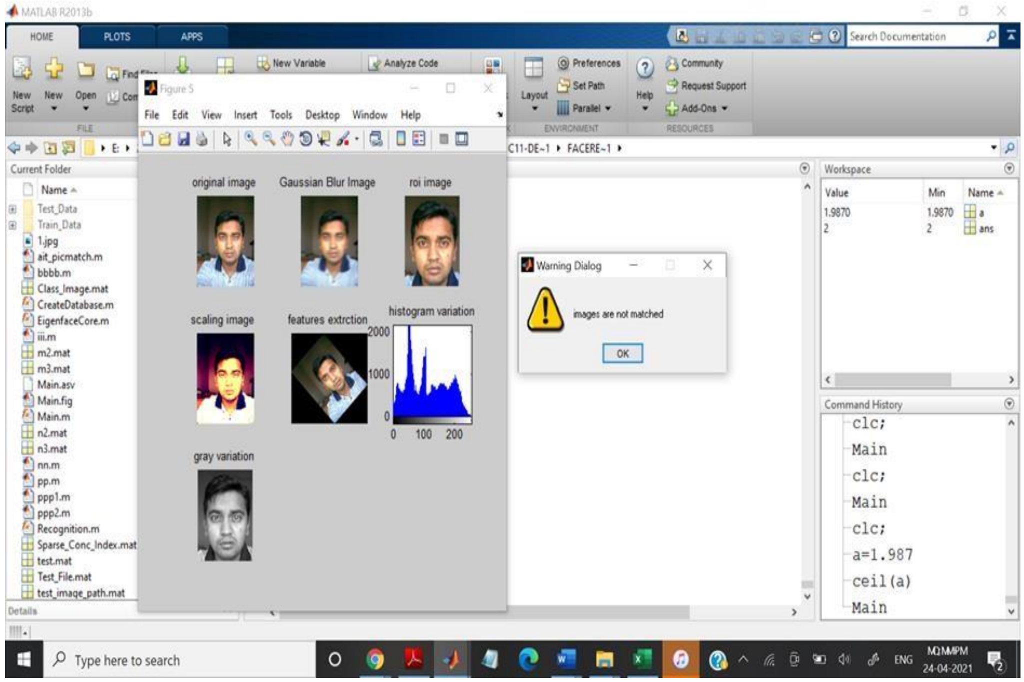

Figure 4-8 Result displaying Images are not Matched

5 PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Yale B+, CMU-PIE databases are selected to evaluate the performance of the method introduced in this project. Face recognition on those databases is still a challenging task owing to their complex lighting conditions. Yale B+ consists of 38 subjects under 64 lighting conditions. The CMU-PIE includes 68 subjects under 21 illumination conditions with a little hair and background in the face images.

Methods	CMU-PIE	Yale B+
PCA+SVM	72.53	85.78
LBP+SVM	80.52	92.16
DBN	84.36	93.61
LBP+DBN	90.12	95.17
PBLGLD	95.80	98.89

Figure 5-1 Overview of testing methods

The recognition rate of Proposed method Based on Log-Gabor, Local binary pattern and Deep belief network (PBLGLBD) is compared with the recognition rate of the methods based on LBP- DBN, DBN, LBP and SVM, PCA and SVM. The experimental selections of training sets and testing sets on Yale B+, and CMU-PIE are exactly the same as the previous experimental selections. The experiments of the PBLGLD and the LBP - DBN are under situations with the best partitioning way and the best hidden unit numbers. For these experimental methods, entire face images need to be directly input. The face recognition experiments are performed 20 times by each face recognition method, and the average of recognition rates

As shown in table above, for these experimental databases, Yale B+, and CMU-PIE, the proposed PBLGLD method can achieve the highest recognition rate on the face databases. The PBLGLD recognition rate is up to 95.80% on CMU-PIE and 98.89% on Yale B+ database. The proposed method has superior performance in face recognition by comparing with that of other methods. The proposed method has superior performance in face recognition by comparing with some state-of-the-arts.

6 CONCLUSION AND FUTURE ENHANCEMENT

This project presented a novel Robust regularized coding (RRC) model and an associated effective iteratively reweighted regularized robust coding (IR3C) algorithm for robust face recognition (FR). One important advantage of RRC is its robustness to various types of outliers (e.g., occlusion, corruption, expression, etc.) by seeking for an approximate MAP (maximum a posterior estimation) solution of the coding problem. By assigning adaptively and iteratively the weights to the pixels according to their coding residuals, the IR3C algorithm could robustly identify the outliers and reduce their effects on the coding process. Meanwhile, we have shown that the $l2$-norm regularization is as powerful as $l1$-norm regularization in RRC but the former has much lower computational cost.

The proposed RRC methods were extensively evaluated on FR with different conditions, including variations of illumination, expression, occlusion, corruption, and face validation. The experimental results clearly demonstrated that RRC outperforms significantly previous state-of-the-art methods, such as Sparse Representation Coding(SRC), correntropy based sparse representation (CESR) and Gradient-based sparse representation (GSRC). In particular, RRC with $l2$-norm regularization could achieve very high recognition rate but with low computational cost, which makes it a very good candidate scheme for practical robust Face Recognition systems.

It can be concluded that, compared with other algorithms, in the case of occlusion factors interfering with the model, the model does not lose stability, and can still distinguish the faces of different people very well, and the recognition rate is higher. In conclusion, compared with traditional algorithms, the algorithm proposed in the paper is more practical in face recognition with occlusion.

PUBLICATION

TITLE OF THE PAPER - Deep Learning For Face Recognition Under Complex Illumination Based On Log-gabor And Lbp

Paper ID - ICSMEC21-0040

Paper Accepted.

DECLARATION

We, the student of **'Bachelor of Technology in Department of Electronics and Communication Engineering'**, session: 2017 – 2021, **St. Martin's Engineering College**, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **'MOBILE CHARGING ON COIN INSERTION'** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

E.PRANEETH REDDY(17K81A04J0)
B.BALAJI (18K85A0427)
B.VAMSHI KRISHNA (17K81A04D6)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. HARI KRISHNA**, **Head &Professor**, the Dept. of Electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our dept. project **coordinator Dr.A.ANAND, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr. G.RAMESH,** Assistant Professor, Department of ECE and our calss project coordinator **Mr.K.NISHKAR**, Professor, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.A.ANAND**, **Professor and Dr. R. SANTHOSH KUMAR,** Associate professor **in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1) E.PRANEETH REDDY

2) B.BALAJI

3) B.VAMSHI KRISHNA

ABSTRACT

This is the smart coin based mobile charging system that charges your mobile for particular amount of time on inserting a coin. The system is to be used by shop owners, public places like railway stations to provide mobile charging facility. So the system consists of a coin recognition module that recognizes valid coins and then signals the microcontroller for further action. If a valid coin is found it signals the microcontroller and microcontroller then starts the mobile charging mechanism providing a 5V supply through a power supply section to the mobile phone, now system also needs to monitor the amount of charging to be provided. So the microcontroller starts a reverse countdown timer to display the charging time for that mobile phone. Now if the user inserts another coin in that time, the microcontroller adds the time to currently remaining charging time and starts the reverse countdown. So the system can be used for smart mobile charging at public places.

CHAPTER-1

INTRODUCTION

1.1. Introduction to the project:

The mobile phone market is a vast industry, and has spread into rural areas as an essential means of communication. While the urban populations use more sophisticated mobiles with good power batteries lasting for several days, the rural populations buy the pre-owned mobile phones that require charging frequently. Many times battery becomes flat in the middle of conversation particularly at inconvenient times when access to a standard charger isn't possible. The coin-based mobile battery chargers are designed to solve this problem. The user has to plug the mobile phone into one of the adapters and insert a coin; the phone will then be given a micro pulse for charging. It does not bring a mobile from 'dead' to fully charged state. The charging capacity of the mobile is designed with the help of pre-defined values. It is of course, possible to continue charging the mobile by inserting more coins. This compact and lightweight product is designed to cater for the growing number of rural mobile users worldwide. A suitable microcontroller is programmed for all the controlling applications. The source for charging is obtained from direct power grid.

CHAPTER-2

INTRODUCTION

2.1 INTRODUCTION ABOUT EMBEDDED SYSTEMS:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

2.1.1 Block Diagram of Embedded System:

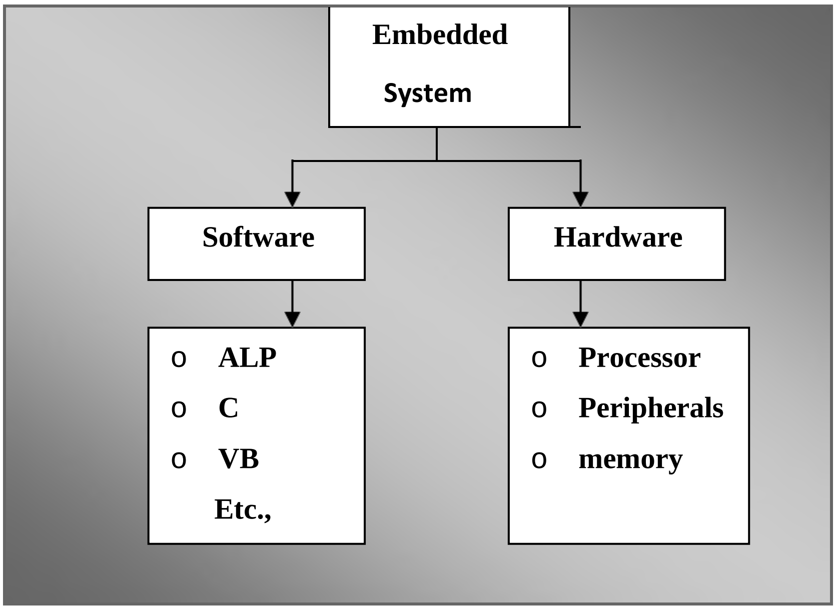

Fig.2.1: Block Diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

2.1.2 Applications of Embedded Systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

2.2 MICRO PROCESSOR (µP):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

2.2.1 Three Basic Elements of A Microprocessor:

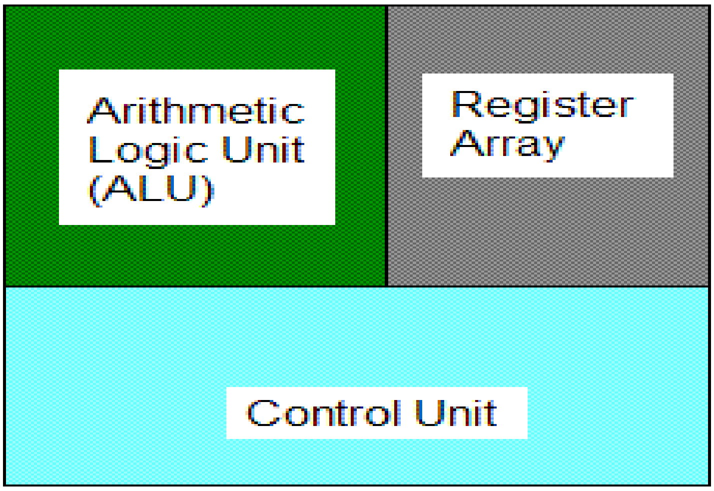

Fig.2.2: Three Basic Elements of a Microprocessor

2.3 HARVARD ARCHITECTURE:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data.

The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

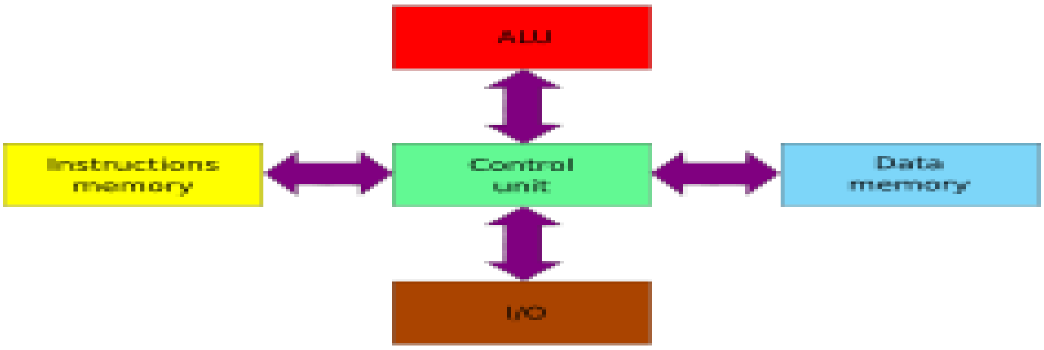

Fig.2.3: Harvard Architecture

2.3.1 Uses of The Harvard Architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access.
- The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.4 VON-NEUMANN ARCHITECTURE

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

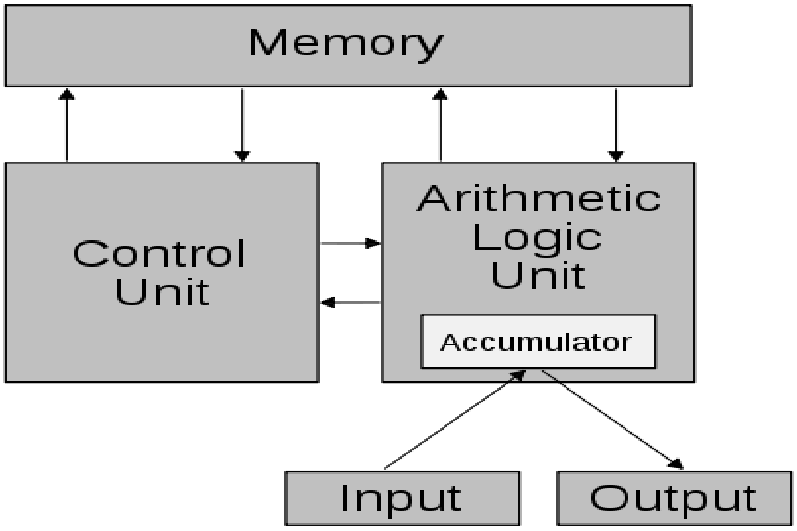

Fig.2.4: Schematic of the Von-Neumann Architecture

CHAPTER-3

LITERATURE SURVEY AND EXISTING METHODS

3.1 LITERATURE SURVEY

In 2017, Dhara G. Rangani, Nikunj V. Tahilramani [1] have presented mobile charging using coin in which their main focus was coin detection for which they have used cantilever type sensor for coin detection. Cantilever type sensor detects weight of 5 rupee coin and gives digital signal to ADC. Using this controller check whether coin is original or duplicate. They have also used solar power for charging the mobile station battery and used greed power when solar power is not available.

In May 2017, Mr. C V Raja Reddy, Uzoigwe Daniel, Rupesh Rai, Balaji R [2] have proposed coin based mobile charging with solar tracking in which their main focus was solar tracking for which they have used LDRs so according to the sunlight intensity LDR resistance will be varied. When the sun intensity is high then LDR offers less resistance, the voltage across each LDR is given to the ADC, then controller checks in accordance with the algorithm designed and rotates the motor in specified direction.

In 2015, Nupur Khera [3] have presented a solution to improve the charging and discharging control of battery. The solar charge controller will prevent the overcharging of the battery thus it will help to increase the life of battery. Solar charge controller will also prevent reverse flow of current from the batteries to the solar panels at night.

In 2013, S. B. Sridevi [4] have provided a solution to solar tracking. As sun rises in the east and sets in the west, So if the system cannot change the direction towards sun then it will not be able to consume maximum sunlight this makes the system inefficient.

3.2 EXISTING METHODS

The existing system in now a days is a payphone (alternative spelling: pay phone) is typically a coin-operated public telephone, often located in a telephone booth or in high-traffic outdoor areas, with pre-payment by inserting money (usually coins) or by billing a credit or debit card, or a telephone card. Prepaid calling cards also facilitate establishing a call by first calling the provided toll-free telephone number, entering the card account number and PIN, then the desired telephone number. An equipment usage fee may be charged as additional units, minutes or tariff fee to the collect/third-party, debit, credit, telephone or prepaid calling card when used at payphones. By agreement with the landlord, either the phone company pays rent for the location and keeps the revenue, or the landlord pays rent for the phone and shares the revenue.

Payphones are often found in public places to contribute to the notion of universal access to basic communication services.In the late 1920's the cost of a pay phone call was a paltry two cents. The 1930's calls were a nickel. By the time pay phones became extinct, the price of a call was fifty cents. [1] One thesis, written as early as 2003, recognised this as a digital divide problem.

In the 20th century, payphones in some countries, such as Spain, used token coins, available for sale at a local retailer, to activate pay phones, instead of legal tender coins. In some cases, these were upgraded to use magnetic cards or credit card readers over the years.

In the past, payphones were ubiquitous worldwide, but their prevalence has decreased significantly over the years due to the increasing availability of mobile phones.

3.3 PROPOSED SYSTEM

This proposed system will charge the mobile phone by inserting coin. For coin insertion we are using coin insertion module which will detect the inserted coin, if appropriate coin is detected then it will give the digital signal to the microcontroller otherwise it will refund the coin. Then the microcontroller will ON the respective relay for specific time interval according to the algorithm. This proposed system will not charge the mobile full from 0% to 100% but it will charge according to number of coins inserted. If we add more coins then time will also get added to the charging and reverse count down time will get displayed on LCD. This proposed system will also use the solar energy for charging the battery at mobile charging station and uses AC power supply as secondary source if sun is not available. We use solar tracking system for maximum utilization of solar energy using LDRs. As we are using 12V battery for storing the solar energy so to protect the battery from over voltage we are using charge controller circuit. If battery voltage exceeds 13.5V then charge controller will automatically cut off the supply to the battery and hence battery will get saved from damage to over voltage.

CHAPTER-4

PROJECT DISCRIPTION

4.1Block diagram:

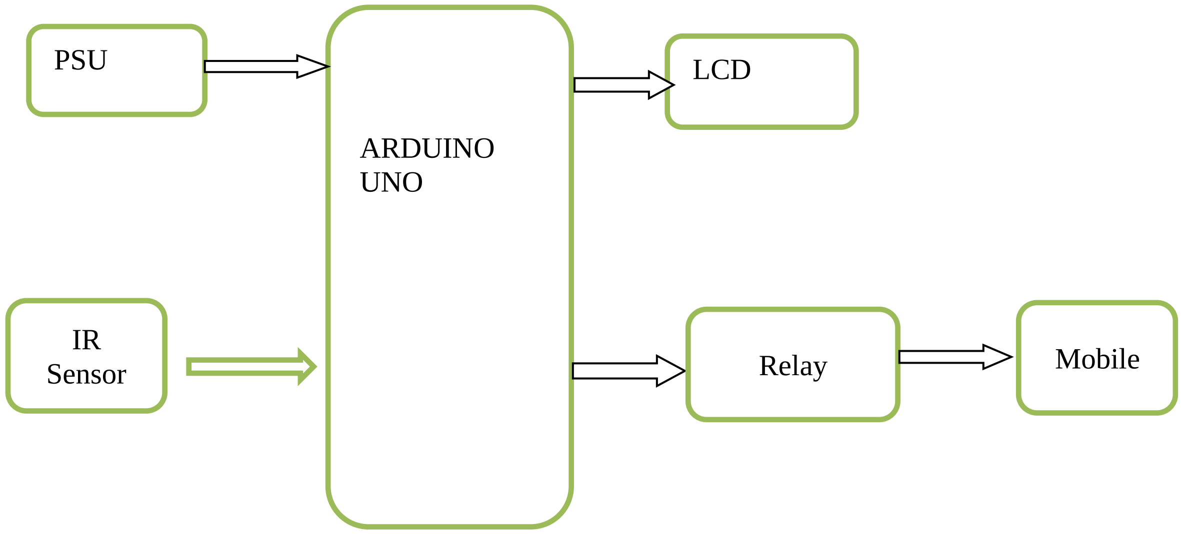

Fig.4.1: Block diagram of the project

4.1.1Components Required

Hardware Requirement:

- Arduino Uno
- Coin Sensor
- DC Regulation
- Coin Module
- LCD
- Power Supply

Software Components:

- Arduino IDE
- Proteous

Arduino Uno

- Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software.

- It consists of a circuit board, which can be programed (referred to as a microcontroller) in a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.
- An Arduino has 17 different kind of pins which have their own operation and every pin has its own importance equally with others.

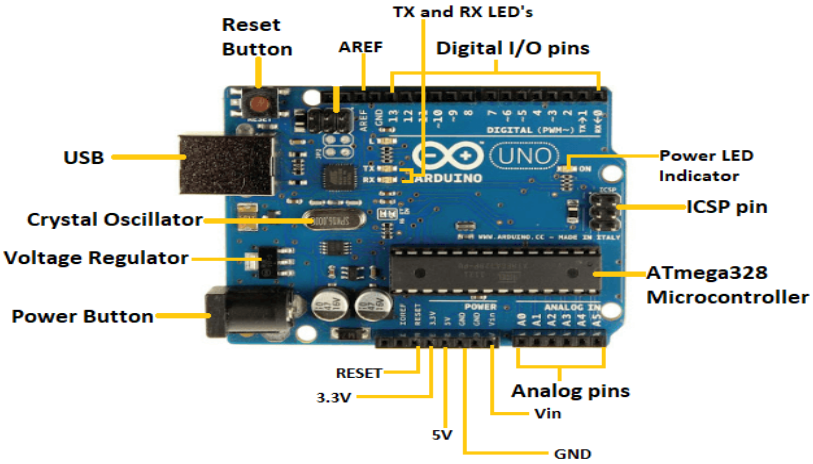

Fig.4.2: Aurdino Uno

Coin Module

- The coin acceptor device accepts the coin through coin insertion slot.
- The sensor inside the coin acceptor device will recognizeand validate the coin based on the coin diameter.
- When the inserted coin is validated, it sends signal to the Arduino for powersupply otherwise the coin will be returned back.

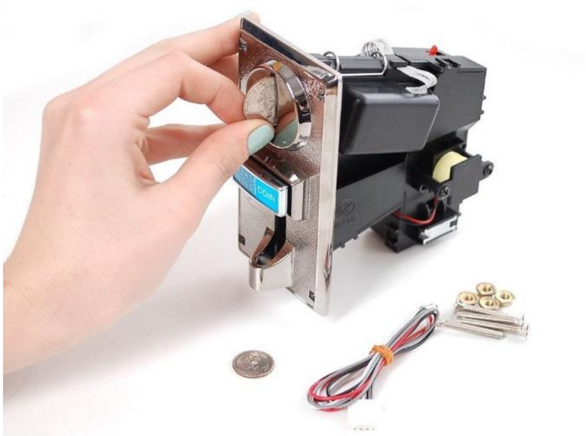

Fig.4.3: Coin Module

IR Sensor

- An infrared (IR) sensor is an electronic device that measures and detects infrared radiation in its surrounding environment.
- When an object comes close to the sensor, the infrared light from the LED reflects off of the object and is detected by the receiver

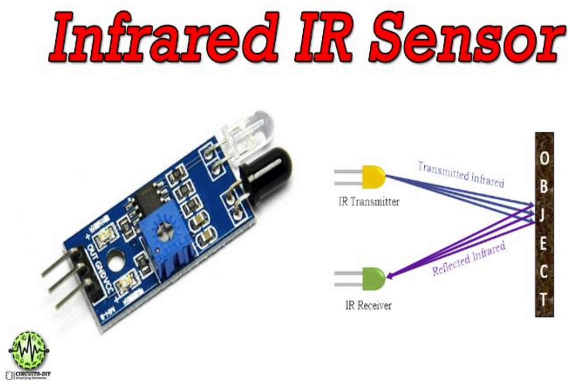

Fig.4.4: IR Sensor

Relay

- A relay is an electrically operated switch.
- Relay controlone electrical circuit by opening and closing contacts in another circuit.
- As relay diagrams show, when a relay contact is normally open (NO), there is an open contact then the relay is not energized.
- When a relay contact is Normally Closed (NC), there is a closed contact then the relay is energized.
- Relays are used throughout the automobile.
- Applications of relay are used as remote control switches.
- A typical vehicle can have 20 relays or more

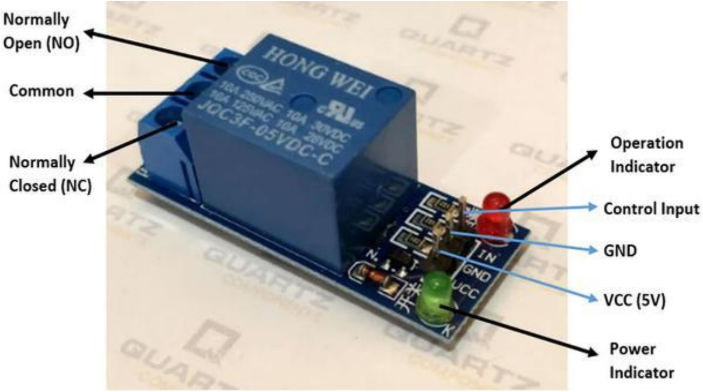

Fig.4.5: Relay

Liquid Crystal Display(LCD)

- A liquid-crystal display is a flat-panel display or other electronically modulated optical device that uses the light-modulating properties of liquid crystals combined with polarizers.
- Liquid crystals do not emit light directly,instead using a backlight or reflector to produce images in color .

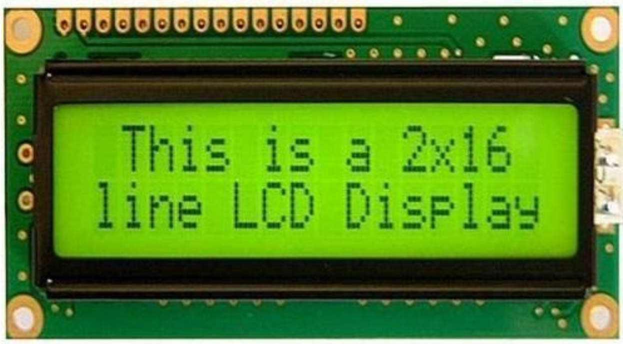

Fig.4.6: Liquid Crystal Display(LCD)

Buzzar

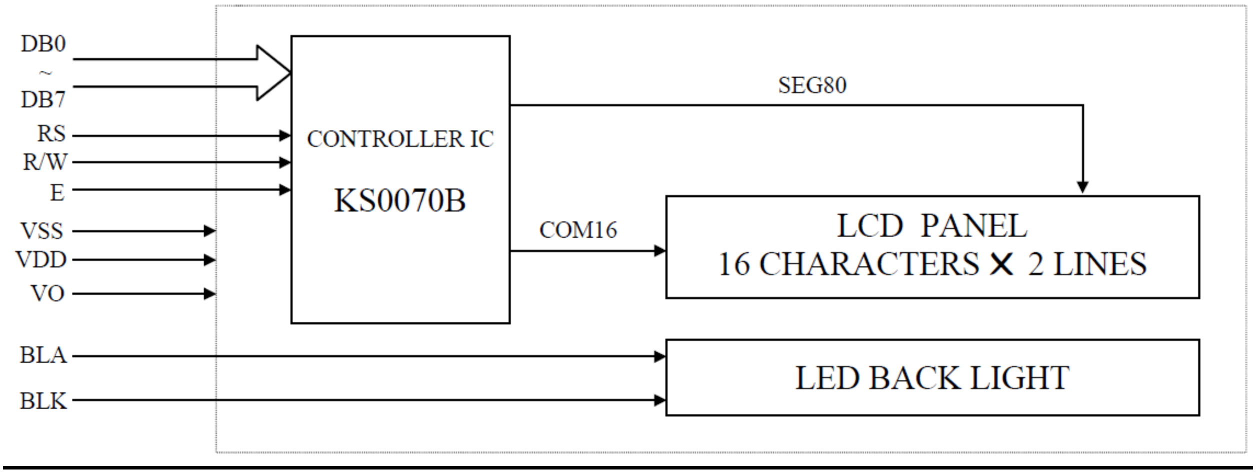
- A buzzer or beeper is an audio signalling device.
- which may be mechanical, electromechanical, or piezoelectric.
- Typical uses of buzzers and beepers include alarm devices, timers, and confirmation of user input such as a mouse click or keystroke.

4.2 16 * 2 Alphanumeric LCD

4.2.1 Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

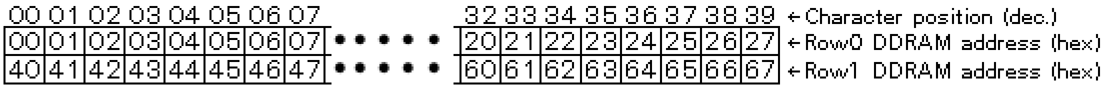
4.2.2 Block Diagram



4.2.3 Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

4.2.4 Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. Userdefined character patterns are also available by mask-programmed ROM.

4.2.5 Busy Flag

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact ammount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

4.2.6Instruction Register(IR) and Data Register(DR)

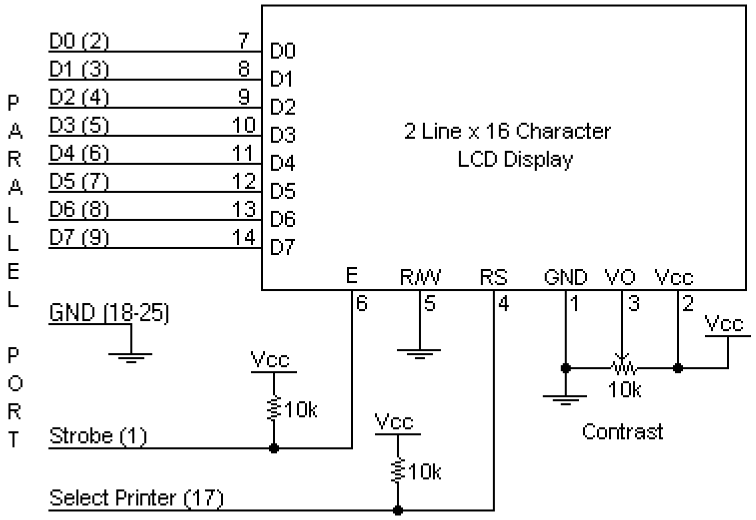
There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.2.7 16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line

- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

4.3 Schematic

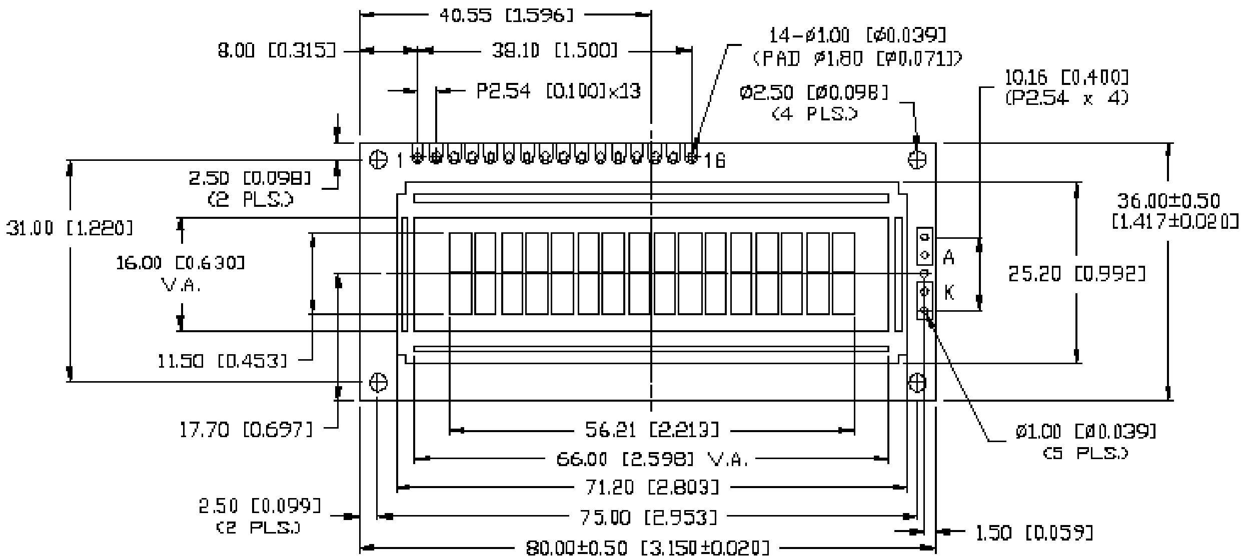


4.4 Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a "1" on the back of the PCB. Do not get confused by this.



4.5 Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

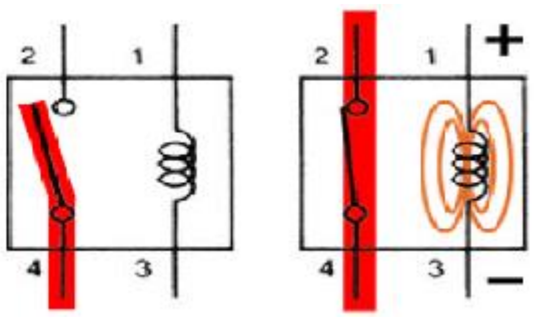
4.6 IR TRANSMITTER & RECEIVER:

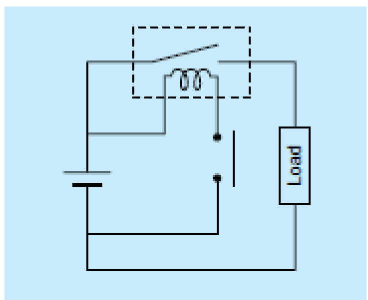
- IR stands infrared red spectrum, by using this region we can detect numbert of obstacles passing through a region.
- IR consists of two sections one is transmitter section and other is receiver section.

- Transmitter section:it consists of a LED which continuosly transmits a modulated signalof range(40 to 250khz).
- Receiver section: Receiver section consists of a photo diode it will continuosly track and receive the ir rays from LED
- Functionality: The IR transmitter will continuosly transmit IR rays and receiver (photo diode) will continuosly receive the rays whenever some obstacle passes through the IR pair the tansmission will be breaked by which we come to know that an intruder have been detected. In this way this communication will help us in safeguarding and many other applications.

4.7 Relays

A relay is an electrically operated switch. These are remote control electrical switches that are controlled by another switch, such as a horn switch or a computer as in a power train control module, devices in industries, home based applications. Relays allow a small current pin, 4-pin, 5-pin, and 6-pin, single switch or dual switches. Relays are used throughout the automobile. Relays which come in assorted sizes, ratings, and applications, are used as remote control switches. A typical vehicle can have 20 relays or more.





4.7.1 BASICS ON RELAY HANDLING

- To maintain initial performance, care should be taken to avoid dropping or hitting the relay.
- Under normal use, the relay is designed so that the case will not detach. To maintain initial performance, the case should not be removed. Relay characteristics cannot be guaranteed if the case is removed.
- Use of the relay in an atmosphere at standard temperature and humidity with minimal amounts of dust, SO 2, H 2 S, or organic gases is recommended.
- Please avoid the use of silicon-based resins near the relay, because doing so may result in contact failure. (This applies to plastic sealed type relays, too.)
- Care should be taken to observe correct coil polarity (+, –) for polarized relays.
- Proper usage requires that the rated voltage be impressed on the coil. Use rectangular waves for DC coils and sine waves for AC coils.
- Be sure the coil impressed voltage does not continuously exceed the maximum allowable voltage.
- Absolutely avoid using switching voltages and currents that exceed the designated values.
- The rated switching power and life are given only as guides. The physical phenomena at the contacts and contact life greatly vary depending on the type of load and the operating conditions. Therefore, be sure to carefully check the
- type of load and operating conditions before use.
- Do not exceed the usable ambient temperature values listed in the catalog.
- Use the flux-resistant type or sealed type if automatic soldering is to be used.
- Use alcohol based cleaning solvents when cleaning is to be performed using a
sealed type relay.
- Avoid ultrasonic cleaning of all types of relays.
- Avoid bending terminals, because it may cause malfunction.
- As a guide, use a Faston mounting pressure of 40 to 70N {4 to 7kgf}for relay with tab terminals.

A relay is used to isolate one electrical circuit from another. It allows a low current control circuit to make or break an electrically isolated high current circuit path. The basic relay consists of a coil and a set of contacts. The most common relay coil is a length of magnet wire wrapped around a metal core. When voltage is applied to the coil, current passes through the wire and creates a magnetic field. This magnetic field pulls the contacts together and holds them there until the current flow in the coil has stopped. The diagram below shows the parts of a simple relay.

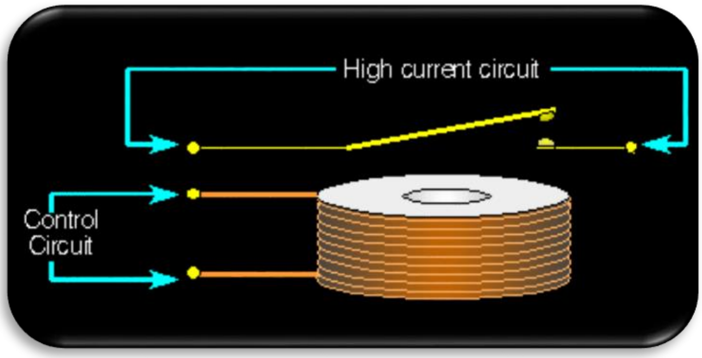


Fig.4.7: Relay

4.7.2 Operation:

When a current flows through the coil, the resulting magnetic field attracts an armature that is mechanically linked to a moving contact. The movement either makes or breaks a connection with a fixed contact. When the current is switched off, the armature is usually returned by a spring to its resting position shown in figure 6.6(b). Latching relays exist that require operation of a second coil to reset the contact position.

By analogy with the functions of the original electromagnetic device, a solid-state relay operates a thyristor or other solid-state switching device with a transformer or light-emitting diode to trigger it.

4.7.3 Pole and throw

Since relays are switches the terminology applied to switches is also applied to relays. A relay will switch one or more *poles*, each of whose contacts can be *thrown* by energizing the coil in one of three ways:

- Normally-open (**NO**) contacts connect the circuit when the relay is activated; the circuit is disconnected when the relay is inactive. It is also called a **Form A** contact or "make" contact.
- Normally-closed (**NC**) contacts disconnect the circuit when the relay is activated; the circuit is connected when the relay is inactive. It is also called a **Form B** contact or "break" contact.
- Change-over (**CO**), or double-throw (**DT**), contacts control two circuits: one normally-open contact and one normally-closed contact with a common terminal. It is also called a **Form C** contact or "transfer" contact ("break before make"). If this type of contact utilizes a "make before break" functionality, then it is called a **Form D** contact.

4.7.4 SPST

SPST relay stands for Single Pole Single Throw relay. Current will only flow through the contacts when the relay coil is energized.

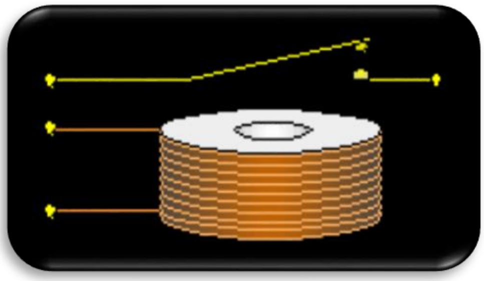

Fig.4.8: SPST Relay

4.7.5 SPDT Relay

SPDT Relay stands for Single Pole Double Throw relay. Current will flow between the movable contact and one fixed contact when the coil is De-energized and between the movable contact and the alternate fixed contact when the relay coil is energized. The most commonly used relay in car audio, the Bosch relay, is a SPDT relay.

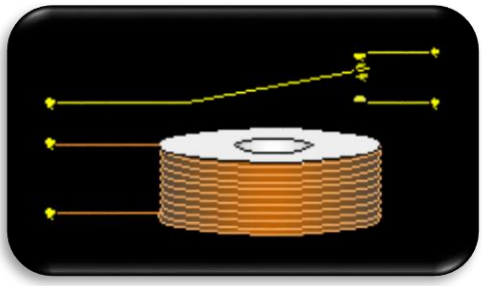

Fig4.9: SPDT Relay

4.7.6 DPST Relay

DPST relay stands for Double Pole Single Throw relay. When the relay coil is energized, two separate and electrically isolated sets of contacts are pulled down to make contact with their stationary counterparts. There is no complete circuit path when the relay is De-energized.

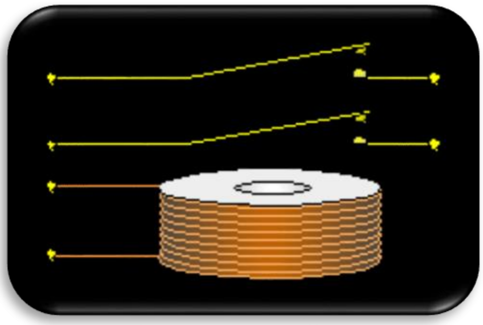

Fig.4.10: DPST Relay

4.7.7 DPDT Relay

DPDT relay stands for Double Pole Double Throw relay. It operates like the SPDT relay but has twice as many contacts. There are two completely isolated sets of contacts.

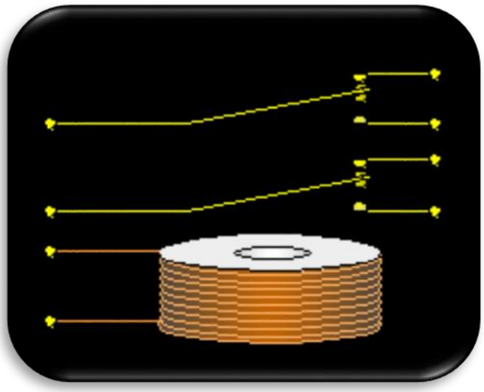

Fig.4.11: DPDT Relay

This is a 4 Pole Double Throw relay. It operates like the SPDT relay but it has 4 sets of isolated contacts.

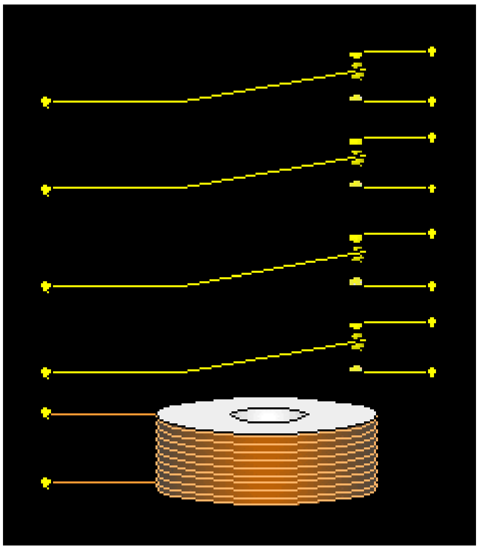

Fig.4.12: 4 Pole Double Throw relay

4.8 Types of relay:

- Latching Relay
- Reed Relay
- Mercury Wetted Relay
- Machine Tool Relay
- Solid State Relay (SSR)

4.8.1 Latching relay

Latching relay, dust cover removed, showing pawl and ratchet mechanism. The ratchet operates a cam, which raises and lowers the moving contact arm, seen edge-on just below it. The moving and fixed contacts are visible at the left side of the image.

A **latching relay** has two relaxed states (bi-stable). These are also called "impulse", "keep", or "stay" relays. When the current is switched off, the relay remains in its last state. This is achieved with a solenoid operating a ratchet and cam mechanism, or by having two opposing coils with an over-center spring or permanent magnet to hold the armature and contacts in position while the coil is relaxed, or with a remanent core. In the ratchet and cam example, the first pulse to the coil turns the relay on and the second pulse turns it off. In the two coil example, a pulse to one coil turns the relay on and a pulse to the opposite coil turns the relay off. This type of relay has the advantage that it consumes power only for an instant, while it is being switched, and it retains its last setting across a power outage. A remanent core latching relay requires a current pulse of opposite polarity and change state.

Fig.4.13: Latching

4.8.2 Reed relay

A reed relay has a set of contacts inside a vacuum or inert gas filled glass tube, which protects the contacts against atmospheric corrosion. The contacts are closed by a magnetic field generated when current passes through a coil around the glass tube. Reed relays are capable of faster switching speeds than larger types of relays, but have low switch current and voltage ratings.

4.8.3 Mercury-wetted relay

A mercury-wetted reed relay is a form of reed relay in which the contacts are wetted with mercury. Such relays are used to switch low-voltage signals (one volt or less) because of their low contact resistance, or for high-speed counting and timing applications where the mercury eliminates contact bounce. Mercury wetted relays are position-sensitive and must be mounted vertically to work properly. Because of the toxicity and expense of liquid mercury, these relays are rarely specified for new equipment. See also mercury switch.

4.8.4 Machine tool relay

A machine tool relay is a type standardized for industrial control of machine tools, transfer machines, and other sequential control. They are characterized by a large number of contacts (sometimes extendable in the field) which are easily converted from normally-open to normally-closed status, easily replaceable coils, and a form factor that allows compactly installing many relays in a control panel. Although such relays once were the backbone of automation in such industries as automobile assembly, the programmable logic controller (PLC) mostly displaced the machine tool relay from sequential control applications.

4.8.5 Solid-state relay

A solid state relay (SSR) is a solid state electronic component that provides a similar function to an electromechanical relay but does not have any moving components, increasing long-term reliability. With early SSR's, the tradeoff came from the fact that every transistor has a small voltage drop across it. This voltage drop limited the amount of current a given SSR could handle. As transistors improved, higher current SSR's, able to handle 100 to 1,200 Amperes, have become commercially available. Compared to electromagnetic relays, they may be falsely triggered by transients.

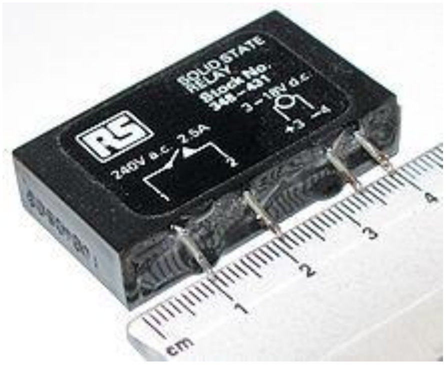

Fig.4.14: Solid relay, which has no moving parts

4.9 Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current
- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

4.10Applications:

Relays are used:

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems.

- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile.
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.
- To perform time delay functions. Relays can be used to act as an mechanical time delay device by controlling the release time by using the effect of residual magnetism by means of a inserting copper disk between the armature and moving blade assembly.

CHAPTER-5

HARDWARE AND SOFTWARE COMPONENTS

MICRO CONTROLLER UNIT

5.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 Analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Table.5.1: Atmega328 Specifications

5.1.1Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

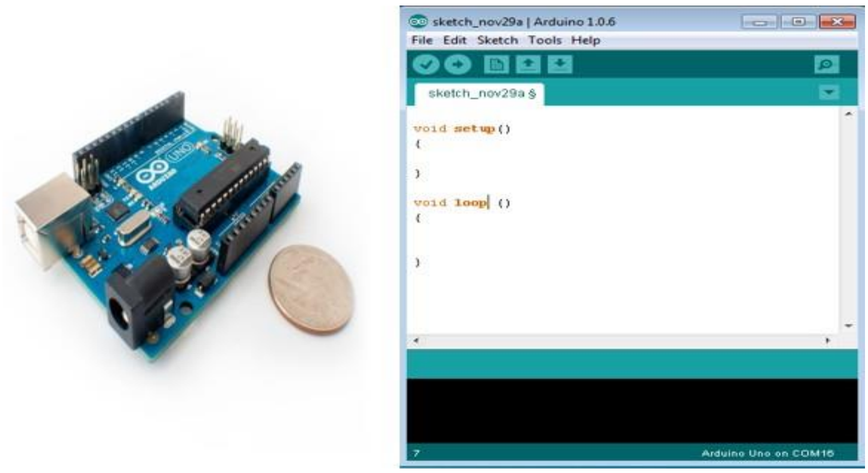

Fig.5.1: Arduino Uno

5.1.2 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

ATMEGA328:

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati

LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

5.1.3 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

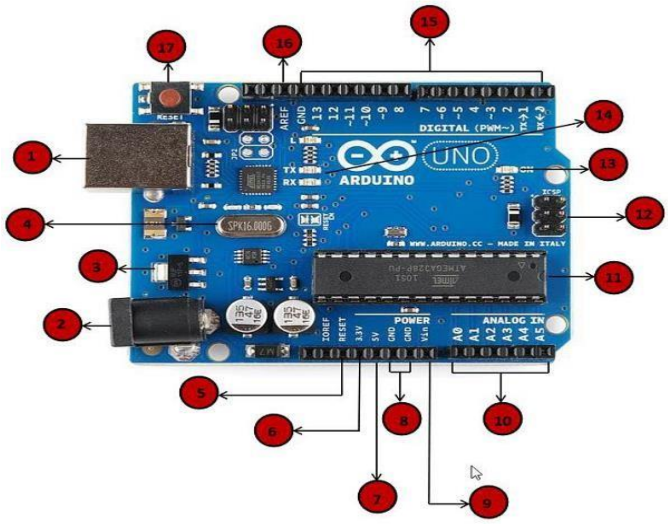

Fig.5.2: Arduino Uno Board Pins

Pin number and Pin Use

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.

4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC.

	For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table.5.6: Pin Explanation of Arduino

5.1.4Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

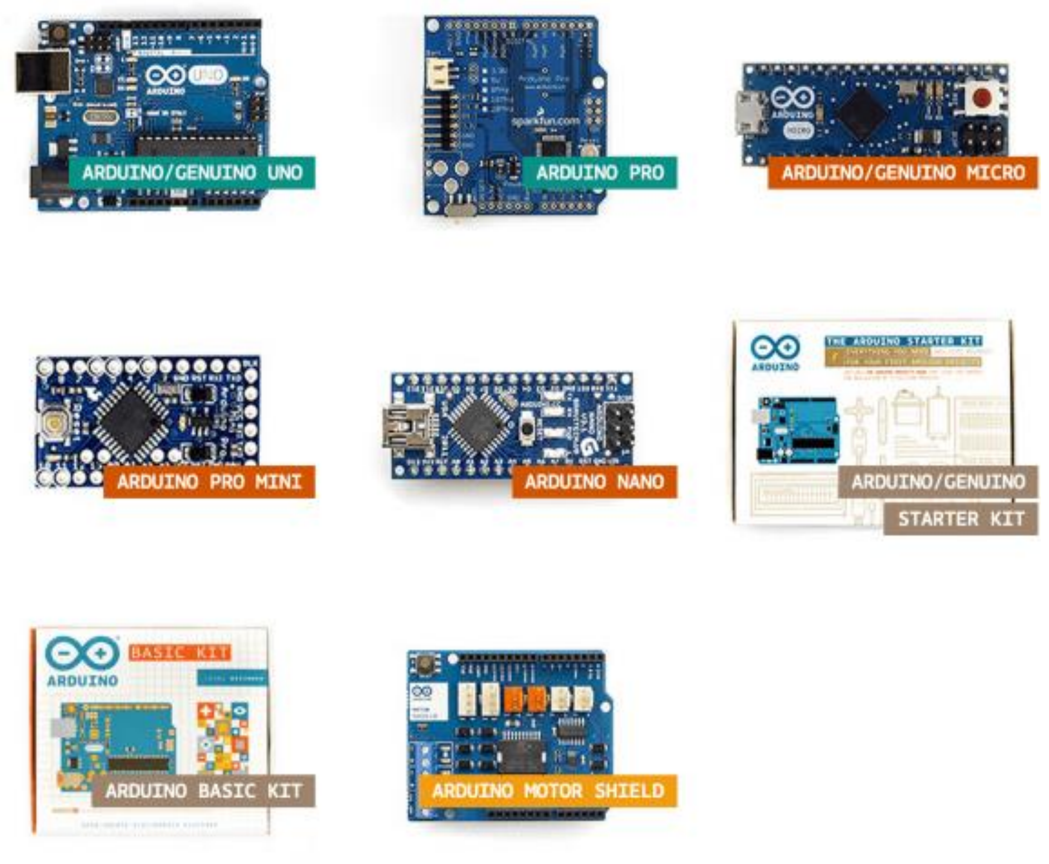

Fig.5.3: Arduino Family

5.1.5 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

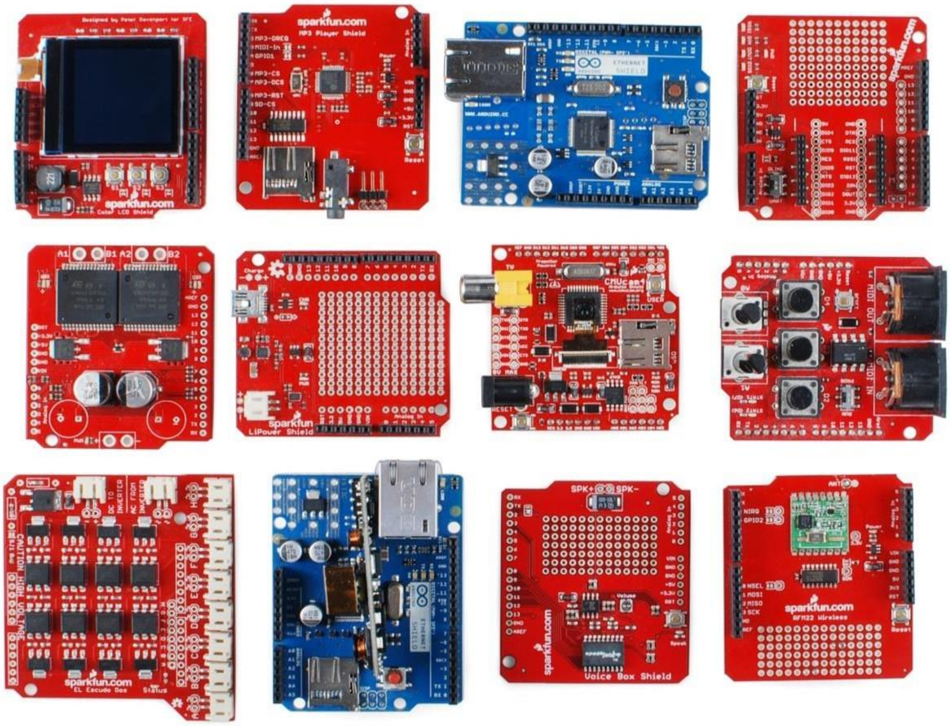

Fig.5.4: Arduino Shields

5.1.6 Pin Description Of Atmega328

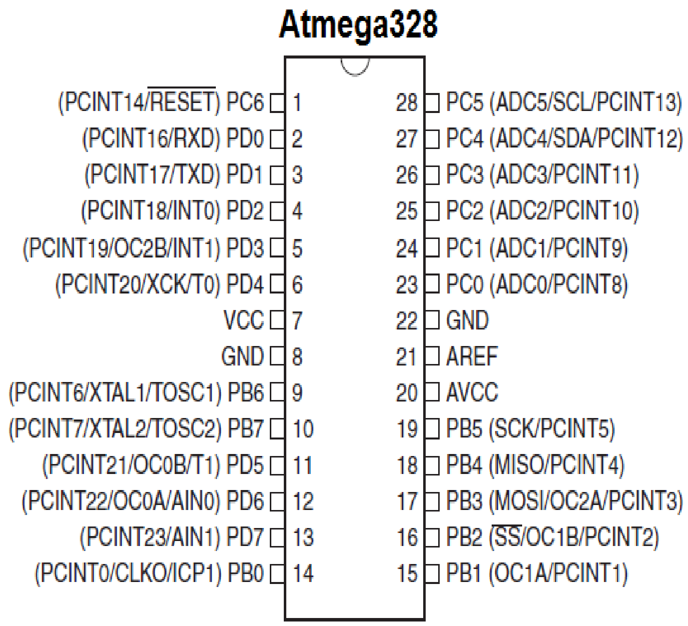

Fig.5.5: Pin Description Of ATMEGA328

5.1.7 Advantages Of Arduino

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

5.1.8 Applications

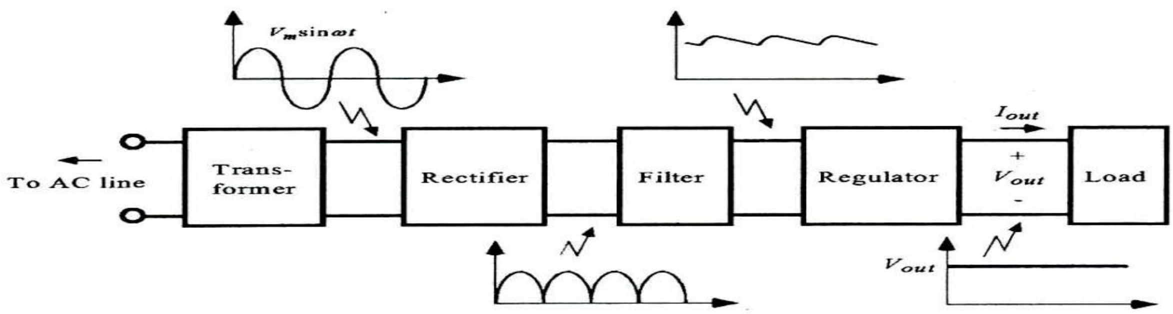
ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

5.2 POWER SUPPLY UNIT

5.2.1 Introduction:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices.A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

Block Diagram Of Power Supply:



Components of a typical linear power supply

Fig.5.6: (a) Block Diagram of Power Supply

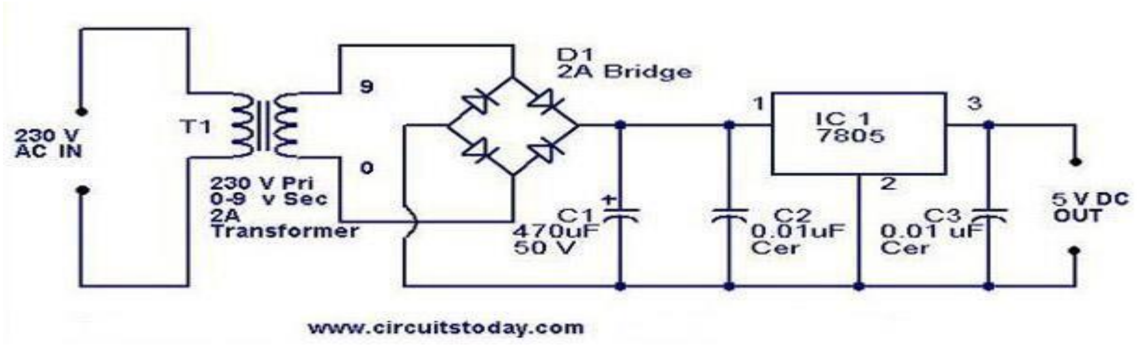


Fig.5.6: (b) Schematic Diagram of Power Supply

Description Of Power Supply:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

5.2.2Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

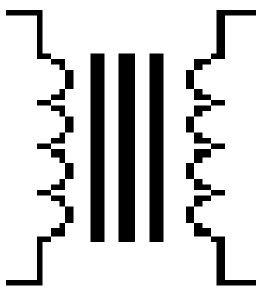

Fig.5.7: (a) Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a tranducer

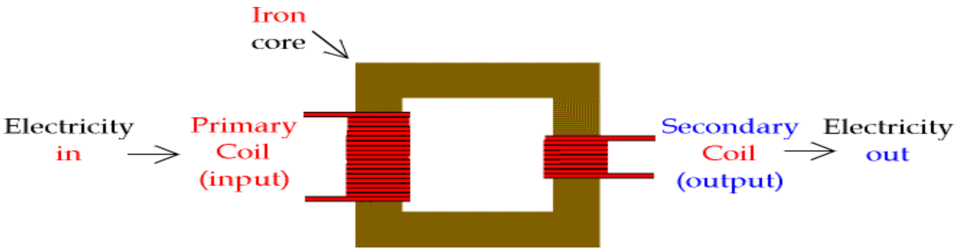

Fig.5.7: (b) Transformer

- **Basic Principle Of Transformer:**

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

- **Working Of Transformer:**

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below.There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

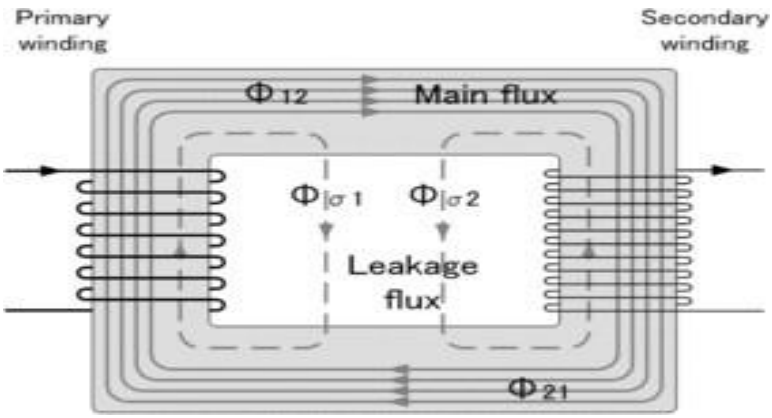

Fig.5.8: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced EMF. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1.They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2.Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

- **Classification Of Transformer:**

  - Step-Up Transformer
  - Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltageapplied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down

transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

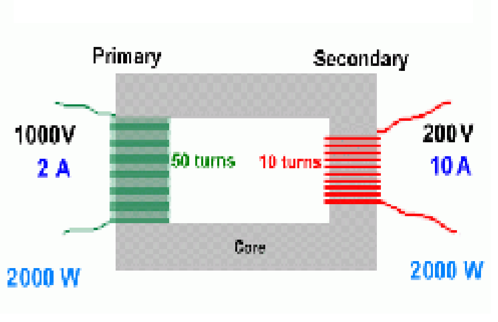

Fig.5.9: (a) Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated.Because of this it is possible to do some non-standard applications using standard transformer.single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.

- **Step-Up Transformer:**

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

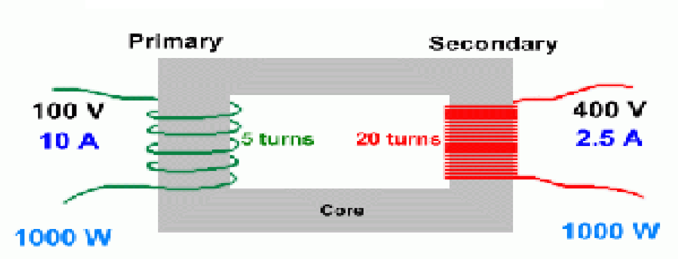

Fig.5.9: (b) Step-Up Transformer

- **Diodes:**

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valve.

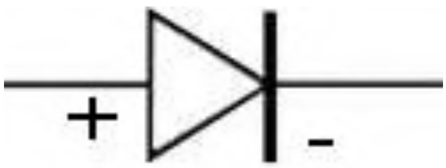

Fig.5.10: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

- **Rectifier:**

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

- o **The Half-Wave Rectifier:**

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

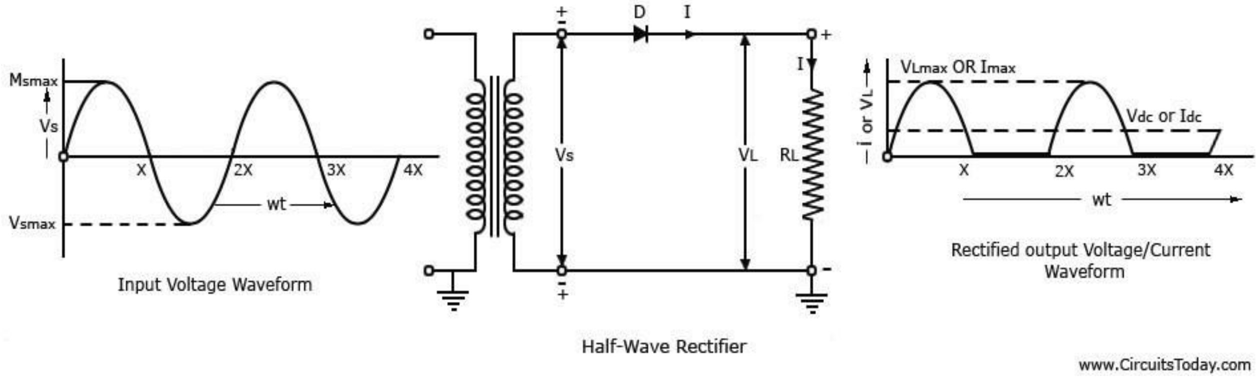

Fig.5.11: (a) Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

- o **The Full-Wave Rectifier:**

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

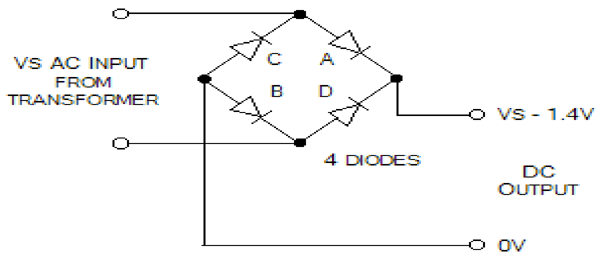

Fig.5.11: (b) Full Wave Rectifier

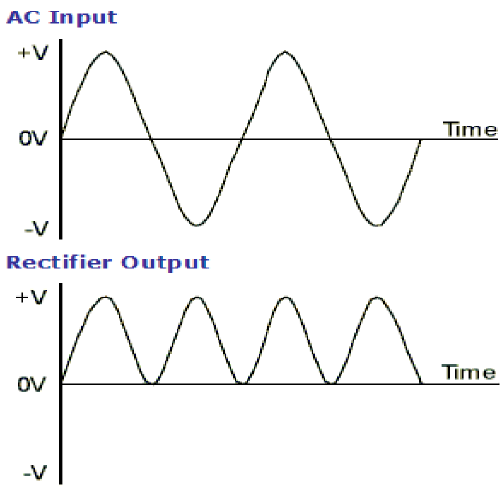

Fig.5.11: (c) Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

- **Capacitor Filter:**

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

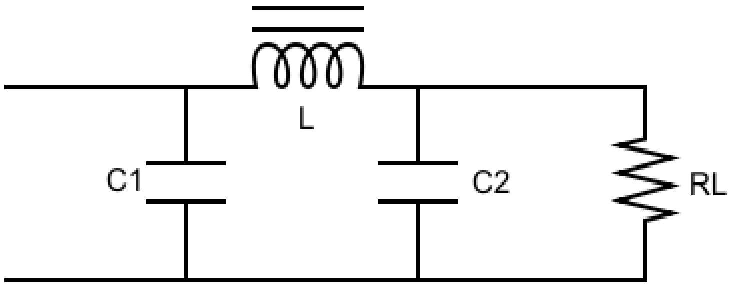

Fig.5.12: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

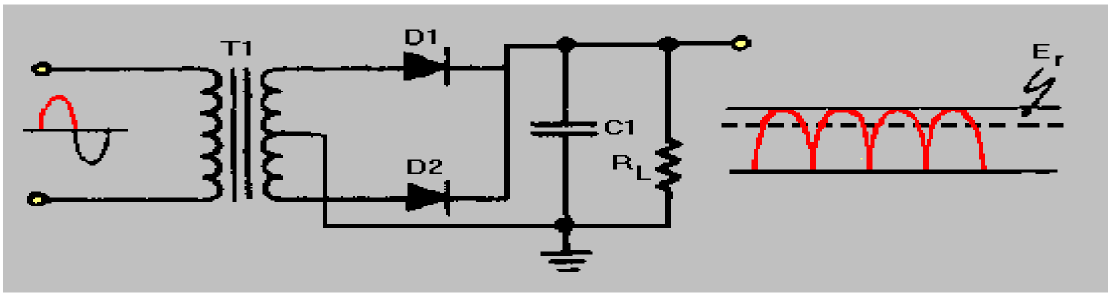

Fig.5.13: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

Voltage Regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages.

There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:’78’ indicate the positive series and ‘xx’ indicates the voltage rating. Suppose 7805 produces the maximum 5V.’05’indicates the regulator output is 5V.

79xx:’78’ indicate the negative series and ‘xx’ indicates the voltage rating. Suppose 7905 produces the maximum -5V.’05’indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

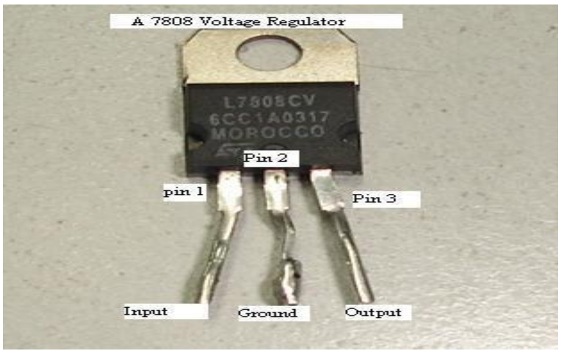

Fig.5.14: Regulator

5.3 SOFTWARE EXPLANATION:

- **Software Requirements**
  - Proteus simulation
  - Arduino software
  - Programming language

5.3.1Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike.

Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IOT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

5.3.2 Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux.

Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments.Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you
want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- Download the Arduino Software(IDE)
- Proceed with board specific instructions.

5.3.3How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

- **Installation:**

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1

First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following imag.

e.

s

Fig.5.15: (a) Standard USB Cable

Fig.5.15: (b) USB cable A to Mini-B

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

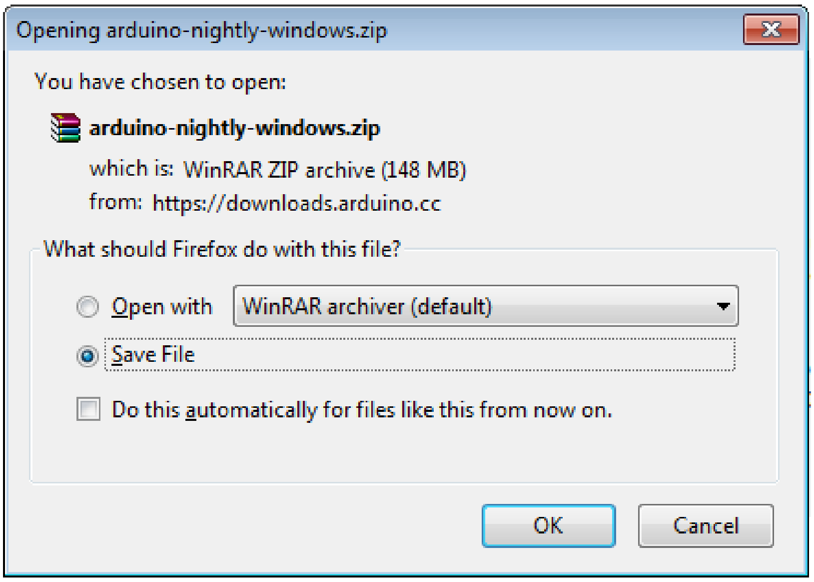

Fig.5.16: Process of Downloading the Arduino

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply.

If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe).

Double-click the icon to start the IDE.

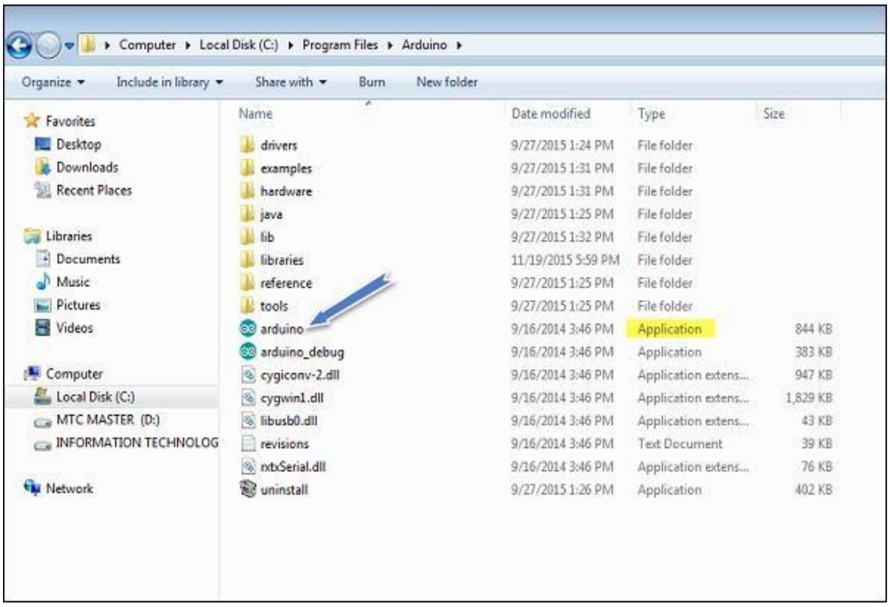

Fig.5.17: Launching Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

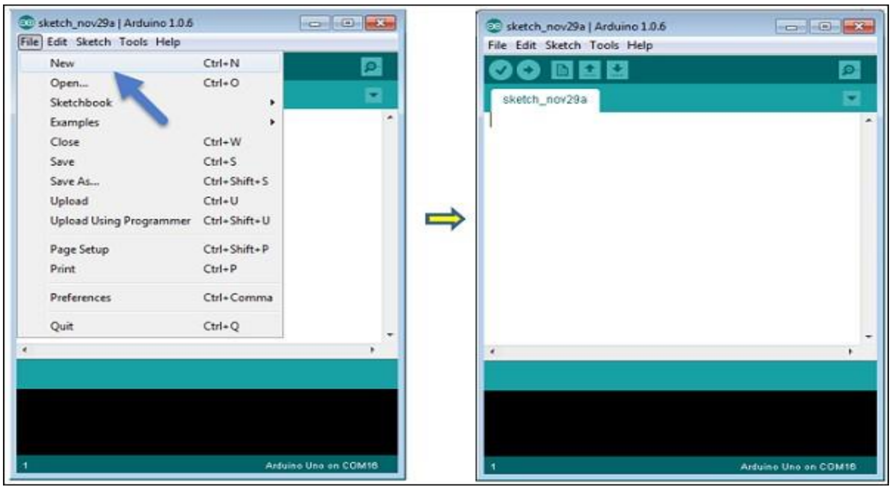

Fig.5.18: Opening Editor Window in IDE

To open an existing project example, select File → Example → Basics → Blink.

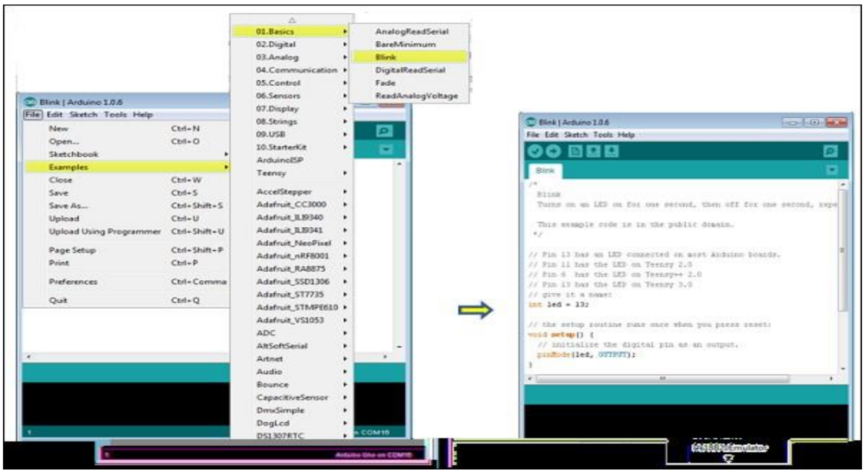

Fig.5.19: Opening Existing File in IDE

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

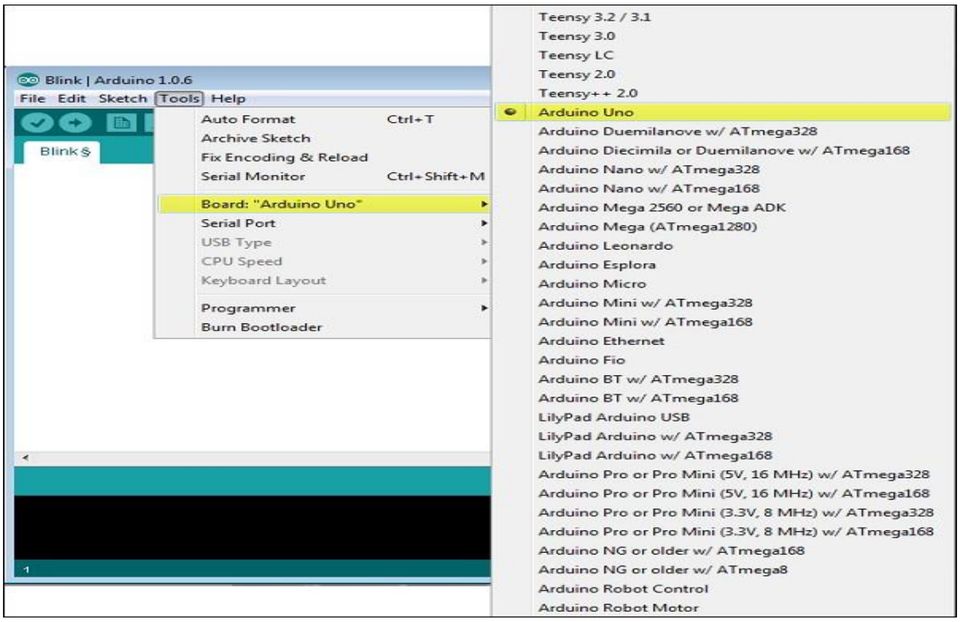

Fig.5.20: Selecting Arduino Board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports).

To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

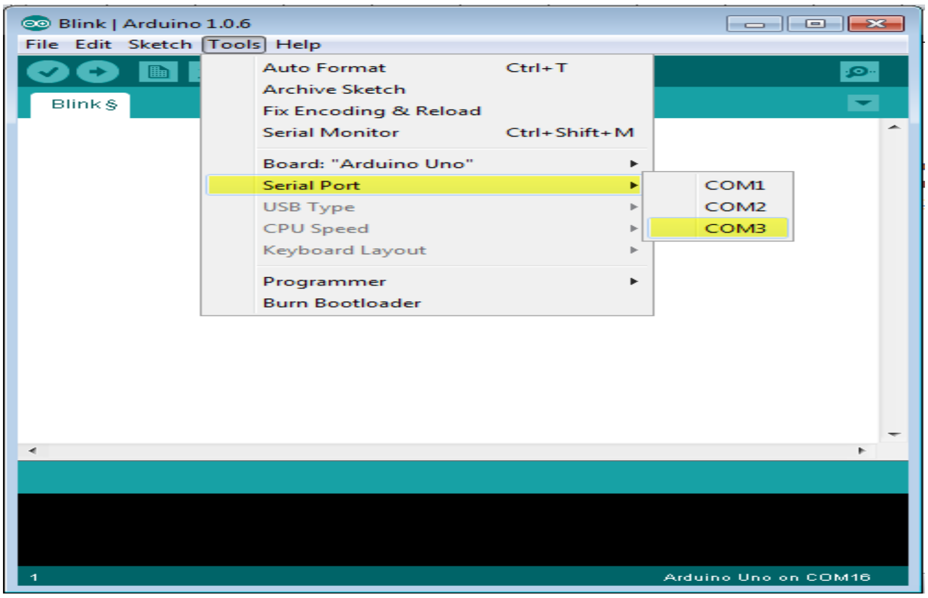

Fig.5.21: Selecting Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

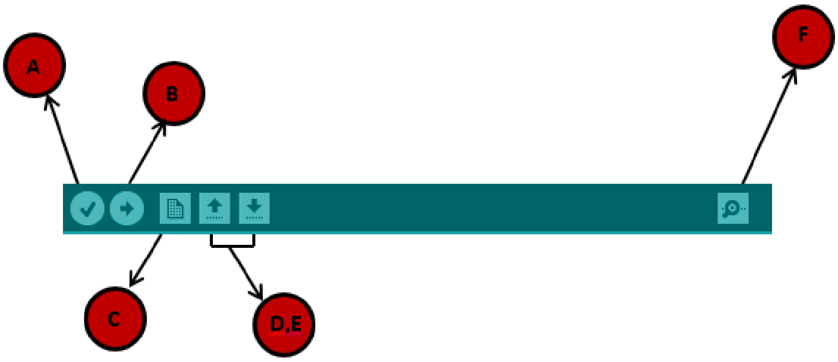

Fig.5.22: IDE Tool Bar

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

5.3.4 Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

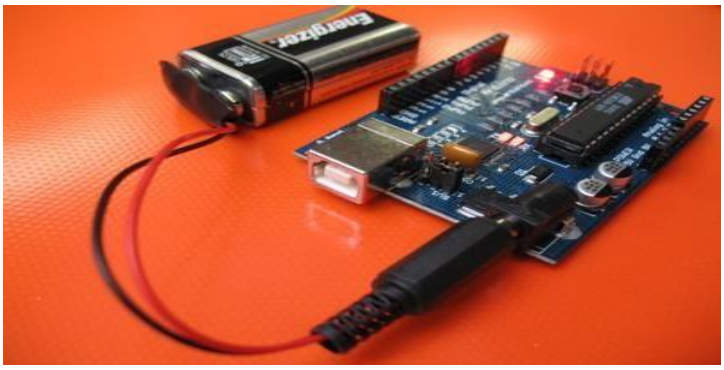

Fig.5.23: Arduino with Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program show in Figure:4.66, paying attention to where semi-colons appear at the end of command lines.

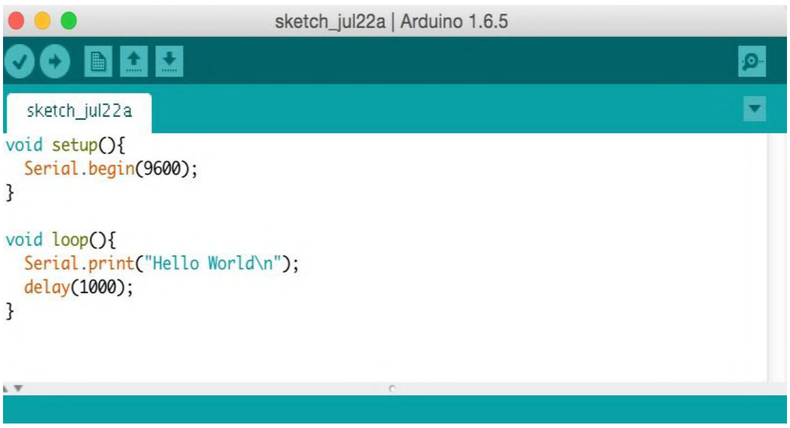

Fig.5.24: Writing the Program in IDE

5.4 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming embedded Systems.There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

5.5 Proteus:

5.5.1 Proteus:

Proteus is a simulation and design software tool developed by Lab Centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

5.5.2 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

5.5.3 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components.

It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

5.5.4 Starting New Design

Step 1: Open ISIS software and select new design in File menu

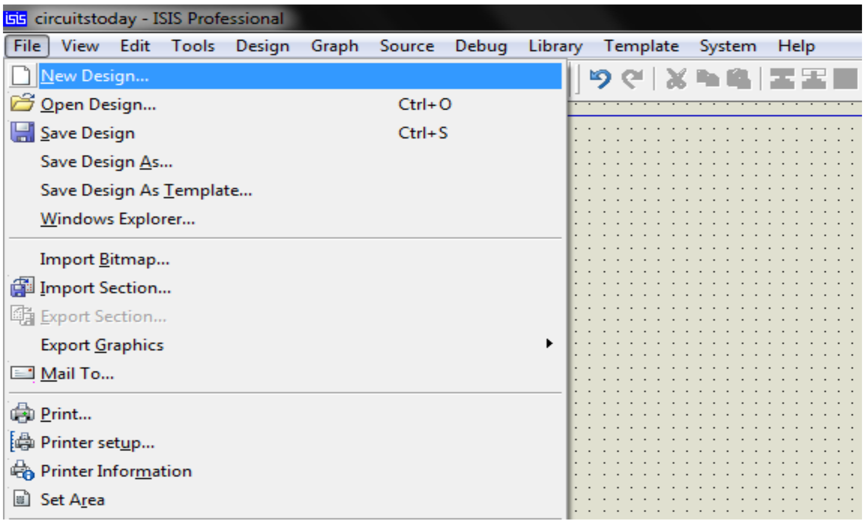

Fig.5.25: Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

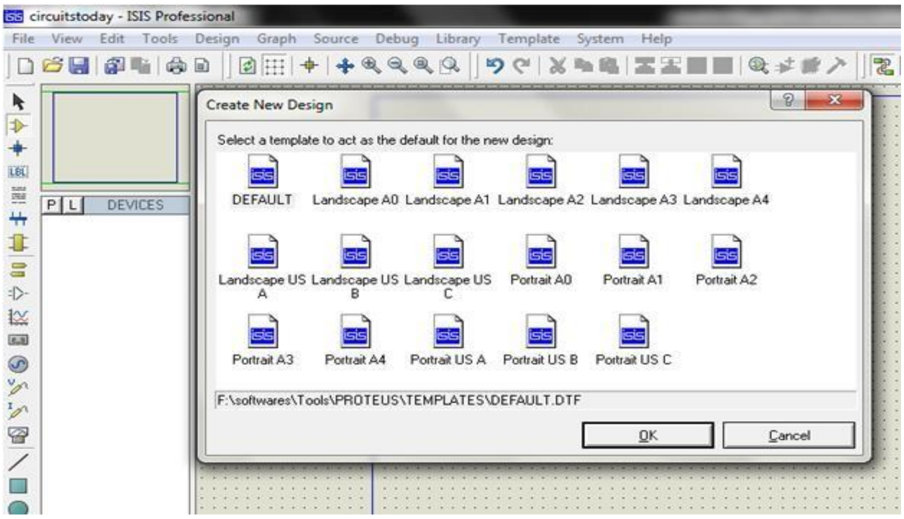

Fig.5.26: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

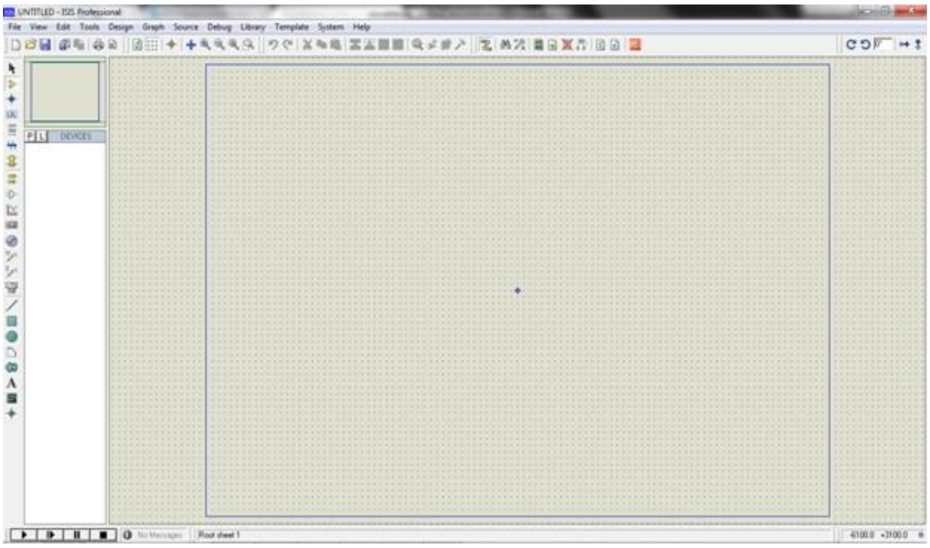

Fig.5.27: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

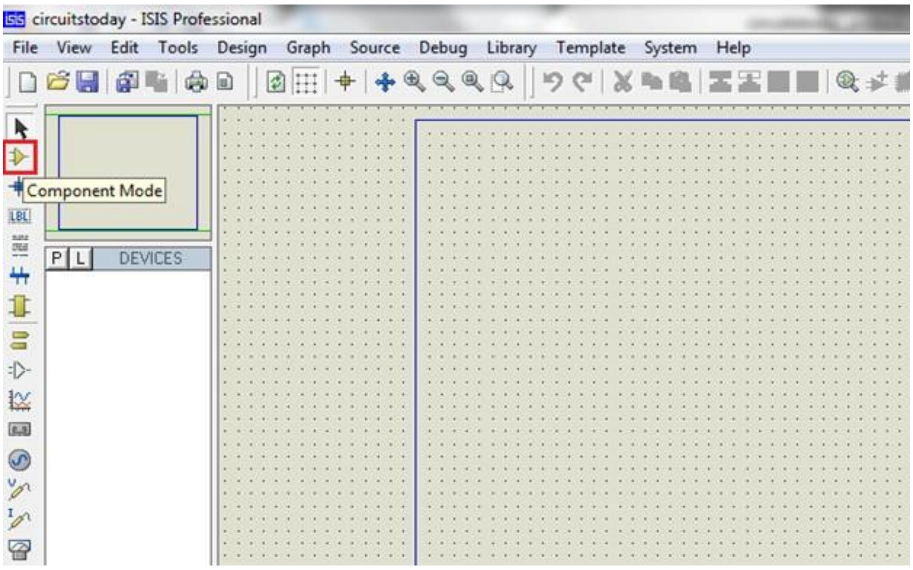

Fig.5.28: Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

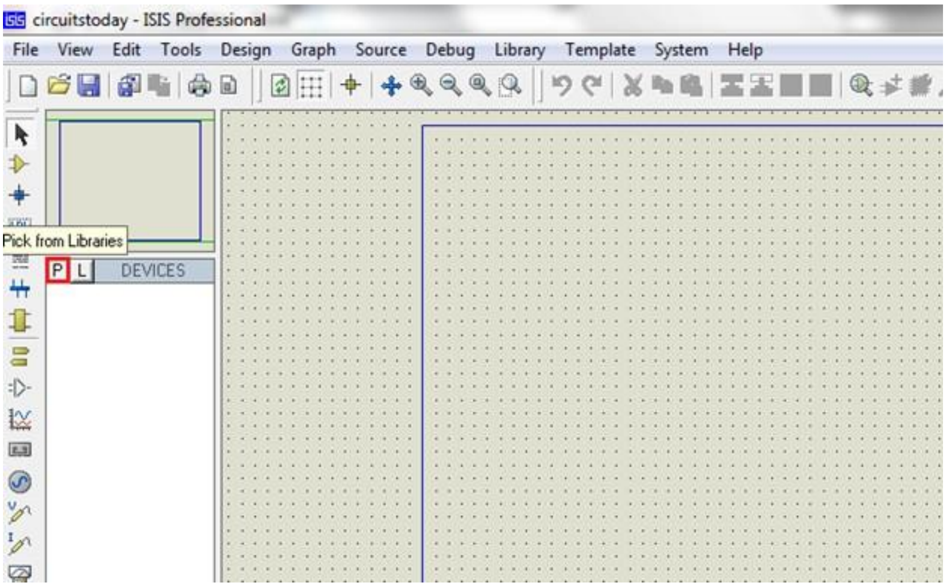

Fig.5.29: Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

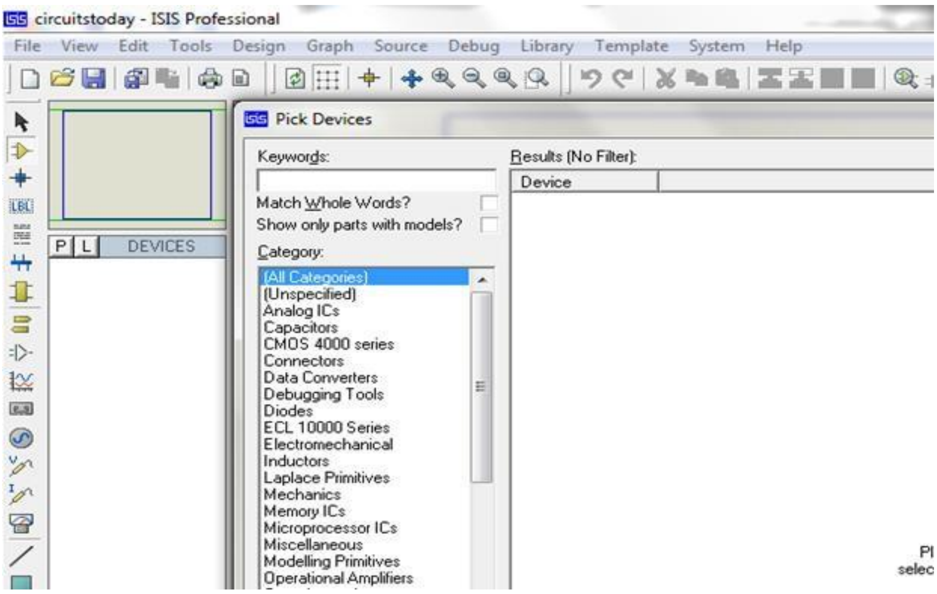

Fig.5.30: Keywords Textbox

Example shows selection of push button. Select the components accordingly.

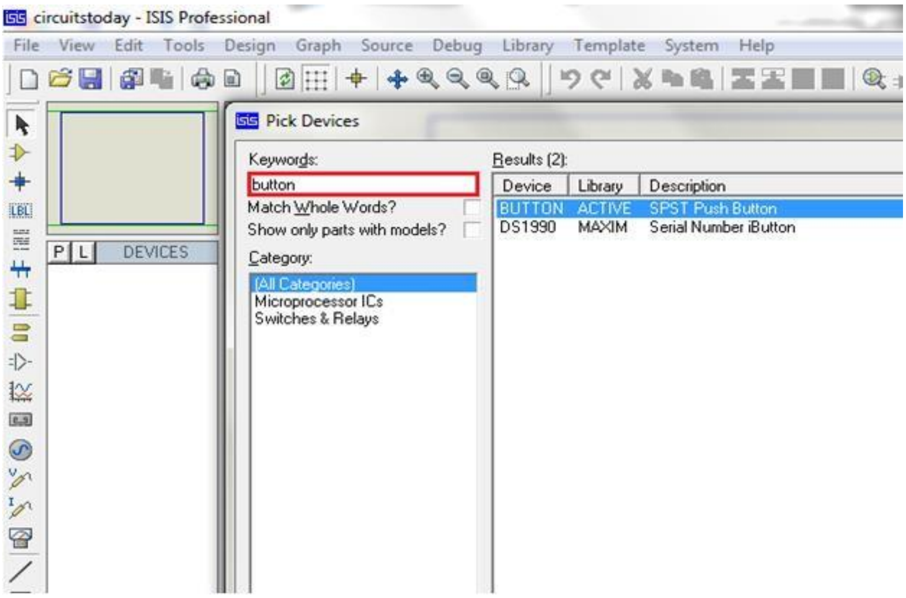

Fig.5.31: Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

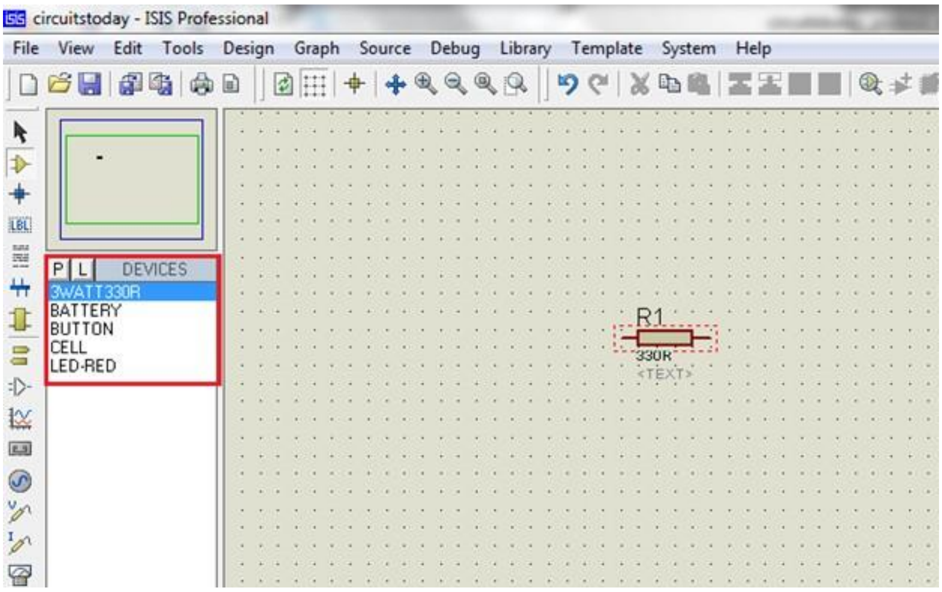

Fig.5.32: Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

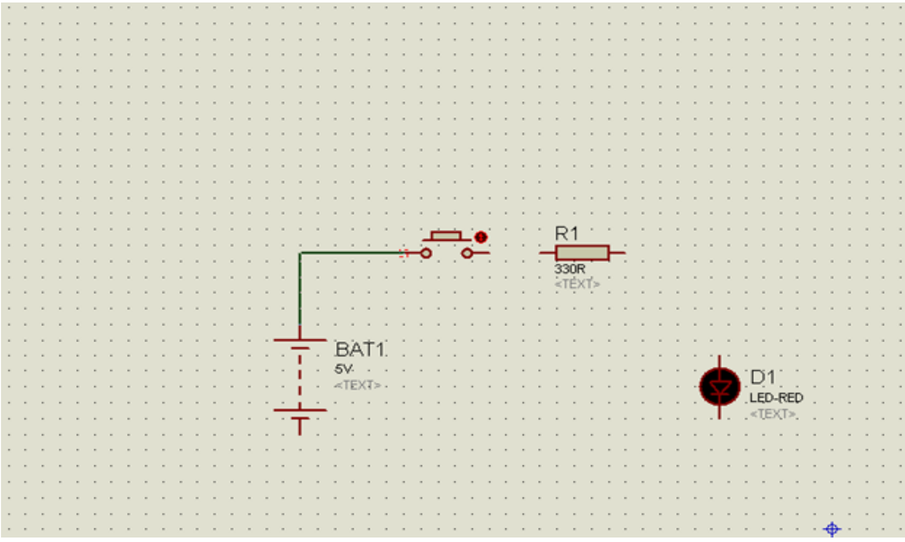

Fig.5.33: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

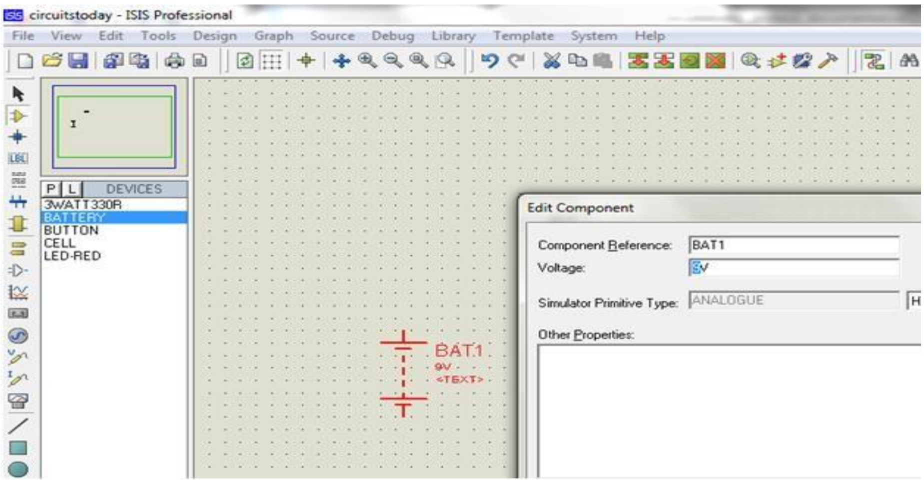

Fig.5.34: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

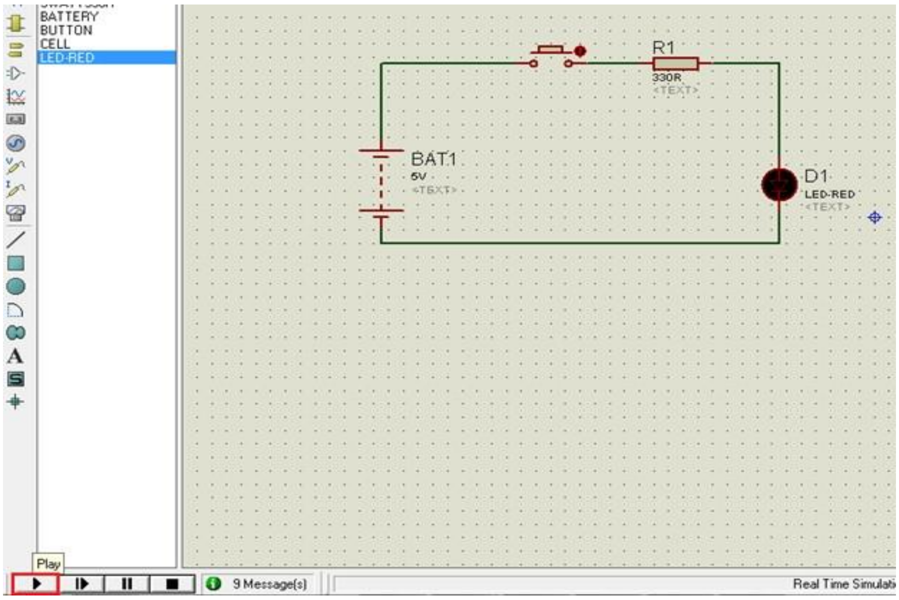

Fig.5.35: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

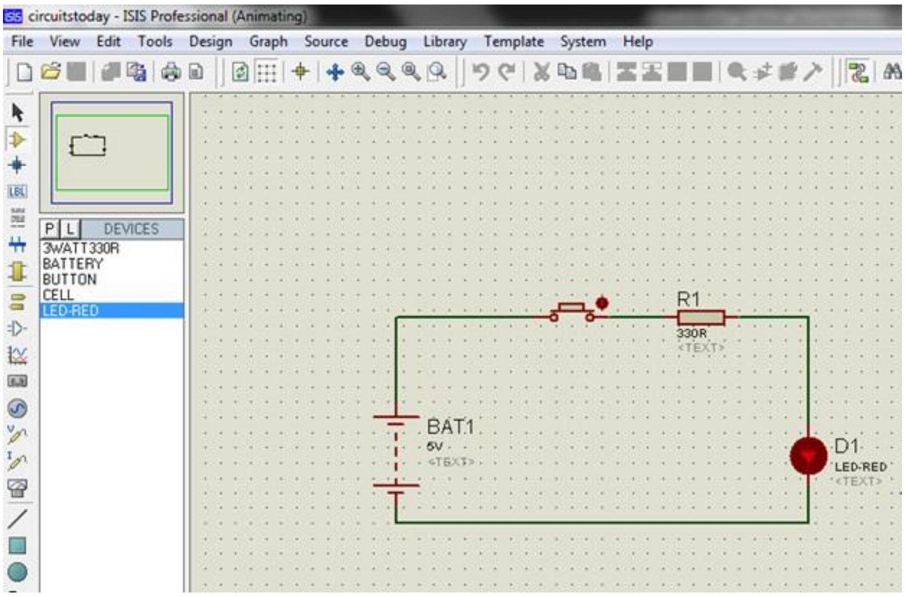

Fig.5.36: Simulation Animating

Simulation can be stepped, paused or stopped at any time.

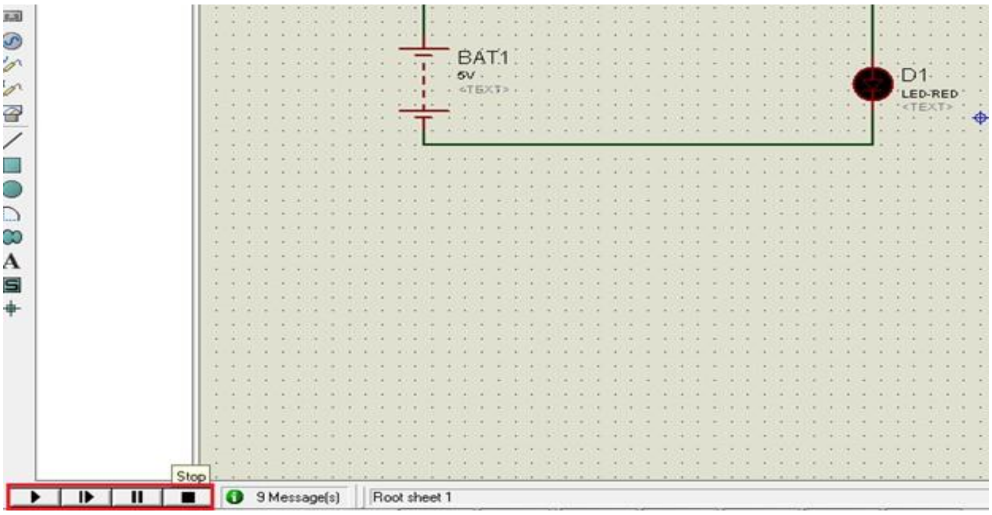

Fig.5.37: Simulation Step-Pause-Stop Buttons

5.5.5 Project Code:

```
#include <LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);

int sense=A4,relay=6,buz=7;

 void setup() {
 Serial.begin(9600);
  pinMode(relay,OUTPUT);
  pinMode(buz,OUTPUT);;
  pinMode(sense,INPUT);

 digitalWrite(relay,LOW);
 digitalWrite(buz,HIGH);

  lcd.begin(16,2);
  lcd.clear();
  lcd.setCursor(0,0);
  lcd.print("MOBILE CHARGING ON COIN INSERTION");

  Serial.begin(9600);
```

```
    delay(3000);

  lcd.clear();lcd.setCursor(0,0);lcd.print("PLS INSERT UR COIN");
              delay(2000);
}

int count = 0,sig = 0;
void loop() {
     while(1)
     {
    // lcd.clear();
     lcd.setCursor(0,1);lcd.print("TIME:");lcd.print(count);delay(2000);
    if(digitalRead(sense)==LOW && sig == 0)
    {
      count =count + 60;
      sig =1;
      // lcd.clear();
       //lcd.setCursor(0,1);lcd.print("TIME:");lcd.print(count);
       digitalWrite(relay,HIGH);
    }
      if(sig == 1)
      {
    //lcd.clear();lcd.setCursor(0,1);lcd.print("TIME:");lcd.print(count);
       //lcd.clear();
     //  lcd.setCursor(0,0);lcd.print("sig");delay(2000);
       count--;
        if ( count <= 10)
       {
         //lcd.clear();

  lcd.setCursor(0,0);lcd.print("LOWBALANCE");digitalWrite(buz,LOW);delay(2000);digital
  Write(buz,HIGH);
       }

        if ( count == 0)
       {
         //lcd.clear();
         lcd.setCursor(0,0);lcd.print("NIL BALANCE");delay(2000);
         digitalWrite(relay,LOW);digitalWrite(buz,HIGH); sig = 0 ;
       }
      }

      //}

       /* if ( count <= 15)
       {
        // lcd.clear();
         lcd.setCursor(0,0);lcd.print("LOW BALANCE");delay(2000);
       }
```

```
 if ( count == 0)
       {
      //  lcd.clear();
        lcd.setCursor(0,0);lcd.print("NIL BALANCE");delay(2000);
        digitalWrite(relay,LOW);sig = 0 ;
      }*/
    // }

     }

}
```

CHAPTER-6

RESULTS & OUTPUTS

6.1 RESULT:

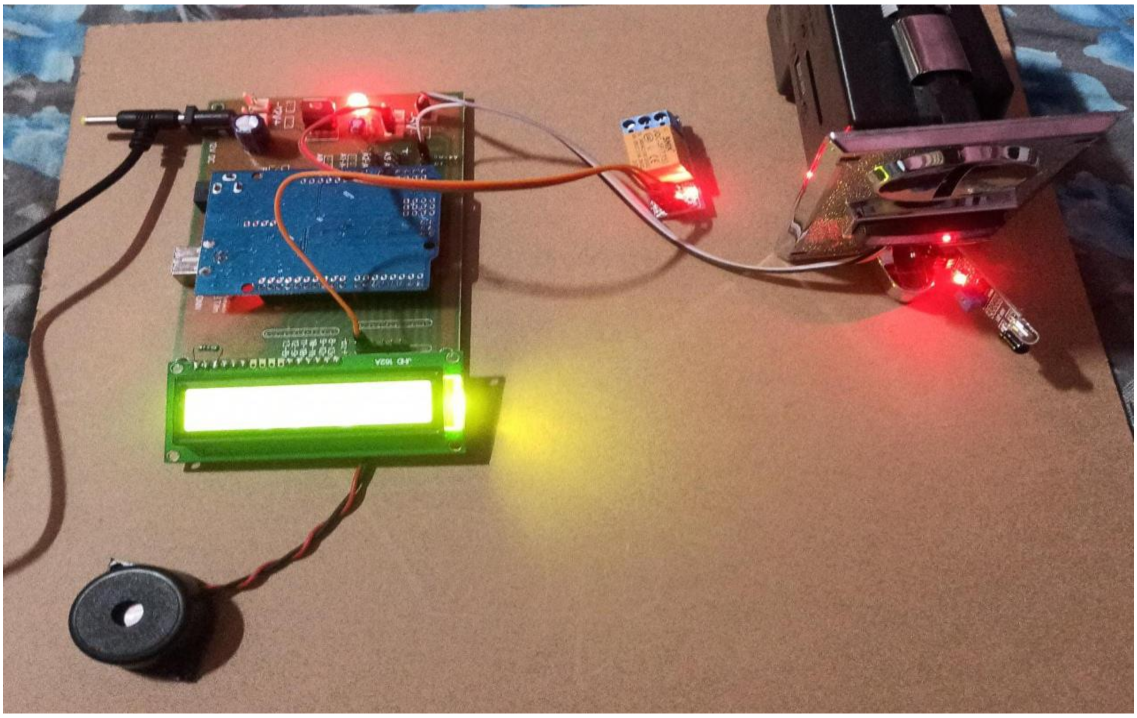

Fig.6.1: Final Output

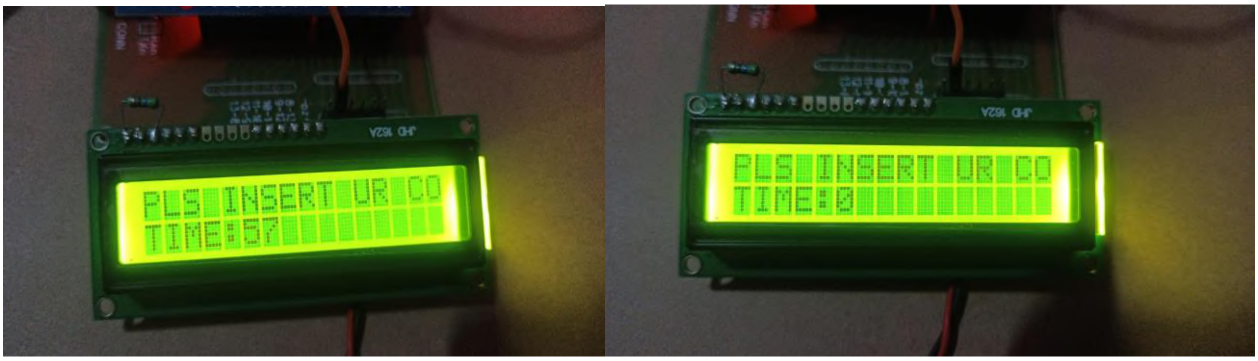

Fig.6.2: LCD Outputs

CHAPTER-7

APPLICATIONS AND ADVNTAGES

7.1 APPLICATIONS OF THE PROJECT:

- Useful to public for using coin to charge the mobile phone at any place.
- It can be used for different type of mobiles.
- It is used for emergency charging purpose.
- It can be installed railway stations, bus stops, villages and rural areas and public places.
- It can be installed in office and colleges for pay charging facility.

7.2 ADDVANTAGES OF THE PROJECT:

- Simple and hand efficient
- Less expensive
- Reduced man power
- Low power consumption
- Installation is easy
- It can be useful while travelling and when we don't have charger with us during travelling.
- Simple to operate

CHAPTER-8

CONCLUSION AND FUTURE SCOPE

8.1 CONCLUSON:

The coin based mobile charger is used in public places for charging all types android cell phones just like charging it normally owing to the fact that it relayed the electrically through the coin based mobile charger nedded to bring the mobile phone back to life as a result it reduces certain risks and my save life. A novel method of charging mobile batteries of different manufactures using solar power has been designed and developed for rural and remote areas where the grid power is not available at any time at any palace

8.2 FUTURE SCOPE:

It can be installed on railway stations, bus stops and public places for pay charging facility.The system is very much useful foe emergency charging purposes or in rural areas.

The project can be used in the following areas

1. Railway station: This type of project is used in railway station for public palace.

2. Shop:-coin based project charger is install any shop and cam money

3. Rural areas:-This project is installing in rural areas where the power grid is not available at any time.

4. Public Place:-This project is very useful to people who are wing mobile phone wihout charging condition in public places

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to our College Management for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra, our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna, Head & Professor,** the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Kumar,** Professor for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our Class Project Coordinator, **Mr. Nishakar, Department of ECE** and our project Internal guide, **Mr. K Naga Venkateshwara Rao, Assistant Professor, Department of ECE** for guidance and encouragement in carrying out this project work.

1. B. Abhinay Reddy (17K81A04D4)
2. B. Aasrita (17K81A04D2)
3. M. Roshan Kumar (17K81A04F8)

ABSTRACT

Adoption of social network sites and use of smart phones with number of sensors in them has digitized user's activities in real-time. Smart phone applications such as calendar, email, and notes contain lot of user information and may other provide a view into user's activities, while sensors such as GPS sensor can be used to passively find information about the user. In addition to this user and device data, these devices have access to the Internet that can be leveraged to build powerful applications. Personal assistant software (smart agent) can be used as an interface to the digital world to make the consumption of this information timely and efficient for the user's specific tasks. Goal of this project is to design personal assistant software that understands the semantics of the task, is able to decompose the task into multiple tasks withinthe context of the user and plan these tasks for the user. It is designed and developed using python (version 3.6) with the help of pycharms community interface.

CHAPTER 1

INTRODUCTION

1.0 INTRODUCTION

In today's era almost all tasks are digitalized. We have Smartphone in hands, and it is nothing less than having world at your fingertips. These days we are not even using fingers. We just speak of the task and it is done. There exist systems where we can say Text Dad, "I'll be late today." And the text is sent. That is the task of a Virtual Assistant. It also supports specialized task such as booking a flight or finding cheapest book online from various ecommerce sites and then providing an interface to book an order are helping automate search, discovery and online order operations.

Virtual Assistants are software programs that help you ease your day to day tasks, such as showing weather report, creating reminders, making shopping lists etc. They can take commands via text (online chat bots) or by voice. Voice based intelligent assistants need an invoking word or wake word to activate the listener, followed by the command. For this project the wake word is Escobar (we can use any of the name we like too). We have so many virtual assistants, such as Apple's Siri, Amazon's Alexa and Microsoft's Cortana. For this project, wake word was chosen as Reddy.

This system is designed to be used efficiently on desktops. Personal assistant software improves user productivity by managing routine tasks of the user and by providing information from online sources to the user. Reddy is effortless to use. Call the wake word 'Reddy' followed by the command. And within seconds, it gets executed.

Voice searches have dominated over text search. Web searches conducted via mobile devices have only just overtaken those carried out using a computer and the analysts are already predicting that 50% of searches will be via voice by 2020.Virtual assistants are turning out to be smarter than ever. Allow your intelligent assistant to make email work for you. Detect intent, pick out important information, automate processes, and deliver personalized responses. This project was started on the premise that there is enough openly available data and information on the web that can be utilized to build a virtual assistant that has access to making intelligent decisions for routine user activities.

1.1 OBJECTIVE OF THE STUDY

The main objective of the project is to build our own virtual assistant with no cost forour daily tasks performed.

1.2 AIM OF THE STUDY

The primary aim for doing this project is to build a virtual assistant on our own in aeasy way and the interfacing is very fast and user friendly.

1.3 MATERIALS REQUIRED

- Personal Computer(PC) with OS(Operating System)
- Python Installer(version > 3.6)
- Pycharm Compiler
- Network(Ethernet or WIFI)

1.4 ORGANIZATIONS OF CHAPTERS

1.4.0 Introduction

Virtual Assistant is a device which is used to reduce the time of user for certainapplications and helps to do tasks.

1.4.1 Literature Survey

Speech recognition has a long history with several waves of major innovations. Speech recognition for dictation, search, and voice commands has become a standard feature on smartphones and wearable devices.

1.4.2 Project Design

- The goal of the project is to build our own virtual assistant.

- Using python language.
- Perform regular tasks by giving voice command.

1.4.3 Project Testing

Virtual Assistant works on giving command by the user. To perform any task, it requires a wake word. So, it will be in listening state if there is no wake word matching by the command given by user.

1.4.4 Conclusion and Future Enhancement

Nowadays all the virtual assistants are being integrated or manufactured at industrial standards and are given to the public. This project deals with making their own virtual assistant at mature level later it may be done even at teen level. In Future we can also build our own hardware of the virtual assistant rather than buying the fully designed product.

CHAPTER 2

LITERATURE SURVEY

2.0 LITERATURE REVIEW ON RESEARCH AREA

A computer primarily based approach for performing a command via a voice consumer interface on a subset of objects. The subset is selected from a fixed of items, each having an object type at least one taggable field is associated with the object type and has a corresponding value. The set of objects is saved in the laptop memory. An utterance is acquired from the person and consists of a command, an object type choice, a tag-gable field selection, and a price for the taggable discipline. Responsive to the utterance, at least one item is retrieved from the set of gadgets, the item of the sort selected through the user and having a price within the taggable area selection that matches the taggable field fee obtained from the user the command is done on the item. The object includes textual content that's converted to voice output [1]. They envisioned that someday computers will recognize natural language and count on what we need, whilst and where we need it, and proactively whole responsibilities on our behalf. However, speech recognition and machine getting to know have persevered to be refined, and based records served through packages and content providers have emerged. We agree with that as computer systems turn out to be smaller and greater ubiquitous [e.g., wearables and Internet of Things (IoT) [2]. The recognizer is designed to change a verbal articulation from a individual into an alternate method of data (e.g., text). A handheld individual colleague including a voice-recognizer and a characteristic dialect processor is disclosed. This snippet of data can be a plan for the day, data in the individual's logbook or data from the individual's address book, Such as a telephone number [3]. Speech recognition has a long history with several waves of major innovations.

Speech recognition for dictation, search, and voice commands has become a standard feature on smartphones and wearable devices. Design of a compact large vocabulary speech recognition system that can run efficiently on mobile devices, accurately and with low latency. [1] This is achieved by using a CTC based LSTM acoustic model which predicts context independent phones and is compressed to a tenth of its original size using a combination of SVD-based compression and quantization. Quantized deep neural networks (DNNs) and on-the-fly language model rescoring to achieve real-time performance on modern smartphones.

2.1 REVIEW ON RELATED LITERATURE

•[1]Veton Këpuska,"Next-Generation of Virtual Personal Assistants, Published in2018-uses of the multi-modal dialogue systems.

• [2]Sumit Kumar Sarda, "VPA: Virtual Personal Assistant" Published in 2017 -reduces the utilization of input devices

•[3]P. Milhorat,"Building the next generation of personal digital Assistants," Published in 2014 -adapted to a user's preferences are in distinct needs.

2.1 CONCLUSIONS ON REVIEWS

As the use and purpose of virtual assistant is easy and more in today's world. This project is to design a free cost virtual assistant.

CHAPTER 3

PROJECT DESIGN

3.0 OVERVIEW OF THE DESIGN

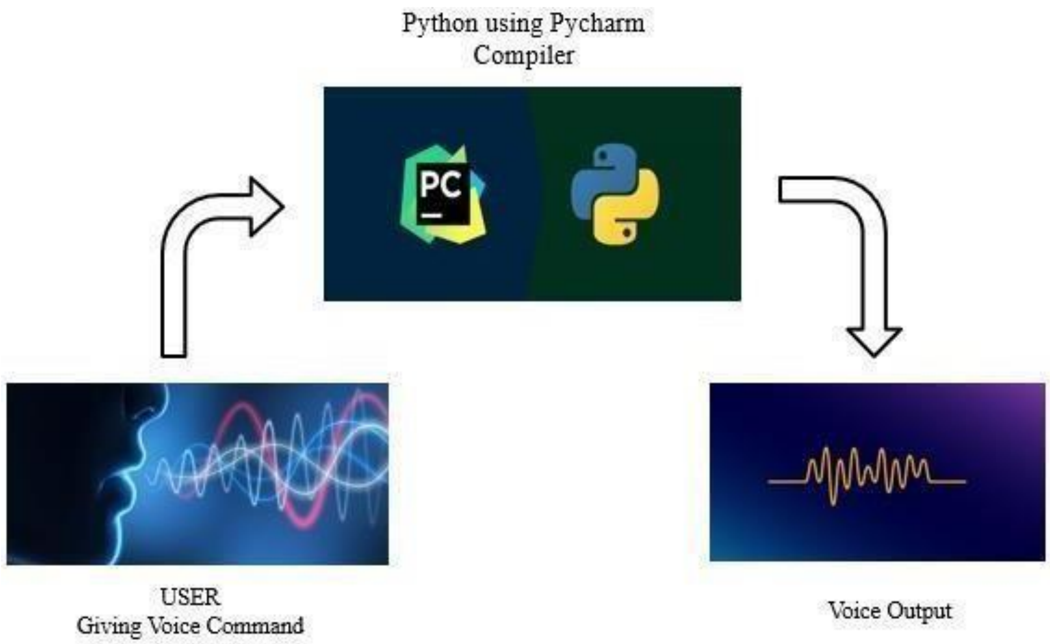

Figure 3. 1 Logic Diagram of Python code Working.

3.0.1 Virtual Assistant

A virtual assistant is an independent contractor who provides administrative services to clients while operating outside of the client's office. A virtual assistant typically operates from a home office but can access the necessary planning documents, such as shared calendars, remotely.

People employed as virtual assistants often have several years of experience as an administrative assistant or office manager. New opportunities are opening up for virtual assistants who are skilled in social media, content management, blog post writing, graphic design, and Internet marketing. As working from home has become more accepted for both workers and employers, the demand for skilled virtual assistants is expected to grow.

3.0.2 Key Points of Virtual Assistant

- A virtual assistant is a self-employed worker who specializes in offering administrative services to clients from a remote location, usually a home office.
- Typical tasks a virtual assistant might perform include scheduling appointments, making phone calls, making travel arrangements, and managing email accounts.
- Some virtual assistants specialize in offering graphic design, blog writing, bookkeeping, social media, and marketing services.
- For an employer, one advantage of hiring a virtual assistant is the flexibility tocontract for just the services they need.

3.0.3 How a Virtual Assistant Works

Virtual assistants have become more prominent as small businesses and startups rely on virtual offices to keep costs down and businesses of all sizes increase their use of the Internet for daily operations. Because a virtual assistant is an independent contractor, a business does not have to provide the same benefits or pay the same taxes that it would for a full-time employee.

Also, since the virtual assistant works offsite, there is no need for a desk or other workspace at the company's office. A virtual assistant is expected to pay for and provide their own computer equipment, commonly used software programs, and high-speed Internet service.

3.0.4 Virtual Assistant Duties

The specific duties of a virtual assistant vary according to the needs of the client and the terms of the contract. Some virtual assistants handle clerical and bookkeeping tasks, while others may post regular updates to social media or write articles for a blog. A well- rounded virtual assistant may also handle travel arrangements, appointment scheduling, data entry, and online file storage.

3.0.5 Virtual Assistant Qualifications

While there are no hard-and-fast educational requirements to become a virtual assistant, many clients will look for virtual assistants who have some higher-level education or specialized training. A few online companies and community colleges offer courses and certification for virtual assistant skills.

A virtual assistant should be tech-savvy, having a wide range of computer skills and a high level of proficiency with commonly used software and business programs. A virtual assistant who specializes in bookkeeping should be adept at basic accounting tasks, such as account reconciliations and double-entry bookkeeping.

3.0.6 Benefits of a Virtual Assistant

For the client, one advantage of hiring a virtual assistant is the flexibility to contract for just the services they need. Depending on the terms of the agreement, some virtual assistants may be paid by the task rather than by the hour. In contrast, employees in a traditional office setting usually must be paid for a fixed number of hours per day.

3.0.7 Coding Techniques

The project is based on the theories related to various aspects of software engineering principles and software development model; Java programming skills and Android tutorials, Database management and network communication technologies. The database and the web service in this project are put on the windows azure cloud; developers will never be required to run the web service and database locally. The cloud platform will handle the execution and maintenance. Hence, cloud computing is an important concept and theory guide the development.

3.0.7.0 Cloud Computing

Cloud computing refers to the delivery of computing and storage capacity as a service to a heterogeneous community of end-recipients. The name comes from the use of clouds as an abstraction for the complex infrastructure it contains in system diagrams. Cloud computing entrusts services with a user's data, software and computation over a network. It has considerable overlap with software as a service (SaaS). [5]

3.0.7.1 Software Engineering Principles

Extreme programming will direct the development process of the project, it focus on the development cycle of defining the requirement, corresponding design and test, integration and simplicity; during the development, there should always be working in pair programming, as well as doing the revision control, calculate the velocity and efficiency. Extreme programming (XP) is a software development methodology which is intended to i mprove software quality and responsiveness to changing customer requirements. As a type of agile software development, it advocates frequent "releases" in short development cycles (t imeboxing), which is intended to improve productivity and introduce checkpoints where new customer requirements can be adopted. [6]

3.0.7.2 Java Programming

Java API and reference, which is helpful in guide programming in eclipse and construction of the framework, and the completion of the functions. Java is a programming language originally developed by James Gosling at Sun Microsystems (which has since merged into Oracle Corporation) and released in 1995 as a core component of Sun Microsystems' Java platform. The language derives much of its syntax from C and C++ but has a simpler object model and fewer low-level facilities. Java applications are typically compiled to bytecode (class file) that can run on any Java Virtual Machine (JVM) regardless of computer architecture. Java is a general-purpose, concurrent, class-based, object-oriented language that is specifically designed to have as few implementation dependencies as possible. It is intended to let application developers "write INTELLIGENT VOICE ASSISTANT 12 once, run anywhere" (WORA), meaning that code that runs on one platform does not need to be recompiled to run on another. Java is currently one of the most popular programming languages in use, particularly for client-server web applications, with a reported 10 million users. [7] [8]

3.0.7.3 Network communication technologies

The communication in this program is based on the predefined protocol, the communication within the program is implemented in following the pre-defined protocol, the other main part of the communication is between the Android program in eclipse and the cloud platform, this will be done by working with URL, WSDL file. Figure-3.2 shows some knowledge of cloud platform, URL and WSDL. [15]

The WSDL describes services as collections of network endpoints, or ports. The WSDL specification provides an XML format for documents for this purpose. The abstract definitions of ports and messages are separated from their concrete use or instance, allowing the reuse of these definitions. A port is defined by associating a network address with a reusable binding, and a collection of ports defines a service. Messages are abstract descriptions of the data being exchanged, and port types are abstract collections of supported operations. The concrete protocol and data format specifications for a INTELLIGENT VOICE ASSISTANT 14 particular port type constitutes a reusable binding, where the operations and messages are then bound to a concrete network protocol and message format. In this way, WSDL describes the public interface to the Web service. [16]

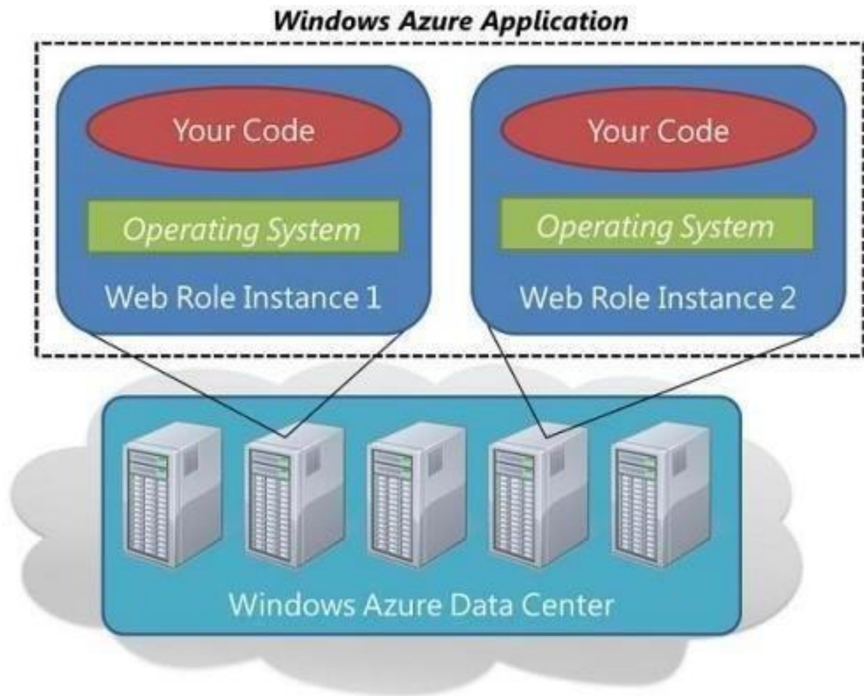

Figure 3. 2 Network Communication Technology

3.1 EQUIPMENT ANALYSIS

3.1.0 PYTHON

"Python is an interpreted, object-oriented, high-level programming language with dynamic semantics".[6] This language consist of mainly data structures which make it very easy for the data scientists to analyse the data very effectively. It does not only help in forecasting and analysis it also helps in connecting the two different languages.Two best features of this programming language is that it does not have any compilation step as compared to the other programming language in which compilation is done before the program is being executed and other one is the reuse of the code, it consist of modules and packages due to which we can use the previously written code any where in between the program whenever is required. There are multiple languages for example R., Java, SQL, Julia, Scala, MATLAB available in market which can be used to analyze and evaluate the data, but due to some outstanding features python is the most famous language used in the field of data science. Python is mostly used and easy among all other programming languages is due to the following reasons.

3.1.1.1 Data Structures In Python

Data structures are the way of storing the data so that we can easily perform different operations on the data whenever its required. When the data has been collected from the data source the data is available in different forms. So later it is easy for the data scientists to perform different operation on the data once it is sorted in to different data structures. Data structures are mainly classified in to two categories and then further their subcategories shown below.

- Primitive data structures
- Non-Primitive data structures

3.1.1 PYCHARM

PyCharm is an integrated development environment (IDE) used in computer programming, specifically for the Python language. It is developed by the Czech company JetBrains (formerly known as IntelliJ).[5] It provides code analysis, a graphical debugger, an integrated unit tester, integration with version control systems (VCSes), and supports web development with Django as well as data science with Anaconda.

PyCharm is cross-platform, with Windows, macOS and Linux versions. The Community Edition is released under the Apache License,[7] and there is also Professional Edition with extra features – released under a proprietary license.

3.2 DEFINE THE MODULES

Following the functions of the data structures in python.

3.2.1 Primitive Data Structures

They are also called as basic data structures.This type of data structures contains simple values of the data.[7]

- Integers - All the whole numbers from negative infinity to positive infinity comes under integer data types. for example 4,9,-2,-6.

- Float - The decimal figure numbers or rational numbers comes under float data types. for example, 3.1,2.2,8.96.
- Strings - Collection of alphabets or characters are called strings. We enclose the string either in single or double quotes in python. for example ’hello’ and ”bread”.
- Boolean- These are the built in data types which take two values that are ’True’ and ’False’. True represents the 1 and False represents 0 in python.

3.2.2 Non-Primitive Data Structures

These are the derived type or reference variables data structures. They are called derived data structures because they derived from the basic data structures such as integer and float. Python has mainly five types of data structures.

- Array - Array is the collection of data types of same type. Arrays data structures are used mostly in the NumPy library of python. In the below example we have first imported the package array from NumPy library and defined the array as variable arr then divided the array by 7 and we have printed our array to get output.

```
In [3]: from numpy import array
        arr = array([28,35,42,56])
        arr = arr/7
        print(arr)

        [4. 5. 6. 8.]
```

Figure 3. 3 Array Example

- List – “A list is a value that contains multiple values in an ordered sequence”.[8]. Values in the list referred to list itself, that is the value can be stored in a variable or passed to a function. List are changeable and values in the list are enclosed inside a square bracket, we can perform

```
In [13]: List = ['orange', 'mango','kiwi','papaya']
         print(List)

         ['orange', 'mango', 'kiwi', 'papaya']
```

Figure 3.4 List Example

- Dictionary- These are nothing but a type of data structure which consist of key value pairs enclosed in the curly brackets. It is same as the any dictionary we use in day to day life in which we find the meaning of the particular words. So if I compare normal dictionary to this python dictionary data structure then the a word in a dictionary will be our key and its meaning will be the value of the dictionary. In the figure name, occupation and hobby are the keys and Suraj, data analyst and vlogging are the values assigned to the keys.

```
In [25]: dictionary = {'name':'Suraj', 'occupation':'data analyst','hobby':'vlogging'}
         dictionary['hobby']

Out[25]: 'vlogging'
```

Figure 3.5 Dictionary Example

- Tuple - A tuple is a list of non-changeable objects. The differences between tuples and lists are that the tuples cannot be changed, tuples use parentheses, whereas list uses square brackets.

```
In [16]: Tuple = ('orange', 'mango','kiwi','papaya')
         #If you can see the change values are same as list but enclosed in parentheses
         print(Tuple)

         ('orange', 'mango', 'kiwi', 'papaya')
```

Figure 3.6 Tuple Example

- Sets - Set are used for calculating mathematical operation such as union, intersection, and symmetric difference.

3.3 MODULE FUNCTIONALITY

3.3.1 Pyttsx3

It is a text-to-speech conversion library in Python. Unlike alternative libraries, itworks offline, and is compatible with both Python 2 and 3.

Installation:

pip install pyttsx3

If you recieve errors such as No module named win32com.client,

Usage:

importpyttsx3

engine = pyttsx3.init()

engine.say("I will speak this text")

engine.runAndWait()

3.3.2 PyWhatKit

PyWhatKit is a Python library with various helpful features. It is an easy to use librarywhich does not requires you to do some additional setup.

Installation:

This library can be installed by the pip command, open your command prompt and typein the following command…

pip install pywhatkit

Functions of this library:

First import the library using the command “import pywhatkit as kit” and then proceed to call the functions.

3.3.2.0 kit.sendwhatmsg()

This function can be used to send WhatsApp message at certain time. To any person with a phone number.

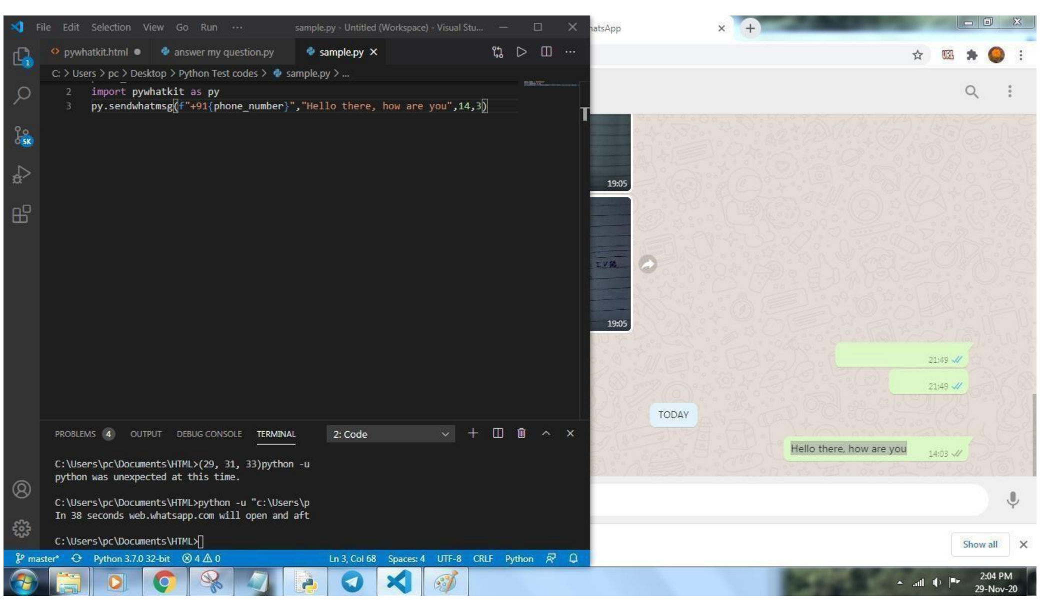

Figure 3.7 Sending WhatsApp message using pywhatkit library

The parameters are

phone_num (required) - Phone number of target with country code

message (required) - Message that you want to sendwhatmsg

time_hour (required) - Hours at which you want to send message in 24 hour format

time_min (required) - Minutes at which you want to send message

wait_time (optional, val=20) - Seconds after which the message will be

sent afteropening the web

print_waitTime (optional, val=True) - Will print the remaining time if set to true
Some common errors

CountryCodeException - Check if the phone number passed into the parameter has

country code

Message not getting delivered - Check internet speed and increase wait_time to

30 orabove.

CallTimeException - The web takes some time to load so some delay is required,

makesure the seconds left is greater than the wait_time

SyntaxError - Make sure the first two parameters are string and the rest are int

3.3.2.1 kit.playonyt()

This function can be used to search and play a particular video on YouTube byusing just the keyword, like "Shape of You song"

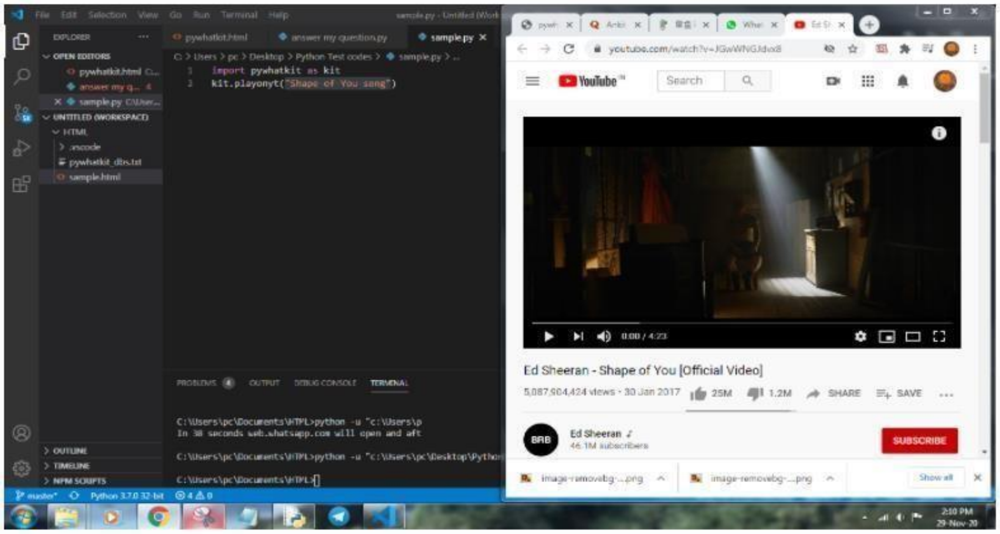

Figure 3.8 Video playing in youtube (Shape of you)

The parameters are topic (required) - Topic or title that is related to the video

Some common errors

Video not opening - Make sure the topic exists or you have provided proper spelling kit.search()

This function can be used to make a google search for any term

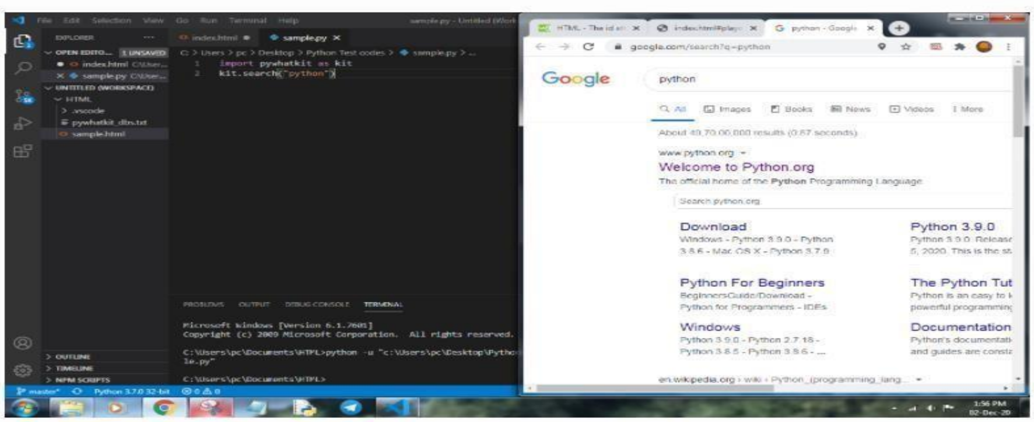

Figure 3.9 Web search

The parameters are
topic (required) - Topic or title that you want to search

3.3.2.2 kit.info()

This function can be used to fetch information about any topic.

The parameters are

topic (required) - Topic or title that you want to get information about lines (optional,val=3) - Number of lines that you want to print about it

Some common errors

Not returning paragraph - Make sure the topic exists and you are providing specifictitle.

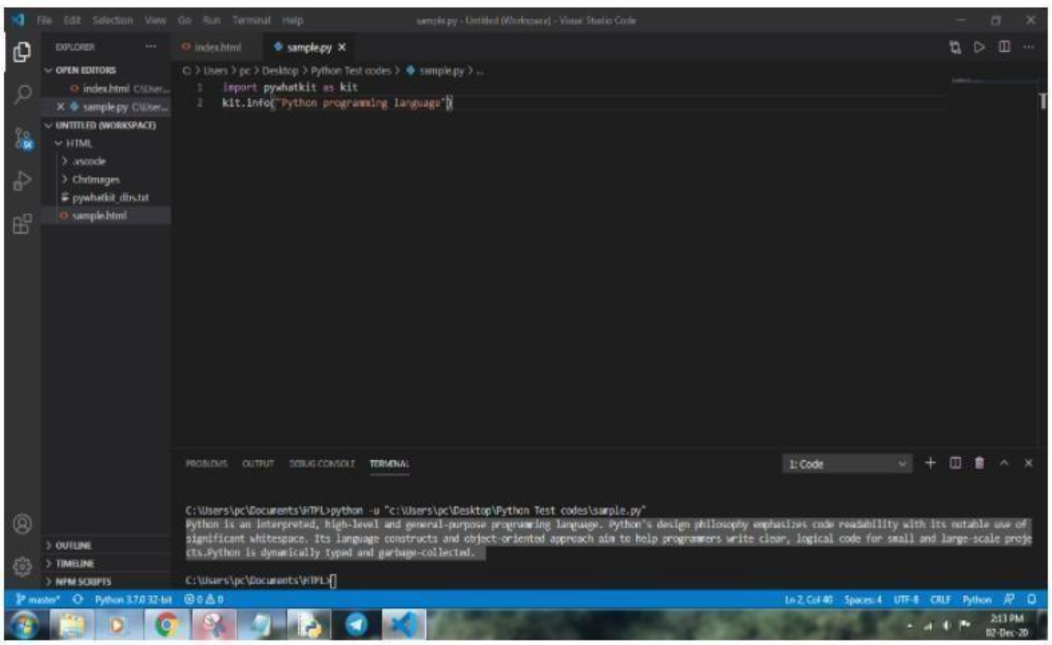

Figure 3.10 Information of Python programming language

3.3.3 PyJokes

One line jokes for programmers (jokes as a service).

Installation

Install the *pyjokes* module with.**Usage**

Once installed, simply call pyjoke from the command line or add it to your. bashrc file tosee a joke every time you open a terminal.

Use the -c flag to get jokes from a specific category.Options:

-c neutral [default] (neutral geek jokes)

-c chuck (Chuck Norris geek jokes)

-c all (all jokes)

-c twister (Tongue-twister)

You can also access the jokes in your own project by importing *pyjokes* and using thefunctions *get_joke* and *get_jokes*.

3.3.4 Wikipedia

Wikipedia is a Python library that makes it easy to access and parse data from Wikipedia.

Search Wikipedia, get article summaries, get data like links and images from a page, and more. Wikipedia wraps the MediaWiki API so you can focus on using Wikipedia data, not getting it.

Installation

To install Wikipedia, simply run:

$ pip install Wikipedia

Wikipedia is compatible with Python 2.6+ (2.7+ to run unittest discover) and Python 3.3+.

3.3.5 Tree Of Data Structure

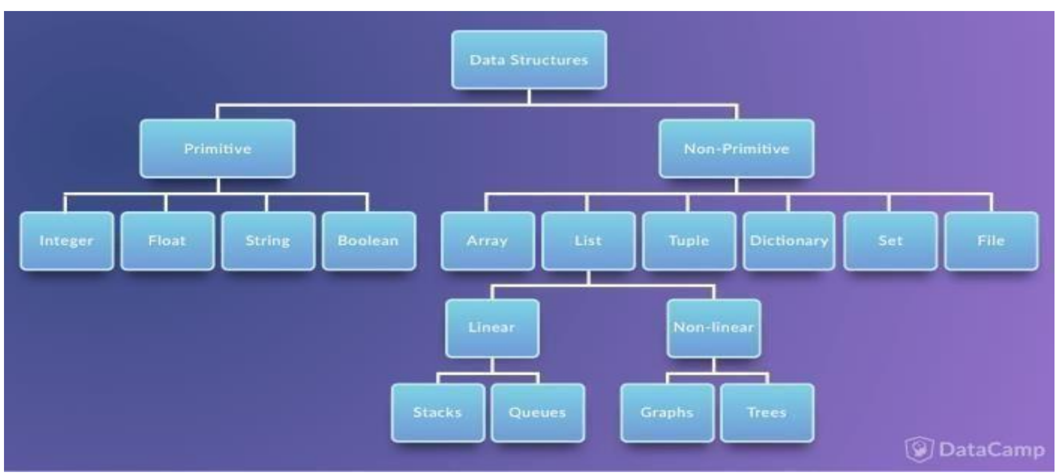

Figure 3.11 A data structure tree at glance

3.3.6 Operators

Operators are the symbols in python that are used to perform Arithmetic or logicaloperations. Following are the different types of operators in python.

3.3.6.1Arithmetic operators

Arithmetic operators carry out mathematical operations and they are mostly usedwith the numeric values.

Arithmetic operators		
Operator	Name	Example
+	Addition	A+B
-	Subtraction	A-B
*	Multiplication	A*B
/	Division	A/B
%	Modulus	A%B
**	Exponentiation	A**B
//	Quotient	A//B

Table 3. 1Arithmetic operators

Where A and B are the numeric values.

3.3.6.2 Assignment Operators

As the name decides this operators are used for assigning the values to thevariables.

ASSIGNMENT OPERATORS		
Operator	Example	may also be writ-ten
=	a = 6	a = 6
+=	a += 3	a = a + 3
-=	a -= 4	a = a - 4
*=	a *= 5	a = a * 5
/=	a /= 6	a = a / 6
%=	a %= 7	a = a % 7
//=	a //= 8	a = a // 8
**=	a **= 9	a = a ** 9
&=	a &= 1	a = a & 1

Table 3. 2 Assignment Operators

Here a is any value and number of operations are performed on this value.

3.3.6.3 Logical Operators

These operators are used to join conditional statements. Logical operators are theand, or and not operators.

Logical Operators		
Operator	Description	Example
and	if both statements are true it returns true	x <5 **and** x <10
or	if any of the two statement is true it returns true	x <4 **or** x <8
not	if the result is true it reverses the result and gives false	**not** (x <4 **and** x <8)

Table 3. 3Logical Operators

Here a is any value provided by us and on which multiple operations can be performed.

3.3.6.4 Comparison Operators

These operators are used to compare two different values.

Comparison operators		
Operator	Name	Example
==	Equal	a == b
!=	Not equal	a!=b
>	Greater than	a >b
<	less than	a <b
>=	Greater than equal to	a>= b
<=	less than equal to	a <=b

Table 3. 4Comparison operators

Here a and b are two different values and these values are compared.

3.3.6.5 Membership Operators

These operators are used to check membership of a particular value. It is used to check whether a specific value is present in the object or not.

Membership operators		
Operator	Description	Example
in	it returns a True if the value is present inside the object	a **in** b
not in	it returns a True if the value is not present inside the object	a **not in** b

Table 3. 5Membership operators

3.4 Condition Statements

3.4.1 If else statements

"The most common type of statement is the if statement. if statement consist of a block which is called as clause",[8] it is the block after if statement, it executed the statement if the condition is true. The statement is omitted if the condition is False. then the statement in the else part is printed.

If statement consist of following-

- If keyword itself
- Condition which may be True or False
- Colon
- If clause or a block of code

Below is the figure shows how If and else statements are used with description inside it.

```
In [4]: x = 32

        if x<40:
            print('x is less than 40')

        else:
            print('x is greater than 40')

        #In the above program we have if and else statements both
        #first line we have assigned value 32 to a variable x
        #second line contain keyword with condition x<40
        #If the condtion is true then the statement is printed
        #else the other condtion is executed in else statement

        x is less than 40
```

Figure 3.12 if else statement

3.4.2 elif statements

In this statement only one statement is executed, There are many cases in which there is only one possibility to execute. "The elif statement is an else if statement that always follows an if or another elif statement"[8]. The elif statement provides another condition that is checked only if any of the previous conditions were False. In code, an elif statement always consists of the following:. The only difference between if else and elif statement is that in elif statement we have the condition where as in else statement we do not have any condition.

elIf statement consist of following-

- elIf keyword itself
- Condition which may be True or False
- Colon
- elIf clause or a block of code

Below is the figure shows how elIf statement is used with description inside it.

```
In [9]: var = 't'

        if var == 'a':
            print('this is the vowel a')
        elif var == 'e':
            print('this is the vowel e')
        elif var == 'i':
            print('this is the vowel i')
        elif var == 'o':
            print('this is the vowel o')
        elif var == 'u':
            print('this is the vowel u')
        else:
            print('The value in variable var is constant')

        #In the above program we have if, else and elif statements.
        #first line we have assigned value t to a variable 'var'
        #second line contain keyword if with condition if var==a
        #If the condtion is true then the statement is printed
        #elif the other condtion is executed in elif statement in furhter lines
        #if all the conditions are not true then we come to else statement
        #and then statement in else block is printed on the output
```

```
The value in variable var is constant
```

Figure 3.13 elif example

3.5 Loops in Python

3.5.1 For loop

When do we use for loops?

for loops are traditionally used when you have a block of code which you want to repeat a fixed number of times. The Python for statement iterates over the members of a sequence in order, executing the block each time.[9]

Range statement –

This statement 'range()' is used with for loop statements where you can specify one value. For example, if you specify 10, the loop statement starts from 1 and ends with9, which is n-1. Also, you can specify the start and end values. The following examples demonstrate loop statements.

```
In [21]: for i in range(10):
             print(i)

0
1
2
3
4
5
6
7
8
9

In [ ]:
```

Figure 3.14 for example with range statement

3.5.2 While loop

While loops are used for repeating the section of code but not same as for loop, the while loop does not run n times, but until a defined condition is no longer met. If the condition is initially false, the loop body will not be executed at all.

The example is shown in figure 3.15 which says about the while loop process being performed.

```
In [30]: i=1 #we have assigned value one to a variable i
         while i<=5: #entering in while loop if condtion is true
             print(i)
             i=i+1
         print('done')
         i=2
         while i<=10:
             print('*'*i)
             i=i+1
         print('done')

3.5.3 Module, Package and Functions

3.5.3.1 Module

Modules are Python files which has extension as .py. The name of the module will be the name of the file. A Python module can have a set of functions, classes or variables defined and implemented. Module has some python codes, this codes can define the classes, functions and variables. The reason behind using the module is that it organizes your python code by grouping the python code so that it is easier to use.

3.5.3.2 Package

A package consist of the collection of modules in which python codes are written with name init.py. It means that each python code inside of the python path, which contains a file named init.py, will be treated as a package by Python. Packages are used for organizing the module by using dotted names.

For Example - We have a package named simple package which consist of two modules a and b. We will import the module from package in following way.

from simple package import a, b

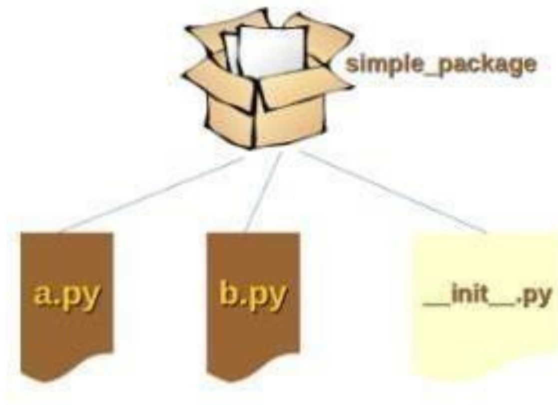

Figure 3.16 Packages Example [10]

3.5.3.3 Functions

A function is a python code which can be reused at any anytime in the whole python code. Function performs specific task whenever it is called during the program. With the help of function the program is divided in to multiple codes.

- **Built in functions** - The functions which are already in the python programming and have specific action to perform are called as built in functions. This function are immutable. Some examples of this functions are - chr() - used to get string print() - used to print an object in terminal min() - used to get minimum value in terminal
- **User defined functions** - This functions are user to defined functions and it starts with the key word 'def' as shown in the example below. We have defined the function names temperature and its task to be performed when called. Below is the example of it.

```
In [36]: def temperature():    #we have defined a function

             #this lines after the function are called function calls

                 print('Temperature is high in summer')
                 print('Temperature is low in winter')

         temperature()

         #when we called the function temperature
         #and everything inside the function is printed

         Temperature is high in summer
         Temperature is low in winter
```

Figure 3.17 Function example

3.5.4 Libraries in Python

Python library is vast. There are built in functions in the library which are written in C language. This library provide access to system functionality such as file input output and that is not accessible to Python programmers. This modules and library provide solution to the many problems in programming.

Following are some Python libraries.

- Matplotlib
- Pandas
- TensorFlow
- Numpy
- Keras
- PyTorch
- LightGBM
- Eli5
- SciPy

Libraries used for project are as follow-

- Pyttsx3
- Pywhatkit
- Datetime
- Wikipedia
- Pyjokes

3.5.5 Matplotlib

"Matplotlib is a plotting library for the Python programming language and its numerical mathematics extension NumPy"[11]. Matlab provides an application that is used in graphical user interface tool kits. Another such libraby is pylab which is almost same as MATLAB.

It is a library for 2D graphics, it finds its application in web application servers, graphical user interface toolkit and shell. Below is the example of a basic plot in python.

```
In [10]: import matplotlib.pyplot as plt
         #we have imported matplotlib library first
         #we have imported the pyplot module from matplotlib library
         #we have give name 'plt' instead of using whole function name
         plt.plot([1,2,3],[1,3,4])
         #we used plot function to plot a graph
         #we have take simple list in plot function
         plt.xlabel('x label') #This function is used to name x axis
         plt.ylabel('y label') #This function is used to name y axis
         plt.title('basic plot') #This function used for title of grapho
         plt.show() #This function show the graph
```

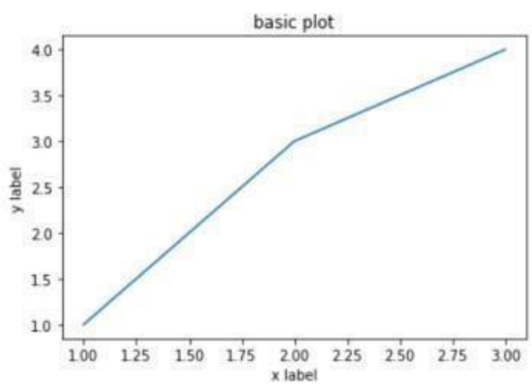

Figure 3.18 Matplotlib basic example

3.5.6 NumPy

NumPy is a library for the Python programming language, adding support for large, multidimensional arrays and matrices, along with a large collection of high-level mathematical functions to operate on these arrays”. The previous similar programming of NumPy is Numeric, and this language was originally created by Jim Hugunin with contributions from several other developers. In 2005, Travis Oliphant created NumPy by incorporating features of the competing Numarray into Numeric, with extensive modifications. [12] It is an open-source library and free of cost.

```
In [7]: import numpy as np  #we have imported numpy library

        data = np.arange(60)
        #arange is the range of the array function
        #we called arange function from numpy libraby
        data.shape = (10,6)
        #there will be 10 rows and 6 columns in array
        #now we have given the number of rows and columns
        print(data) #print the data
        print(len(data)) #gives length of array
        print(data.ndim) #gives dimension of array

        [[ 0  1  2  3  4  5]
         [ 6  7  8  9 10 11]
         [12 13 14 15 16 17]
         [18 19 20 21 22 23]
         [24 25 26 27 28 29]
         [30 31 32 33 34 35]
         [36 37 38 39 40 41]
         [42 43 44 45 46 47]
         [48 49 50 51 52 53]
         [54 55 56 57 58 59]]
        10
        2
```

Figure 3.19 NumPy basic example

3.5.7 Commercially Available Python Compilers

There are many compilers for python code which are using in our daily life, some of them are IDLE, SPYDER, Microsoft Visual Studio, Pycharm etc. and online compilers too. For our project we are using Pycharm compiler which is developed by JetBrains.

3.5.7.1 Pycharm

PyCharm is the most popular IDE used for Python scripting language. This chapter will give you an introduction to PyCharm and explains its features.

PyCharm offers some of the best features to its users and developers in the following aspects

- Code completion and inspection
- Advanced debugging
- Support for web programming and frameworks such as Django and FlaskFeatures of PyCharm

Besides, a developer will find PyCharm comfortable to work with because of thefeatures mentioned below −

Code Completion

PyCharm enables smoother code completion whether it is for built in or for an external package.

SQLAlchemy as Debugger

You can set a breakpoint, pause in the debugger and can see the SQL representation of the user expression for SQL Language code.

Git Visualization in Editor

When coding in Python, queries are normal for a developer. You can check the last commit easily in PyCharm as it has the blue sections that can define the difference between the last commit and the current one.

Code Coverage in Editor

You can run .py files outside PyCharm Editor as well marking it as code coverage details elsewhere in the project tree, in the summary section etc.

Package Management

All the installed packages are displayed with proper visual representation. This includes list of installed packages and the ability to search and add new packages.

Local History

Local History is always keeping track of the changes in a way that complements like Git. Local history in PyCharm gives complete details of what is needed to rollback and what is to be added.

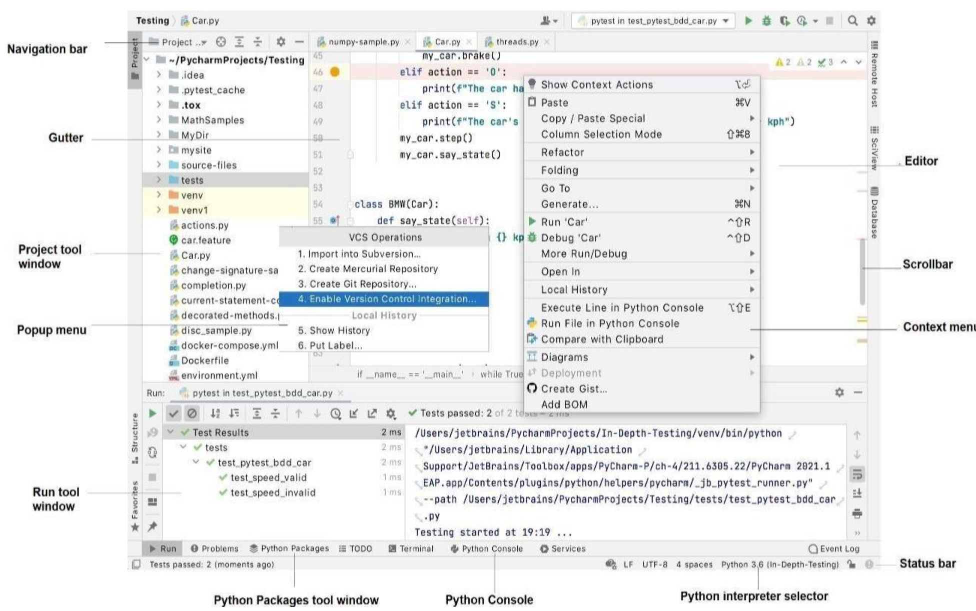
Refactoring

Refactoring is the process of renaming one or more files at a time and PyCharm includes various shortcuts for a smooth refactoring process.

3.5.7.1.1User Interface of PyCharm Editor

The user interface of PyCharm editor is shown as given below. Observe that the editor includes various features to create a new project or import from an existing project.

When you open a project in PyCharm, the default user interface looks as follows:



Depending on the set of plugins, PyCharm edition , and configuration settings, your IDE maylook and behave differently.

3.5.7.1.2 Editor

Focus: Escape

Use the editor to read, write, and explore your source code.

3.5.7.1.3 Action indicators and action list

Open action list: Alt+Enter

Different icons that appear in the left editor gutter are action indicators that help you notice available quick fixes and other actions.

Quick fixes and other commands relevant for the current caret position are available in the action list that you can open with Alt+Enter or by cliking an action indicator.

3.5.7.1.4 Navigation bar

Focus: Alt+Home

Show/hide: View | Appearance | Navigation Bar

The navigation bar at the top is a quick alternative to the Project tool window Workspace tool window where you can navigate the structure of your project and open files for editing.

Note: If VCS integration is enabled, items in the navigation bar are highlighted accordingto VCS file status colors.

Use the buttons to the right of the navigation bar to build run and debug your application, and perform basic version control operations (if the version control integration is configured). It also contains buttons to Run Anything (press Ctrl twice) and Search Everywhere (press Shift twice).

Note: The main toolbar with buttons for opening and saving files, undo and redo actions is hidden by default. To show it, select View | Appearance | Toolbar.

3.5.7.1.4 Status bar

Show/hide: **View | Appearance | Status Bar**

The left part of the status bar at the bottom of the main window shows the most recent event messages and descriptions of actions when you hover over them with the mouse pointer. Click a message in the status bar to open it in the Event Log. Right-click the message in the status bar and select Copy to paste the message text when you are

searching for a solution to a problem or need to add it to a support ticket or to the PyCharm issue tracker.

Use the quick access button to switch between tool windows and hide the tool window bars.

The status bar also shows the progress of background tasks. You can click to show the Background Tasks manager.

The right part of the status bar contains widgets that indicate the overall project and IDE status and provide access to various settings. Depending on the set of plugins and configuration settings, the set of widgets can change. Right-click the status bar to select the widgets that you want to show or hide.

View | Tool Windows

Tool windows provide functionality that supplements editing code.

For example, the Project tool window shows you the structure of your project, and the Run tool window displays the output of your application when you run it.

By default, tool windows are docked to the sides and bottom of the main window. You can arrange them as necessary, undock, resize, hide, and so on. Right-click the title of the tool window or click in the title for its arrangement options.

You can assign shortcuts to quickly access the tool windows that you frequently use. Some of them have shortcuts by default. For example, to open the Project tool window, press Alt+1, and to open the Terminal tool window, press Alt+F12. To jump from the editor to the last active tool window, press F12.

3.5.7.1.5 Context menu:

You can right-click various elements of the interface to see the actions available in the current context. For example, right-click a file in the Project tool window for actions

related to that file, or right-click in the editor to see actions that apply to the current codefragment.

Most of these actions can also be performed from the main menu at the top of the screenor the main window. Actions with shortcuts show the shortcut next to the action name.

3.5.7.1.6 Popup menus

Popup menus provide quick access for actions related to the current context. Here aresome useful popup menus and their shortcuts:

- Alt+Insert opens the **Generate** popup for generating boilerplate code based onthe context.
- Ctrl+Alt+Shift+T opens the **Refactor This** popup with a list of contextuallyavailable refactorings.
- Alt+Insert in the Project tool window opens the **New** popup for adding new filesand directories to your project.
- Alt+` opens the **VCS Operations** popup with contextually available actions foryour version control system.

You can create custom popup menus using quick lists of actions that you often use.

3.5.7.1.7 Main window

The main window contains all the information for a single PyCharm project. You can open multiple projects in multiple windows. By default, the window header contains the name of the project and the name of the currently open file. If there are multiple modules, it will also show the name of the relevant module.

Show full paths in the header

In the Settings/Preferences dialog Ctrl+Alt+S, open Appearance & Behavior |Appearance and select the Always show full paths in window header checkbox.

This will show the path to the project and to the current file.

CHAPTER 4

PROJECT IMPLEMENTATION

4.0 IMPLANTATION STAGES

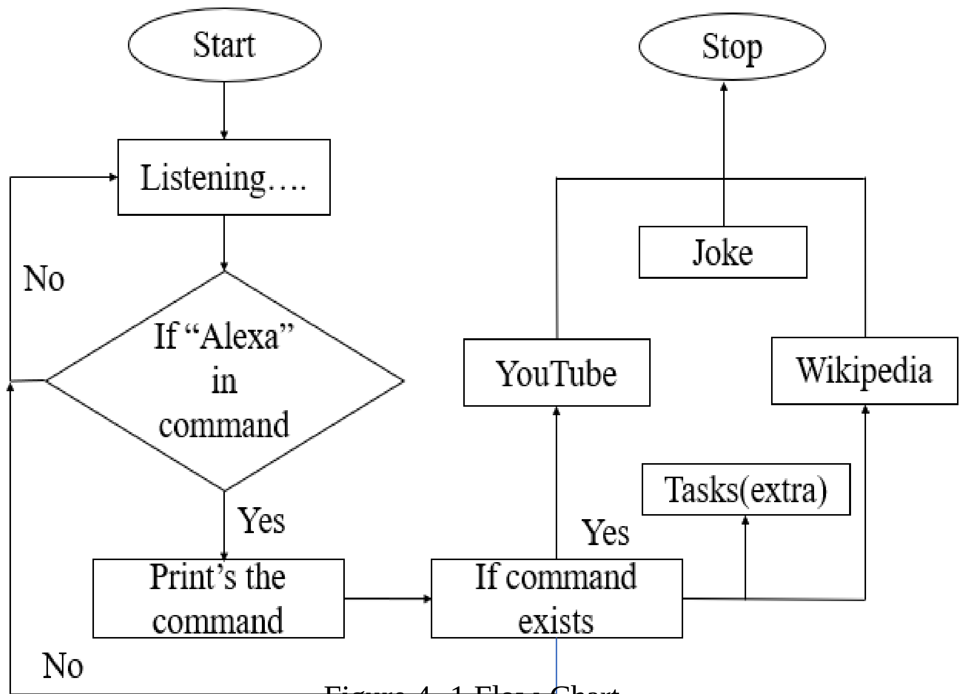


Figure 4. 1 Flow Chart

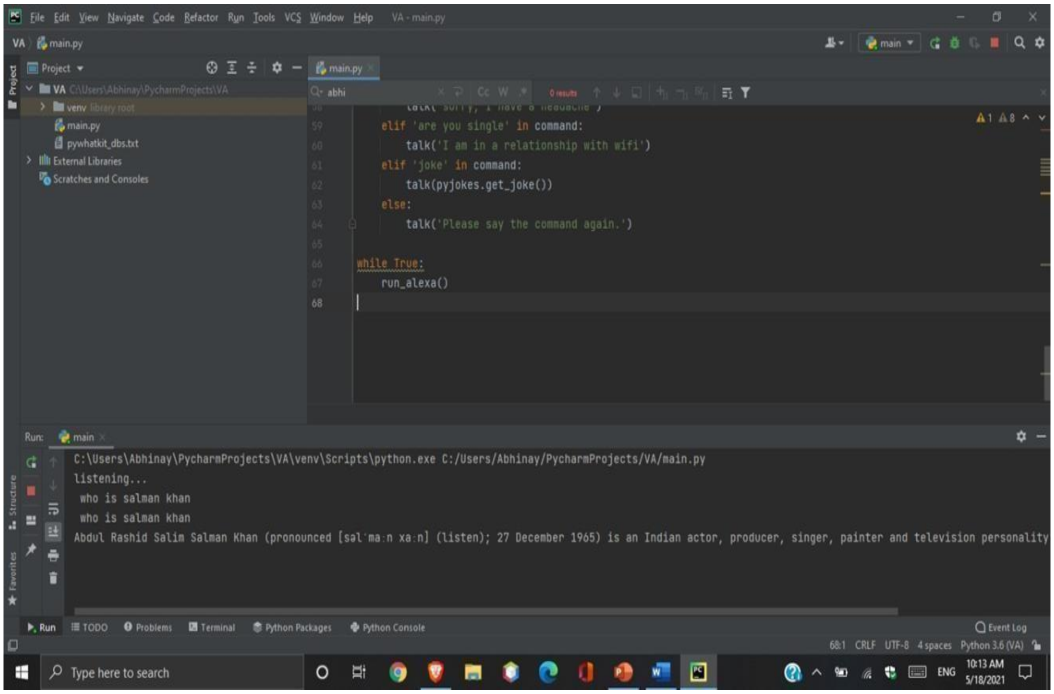
Stage 1: Switch on the PC/laptop.

Stage 2: Open pycharm community software and create new project for our virtualassistant software.

Stage 3: Write the required code for our VA using python language, which is easy to use.

Stage 4: Before running the code open terminal of software and import required librariesand download.

Stage 5: Now run the code and start talking to the assistant which will help us to do tasks.



4.1 RESULTS
