Here, the command given by the user is "Who is Salman Khan" with the wake word "Escobar". This is the request given by the user. The output by virtual assistant is in the form of Voice and Text out as seen in the screen.

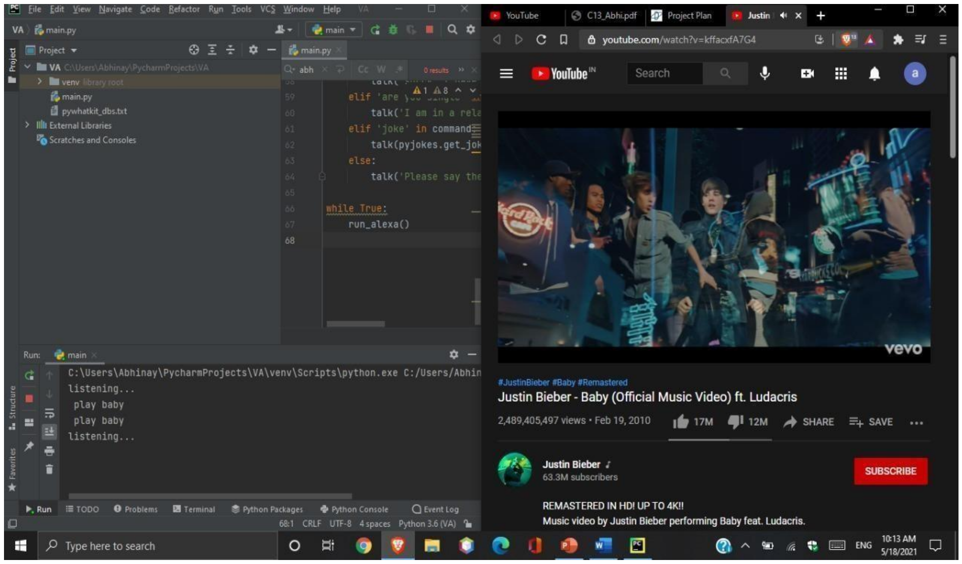

Figure 4. 3 Playing Song

Here, the command given by the user is “Play BABY” with the wake word “Escobar”. This is the request given by the user. The output by virtual assistant is in the form of Voice output by opening YouTube as seen in the screen. BABY(Song) is a trending song in internet past 10 years.

Similarly, there are many other applications like saying a JOKE, Time etc.

CHAPTER 5

CONCLUSION AND FUTURE ENHANCEMENT

Personal assistant software improves user productivity by managing routine tasks of the user and by providing information from online sources to the user. As discussed earlier, technologies such as web services, sharing of data, linked data, shared ontologies, knowledge databases, and mobile devices are proving to be enablers for tools such as personal assistant software.

Nowadays all the virtual assistants are being integrated or manufactured at industrial standards and are given to the public. This paper deals with making their own virtual assistant at mature level later it may be done even at teen level.

PUBLICATION

- Publication : ICSMEC-21
- Paper ID : ICSMEC21-0015
- Paper Title : BUILD, OWN VIRTUAL ASSISTANT

Dear Author(s),

Warm Greetings from St.Martins Engineering College.

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in the online mega International Conference on "Smart Modernistic in Electronics and Communication" (ICSMEC-21).

Paper ID:ICSMEC21-0015
Paper Title: BUILD, OWN VIRTUAL ASSISTANT

Paper Accepted.

Please Send the final camera ready paper Paper After Registration

DECLARATION

We, the student of Bachelor of Technology in Department of 'Electronics and Communication Engineering ', session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled as "Broth Culture Acidity Control On NFT –based Hydroponic Plants" , is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

K.Jagadeesh	**Nikhil Sharma**	**V.Hareesh**
(17K81A04F2)	**(17K81A04G0)**	**(17K81A04H6)**

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head & Professor**, the Dept. of **Electronics and Communication Engineering**, for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand**, for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri, Professor in IT and Dr.R.Santosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work.

1. K.Jagadeesh
2. Nikhil Sharma
3. V.Hareesh

ABSTRACT

Nutrient Film Technique (NFT) hydroponic cultivation could be an alternative to overcome the increasing food need. Nutritional needs supply of hydroponic plant are one of parameters that need to be considered. NFT hydroponic nutrient controlling system aims to facilitate farmers to maintain the amount of nutrition according to plant needs. This system uses linear regression method to control the amount of nutrients. The accuracy results obtained from controlling system experiment are 87.84%.

CHAPTER-1

INTRODUCTION

1.1 Overview of the project:

There is an increasing need to re-circulate and reuse nutrient solutions in order to reduce environmental and economic costs. However, managing the nutrient solution is one of biggest challenges in hydroponics. Many research scientists dump out nutrient solutions and refill at weekly intervals. Some authors have recommended automated measurement and control of individual nutrients in solution as essential to nutrient control. However, two decades of research in hydroponics has shown us that dumping and replacing solution is unnecessary. Monitoring ions in solution at frequent intervals is extremely expensive and not always necessary; in fact the rapid absorption and consequent depletion of some nutrients often causes people to add toxic amounts of nutrients to the solution.

Managing nutrients by mass balance. During the past 18 years, we have managed nutrients in closed hydroponic systems according to the principle of "mass balance," which means that the mass of nutrients is either in solution or in the plants. We add nutrients to the solution depending on what we want the plant to take up. Plants quickly remove their daily ration of some nutrients while other nutrients accumulate in the solution. This means that the concentrations of nitrogen, phosphorous, and potassium can be at low levels in the solution (0.1 mM or a few ppm) because these nutrients are in the plant, where we want them. Maintaining a high concentration of nutrients in the solution can result in excessive uptake that can lead to nutrient imbalances. For example, the water removed from solution through transpiration must be replaced and it is necessary to have about 0.5 mM phosphorous in the refill solution. If the refill solution was added once each day, the phosphorous would be absorbed by the plant in a few hours and the solution phosphorous concentration would be close to zero. This does not indicate a deficiency; rather it indicates a healthy plant with rapid nutrient uptake. If phosphorous was maintained at 0.5 mM in the recirculating solution, the phosphorous concentration in the plant could increase to 1% of the dry mass, which is 3 times higher than the optimum in most plants. This high phosphorous level can induce iron and zinc deficiency (Chaney and Coulombe, 1982). Feeding plants in this way is like the daily feeding of a pet dog, some dogs would be seriously overweight if their food bowls were kept continuously full.

1.2 Objectives of the Study:

High yielding and high grade of crops are essential in modern day agriculture, this can only be achieved by smart farming technology which is used for making farms more intelligent in sensing its controlling parameters. Manual monitoring is in practice which is a very trivial task because the plants may die out if there is no proper care is taken. The architecture of this hydroponic system which is fully automatic that can be integrated into the agricultural curriculum while introducing business skills. The automatic monitoring and control of the environmental events such as light intensity, pH, electrical conductivity, water temperature, and relative humidity is carried out by lodging sensors and actuators onto the system. The maintenance and automated monitoring are done by the intervention of the IoT that are used to transfer and retrieve data to the internet (mass storage) and a mobile app is used to communicate the current status of the hydroponic system to the user through the use of internet to their mobile phones. This futuristic system can use high data analytics and prolonged data gathering to improve the accuracy of reckoning.

1.3 Scope of the Study:

Hydroponic is a method where the crops are grown in the absence of soil the nutrients that are acquired from the soil are given to them artificially. The term Hydroponics was acquired from the Greek words ‘hydro’ means water and ‘ponos’ means labour. This soil less culture of originating crops often involves their roots to be immersed in the nutrient solution along with some gravels or perlite medium. The maximum yield is achieved by the supply of sufficient quantity of nutrients and optimum microclimatic conditions are the main goal of hydroponics. Since soil is excluded from production process there will not be any problem related to soil borne diseases, pests and weeds. By the exclusion of these problems, there will not be any usage of harmful plant protection chemicals, so that there is a fresh and healthy yield of crops by the hydroponic method. The set-up of hydroponic only demands limited space and limited quantity of water as they recirculate and reuse the water. This eliminates the problems that are caused by soil. This limited space requirement also favours hydroponic as it can be accommodated in terraces, balconies and courtyards. So, there is a high probability of growing crops in urban areas, where cultivable land is limited. Hydroponics does not cause any adverse effect on the quality of fruits and flowers produced by it.

1.4 Methodology:

The seed of the desired crop is used and placed in the crop bed in phase-2 manually. A domestic power source is used to power the system. The user can select the crop that is to be planted from his mobile application which is connected through IoT. After the crop selection is done, the water is pumped from the main tank to the automatic nutrient mixing tank, the water pump stops pumping once the water level is reached. Here the water is mixed with the nutrients inappropriate proportions according to selected crop. After the completion of this process the user is notified through the mobile application. Users can also see level of nutrients present in water through his mobile application. The nutrient rich water is then flowed through pH tank with the help of solenoid valve. The user is notified once the pH tank is filled with the nutrient rich water. The pH tank has a pH sensor which monitors the pH of the water. If the pH of water is undesirable, then the system sends an alert to the user that pH is not in correct proportion and asks the user to enable the solenoid valve S2 with 'YES' or 'NO'. If the answer is 'YES' than the solenoid valve S2 opens and the water is poured out to reuse tank. If the pH of water is in correct proportion then the water is oxygenated by the oxygen pump. Once the water is completely oxygenated the user gets notified that pH is OK and water is oxygenated and ready to flow to the plants. Water pump P2 is used to pump water to the plants as well as from the plants by this way the water is circulated. The temperature and humidity of the environment is measured by temperature sensor and the readings are shown in the mobile application. Normally a camera is used to monitor the growth of the plants and also looks for any infection on the plants, these processes are updated to the user through the mobile application. Once the plants are ready to harvest, system sends the notification, your plant is ready to harvest. If the camera spots any infection in plants due to insects or disease, this turns the system into red alert by sending the red alert message to the user via application. Here digital image processing is used to point out the infection on the plants, the user is notified once the infection is detected. The system compares this image with the data in the cloud. If the symptoms of the image taken with the existing data are similar, then the system identifies the name of the disease or insect that has infected the plant and sends the complete details about the infection with its cure to the user via application.

CHAPTER-2

LITERATURE SURVEY

2.1 Key concept:

Hydroponics or soilless cultivation has been widely used in different countries because of its feasibility and environmental safety. This technique can be considered as the best alternative in areas where serious soil and water problems like soil born pests and diseases, soil and water salinity, chemical residues in soil and water, shortage of water etc. exist. In hydroponics, plants are grown by directly supplying optimum amount of nutrients in water. Composition of nutrient solution, electrical conductivity, pH and oxygen concentration have direct influence on the yield and quality of crops grown under hydroponics. If any of these factors are non-optimal, crops expresses stress symptoms.

Comparison of Land, Water and Energy requirement of Lettuce grown using Hydroponic cultivation vs conventional cultivation

Hydroponics is more efficient compared to traditional land based agricultural methods. In the case of lettuce, hydroponics offered 11 ± 1.7 times higher yields per area and saved up to 95% of water (20 ± 3.8 L/kg/y of hydroponics vs. 250 ± 25 L/kg/y of traditional land based)– mainly lost through evaporation, if not absorbed. The downside is that it required a tremendous amount of energy (90,000 ± 11,000 kJ/kg/y) compared to the 1100 ± 75 kJ/kg/y of traditional land based.

The literature work regarding the project was started in the initial weeks of 2021, few fundamental publishing and the writings helped to understand about the subject and it's evolution over time and even it's limitations. The present subject deals with, how to make the existing system more efficient by employing Embedded System technologies.

1. The writing work By Stephanie Mohammed , in the year 2018, titled as 'Tomorrow's Agriculture "NFT Hydroponics"-- Grow Within Your Budget'. This brilliant piece of work, highlights this culture of growing as one of the most efficient agricultural practices for a sustainable market using particularly NFT which opened doors for further research in the field.
2. D. Yolanda, H. Hindersah, F. Hadiatna and M. A. Triawan, "Implementation of Real-Time Fuzzy Logic Control for NFT-Based Hydroponic System on Internet of Things Environment", *ICSET*,2016, ***in desta's research, fuzzy logic was used** *

.

CHAPTER-3

PROJECT DESIGN

3.1 Introduction to Embedded System:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious. All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

3.2 Block diagram of embedded system:

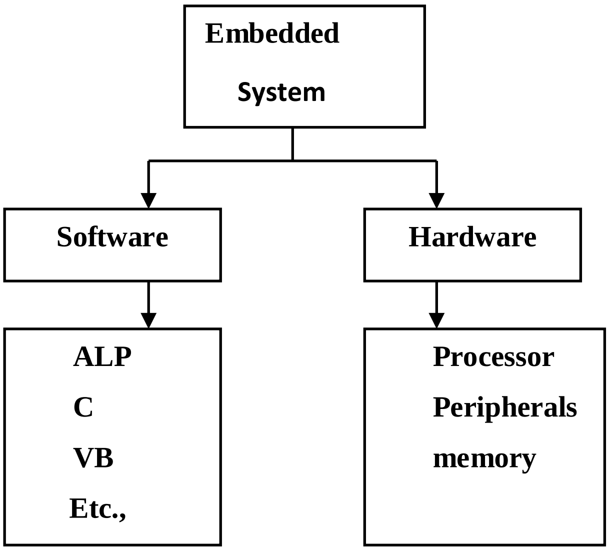

Fig 1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

3.3 Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

3.4 Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

3.5 Three Basic Elements of a Microprocessor:

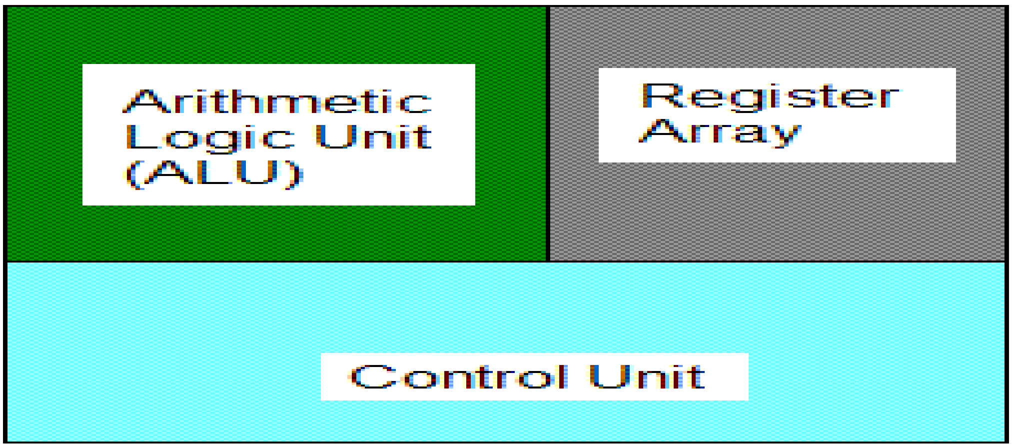

Fig 2:Three basic elements of a microprocessor

3.6 Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electromechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

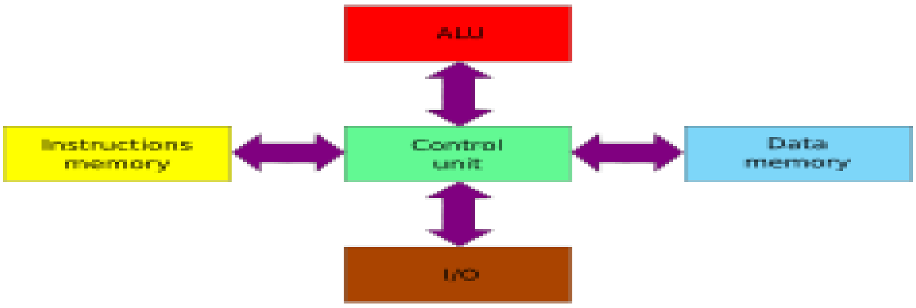

Fig 3: Harvard Architecture

3.6.1 Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

➢ Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

➢ Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

3.6.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

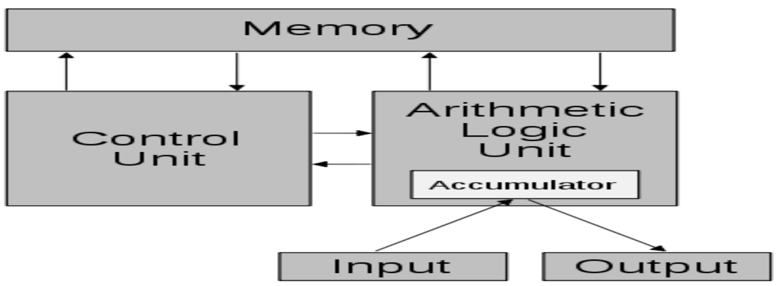

Fig 4: Schematic of the Von-Neumann Architecture

3.7 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Table 1: Atmega328 specifications

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

3.7.1 Arduino:

Arduino is a prototype platform (open source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

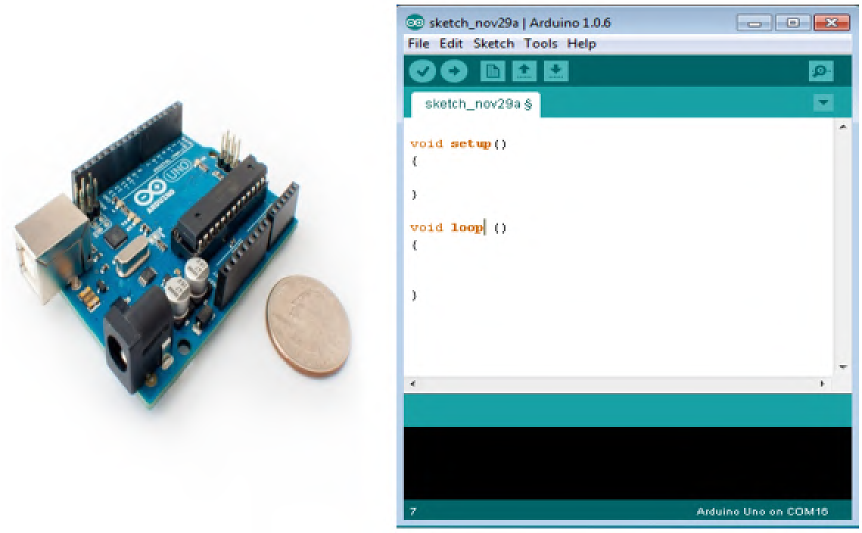

Fig 5: Arduino Uno

3.8 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 2: Arduino boards based on ATMEGA328 microcontroller

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3: Arduino boards based on ATMEGA32u4 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

Table 4: Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header

Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

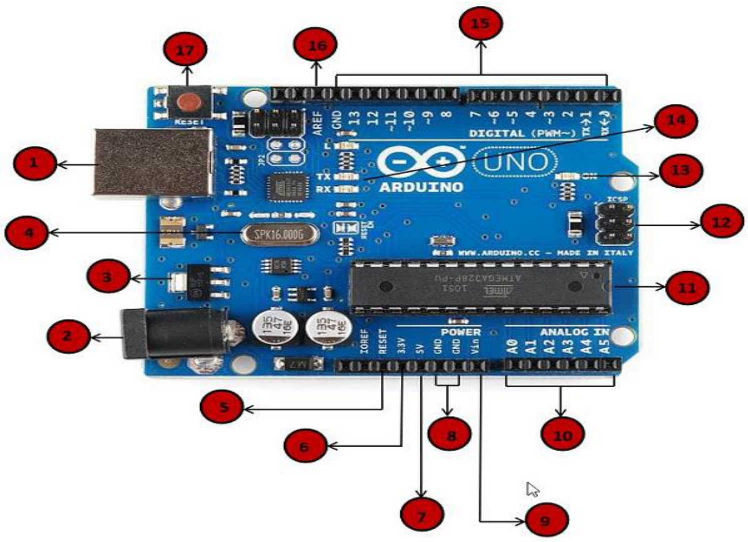
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

3.8.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.

11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage

	(between 0 and 5 Volts) as the upper limit for the analog input pins.

3.9 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

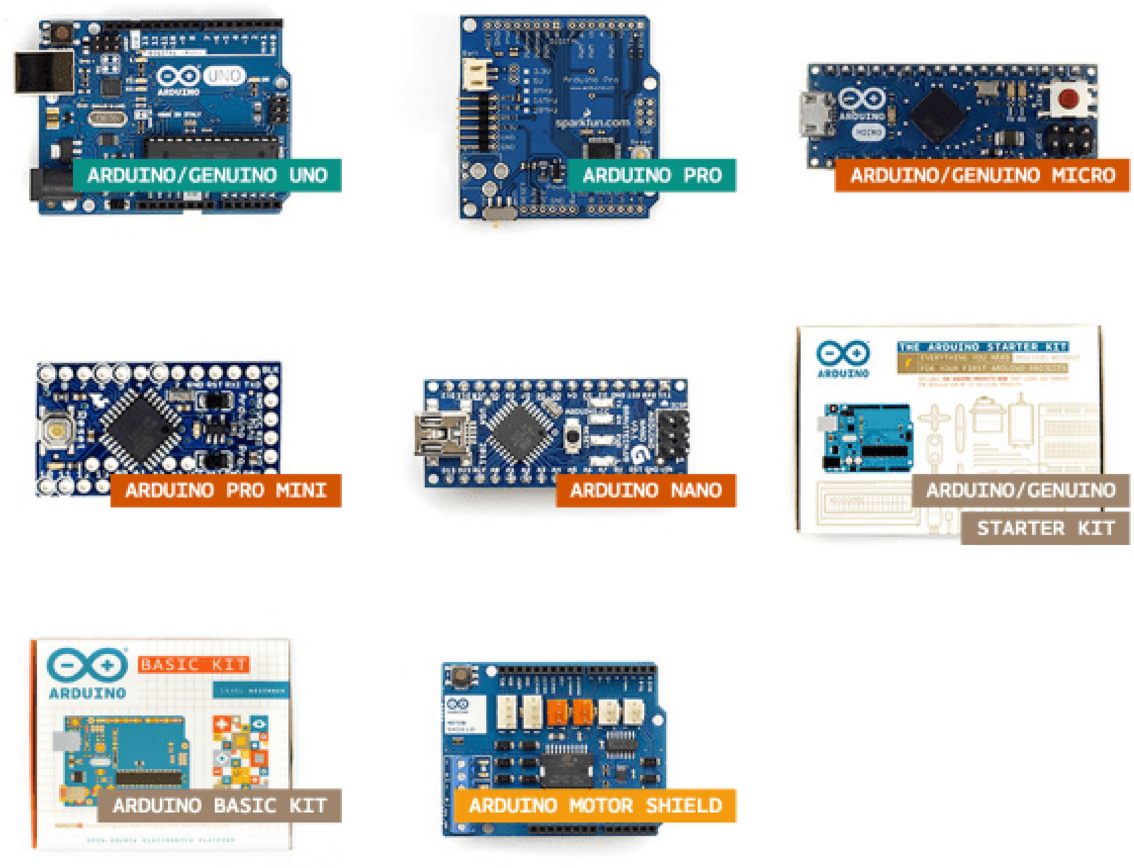


Fig 6: Arduino Family

3.10 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

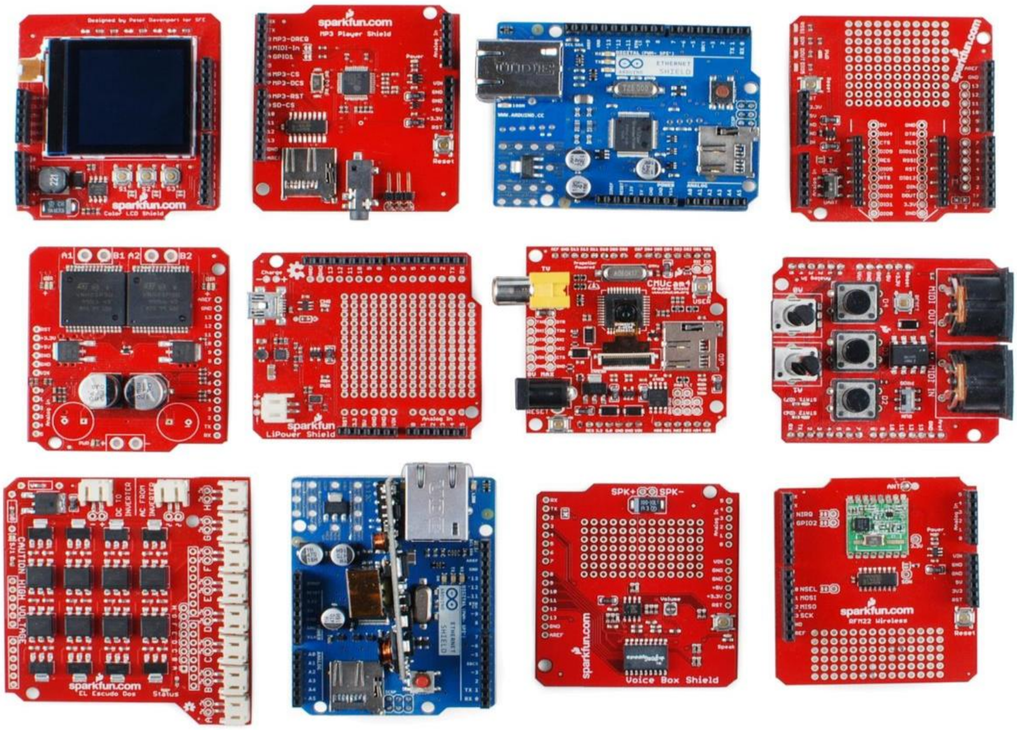

Fig 7: Arduino Shields

3.11 Pin description of ATMEGA328

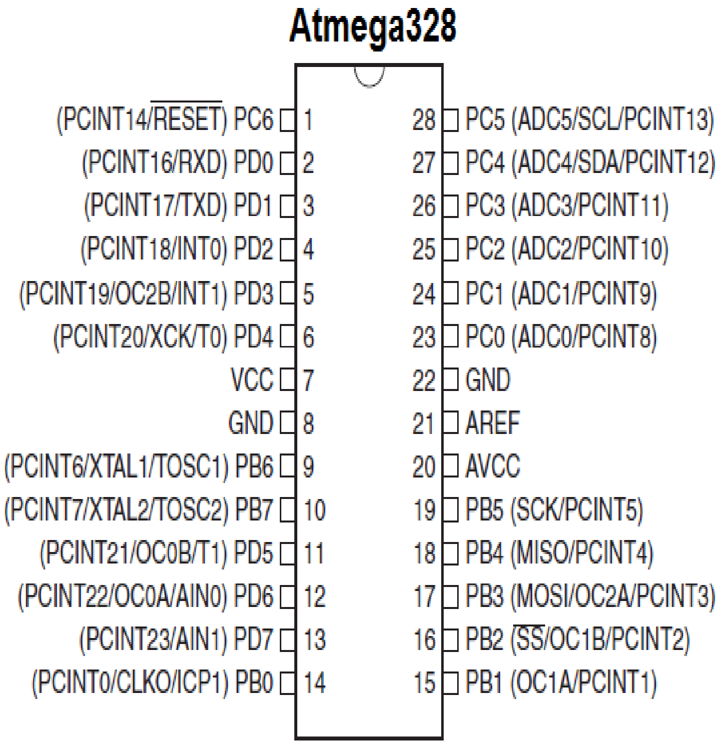

Fig 8: Pin description of ATMEGA328

3.12 Advantages of arduino

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

3.13 Applications

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.14 Power Supply Unit

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as "Regulated D.C Power Supply".

3.14.1 Block Diagram Of Power Supply:

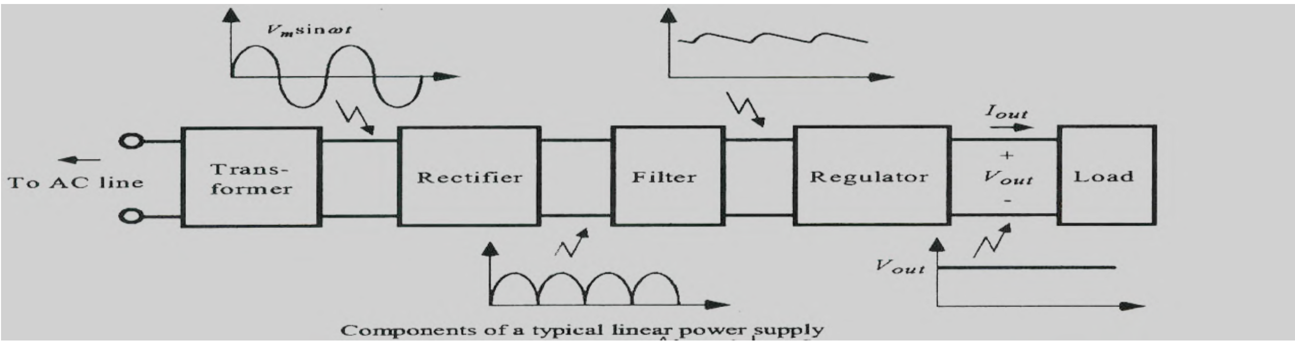

Fig 9: Block Diagram of Power Supply

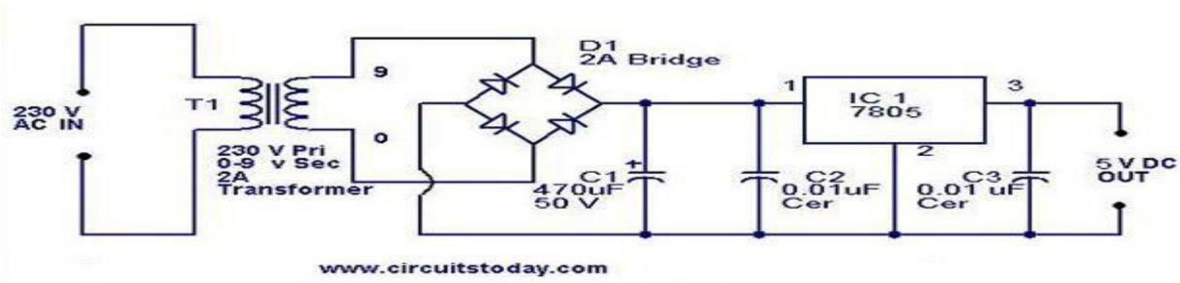

Fig 10: Schematic Diagram of Power Supply

3.14.2 Description Of Power Supply:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.15 Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

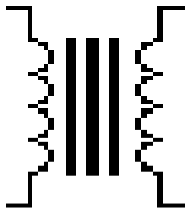

Fig 11: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

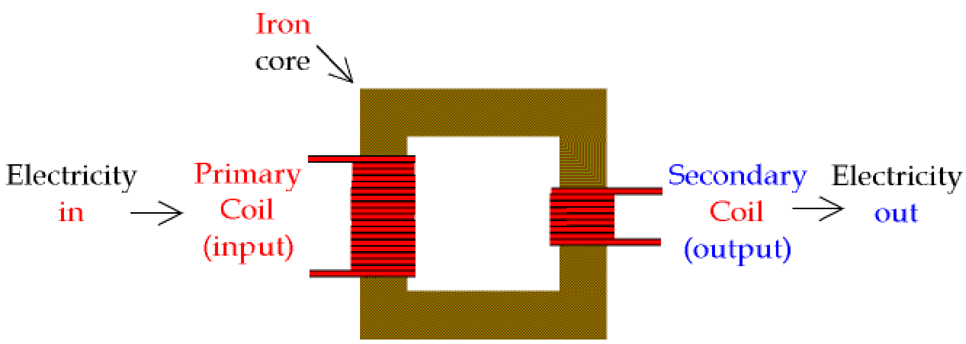

Fig 12: Transformer

3.15.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

3.15.2 Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

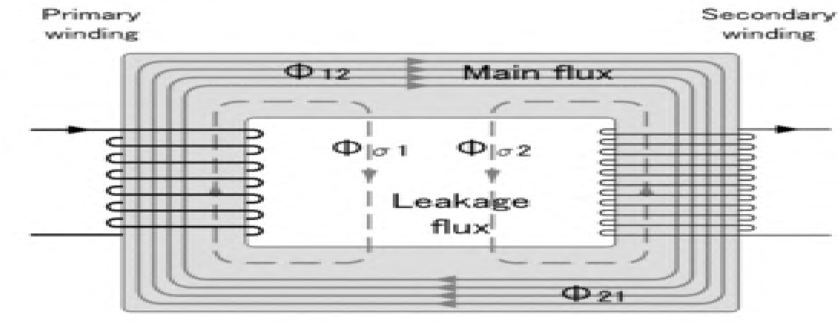

Fig 13: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.15.3 Classification Of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

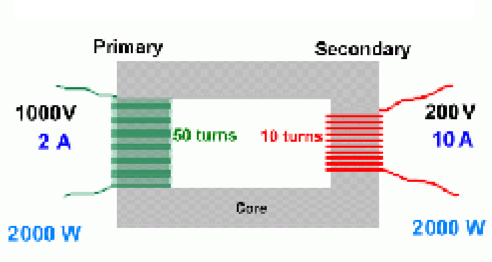

Fig 14: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

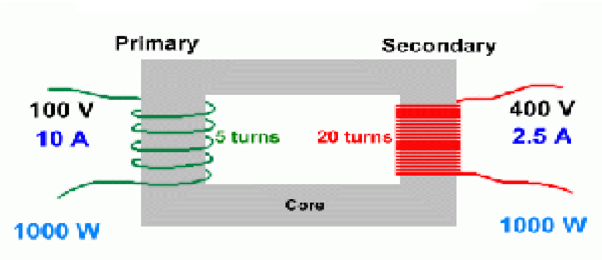

Fig 15: Step-Up Transformer

3.16 Diodes:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

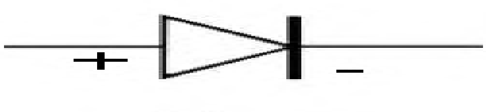

Fig 16: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.17 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

3.17.1 The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

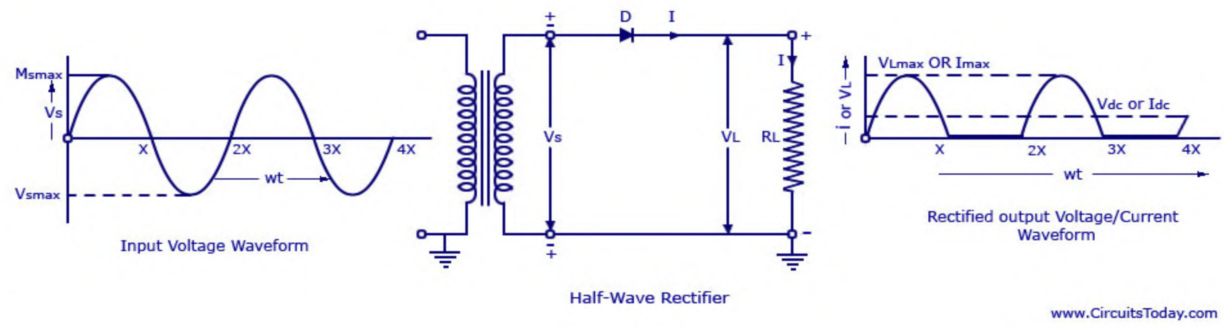

Fig 17): Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

3.17.2 The Full-Wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

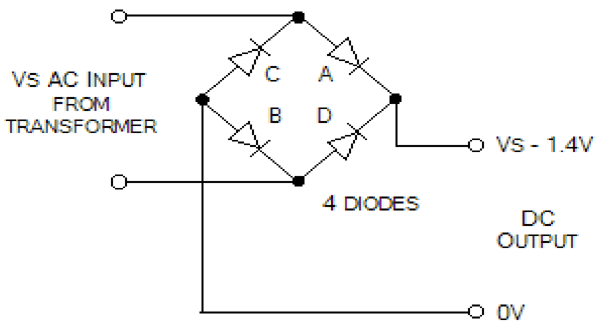

Fig 18: Full-Wave Rectifier

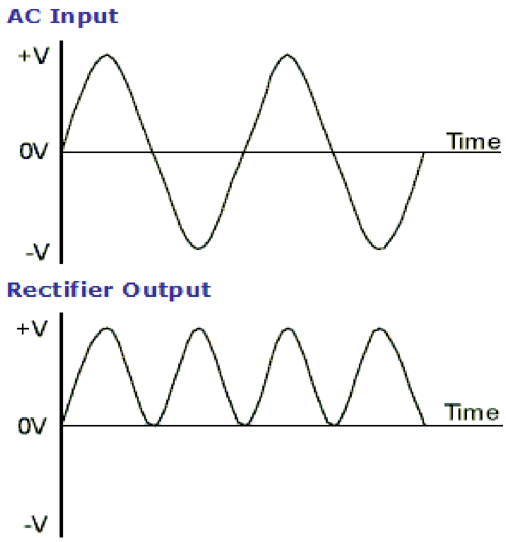

Fig 19): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

3.18 Capacitor filter:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

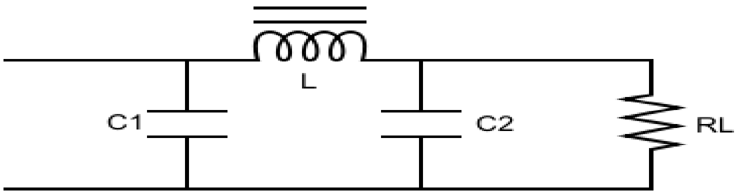

Fig 20 : Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

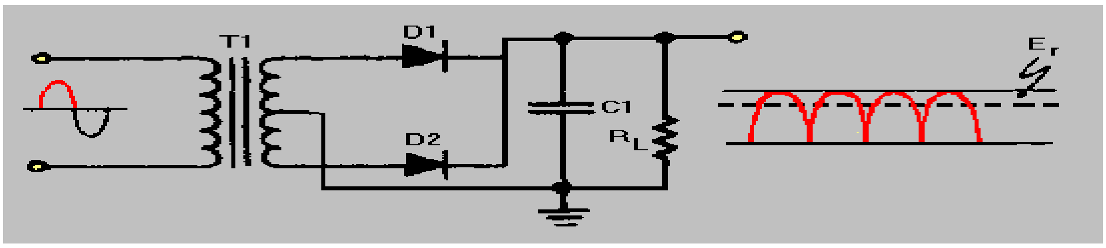

Fig 21: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.19 Voltage regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

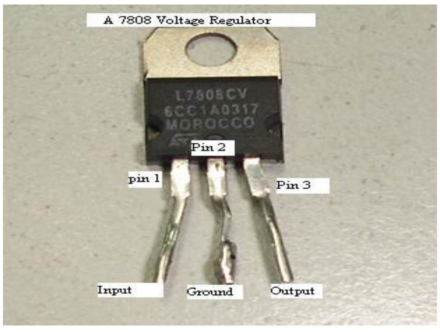

Fig 22: Regulator

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 Hardware Requirement:

- Arduino Uno
- LCD
- Relays
- AC Pump
- DC Pumps
- Ultrasonic Sensor
- TDS Control
- pH Sensor
- WIFI Module

4.2 Block Diagram Of Projet:

Block Diagram:

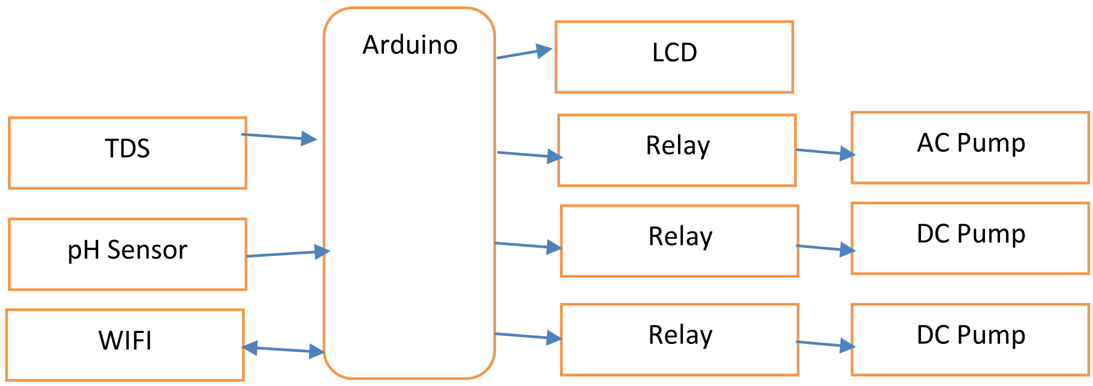

Fig 23: Block diagram of the project

4.3 ESP8266 WIFI Module:

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

4.3.1 Character configuration:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I²C) serial communication protocol,
- Analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I²S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

4.3.2 Applications:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring
- Natural Language-based voice assistants

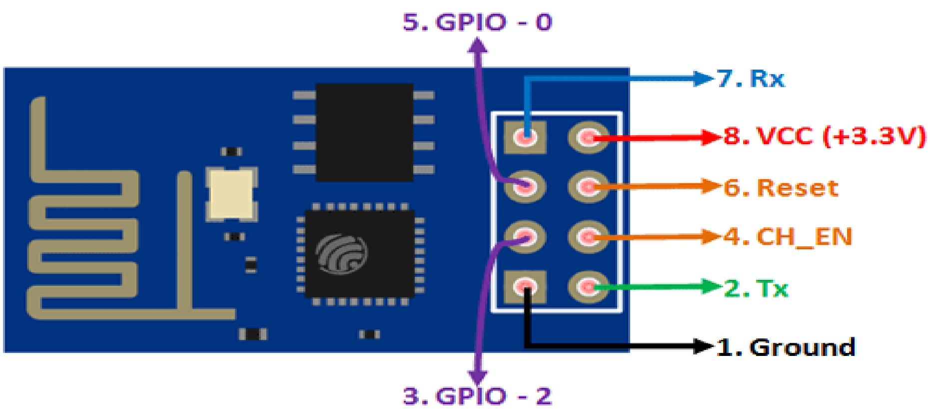

Fig 24: ESP8266 wifi module pin out

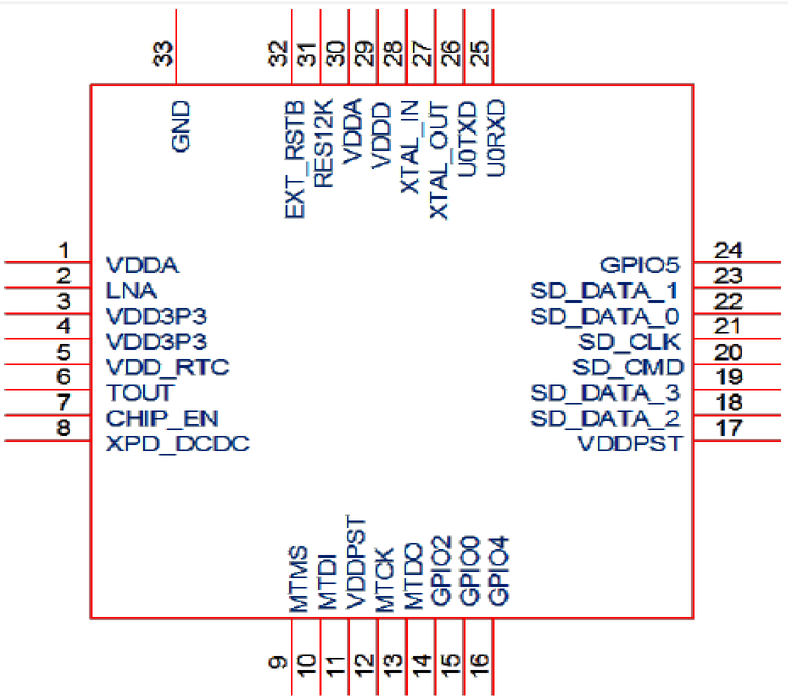
4.3.3 Structure and configuration:

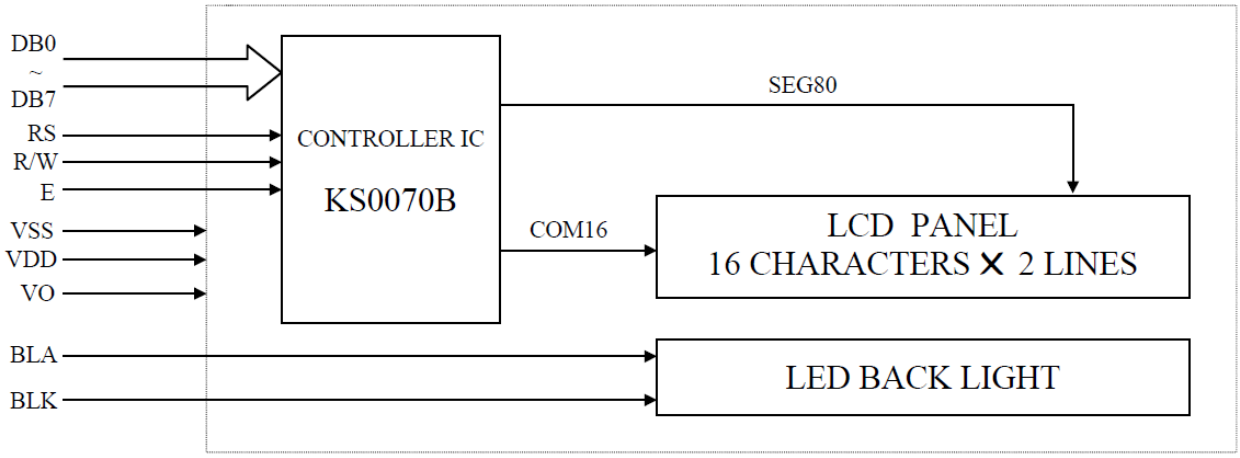


4.4 16 * 2 Alphanumeric LCD:

4.4.1 Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

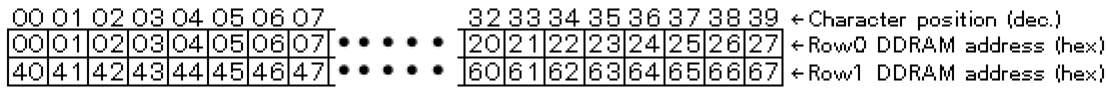
4.4.2 Block Diagram



4.4.3 Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

4.4.4 Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 4 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. Userdefined character patterns are also available by mask-programmed ROM.

4.4.5 Busy Flag

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

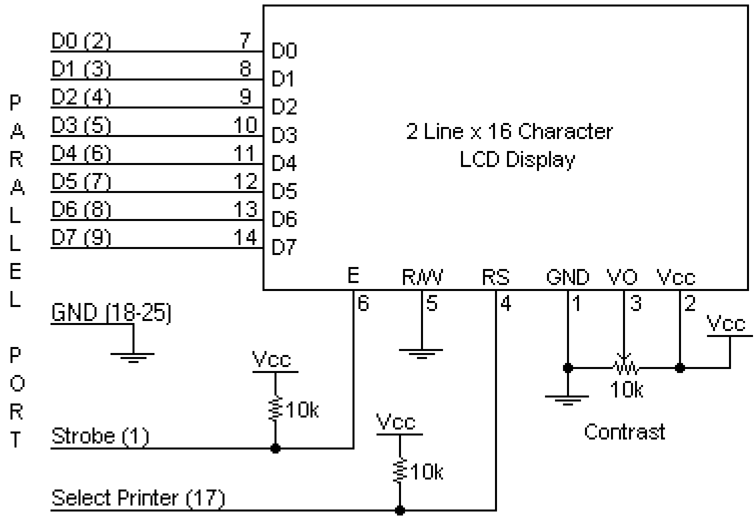
4.4.6 Instruction Register(IR) and Data Register(DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.4.7 16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

4.4.8 Schematic



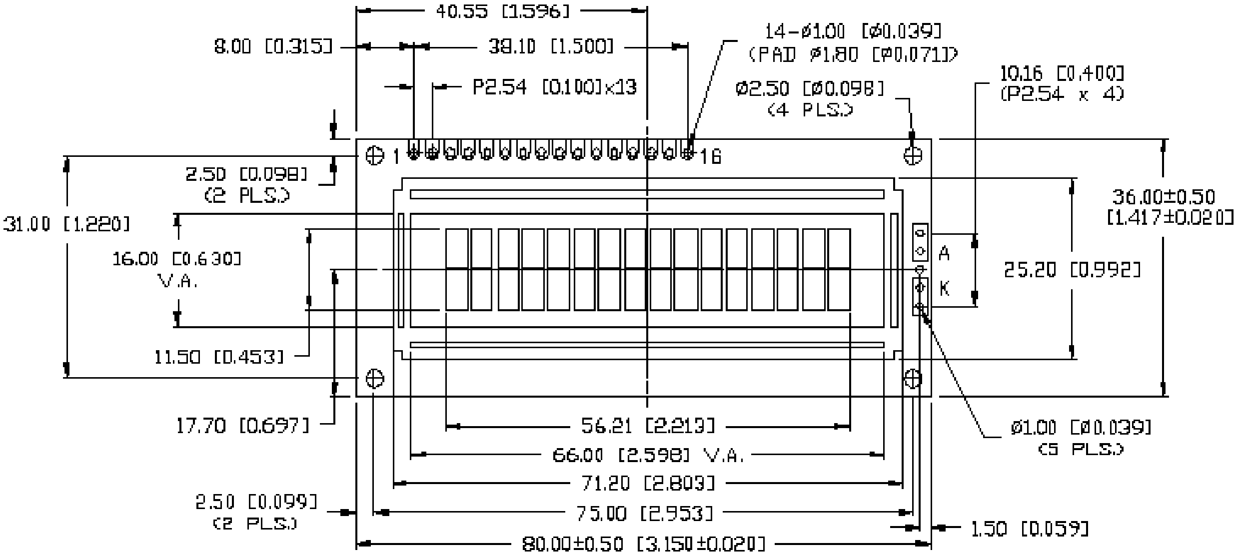
4.4.9 Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.

Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.



Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

4.5 Relay

A relay is used to isolate one electrical circuit from another. It allows a low current control circuit to make or break an electrically isolated high current circuit path. The basic relay consists of a coil and a set of contacts. The most common relay coil is a length of magnet wire wrapped around a metal core. When voltage is applied to the coil, current passes through the wire and creates a magnetic field. This magnetic field pulls the contacts together and holds them there until the current flow in the coil has stopped. The diagram below shows the parts of a simple relay.

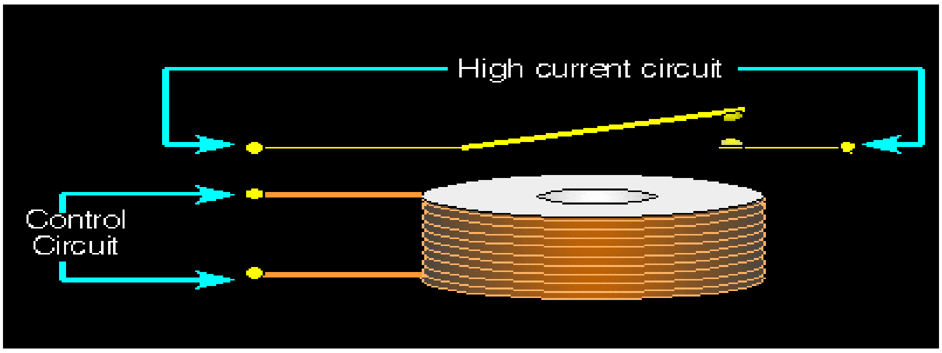


Figure:5.6 Relay

Operation:

When a current flows through the coil, the resulting magnetic field attracts an armature that is mechanically linked to a moving contact. The movement either makes or breaks a connection with a fixed contact. When the current is switched off, the armature is usually returned by a spring to its resting position shown in figure 6.6(b). Latching relays exist that require operation of a second coil to reset the contact position.

By analogy with the functions of the original electromagnetic device, a solid-state relay operates a thyristor or other solid-state switching device with a transformer or light-emitting diode to trigger it.

4.5.1 Pole and throw

SPST

SPST relay stands for Single Pole Single Throw relay. Current will only flow through the contacts when the relay coil is energized.

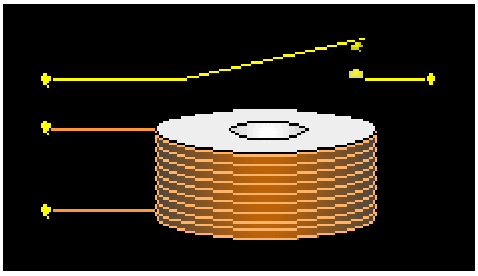

Fig 25: SPST Relay

SPDT Relay

SPDT Relay stands for Single Pole Double Throw relay. Current will flow between the movable contact and one fixed contact when the coil is De-energized and between the movable contact and the alternate fixed contact when the relay coil is energized. The most commonly used relay in car audio, the Bosch relay, is a SPDT relay.

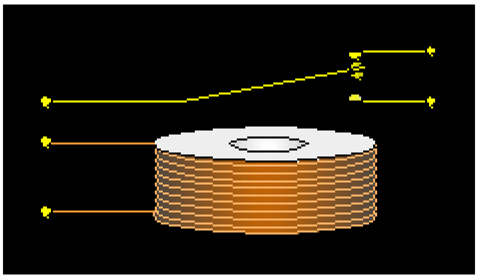

Fig 26: SPDT Relay

DPST Relay

DPST relay stands for Double Pole Single Throw relay. When the relay coil is energized, two separate and electrically isolated sets of contacts are pulled down to make contact with their stationary counterparts. There is no complete circuit path when the relay is De-energized.

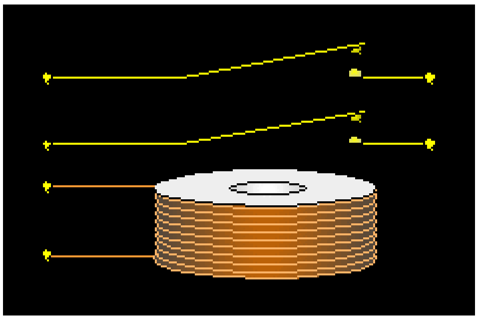

Fig 27: DPST Relay

DPDT Relay

DPDT relay stands for Double Pole Double Throw relay. It operates like the SPDT relay but has twice as many contacts. There are two completely isolated sets of contacts.

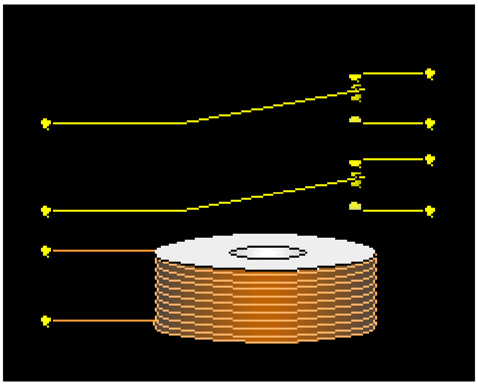

Fig 28: DPDT Relay

This is a 4 Pole Double Throw relay. It operates like the SPDT relay but it has 4 sets of isolated contacts.

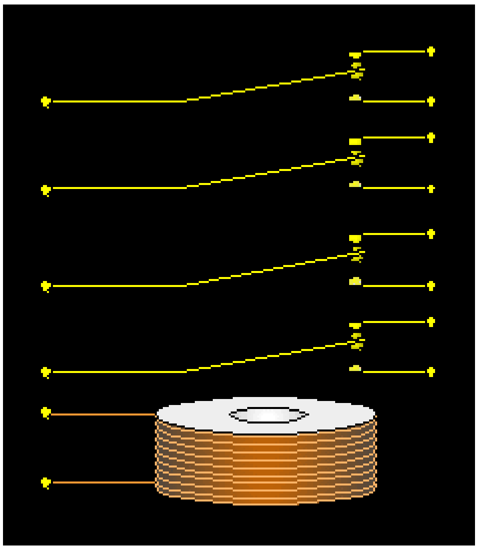

Fig 29: Pole Double Throw relay

4.5.2 Types of relay:

1. Latching Relay
2. Reed Relay
3. Mercury Wetted Relay
4. Machine Tool Relay
5. Solid State Relay (SSR)

Latching relay

Latching relay, dust cover removed, showing pawl and ratchet mechanism. The ratchet operates a cam, which raises and lowers the moving contact arm, seen edge-on just below it. The moving and fixed contacts are visible at the left side of the image.

A **latching relay** has two relaxed states (bi-stable). These are also called "impulse", "keep", or "stay" relays. When the current is switched off, the relay remains in its last state. This is achieved with a solenoid operating a ratchet and cam mechanism, or by having two opposing coils with an over-center spring or permanent magnet to hold the armature and contacts in position while the coil is relaxed, or with a remanent core. In the ratchet and cam example, the first pulse to the coil turns the relay on and the second pulse turns it off. In the two coil example, a pulse to one coil turns the relay on and a pulse to the opposite coil turns the relay off. This type of relay has the advantage that it consumes power only for an instant, while it is being switched, and it retains its last setting across a power outage. A remanent core latching relay requires a current pulse of opposite polarity to make it change state.

Fig 30: Latching relay

Reed relay

A reed relay has a set of contacts inside a vacuum or inert gas filled glass tube, which protects the contacts against atmospheric corrosion. The contacts are closed by a magnetic field generated when current passes through a coil around the glass tube. Reed relays are capable of faster switching speeds than larger types of relays, but have low switch current and voltage ratings.

Mercury-wetted relay

A mercury-wetted reed relay is a form of reed relay in which the contacts are wetted with mercury. Such relays are used to switch low-voltage signals (one volt or less) because of their low contact resistance, or for high-speed counting and timing applications where the mercury eliminates contact bounce. Mercury wetted relays are position-sensitive and must be mounted vertically to work properly. Because of the toxicity and expense of liquid mercury, these relays are rarely specified for new equipment. See also mercury switch.

Machine tool relay

A machine tool relay is a type standardized for industrial control of machine tools, transfer machines, and other sequential control. They are characterized by a large number of contacts (sometimes extendable in the field) which are easily converted from normally-open to normally-closed status, easily replaceable coils, and a form factor that allows compactly installing many relays in a control panel. Although such relays once were the backbone of automation in such industries as automobile assembly, the programmable logic controller (PLC) mostly displaced the machine tool relay from sequential control applications.

Solid-state relay

A solid state relay (SSR) is a solid state electronic component that provides a similar function to an electromechanical relay but does not have any moving components, increasing long-term reliability. With early SSR's, the tradeoff came from the fact that every transistor has a small voltage drop across it. This voltage drop limited the amount of current a given SSR could handle. As transistors improved, higher current SSR's, able to handle 100 to 1,200 Amperes, have become commercially available. Compared to electromagnetic relays, they may be falsely triggered by transients.

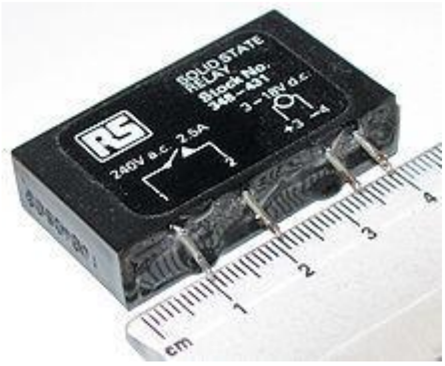

Fig 31: Solid relay, which has no moving parts

4.5.3 Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current
- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

4.5.4 Applications:

Relays are used

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems,
- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.
- To perform time delay functions. Relays can be used to act as an mechanical time delay device by controlling the release time by using the effect of residual magnetism

by means of a inserting copper disk between the armature and moving blade assembly.

4.6 Software Requirements

- Proteus simulation
- MC Programming Language: Embedded C
- Arduino software

4.6.1 Arduino Software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software(IDE)
- ✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

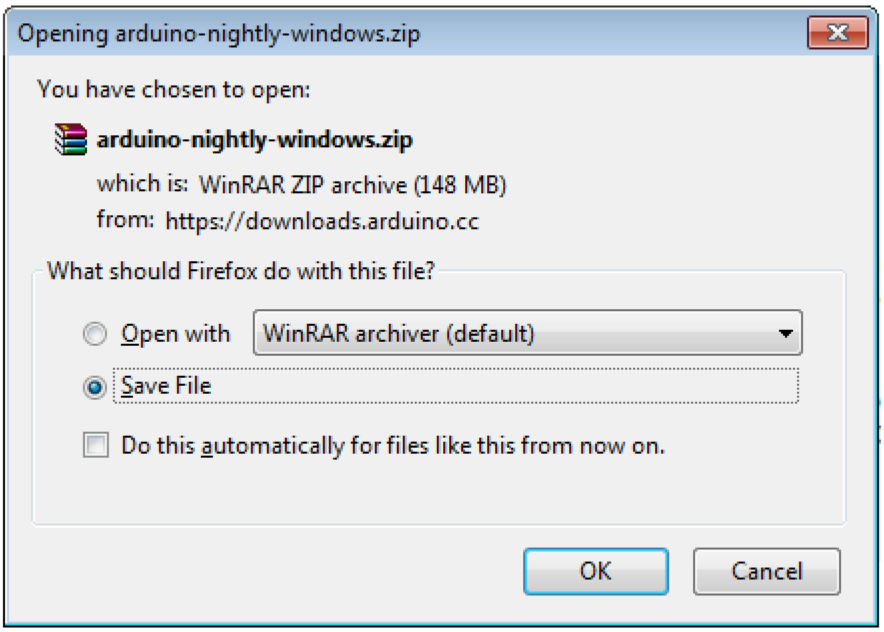
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



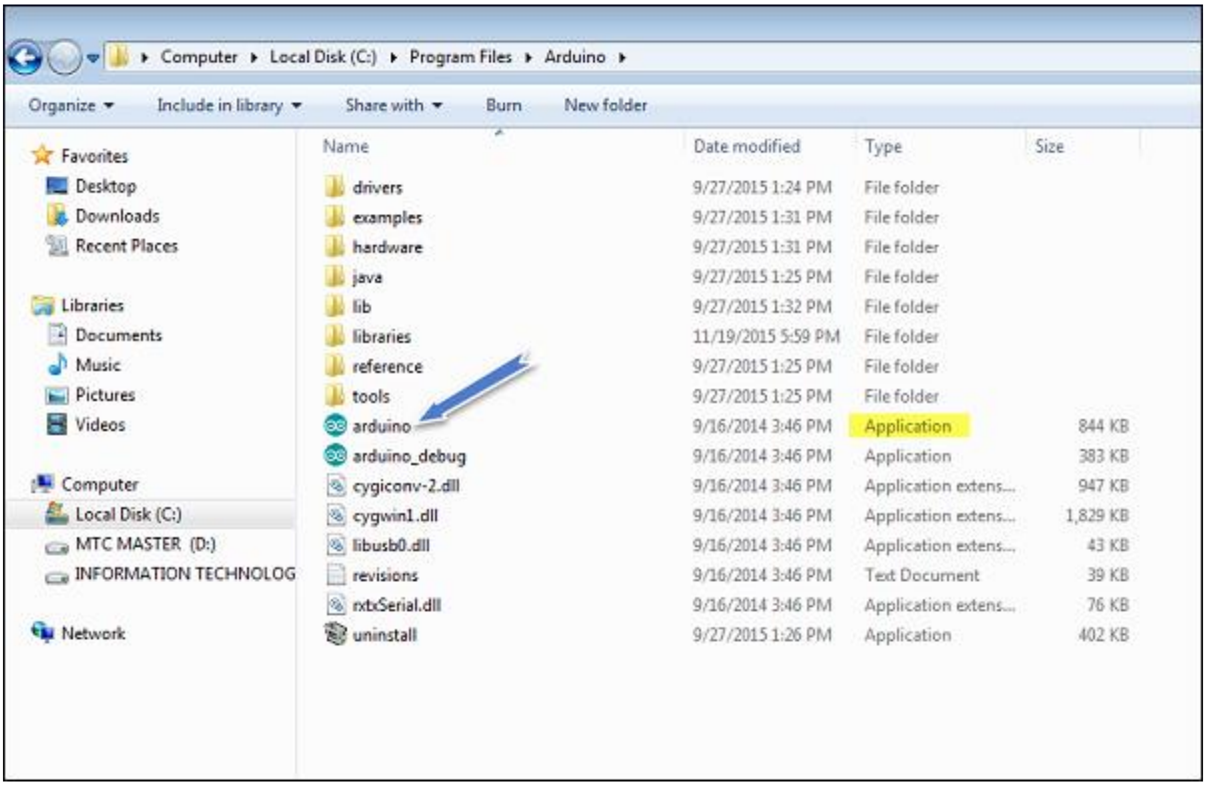
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

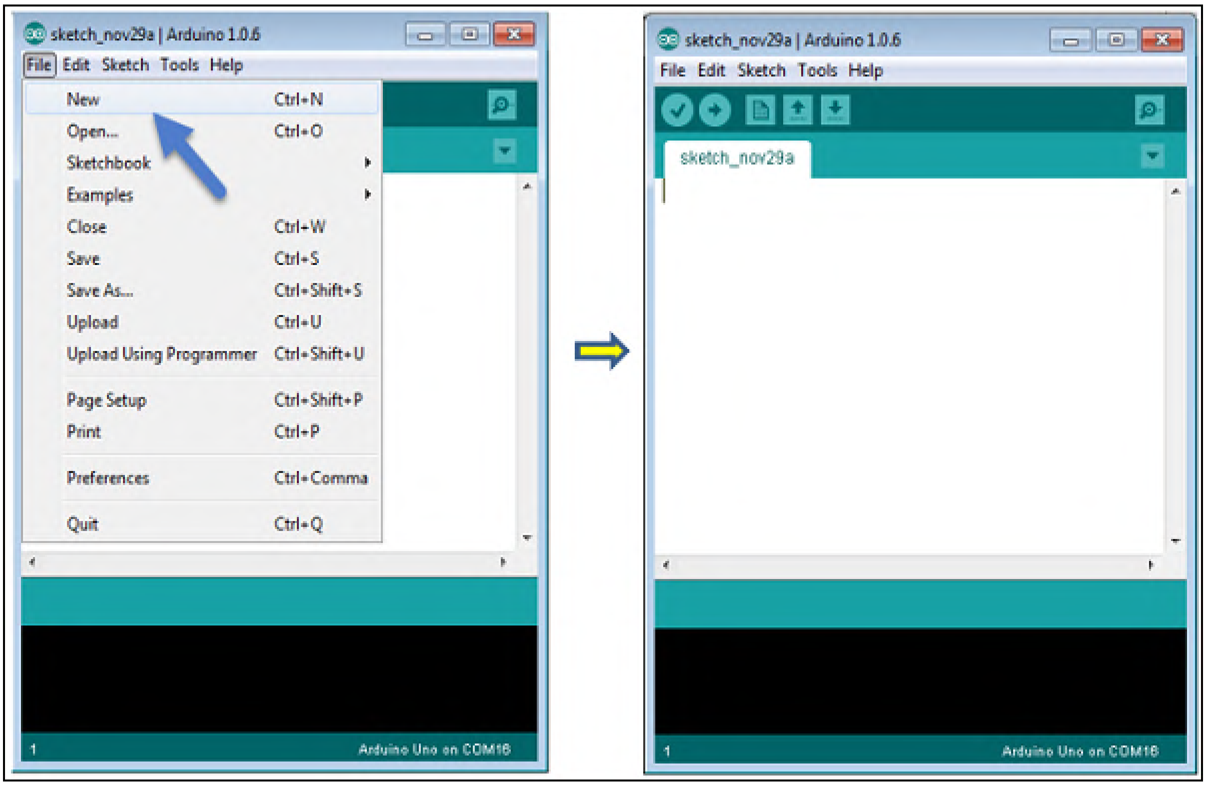


Step 5 – Open your first project.

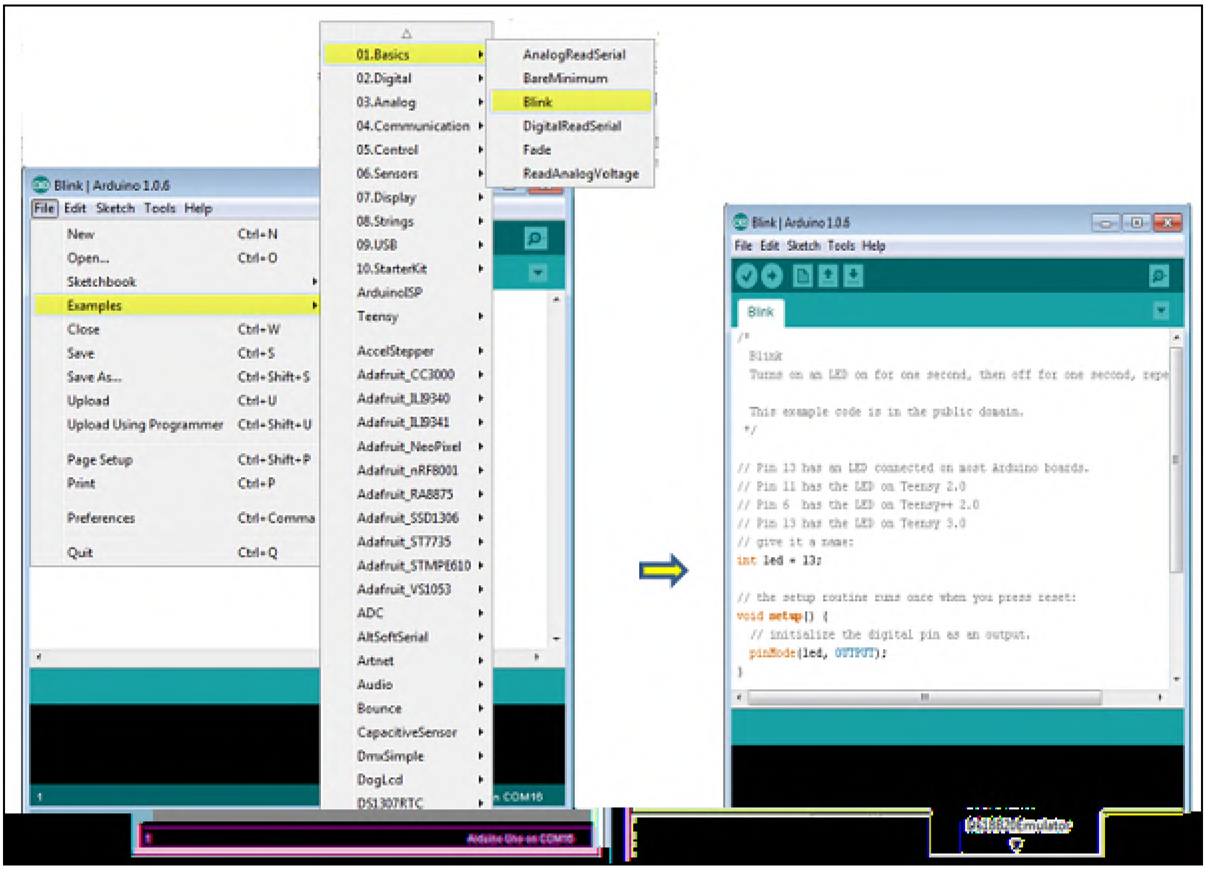
Once the software starts, you have two options –

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

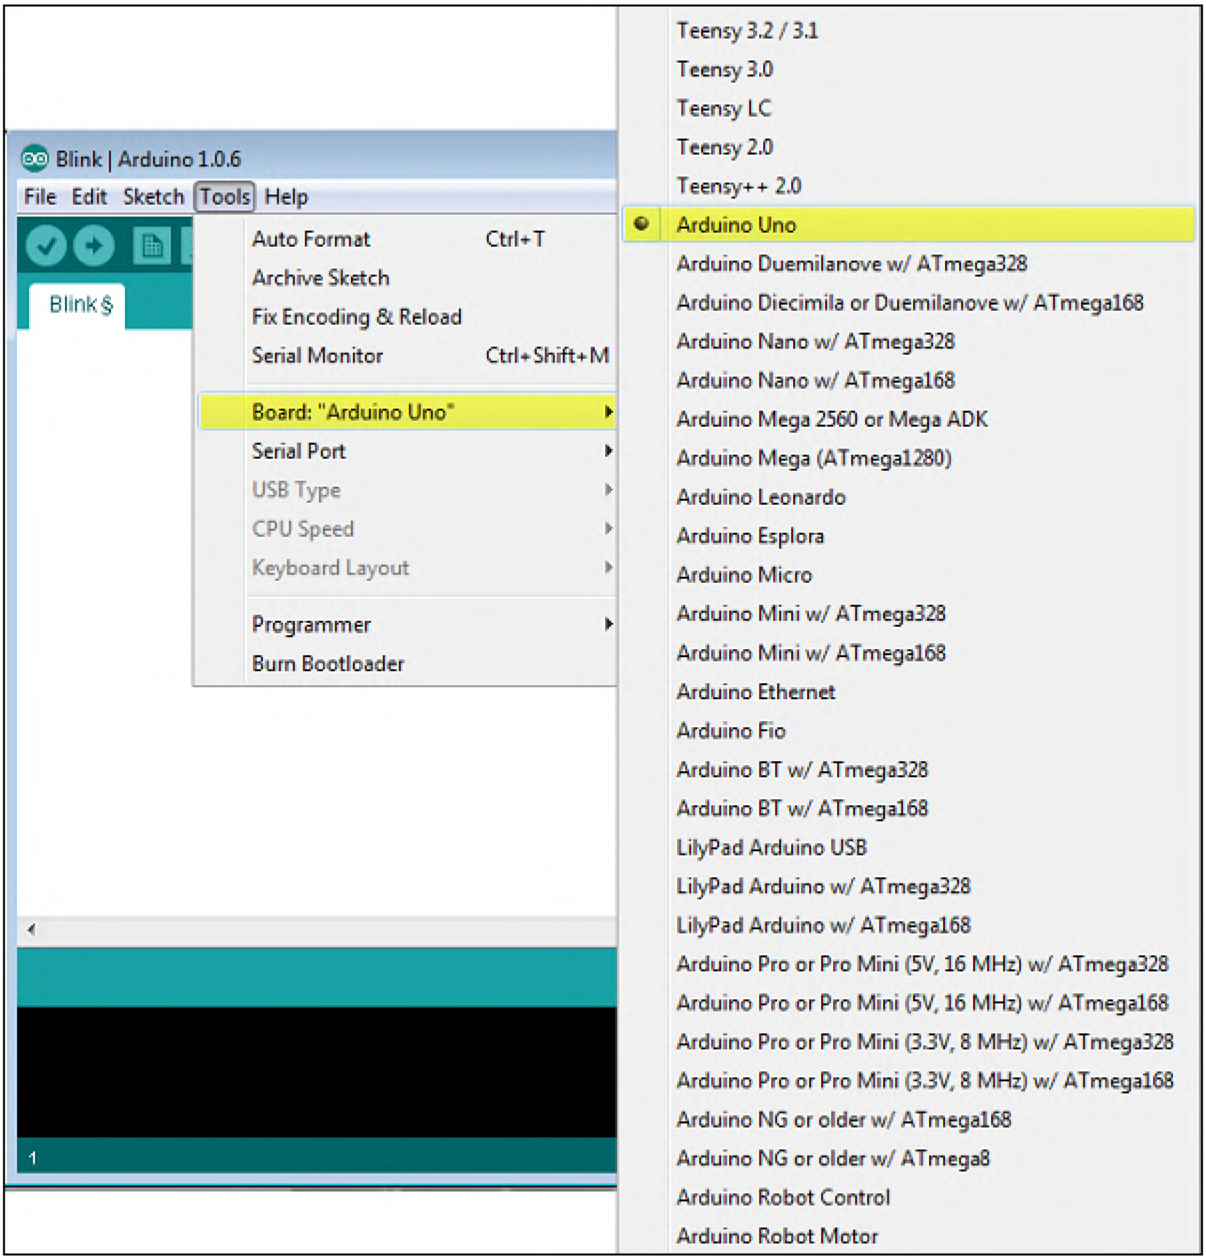


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

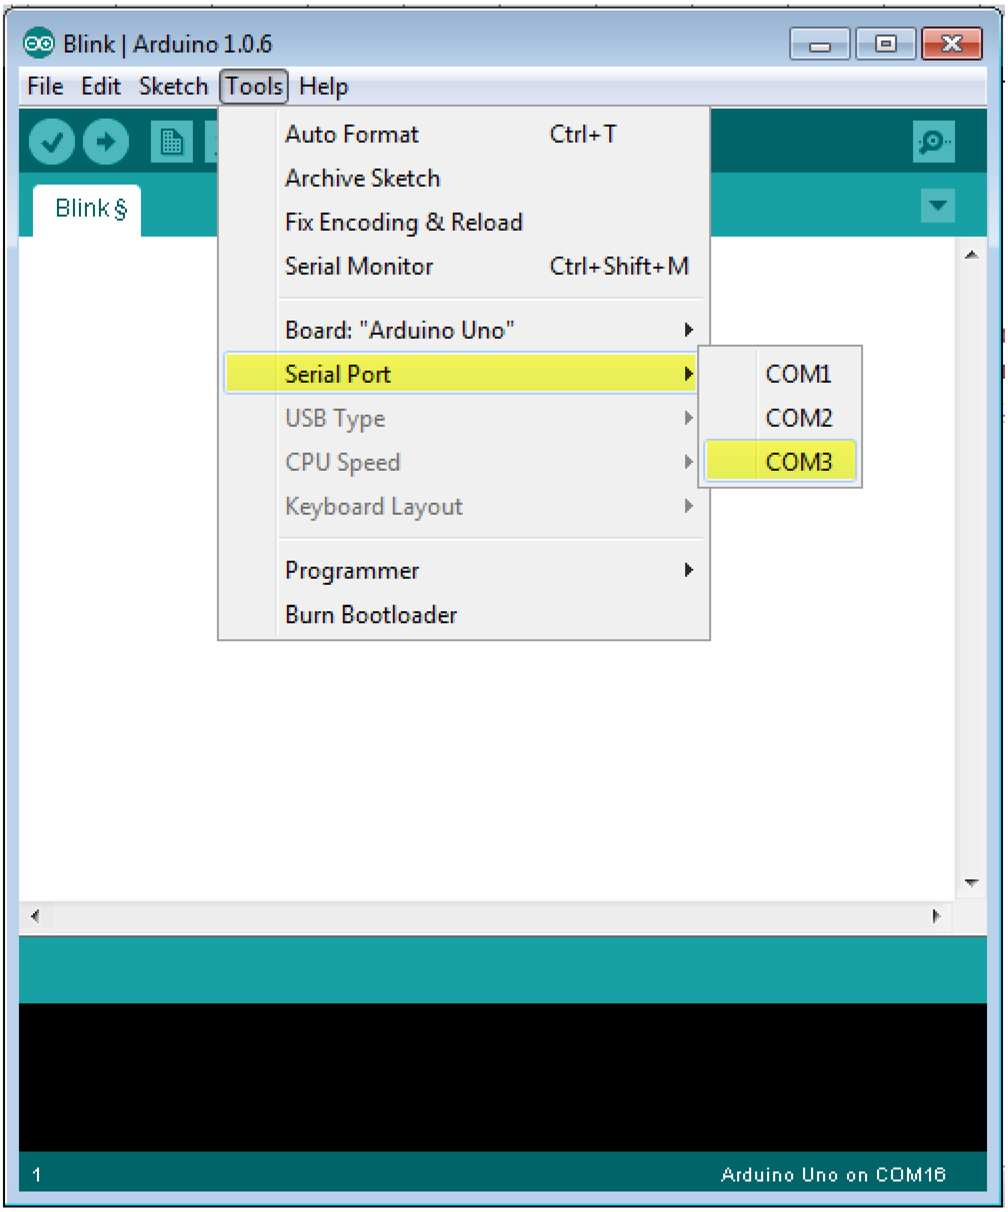
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

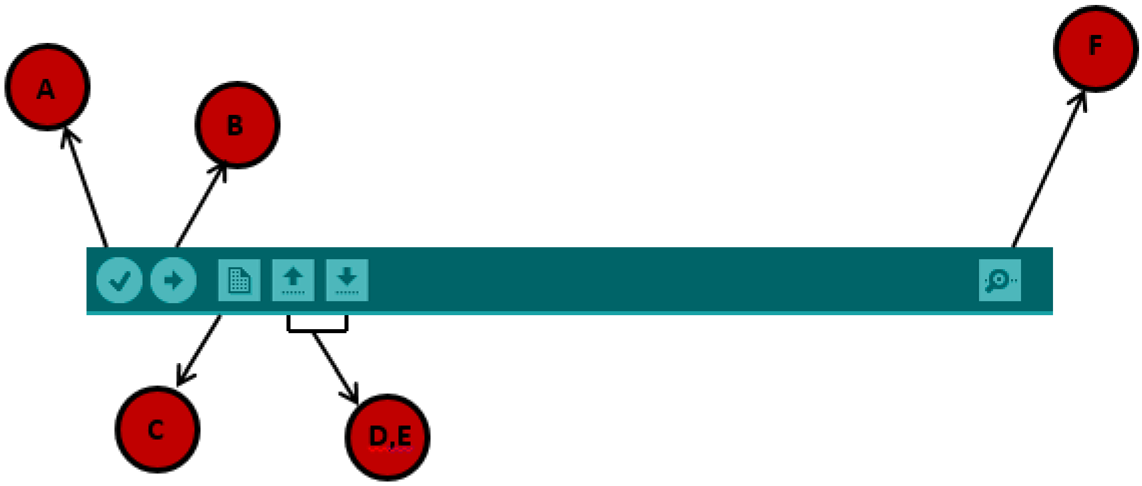
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

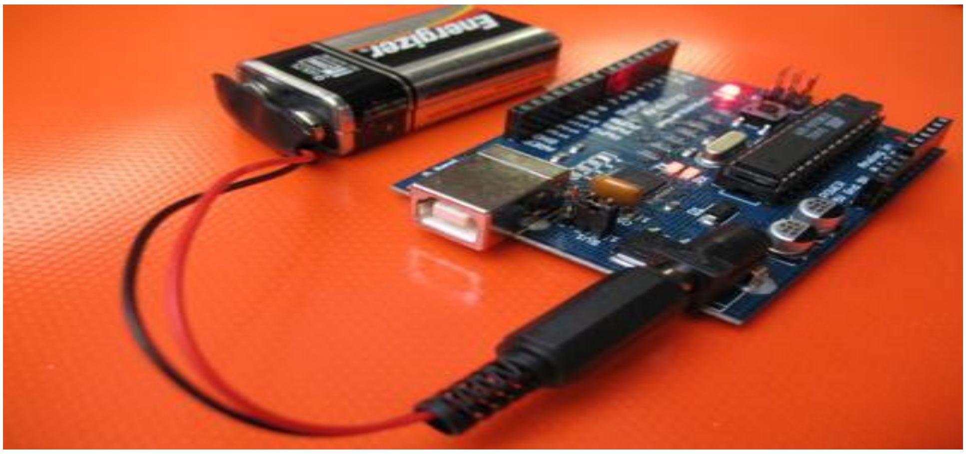


Fig 32: Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

4.7 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

4.8 Proteus:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

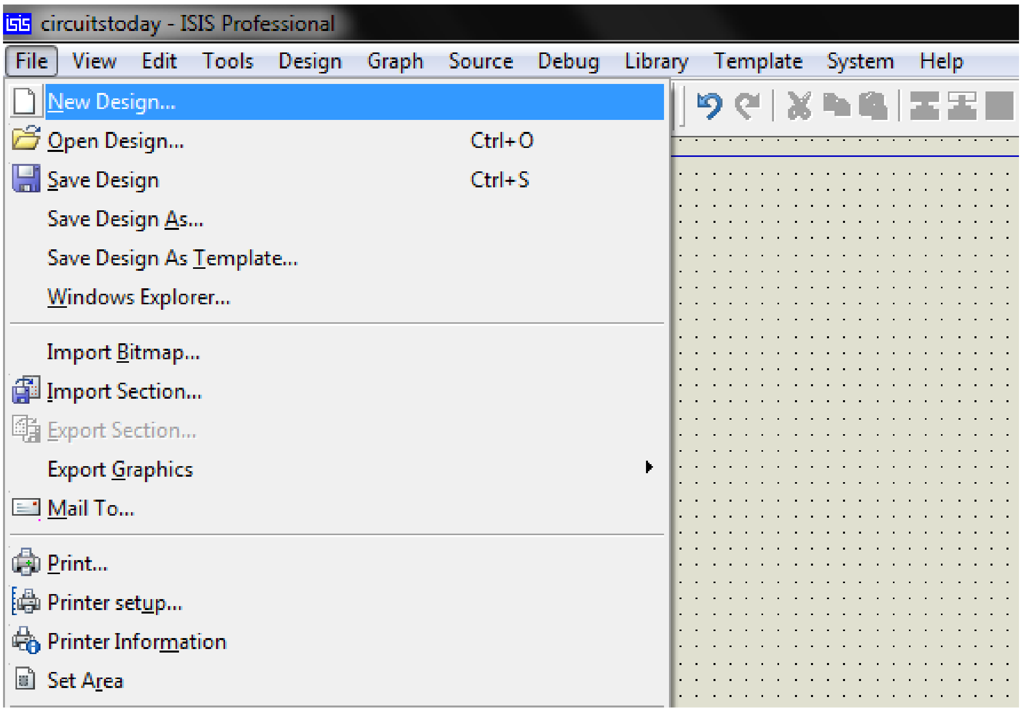

Fig 33: Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

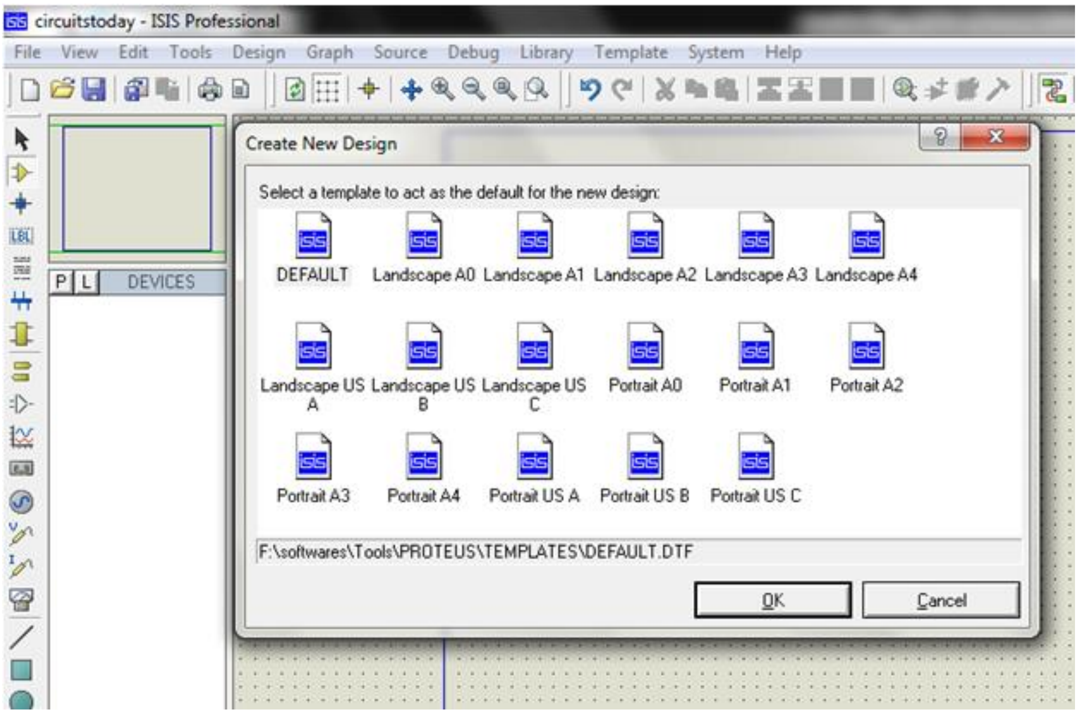

Fig 34: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

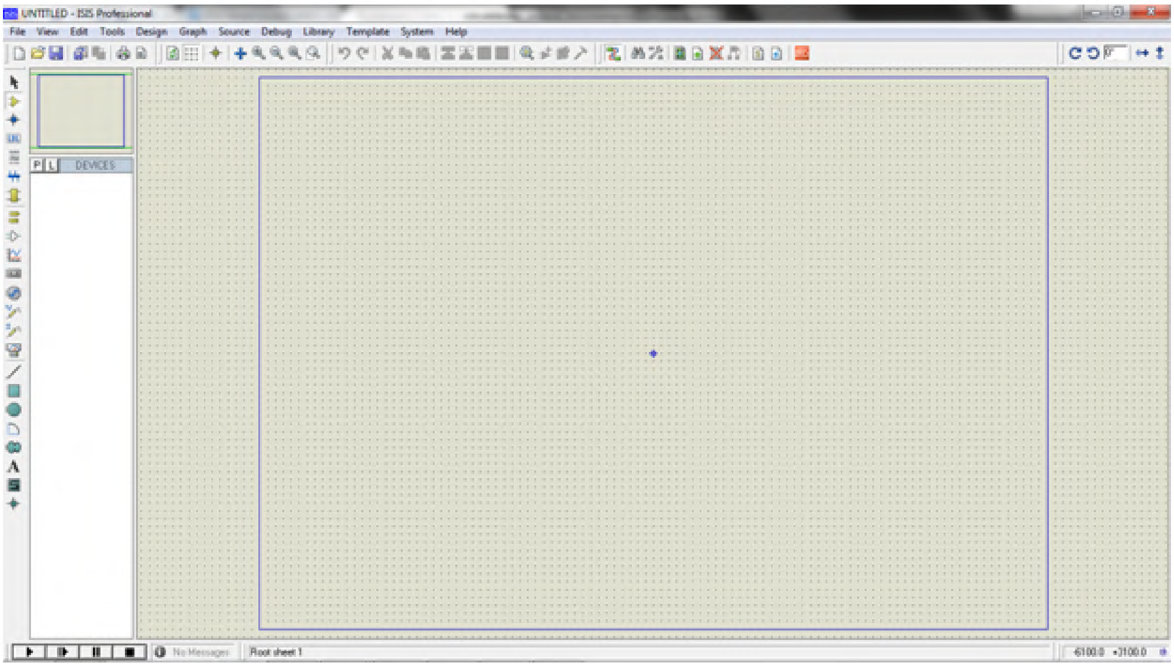

Fig 35: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

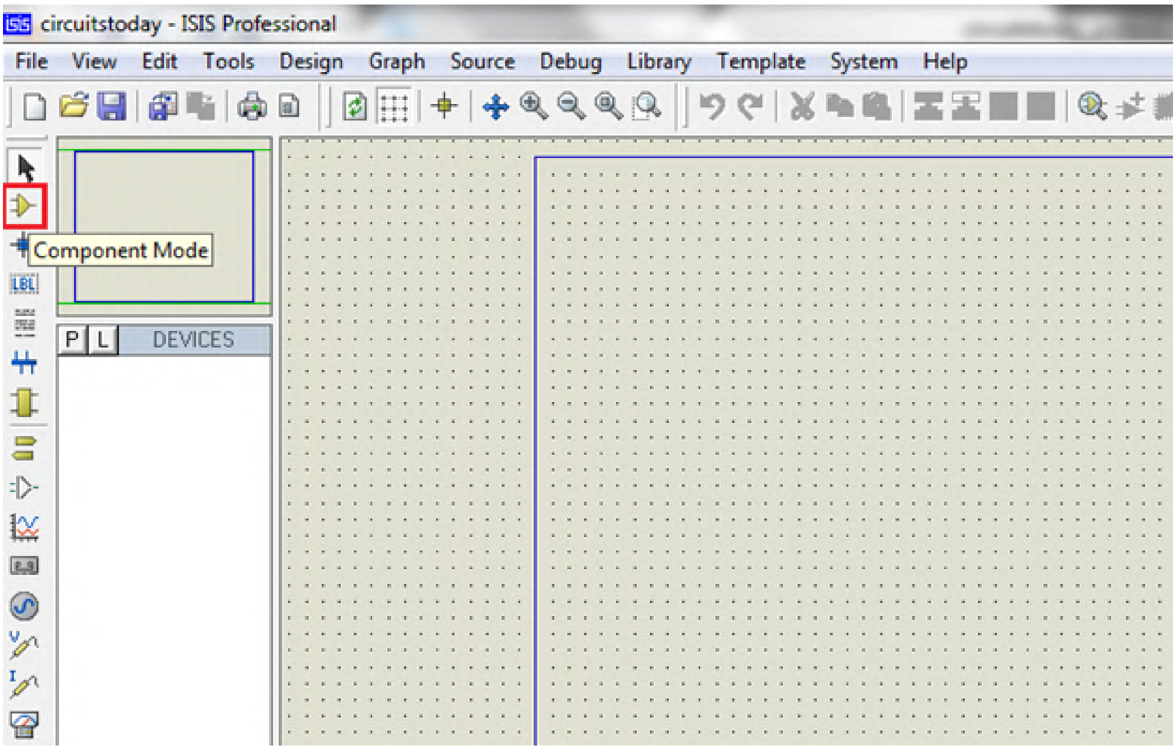

Fig 36: Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

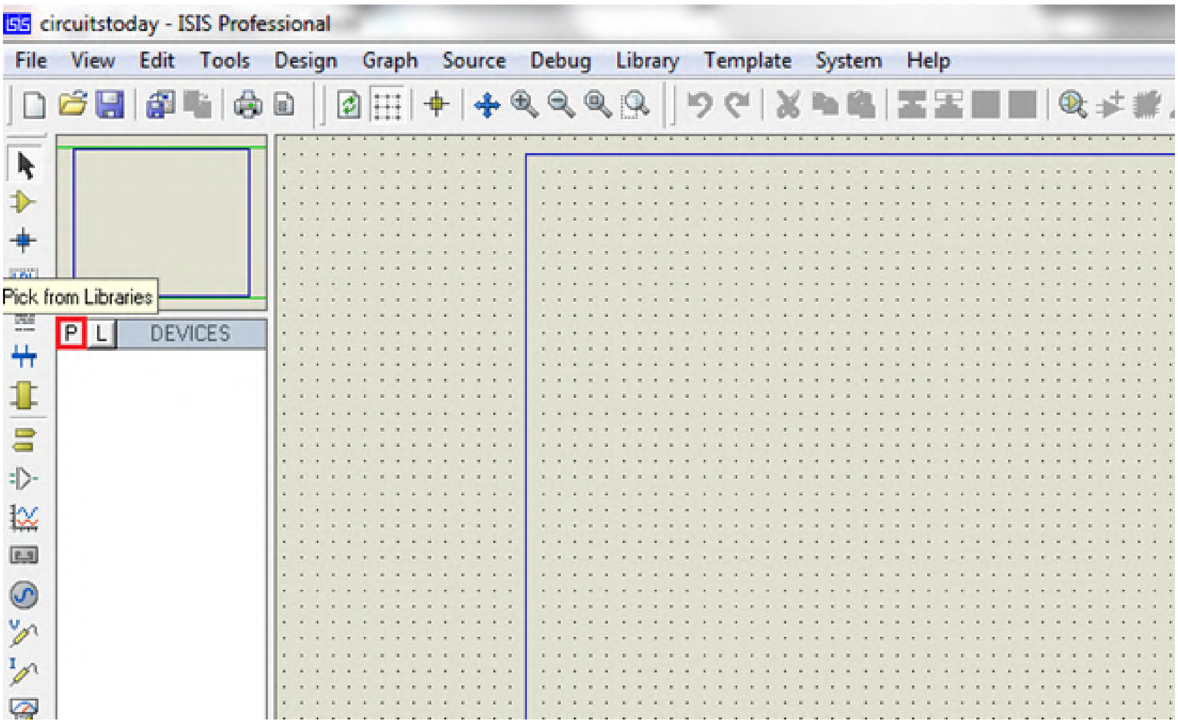

Fig 37: Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

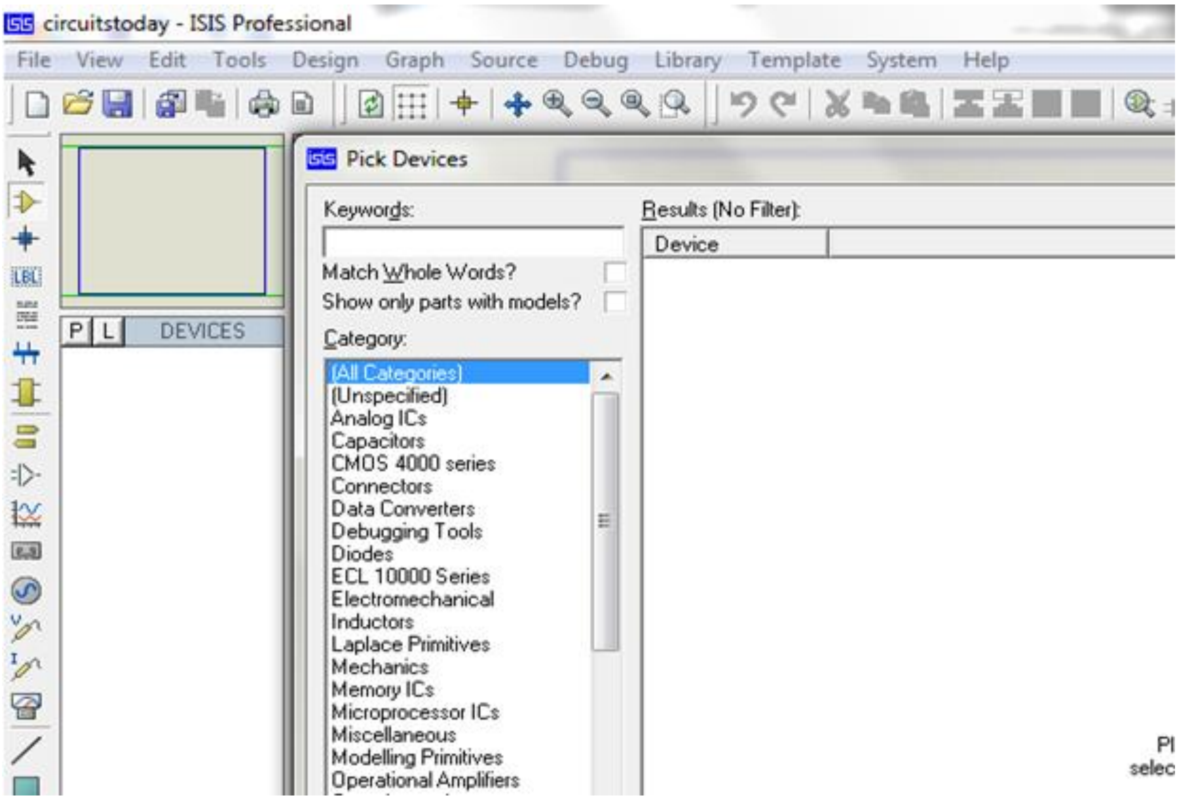

Fig 38: Keywords Textbox

Example shows selection of push button. Select the components accordingly.

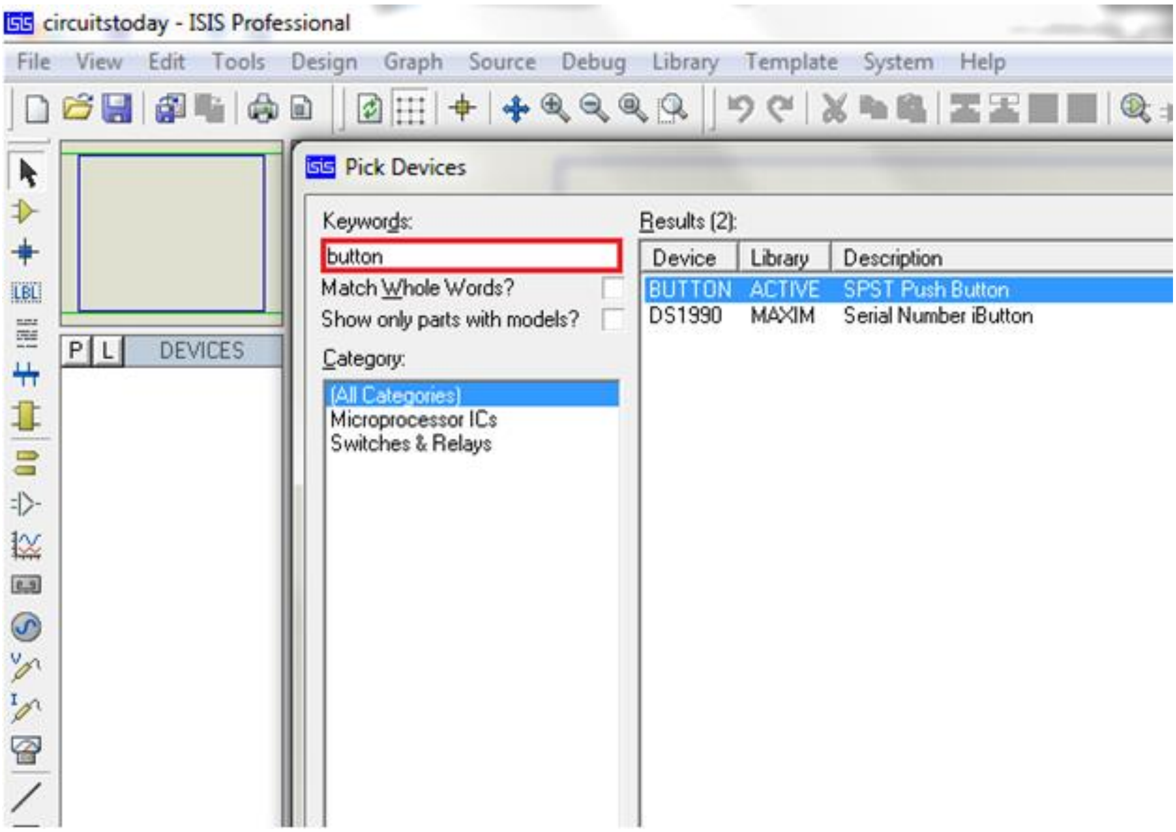

Fig 39: Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

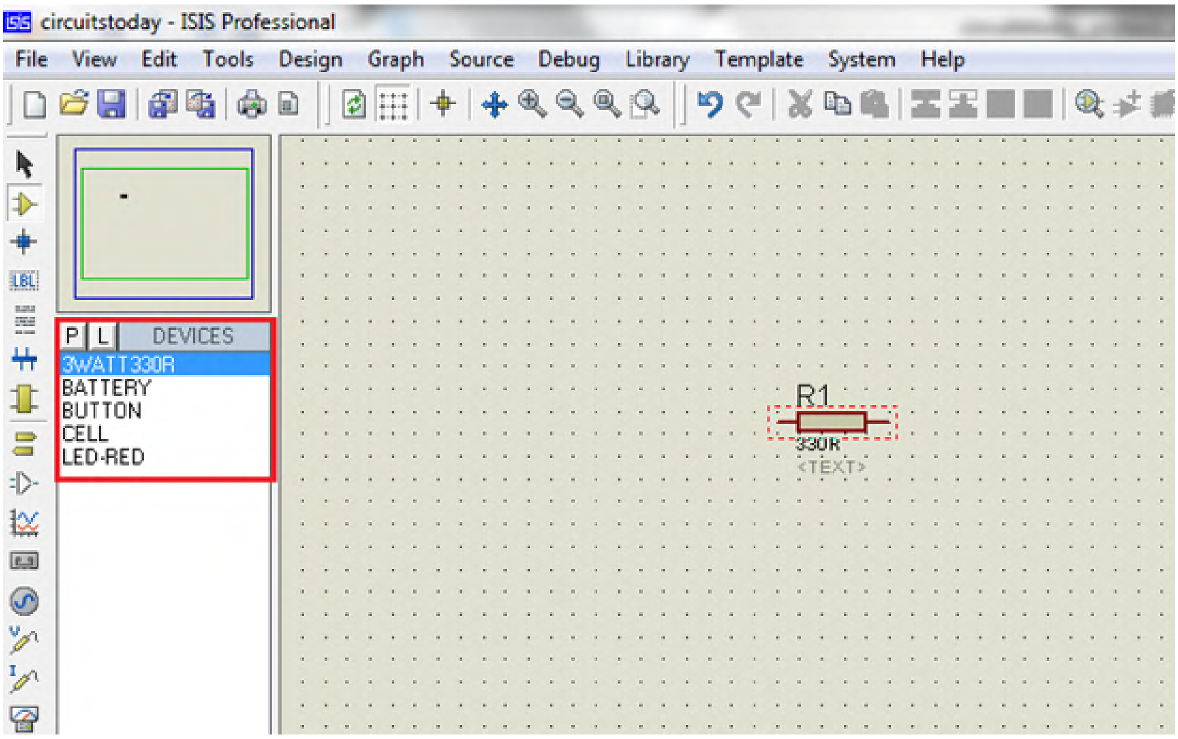

Fig 40: Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

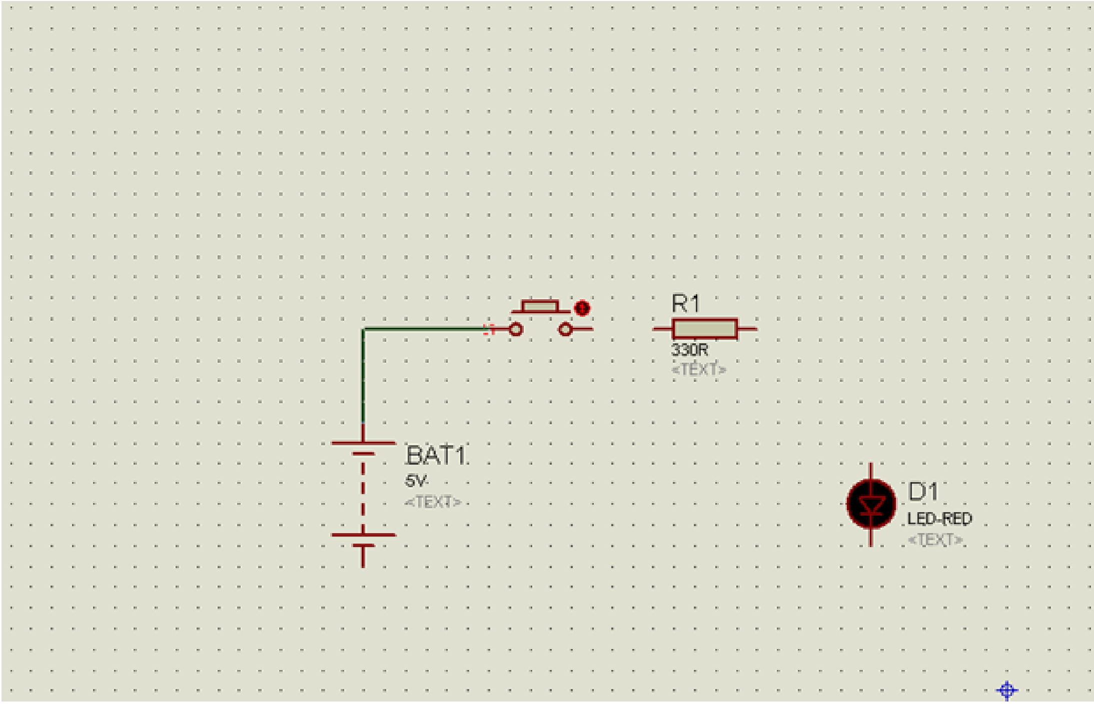

Fig 41: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

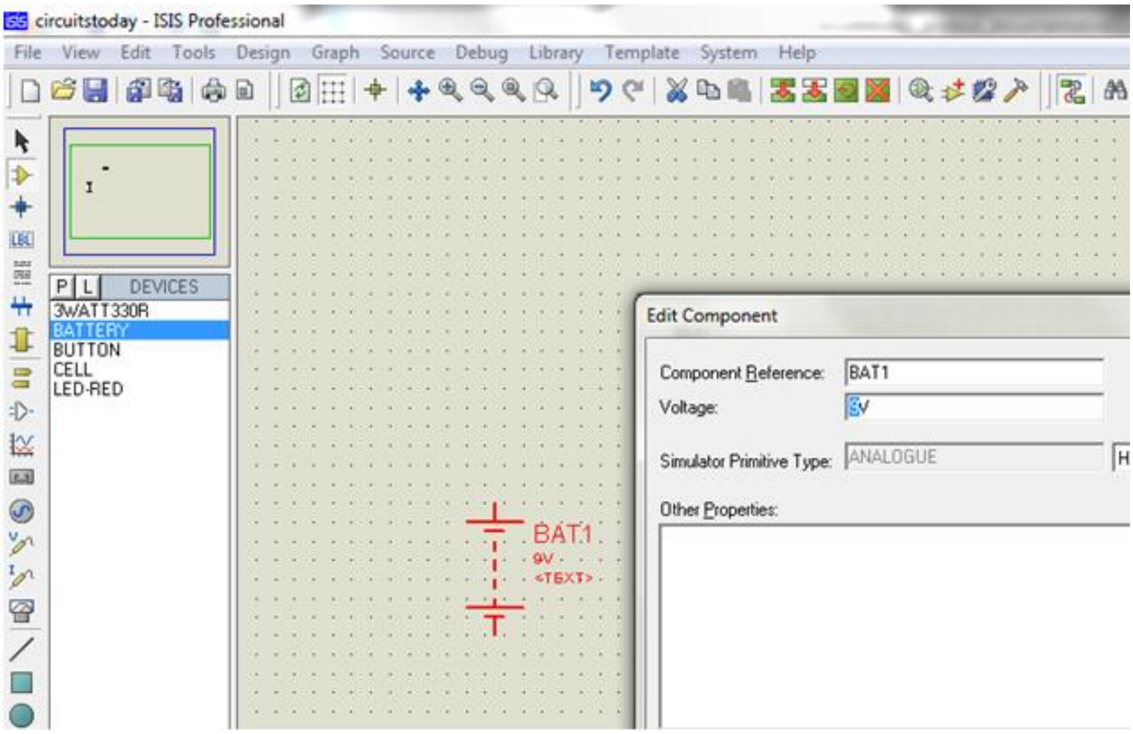

Fig 42: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

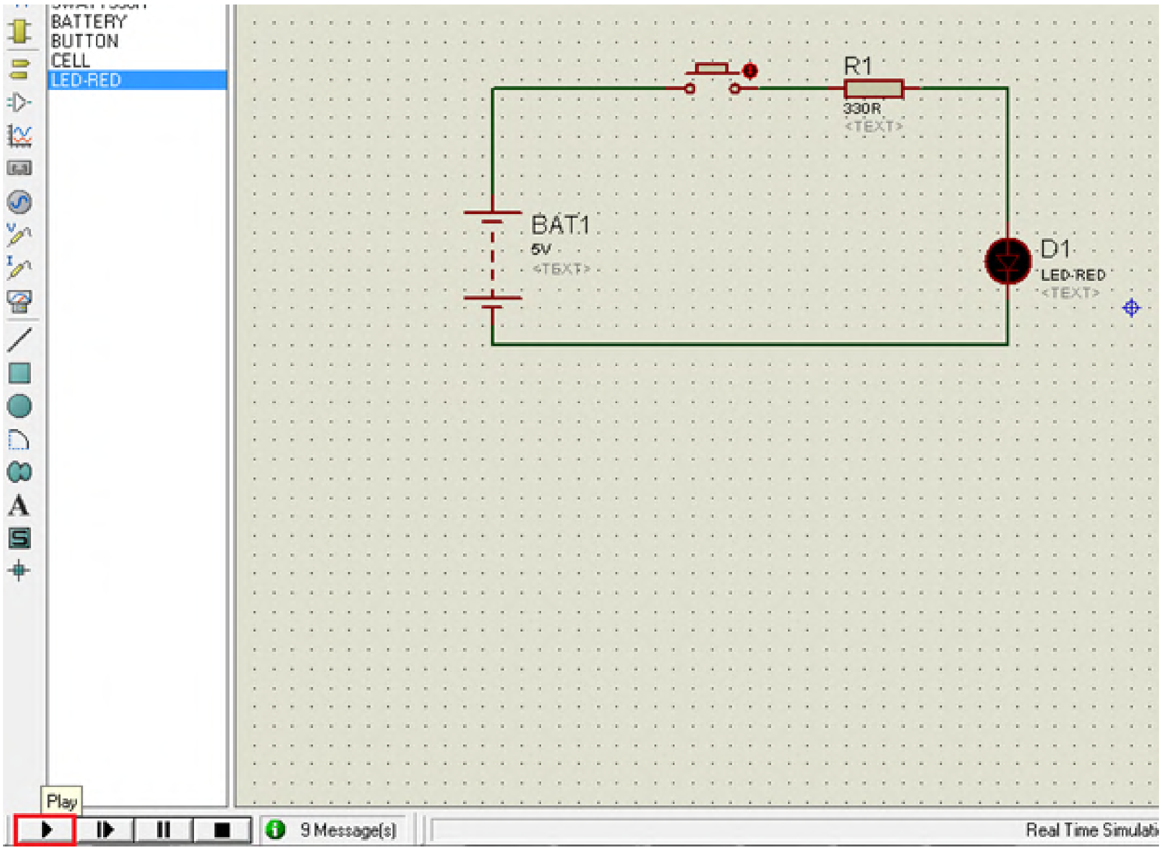

Fig 43: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

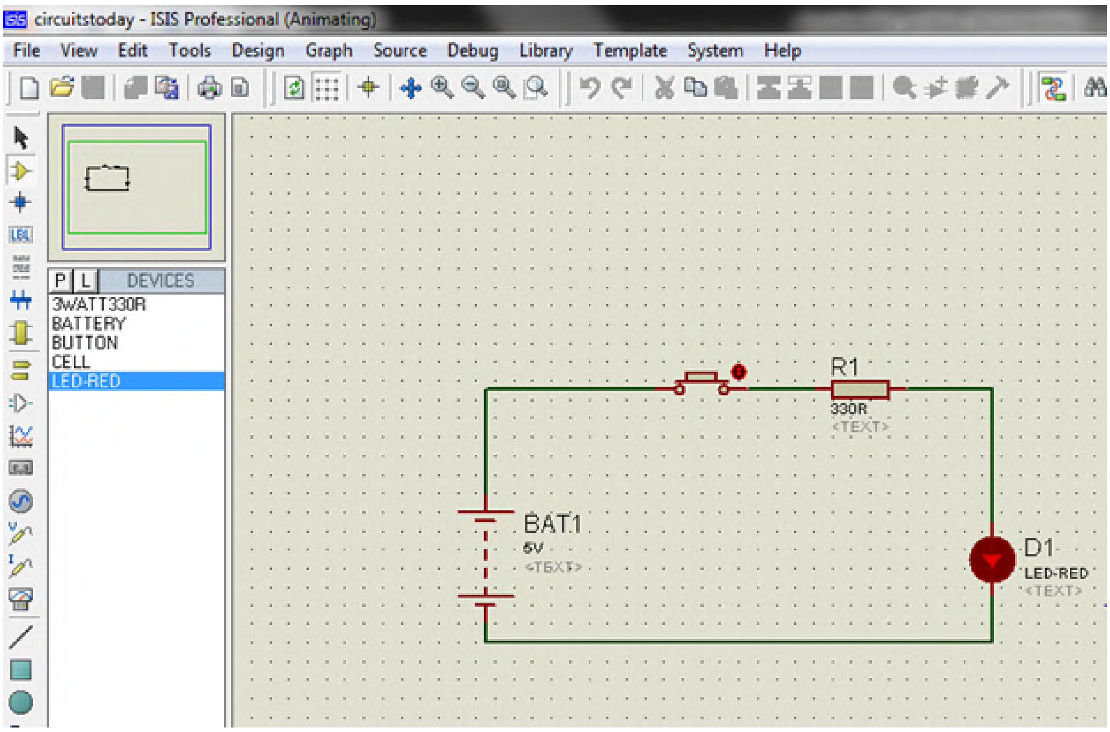

Fig 44: Simulation Animating

Simulation can be stepped, paused or stopped at any time.

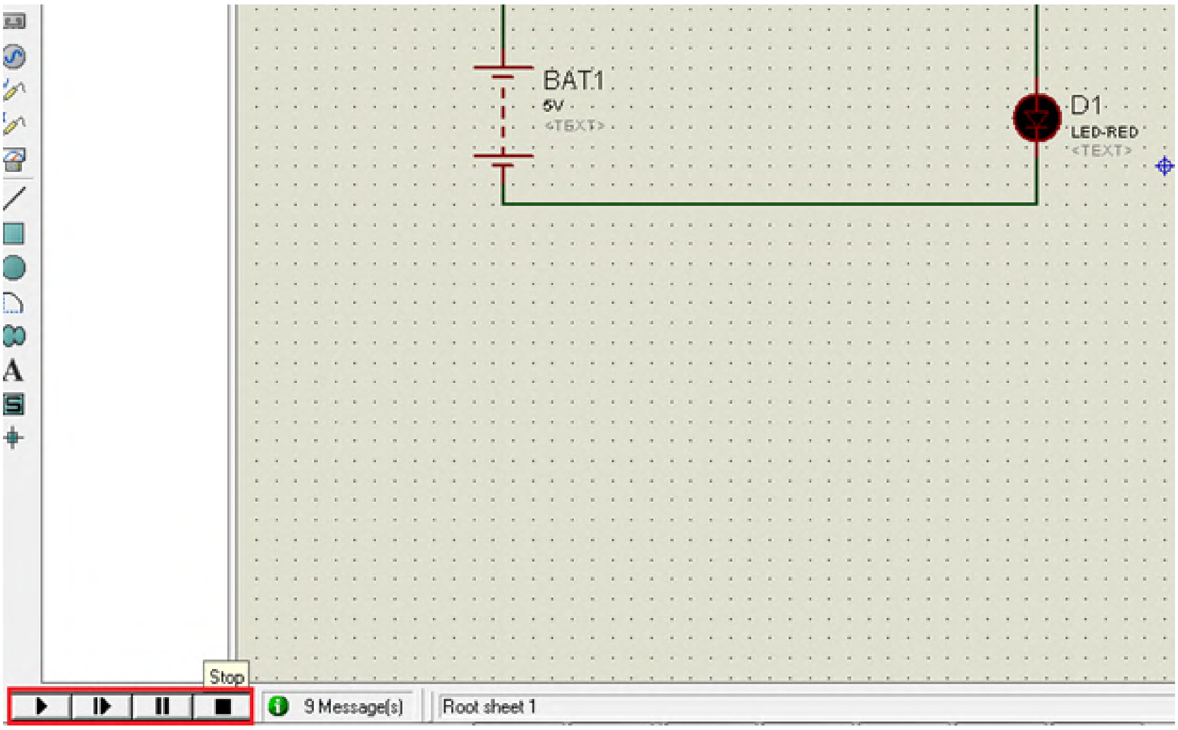

Fig 45: Simulation Step-Pause-Stop Buttons

4.9 Telnet:

Telnet is a client-server protocol, based on a reliable connection-oriented transport. Typically, this protocol is used to establish a connection to Transmission Control Protocol (TCP) port number 23, where a Telnet server application (telnetd) is listening. Telnet, however, predates TCP/IP and was originally run over Network Control Program (NCP) protocols.

Even though Telnet was an ad hoc protocol with no official definition until March 5, 1973,[3] the name actually referred to *Teletype Over Network Protocol* as the RFC 206 (NIC 7176) on Telnet makes the connection clear:[4]

The TELNET protocol is based upon the notion of a virtual teletype, employing a 7-bit ASCII character set. The primary function of a User TELNET, then, is to provide the means by which its users can 'hit' all the keys on that virtual teletype.[5]

Essentially, it used an 8-bit channel to exchange 7-bit ASCII data. Any byte with the high bit set was a special Telnet character. On March 5, 1973, a Telnet protocol standard was defined at UCLA[6] with the publication of two NIC documents: Telnet Protocol Specification, NIC 15372, and Telnet Option Specifications, NIC 15373.

Many extensions were made for Telnet because of its negotiable options protocol architecture. Some of these extensions have been adopted as Internet standards, IETF documents STD 27 through STD 32. Some extensions have been widely implemented and others are proposed standards on the IETF standards track (see below) Telnet is best understood in the context of a user with a simple terminal using the local Telnet program (known as the client program) to run a logon session on a remote computer where the user's communications needs are handled by a Telnet server program.

When Telnet was initially developed in 1969, most users of networked computers were in the computer departments of academic institutions, or at large private and government research facilities. In this environment, security was not nearly as much a concern as it became after the bandwidth explosion of the 1990s. The rise in the number of people with access to the Internet, and by extension the number of people attempting to hack other people's servers, made encrypted alternatives necessary.

Experts in computer security, such as SANS Institute, recommend that the use of Telnet for remote logins should be discontinued under all normal circumstances, for the following reasons:

- Telnet, by default, does not encrypt any data sent over the connection (including passwords), and so it is often feasible to eavesdrop on the communications and use the password later for malicious purposes; anybody who has access to a router, switch, hub or gateway located on the network between the two hosts where Telnet is being used can intercept the packets passing by and obtain login, password and whatever else is typed with a packet analyzer.
- Most implementations of Telnet have no authentication that would ensure communication is carried out between the two desired hosts and not intercepted in the middle.
- Several vulnerabilities have been discovered over the years in commonly used Telnet daemons.

These security-related shortcomings have seen the usage of the Telnet protocol drop rapidly,[7] especially on the public Internet, in favour of the Secure Shell (SSH) protocol, first released in 1995. SSH has practically replaced Telnet, and the older protocol is used these days only in rare cases to access decades old legacy equipment that does not support more modern protocols.[8] SSH provides much of the functionality of telnet, with the addition of strong encryption to prevent sensitive data such as passwords from being intercepted, and public key authentication, to ensure that the remote computer is actually who it claims to be. As has happened with other early Internet protocols, extensions to the Telnet protocol provide Transport Layer Security (TLS) security and Simple Authentication and Security Layer (SASL) authentication that address the above concerns. However, most Telnet implementations do not support these extensions; and there has been relatively little interest in implementing these as SSH is adequate for most purposes.

It is of note that there are a large number of industrial and scientific devices which have only Telnet available as a communication option. Some are built with only a standard RS-232 port and use a serial server hardware appliance to provide the translation between the TCP/Telnet data and the RS-232 serial data. In such cases, SSH is not an option unless the interface appliance can be configured for SSH.

Telnet is still used by hobbyists, especially among Amateur radio operators.
The Winlink protocol supports packet radio via a Telnet connection.

4.9.1 Telnet 5250

IBM 5250 or 3270 workstation emulation is supported via custom telnet clients, TN5250/TN3270, and IBM servers. Clients and servers designed to pass IBM 5250 data streams over Telnet generally do support SSL encryption, as SSH does not include 5250 emulation. Under IBM i (also known as OS/400), port 992 is the default port for secured telnet.

CHAPTER-5

RESULT & CONCLUSION

5.1 Application of the Project:

- Food production Industry
- Hydroponic Farming machinery
- Agricultural Industry
- and many technologies in the emerging time

5.2 Advantages of the Project:

- Maximizes space utilization
- Conserves water
- Produces high yield per area
- And the nest part is "needs no soil"

5.3 Result:

Fig 46: The Prototype ready Image

Fig 47: LCD output 1

Fig 48: LCD output 2

5.4 Conclusion:

We are trying here too develop a hydroponic farm that help in managing the time in planting of crop using wireless sensor network which will be deployed at various points and senses various environmental parameters, gather data to the center node by using wireless protocol through IoT. Still it has been observed that to monitor the environmental factors is not the total solution to increase the yield of cropping, hence automation in agriculture can only avoid the other factors and problems that reduces the productivity. We are expecting that our proposed system can effectively control the PH value or concentration and electrical conductivity in nutrition liquid. Plant performance may be optimized by controlling the climate and lighting. There will be lesser requirements in cost and also easy to maintain which controls the important factors such as light, water level temperature and humidity throughout the year is needed.

5.5 Future Scope:

One can implement a few more sensors and connect it to the satellite as a global feature of this system,

1) Adding more sensor to monitor other environmental parameters such as CO2,Pressure and Oxygen Sensor
2) In aircraft, navigation and military there is a great scope of this real-time system.

3) It can also be implemented in hospitals or medical institutes for the research & study in “Effect of Weather on Health and Diseases”, hence to provide better precaution alerts.
4) To make the system solar powered.
5) To install Portable, lightweight and sturdy systems; compatible for use in urban environment.

DECLARATION

We declare that this project report titled "6G WIRELESS COMMUNICATIONS: VISION AND POTENTIAL TECHNIQUES" submitted in partial fulfillment of the degree of B. Tech in Electronics And Communication Engineering record of original work carried out by us under the guidance and supervision of Mrs. G. Laxmi Priyanka, and has not formed the name basis for the award of any other degree or diploma, in this or any other Institution or University. In keeping with the ethical practice in reporting scientific information, due acknowledgements have been made wherever the findings of others have be encited.

Ramya Baki	**B. Mahitha Reddy**	**P.Krishna Vamsi**
(17K81A04C9)	**(17K81A04D9)**	**(17K81A04G4)**

// ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

We extended our deep sense of gratitude to Principal, **Dr. P. SANTOSH KUMAR PATRA**, St. Martin's Engineering College, Dhulapally, for permitting us to undertake this project.

We are also thankful to **Dr.B.Hari Krishna** Head of the Department, Electronics And Communications, St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project and as well as our project coordinator **Dr.A.Anand**, Professor in Electronics And Communication Engineering, for his valuable support.

We would like to express our sincere gratitude and indebtedness to our project guide **Mrs.G.Laxmi Priyanka**, Assistant Professor, department of Electronics and Communication and our class project coordinator **Mr.K.Nishakar**, Assosiate professor, department of Electronics and Communication, St. Martin's Engineering College, Dhulapally, for their support and guidance throughout our project.

Finally, we express thanks to our college level project coordinators **Dr.Malayadri, professor in IT and Dr.R.Santhosh Kumar,Associate professor in CSE** for helping and advising us to successfully complete this project. Furthermore, we would like to thank our family and friends for their moral support and encouragement.

We express thanks to all those who have helped us in successfully completing the project.

.

1. Ramya Baki
2. B. Mahitha Reddy
3. P. Krishna Vamshi

ABSTRACT

The demand for wireless connectivity has grown exponentially over the last few decades. With the fast development of smart terminals and emerging new applications (e.g., real-time and interactive services), wireless data traffic has drastically increased, and current cellular networks (even the forthcoming 5G) cannot completely match the quickly rising technical requirements. To meet the coming challenges, the sixth generation (6G) mobile network is expected to cast the high technical standard of new spectrum and energy-efficient transmission techniques. In this Project, we sketch the potential requirements and present an overview of the latest research on the promising techniques evolving to 6G, which have recently attracted considerable attention. Moreover, we outline a number of key technical challenges as well as the potential solutions associated with 6G, including physical-layer transmission techniques, network designs, security approaches, and test bed developments.

TABLE OF CONTENTS

LIST OF FIGURES

CHAPTER-1

INTRODUCTION

1.1 Introduction to project:

With the maturity and forthcoming commercialization of the fifth generation (5G), the expectation and development of 6G mobile network have attracted a great deal of attention. In the past two years, some countries have released relevant research plans concerning the development of 6G. For example, in September 2017, the European Union launched a three-year research project on the basic 6G technologies. The main task is to study the next generation forward error correction coding, advanced channel coding, and channel modulation technologies for wireless terabit networks (https://futurecomresearch.eu). At the end of 2017, China began to study the 6G mobile communication system to meet the inconstant and rich demands of the Internet of Things (IoT) in the future, such as medical imaging, augmented reality, and sensing (www.china.org.cn). In April 2018, the Academy of Finland announced an eight-year research program, "6Genesis," to conceptualize 6G through a joint effort of the University of Oulu and Nokia. More recently, the U.K. government has invested in some potential techniques (e.g., €15 million in quantum technology studies) for 6G and beyond (https://www.standard.co.uk/ tech/quantum-technologies), some universities in the United States have lunched research on terahertz-based 6G wireless networks, and South Korea Telecom (SKT) has started 6G research based on the cell-free and non-terrestrial network techniques. In [1], based on the regularity of market entry of past commercial wireless communication systems and the expectation for 6G, the authors forecasted that 6G will start its commercialization in 10 years.

1.2 Project Overview:

The sixth generation mobile and wireless communication network can integrate the satellite communication networks and 5G to provide global coverage. The satellite communication network may consist of telecommunication satellite networks, earth imaging satellite networks and navigation satellite networks. The goal of 6G is to integrate these kinds of satellite networks to provide network position identifier, multimedia and internet connectivity, and weather information services to the mobile users. The four countries which have these satellite systems are: The Global Position

System(GPS) by USA, the Galileo by Europe, the COMPASS by China and the GLONASS by Russia. If 6G integrates with 5G with these satellite networks, it would have four different standards. So handoff and roaming will be a big issue in 6G.The radio over fiber system is already in existence, but with the advent of 6G technology, mankind will be more close to any extraterrestrial civilization in the universe.

1.3 Project Objective:

The objective of our project is

- Multiband Ultrafast speed transmission.
- Super flexible integrated network.
- Multi-mode multi domain joint transmission.
- Intelligent transmission.

CHAPTER 2
LITERATURE SURVEY

2.1 Literature Survey:

Estimated that the international standardization bodies will sort out the standards for

year 2035. While the rollout of 5G is still underway, the researchers across the tentative timeline for the implementation of 5G, B5G, and 6G standards by2020 (IMT-2020 Standard) in 2015 for the 5G network standards. At the same time, standardization of 6G (ITU-R IMT-2030) by the end of the year 2030, whereas 3GPP

workgroup for exploring the system technologies for B5G/6G systems in July communication technologies .

The vision of 5G technologies is extended for the 6G networks by speculating the visionary technologies for next-generation wireless systems in [5]. Different networking scenarios are presented in [15]. The authors in [12] and [13] give a predictive technical framework for industries in future generations of communication systems mainly focusing on the specifications of future generations of the communication system. Cell-less architecture, decentralized networking, and resource allocation, and three- dimensional radio connectivity including the vertical direction are expected in next- generation communication systems. The evolution of wireless systems from 1G to 6G is outlined in [14]. The authors in [15] presented the role of intelligent surfaces in the architecture of 6G networks.

The authors in [16,17] presents the expected technologies, possible applications of 6G. The articles present the system-level perspective of the 6G scenario with use cases, vision, and technologies. The authors in [25] analyze the application of blockchain for the security and privacy measures in upcoming 6G networks. The potential role of optical communication in 5G/B5G and 6G communication networks is described in [5]. The article [26] presents the feasibility of the application of mmWave communication in satellite communication as an enabler of 6G networks. The article [27] gives an analysis of potential applications of device-to-device communication in 6G. The authors in [9] elaborate on the multiple challenges in integrating artificial intelligence (AI) and its potential role in future communication networks.

The authors in [31, 32], have focused on the vision for the next generation of wireless communication systems. Blockchain and AI are the potential technologies for the next generation communication systems. Blockchain can be used for efficient resource sharing and AI can be implemented for the robust, self-organizing, self-healing, and self-optimizing wireless network [33].

By using millimeter-wave (mmWave) and terahertz (THz) frequency bands, massive bandwidth, and highly directive antennas will be available to the 6G mobile devices to enable new applications and seamless coverage [33]. Federal Communications Commission (FCC) has commercialized these frequency bands in 2019 [34]. Ultra-high-precise positioning will become available with 6G due to high-end imaging and direction-finding sensors, just like human eyes and ears. 6G mobile phones could be equipped with capable robots and intelligent algorithms [5].

The latency of the network in 6G will be minimized by using super-fast and high computational power processors both at the network and end devices. The mobile phone of the future network will be intelligent enough to sense the environment and give the precautionary and preventive measures. For example, these mobile phones will be capable to detect the air pollution level, toxic food materials, and explosive materials around us. These phones will replace the wallet, hard cash, and wristwatches by providing digital currencies, and smart watches, respectively. Similarly, smart goggles will replace glasses and smart phones. It is anticipated that 6G cellphones, coupled with the incredibly high directive and beam-steering antennas, would be capable enough to see through the walls by reconstructing the images by receiving the signals from multiple levels of density of the environment in the vicinity [9]. This feature would be useful for extracting minerals and elements from rocks, exploring underground natural reserves, and detecting arms. Apart from this, 6G mobile phones will have tremendous features of providing position, location, and range with very high accuracy. This will be helpful for maritime and underwater communication and positioning.

Self-driving cars, which are already being developed in the initial phase these days, would make human life safer and more comfortable [5]. Holographic technologies and VR/augmented reality (AR) will break the barrier of distances. The digital revolution has transformed the way we play, talk, or work. In the recent era of the digital revolution, 5G has become the center of attention for everyone. Soon the mobile devices in our pockets will get the wireless speed approaching the fiber optic transmission speed, bringing 3D imagery, television, online games, and many other applications that we never imagined into our tablets or mobiles.

Special attention is paid to the improvement of the traffic prediction in [35]. Following the 6G vision and service requirements, some use case scenarios for the 6G, such as autonomous vehicles, smart cities, flying networks, holographic, telemedicine, and Tactile Internet, are discussed in [36]. Moreover, the reliability of the future wireless network is forecasted to be at the same or higher level as that of today's wired communication networks.

Some potential key enabling technologies encompassing block chain-aided decentralization of the network and machine learning (ML)-based intelligent communication system for the 6G are discussed in [37]. A comparative analysis between the key performance indicators (KPIs) for 5G and 6G is carried out in [31]. Practical applications including holography, ML, VR, Internet-of-Things, visible light communication (VLC), automated driving is discussed in [38].

2.2 Existing system:

The existing systems are 1G, 2G, 3G, 4G, 5G. The 1G network was all about voice. 2G network was all about voice and texting. 3G network was all about voice, texting, data. 4G network was everything in 3G but faster version and the 5G is even faster, has better battery life and very low latency than 4G.

2.3 Proposed system:

In general, the 6G mobile network is expected to provide ultrafast speed, greater capacity, and ultra-low latency for supporting the possibility of new applications, such as fine medicine, intelligence disaster prediction, and surreal virtual reality (VR). Based on the former evolution rule of mobile networks, early 6G networks will be mainly based on the existing 5G architecture, inheriting the benefits achieved in 5G (e.g., the increased authorized frequency bands and the optimized de-centralized network architecture) and prodigiously changing the way we work and play. Around 2030, our society will likely become data-driven, enabled by nearly instantaneous, unlimited wireless connectivity [1]. As a result, 6G is expected to advance the wireless technologies we are familiar with today and achieve considerably enhanced system performance. As a vision for the future, in terms of speed, 6G will probably utilize higher frequency spectrum than previous generations in order to improve the data rate expected to be 100 to 1000 times faster than that of 5G [2]. To be specific, 6G networks will allow hundred gigabits per second to terabit-per-second links by making use of multi-band high-spread spectrum; for example, the combination use of 1–3 GHz band, millimeter-wave (mmWave) band (30–300 GHz), and terahertz band (0.06–10 THz) [3]. On the other hand, in terms of capacity, compared to 5G, 6G will be able to flexibly and efficiently connect upper trillion-level objects rather than the current billion-level mobile devices. As a result, the 6G network becomes extremely dense, and its capacity may be 10 to 1000 times higher than that of 5G systems and networks. Furthermore, in terms of latency, from 2G to 5G, the evolution of mobile communication networks is centered on service people, and hence latency depends on human reaction times, such as the auditory reaction time (~100 ms), the visual reaction time (~10 ms), and the perceptual response time (~1ms).

For the application of tactile Internet, 5G technology will allow for a latency time of 1 ms; however, this is too long for Industrial IoT and some other latency-sensitive applications. For example, a minimal latency time is essential for decreasing collision rates and improving the safety in autonomous vehicles. For this purpose, 6G aims for an undectable or even nonexistent latency, since it can enhance the application of autonomous vehicles, augmented reality, and medical imaging. Indeed, with the emergence of more new unmanned and autonomous applications, the latency time no longer solely depends on human reaction times. While the preliminary sketch of 6Gis

being drawn up, efforts on configuring the potential techniques to match the aforementioned appealing vision remain in a nascent stage. It is worth noting that in [1], the authors first provided a general survey of different wireless generations and then highlighted an initial sketch of 6G based on the requirements of future users. Compared to [1], this article summarizes the potential requirements and the latest research on promising techniques toward the evolution to 6G. Another important purpose of this article is to provide the scientific community with an overview of the most challenging aspects in the focused context of 6G mobile networks and to give helpful suggestions for overcoming these challenges.

Laptops, mobile data traffic has observed an exponential growth during the past few years, and this growth is expected in next few years as well. With the increase in the number of mobile users, not only the mobile traffic has increased but every user wants higher data rate with more accuracy and reliability. This considerable amount of mobile data traffic is challenging to manage with current technologies.

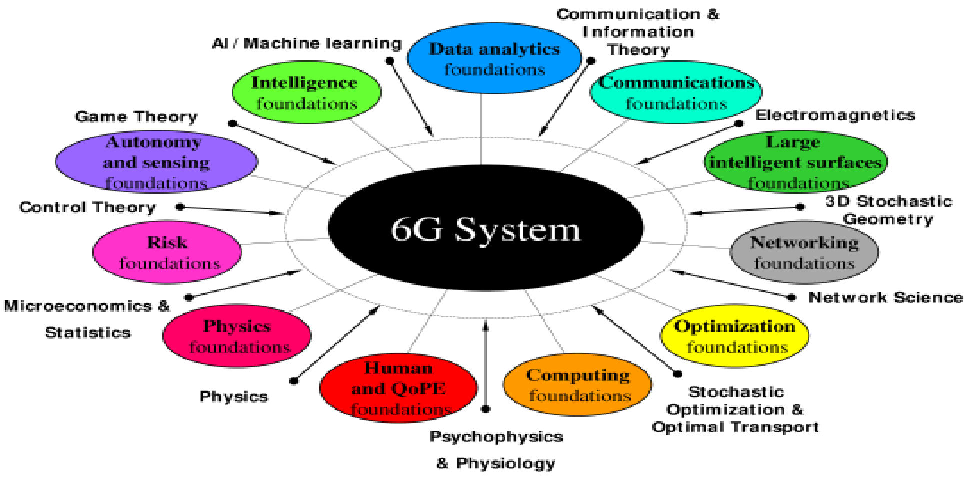

Fig 2.1:Vision of 6G wireless systems.

Future generation network called fifth generation (5G) must accommodate this huge traffic and address the current limitation of data rates reliability, and efficiency. Currently, many technologies are trying to answer all these problems in mobile communication, but none have found an optimal solution. On the top of that, these technologies must take complexity, energy efficiency, reliability into account while designing the new system. Recently, a technology called massive MIMO has been proposed, which uses hundreds or even thousands of antennas at the base station, and it can serve tens of user simultaneously [1]. These thousands of antennas focus the transmission and reception of signal onto smaller region and help the system to achieve high diversity and multiplexing gains to improve reliability and increase data rate [2]. In massive MIMO systems, a user sends pilot towards the base station and based on these pilot signals base station estimates the channel between it and the user. The base station should have knowledge of channel during both uplink and downlink as massive MIMO is a technology that is dependent upon spatial multiplexing [3]. There are several advantages of using these systems such as high spectral efficiency, antenna array gain, high reliability, robustness to internal jamming and interference and energy efficiency. Along with these advantages, Massive MIMO comes up with certain challenges as well, and one of the major challenges that massive MIMO is facing is high computational complexity and poor bit error rate (BER) performance during received signal detection at the base station which due to the higher number of antennas at the base station and more number of users. In Massive MIMO, all the signal transmitted by the user terminals superimpose at the base station and thus interfere with each other. There are several algorithms or methods for Massive MIMO detection and non- linear detectors like sphere detector, and successive interference cancellation detector are computationally very complex. Therefore, these methods are not recommended. Linear detectors are computationally less complex than non-linear detector, but the performance is much degraded. All the conventional detection methods like Maximum Likelihood detection (ML), Minimum mean square error detection (MMSE), Zero-forcing detection (ZF) are not very efficient in terms of performance and complexity. During detection, these linear methods include inversion of high dimensional matrices which drastically increases the complexity of the system and this complexity increases exponentially with more number of antennas. [4]. In this paper, we present a low complex and efficient algorithm for detection of Massive MIMO systems which is based upon modified Approximate Message Passing(AMP)algorithm.

Wireless data traffic had been dramatically increasing over the past few years. Nonetheless, the existing techniques are not satisfying with the users' needs in terms of the emergence of applications for daily routines (e.g., proximity aware services). Therefore, there is a wave of popular interest to seek for new paradigms to deal with this problem. In the coming fifth generation (5G) cellular networks, emerging technologies will lead to both disruptive architectural and component design changes. For instance, in 5G wireless communication systems, diverse researchers study different aspects of millimeter wave transmission, which are plentiful because spectrums have become scarce at microwave frequencies. Massive multiple-input multiple-output, which could increase the system throughput is proposed to utilize a very high number of antennas. We know that 2G–3G–4G cellular networks were built under the design premise of having complete control from the infrastructure side. However, this assumption should be dropped in the 5G systems. The base-station-centric architecture of cellular systems may change, and intelligence at the device side, within different layers of protocol stack, should be exploited, for example, by allowing device-to device (D2D)connectivity.

Device-to-device communication defined as a direct communication between two mobile users without traversing the base station or the core network is considered to be a promising technique, which also offloads the increasing data traffic into user equipments (UEs). In a traditional cellular network, it is implicitly implied that two parties willing to establish the same call will not be in close proximity to each other.

Therefore, all communications must go through the base station. However, in the age of data, mobile users in today's cellular networks are potentially in range for direct communicationsusinghighdatarateservices.

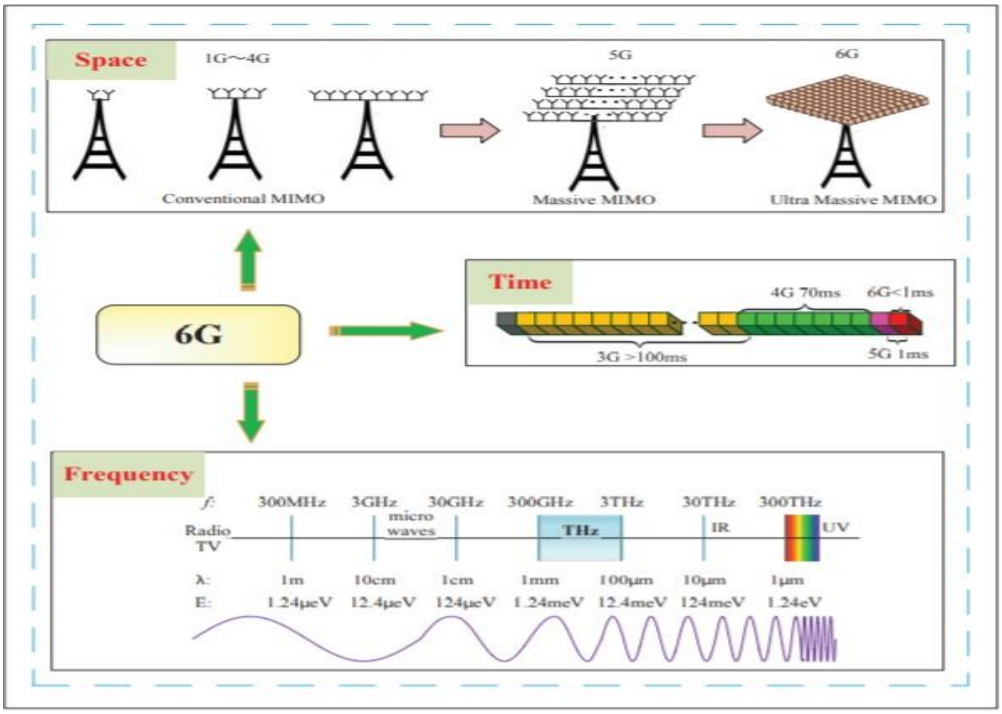

Fig 2.2 : A sketch of 6G based on the time-frequency-space resource utilization.

Thus,D2Dcommunication,whichcan decrease latency and increase resource utilization had been proposed as a means of taking advantage of the physical proximity of communicating devices. Figure 1 shows a simple example of D2D communication. The majority of the literatures in D2D communication proposed to use the cellular spectrum for both D2D and cellular communication. Most of these previous studies have focused on issues such as resource allocation and interference mitigation. Although, few existing studies have investigated the D2D access procedure. Here we review the literatures related to device discovery and access procedure. In TR 22.803, the D2D discovery is categorized into several types, which are summarized in. In addition, the D2D discovery procedure and long-term evolution (LTE)-based design are also discussed in. Yanget al. proposed a distributed peer discovery protocol for LTE-A networks. In, they provided an overview of the new agreements in third generation partners hip project LTE radio access networks related to evaluation methodology and channel modelling for D2D discovery and communications. Honget al. proposed a D2D discovery and link setup procedure and analyzed its performance in terms of energy consumption and delay by utilizing the measurement results of real

LTE smart phones. However, all of the existing works lack the overall performance analysis based on the Markov process model. In this work, we will provide the system model based on the Markov process and present the performance analysis. Moreover, we give our proposal on the Vienna Matlab platform, which is a system level Matlab simulator developed by Vienna University of Technology and obtain the simulation results.

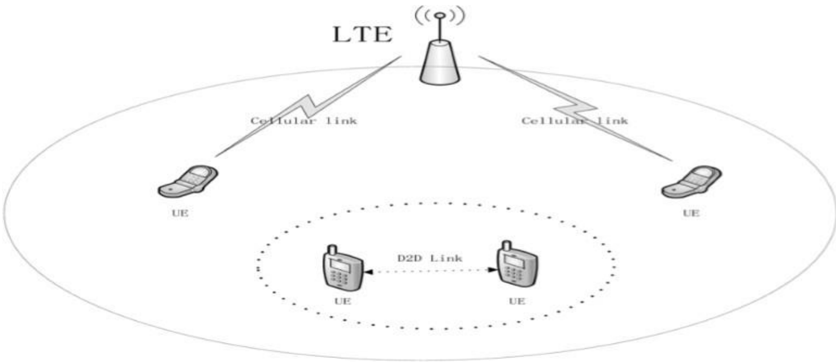

Fig 2.3 : Device-to-device communication in a cellular network.

CHAPTER 3
SOFTWARE INTRODUCTION

3.1 Introduction to MATLAB:

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation.

- Typical uses include.
- Math and computation.
- Algorithm development.
- Data acquisition.
- Modelling, simulation, and prototyping.
- Data analysis, exploration, and visualization.
- Scientific and engineering graphics.
- Application development, including graphical user interface building.

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN. The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation. MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 The MATLAB system:

The MATLAB system consists of five main parts

3.2.1 Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

3.2.2 The MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

3.2.3 The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

3.2.4 Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully

customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

3.2.5 The MATLAB Application Program Interface(API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files. Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

3.3GRAPHICAL USER INTERFACE(GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions)files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed. To launch GUIDE from the MATLAB command window, type guide filename Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank)window.

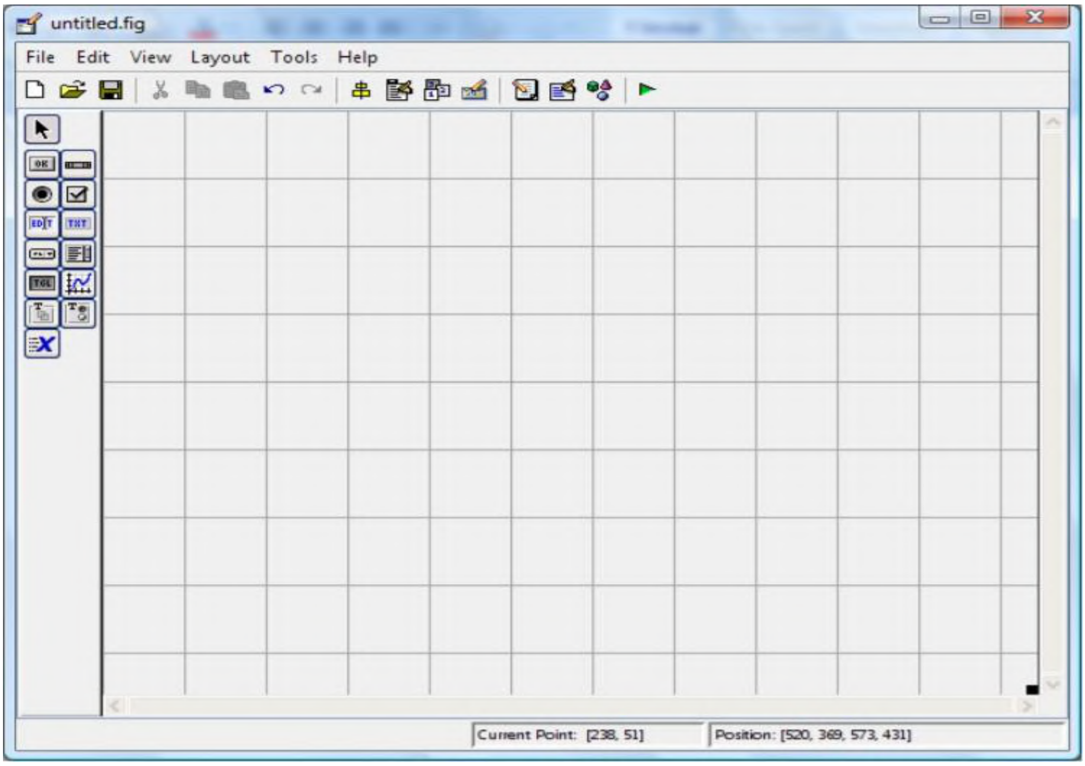

Fig 3.1 :Matlab procedure.

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed. GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 Getting Started:

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos. At the heart of MATLAB is a new language you must learn before you can fully exploit its power. YoucanlearnthebasicsofMATLABquickly,andmasterycomesshortlyafter.You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.5 Introduction:

Describes the components of the MATLAB system.7

3.5.1 Development Environment:

Introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.5.2 Manipulating Matrices:

Introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.5.3 Graphics:

Introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

3.5.4 Programming with MATLAB:

Describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.6 DEVELOPMENT ENVIRONMENT :

3.6.1 Introduction:

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

3.6.2 Starting and Quitting MATLAB :

- **Starting MATLAB:**

On a Microsoft Windows platform, to start MATLAB, double-click the

MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop. You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

- **Quitting MATLAB:**

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.6.3 MATLAB Desktop:

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.6.4 Desktop Tools:

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools.

The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger

- Command Window
- Command History
- Launch Pad
- Help Browser

- **Command Window:**

Use the Command Window to enter variables and run functions and M-files.

- **Command History:**

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

- **Running External Programs:**

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m.

When you quit the external program, the operating system returns control to MATLAB.

- **Launch Pad:**

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

- **Help Browser:**

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

- **Help Navigator:**

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

- **Display Pane:**

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

- **Browse to other pages:**

Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

- **Bookmark pages:**

Click the Add to Favorites button in the toolbar.

- **Print pages:**

Click the print button in the toolbar.

- **Find a term in the page:**

Type a term in the Find in page field in the toolbar and click Go. Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

- **Current Directory Browser:**

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

- **Search Path:**

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system.

Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and Math Works toolboxes are included in the search path.

3.6.5 Workspace Browser:

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session.

To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

3.6.6 Array Editor:

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

3.6.7 Editor/Debugger:

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

3.6.8 Creating GUIs with GUIDE:

MATLAB implements GUIs as Figure windows containing various styles of unicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of the set asks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.7 GUI Development Environment:

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks – the functions that execute when users activate components in the GUI.

3.7.1 The Implementation of a GUI:

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIGURE-file - contains a complete description of the GUI Figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as theapplication M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIGURE-file.

The following diagram illustrates the parts of a GUI implementation.

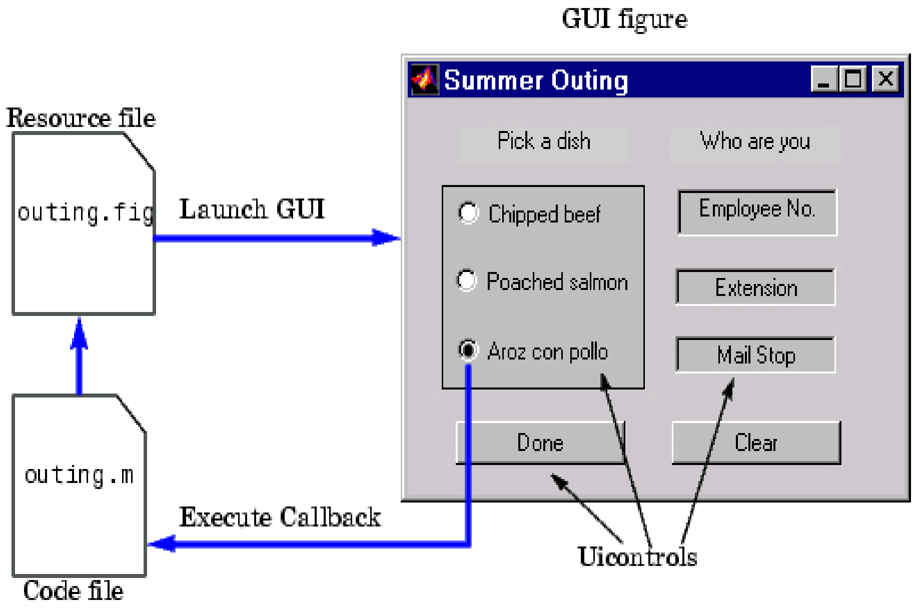

Fig 3.2 Graphical user blocks.

3.7.2 Features of the GUIDE-Generated Application M-Fil:

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Con Figuring Application Options for information on these features). The M- file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIGURE-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIGURE-file generated by the Layout Editor.

3.7.3 Beginning the Implementation Process:

To begin implementing your GUI, proceed to the following sections: Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIGURE-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

3.7.4 Command-Line Accessibility:

When MATLAB creates a graph, the Figures and axes are included in the list of children of their respective parents and their handles are available through commands such as find object, set, and get. If you issue another plotting command, the output is directed to the current Figure and axes.

GUIs are also created in Figure windows. Generally, you do not want GUI Figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI Figures, resulting in the graph appearing the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.7.5 User Interface Control:

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB unicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons

- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

- **Push Buttons**

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its non depressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

- **Programming the Callback**

When the user clicks on the pushbutton, its callback executes. Push buttons do not return a value or maintain a state.

- **Toggle Buttons**

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the non depressed state and again executes its callback.

- **Programming the Callback**

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

 % toggle button is pressed elseif button_state == get(h,'Min')

 % toggle button is not pressed end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) =rand(16,128);
a(:,:,2) =rand(16,128);
a(:,:,3) =rand(16,128);
set(h,'CData',a)
```

- **Radio Buttons**

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected. Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group.

MATLAB sets the Value propertyto1onthe radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

Functionmutual_exclude(off) set(off,'Value',0)

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual exclude being made from the first radio button's callback in a group of four radio buttons.

function varargout = radiobutton1_Callback(h,eventdata,handles,varargin) off =

[handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

- **Checkboxes**

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode(e.g., display a toolbar or generate callback function prototypes). The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked. Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

functioncheckbox1_Callback(h,eventdata,handles,varargin) if (get(h,'Value') == get(h,'Max'))

% then checkbox is checked-take approriate action else

% checkboxis not checked-take approriate action end

- **Edit Text**

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback. function

edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (is nan) and displays an error dialog(errordlg).

functionedittext1_Callback(h,eventdata,handles,varargin)user_entry

=str2double(get(h,'string'));

if isnan(user_entry)

errordlg('You must enter a numeric value','BadInput','modal') end

% proceed with callback... Triggering Callback Execution

On UNIX systems, clicking on the menu bar of the Figureure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editabletextboxhasfocus,clickingonthemenubardoesnotcausetheeditabletext callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

- **Static Text**

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it.

- **Frames**

Frames are boxes that enclose regions of a Figureure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

- **List Boxes**

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The Listbox Top property defines which string in the list displays as the topmost item when the list box is not large enough to display all list entries. Listbox Top is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer Single or Multiple Selection.

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection. Selection Type

Listboxes differentiate between single and double clicks on an item and set the Figures Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This

means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the listbox Value property (and possibly the Figures Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string (") and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

- **Popup Menus**

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

- **Programming the Popup Menu:**

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

function varargout = popupmenu1_Callback(h,eventdata,handles,varargin) val =

get(h,'Value');

switch valcase 1

% The user selected the first item case 2

% The user selected the second item

% etc.

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

function varargout =popupmenu1_Callback(h,eventdata,handles,varargin) val =get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string% etc.

- **Enabling or Disabling Controls**

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out
inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback

routines to execute: First the Figures Window Button DownFcn callback executes. Then the control's Button DownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

- **Axes:**

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

- **Axes Callbacks:**

Axes are not uicontrol objects, but can be programmed to execute a callback whenusersclickamousebuttonintheaxes.UsetheaxesButtonDownFcnproperty to define the callback.

3.7.6 Plotting to Axes in GUIs:

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example, axes(handles.axes1) makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

3.7.7 Figure:

Figure are the windows that contain the GUI you design with the Layout Editor. See the description of Figure properties for information on what Figure characteristics you can control.

CHAPTER 4

ARCHITECTURE OF 6G NETWORK

4.1 Architecture of 6GNetwork:

Next-generation wireless networks will consist of massive number of connected devices and with the base stations (BSs)/access points (APs) leading to mMTC. Multiple BSs/APs may serve one or more devices simultaneously to form a coordinated multi-point (CoMP) transmission [39]. The huge amount of data produced by massive devices will require very high-performance processing units and robust backhauling links. The central processing units may utilize ML and AI algorithms and the backhauling links may utilize optical fiber and or photonic communications. Remote user, in 6G communication systems, can use several relays or transmitters for a remote user to transmit, and the user's SINR may be improved by using the technique of diversity as in virtual MIMOsystems.

By intelligent networking, all the end devices would be aware of the location and features of BSs/APs in their vicinity, and all of the BSs/APs would be aware of the locations, features, and QoS requirements of devices in their vicinity. Robust interference management/optimization techniques can be applied to maximize the efficiency of the wireless network. Central processing units will be fast enough to manage and switch the resources (bandwidth, time, power) among multiple end-users, and data processing will be conducted at the base-band processing units (BPUs). The air interface is the main component that causes a major improvement in the wireless generations. Orthogonal frequency division multiplexing (OFDM) played a major role in the development of 4G, as code division multiple access (CDMA) was the key player in 3G. Similarly, the development of the new air interface will be an essential component of 6G system architecture.

AI and ML is another crucial component of the 6G system architecture. AI and ML will play an important role in the self-organization, self-healing, self-configuration of 6G wireless systems. Spectrum congestion has also pushed the 6G to adopt a new spectrum for communication. Therefore, this new spectrum will also be an active component in the 6G system architecture. Since 6G will accommodate a wide range of communication devices ranging from IoTs to live HD video transmission, 6G will need to be in line with all previous technologies. Therefore, a flexible and multi-radio access technologies (RAT) system architecture will be an essential component in the 6G network.

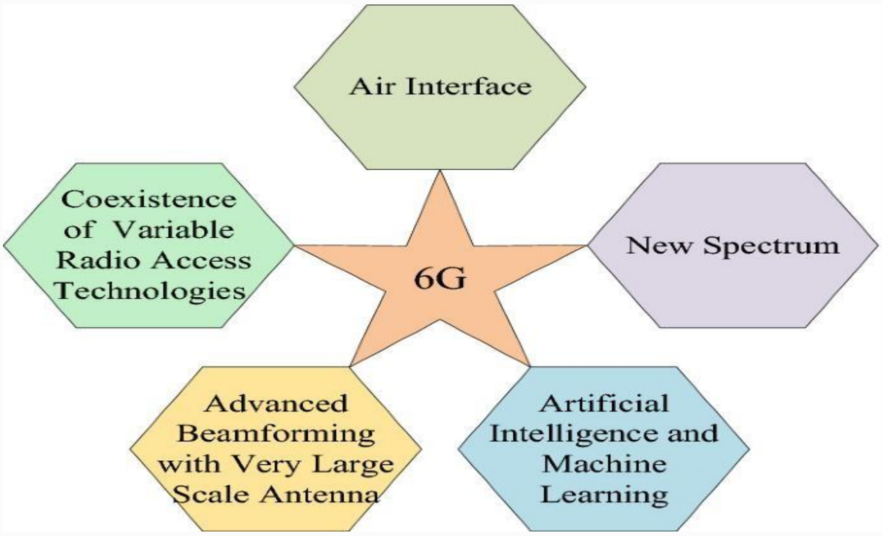

Fig 4.1 : Architecture of 6G network.

4.1.1 Air interface:

Since 6G will concentrate on the current terahertz frequency range with extremely wide bandwidths available, it will bring up new obstacles to interact efficiently at these frequencies. Getting a secure transmission infrastructure that has an adequate range and isn't power-hungry will be the answer here. The availability of incredibly wide bandwidths would change the emphasis from spectrally optimized solutions to improved coverage solutions. In these new frequency spectrums, the tradeoff between spectrum performance, power efficiency, and coverage will play a key role in developing devices. This will lead to the design of a modern air interface where more consideration can be paid to single-carrier systems. The OFDM scheme would be revisited for lower frequency ranges where spectral efficiency will be important as it does not use the energy effectively because of the cyclic prefix, which is just the duplication of information and does not hold any additional information. Furthermore, a high peak-to-average power ratio (PAPR) makes the power amplifiers complex and expensive.

Many researchers have proposed the non – orthogonal multi places (NOMA)as a promising new scheme for the B5G/6G mobile networks [40,41,42]. In NOMA, all of the users are allowed to access the complete resource(frequency band) simultaneously. Some researchers have suggested the rate-splitting multiple access (RSMA) as a new access technology for 6G communication systems [43,44,45]. Both NOMA and RSMA rely on the successive interference cancellations (SIC) to decode the information for the user. RSMA uses the SICs to decode the common message firstly and then decode the private message. Both schemes need to be matured enough before practical deployment. A new AI-based software-defined air interface is presented in [46], where the authors proposed an intelligent air interface switching system for user QoS enhancement.

3GPP release 15, reveals the specifications for the 5G-New Radios (NR), in which multiple waveform configurations and two sets of frequencies are defined. By adopting the variable numerologies (symbol duration, sub-carrier spacing, and pilot spacing), we can give the transmitter leverage to self-organize and self-configure according to the channel conditions and service required. This is often useful on different measurements. For instance, by reducing the symbol length, low latency can be achieved, and increasing the spacing of the sub-carrier can be helpful in reducing the phase noise in mmWave and sub-mmWave. In high mobility situations, optimizing the sub-carrier width can also be helpful for Doppler shift compensation.

4.1.2 New spectrum:

mmWave is already a candidate for 5G, but it is not exploited to its full potential as the beam forming algorithms are not mature enough. It requires improvements in the networks when personal BSs and satellite connectivity can get merged into cellular communication. In the previous generations, the spectrum is divided for multiple services, for instance, television (TV) services, military communications, and cellular communication [47].

Therefore, the idea of using an unlicensed spectrum is proposed, i.e., to use the mmWave, THz band, and visible light spectrum, simultaneously [48,49,50,51,52]. These bands are never used for any communication. The problem with the higher frequency band, though, is that the signal is attenuated very rapidly about the distance travelled. For example, a 3G or 4G BS can have a coverage of about several miles whereas a 5G or 6G BS coverage may limit to only a few hundreds of meters. To resolve this issue in mmWave and THz communications, the idea of using massive multiple inputs and multiple outputs (MIMO) and beam forming emerged, which is described in the next subsections.

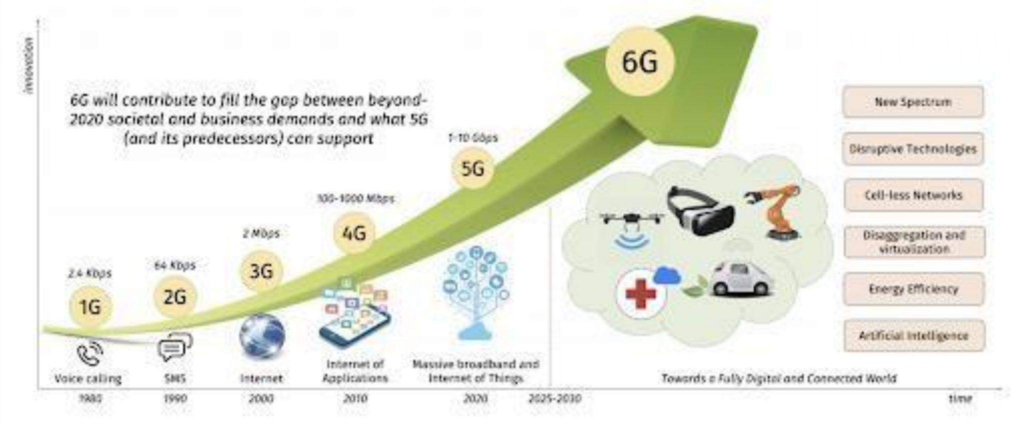

Fig 4.2 :mmWave network dimensions.

4.1.3 Artificial intelligence/machine learning:

By offering pervasive, secure, and close proximity-instant wireless networking for humans and computers, 6G wireless communication networks would be the core of society’s digital transition. A broad variety of emerging developments, such as self-driving cars and voice assistants, have been made possible by recent advancements in ML research. B5G/6G wireless networks have increased complexity, requiring smarter methods for handling any losses and handling network features, detecting anomalies, and understanding KPI trends. This can be done by introducing solutions for ML and SDN. In order to preserve a certain level of KPI, ML/AI will boost the decision-making process. The operation and implementation of RAN for 6G needs a new strategy. Incorporating AI in wireless algorithms (e.g., for channel estimation, for channel state information (CSI) feedback, and decoding, etc.) may bring a change in the direction of these algorithms [53]. Application of ML, DL [54], and AI algorithms to the communication network, we can instantly manage the resources as per the user requirements. The probability of choosing the best solution is improved in this way and the network can maintain its optimum state.

4.1.4 Advanced beam forming with very large scale antenna (VLSA):

The idea of beam forming is to steer the beam to only the desired direction or user. Since energy is not spread in all directions, the transmission range is thus improved by concentrating the beam in one direction.

4.1.5 Intelligent reflecting surfaces(IRSs):

Intelligent Reflecting Surfaces (IRSs) can be the potential area for beam forming in 6G [55].IRSs are composed of thin electromagnetic materials, which can reflect/configure the incoming electromagnetic rays in an intelligent way by configuring the phase of reflected rays by a software [55]. Indeed, IRSs use at a large number of low-power and low-cost passive elements to reflect the incident signals with configurable phase shifts without the requirements of additional power, encoding, decoding, modulation, demodulation requirements. IRSs are installed on the important points and locations such as high-rise buildings, advertising panels, vehicles (cars, airplanes, unmanned aerial vehicles (UAVs)), and even the clothes of the pedestrians. The main advantage of the IRS is that it can enhance the signal-to-interference-plus-noise-ratio (SINR) with no change in the infrastructure or the hardware of the communication network. Also, there is no need for extra power required for the installation.

IRS can reduce the hardware complexity at the receiver and the transmitter by reducing the number of antennae installed at them, thereby, reducing the radio frequency (RF) chains at the transmitter and the receiver. IRS can replace the conventional relays system due to its advantages in terms of power, spectral efficiency, and reduced hardware complexity [56]. IRS can be used in the deep-fade and non-line-of-sight (NLOS) communication environment. The principle by which SINR is enhanced at the receiver is optimally controlling the phases of the incident ray at multiple elements of the IRS, to produce useful beam forming at the receiver [56]. Degradation factors such as noise and interference have no impact on the IRS. All these features of the IRS make it a promising technique for the B5G/6G communication systems.

4.1.6 Orbital angular momentum (OAM)-aided MIMO:

A new dimensional property of the electromagnetic waves (EW) was discovered in the 1990s termed as the orbital angular momentum (OAM). This discovery promised the transmission of multiple data streams over the same spatial channel. An EM wave carrying the OAM has the phase rotation factor of $\exp(-jl\phi)\exp(-jl\phi)$, where l is OAM state number represented in integer and $\phi\phi$ is transverse azimuth angle [57,58,59]. The main advantage of OAM over other beam forming techniques is that OAM can have an unlimited number of orthogonal modes, which allows the EW to multiplex multiple data streams over the same spatial channel, thereby, enhancing the spectral efficiency and transmission capacity. OAM support a high number of user in mode division multiple access (MDMA) scheme without utilizing extra resources (i.e., frequency, time, and power). The flexibility of OAM to be used in narrowband and wideband frequency hopping scheme makes it an attractive scheme for low probability of interception (LPI) applications. OAM-based MIMO systems have advantages over the conventional MIMO systems in terms of capacity and long-distance line-of-sight (LoS) coverage [60]. Therefore, OAM has great potential for applications in 6G wireless networks.

4.1.7 Coexistence of variable radio access technologies:

6G can lead to a ubiquitous networking infrastructure where users would not only be left with the option of selecting the best communication network. Each node in this network would, however, be intelligent enough to sense the conditions of the channel and the specifications of QoS at any other node. For example, the use case and the availability of network will decide the network as cellular, wireless LAN, Bluetooth, and ultra-wideband (UWB), etc. 6G communication standard should, therefore, be designed in such a way that it will converge all of the wireless technologies. Communication with Wi-Fi, Bluetooth, UWB, VLC, UAVs, biosensors, and satellite communications can all integrate into 6G and should fall under one standard such that all of them can connect with each other. The Wi-Fi operating at 2.4 GHz has already entered deeply into IoTs as most of the appliances are now connected through this network [61,62,63].

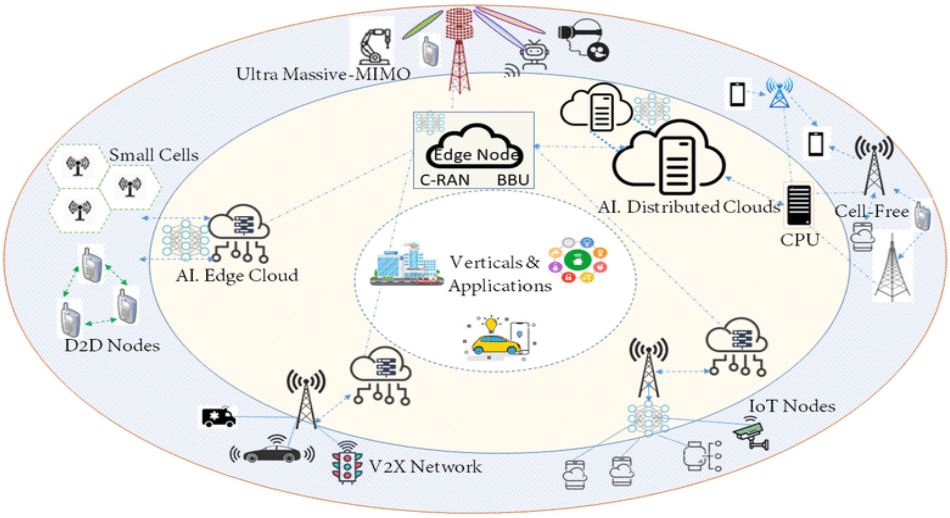

Fig 4.3 : Network level of 6G architecture.

By merging all these technologies, 6G would be able to utilize the massive infrastructure deployed by previous technologies, which otherwise can cost 6G a huge revenue. The features in the previous technologies, such as network densification, high spectral efficiency, high throughput, low latency, high reliability, and massive connectivity should be converged in 6G. 6G technology should also keep the trend of offering new services by applying the new technologies, such as AI/ML, VLC, quantum communications (QC), and quantum machine learning (QML). These services may include but are not limited to smart cars, smart homes, smart wearable, and 3D mapping [64].

4G introduced mobile Internet, mobile TV, and HD videos. AR/VR, ultra-HD (UHD) videos, wearable devices, vehicle-to-infrastructure (V2X), smart city, telemedicine, and IoTs concepts are introduced in 5G. 6G is projected to have applications such as space tourism, Tactile Internet, fully automated cars, holographic verticals, deep-sea sight, digital sensing, and Internet-of-bio-Nano-things (IoBNT). Figure 4b shows that how KPIs are changing with the evolution of wireless generations from 1G to 6G. All Internet protocol (IP) and the ultra-broadband concept is introduced in 4G. The concepts of cloudification, softwarization, slicing, virtualization, and wireless worldwide web (WWW) are introduced in 5G. Integration of intelligence with cloudification, softwarization, slicing, and virtualization will be introduced in 6G communication systems. The initial stage of the wireless communication system is the development of the advanced mobile phone system (AMPS). Global systems for mobile (GSM) and general packet radio systems (GPRS) family is developed in 2G wireless systems. Code-division multiple access (CDMA) family shifted the wireless systems from 2G to the 3G. OFDM with the integration of turbo codes and MIMO systems is the key technology for 4G communication systems. 5G communication systems brought some new technologies such as cloud/fog/edge computing, massive MIMO, SDN, mmWave and sub mmWave (NR) along with low-density parity-check (LDPC) and polar codes. ML, AI, blockchain, THz communication, orbital angular momentum multiplexing (OAM Mux), spatial Modulation (SM)-MIMO and intelligent re-configurable reflecting surfaces are the new technological domains in 6G.

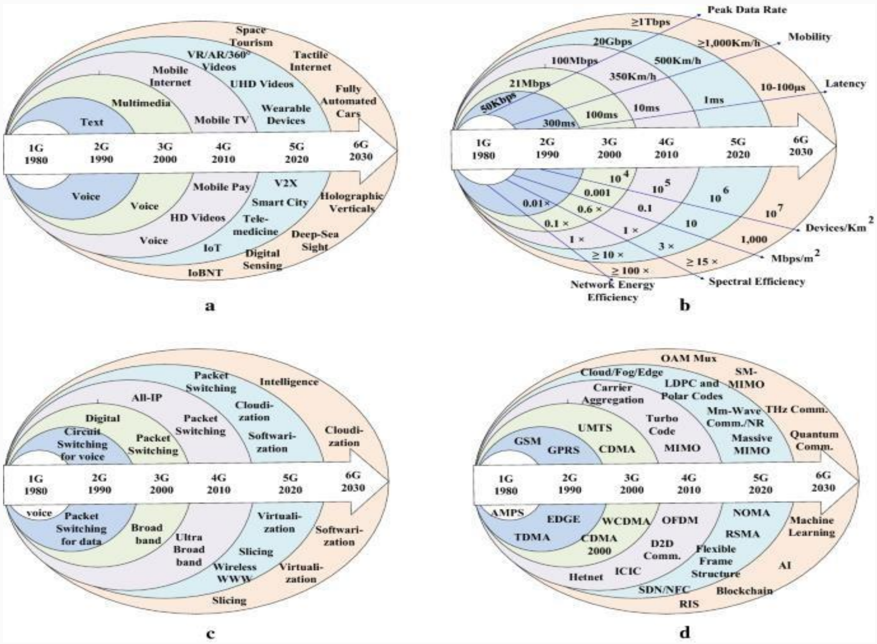

Fig 4.4 : Evolution of wireless communication, with timeline, from 1G to 6Gbased on (a) Applications (b) KPIs (c) Network characteristics and (d)Technological development.

CHAPTER 5

NETWORK DIMENSIONS AND POTENTIAL TECHNIQUES

Network intelligence will be an essential component of 6G networks and the network will take actions dynamically according to the environmental conditions. The idea of clouds, fog, and edge computing is applied for fast access to services. The features of self-optimization, self-organization, self-reconfiguration will be achieved through softwarization, virtualization, and slicing. The detailed discussion on each network dimension is given as follows.

5.1 Intelligence:

Researchers believe that AI will play a defining role in the IoTs and IoBNTs driven world [65]. The potential shift from 5G to the 6G will be to determine an efficient way to transmit data. The ideal system will be the one that is free from human intervention at all [66].

5.2 Cloudification/fog/edge:

Thousands of sensors are installed in the industries and hundreds of the sensors are installed in homes. It is very difficult to connect all these sensors with wires [67], and, all these devices can produce a large amount of data. Also, these devices are smart and intelligent, capable of making smart decisions and less processing power. Therefore, we need to offload the data from cloud to edge and device end. To reduce the processing delay, we need to shift the process near to end devices in terms of cloud/fog. We need to place the workload closer to the edge for a better quality of service.

5.3 Softwarization:

Main driving force behind the development of B5G and 6G networks is to provide services such as self-organization, configurability, programmability, flexibility, and heterogeneous use-cases. It is difficult to install the hardware equipment which provides all of the mentioned functionalities. By realizing the functionalitiesby underlying networks, softwarization and virtualization have emerged as the two most demanding paradigms for B5G/6G networks [68].

Softwarization is the term used for the set of interfaces and protocols which can allow the network to be configured in software by decoupling the control and user plane. The user plan usually consists of a set of distributed and stateless routing tables at which packet switching is performed at a very high speed. These tables are updated by the centralized control plan which maintains the end-to-end routing information for multiple services. Data and control management operations are exchanged between the service consumer and the SDN provider [36]. SDN provider ultimately forwards the required service to the service consumer. These services are controlled by the service consumer by taking acting on these virtual resources.

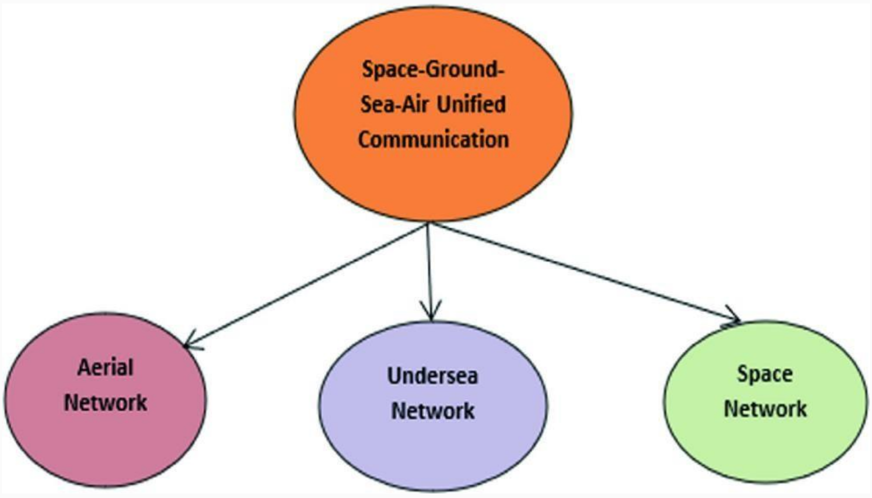

Fig 5.1 : Green 6G network era.

5.4 Virtualization:

Network function virtualization enables the software functions to be performed in the virtual machines and allows the access of common shared physical resources such as storage, networking, and computations. Containers are used to instantiate multiple functions within the same virtual machine. Dynamically varying network demand such as offered services and network traffic can be handled by dynamically instantiating the virtual machines. The services, which can be virtualized, include but are not limited to load management, mobility management, baseband processing unit services, evolved packet core (EPC) functions. Network function virtualization(NFV), unlike traditional mobile networks, provides the leverage to route the packet of each service between virtual network functions (VNFs) [69]. Further, the routing services are provided with very few overheads. Also, routing and traffic flow are smoothly maintained without any interruption even if a new VNF is added or removed according to the traffic demands.

5.5 Slicing:

One of the key network abilities that will allow us to build a flexible network on top of the common physical infrastructure is network slicing. As 5G continues to take shape, network slicing will become the fundamental technology to enable a wide range of use cases. Taking a single piece of network infrastructure and being able to cost-effectively deliver multiple logical networks over the same common physical infrastructure [69]. The slices can be allocated to some specific use-cases such that we can have a slice for IoTs, slices can be allocated to a class of service, slices can be allocated to a class of customers, slices can be allocated to some specific mobile network operators, slices can also be allocated to network types such as wireless vs wired or consumer vs businesses.

In network slicing, the biggest difficulty is configuring new slices, since it affects all the network components. However, with the need to create customized services and deliver a service with a very specific requirement, we can create slices such as slice for automotive, healthcare, utility.

It is possible to communicate with the devices with very low data-rates such as biosensor and IoTs, and at the same time, it will enable high data rate communication such as HD video transmission in smart cities. Communication will be possible in a fast-moving bullet train, airplane. It also shows that all of the networks will be merged all together. Further, the buildings and surfaces in smart cities can be equipped with the IRS that could enhance the coverage and quality of service (QoS) of each communicating device. For the maritime communication scenarios, the robust underwater data links will enable the communication between ships, submarines, and sensors at the deep sea level [70, 71]. Besides, innovative technologies such as

AR/VR, haptics, and ML will further reduce the effect of physical distances around the globe.

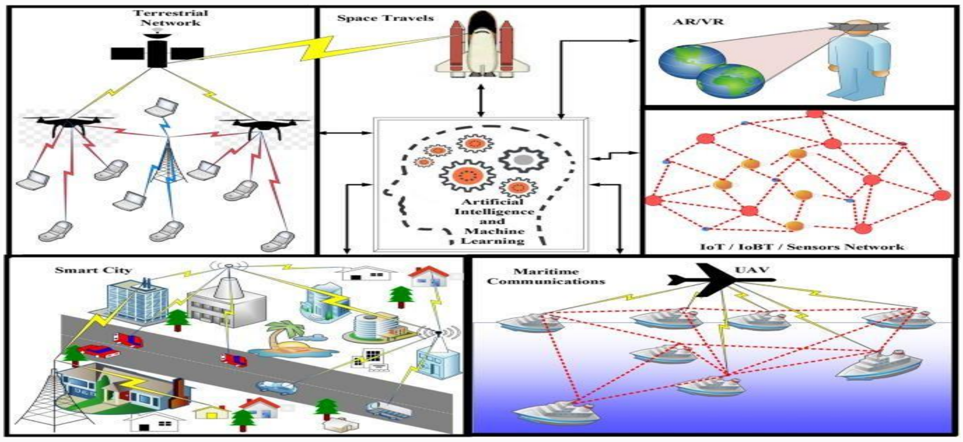

Fig5.2 : Depiction of space-air-ground-sea based integrated next-generation communication system.

The 6G core network is shown to have upgraded to the basic 5G core network based on intelligence, high computational power, and high capacity. By integrating BSs/APs, satellites, and UAVs, the access network is upgraded similarly. There is a vertical hand-off in 6G in addition to the horizontal as in that of 5G. Besides, fog computing and MEC are an integral component of the 6G network infrastructure, that reduces latency and bandwidth utilization for regularly needed services by a massive number of devices on the user plan.

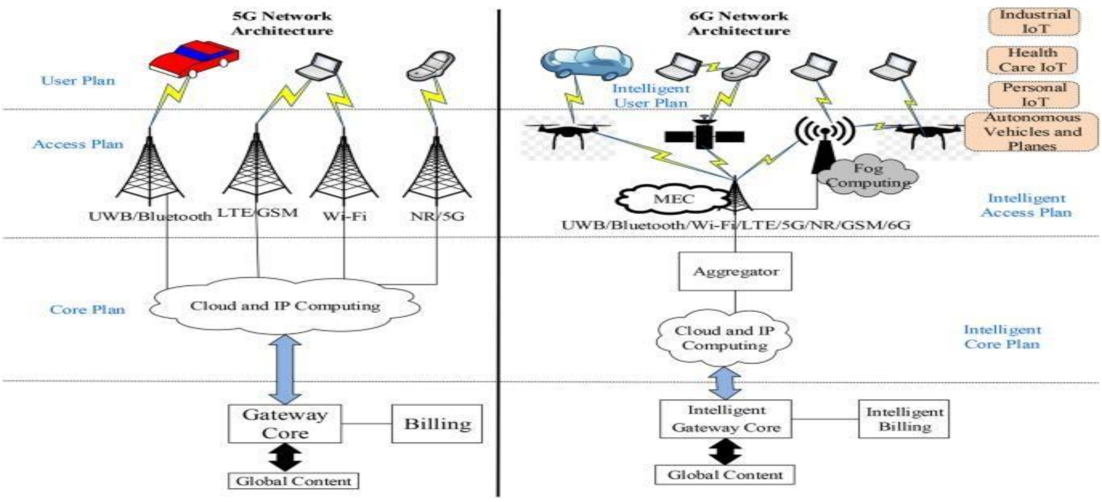

Fig 5.3 : A comparative analysis between 5G and 6G network architecture.

5.6 Device to device communication:

Device-to-Device (D2D) communication in cellular networks is defined as direct communication between two mobile users without traversing the Base Station (BS) or core network. D2D communication is generally non-transparent to the cellular network and it can occur on the cellular frequencies (i.e., inband) or un licensed spectrum (i.e.,outband).

In a traditional cellular network, all communications must go through the BS even if communicating parties are in range for proximity-based D2D communication. Communication through BS suits conventional low data rate mobile services such as voice call and text messaging in which users are seldom close enough for direct communication. However, mobile users in today's cellular networks use high data rate services (e.g., video sharing, gaming, proximity-aware social networking) in which they could potentially be in range for direct communications (i.e., D2D). Hence, D2D communications in such scenarios can greatly increase the spectral efficiency of the network. The advantages of D2D communications go beyond spectral efficiency; they can potentially improve throughput, energy efficiency, delay, and fairness.

Table I. Device-to-device strategy list.

Parameters	Length/bit	Value	
Communication patterns	2	00	Orthogonal
		01	Reused
		10	Cellular
Power indicator	1	0	High
		1	Low
Spectrum	8	0	Whole spectrum
		[7:4]	Starting
		[3:0]	Ending
Scan time	8	Unit: ms	

Fig 5.4 : Device to device strategy list.

5.7 Data delivery in non-cooperative D2Dcommunication:

Existing data delivery protocols in D2D communications mainly assume that mobile nodes willingly participate in data delivery, share their resources with each other, and follow the rules of underlying networking protocols. Nevertheless, rational nodes in real-world scenarios have strategic interactions and may act selfishly for various reasons (such as resource limitations, the lack of interest in data, or social preferences).

For example, if a node has limited battery resources or the cost of the network bandwidth delivered by mobile network operators is high, it would not willingly relay data for others until appropriate incentives are provided. Meanwhile, malicious nodes may attack the network in different ways to disturb the normal operation of the data transmission process. An adversary, for example, may drop received messages but produce forged routing metrics or false information with the aim of attracting more messages or decreasing its detection probability. This issue becomes more challenging when colluding attackers boost their metrics to deceive the attack detection systems. Dealing with non-cooperative mobile nodes is very challenging because of the distributed network model and intermittent access of nodes to central authorities.

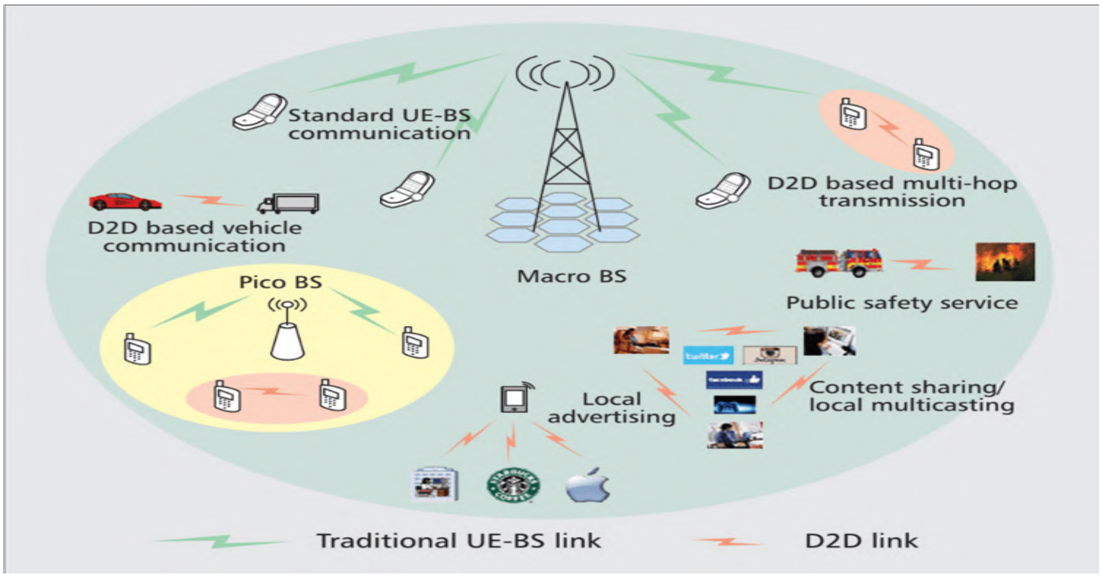

Fig 5.5 : Device to device communication.

5.8 D2Dapplications:

D2D Communications is used for

- Local Services: In local service, user data is directly transmitted directly between the terminals and doesn’t involves network side, e.g. social media apps, which are based on proximity service.

- Emergency communications: In case of natural disasters like hurricanes, earthquakes etc., traditional communication network may not work due to the damage caused. Ad-hoc network can be established via D2D which could be used for such communication in such situations.

- IoT Enhancement: By combining D2D with Internet of things (IoT) , a truly interconnected wireless network will be created. Example of D2D-based IoT enhancement is vehicle-to-vehicle (V2V) communication in the Internet of Vehicles (IoV). When running at high speeds, a vehicle can warn nearby vehicles in D2D mode before it changes lanes or slows down.

5.9 Potential Features:

In order to provide satisfying services for Industry 4.0, personalized health services, virtual presence, and other challenging anticipated applications in the future, 6G needs to further enhance its scalability, flexibility, and efficiency by embracing novel techniques. Like the emergence of many new technologies when the wireless world moves toward 5G, the new requirements of 6G will influence the main technology trends in its evolution process. The success of 6G will have to leverage breakthroughs in novel technological concepts.

A vide range of recent research findings related to 6G design, including multi-band ultrafast-speed transmission techniques, super-flexible integrated network designs, multi-mode multi-domain joint transmission, as well as machine learning and big-data-assisted intelligent approaches.

5.9.1 Multi-Band Ultrafast-Speed Transmission:

For our bandwidth-hungry society, 2G, 3G, and 4G have used frequencies that reach approximately up to 6 GHz, while 5G systems exploit the range of less than 6 GHz as efficiently as possible by combining 24–100 GHz. Recently, developers are realizing that the current frequency bands may not be enough to serve the growing demands; for example, an uncompressed ultra high-definition video may reach 24 Gb/s, and some 3D videos may reach to 100 Gb/s [3]. As a result, in 6G, we will jump above 100 GHz, and the new radio will consider not only the traditional sub-5 GHz band but also validate little-explored frequency sources such as mmWave and terahertz bands to overcome the spectrum scarcity and provide wide bandwidth from hundreds of megahertz to several gigahertz and even to terahertz. In recent years, a flurry of research activities have been reported concerning the use of multiple high-frequency bands for ultrafast-speed transmissions, which are recommended as promising solutions for 6G. Specifically, a consortium of DARPA, IBM, and Intel has focused on research into using 140 GHz, 220 GHz, and 340 GHz frequencies (https://spectrum.ieee.org). In early 2014, Akyildiz et al. provided an in-depth view of terahertz band in the range of 0.1–10 THz for supporting terabit-per-second high-speed communications [4]. A further advance of terahertz band communication is that it is enabled to simultaneously support macro-scale and micro-scale applications, such as terabit wireless local area networks (WLAN) and nano sensor networks. Teams at New York University are already working on terahertz research and quantum devices, with the goal that transmit rates in 6G are expected to be 1000 times faster than those in 5G. Researchers from the Fraunhofer Institute have cooperated with researchers from Heinrich Hertz Institute and other partners from industry to build a network connection in the terahertz frequency range that is sufficiently stable to allow for wireless data transmission at speeds of up to 400 Gb/s (https://www.networkworld.com). In [3], several terahertz-based medium access protocols for mobile heterogeneous networks were investigated, where conventional mWave, mmWave, and terahertz bands could coexist. Moreover, another trend in 6G may be dynamically using different frequencies, especially these unlicensed bands, in order to enjoy the benefits of the sharing architecture. For example, as predicted in [1], optical indoor communication (visible-light frequency band) is a promising high rate technique to replace conventional WLAN, since people spend most of their time indoors (more than 80 percent). Furthermore, we can also combine the fiber optic technology with the wireless-type transmissions for further improvement. The coexistence of multiple high-frequency bands and the dynamic utilization of different frequencies can be realized by advanced software defined radio (SDR) and software defined networking (SDN) techniques. Moreover, the emerging block chain technique may be an appealing solution to facilitate dynamic spectrum sharing in the future (https://venturebeat.com/). With these aforementioned novel techniques, it is expected that 6G networks will be easier to upgrade based on the existing 4G and future 5G equipment.

5.9.2 Super Flexible Integrated Network:

6G systems will also need to serve a wide range of applications in diverse scenarios, which have been defined in 5G. Moreover, with the rise of smart homes, buildings, cities, and society, 6G will meet the increased demands for human-to-machine and machine-to-machine communications, especially with the development of robotic and autonomous drone systems. For the purpose of the Internet of Everything (IoE) in the 6G systems will also need to serve a wide range of applications in diverse scenarios, which have been defined in 5G. Moreover, with the rise of smart homes, buildings, cities, and society, 6G will meet the increased demands for human-to-machine and machine-to-machine communications, especially with the development of robotic and autonomous drone systems. For the purpose of the Internet of Everything (IoE) in the 6G systems will also need to serve a wide range of applications in diverse scenarios, which have been defined in 5G. Moreover, with the rise of smart homes, buildings, cities, and society, 6G will meet the increased demands for human-to-machine and machine-to-machine communications, especially with the development of robotic and autonomous drone systems. For the purpose of the Internet of Everything (IoE) in the 6G systems will also need to serve a wide range of applications in diverse scenarios, which have been defined in 5G. Moreover, with the rise of smart homes, buildings, cities, and society, 6G will meet the increased demands for human-to-machine and machine-to-machine communications, especially with the development of robotic and autonomous drone systems. For the purpose of the Internet of Everything (IoE) in the 6G systems will also need to serve a wide range of applications in diverse scenarios, which have been defined in 5G. Moreover, with the rise of smart homes, buildings, cities, and society, 6G will meet the increased demands for human-to-machine and machine-to-machine communications, especially with the development of robotic and autonomous drone systems. For the purpose of the Internet of Everything (IoE) in the future, 6G will be an ultra-dense network with super flexibility, which can deftly integrate different techniques to simultaneously satisfy various different service requirements. Moreover, 6G networks will be decentralized and designed based on the integration of terrestrial communications, aerial networks, and satellite systems in order to accommodate emerging and urgently needed services (e.g., disaster prediction), and to realize global coverage and stringent seamless access, even for ocean and mountain areas. Recently, many efforts have been devoted to designing super flexible integrated networks. Specifically, in [3] the authors proposed a scalable heterogeneous network architecture for supporting THz band communications, where a novel medium access control (MAC) protocol facilitating multi-band transmission was proposed. In [5], a potential architecture of the space-terrestrial integrated network (STIN) that integrates the space network, Internet, and mobile wireless network was introduced. In general, STIN is a large-scale heterogeneous network with high flexibility, complex structure, and dynamic topology. By jointly exploiting the advantages of satellite systems, air segment networks, and ground segment systems, this multidimensional network will bring lots of benefits for future 6G wireless communications. In particular, as shown in [6], with the increasing number and types of aerial vehicles, such as balloon, airship, and unmanned aerial vehicle (UAV), the flying base station (FBS) assisted dynamic networks can be built to improve the conventional static structure. For example, in recent years, many different FBS projects have sprung up, such as the Google Loon project, the Facebook Aquila project, the ABSOLUTE project, and the Matternet project[6].

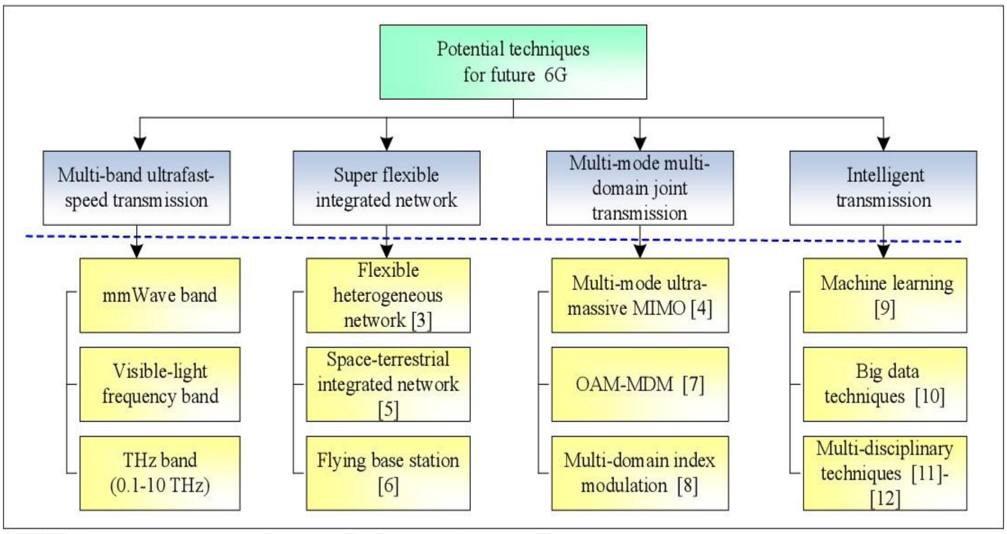

Fig 5.6 :Potential techniques of 6G.

5.9.3 Multi-Mode Multi-Domain Joint Transmission:

One of the most challenging tasks in 6G is to conceive suitable physical-layer transmission techniques to support the newly used spectral bands and enable new applications, including ultrahigh-speed indoor wireless services. For example, when THz band frequencies are utilized, how to deal with the high spreading loss and molecular absorption is a vital issue. For this research objective, many universities and research centers have begun to study the next generation forward error correction coding, advanced channel coding, and channel modulation technologies for multi-band ultrafast-speed wireless communications [1, 4]. In [4], a distance-adaptive physical layer design was proposed for mmWave and THz band communications, where each GHz (even THz) ultra-wide band was divided into narrower but still broadband sub-windows for allowing parallel multiple wide band transmissions.

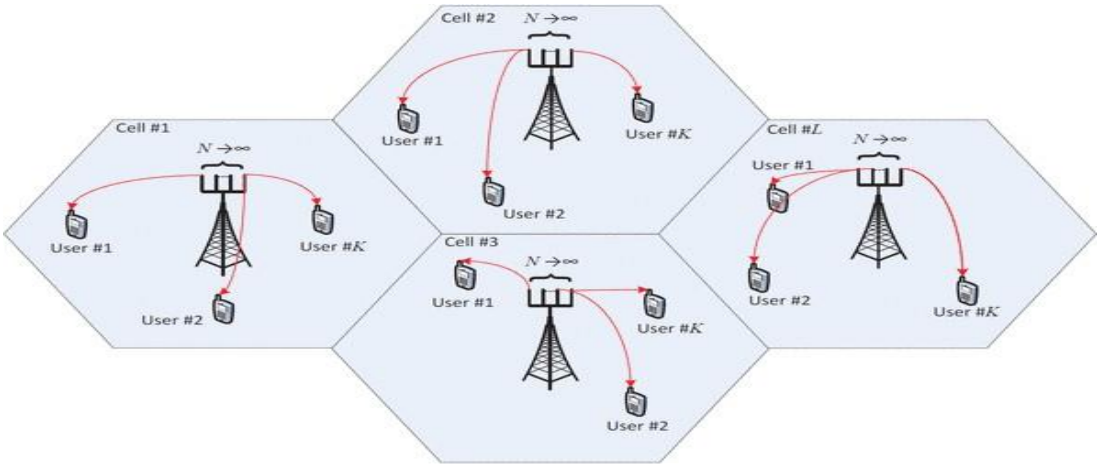

Fig 5.7 : Massive MIMO.

In each band, to add efficiency, novel multiple antenna techniques can be adapted, such as the PM-MI - MO technique. Specifically, as shown in [4], a novel class of PM-MIMO, namely UM-MIMO, is a promising solution for increasing the communication distance and improving the attainable capacity of the THz-band networks. Moreover, for further enhancing the PM-MIMO design, the multi-mode multiple antenna techniques, such as beam forming (BF) and spatial multiplexing (SMX), can be dynamically combined and adapted. BF can effectively decrease the effects of high attenuation at mmWave and THz bands, while SMX is able to increase the capacity per user. The above benefits of BF and SMX can be simultaneously obtained by adopting their combination in these parallel broad bands. Furthermore, to achieve the diversity gain inherited in MIMO for some specific applications, space diversity techniques, such as some classic space-time block codes (STBCs), can also be integrated. Besides the multi-mode techniques, multi-do-main joint transmission techniques are also promising for future 6G transmission. For example, orbital angular momentum-based mode-division multiplexing (OAM-MDM) is an emerging low-complexity but high-spectral-efficiency physical layer solution for short-distance line-of-sight wireless communications, which is capable of employing all available DoFs to convey the information over wireless links, including phase, polarization state, and other spatial DoFs [7]. In contrast, for innovatively exploiting the DoFs of multiple antennas (space-domain) and multiple carriers (frequency domain), in [8] a multi-do - main index modulation (MD-IM) technique was proposed, which relies on the generalized on/ off keying principle applied to any of the available signal resource domains to modulate the information bits on to the indices of the transmit resources, including the indices of subcarriers, transmit/receive antennas, code types, dispersion matrices, signal powers, precoding matrices, and so on. In general, OAM-MDM and MDIM create completely new dimensions for data transmission. The main benefit of OAM-MDM and MD-IM techniques is that they can be flexibly configured to satisfy different performance requirements for supporting a wide variety of applications, which is in accord with the basic requirement of 6G network design. As a further advance, the above-mentioned multi-mode and multi-domain techniques can be roundly and penetratively combined for more efficient and flexible designs.

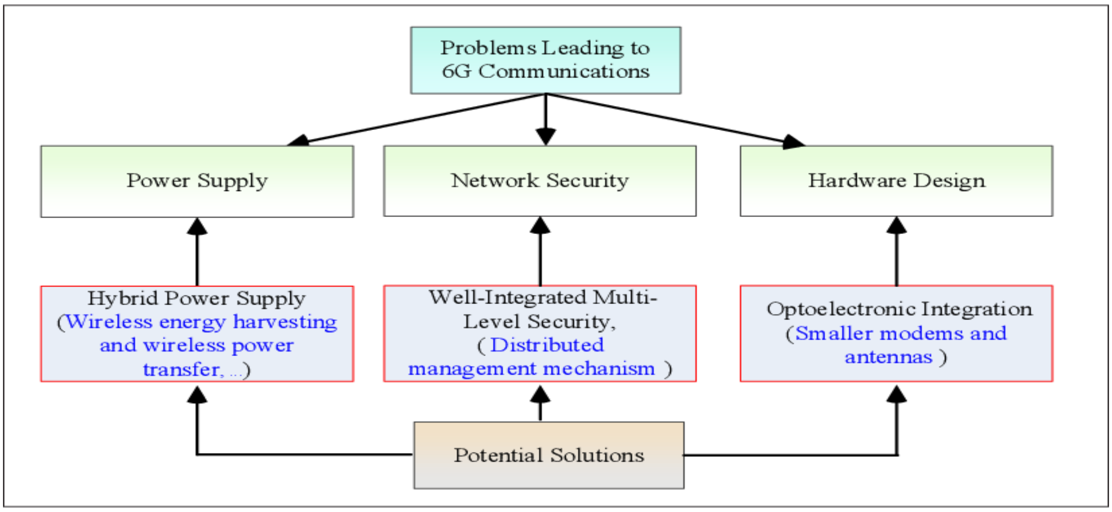

FIGURE 3. Some potential problems for 6G development and their promising solutions.

Fig 5.8 : Potential problems for 6G development.

5.9.4 Machine Learning and Big Data Assisted Intelligent Transmission:

Another trend predicted for 6G is intelligent networks and technologies to enable a fully immersive experience for users. For this research objective, 6G needs to be innovated by using and combining technologies from other fields. In recent years, breakthroughs have been made in the fields of artificial intelligence and machine learning technologies, such as deep learning neural network (DNN) algorithms [9]. In machine learning, the optimal solution (e.g., the optimal transmit mode) is capable of being obtained by classification or neural network learning instead of tedious calculation, where the classifiers and DNNs can be trained by offline datasets. These machine-learning-based methods are the best candidates to improve the design and optimization of wireless communication systems. Specifically, the key issues behind synchronization, channel estimation, equalization, MIMO signal detection, iterative decoding, and multi-user detection in wireless communication systems are similar to the theoretical basis of machine learning. 6G will be a big data-driven network, since it is expected to support extremely high data rates with heterogeneity in applications, devices, and networks. As a result, besides the machine learning techniques, some emerging big data techniques can be employed for further improving the 6G network design. For example, the latency will be improved through the use of machine learning and big data to determine the best way to transmit data from the user to the base station, since an intelligent 6G network will be capable of providing predictive analysis. Motivated by the above-mentioned appealing characteristics of machine learning and big data techniques, a flurry of research activities on intelligent wireless communication system designs have been sparked. Specifically, machine learning was considered as a key approaching [1] for realizing 6G fro mauser perspective. In [9] the authors summarized the machine learning techniques for massive MIMO optimization, heterogeneous network design, and device-to-device communications. In [10], a novel mobile network architecture enabling big data analytics was proposed for facilitating physical layer optimizations. It is worth noting in [9–11] that machine learning and big data techniques will not only deliver compelling system performance but also profoundly change the design and configuration of the future 6G networks (e. g., the physical-layer processing and MAC protocol). Furthermore, machine learning and big data analytics are not independent and unrelated in future 6G network design.

As noted in [11], by jointly utilizing these techniques, the mobile networks will become more promising in terms of self-adaptive, self-aware, and predictive ability. Indeed, intelligent 6G network design requires knowledge and methods from multi-disciplinary aspects. To be specific, methods in optimization theory, data mining, computer science, and even life science will be involved. Recently, based on the development of brain-machine interface techniques, mind-controlled machines are gradually being realized [12], which have led some scientists to speculate that mind-to-mind communications may be possible in 6G and beyond (https://www.iflscience.com/). Moreover, a 6G network may also include other communication types, such as molecular communications [13] for future micro- or nanoscale medical applications. In these long-term, forward-looking, and service-oriented visions, the biology and chemistry fields are involved in future communication theory.

5.10 Beam Management :

Even though 3GPP would not preclude the use of Sub 6 GHz deployment of 5G(NR), at least based on the current status it seems that most of the deployment would be in very high frequency (millimeter wave) and this high frequency deployment would be one of the most important characteristics of 5G (NR).

5.10.1 Why we need Beam ?

Mostly by Nature of the wave (by Physics), when we use low and mid range of frequency, we can transmit a signal in all direction (as in (A)) or relatively wide angles (as in (B)). However, when we use very high frequency, we would not have much choice except using a huge antenna array. As a result of using this kind of huge antenna array, the resulting radiation would be a beam as in (C). Refer to Why Massive MIMO page for the details of this background.

5.10.2 Why Beam Management / Beam Control?

I don't think transmitting signal in Beam in high frequency deployment would be the matter of choice. It is a kind of 'MUST' implementation. In case of low / mid frequency region without using massive antenna array (as in (A) / (B)), a single transmission would cover a lot of UEs simultaneously. However, when the radiation become beam-shaped as (C), it is very difficult to cover multiple UEs in single transmission unless those multiple UEs are located in very close proximity. To handle this problem, we need a very sophisticated idea of managing/controlling the beam to cover the multiple devices scattered in all directions and the management/control mechanism should be different depending on the situations. All of these collection of idea would fall into the title of "Beam Management" in the specification.

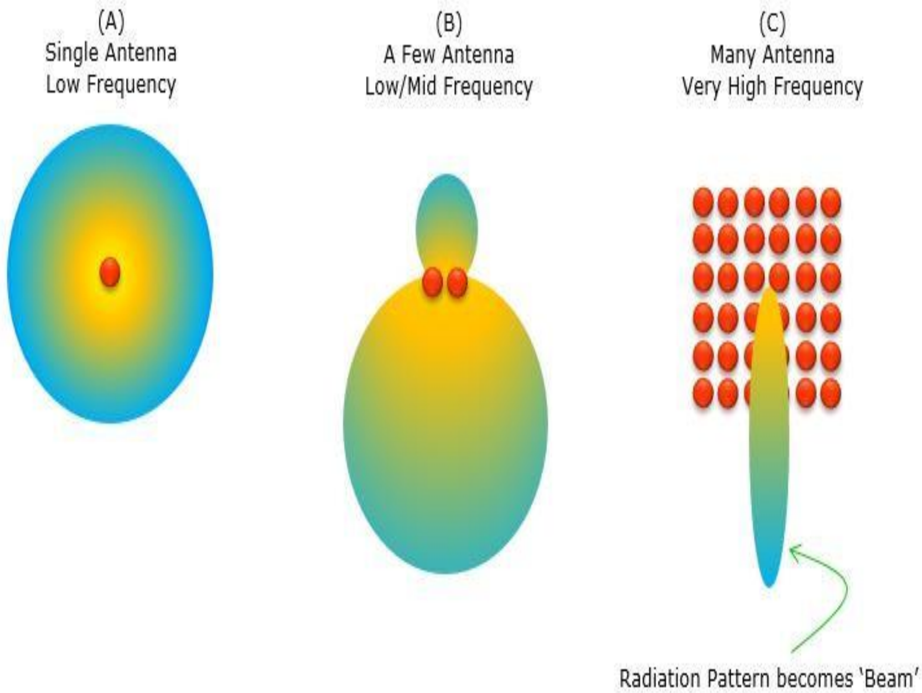

Fig 5.9 : 6G Beam radiation pattern.

5.10.3Beam Management/Control when a transmitter has no information on the location of the receiver

Now let's look into a more specific cases where the Beam Management/Control become crucial. As an example, let's think of following case. There is a Base Station with Massive MIMO operating at the very high frequency. There is a UE around the Base Station and you are just about to turning on the UE. Once the UE is turned on, it would start Synchronization process. For this step, the Base Station would transmit the special signal called Synchronization Signal and the signal should be able to reach to every UEs around the base station. However, here comes a serious problem with the base station sending signal in Beam. It is the fact that the signal beam can point to a very narrow area and it cannot cover a very wide area at the same time. Simply put, now you have the following question.

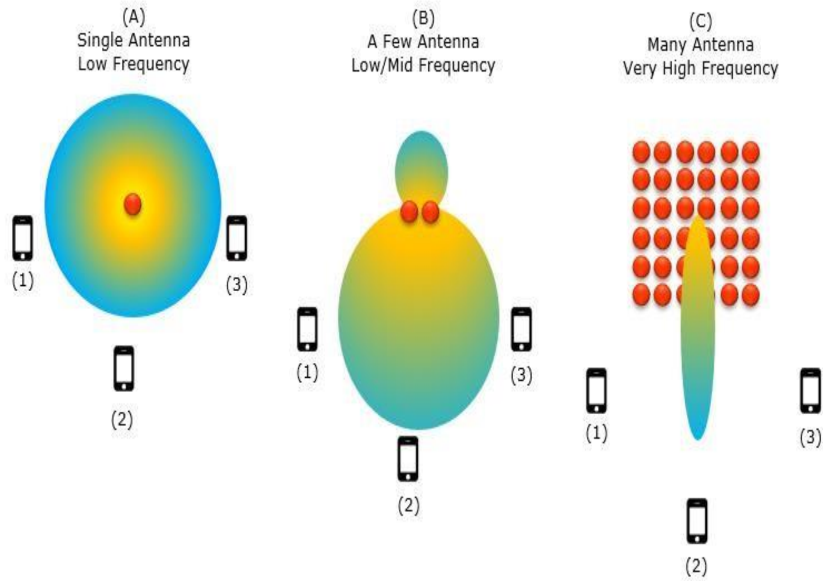

Fig 5.10 : Antenna range of 6G.

Fig 5.11 : Signal sharing.

What would be the answer for this ? If everything works as you draw in power point, you may draw a solution as follows. You may want to transmit a lot of beams in all direction simultaneously. Looks good ? Looks like a flower :).

Would the solution above be feasible, reasonable and effective ? The simple answer is NO (I would not explain why. You may easily guess why).

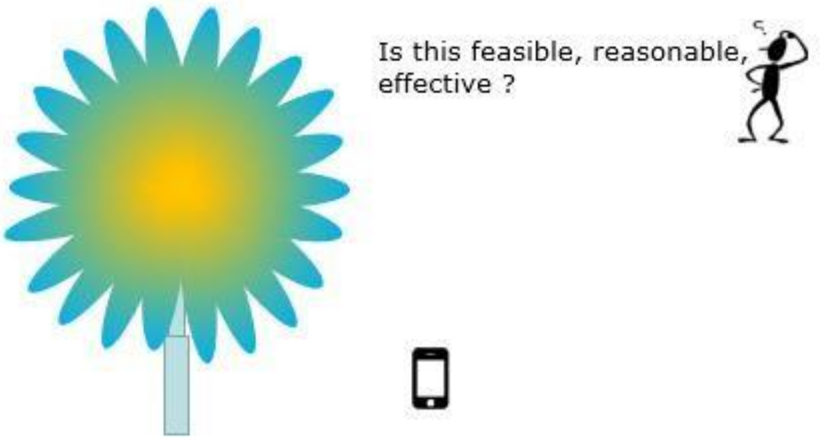

Fig 5.12 : Signal sharing Q/A.

Then what can be another idea (possible solution) for the problem ? There can be multiple ideas and proposals, but the most popular proposal as of now seems to be that the base station transmit the beam to a specific direction at a specific time and then change the direction a little bit in a next time frame and so on until it can scan all the area it should cover.

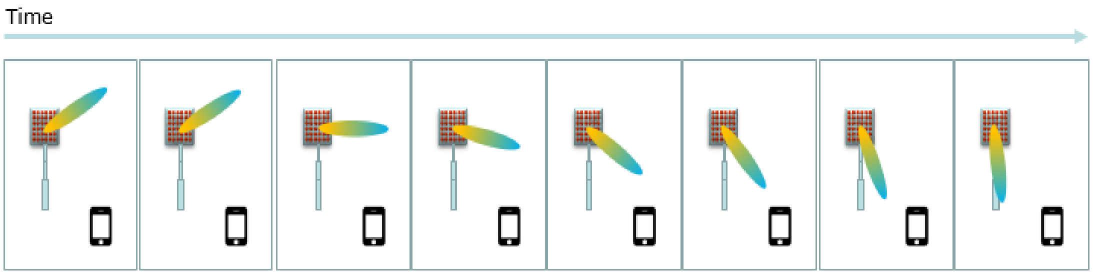

Fig 5.13 : 6G NR initial access procedure.

Then, the next question would be "how to reflect / implement this concept in the radio frame design ?". I would not go too much detail on this until this is explicitely determined in 3GPP TS (Technical Specification) document, but you can get the general ideas on various options /proposals from TDocs listed in Reference Section.

// Now that 3GPP Technical Specification on Beam Management has been released and I could write on this mechanism based on the formal specification. You may jump to NR Beam Management in a Nutshell section and read from there if you are interested in the formal specification.

5.10.4 Beam Management/Control when the connection is already established.

Now let's talk about more serious case of Beam Management. In terms of 3GPP TDocs, Beam Management handles mostly with this topic (Beam Management during the connected states) and the one mentioned in previous section are described as a part of the topic Cell Search / Initial Access.

Once UE gets into a connection states with a Network, at least one beam (or multiple beam) is properly in connection between UE and the network. Theoretically there can be so many different ways in which UE and Network beam is connected, but we can reduce it down to roughly four differences case as shown below.

In case 1, UE and Network is connected through a single TRP (Tx/Rx Point) and a single beam.

In case 2, UE and Network is connected through multiple TRP (Tx/Rx Point) and a single beam for each TRP.

In case 3, UE and Network is connected through a single TRP (Tx/Rx Point) and multiple beams.

In case 4, UE and Network is connected through multiple TRP (Tx/Rx Point) and multiple beams for each TRP.

You may think of many other cases and ask "How about this case ? How about that case ?". Whatever you think of and whatever you are asking, I think all of those would be valid thinking and valid question until 3GPP reach a explicit conclusion. So keep asking and try to find your own answers until you see the explicit 3GPP specification.

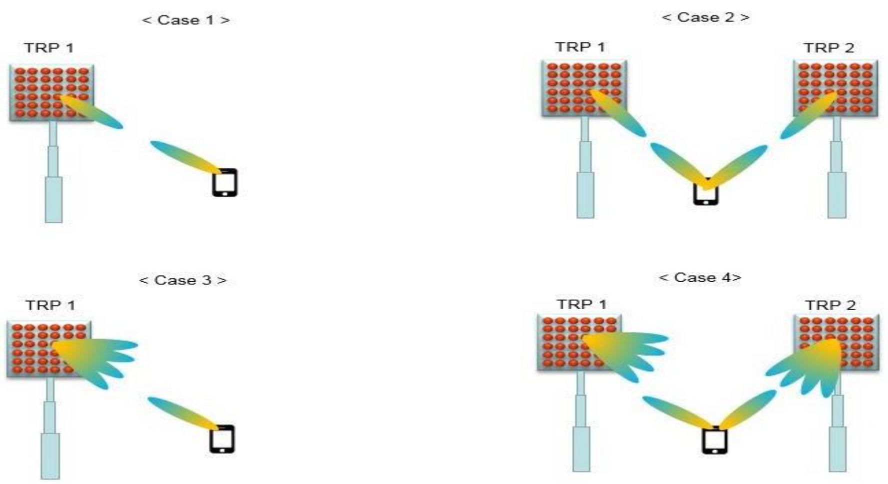

Fig 5.14 : Beam forcing.

Now the important and tough task is to maintain the connection. For this, I would not write much details until 3GPP specifies it in detail. Sorry for skipping too much with the excuse of 3GPP specification unavailability :). But I don't want to write many things now and rewrite too much after 3GPP Technical Specification come out. For now, my purpose is to give you very broad and general idea, and let you know what you may need to study in further details if you are really interested in technical details. For this purpose, I will list up most of TDocs about each topics in Reference section, so that you can get more detailed idea proposed by many companies / organizations in the industry.

The general idea of the beam management during the connected states would be

5.10.3 Network transmit a specific reference signal for beam management

5.10.4 UE detect the signal and perform some measurement and send feedback to Network

As you may notice, the general idea would be very similar to CSI report mechanism that are currently used in current LTE. However, a lot of details are yet to be determined. For example,

i) Baseband Signal (Symbol) generation formula

ii) Resource Allocation mapping (How to allocate these reference symbols to which specific resource element)

iii) How often UE need to perform these measurement

iv) How UE report the measurement result ? (via RRC messages ? or via MAC / PHY layer transactions ?)

NOTE : Now that the technical specification on all of the questions listed above has been released and I wrote a few separate pages regarding this topic. Refer to CSI RSsignal page and CSI Report page for further details based on 3GPP technical specification.

5.10.5 Where to point my beam?

We can think of this question in terms of two different cases : transmitting case and receiving case.

- **When transmitting?**

Now let's think of which direction a gNB or UE has to point its beam when they try to transmit the signal ?

The answer is simple. They (gNB or UE) has to transmit the signal in the direction that can reach the receiver with the best signal quality.

Then you would have another question. How can they(gNB or UE) figure out which direction is the one that can reach the receiver with the best signal quality ?

Now the answer would be a little bit trickier, but the big picture is as follows.

- When gNB is transmitting, gNB figure out this direction by evaluating the quality of a specific reference signal of multiple beam from UE. gNB evaluate the quality of the reference signal from each of the multiple beam and chose the best one. The reference signal from UE is called SRS.
- When UE is transmitting, UE figure out this direction by evaluating the quality of a specific reference signal of multiple beam from gNB. UE evaluate the quality of the reference signal from each of the multiple beam and chose the best one. The reference signal from gNB in this case can vary depending on situation. Sometimes it can be SSB and sometimes it can be CSI-RS. (NOTE : CSI-RS play many different roles in addition to beam management and very complex topic. Refer to CSI-RS signal generation and CSI report page for further details).

  NOTE : This kind of estimation of reference signal quality should be done sometime before they transmit signal.

3GPP TR 38.802 (V14.2.0)-6.1.6.1 describes on this situation as follows :

- TRP is able to determine a TRP Tx beam for the downlink transmission based on TRP's uplink measurement on TRP's one or more Rxbeams
- UE is able to determine a UE Tx beam for the uplink transmission based on UE's downlink measurement on UE's one or more Rxbeams

  NOTE : TRP is a transmission point of a gNB.

- ## When receiving?

Now let's think of which direction a gNB or UE has to point its beam when they try to receive signal ? (In this case, the word 'beam' may be a little misleading because the receiver does not form any real beam. So it would be better to change the phrase 'to point its beam' to 'to tune its receiver to a certain direction').

The answer is simple. They (gNB or UE) has to tune their receiver in the direction in which they can receive the signal from the transmitter with best quality.

Then you would have another question. How can they(gNB or UE) figure out which direction is the one in which they can receive the signal from the transmitter with best quality ?

Overall logic is as follows :

- When gNB receiving signal from UE, (before doing this) gNB is supposed to get the information of the best direction from UE in the form of CSI report.
- When UE receiving signal from gNB, (before doing this) UE is supposed to get the information of the best direction from gNB (gNB has detected the best direction based on the measurement of SRS signal quality of multiple beams from UE and indicates the UE of the best direction).

3GPP TR 38.802 (V14.2.0)-6.1.6.1 describes on this situation as follows :

- TRP is able to determine a TRP Rx beam for the uplink reception based on UE’s downlink measurement on TRP’s one or more Txbeams.
- UE is able to determine a UE Rx beam for the downlink reception based on TRP’s indication based on uplink measurement on UE’s one or more Tx beams.

CHAPTER 6

METHODOLOGY

6.1 System Model:

6.1.1 Block Diagram:

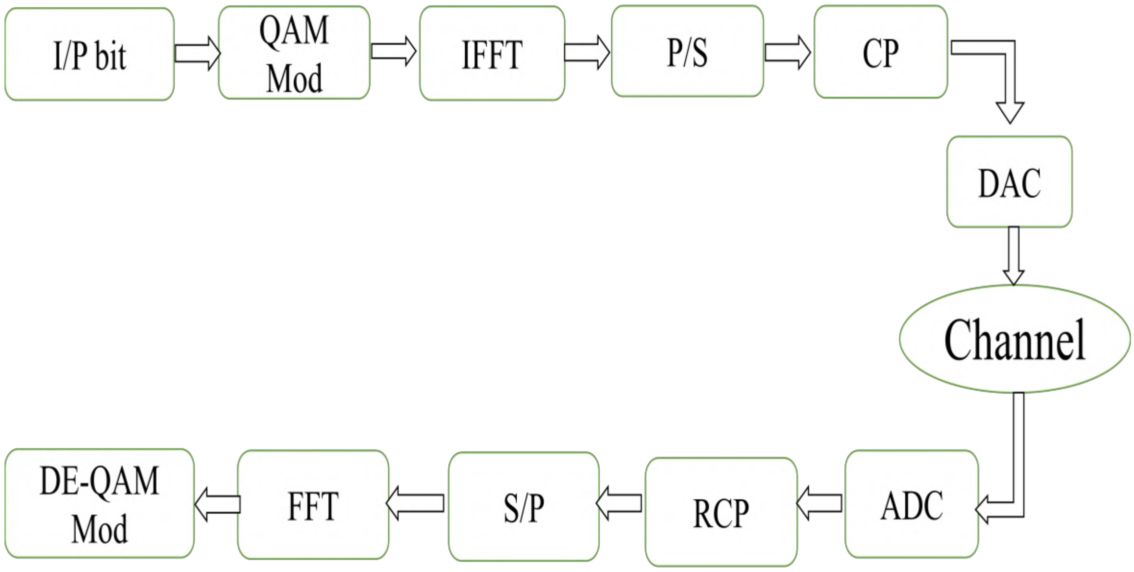

Fig 6.1:Block diagram.

- 6G is the sixth generation standard currently under development for wireless communications technologies supporting cellular data networks.
- 6G is not yet a functioning technology, and is instead in the early research phase. Mobile telecom companies are much too focused on 5G to deal with 6G in any significant way.
- Though researchers can't define how fast 6G will be yet, but estimates to have it around 100 times faster than 5G.

6.1.2 Flow Chart:

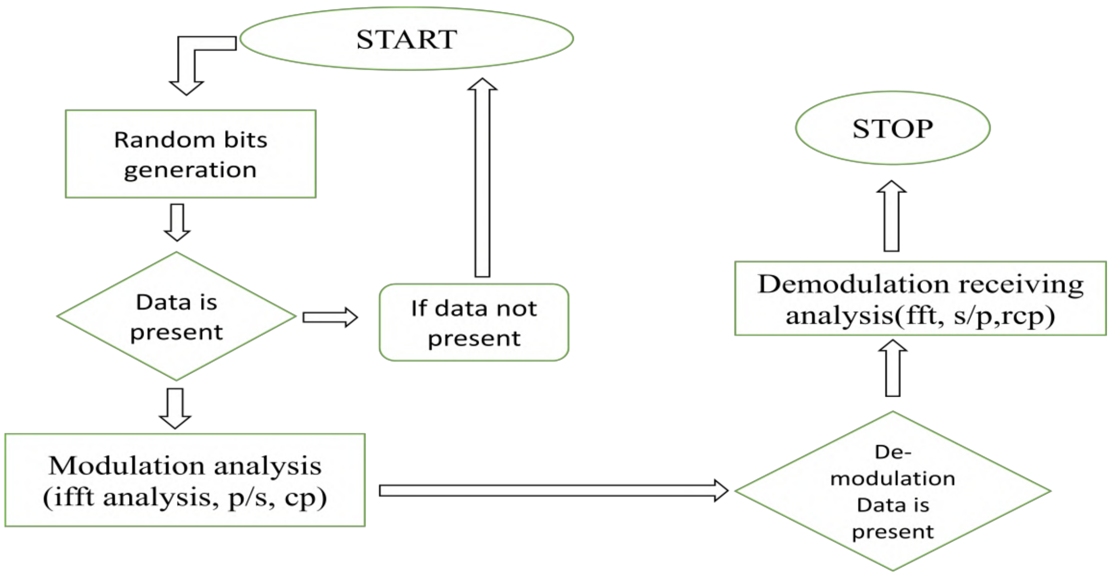

Fig 6.2:Flow chart.

From starting the process the digital signal in the form of input bits undergoes QAM modulation which undergoes changes in phase, amplitude and frequency. Then the output signal passes through IFFT where the bits in the data forms summation of all N sinusoids. IFFT block provides a simple way to modulate data onto N orthogonal subcarriers. The block of N output samples from IFFT make up a single OFDM signal and then it passes to cyclic prefix which enables the OFDM signal to operate reliably. The cyclic prefix acts as a buffer region to protect the OFDM signal from inter symbol interface. Then the signal is converted to analog and is sent into a channel to reduce the SNR and same process is repeated in reverse manner to require digital output for working.

CHAPTER 7
RESULT

7.1 Result:

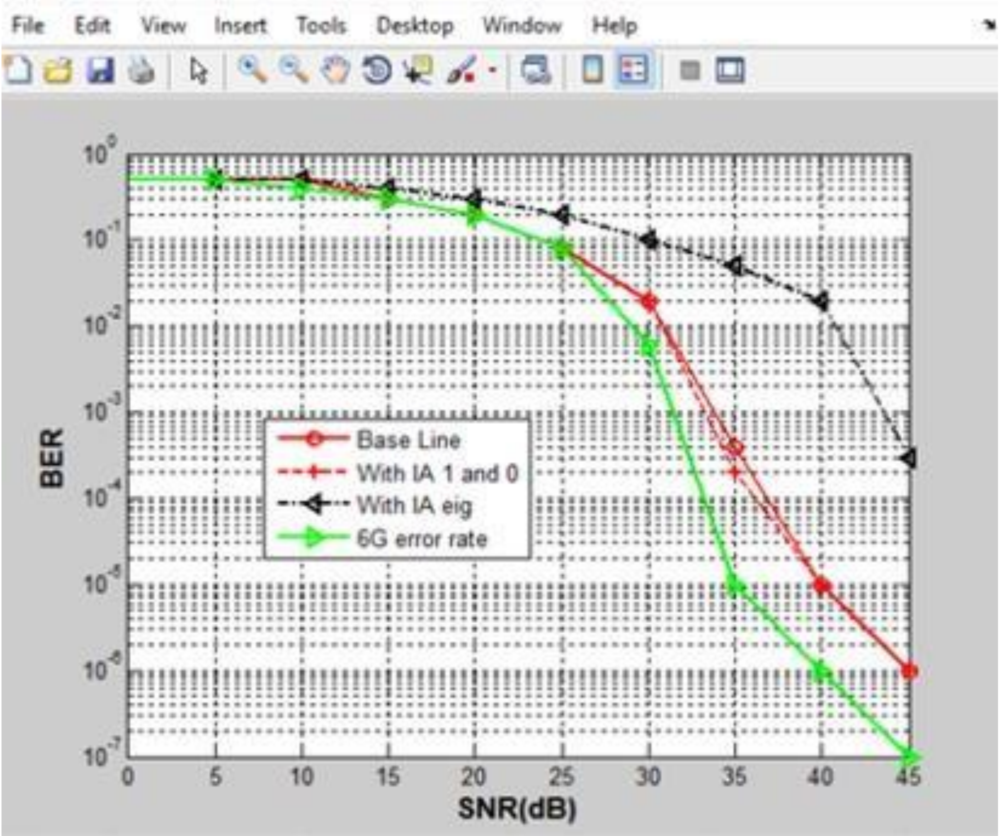

Fig 7.1 : Output 1 using 32:32 SNR algorithm.

Here in our project we obtained our output comparing the latancy rate and BER(Bit Error Rate) of 6G network and other networks.

Output 1 result shows the comparision of 6G and 5G networks BER using 32: 32 algorithm. In the above graph the green line indicates the 6G network and red line indicates the 5G network. The X-axis shows the SNR(Signal to Noise ratio) and Y- axis shows the BER. On comparing the 6G and 5G networks the green line i.e., 6G networks is showing the low BER around 10^-7 which is low compared to the 5G network. Low BER indicates the reduce of SNR and the data transmitted with low latency to the receiver.

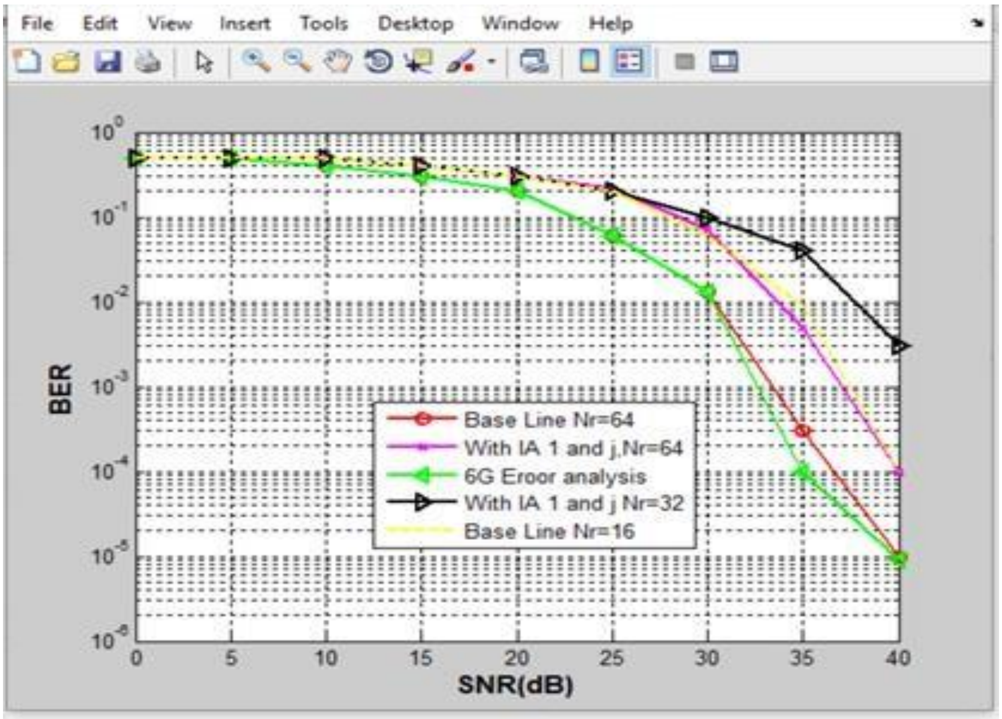

Fig 7.2: Output 2 using 64:64 SNR algorithm.

In this project, we put our proposal into the Vienna Matlab platform and receive the simulation results. Here, we assume that D2D communication reuses the downlink resource for transmission. Otherwise, the collision probability reduces as m increases. Therefore, we need to choose a suitable m that considers both the collision probability and the access probability. At this point, we assume that the arrival of the D2DUE's access request follows the Poisson process. This result will satisfy the need of a practical system performance. Through numerical simulation on the Vienna Matlab platform, we can obtain the average access delay under the premise of a differing number of preambles.

CHAPTER 8

CONCLUSION AND FUTURE SCOPE

8.1 Conclusion:

We have presented a vision for 6G mobile net - works, which can cater to the growing demands of IoE. We commence with a sketch of 6G from the viewpoint of time, frequency, and space resource utilization. Then we review some promising recent approaches that could move this vision closer to reality. Finally, we focus our attention on some challenges in 6G communication systems, which will hopefully serve as guidelines for their future development. We note that the major features of 6G networks are their flexibility and versatility, and the design of 6G networks is a truly multidisciplinary field of science. We expect that the new research on 6G will also impact the areas of medical imaging, semiconductors, spectroscopy, chemistry, and even biotechnology.

8.2 Future Scope:

In future 6G can be implemented for following:

- How to provide security.
- Virtualization of radio access interface.
- Mobility and localization.
- Rural Connectivity.

ACKNOWLEDGEMENT

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head & Professor**, the Dept. of Electronics and communication Engineering for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept .project coordinator Dr.A.ANAND , Professor** for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide Mr.M.SureshKumar Assistant professor,Department of ECE and our class project coordinator Mr.M.Nishakar Assiatant professor,Department of ECE for guidance and encouragement in carrying out this project work

Finally, We are highly grateful and obliged to **our college level Project Coordinator Dr. Maalyadri, Professor in IT and Dr. Santosh Kumar, Assistant Professor in CSE,** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

3. BK.YASH KUMAR

ABSTRACT

Nowadays Women Safety is the biggest concern in many parts of the world. There is still a fear in alone areas for women as well as men. So here we propose a security patrolling robot using Arduino. The robotic vehicle moves at particular path and is equipped with sound sensors and camera which continuously sends live streaming of robot premises to server. It uses a predefined line to follow its path while patrolling. It stops at particular points and moves to next points if sound is detected. It monitors each area to detect any problems. It has the ability to monitor sound in the premises. Robot hears any sound after area is quite and it starts moving towards the sound on its predefined path. Thus we put forward a fully autonomous security robot that operates tirelessly and patrols large areas on its own to secure the facility.

CHAPTER-1

INTRODUCTION

1.1 INTRODUCTION ABOUT EMBEDDED SYSTEMS:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.
The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.
The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

1.1.1 Block Diagram of Embedded System:

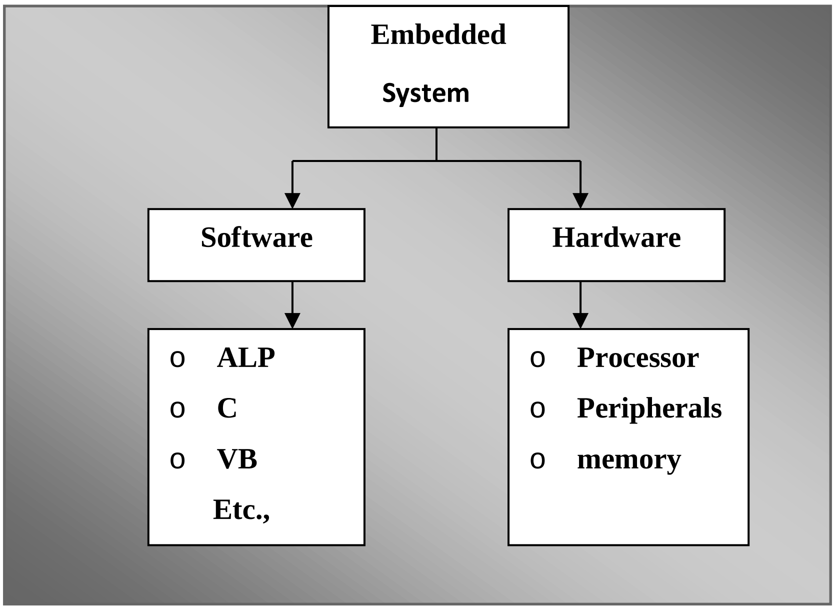

Fig.1.1: Block Diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

1.1.2 Applications of Embedded Systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

1.2 MICRO PROCESSOR (µP):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

1.2.1 Three Basic Elements of A Microprocessor:

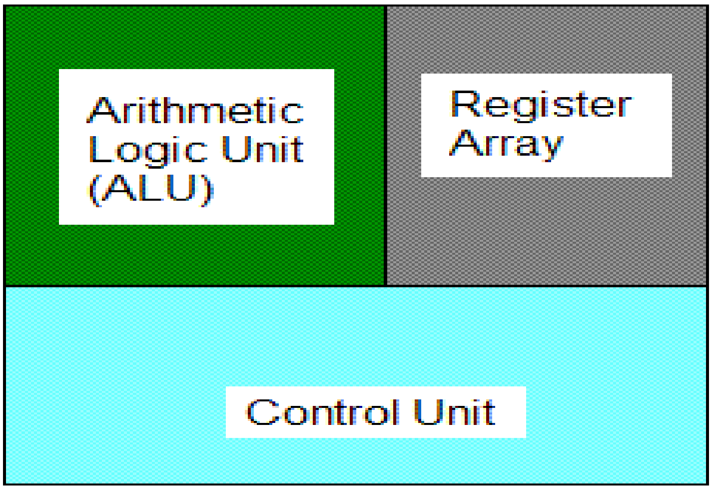

Fig.1.2: Three Basic Elements of a Microprocessor

1.3 HARVARD ARCHITECTURE:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data.

The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

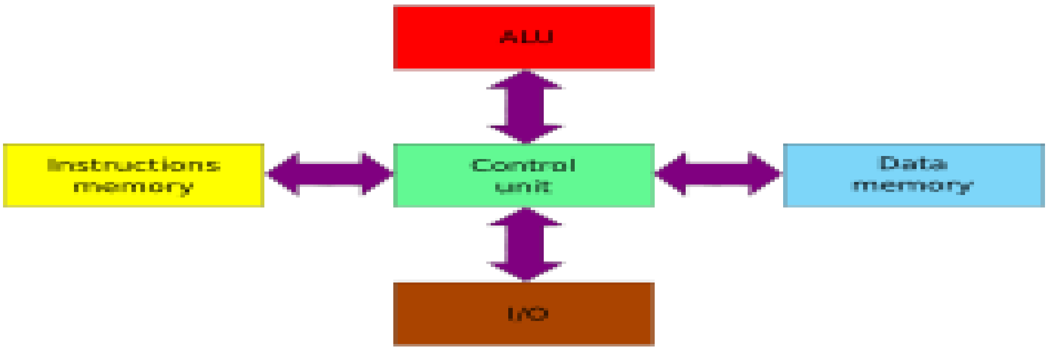

Fig.1.3: Harvard Architecture

1.3.1 Uses of The Harvard Architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

➢ Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access.
- The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

1.4 VON-NEUMANN ARCHITECTURE

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

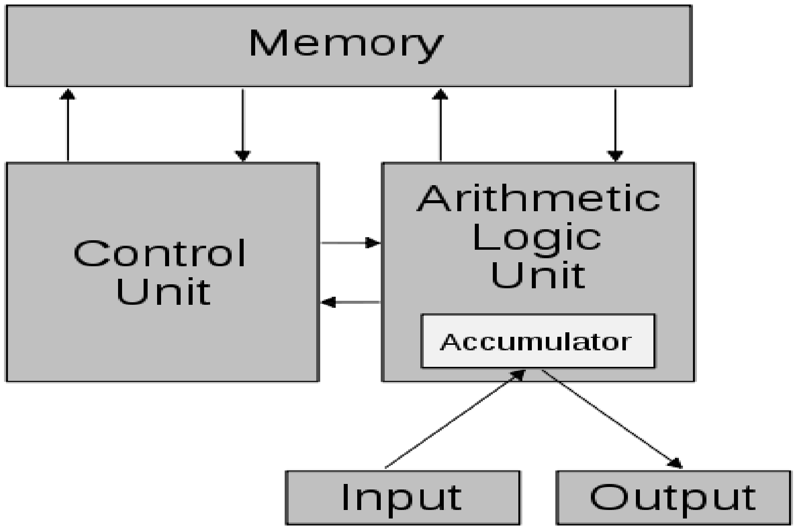

Fig.1.4: Schematic of the Von-Neumann Architecture

1.5 PROJECT DESCRIPTION

1.5.1 Objective:

The main objective of the project is to design and implement women safety patrolling robot using Arduino Uno. The system uses ESP32 camera-Night Vision and Sound Sensors mounted on robotic vehicle for securing women in any premises. The robotic vehicle moves at particular path and is equipped with ESP32camera and sound sensors. It uses a predefined line to follow its path while patrolling. It stops at particular points and moves to next points if sound is detected. The ESP32 Camera always set to ON to monitor premises even during night, works similar to CCTV cameras. Robot hears the sounds after area is quite and it starts moving towards the sound on its predefined path. Camera continuously sends the live video of surroundings to the to the IOT website. Here we use EMBEDDED SPOT website in which a person can provide Username and password and observes the live streaming of premises where the robot present.

Thus we put forward a fully autonomous women Safety robot that operates tirelessly and patrols large areas on its own.

1.5.2 Aim:

We are all aware of importance of women's safety, but we must realize that they should be properly protected. Women are not as physically strong as men, in an emergency situation a helping hand would be a relief for them. The best way to minimize your chances of becoming a victim of violent crime (robbery, sexual assault, rape, domestic violence) is to identify and call on resources to help them out of dangerous situations. Having these applications can reduce the risk and bring assistance when needed.

The main aim of this project to design a robot that is designed solely to serve the purpose of providing security and safety to women so that they never feel helpless while facing such social challenges

1.5.3 Components Used:

- Sound Sensor-2
- ESP-01 Wi-Fi Module
- LCD
- Power Supply
- L293D
- Motors
- ESP Camera
- Arduino
- Robot chassis

CHAPTER-2

LITERATURE SURVEY AND EXISTING METHODS

2.1 LITERATURE SURVEY

JGhanem Osman Elhaj Abdalla, finished a recognition framework with a covert authority robot with the raspberry Pi utilizing web protocol. It gives different thoughts concerning the observation of outskirts areas. Results from the camera are sent to the clients through the web server which can be posted on the website page simultaneously.

In 2013, Cheng Tang, Qunqun Xie, Guolai Jiang, Yongsheng Ou, make a street night subject to a planar reflection model. Till now, various structures are normal for daytime rehearses yet for night there is no such sort of research. This progress puts the any unused movement zone around evening. Here a planar reflection model is sensible to get the force transport of various pixels with an infrared camera. With that, a pixel-based arrangement is utilized to check the various pixels have a spot with the street or not.

In 2017, Kirk Mac Tavish , Michael Paton, and Timothy D. Barfoot , made night rider: visual odometry utilizing headlights.

2.2 EXISTING METHODS

In the existing system, the robot has to be controlled remotely where the person has to monitor the area using the remote control and more human resource is needed for this operation of the patrol robot. Some systems require a smartphone for controlling the night vision robot. Lacking few parts, autonomous operation requires a workforce to operate. Here In these project, we upgrade the robot from remotely controlled to autonomous and even used night vision camera to continuously monitor the robot surroundings through video which is sent to localhost network, therefore, human resource is reduced.

2.3 PROPOSED SYSTEM

In this proposed system, Arduino is installed with the night vision camera and sound sensors which help the system to go for the automation. Help to find the human or any problem detected using the sound sensor and according to the sound produced, it automatically goes to that area and it continuously send the live streaming of the robot premises to IOT server over the internet, In this project we use 2 sound sensors for detecting the sound from left and right, here we use the “HELP” command to be the sound to be detected whenever sound sensor-1 detects the sound the output goes low and moves to left side and similarly with right sound sensor, we use night vision camera’s so that, a person can monitor the premises of robot at any time ,therefore patrolling can be done even in night.

By simply entering the IP address of ESP32-CAM in any IoT web server any person can monitor the place and take actions accordingly to help the Women.

3.1 BLOCK DIAGRAM

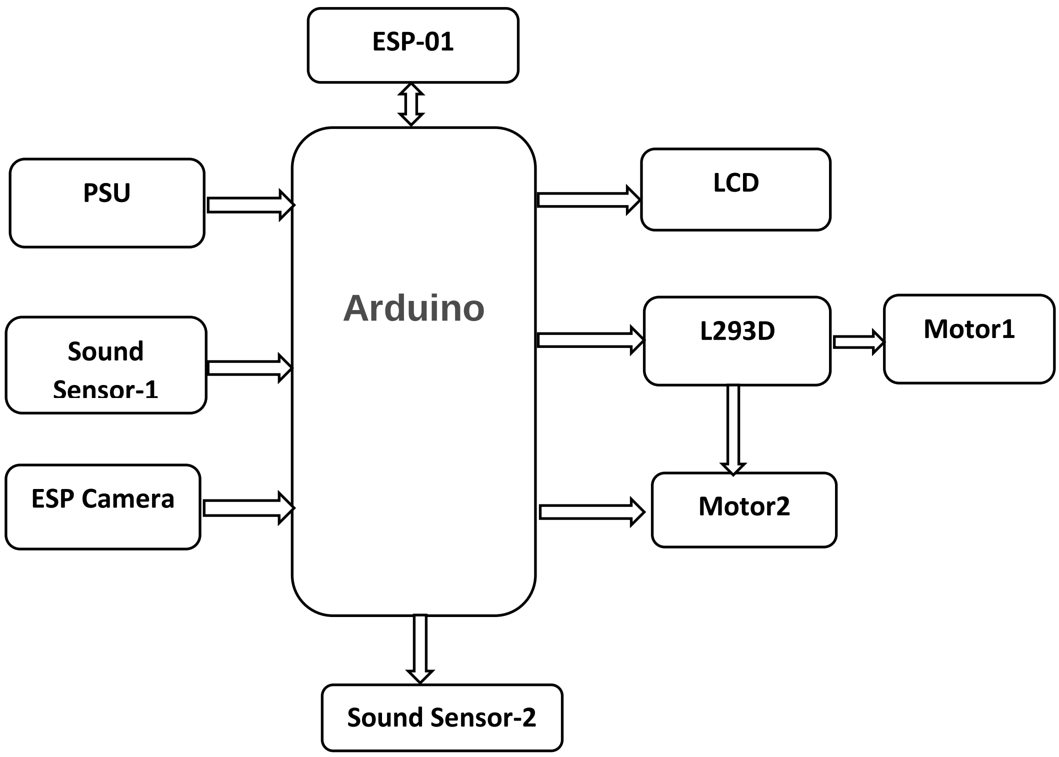

Fig.3.1: Block Diagram of The Project

The block diagram of women Safety patrolling Robot Using IOT is shown in above figure. The blocks of the circuit are

- Arduino UNO
- ESP-01(Wi-Fi Module)
- ESP Camera
- Sound Sensor -1
- Sound Sensor -2
- LCD
- L293D Motor Driver
- Motor-1
- Motor-2
- Power Supply Unit

3.2 SCHEMATIC EXPLANATION

3.2.1 Interfacing Between LCD and Arduino

The following circuit diagram shoes the liquid crystal display with Arduino module. From the circuit diagram, we can observe that the RS pin of the LCD is connected to the pin 7 of the Arduino. The LCD of R/W pin is connected to the ground. The pin 6 of the Arduino is connected to the enable signal pin of LCD module. The LCD module & Arduino module are interfaced with the 4-bit mode in this project. Hence there are four input lines which are DB4 to DB7 of the LCD. This process very simple, it requires fewer connection cables and also we can utilize the most potential of the LCD module.

The digital input lines (DB4-DB7) are interfaced with the Arduino pins from 2-5. To adjust the contrast of the display here we are using a 10K potentiometer. The current through the back LED light is from the 560-ohm resistor. The external power jack is provided by the board to the Arduino. Using the PC through the USB port the Arduino can power. Some parts of the circuit can require the +5V power supply it is taken from the 5V source on the Arduino board.

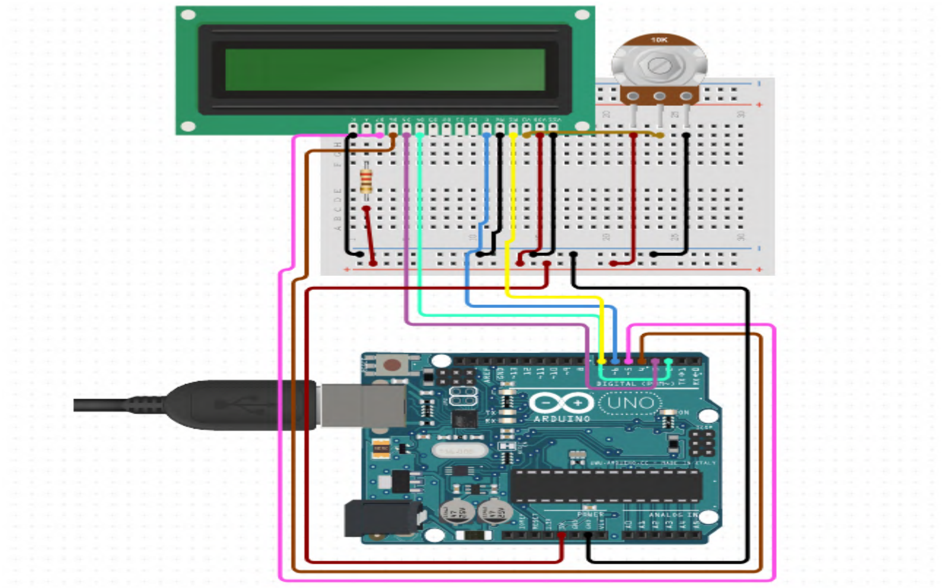

Fig.3.2: Interfacing Between LCD and Arduino

3.2.2 Interfacing Between Soundsensors and Arduino

The following figure shows the interfacing of sound sensors with Arduino, The Sound Sensor used in this project is shown in the image below .It consists of a microphone, a voltage comparator IC (LM393), a potentiometer, a transistor, couple of LEDS and a few other passive components (resistors and capacitors).

The VCC pin sound sensor is connected to 3.3v or 5v and GND pin of sensor to ground pin, the sound sensor-1 output is connected to Analog pin of A4 and sound sensor-2 output pin is connected to Analog pin of A5,when
the sound sensor will produce a logic LOW when sound is detected and a logic HIGH when there is no sound.

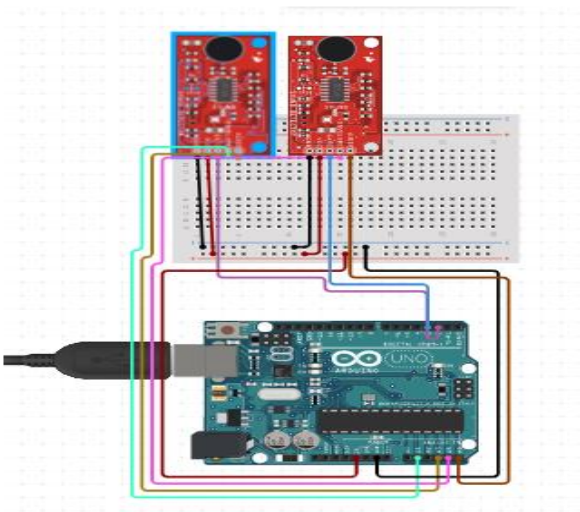

Fig.3.3: Interfacing Between Sound Sensors and Arduino

3.2.3 Interfacing between Camera and Wi-Fi Module

The UOT pin of camera is connected to receiver of Wi-Fi module, and UOR pin of ESP32-cam is connected with transmitter of Wi-Fi.

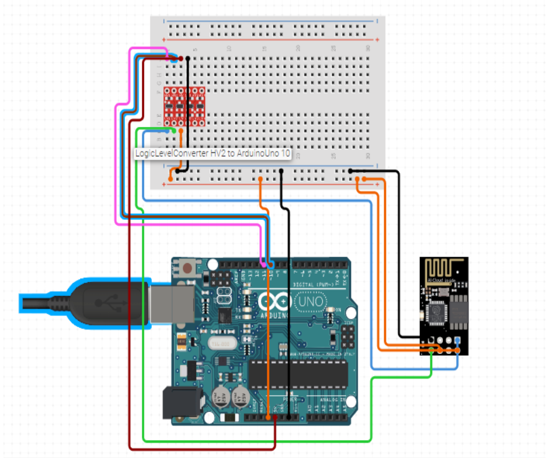

Fig.3.4: Interfacing Between Wi-Fi Module And Arduino

Fig.3.5: Wi-Fi Module

3.2.4 Interfacing between Arduino and L293D

4-7 numbered digital pins act as output pins from Arduino are connected to the motor driver module i.e L293D as input and output of the module is connected to motors for forward or backward movements,

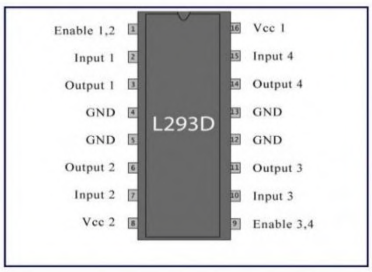

Fig.3.6: L293D Motor Driver

All the Ground pins should be grounded. There are two power pins for this IC, one is the Vss (Vcc1) which provides the voltage for the IC to work, this must be connected to +5V. The other is Vs (Vcc2) which provides voltage for the motors to run, based on the specification of your motor you can connect this pin to anywhere between 4.5V to 36V, here I have connected to +12V.

From the figure Enable pins (Enable 1, 2 and Enable 3, 4) are used to Enable Input pins for Motor 1 and Motor 2 respectively. Since in most cases we will be using both the motors both the pins are held high by default by connecting to +5V supply. The input pins Input 1, 2 which are digital pins 4,5 from Arduino are used to control the motor 1 and Input pins 3, 4 which are digital pins 6,7 from Arduino are used to control the Motor 2. The input pins are connected to the any Digital circuit or microcontroller to control the speed and direction of the motor. You can toggle the input pins based on the following table to control your motor.

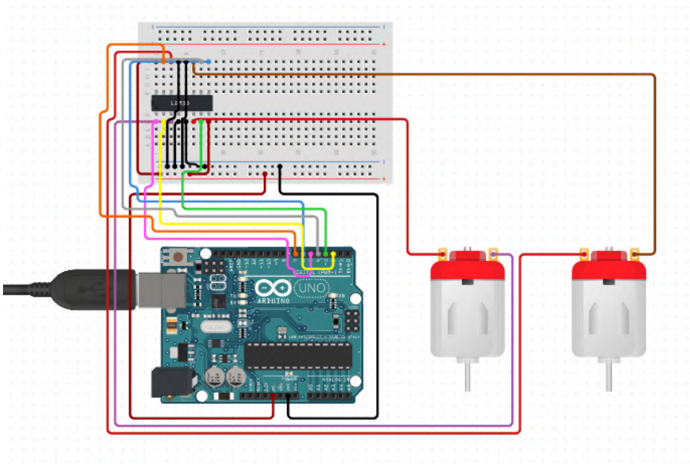

Fig.3.7: Interfacing Between Arduino and L293D

3.2.5 Interfacing between Components

we used 8-13 numbered digital pins of Arduino to connect to LCD to display acknowledgment messages, 4-7 numbered digital pins act as output pins from Arduino are connected to the motor driver module i.e L293D as input and output of the module is connected to motors for forward or backward movements, A4 and A5 Analog pins of Arduino act as input and is connected to two Sound Sensors which takes sound as Input and then we apply Digital Read Function to that input then ESP-cam is connected with Wi-Fi module is ready to stream .

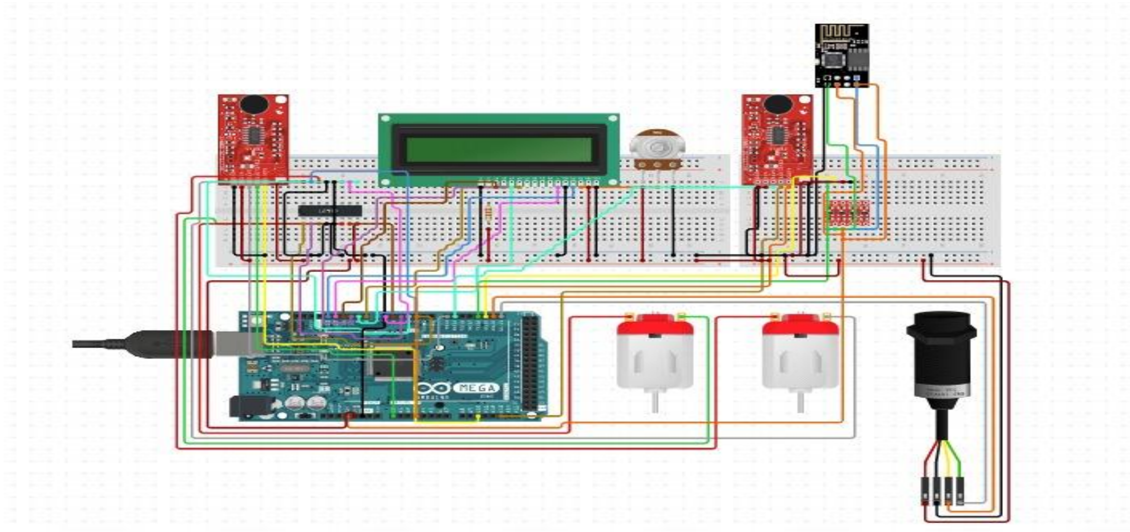

Fig.3.8: Schematic Diagram of All Components

3.2.6 WORKING:

we used Arduino UNO installed with ESP32 camera and Sound Sensors, we used 8-13 numbered digital pins of Arduino to connect to LCD to display acknowledgment messages, 4-7 numbered digital pins act as output pins from Arduino are connected to the motor driver module i.e L293D as input and output of the module is connected to motors for forward or backward movements,

A4 and A5 Analog pins of Arduino act as input and is connected to two Sound Sensors which takes sound as Input and then we apply digital Read Function to that input.

when we supply power to the robot initialization of all the inputs was done and displays "Welcome" message in LCD, ESP32 Camera starts to send live streaming of robot premises over the internet to the IOT web server by using ESP-01 Wi-Fi Module.

It uses a predefined line to follow its path while patrolling. It stops at particular points and moves to the next points if a specific sound command is detected, here we use the loud sounds for the robot to respond. if the surrounding is quiet it displays a message "Everything Is Fine" on LCD,

If the sound is detected the digital read function in the program reads input as High, displays a message "LOCATION 1:ALERT" if sound sensor-1 receives the sound and moves to left and similar with the right sound sensor

While it moves accordingly with the sound it also continuously sends the live video of the surroundings to the IOT web server, this robot still works fine at night as we use a night vision camera therefore patrolling can be done even at night.

Live videos are monitored by a human in the IOT server by entering the login details, any person who is in the local range can monitor the videos.

CHAPTER-4

HARDWARE AND SOFTWARE COMPONENTS

MICRO CONTROLLER UNIT

4.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 Analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Table.4.1: Atmega328 Specifications

4.1.1 Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

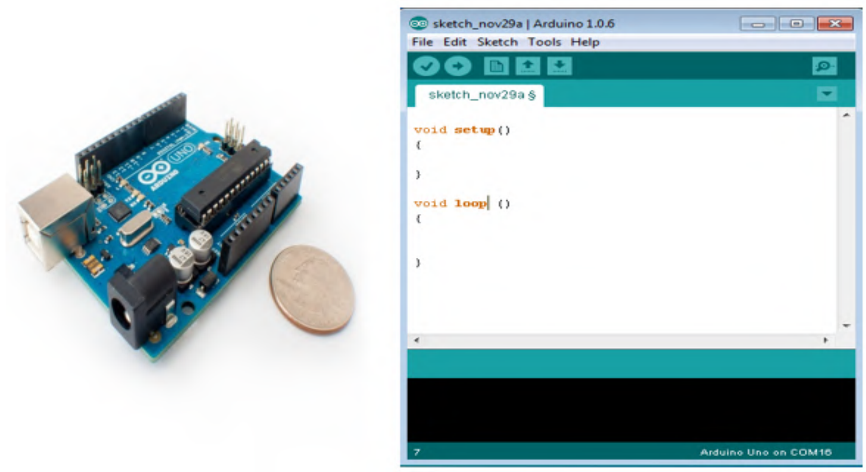

Fig.4.1: Arduino Uno

4.1.2 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

ATMEGA328:

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati

LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

4.1.3 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

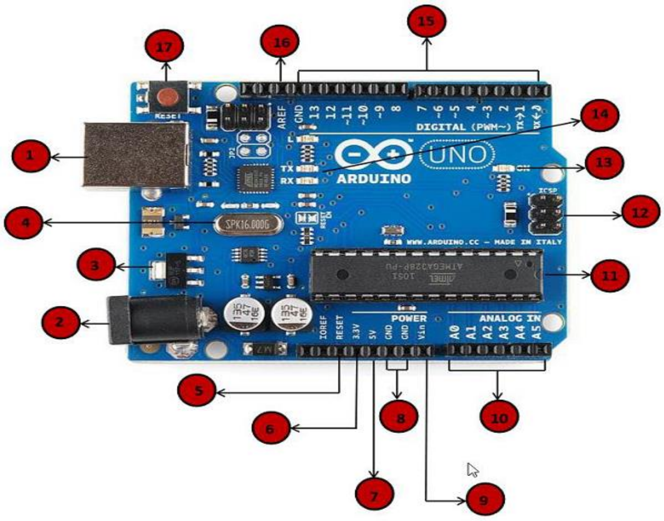

Fig.4.2: Arduino Uno Board Pins

Pin number and Pin Use

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.

<table>
<tr><td>4</td><td>Crystal Oscillator
The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.</td></tr>
<tr><td>5, 17</td><td>Arduino Reset
You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).</td></tr>
<tr><td>6, 7, 8, 9</td><td>Pins (3.3, 5, GND, Vin)
3.3V (6) − Supply 3.3 output volt
5V (7) − Supply 5 output volt
Most of the components used with Arduino board works fine with 3.3 volt and 5 volt.
GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit.
Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.</td></tr>
<tr><td>10</td><td>Analog pins
The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.</td></tr>
<tr><td>11</td><td>Main microcontroller
Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC.</td></tr>
</table>

	For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table.4.6: Pin Explanation of Arduino

4.1.4 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

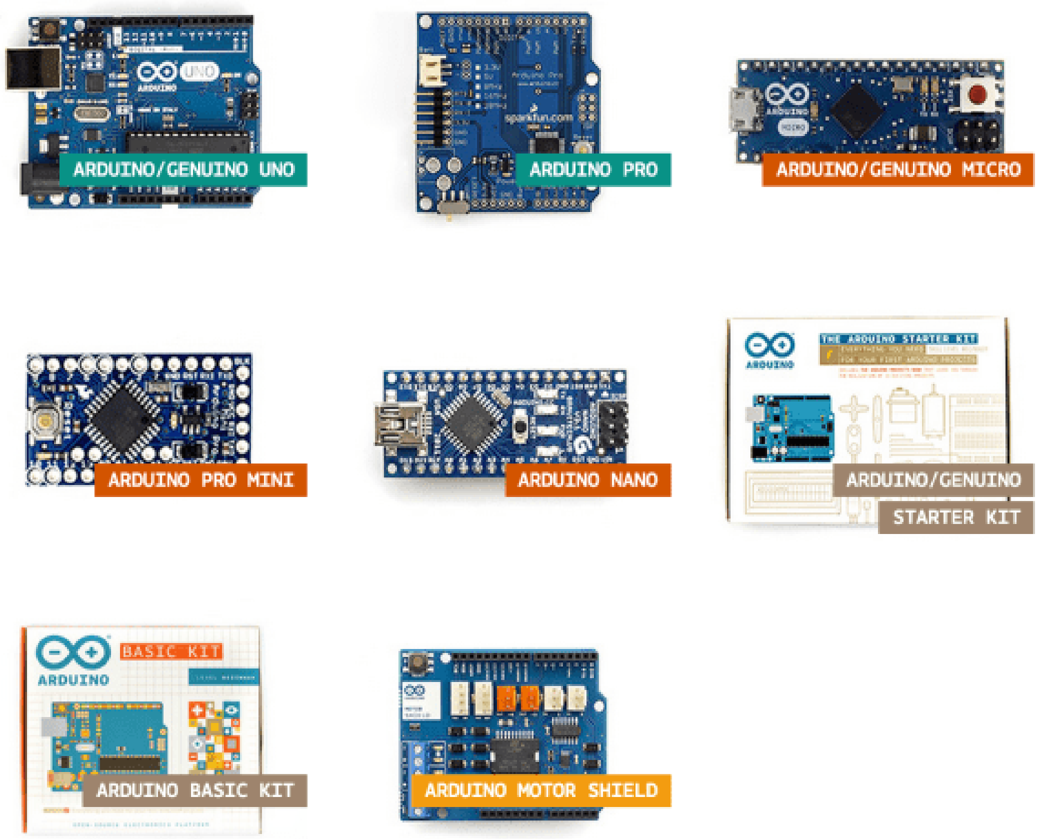

Fig.4.3: Arduino Family

4.1.5 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

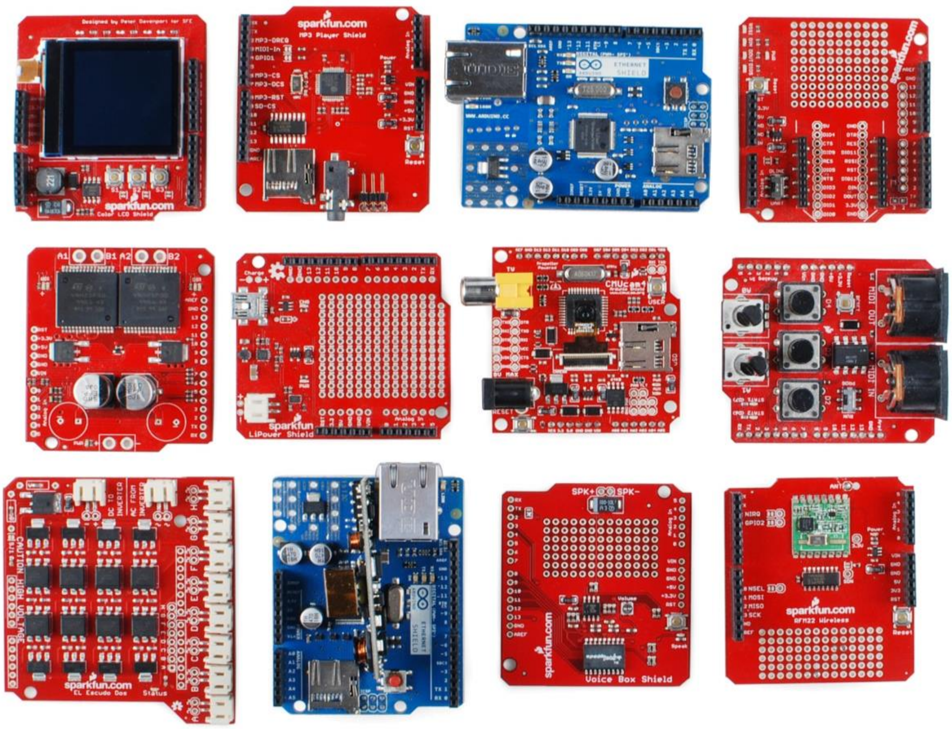

Fig.4.4: Arduino Shields

4.1.6 Pin Description Of Atmega328

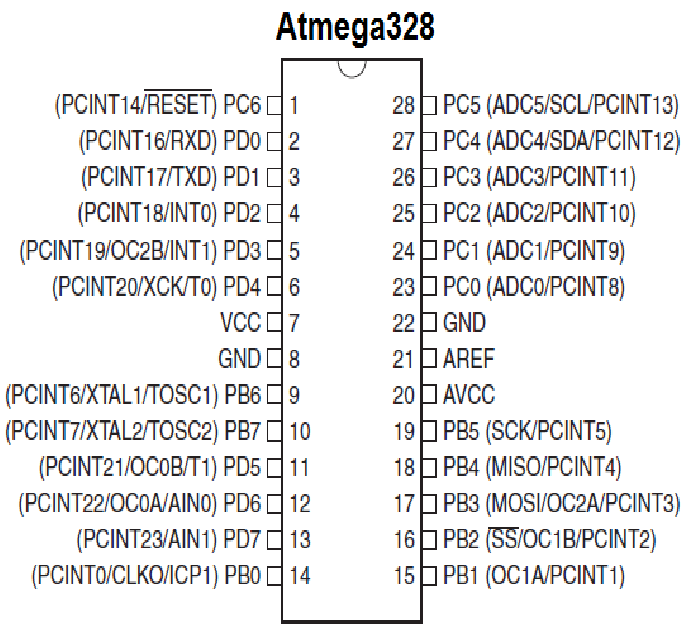

Fig.4.5: Pin Description Of ATMEGA328

4.1.7 Advantages Of Arduino

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

4.1.8 Applications

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

4.2 POWER SUPPLY UNIT

4.2.1 Introduction:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices.

A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

- **Block Diagram Of Power Supply:**

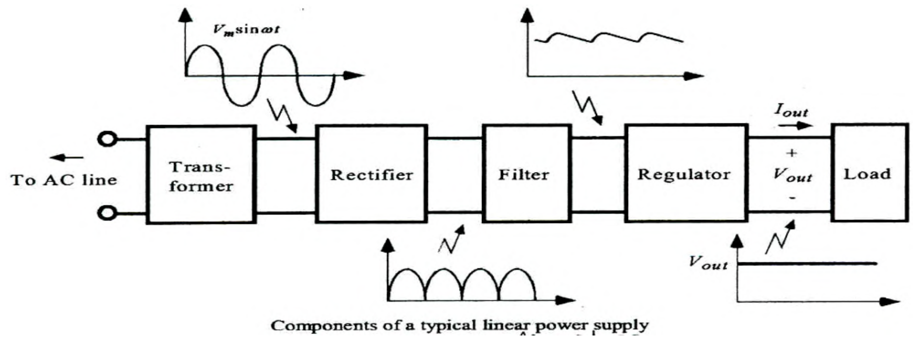

Fig.4.6: (a) Block Diagram of Power Supply

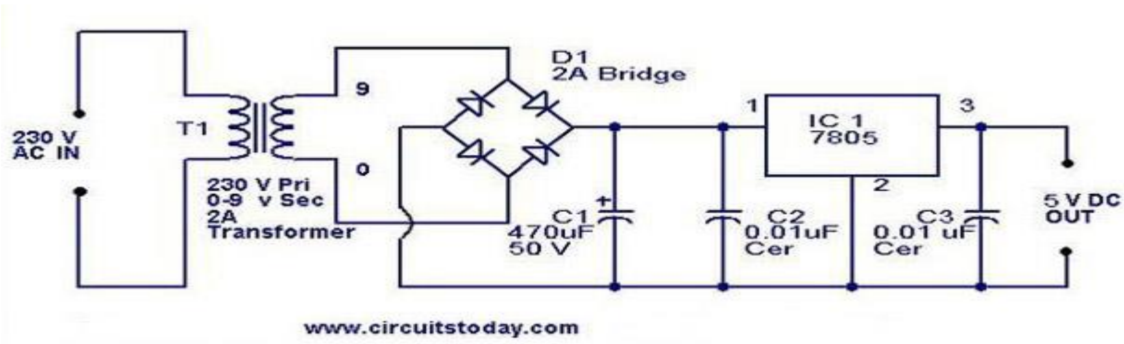

Fig.4.6: (b) Schematic Diagram of Power Supply

- **Description Of Power Supply:**

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered.

For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.2.2 Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

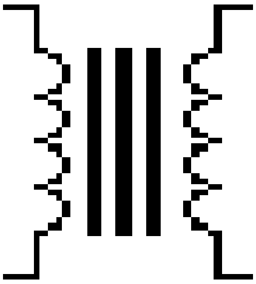

Fig.4.7: (a) Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

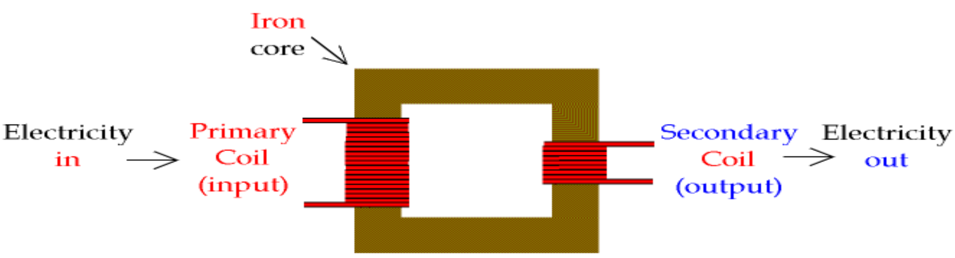

Fig.4.7: (b) Transformer

- **Basic Principle Of Transformer:**

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

- **Working Of Transformer:**

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below.

There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

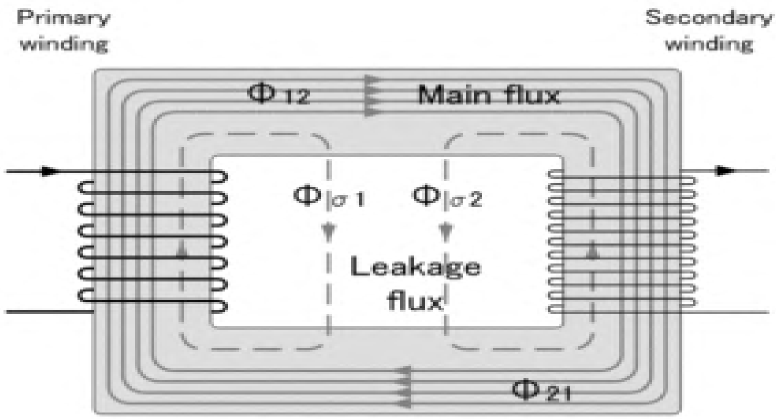

Fig.4.8: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced EMF. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

- ## Classification Of Transformer:

➢ Step-Up Transformer
➢ Step-Down Transformer

o Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage

applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

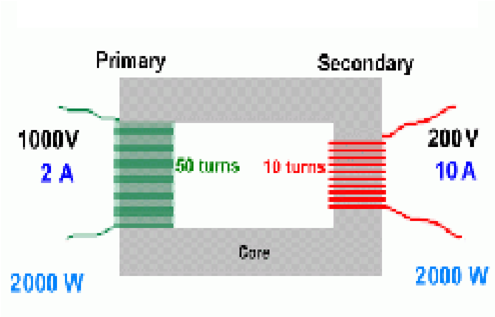

Fig.4.9: (a) Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.**Step down transformers can be considered nothing more than a voltage ratio device.**

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated.

Because of this it is possible to do some non-standard applications using standard transformer.single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.

- **Step-Up Transformer:**

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

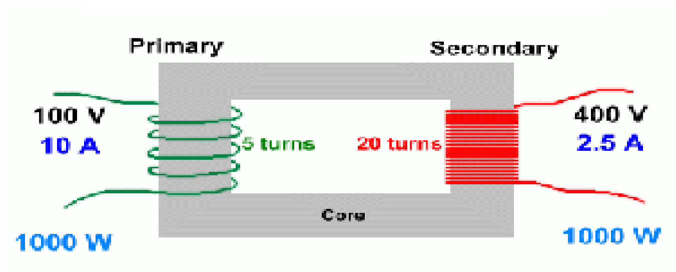

Fig.4.9: (b) Step-Up Transformer

- **Diodes:**

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

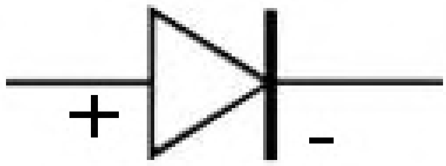

Fig.4.10: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

- **Rectifier:**

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

- **The Half-Wave Rectifier:**

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

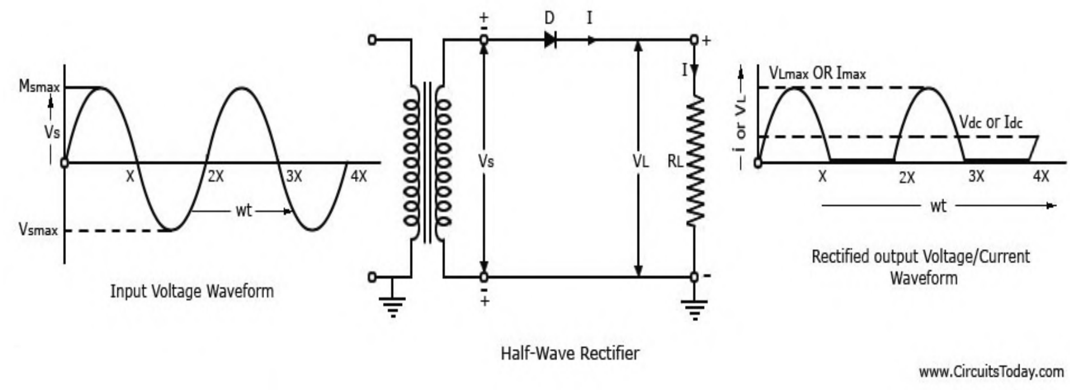

Fig.4.11: (a) Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

- **The Full-Wave Rectifier:**

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

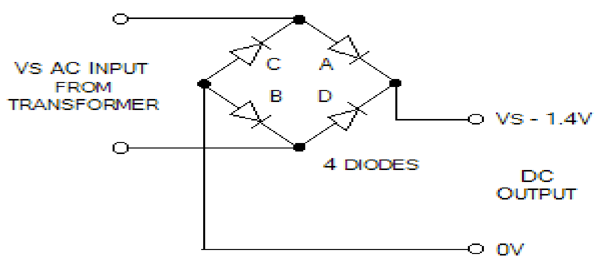

Fig.4.11: (b) Full-Wave Rectifier

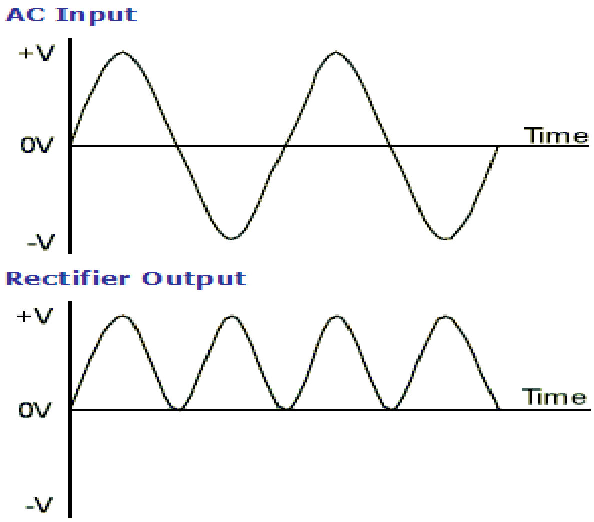

Fig.4.11: (c) Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

- **Capacitor Filter:**

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

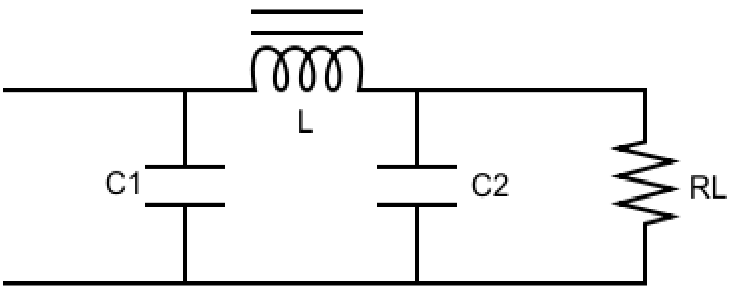

Fig.4.12: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

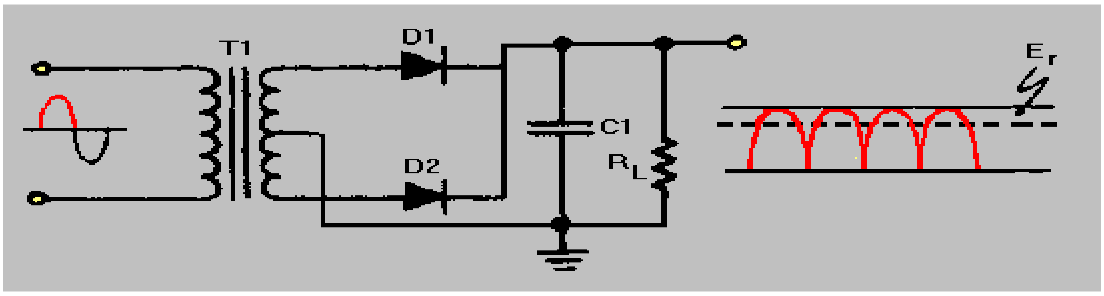

Fig.4.13: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

- **Voltage Regulator:**

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages.

There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

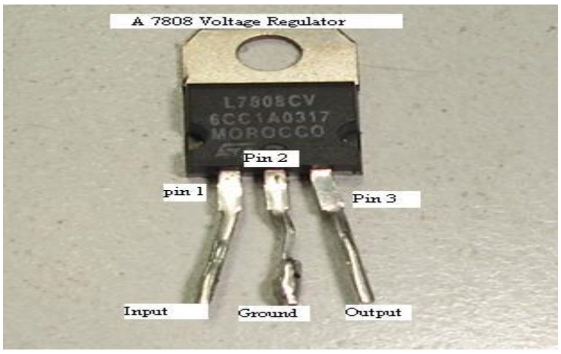

Fig.4.14: Regulator

4.3 WIFI MODULE:

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IOT devices. We've featured several projects using this module, such as How To Make Smart Home Electronics: A Smart Mailbox and How To Read Your Arduino's Mind: Building A Childproof Lock. This tutorial will walk you through setting up ESP8266 Wi-Fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

4.3.1What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IOT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

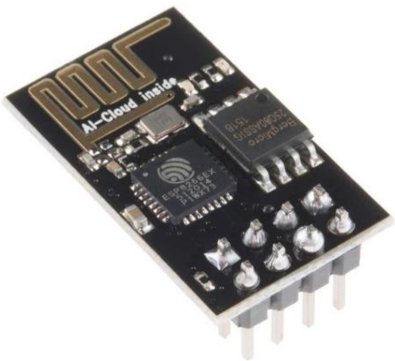

Fig.4.15: ESP8266 ESP-01 Module

ESP-01 Features – Spark fun**:**

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266's pins are according to the following diagram:

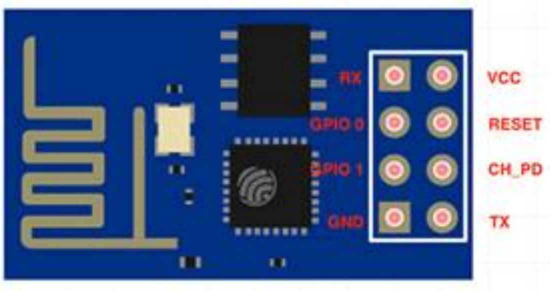

Fig.4.16: ESP8266 Pinout

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc(Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wifi network the module will be connected to.

To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program.

Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

Use the following diagram to connect the ESP8266 module to the Arduino:

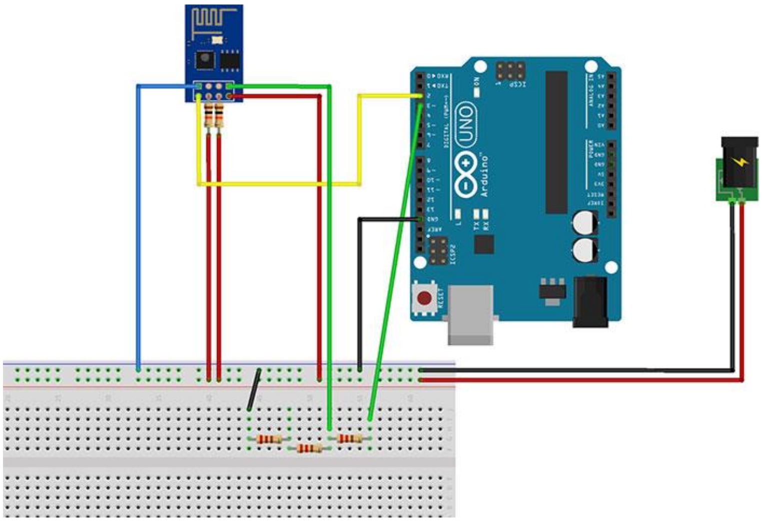

Fig.4.17: Connection Between ESP8266 And Arduino Uno

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
    - You can use something like this: https://www.sparkfun.com/products/114
- Breadboard and jumper wires

A couple of features of this circuit stand out immediately.

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts.

Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, You should not only connect the VCC and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device.

We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

4.3.2 ESP32 Camera

The ESP32-CAM is a very small camera module with the ESP32-S chip that costs approximately $10. Besides the OV2640 camera, and several GPIOs to connect peripherals, it also features a microSD card slot that can be useful to store images taken with the camera or to store files to serve to clients.

Step 1: Components required

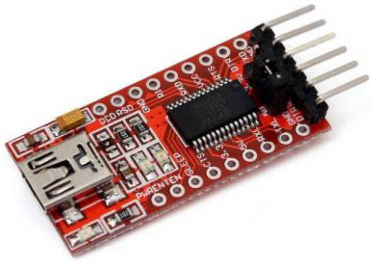

Fig.4.18: (a) WIFI Module

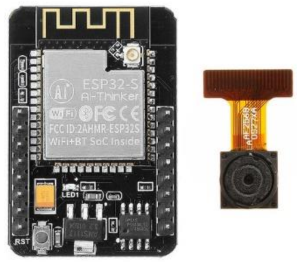

Fig.4.18: (b) ESP32-CAM

Step 2: Pin Configuration & Features

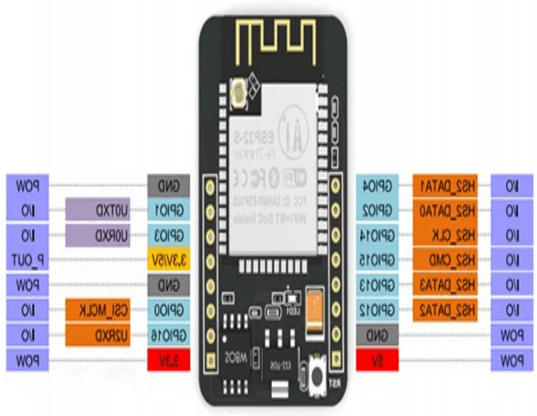

Fig.4.19: ESP32-CAM Pin Configuration

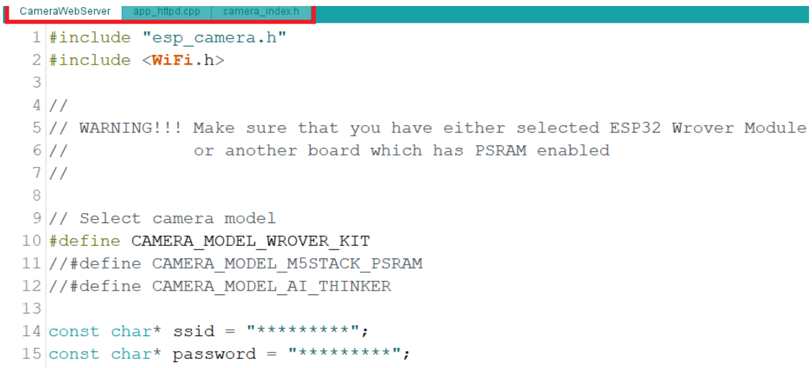
The smallest 802.11b/g/n Wi-Fi BT SoC module Low power 32-bit CPU, can also serve the application processor Up to 160MHz clock speed, summary computing power up to 600 DMIPS Built-in 520 KB SRAM,

- external 4MPSRAM
- Supports UART/SPI/I2C/PWM/ADC/DAC
- Support OV2640 and OV7670 cameras, built-in flash lamp
- Support image Wi-Fi upload

- Support TF card Supports multiple sleep modes
- Embedded Lwip and Free RTOS Supports STA/AP/STA+AP operation mode
- Support Smart Config/AirKiss technology
- Support for serial port local and remote firmware upgrades (FOTA)

Step 3: Code



```
#include "esp_camera.h"
#include <WiFi.h>

//
// WARNING!!! Make sure that you have either selected ESP32 Wrover Module
//            or another board which has PSRAM enabled
//

// Select camera model
#define CAMERA_MODEL_WROVER_KIT
//#define CAMERA_MODEL_M5STACK_PSRAM
//#define CAMERA_MODEL_AI_THINKER

const char* ssid = "*********";
const char* password = "*********";
```

Fig.4.20: Arduino Code For ESP32-CAM

In your Arduino IDE, go to File > Examples > ESP32 > Camera and open the Camera Web Server example.

Step 5: Schematics for Programming the Board

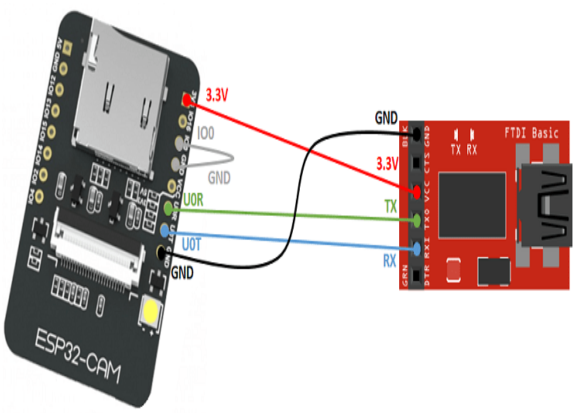


Fig.4.21: Connecting between Wi-Fi-Module with ESP32-CAM

The ESP32-CAM doesn’t have a USB connector, so you need to use FTDI to upload code through the U0R and U0T pins (serial pins) in ESP32 CAM Board.

Step 6: Uploading of the Code

Before uploading the code, you need to input your Wi-Fi credentials in the following part of **code**:

const char* ssid = "REPLACE_WITH_YOUR_SSID";

const char* password = "REPLACE_WITH_YOUR_PASSWORD";

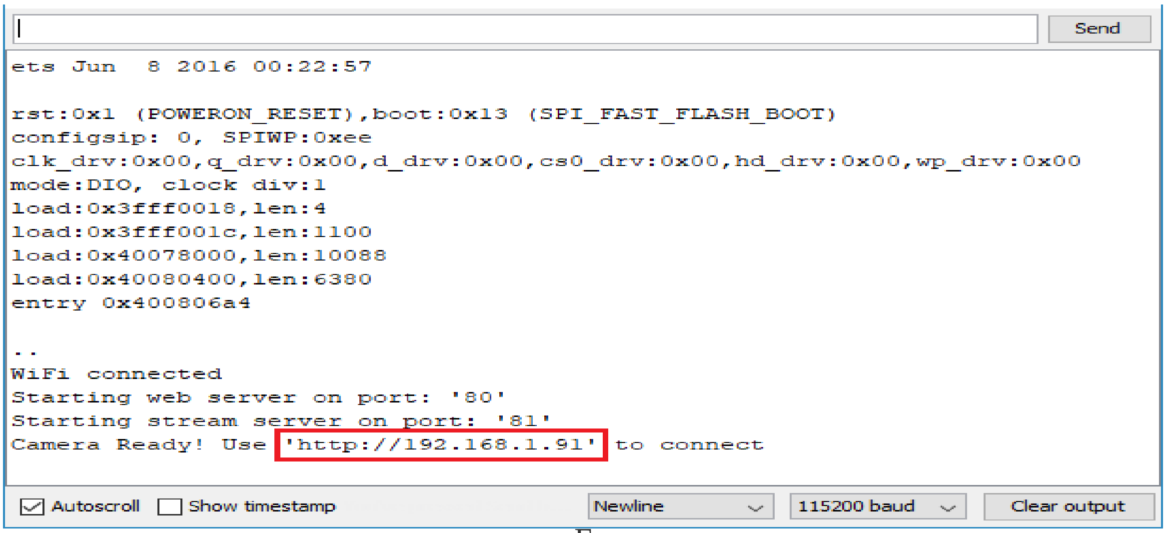
and make sure you select the right camera module. As here we’re using the AI-THINKER Model so select the following So, comment all the other models and uncomment this one:

#define CAMERA_MODEL_AI_THINKER

Follow these steps to upload the code :

Go to Tools > Board and select ESP32 wrover Module Go to Tools > Port and select the COM port the ESP32 is connected to In Tools > Partition Scheme, select “Huge APP (3MB No OTA)“Then, click the upload button to upload the code.

Step 7: Getting IP From Serial Monitor



F

FF

Fig.4.22: Getting IP Address From Serial Monitor

Remove the jumper connected between GPIO0 & GND then, Open the Serial Monitor with the baud rate : 115200. Press the ESP32-CAM on-board Reset button and wait for the IP to appear and wait for few seconds and then hit reset again.

4.4 16 * 2 ALPHANUMERIC LCD

4.4.1 Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

4.4.2 Block diagram

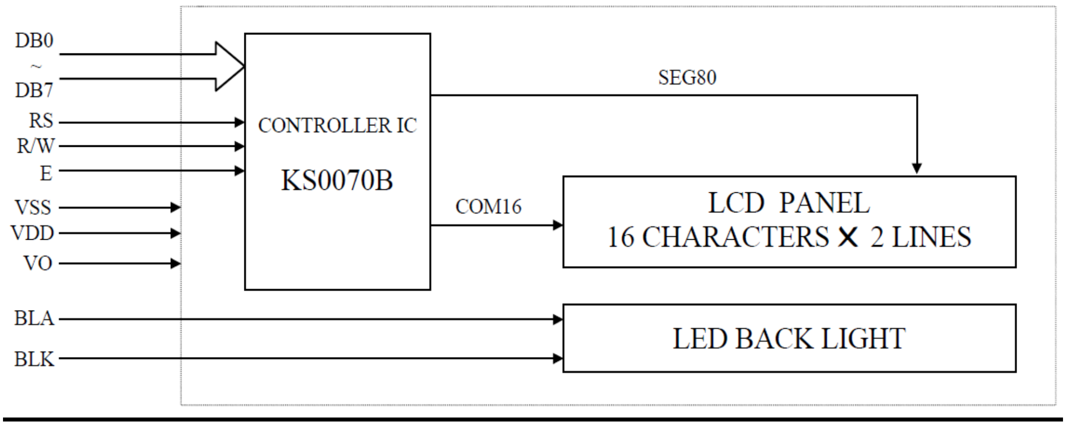


Fig.4.23: Block Diagram Of LCD Display

- **Display Data Ram**

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD.

For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

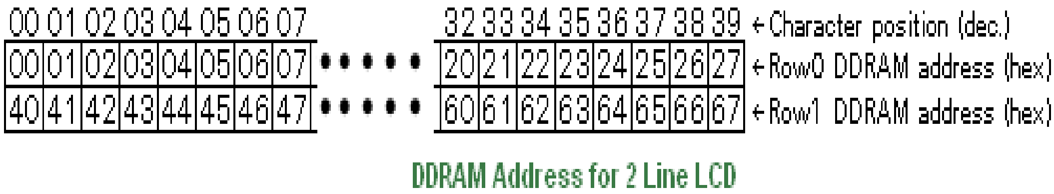

Fig.4.24: DDRAM Address of 2 Line LCD

- **Character Generator Rom**

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

- **Busy Flag**

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0).

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

- **Instruction Register (IR) And Data Register (DR)**

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD.

When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.4.3 16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

- **Schematic**

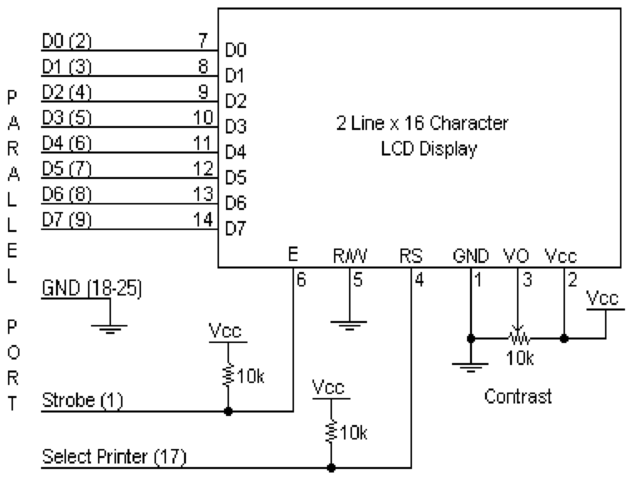

Fig.4.25: Schematic of 2 x16 Character LCD Display

- ## Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.

Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.

Table.4.7: Connector Pin Assignment

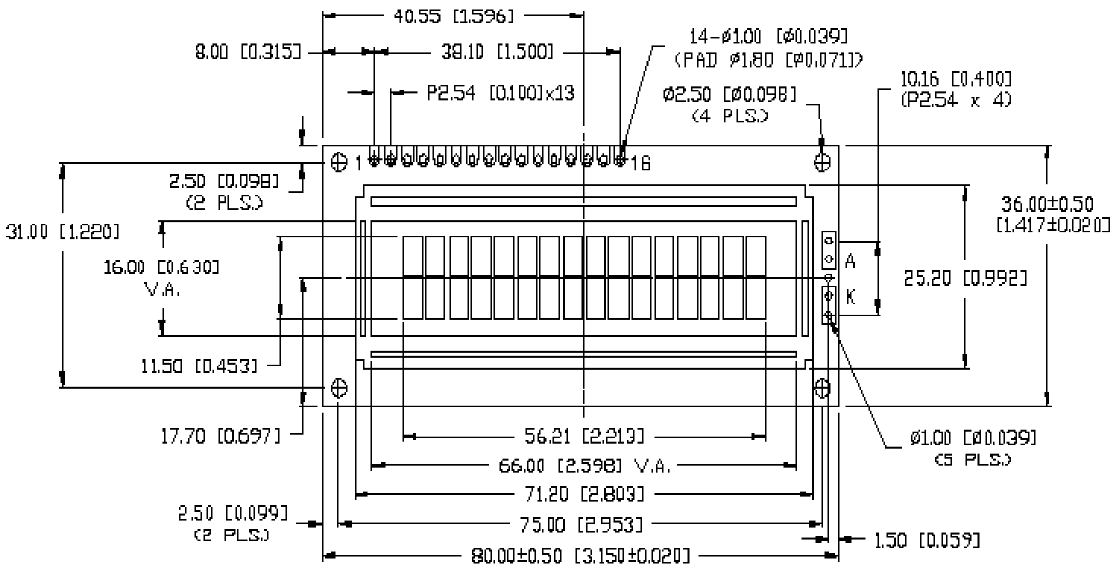

Fig.4.26: Internal Voltage and Current Distribution

- ## Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output.

While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

4.5 L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to Built in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

4.5.1 Introduction to L293D

L293D is basically a motor driver or controller. It has two built in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc.

Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

Fig.4.27: L293D

1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	V_{CC2}
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	V_{CC1}

Table.4.8: L293D Pin

3. L293D Pinout

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.
- L293D pinout diagram is shown in the figure given below.

Fig.4.28: L293D Pin Configuration

4.6 MOTORS

4.6.1 Definition

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine. It may also refer to:

Electric motor, a machine that converts electricity into a mechanical motion

- AC motor, an electric motor that is driven by alternating current
  - Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
  - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction

- DC motor, an electric motor that runs on direct current electricity
  - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
  - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes

- Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
- Servo motor, an electric motor that operates a servo, commonly used in robotics
- Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

4.6.2 Types of Motors

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

1. **AC Motors**

The most common and simple industrial motor is the three phase AC induction motor, sometimes known as the "squirrel cage" motor. Substantial information can be found about any motor by checking its (nameplate).

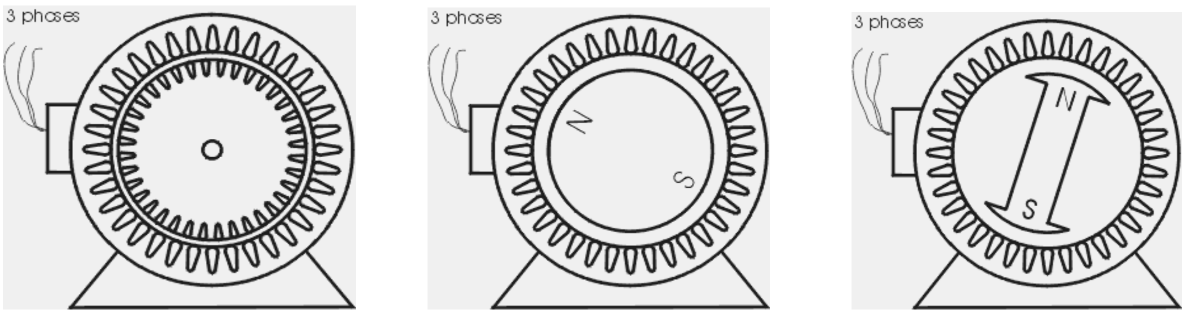

Fig.4.29: 3 Phase AC Induction Motor

- **Advantages**
    - Simple Design
    - Low Cost
    - Reliable Operation
    - Easily Found Replacements
    - Variety of Mounting Styles
    - Many Different Environmental Enclosures

Simple Design

The simple design of the AC motor -- simply a series of three windings in the exterior (stator) section with a simple rotating section (rotor). The changing field caused by the 50 or 60 Hertz AC line voltage causes the rotor to rotate around the axis of the motor.

The speed of the AC motor depends only on three variables:

1. The fixed number of winding sets (known as poles) built into the motor, which determines the motor's base speed.
2. The frequency of the AC line voltage. Variable speed drives change this frequency to change the speed of the motor.
3. The amount of torque loading on the motor, which causes slip.

Low Cost

The AC motor has the advantage of being the lowest cost motor for applications requiring more than about 1/2 hp (325 watts) of power. This is due to the simple design of the motor. For this reason, AC motors are overwhelmingly preferred for fixed speed applications in industrial applications and for commercial and domestic applications where AC line power can be easily attached. Over 90% of all motors are AC induction motors.

They are found in air conditioners, washers, dryers, industrial machinery, fans, blowers, vacuum cleaners, and many, many other applications.

- **Reliable Operation**

The simple design of the AC motor results in extremely reliable, low maintenance operation. Unlike the DC motor, there are no brushes to replace. If run in the appropriate environment for its enclosure, the AC motor can expect to need new bearings after several years of operation. If the application is well designed, an AC motor may not need new bearings for more than a decade.

- **Easily Found Replacements**

The wide use of the AC motor has resulted in easily found replacements. Many manufacturers adhere to either European (metric) or American (NEMA) standards. (For Replacement Motors) Variety of Mounting Styles

AC Motors are available in many different mounting styles such as:

- Foot Mount
- C-Face
- Large Flange
- Vertical
- Specialty

2. DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

- **Advantages**
  - Easy to understand design
  - Easy to control speed
  - Easy to control torque
  - Simple, cheap drive design

- **Easy to understand design**

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings.

Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

- **Easy to control speed**

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjunction with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparable AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

- **Easy to control torque**

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

- **Simple, cheap drive design**

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance trade offs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

- **Disadvantages**
  - Expensive to produce
  - Can't reliably control at lowest speeds
  - Physically larger
  - High maintenance
  - Dust

4.6.3 WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.

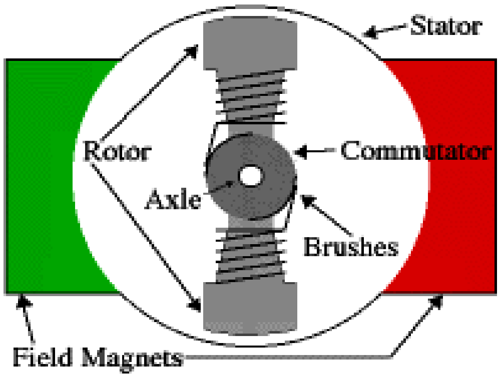

Fig.4.30: Internal Components of Motor

- **Principle**

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously. When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator.

You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).

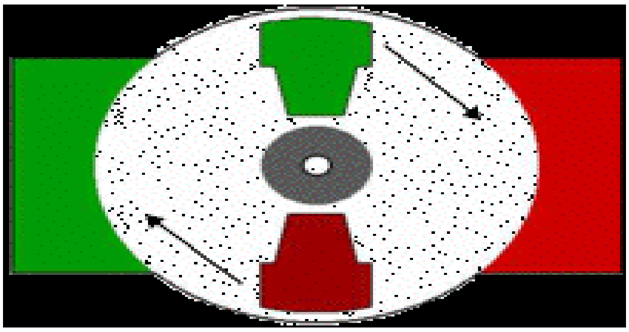

Fig.4.31: Rotation Of Two Polar Motor

- **Construction and Working**

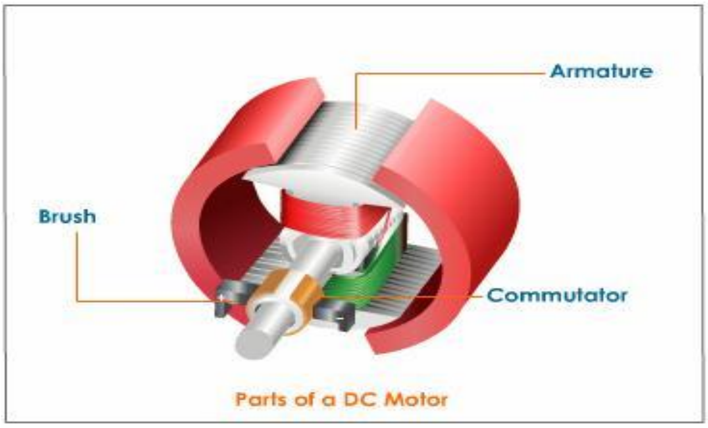

Fig.4.32: Parts of DC Motor

4.6.4 Parts of a DC Motor

- **Armature**

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

- **Commutator**

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.

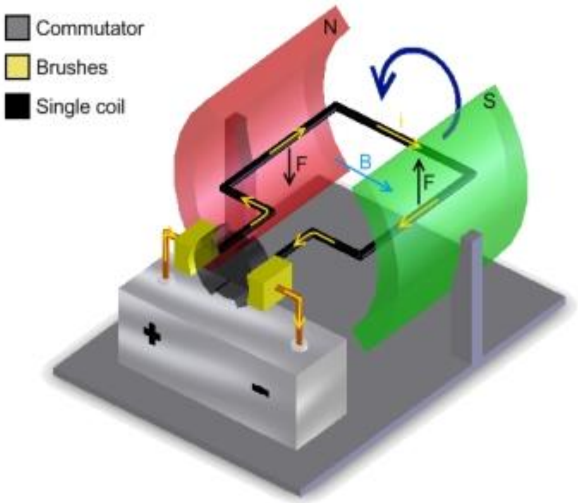

Fig.4.33: Commutator

- **Brushes**

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

- **Working of a DC Motor**

When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.

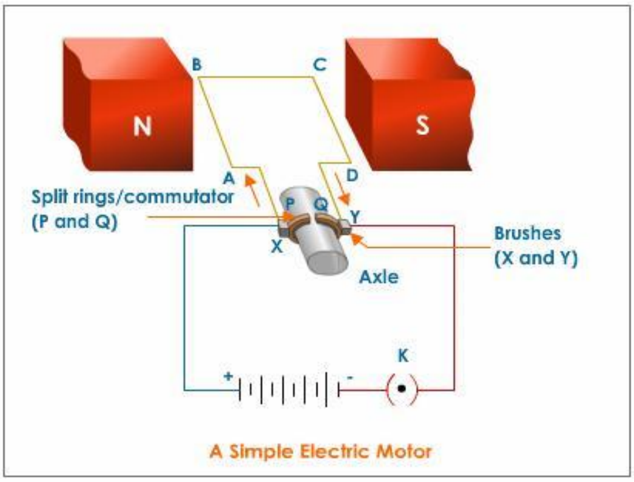

Fig.4.34: Simple Electric Motor

When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

However the coil keeps turning because of its own momentum. Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.

4.6.5 Parameters of the Dc Motors

- Direction of rotation
- Motor Speed
- Motor Torque
- Motor Start and Stop

▪ Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.

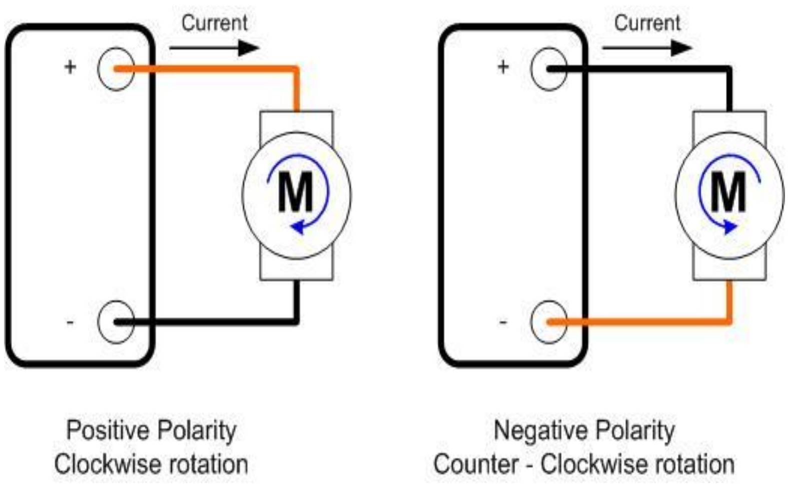

Fig.4.35: Motor rotation with Polarity

▪ DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.
- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

- **DC Motor Speed**

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as attract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attraction will try to take place. As a result, motor speed is directly proportional to applied voltage.

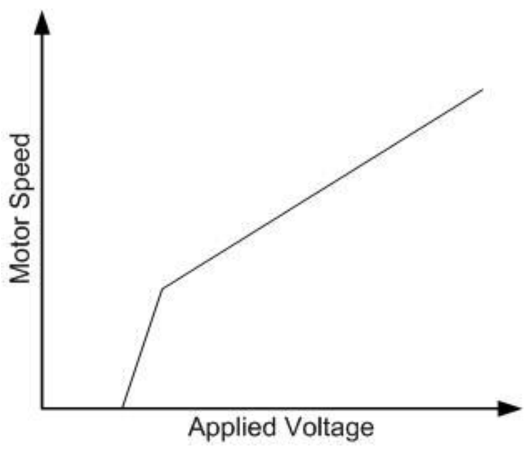

Fig.4.36: Motor Speed Vs Applied Voltage

- **Motor Speed Curve**

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will simply not move. This is because the magnetic field strength is not enough to overcome friction.

Once friction is overcome, motor speed will start to increase as voltage increase. The following video shows the concept of speed control and offers some ideas on how this can be achieved.

- ## Motor Torque

In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.

Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy cannot be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

$$\mathbf{P = IV}$$

Where P is power, I is motor current and V is motor voltage. Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current.As you increase load (or torque requirements) current must also increase.

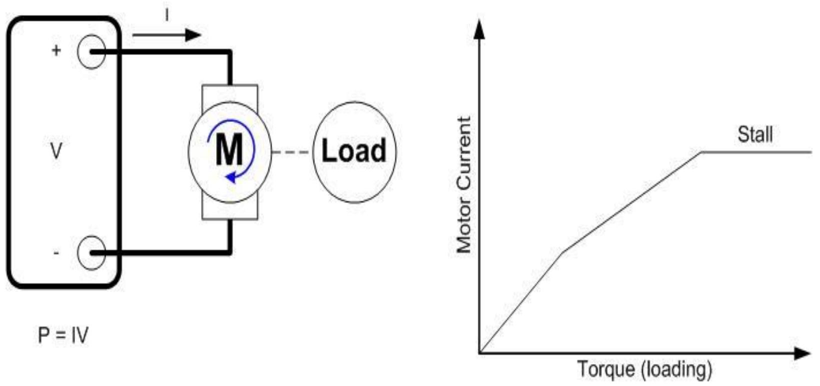

Fig.4.37: Torque Vs Motor Current

- ## Motor Loading

One aspect about DC motors which we must not forget is that loading or increase of torque cannot be infinite as there is a point in which the motor simply cannot move. When this happens, we call this loading “Stalling Torque”. At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

- ## Motor Start and Stop

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current cannot change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.

Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.

Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs.

The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back EMF is directly proportional to speed, making Back EMF = 0, also means making speed = 0.

4.6.6 MOTOR DRIVER CIRCUIT

The name "H-Bridge" is derived from the actual shape of the switching circuit which control the motion of the motor. It is also known as "Full Bridge". Basically there are four switching elements in the H-Bridge as shown in the figure below.

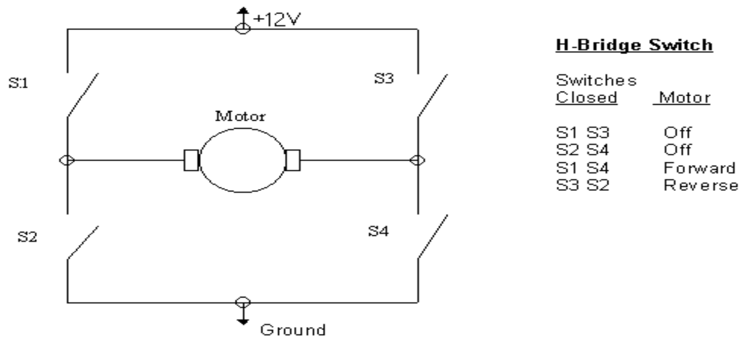

Fig.4.38: (a) H-Bridge

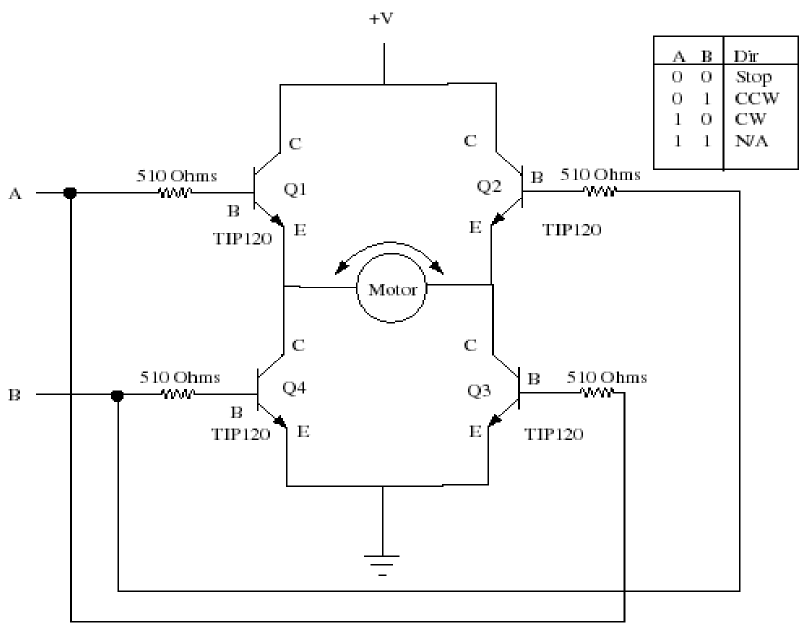

Fig.4.38: (b) Motor Driver Circuit

As you can see in the figure above there are four switching elements named as "High side left", "High side right", "Low side right", "Low side left". When these switches are turned on in pairs motor changes its direction accordingly. Like, if we switch on High side left and Low side right then motor rotate in forward direction, as current flows from Power supply

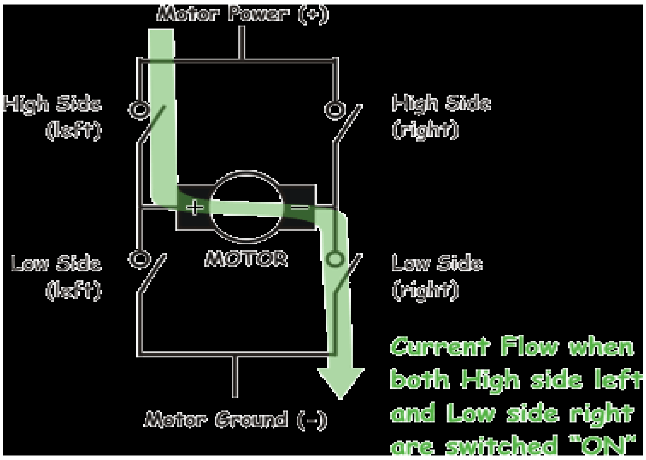

Fig.4.39: Current in Motor Circuit

Similarly, when you switch on low side left and high side right, the current flows in opposite direction and motor rotates in backward direction. This is the basic working of H-Bridge. We can also make a small truth table according to the switching of H-Bridge explained above.

Truth Table

High Left	High Right	Low Left	Low Right	Description
On	Off	Off	On	Motor runs clockwise
Off	On	On	Off	Motor runs anti-clockwise
On	On	Off	Off	Motor stops or decelerates
Off	Off	On	On	Motor stops or decelerates

Table.4.9: Truth Tables

As already said, H-bridge can be made with the help of transistors as well as MOSFETs, the only thing is the power handling capacity of the circuit. If motors are needed to run with high current then lot of dissipation is there. So head sinks are needed to cool the circuit.

Now you might be thinking why I did not discuss the cases like High side left on and Low side left on or high side right on and low side right on. Clearly seen in the diagram, you don't want to burn your power supply by shorting them. So that is why those combinations are not discussed in the truth table.

4.7 SOUND SENSOR:

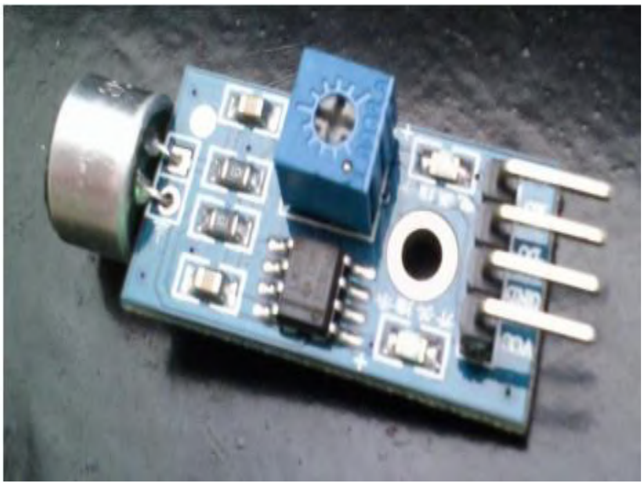

Fig.4.40: Sound Sensor

4.7.1 Description

The sound sensor module provides an easy way to detect sound and is generally used for detecting sound intensity. This module can be used for security, switch, and monitoring applications. Its accuracy can be easily adjusted for the convenience of usage. It uses a microphone which supplies the input to an amplifier, peak detector and buffer. When the sensor detects a sound, it processes an output signal voltage which is sent to a microcontroller then performs necessary processing.

Sound Sensor is designed to be used with a PASCO computer interface to make measurements of relative intensity of sound. The sensing element of the Sound Sensor is an electret condenser microphone, which consists of an electret membrane, metal electrode, and field effect transistor that are in an efficient configuration yielding superior signal to-noise ratios (>60 dB) and excellent frequency response (20 to 16,000 Hz).

Two stages of amplification are provided to condition the low-level signal from the microphone for input into the Science Workshop computer interface.

The output from the sensor is bipolar and ranges between ±10 volts. When the sensitivity is raised to high in Science Workshop (700 interface only), the Sound Sensor detects voltage levels as low as 0.0005 volts, corresponding to sound levels that are barely audible to the human ear.

Sound levels ranging from classroom background noise (45 dB) to levels exceeding 100 dB are easily detected with the Sound Sensor. The Oscilloscope and Fast Fourier Transform (FFT) functions of Science Workshop may be used effectively Equipment Included:

• Sound sensor in sensor box

• 6-foot cable with 8-pin DIN connectors

- **Additional Equipment Required**:

• Any PASCO Science Workshop™ computer interface (300, 500, or 700 series for Macintosh or Windows) or the 6500 series interface for DOS with the Sound Sensor: the Oscilloscope allows the student to view the Sound Sensor output directly, and the FFT function will transform the time domain signal from the sensor to a frequency domain display. These two functions allow the student to investigate the frequency composition of sound produced by the human voice, a tuning fork, or loud speaker driven by a complex waveform such as a square wave. Both the Oscilloscope and FFT functions may be used simultaneously. The Sound Sensor can be plugged directly into any PASCO computer interface box or can be connected to the interface box using the supplied cable with 8-pin DIN connectors. SOUND SENSOR CI-6506B aperture for sensor Sound Sensor interface cable with DIN connectors DIN connector to computer interface 012-06296B 2 Sound Sensor ② Open the Experiment Setup window in Science Workshop. Click and drag the analog plug icon to the analog channel icon that matches the analog port you are using for the Sound Sensor (Figure 2). Figure 2. Activating the analog channel in Science Workshop. Setup Procedure A B Plug into any analog channel. Plug into any analog channel. Figure 1. Connecting the Sound Sensor into the computer interface. ③ Select "Sound Sensor" from the drop-down menu (Figure 3). ④ Open a display window, such as the Oscilloscope display, by dragging and dropping the appropriate display icon to the Sound Sensor icon (Figure 4). Figure 3. Setting up the Sound Sensor in Science Workshop. Additional Equipment Suggested:

• Tuning Forks (SE-9325 or SE-9326) • Organ Pipe with Sliding Piston (SF-9328)

• Acoustics Demonstration Disk (SF-9410) ① Connect the Sound Sensor and any Analog channel on the computer interface box with interface cable (Figure 1A), or insert the DIN plug of the Sound Sensor into the jack of any Analog channel on the computer interface box (Figure 1B). The sound level, which is measured in decibels can be calculated from amplitude of the voltage.

The formula is.

B = 10 * log(A^2/A(0)^2)

Where A is the amplitude of the voltage and A(0) is the theoretical amplitude for a sound level of 0 dB. At a frequency of 440 Hz, A(0) = 10 ^ -4 volts approximately. To have Data Studio perform this calculation, click on th Calculate button and type the following equation: sound level = 10*log(amplitude (10,10,.001, v^2)/(10^- 8). In the Variables section of the Calculator, define v as Voltage, Ch A. This equation is optimized for a sine wave at 440 Hz, so you may need to adjust the third argument of the amplitude function (it should be about equal to the period of the wave). The value of 10^-4 volts is also optimized for 440 Hz. Since the response of the sound sensor varies with frequency, you may want to calibrate the equation for a different frequency. To do so, you would need a stand-alone sound level meter. Measure the sound level of as sound (B) with the meter, and the voltage amplitude (A) with the sound sensor. Use these values to solve for A (0) in the first equation above.

ON ANALOG CHANNELS B DIGITAL CHANNELS Science Workshop™ SOUND SENSOR CI-6506B 012-06296B Sound Sensor 3 Calibration and Sensitivity Adjustment in Science Workshop To open the Sound Sensor's calibration window, double-click on the Sound Sensor icon in the Experiment Setup window . The sensitivity (gain) of channels A and B of the 300, 500, and 700 interfaces in Science Workshop can be adjusted by selecting the appropriate level from the drop-down menu .If the Sound Sensor is producing voltage above 1 V, the sensitivity should be set to Low (1x). If the Sound Sensor is producing voltages between +1 V and -1 V, select Medium (10x). With the Science Workshop 700 interface, the sensitivity can be set to High (100x) if the voltage is very low (between +0.1 V and -0.1 V).

4.7.2 Specifications

- Operating voltage 3.3V-5V
- Output model: digital switch outputs (0 and 1, high or low level)
- With a mounting screw hole
- PCB size: 3.4cm * 1.6cm

  if(digitalRead(2) == 0) Serial.println("no sound detected");
  else Serial.println("sound detected");
  delay(250);
}
```

Fig.4.44: Simple Code For Sound Detection Using Sound Sensor

4.7.5 How to test

The components to be used are: – Microcontroller (any compatible arduino) – Sound sensor module – 1 Pin M-M connectors – Breadboard – USB cable 1. Connect the components based on the figure shown in the wiring diagram using a M-M pin connector.

VCC pin is connected to the 3.3V or 5V power supply, GND pin is connected to the GND, DO pin is connected to a digital I/O pin and AO pin is connected to an analog pin. Pin number will be based on the actual program code. 2. After hardware connection, insert the sample sketch into the Arduino IDE. 3. Using a USB cable, connect the ports from the microcontroller to the computer. 4. Upload the program. 5. See the results in the serial monitor.

4.7.6 Testing Results

The figure below shows when the module was not subjected to sound.

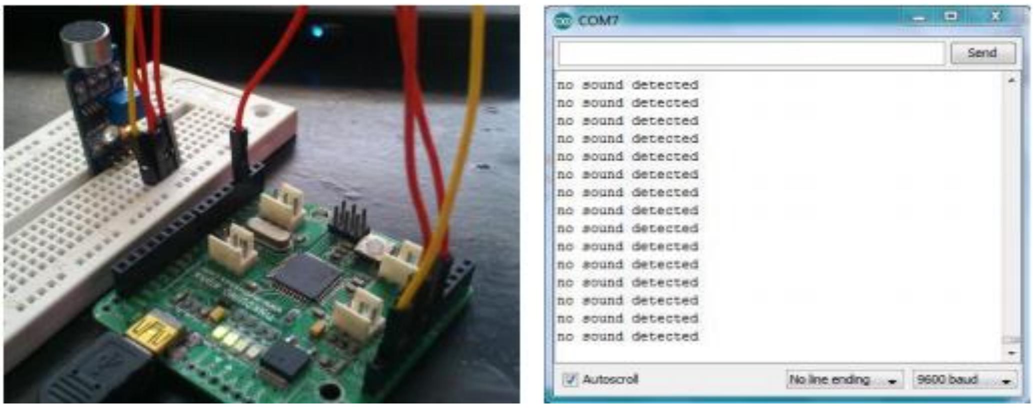

Fig.4.45: Output When Sound Is Not Detected

The figure below shows when the module was subjected to sound. Note that the red LED should also light up when sound is detected

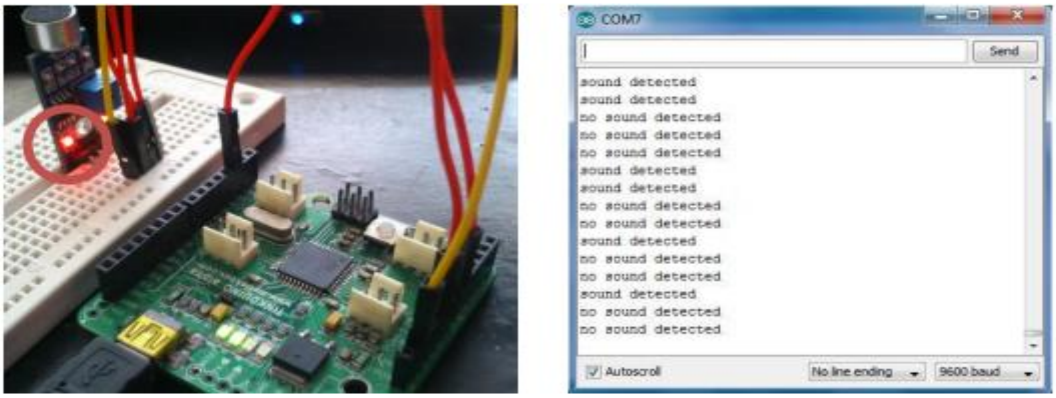

Fig.4.46: Output When Sound Is Detected

4.8 SOFTWARE EXPLANATION:

- **Software Requirements**
  - Proteus simulation
  - Arduino software
  - Programming language

4.8.1 Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike.

Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IOT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

4.8.2 Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux.

Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments.

Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version

- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- Download the Arduino Software(IDE)
- Proceed with board specific instructions.

4.8.3 How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

- **Installation:**

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1

First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.47: (a) Standard USB Cable

Fig.4.47: (b) USB cable A to Mini-B

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

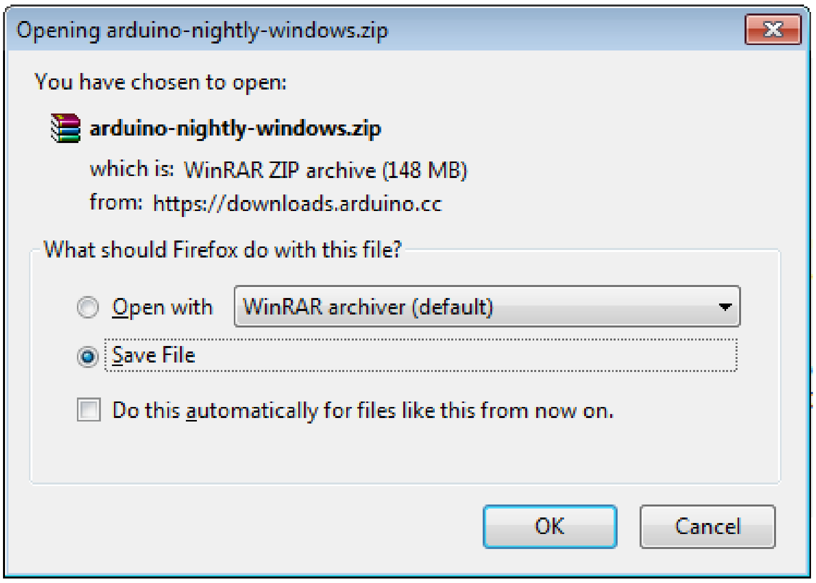

Fig.4.48: Process of Downloading the Arduino

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply.

If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe).

Double-click the icon to start the IDE.

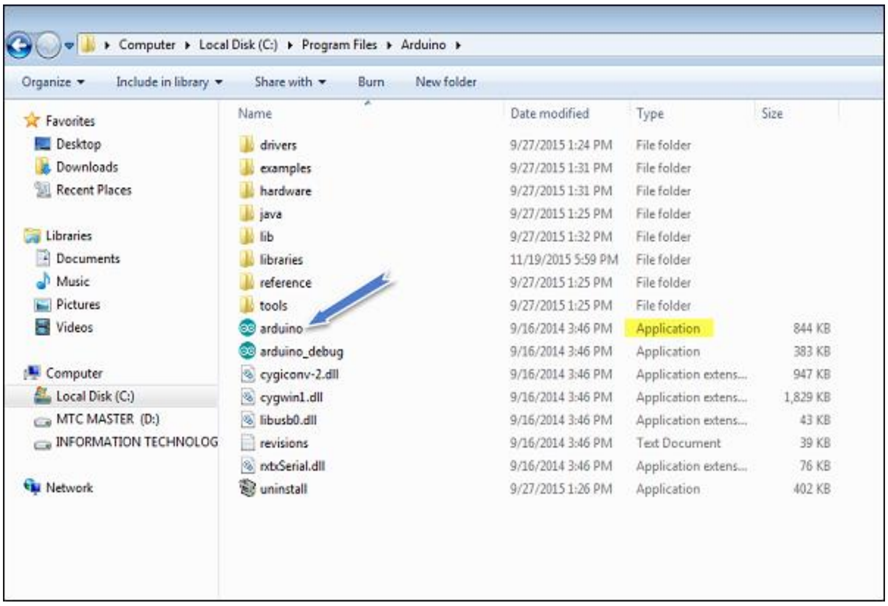

Fig.4.49: Launching Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

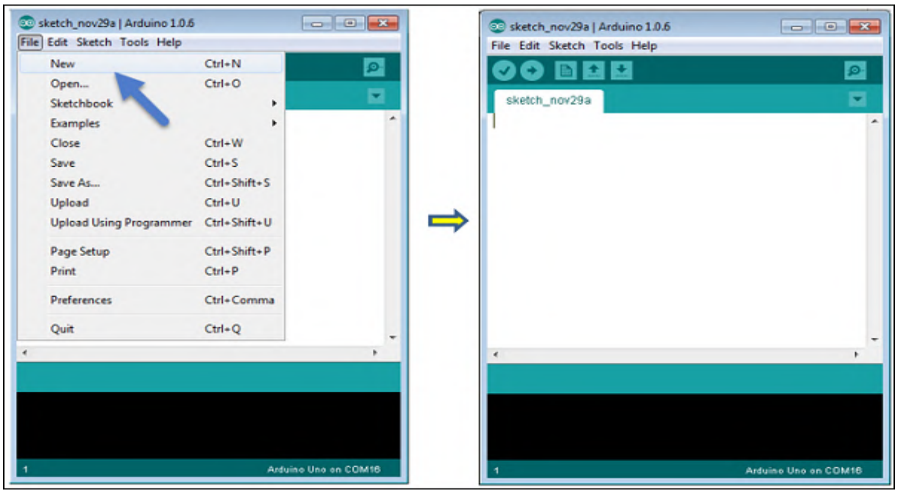

Fig.4.50: Opening Editor Window in IDE

To open an existing project example, select File → Example → Basics → Blink.

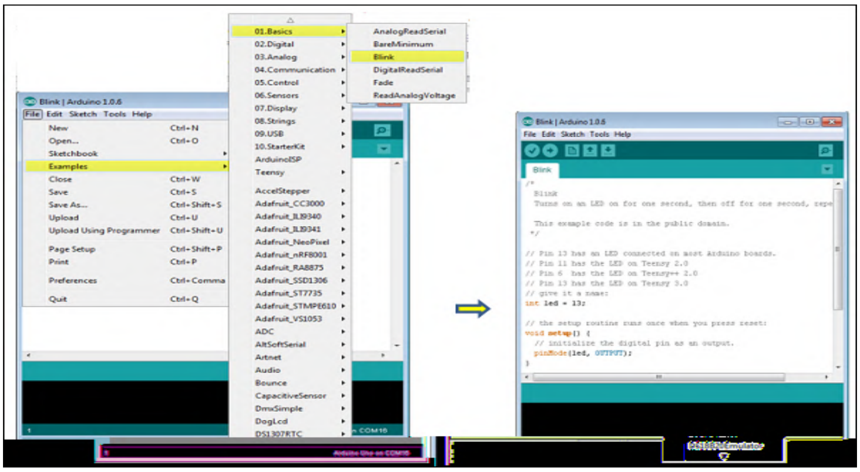

Fig.4.51: Opening Existing File in IDE

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

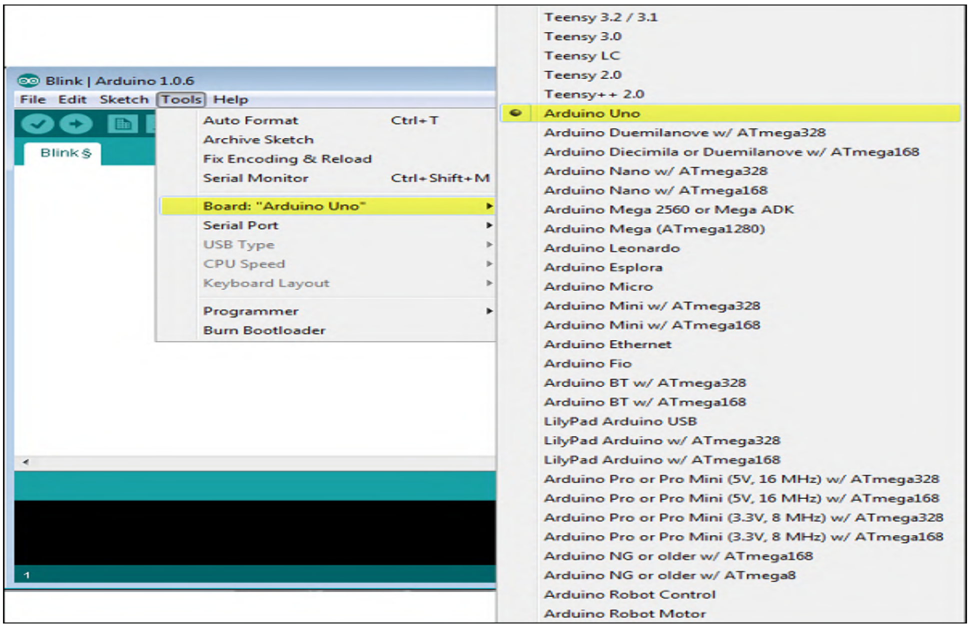

Fig.4.52: Selecting Arduino Board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports).

To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

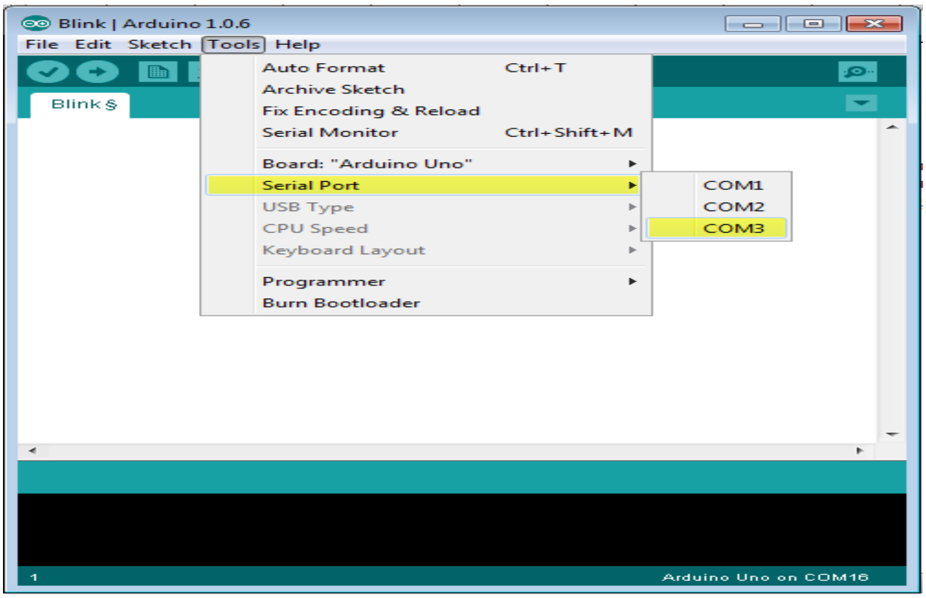

Fig.4.53: Selecting Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

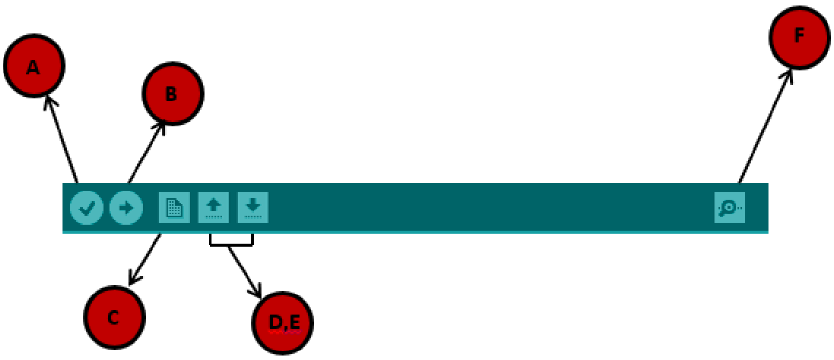

Fig.4.54: IDE Tool Bar

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

4.8.4 Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

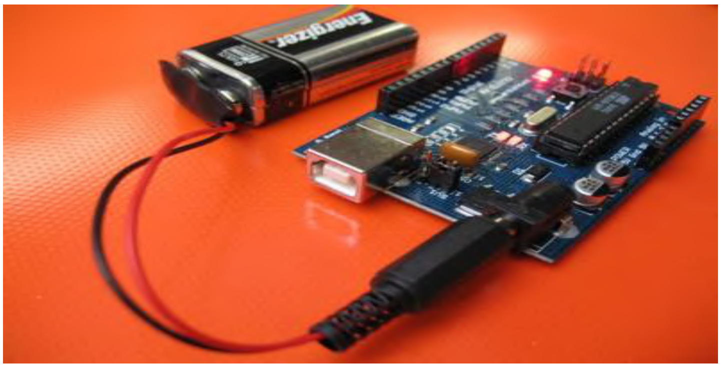

Fig.4.55: Arduino with Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program show in Figure:4.66, paying attention to where semi-colons appear at the end of command lines.

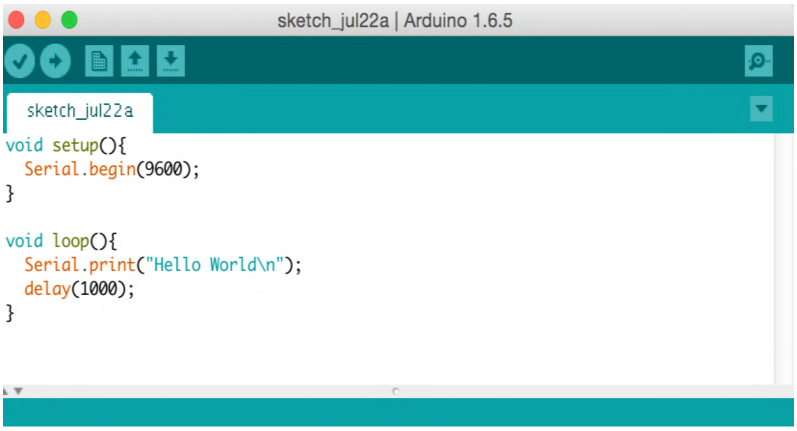

Fig.4.56: Writing the Program in IDE

4.9 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems.

There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

4.10 Proteus:

4.10.1 Proteus:

Proteus is a simulation and design software tool developed by Lab Centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.10.2 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

4.10.3 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components.

It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.10.4 Starting New Design

Step 1: Open ISIS software and select new design in File menu

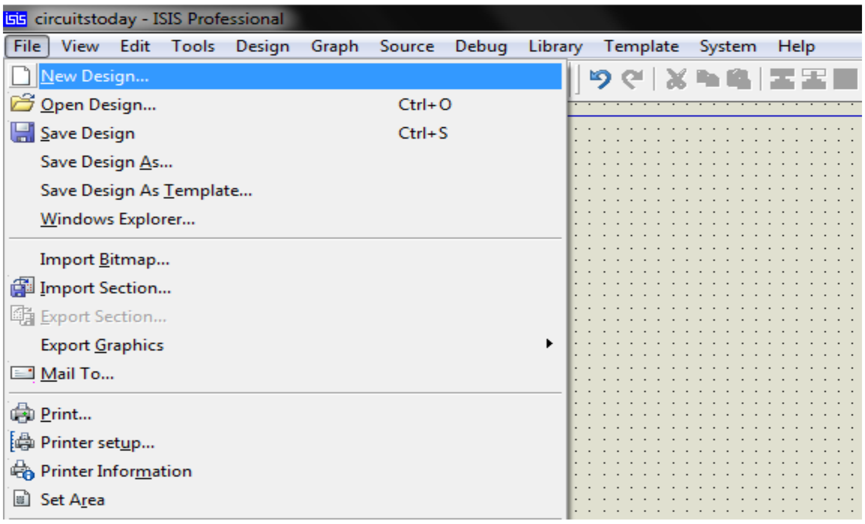

Fig.4.57: Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

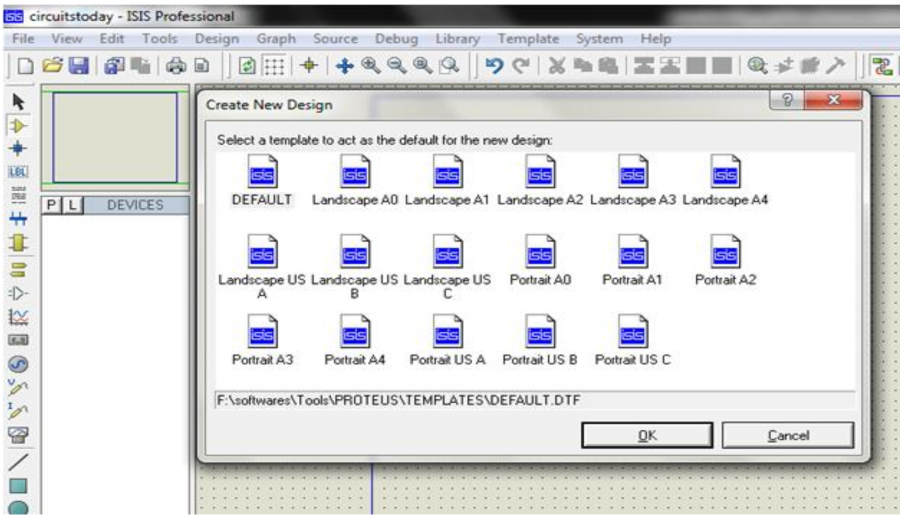

Fig.4.58: Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

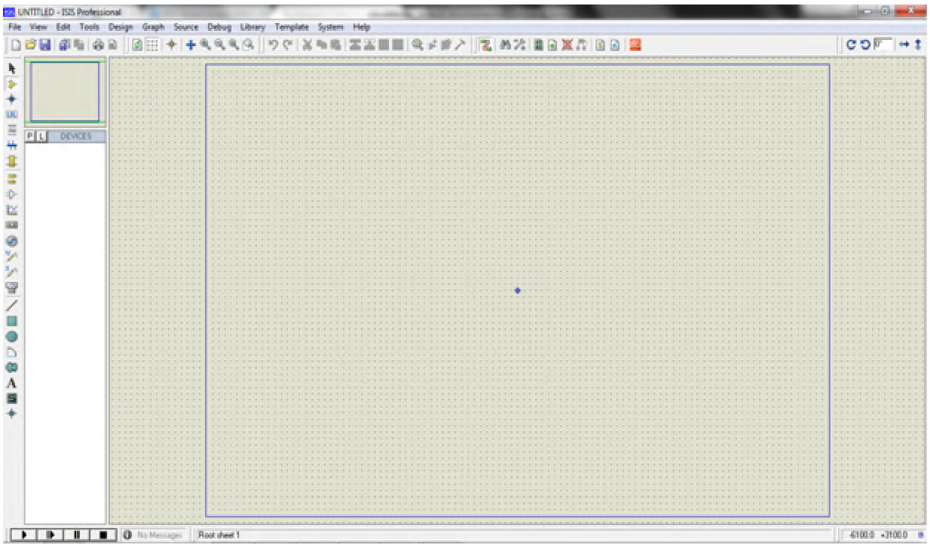

Fig.4.59: Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

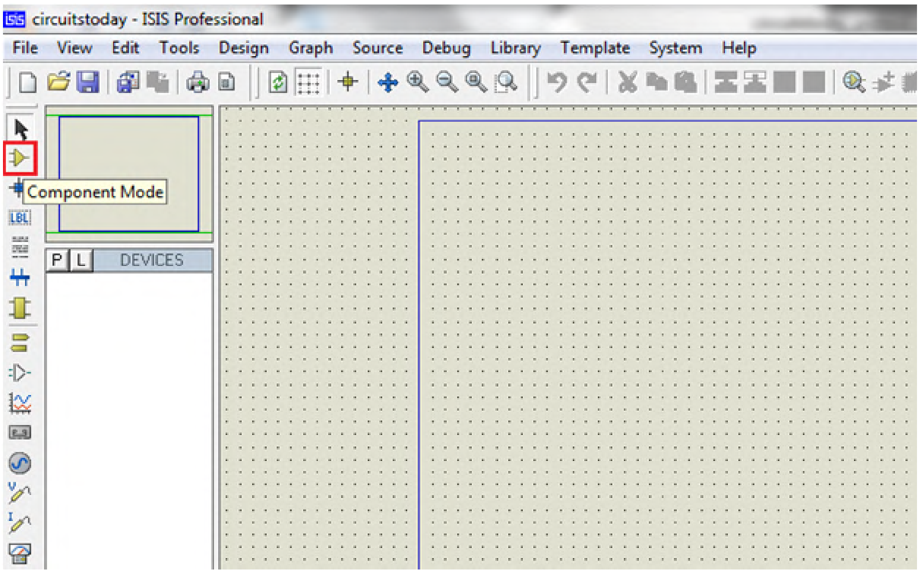

Fig.4.60: Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

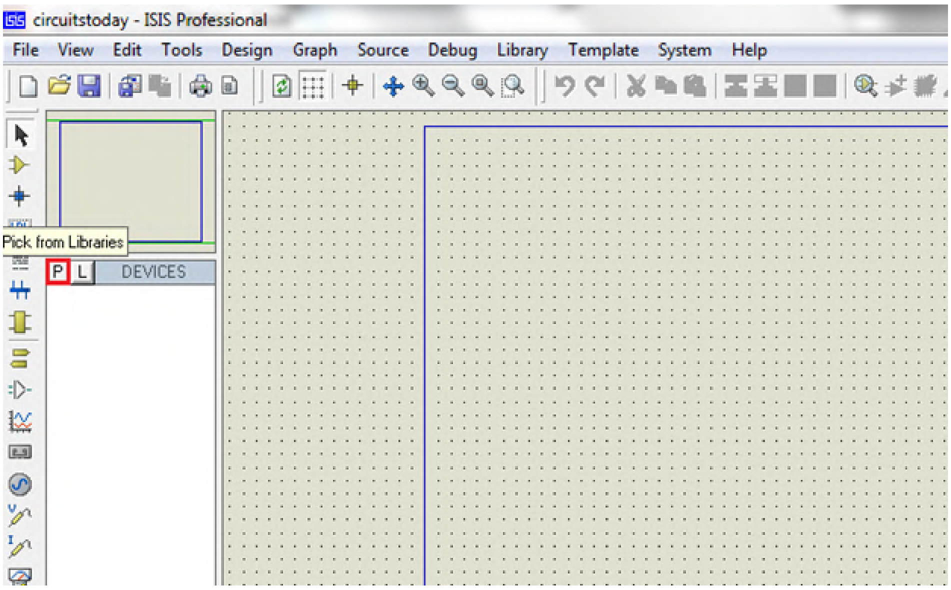

Fig.4.61: Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

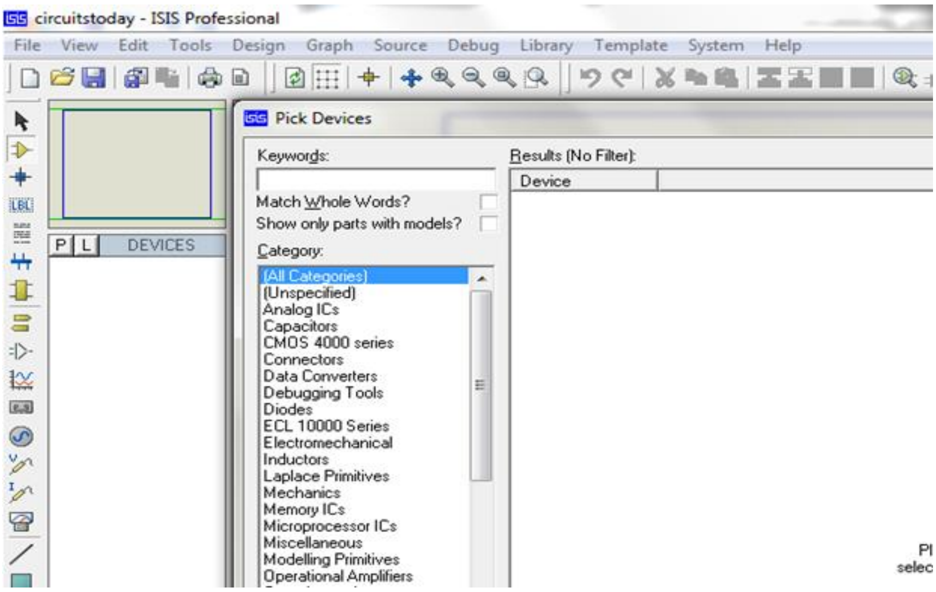

Fig.4.62: Keywords Textbox

Example shows selection of push button. Select the components accordingly.

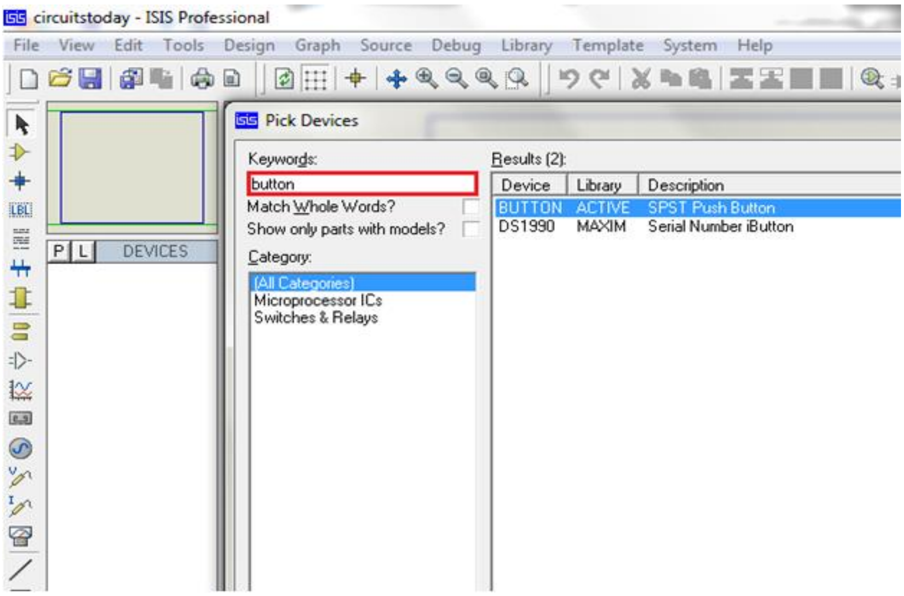

Fig.4.63: Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

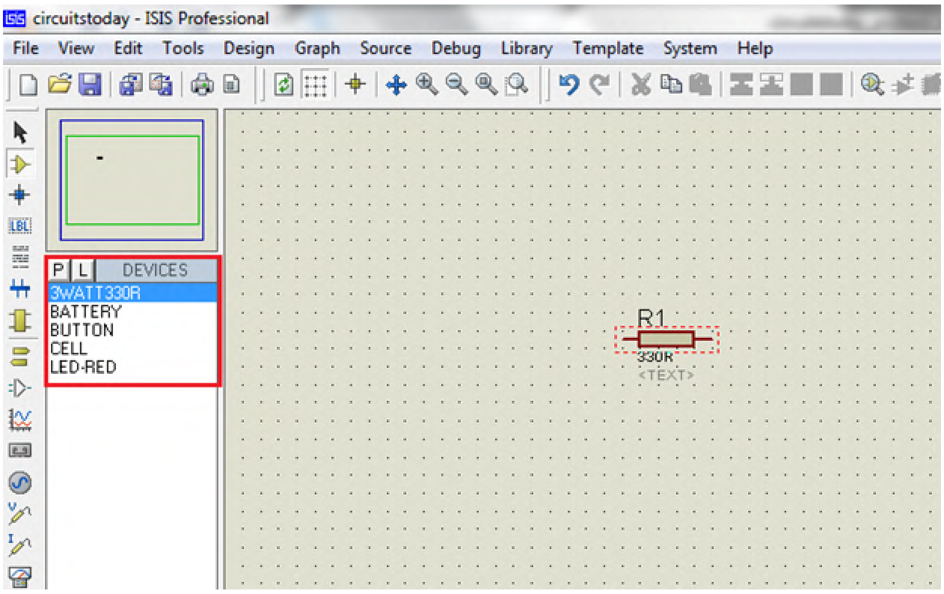

Fig.4.64: Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

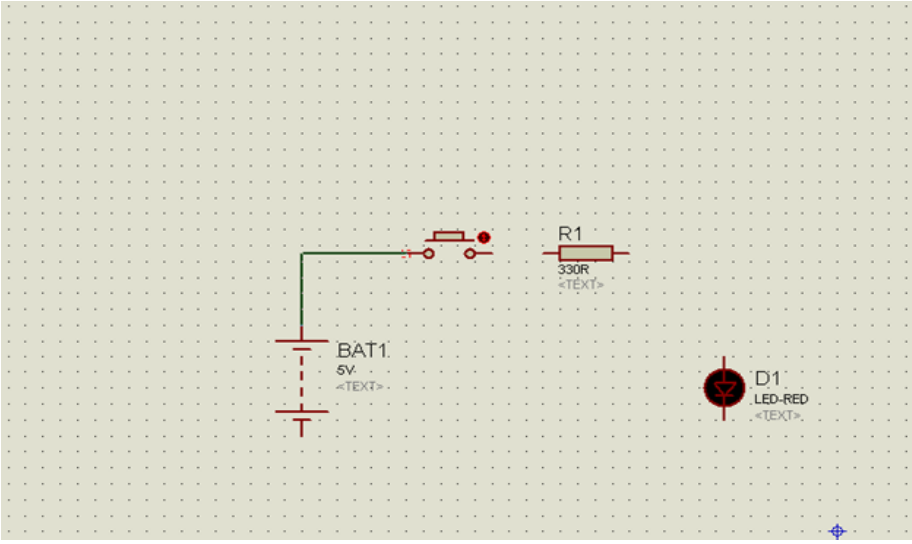

Fig.4.65: Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

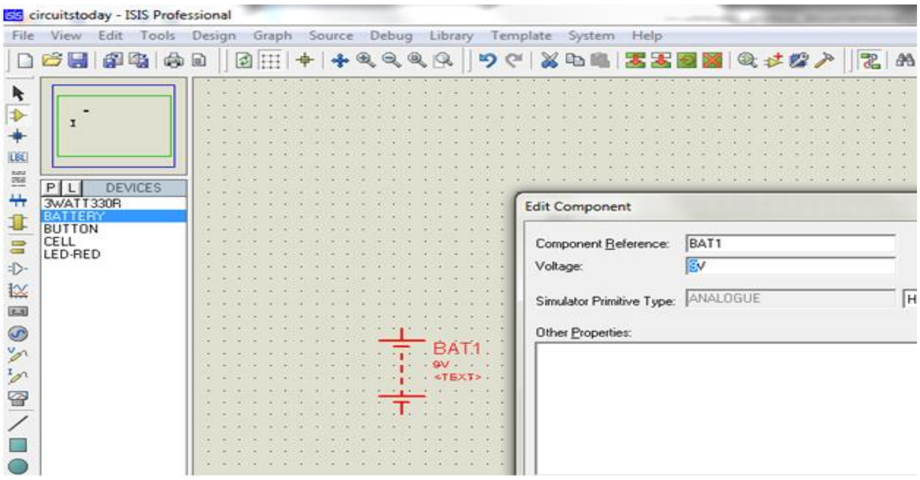

Fig.4.66: Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

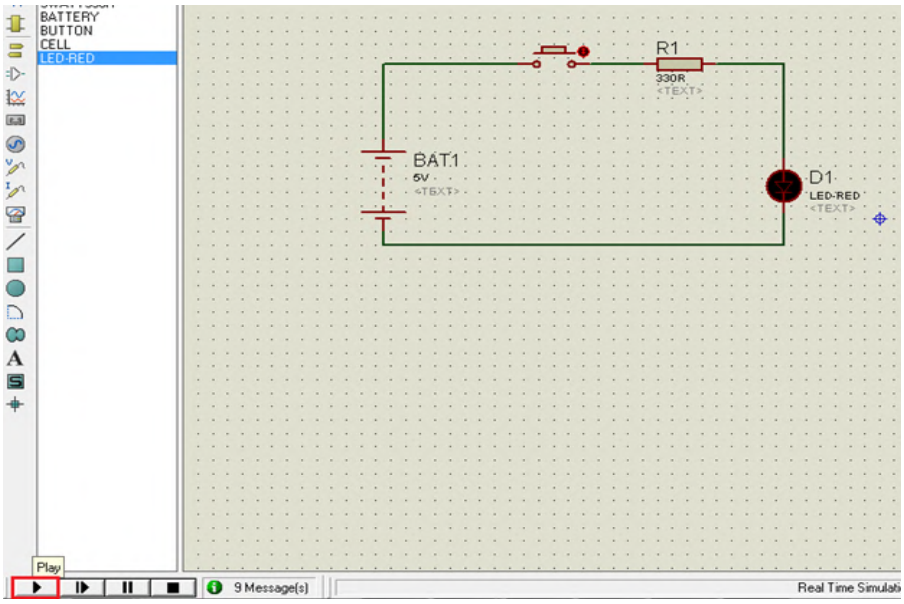

Fig.4.67: Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

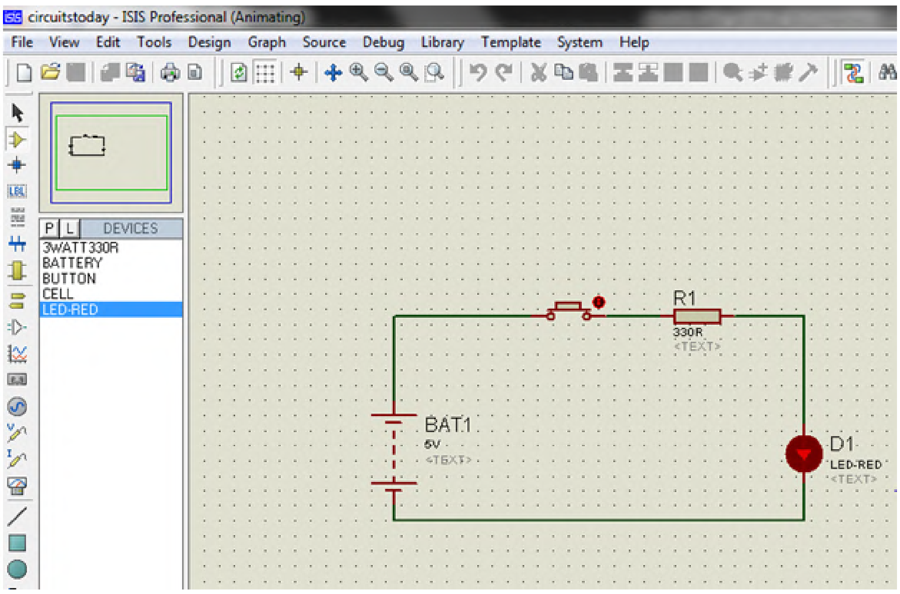

Fig.4.68: Simulation Animating

Simulation can be stepped, paused or stopped at any time.

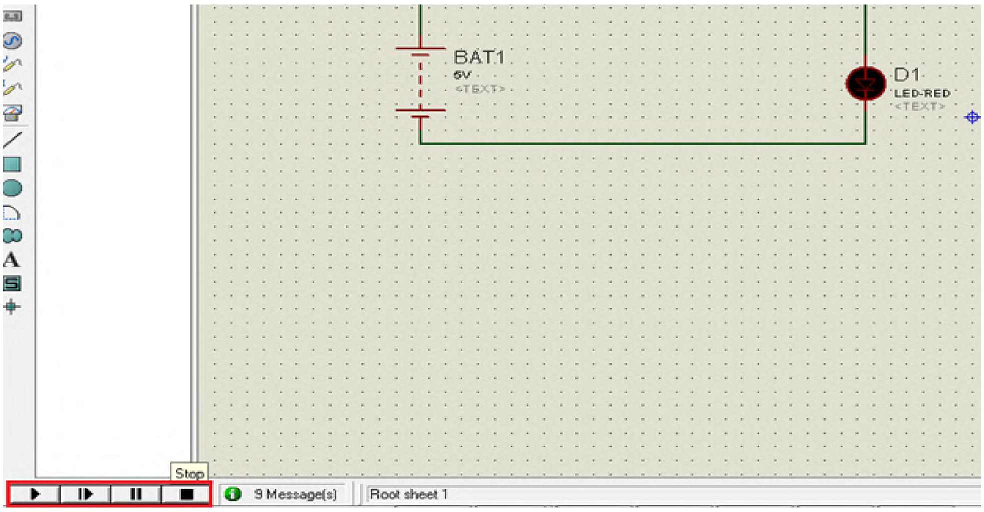

Fig.4.69: Simulation Step-Pause-Stop Buttons

4.10.4 Project Code:

```
#include <LiquidCrystal.h>

LiquidCrystal lcd(13,12,11,10,9,8);
int sw1=4,sw2=5,sw3=6,sw4=7;
int v1=A4,v2=A5;

void setup()
{
  Serial.begin(9600);

  pinMode(sw1,OUTPUT);
  pinMode(sw2,OUTPUT);
  pinMode(sw3,OUTPUT);
  pinMode(sw4,OUTPUT);
  pinMode(v1,INPUT);
  pinMode(v2,INPUT);
```

```
   digitalWrite(sw1,LOW);
   digitalWrite(sw2,LOW);
   digitalWrite(sw3,LOW);
   digitalWrite(sw4,LOW);

   lcd.begin(16,2);
   lcd.clear();
   lcd.setCursor(0,0);
   lcd.print("***WELCOME***");

   Serial.begin(9600);
   delay(3000);
}

void loop() {
    int v1d = digitalRead(v1);
    int v2d = digitalRead(v2);

    lcd.clear();lcd.setCursor(0,1);lcd.print("S1:");lcd.print(v1d);
    lcd.setCursor(8,1);lcd.print("S2:");lcd.print(v2d);delay(2000);

 if (v1d == LOW)
   {
   lcd.clear();lcd.setCursor(0,1);lcd.print("LOCATION 1: ALERT");
   digitalWrite(sw1,HIGH);digitalWrite(sw3,HIGH);
   digitalWrite(sw2,LOW);digitalWrite(sw4,LOW);
   Serial.print("*1");
   delay(2000);
   digitalWrite(sw1,LOW);digitalWrite(sw3,LOW);
   digitalWrite(sw2,LOW);digitalWrite(sw4,LOW);
   }
```

```
else if (v2d == LOW)
   {
   lcd.clear();lcd.setCursor(0,1);lcd.print("LOCATION 2: ALERT");
   digitalWrite(sw2,HIGH);digitalWrite(sw4,HIGH);
   digitalWrite(sw1,LOW);digitalWrite(sw3,LOW);
   Serial.print("*1");
   delay(2000);
   digitalWrite(sw1,LOW);digitalWrite(sw3,LOW);
   digitalWrite(sw2,LOW);digitalWrite(sw4,LOW);
   }

else
   {
   lcd.clear();lcd.setCursor(0,1);lcd.print("EVRYTHING FINE...");
   digitalWrite(sw1,LOW);digitalWrite(sw3,LOW);
   digitalWrite(sw2,LOW);digitalWrite(sw4,LOW);
   delay(1000);
   }

}
```

CHAPTER-5

RESULTS & OUTPUTS

5.1 RESULT:

The outcome of the project "women safety patrolling robot using IOT " after aligning all components is shown in figure.5.1 and figure.5.2, all the components are placed over the robot chassis, a caster wheel is placed for comfortable movements in any directions.

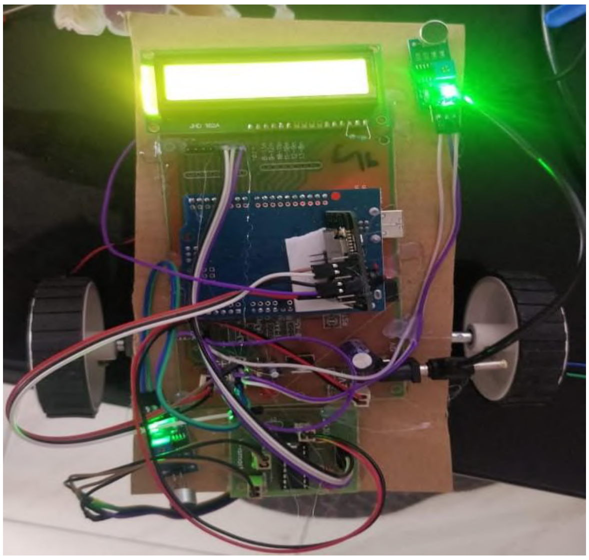

Fig.5.1: Women Safety Patrolling Robot Top View

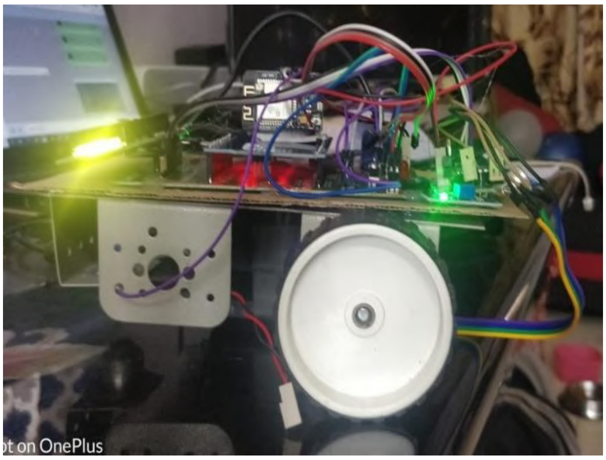

Fig.5.2: Women Safety Patrolling Robot Side View

Initially, the robot is set to ON by using a power supply unit of a 12Volts battery and regulated to a voltage of 5 to power the Arduino

Initially, the threshold detection level of the sound sensor is set to an intensity level of 540 by rotating the potentiometer of the sound sensor, and ESP32-CAM which is of 2MP 150 degrees wide-angle view is adjusted properly to cover the area properly and it is set to work properly.

After the kit is ON, ESP32-CAM continuously monitors the robot premises and sends the live streaming to the server which is observed in figure 5.3.as well as a message "Everything is Fine" is displayed on LCD, when no sound is detected and is shown in figure 5.4

The outputs of the projects are shown below.

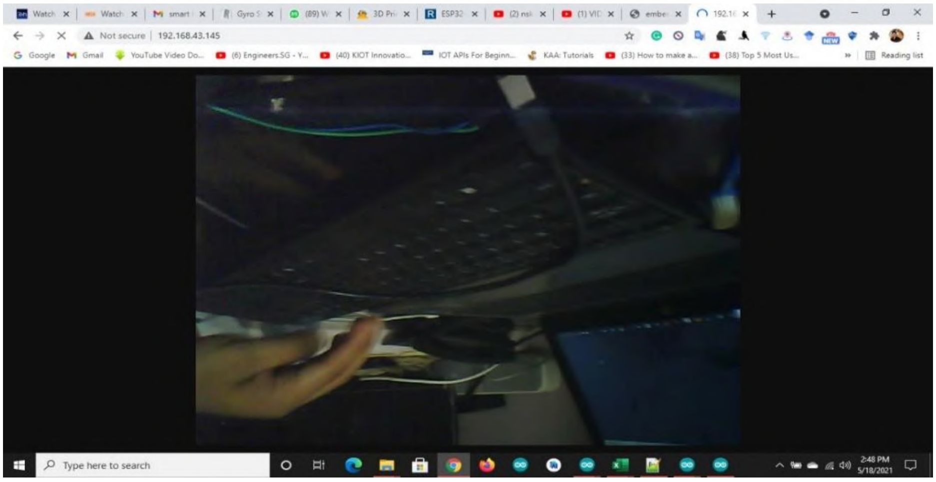

Fig.5.3: Screenshot Of Live Video Monitoring With ESP32 Camera Module Over Internet

The live streaming of robot premises can be observed by entering the IP address provided to the ESP32-CAM in the IOT web server, here we used “Embeddedspot.top” website for monitoring.

Fig.5.4: Displays When No Sound Is Detected

Fig.5.5: Displays If Sound Sensor1 Detects The Sound

Fig.5.6: Displays If Sound Sensor2 Is Detects The Sound

Whenever a Sound is detected in a range of 0.5meters, and if sound sensor-1 detects the sound, the output of the sound sensor becomes low and it is monitored by Arduino displays a message of "Location Alert: 1" on LCD and sets the output pins sw1 and sw2 to high such that robot moves left, similarly with the sound sensor-2 the LCD messages can be seen in Figures 5.5 and 5.6.

CHAPTER-6

APPLICATIONS, ADVANTAGES AND LIMITATIONS

6.1 APPLICATIONS OF THE PROJECT:

- By joining camera highlights with the robot we can undoubtedly screen indoor just as outside areas during daytime and around evening time.
- Remote regions can likewise be investigated.
- Used to record and send video yield of the necessary condition, expels human nearness of observing.
- Used for the safety of children.
- Used for the safety of physically challenged people
- Used as a legal evidence of crime with exact location information for prosecution

6.2 ADVANTAGES OF THE PROJECT:

- Easy and fast to install- These system will be easy to handle.
- Low cost with high performance- The device will be in a low cost which will work with a good performance.
- Environmental friendly system- The system will not harmful for the surroundings.
- Involvement of human force is reduced up to some extent.
- Patrolling is done autonomously
- It has a scope to catch the culprits as it works like movable CCTV

6.3 LIMITATIONS:

- Need a Human to Monitor the Video and Location
- Limited to local server.
- Obstacles in the path can be distractors.

CHAPTER-7

CONCLUSION AND FUTURE SCOPE

7.1 CONCLUSION:

Patrolling Robots are designed to help women from the dangerous situations. Women can rescue and protect themselves in any circumstances, so that she will never feel helpless at any sort locale and can protect herself even at late night. These techniques will also help police to arrest and search for the culprits.

7.2 FUTURE SCOPE:

- One can implement a few more sensors and connect it to the satellite as a global feature of this system.
- Adding more sensor to monitor other environmental parameters such as CO2,Pressure and Oxygen Sensor
- In aircraft, navigation and military there is a great scope of this real-time system.
- One can add GPS tracking and face detection algorithms to efficiently use the robot.
- It can also be implemented in hospitals or medical institutes for the research & study in “Effect of Weather on Health and Diseases”, hence to provide better precaution alerts.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Kumar, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mr. K. Nishakar,** Department of ECE and our project **Internal guide, Mrs. G. Vinatha, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. B. Reethika
2. G.Samyuktha Reddy
3. V.Shivani Reddy

ABSTRACT

Authentication has always been a major challenge in all types of examination. Verification of the authentic candidate is not an easy task, and also it consumes a lot of time and process. This led to the design of Fingerprint based exam hall authentication system that is designed to pass only users verified by their fingerprint scan and block non verified users. Formal examination can rightly be defined as the assessment of a person‘s Performance, when confronted with a series of questions, problems, or tasks set him/her, in order to ascertain the amount of knowledge that he has acquired, the extent to which he is able to utilize it, or the quality and effectiveness of the skills he/she has developed. During the 19th century, formal written examinations became regular in universities, schools, and other educational institutions. Examinations were also increasingly employed for the selection of recruits to the civil service, and the professions, and to posts in industry and commence.

Over the ages, standardized testing has been the most common methodology, yet the validity and credibility of the expanded range of contemporary assessment techniques have been called into question. There are two types of systems that help automatically establish the identity of a person: 1) Authentication (verification) systems and 2) Identification systems. In a verification system, a person desired to be identified submits an identity claim to the system, usually via a magnetic stripe card, login name, smart card, etc., and the system either rejects or accepts the submitted claim of identity (Am I who I claim I am?). In an identification system, the system establishes a subject‘s identity (or fails if the subject is not enrolled in the system database) without the subject‘s having to claim an identity (Who am I?). The topic of this paper is channel towards the development of examination impersonation elimination system and this system would strictly do with the unique feature of identification by means of finger print. A verification system based on fingerprints, and the terms verification, authentication, and identification are used in a loose sense and synonymously.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

CHAPTER 1

INTRODUCTION

1.0 OVERVEIW OF THE PROJECT:

Biometrics is the science and technology of measuring and analyzing biological data. Biometrics refers to technologies that measure and analyze human body characteristics, such as DNA, fingerprints, eye retinas and irises, voice patterns, facial patterns and hand measurements, for authentication purposes. The field of biometrics was formed and has since expanded on to many types of physical identification. Among the several human fingerprints remain a very common identifier and the biometric method of choice among law enforcement. These concepts of human identification have lead to the development of fingerprint scanners that serve to quickly identify individuals and assign access privileges. The basic point of these devices is also to examine the fingerprint data of an individual and compare it to a database of other fingerprints . In our project we have used fingerprint for the purpose of voter identification or authentication. As the thumb impression of every individual is unique, it helps in minimizing the error. A database is created containing the fingerprint images of all the voters as required. Illegal votes and repetition of votes is checked for in this system with accurate coding. Hence with the application of this fingerprint based EVM system elections could be made fair and free from rigging. Further that the elections would are no longer a tedious and expensive job.

1.1 OBJECTIVES OF STUDY:

Fingerprint based security system is the most secured system as compared to other systems. Reason is that RFID card or Keys of lock can be stolen, password may be leaked. However, thumbnail of every human being is unique, so lock will not open unless the same person is present to give the impression of fingerprint. This system was been designed to control thefts in private areas and to provide more security and authenticity to the users, as we are using finger prints for identifying the persons this was one of the most efficient way to identify people because the fingerprints will acts as the unique IDs for persons.

The development steps or method that outlines the way to achieve certain goal or in this case design and build a prototype Fingerprint based exam hall authentication. In other words, it is a constructive framework. Below in figure , methodology flow block diagram of this project is shown.

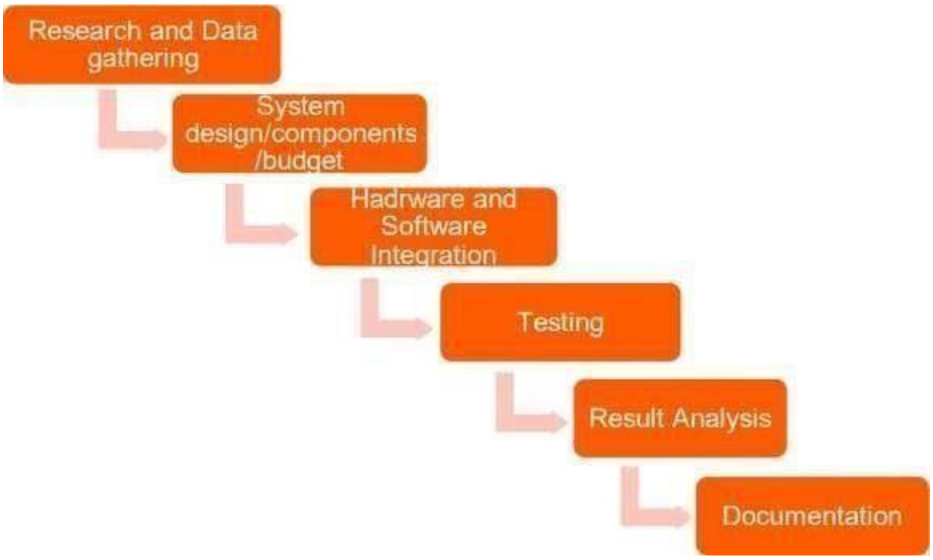

Fig 1.1: Flow diagram methodology

1.2 SCOPE OF THE STUDY:

The world is going through a global crisis due to the contemporary COVID 19 pandemic situations. In these taxing times, students have been severely affected. So our government has not compromised their future and has decided to conduct all competitive examinations. Thus, it becomes crucial for the students to register for the exams. However, the traditional exam hall authentication system does not assure that the students would not be exposed to the infection. So it is important to come up with a solution for this scenario. This paper presents a model in which the student's registration and authentication happen using the fingerprint sensor and Atmega328 microcontroller in addition to recording the student's body temperature by the LM35 temperature sensor. The data is transferred to a cloud server where it can be monitored and analyzed. The system integrates different hardware components like microcontroller, fingerprint module, LEDs, switches that facilitates a flawless authentication. For the implementation of this system, DY50 fingerprint sensor is used to take user finger print image and store in internal memory, these images are further processed and analyzed using Arduino. The user interface is implemented using LCD screen, which is mainly used to print user instructions during the execution of the process and the result.

1.3 MATERIALS REQUIREMENT:

1.3.1 HARDWARE COMPONENTS:

- ARDUINO UNO (ATMEGA328) MICROCONTROLLER BOARD

Fig:1.2 Arduino Uno board

- FINGER PRINT SCANNER ALONG WITH 3 PUSHBUTTONS

Fig:1.3 Fingerprint scanner

- LCD DISPLAY (16*2)

Fig:1.4 LCD Display

- POTENTIOMETER

Fig:1.5 POTENTIOMETER

- MB27L-12V PIEZO BUZZER

Fig:1.6 Piezo buzzer

1.3.2 SOFTWARE REQUIREMENTS:

1.3.2.1 ARDUINO IDE SOFTWARE:

This software is basically used for giving commands to ARDUNO Microcontroller**.**

STEPS FOR INSTALLING ARDUNO IDE SOFTWARE:

1. Download Arduino IDE Software in your PC.

2. When the download finishes, proceed with the installation.

3. Allow the driver installation process when you get a warning from the operating system.

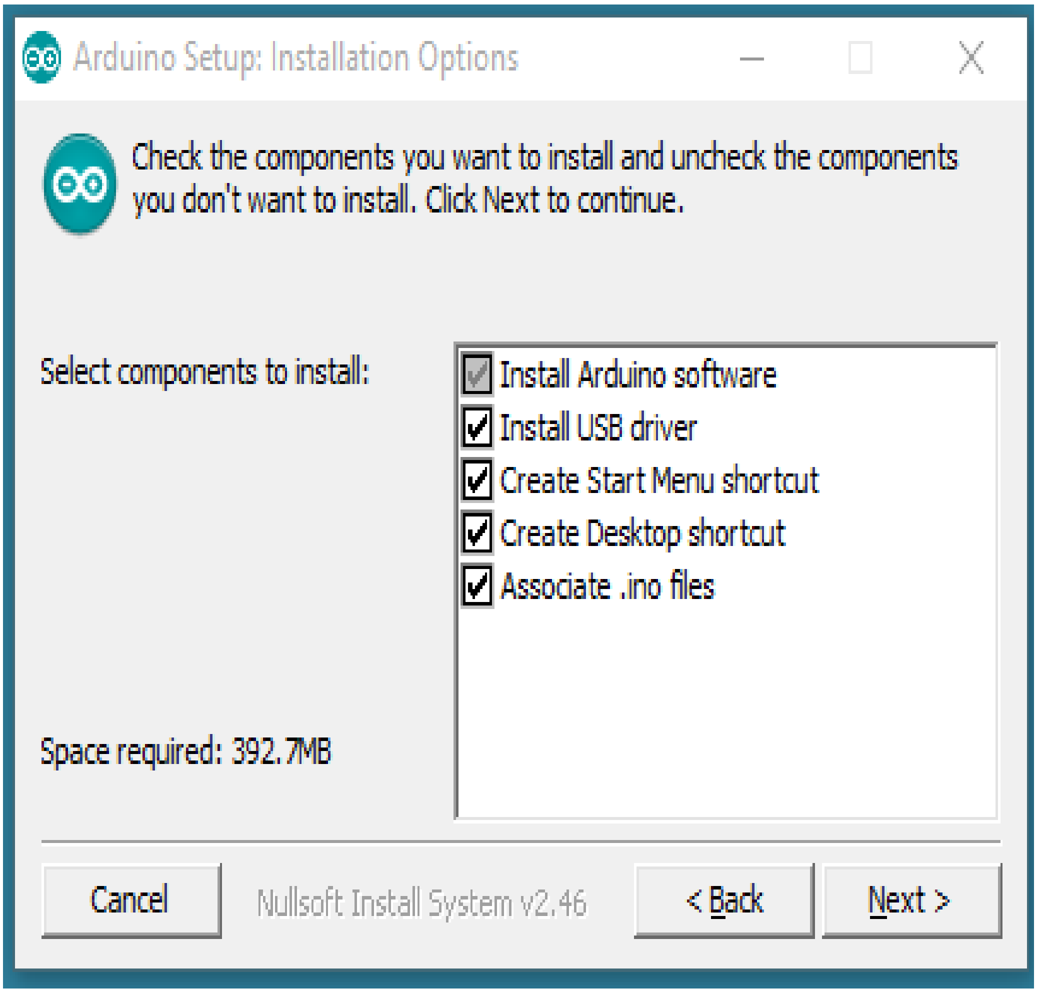

Fig:1.7 Installation process of driver

4. Choose the components to install

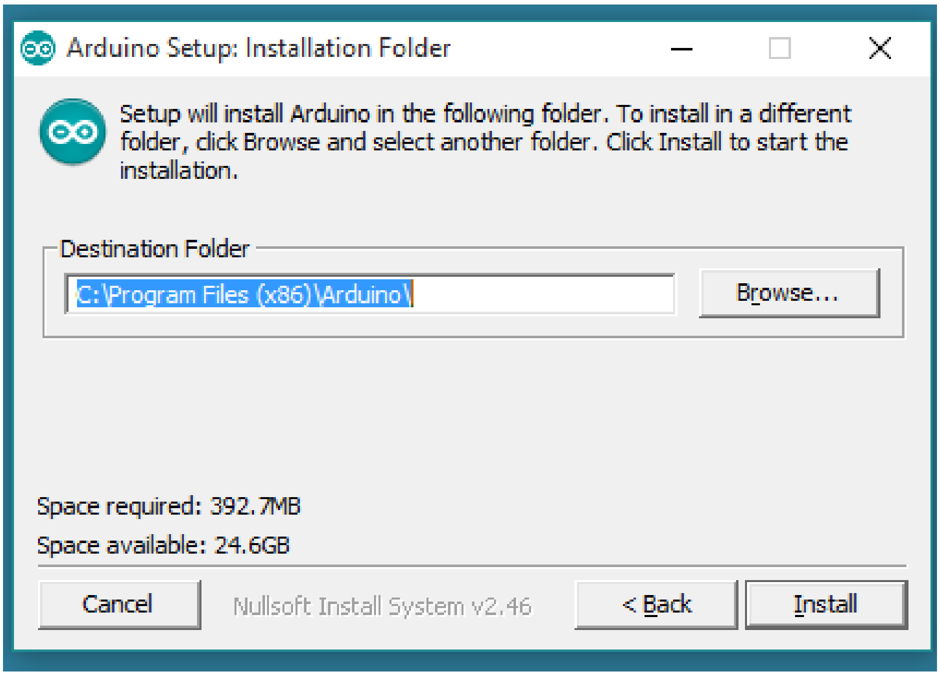

Fig 1.8 Setting destination folder

5. Choose the installation directory (we suggest to keep the default one)

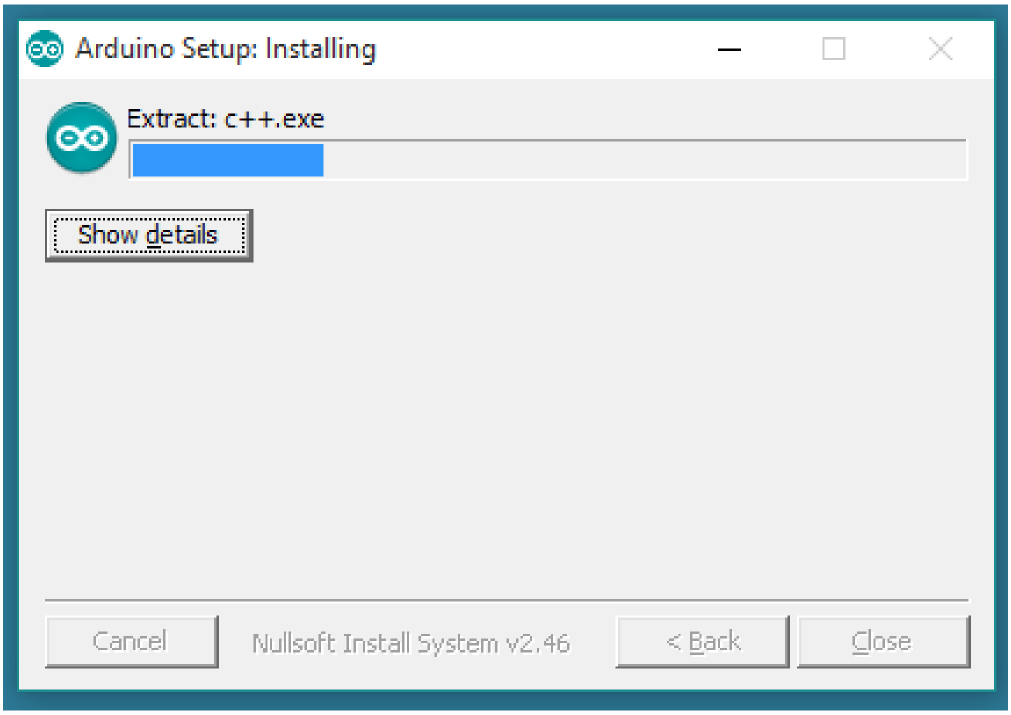

Fig:1.9 Installing directory

6. Successfully completed Installation of Software

7.Writing code on IDE platform

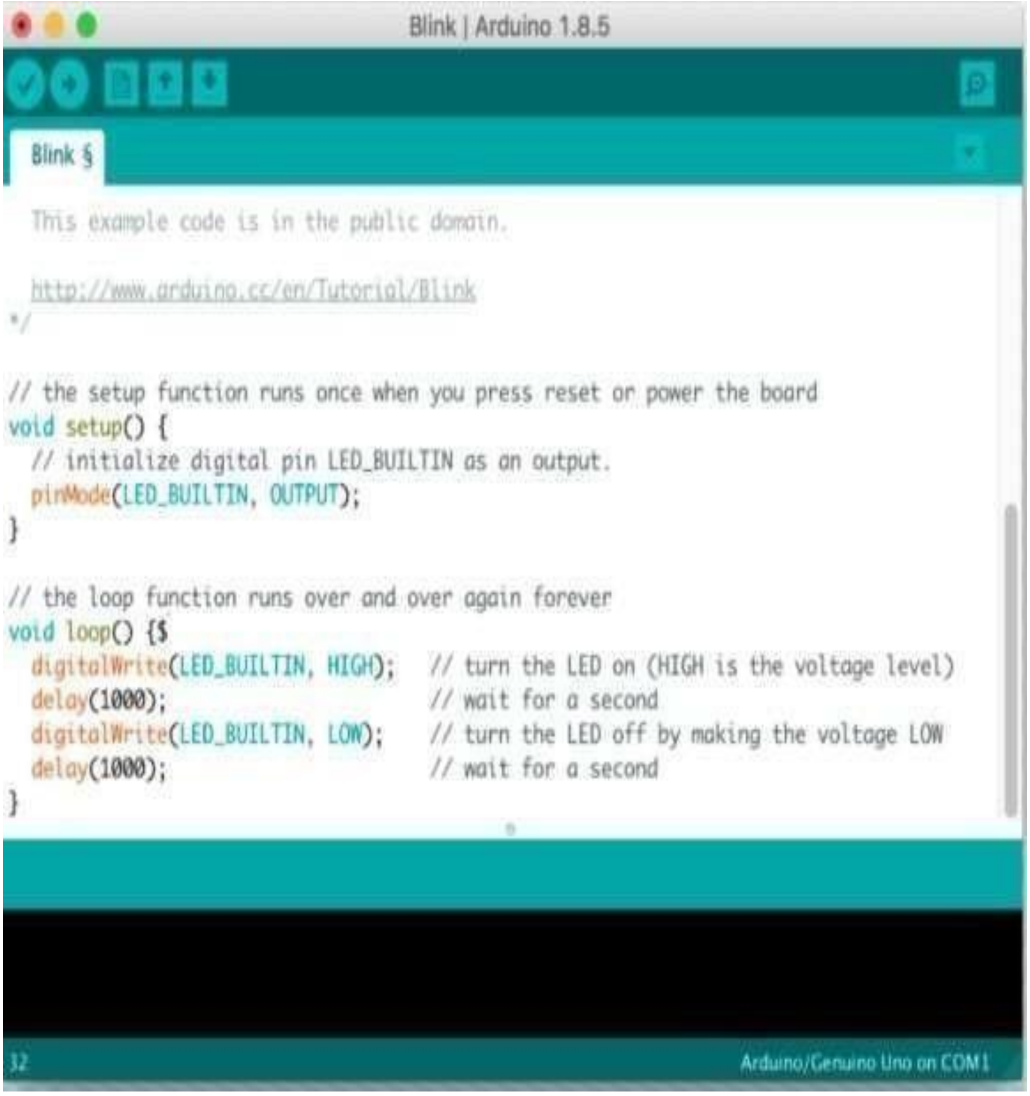

Fig:1.10 Source code written on IDE platform

1.3.2 PROTEUS SOFTWARE:

Through this software Schematic implementation of the embedded system will be done**.**

The topic of this paper is channel of this development of impersonation elimination system and this system would strictly with the subject having to claim as identify. The topic of this paper is channeled towards the unique feature of identification of fingerprint. A verification system based on the fingerprint and the term verification.

STEPS FOR DESIGNING SYSTEM ON PROTEUS DESIGN SUITE:

Step 1**:** Open ISIS software and select new design in File menu

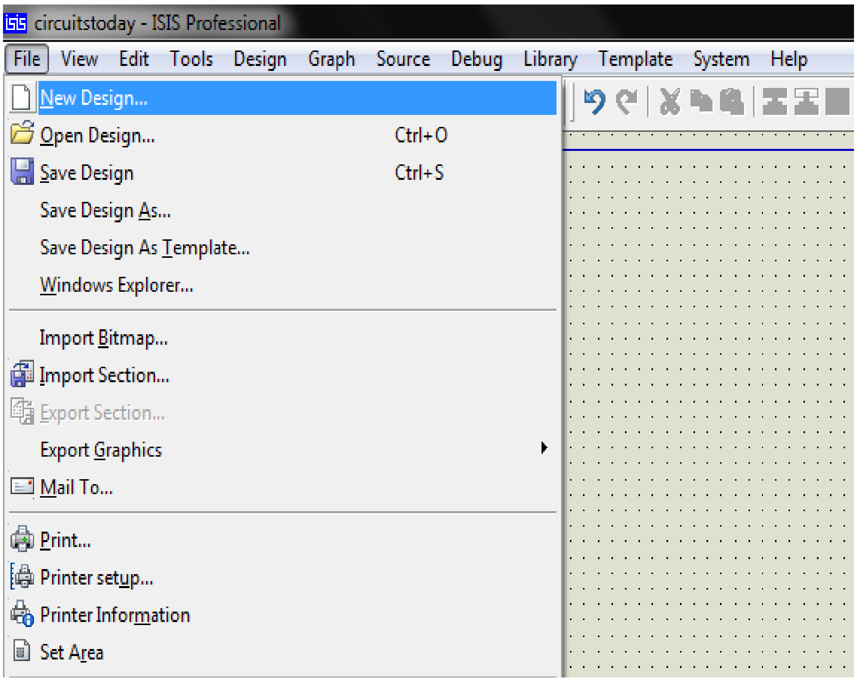

Fig:1.11 Simulation Procedure 1

Step 2**:** A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

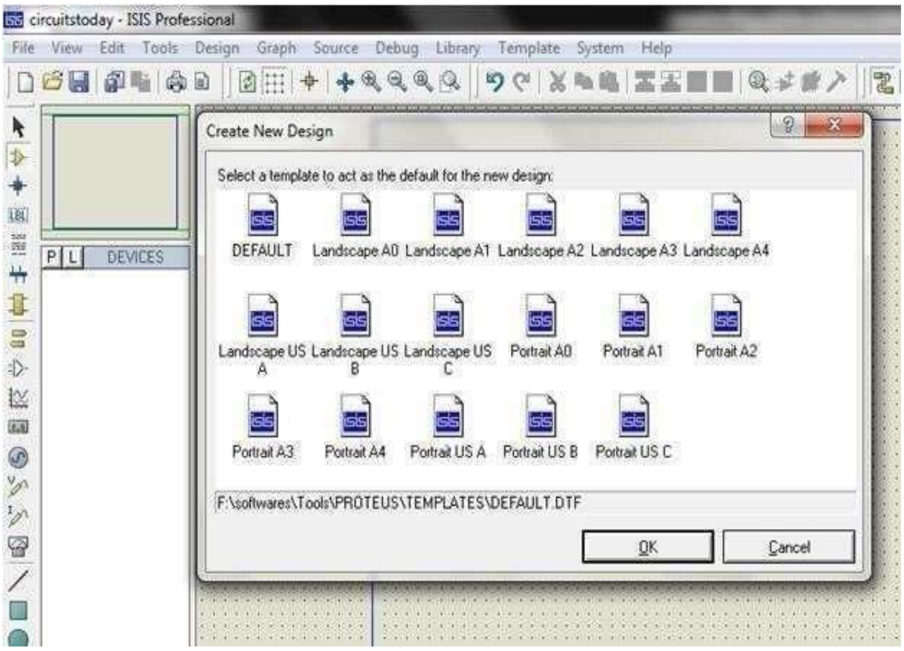

Fig:1.12 Simulation Procedure 2

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design.

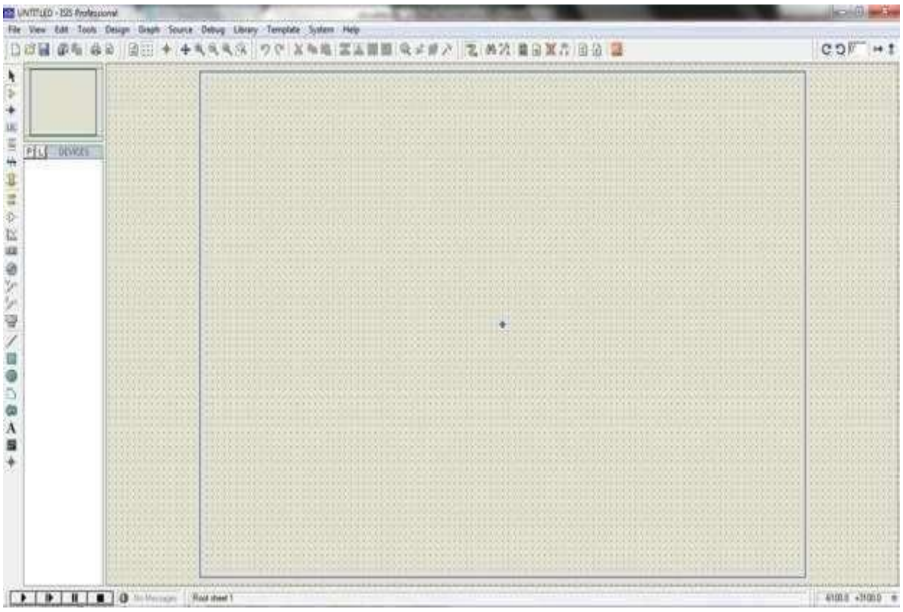

Fig:1.13 Simulation Procedure 3

Step 4: To Select components, Click on the component mode button.

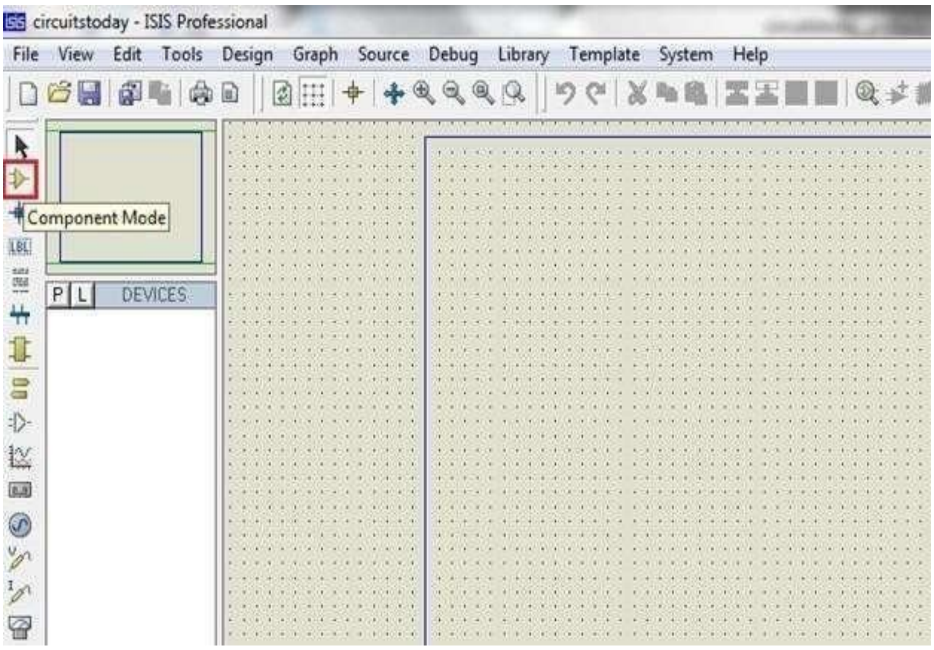

Fig:1.14 Simulation Procedure 4

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

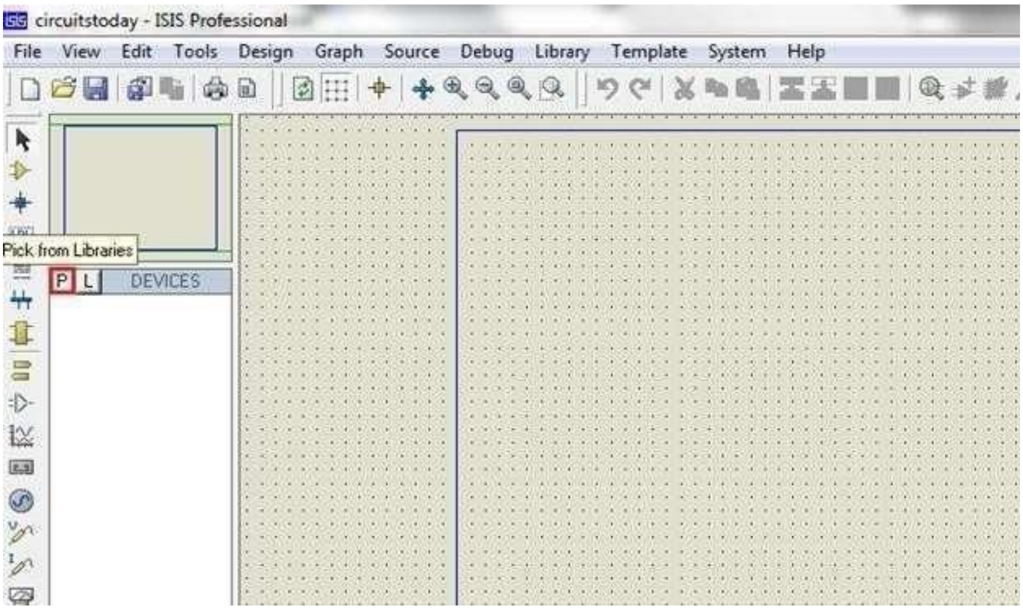

Fig:1.15 Simulation Procedure 5

Step 6: Select the components from categories or type the part name in Keyword's text box.

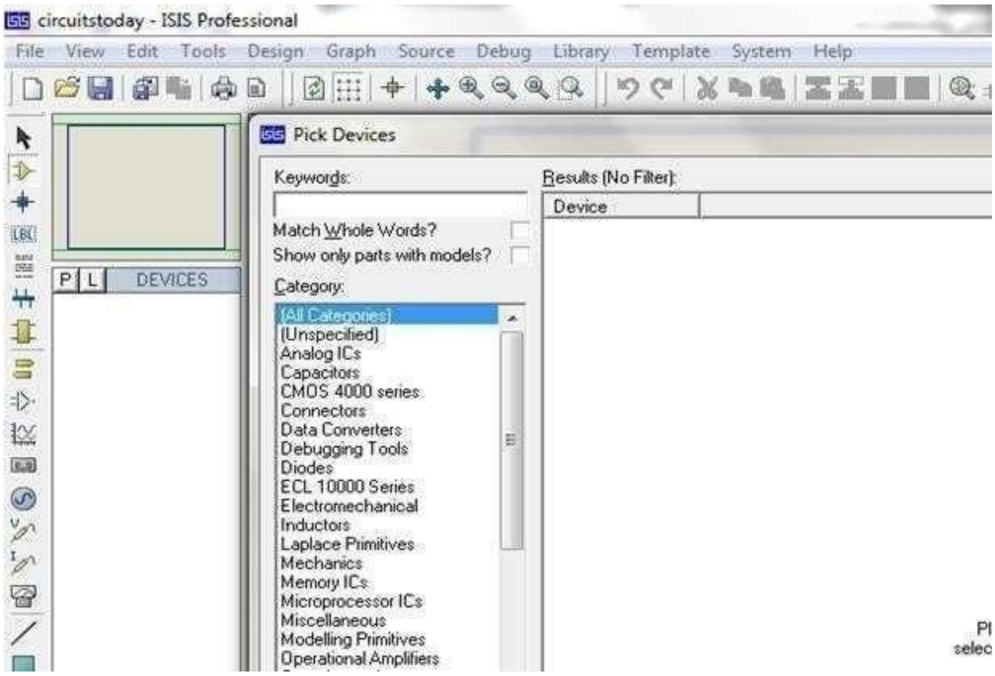

Fig:1.16 Simulation Procedure 6

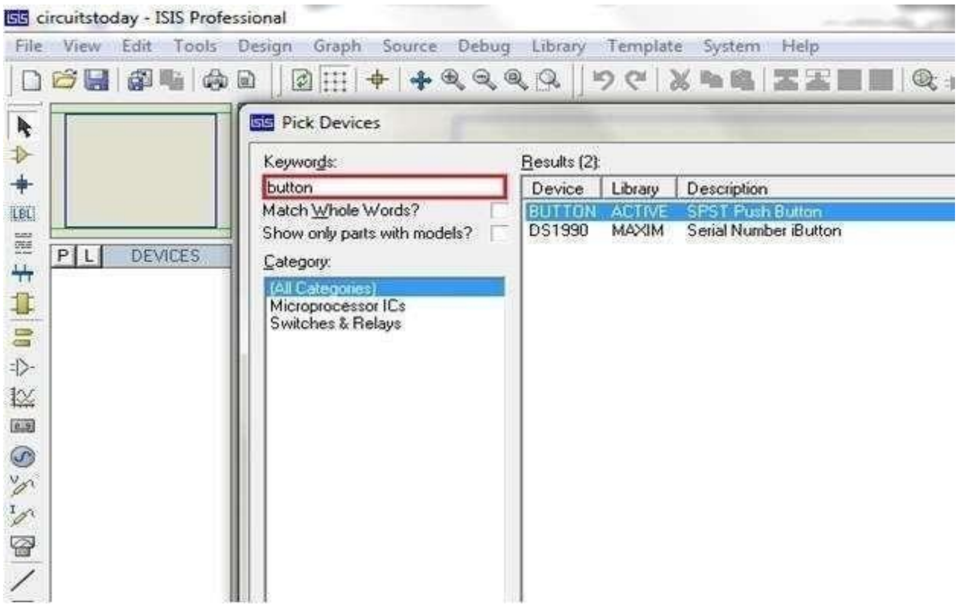

Fig:1.17 Simulation Procedure 7

Step 7**:** The selected components will appear in the devices list. Select the component and place it in the design sheet by left-cl.

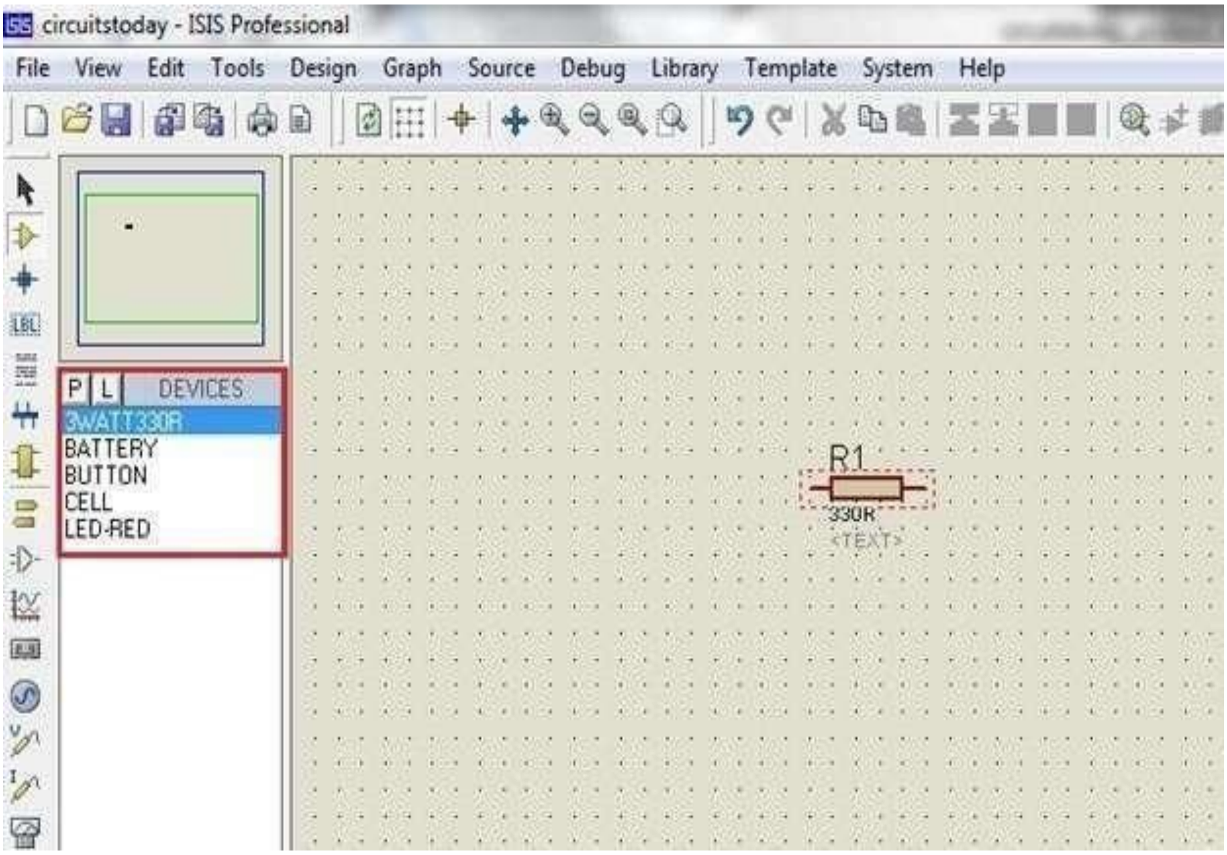

Fig:1.18 Simulation Procedure 8

Step 8: Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

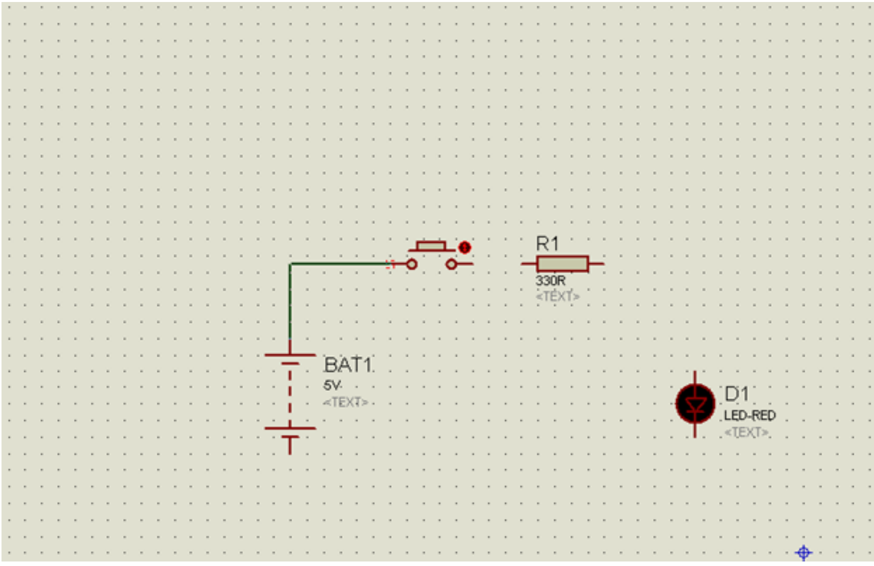

Fig:1.19 Simulation Procedure 9

Step 9: Double click on the component to edit the properties of the components and click on Ok.

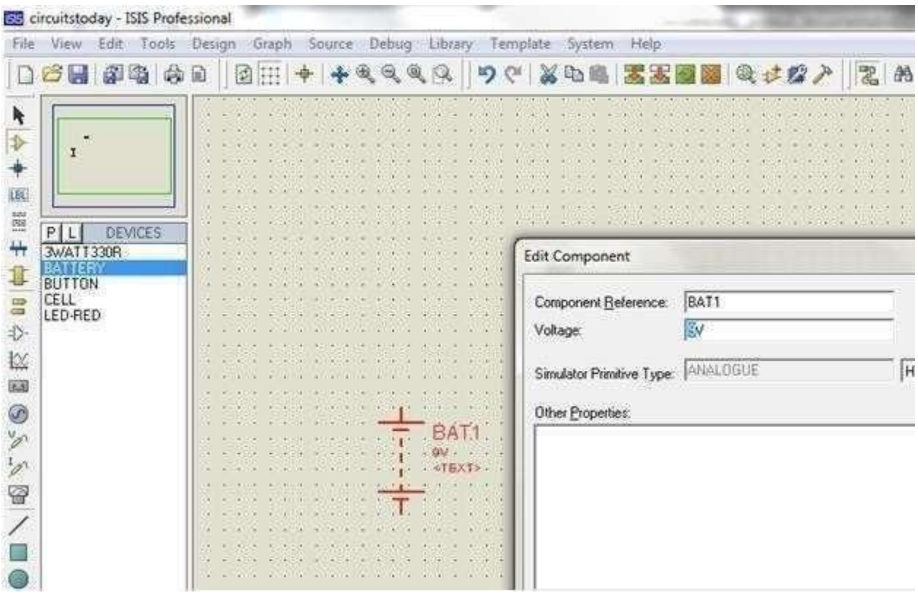

Fig.1.20 Simulation Procedure 10

Step 10: In this example simulation, the button is depressed during simulation by clicking on it to make LED

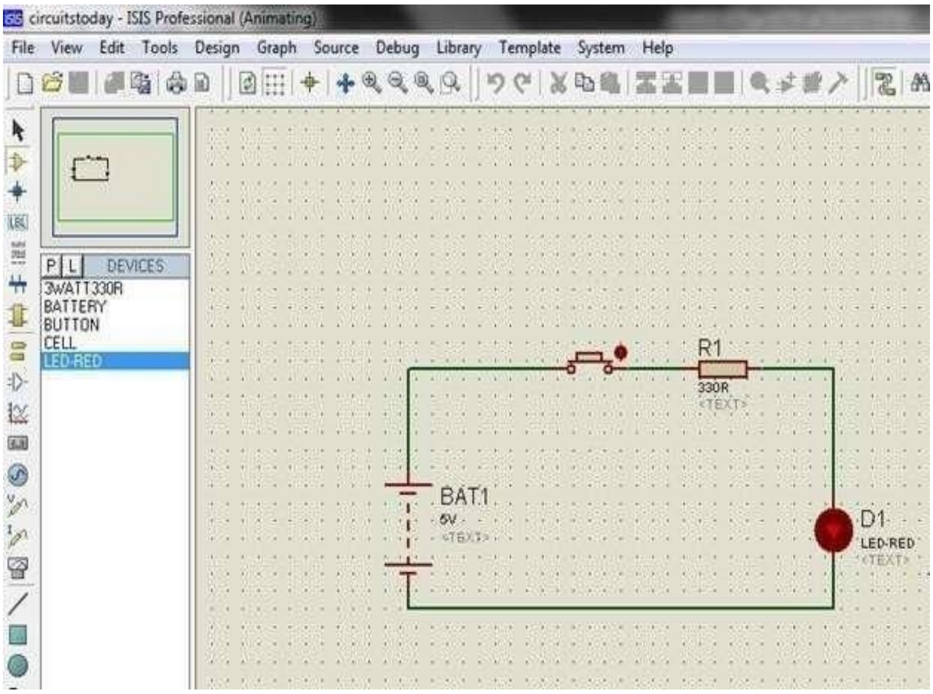

Fig:1.21 Simulation Procedure 11

Step 11: Simulation can be stepped, paused or stopped at any time.

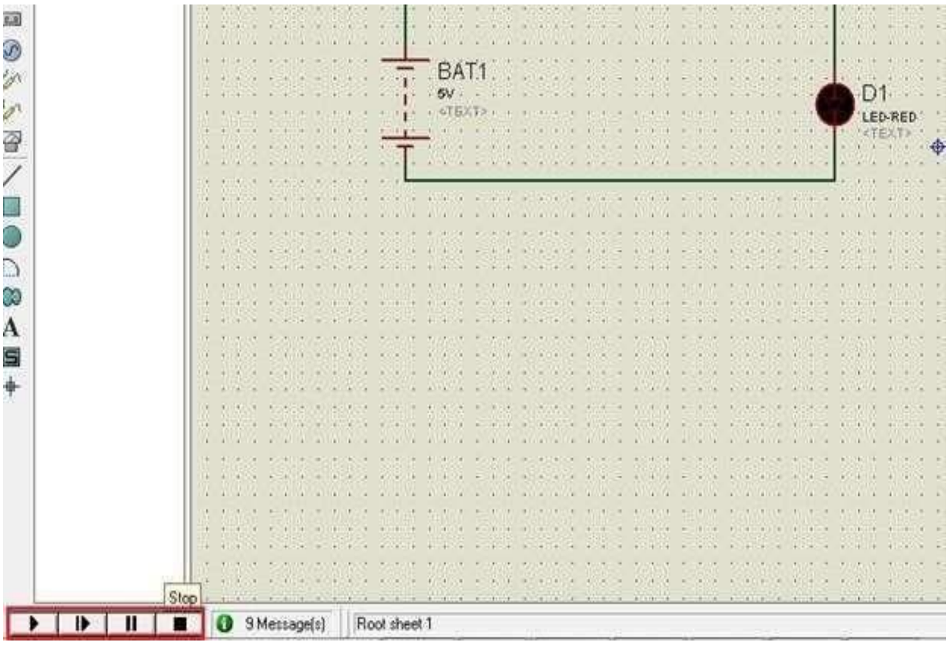

Fig:1.22 Simulation Procedure 12

1.4 PROCURMENT OF EQUIPMENT:

Fingerprints—the small ridges of skin on the fingertips which may enhance texture perception and grip friction—are unique to each person and have been used in identification for more than 100 years. Identification, the process of comparing a set of prints or a single print to others in a database, is used in many aspects of law enforcement and counterterrorism operations and investigations. Fingerprints may be compared to local and national databases for criminal history or to watch lists for border security. Latent prints from crime scenes are used in forensic investigations. Fingerprints can also be used to identify victims and for access control. Each application involves different processes for fingerprint capture and database searching and matching.

1.4.1 Components of Fingerprint Identification Systems

Fig:1.23 Finger print capture device

Fingerprint Capture the first step in fingerprint identification is obtaining an image of prints interest. Fingerprints deliberately collected from an individual are called exemplar prints, and may include simultaneous four finger images or rolled prints, which capture an image of each side the fingernail to the other. Exemplar prints have historically been obtained using paper and ink, which must then be optically scanned for database input. Live scanners electronically capture and store a digital image, eliminating paper and ink. Digitized prints are transmitted electronically for AFIS searches. Most current live scanners are based on optical sensors. Emerging technologies include thermal, capacitive, and ultrasound sensors, and some have to use a striped pattern projected onto the fingertip to obtain a three- dimensional image.

Minutiae Encoding

The second step in fingerprint identification is to extract the fingerprints which are identifiable characteristics to be used in a database search. Fingerprints can be sorted into general classification by pattern type, such as arch, loop, or whorl, but minute details such as the ridge endings or burifications are unique to each individual. Software identifies these minutiae and converts them into a system of numerical values. These minutiae templates are stored and used in searches instead of the whole image to reduce data and time requirements.

Recognition Software

An AFIS search involves the interaction of various databases where the minutiae are stored. Depending on the application, proprietary algorithms search segments of the database. For example, software may search the minutiae of two fingerprints of each subject, such as two index fingers, two thumbs, or a combination of finger and thumb. In other cases it may be necessary to search a database of all ten fingers. The simplest type of search is an identity verification used for access control or credentialing applications. Another identifier, such as a username, is submitted with a single fingerprint to specify who is attempting the authentication.

Certifications and Evaluations

A wide variety of fingerprint capture equipment and proprietary matching algorithms are commercially available. Interoperability is critical to the identification process and is achieved through standards and certification. The FBI has established image quality specifications for fingerprint images as well as data compression requirements for storage and transmission. The FBI certifies equipment compatible with the IAFIS, including live scanners, card scanners, and printers. Certified products are listed at https://www.fbibiospecs.org/IAFIS/Default.aspx. The National Institute of Standards and Technology (NIST) leads developments in automating fingerprint identification and conducts evaluations of hardware and software. Some examples are fast Capture, an initiative to improve technology to capture 10 rolled equivalent prints in less than 15 seconds in a portable, rugged system; the Minutiae Interoperability Exchange (MINEX), which tests the use of a standardized minutiae template, rather than entire fingerprint images, for exchange of data between 1:1 matching systems; and the Fingerprint Vendor Technology evaluation 2012, which assesses the performance of 1:N matching algorithms based on proprietary fingerprint templates using a database of millions of fingerprint sets, including live scan and scanned inked cards.

Standards

Two standards are currently used in FBI certification. The image quality specifications for interoperability with IAFIS for fingerprint scanners and printers are contained in Appendix F of IAFIS- DOC-01078-9.3 Criminal Justice Information Services Electronic Biometric Transmission Specification. Fingerprint verification using 1:1 matching is the focus of the standard PIV-071006.

Development of national and international standards for fingerprint technology is ongoing, and many other standards are available. For example, ANSI/INCITS 381-2004 specifies data compression for image storage and transmission, and ANSI/INCITS 378-2009 defines a fingerprint standard minutiae template.

1.5.3 PROJECT DESIGN

1.5.4 PROJECT IMPLEMENTATION

1.5.5 PROJECT TESTING

1.5.6 CONCLUSION AND FUTURE ENHANCEMENT

CHAPTER 2

LITERATURE SURVEY

This chapter gives a brief overview of previous works done related to Fingerprint system.

2.0 INTRODUCTION:

The main idea of our project is to secure the places by using fingerprint sensor used to scan the finger of n the persons, the authorized people have to register their fingerprints to the system by using fingerprint sensor and each person is provided a particular ID which is stored in the data, Authorized people are the only eligible for vote, while the remaining people can't. For more security, the project is done along with buzzer indicator.

2.1 RELATED WORK:

Biometrics is a way used to recognize a person based on his physical nature. The fingerprint, iris, face, voice, etc. are the mainly used biometrics to recognize a person. There are two key functions for biometrics, first is one to one matching and other is one too many matchings. In one to many matching the biometric sample is compared with the already stored samples. In one to one matching, it compares with the previously stored sample. Biometric method results in a faster security, and more convenient method for user verification. Biometric method is better than password security. Fingerprint is unique for each individual so it can be used as a mark of signature, verification and authentication. Fingerprint is the biometric which is used in this project. Finger-print will be different for each individual. In this project, fingerprint is used for the authentication of the user on his fingerprint image. Finger-print matching can be divided into three types: correlation based matching, minutiae-based matching, pattern- based (or image- based) matching. In correlation based matching, two fingerprint images are superimposed and therefore the correlation between corresponding pixels is computed for various alignments. In minutiae- based matching, minutiae from the two fingerprints are extracted and stored in a two-dimensional plane as a set. This matching method consists of finding the alignment between the template and the input minutiae sets that result in the maximum number of minutiae pairings. In pattern-based (or image-based) matching method it compares with stored template and the candidate's fingerprint. This requires that the images to be aligned within the same orientation. To do this, the algorithm finds a central point within the fingerprint image and centers there on. In a pattern- based algorithm, the template contains the sort, size, and orientation of patterns within the aligned fingerprint image. Almost all the sectors are storing data digitally. To create digital India, most of the tasks are made through on-line. and implementation of ID authentication system based on Fingerprint Identification is designed, and finally. the problem at hand, which is exam student impersonation and corruption is Tertial Education will be demolished and to demonstrate that anything can be achieved using computer technology in this fast growing Information Technology and computer communication world . Simulation phase of this project has been achieved, with the following devices: Microcontroller (Atmega 328), LCD display device (LM016L), regulated DC power supply, Keypad-phone, Virtual Terminal, X1 Crystal clocking, Variable Resistor, and Capacitors. Regulated DC power supply is used for powering the devices on the system and it has to be regulated to avoid too much power to burn the device and to be too low for it to be insufficient for the devices operations. Microcontroller, this is the heart of the whole system, it is there to facilitate the connection between devices, control the operation of every device connected on this system, it has clocking equipment that must be synchronised with the crystal clocking device to ensure precise operation of the system. Keypad, this device is used as a input device used by the user (student) when they are entering their password during authentication process. LCD display is used as the output device of the whole system because, every message that the system need to convey to the user, is display on here, starting from displaying the name of the system (Fingerprint based exam hall authentication), asking the user to place their fingers (Put your finger), displaying the results of the authentication (Enter the passkey or Access denied student not registered) and the final display if the user's passkey is correct (Access granted). Variable resistor, this is to give brightness to the LCD display. Crystal Clocking, this has the simple task, which is to provide clocking to the system, clocking which is synchronised with the clock of the microcontroller.

Virtual Terminal is used as input device as well to input the student number of the student when the system ask the user to put their finger, because there is no fingerprint scanner on the system, so this device is used in the simulation phase. And the final device are the capacitors, which are used to prevent the unwanted current from entering the system.

Although it was not an easy job, to prove that the proposed system is working according to how the real systems work. This was proved by implementing the project in simulation but its working according to the way it is intended to work. By simulating this project one will see the display on the LCD, the system writing the name of the project "Fingerprint based exam hall Authentication", few seconds later it will display the following message: "PUT YOUR FINGER" this is just to tell the subject (student) to be authenticated to put her/his finger on the fingerprint scanner for it to be able to read his/her fingerprints, after that if the student is authentic then the following message will be displayed: "ENTER YOUR PASSKEY", this is a password that every registered student got during registration/enrolment phase.

2.2 EXISTING METHODOLOGY:

Paper Ballots were used in India before 1997 for conducting the public elections. The existing system that we are using right now is very inefficient, time consuming and requires lot of patience to handle the situation. It requires man time to complete this process. For entering an exam hall the teacher should check the students ID and then make sure the person is suitable or not through ID cards, due to this there is lot of possibility of malpractices. Sometimes there might be a chance that the teacher or the guardian of the exam hall might not check the ID cards and because of that some other person might write the exam instead of the main person. This process that we are using right now is very time consuming, checking each and every student details is not a very easy task. The system that we using now currently are not secured because it requires student to provide certain physical documents such as student cards, examination application, etc. This kind of methods can be forged by almost anyone in the fast growing computer technology word.

2.3 PROPOSED METHODOLOGY:

The purpose of this project is to use the fingerprint identification to authenticate the identity of a private and therefore the main aim of this project is to differentiate between a licensed person (student) and an imposter before entering the examination hall. Here we proposed a finger print based exam hall authentication system. The system is meant to permit only users verified by their fingerprint scan and doesn't allow non verified users. Our system consists of a fingerprint scanner connected to microcontroller circuit. In registration mode the system allows to register user's information and save their identity with respective ID numbers within the system memory. After registration the person must scan his/her finger with the help of the scanner. The microcontroller checks the person's fingerprint. If the fingerprint valid the motor driver send a massage to open a door. This ensures only authorized users are allowed to enter the examination section and unauthorized users aren't allowed to enter the room.

CHAPTER 3

PROJECT DESIGN

3.0 OVERVEIW OF THE SYSTEM DESIGN

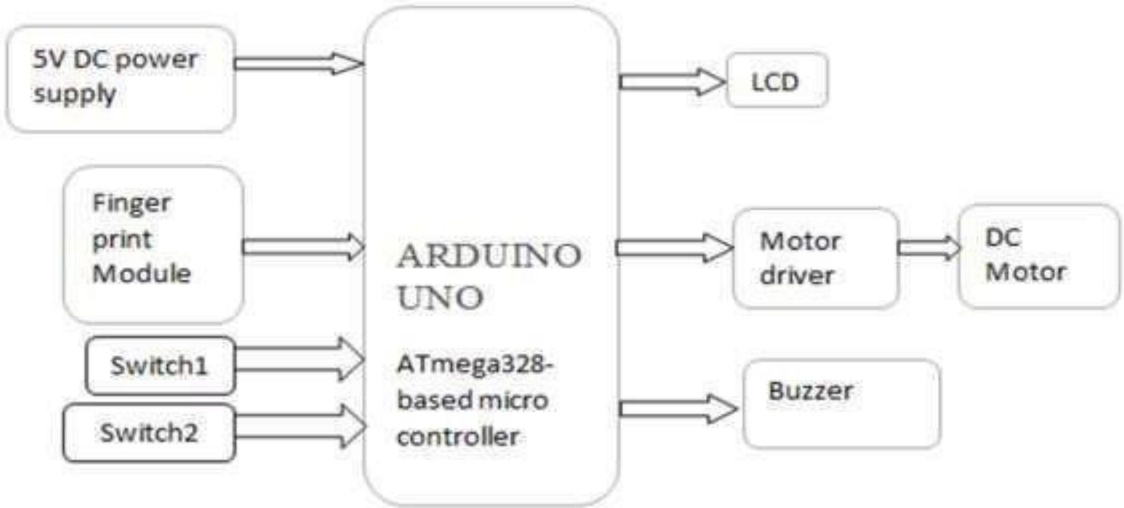

Fig:3.1 Block Diagram of finger print based exam hall authentication

3.1 SCHEMATIC DIAGRAM:

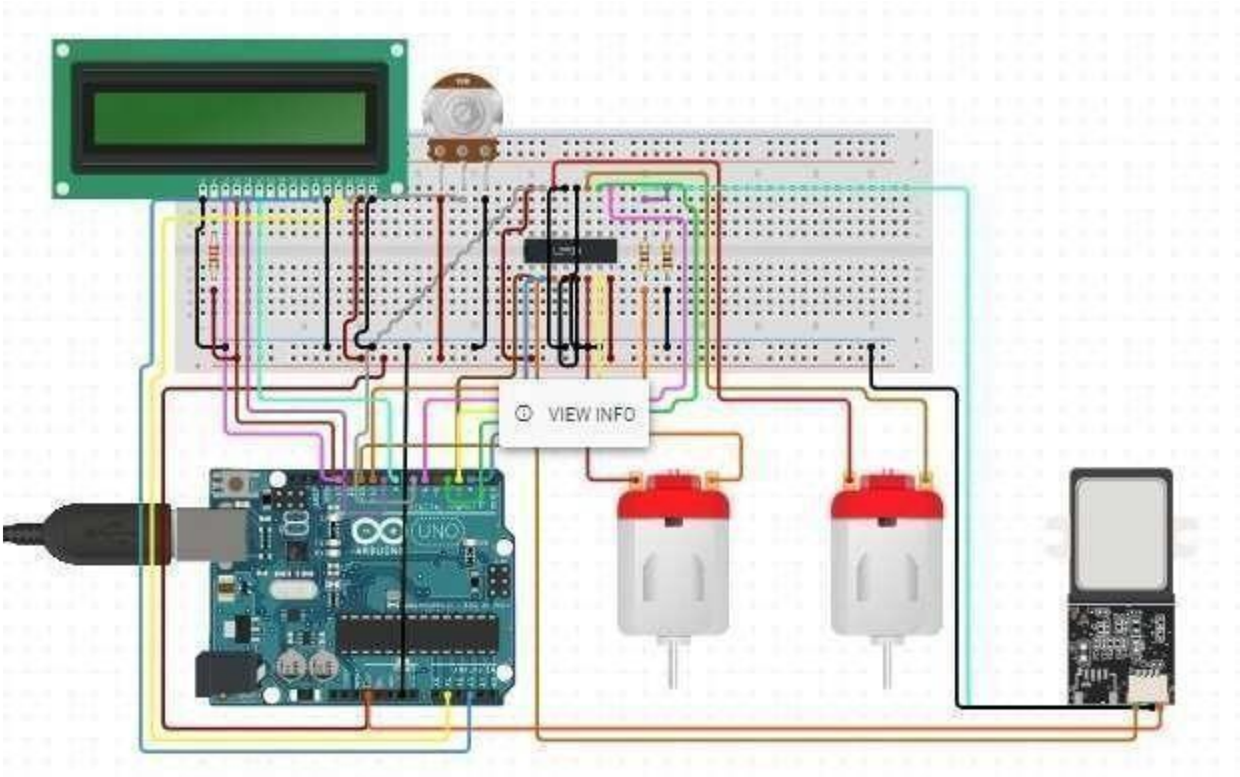

Fig:3.2 Simulation layout

The above schematic diagram of Finger Print Based exam hall authentication explains the interfacing section of each component with Arduino uno and input output modules

3.2 DEFINE THE MODULES:

3.2.1 FINGER PRINT MODULE:

Fingerprint Module consists of optical fingerprint sensor, high-speed DSP processor, high performance fingerprint alignment algorithm, high-capacity FLASH chips and other hardware and software composition, stable performance, simple structure, with fingerprint entry, image processing, fingerprint matching, search and template storage and other functions. Fingerprint module has two interface TTL UART and USB2.0, USB2.0 interface are often connected to the computer; RS232 interface may be a TTL level, the default baud is 57600, can be changed, ask a communication protocol, microcontrollers like ARM, DSP and other serial devices with a connection, 3.3V- 5V microcontroller are often connected directly.

Fig 3.3 : Fingerprint module

Specifications:

Here's the specifications of the fingerprint sensor module we're using (you should check your sensor datasheet or the specifications provided by your supplier – they shouldn't be much different than these):

- Voltage supply: DC 3.6 to 6.0V
- Current supply: <120mA
- Backlight color: green
- Interface: UART
- Bad rate: 9600
- Safety level: five (from low to high: 1,2,3,4,5)
- False Accept Rate (FAR): <0.001% (security level 3)
- False Reject Rate (FRR): <1.0% (security level 3)
- Able to store 127 different fingerprints

3.2.2 LCDMODULE:

An LCD (Liquid Crystal Display) screen is an electronic display module and has a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. A 16x2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5x7 pixel matrix. The 16 x 2 intelligent alphanumeric dot matrix display is capable of displaying 224 different characters and symbols. This LCD has two registers, namely, Command and Data.

Command register stores various commands given to the display. Data register stores data to be displayed. The process of controlling the display involves putting the data that form the image of what you want to display into the data registers, then putting instructions in the instruction register. In your arduino project Liquid Crystal Library simplifies this for you so you don't need to know the low-level instructions. Contrast of the display can be adjusted by adjusting the potentiometer to be connected across VEE pin.

3.3 MODULES FUNCTIONALITIES:

3.3.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are :

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

3.3.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino

IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	**Operation volt**	**Clock speed**	**digital i/o**	**Analog inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Table:3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
Lily pad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

3.3.1.2 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common

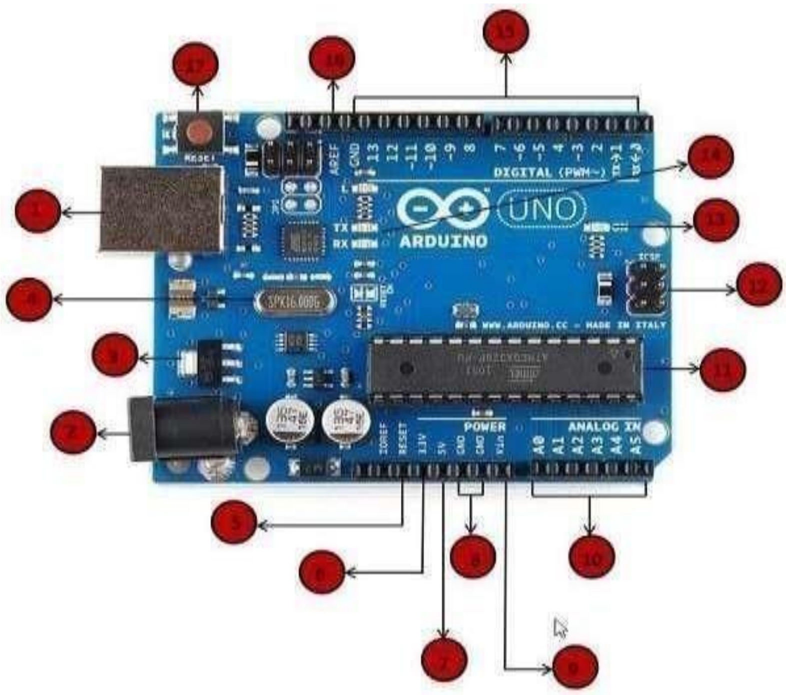

Fig:3.4 Board description of Arduino uno

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. GND (8) (Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.

10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

3.4 Liquid Crystal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D6).

When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller

3.4.1 Description of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

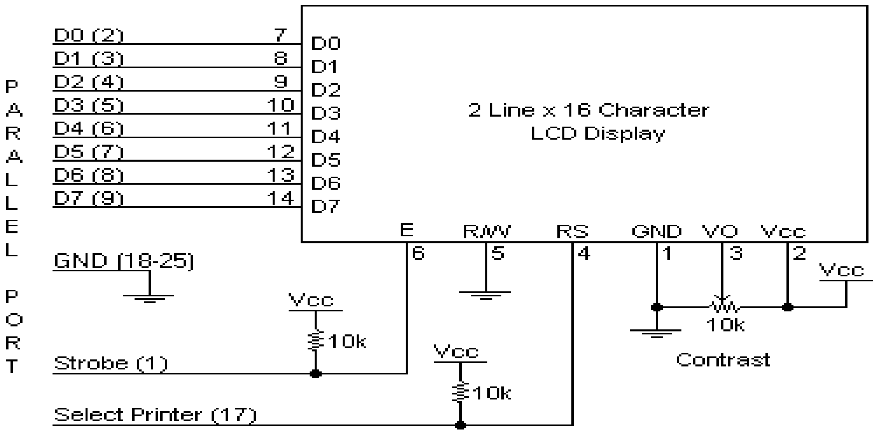

Fig 3.5: Schematic diagram

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

- We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use an onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

3.4.2 16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area.
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line.
- Can display 224 different symbols.
- Low power consumption (1 mA typical).
- Powerful command set and user-produced characters.
- TTL and CMOS compatible.
- Connector for standard 0.1-pitch pin headers.

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/ L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H>L	Enable

Table:3.5 16x2 LCD Features

3.4.3 FEATURES:

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Table:3.5 Data Location in LCD

3.4.4 Figure Address locations for a 1x16 line LCD

Even limited to character-based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one-, two- and four-line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improvedcontrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

3.4.5 Pin Description In LCD:

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers has 16 Pins (two pins are extra in both for back-light LED connections).

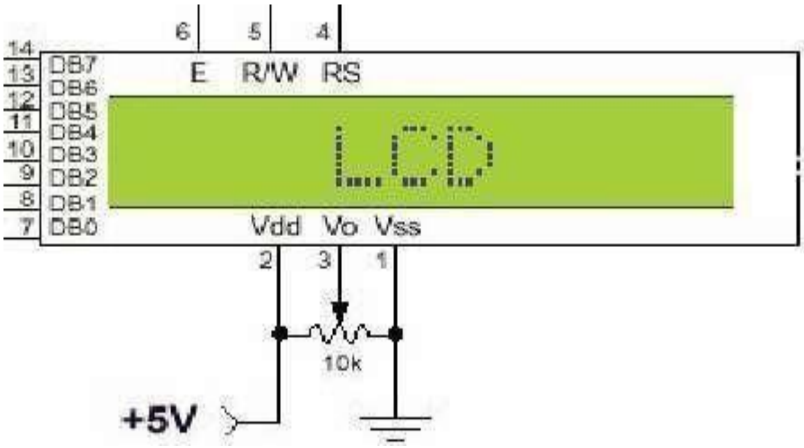

Fig:3.6 Pin Description of 1x16 lines

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table 3.7 Pin specifications

3.4.6 CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5,DB6,and DV.

Logic status on control lines

- E - 0 Access to LCD disabled.
- 1 Access to LCD enabled.
- R/W - 0 Writing data to LCD.
- 1 Reading data from LCD.
- RS - 0 Instructions.
- 1 Character.

Writing data to the LCD

- Set R/W bit to low.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Read data from data lines (if it is reading) on LCD

- Set R/W bit to high.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Entering Text

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table:3.8 LCD Commands

3.5 Fingerprint Sensor

The fingerprint sensor can read different fingerprints and store in its own flash memory. The sensor can perform three functions namely Add (Enroll), Empty Database or search database and return the ID of stored fingerprint. Any of three functions can be called simply by making the pin low of the sensor or pressing onboard three switches. The response is either error or ok which is indicated by onboard LED. The response is also returned as single serial data byte.

The return byte is a valid ID or error code. The response byte is a single byte at 9600 bps thus making whole sensor very easy to use. We have provided indicating LEDs and function switch already so it’s ready to use when you receive it. Just give power and start using the sensor using onboard switches. Then you can move on making external application using these functions.

3.5.1 Inputs and Outputs of Sensor

Input: Two ways to trigger the function of fingerprint sensor

- Onboard switch: Add, Empty or Search.
- Make pin low from external microcontroller for 5ms as per function required to be executed.

Output: Two ways to monitor output response after a function is executed

- Onboard LEDs: ERROR or OK.
- Read byte after executing function.

3.5.2 Types of Sensor Function

There are namely three functions you can call for the fingerprint sensor. We will see each in brief.

Add (Enroll) Function: Adds a fingerprint to database and return a byte of newly added ID. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function

Search Function: When a finger is put and search function is called, it returns a matching ID if found in its existing memory. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function.

Empty Function: When you wish to empty all fingerprint, data stored on sensor you can use this function. After executing this function, you will get 0xCC as OK or 0xFF in case of error.

3.5.3 Fingerprint Recognition Sensor Module

The sensor is a solid-state fingerprint sensor that reliably captures fingerprint information. It is designed to integrate into devices for improved security and convenience. The sensor provides are liable, quick and user-friendly alternative to passwords, PIN's and other forms of user authentication. This fingerprint scanner is capable of gathering and storing unique finger prints. Simply hold your finger on the optical scanner, query the device over serial, and you will be issued a unique ID. Use that ID within your embedded system to determine access levels, time clocks, door locks, etc. Unit includes 4 pin connector cable to connect and read to controller. The outputs are TTL level serial data. A biometric sensor, fingerprint sensor to be specific, also known as the fingerprint reader, is a fingerprint image capture device, the very front end of the biometric fingerprint identification/verification module. The fingerprint sensor captures the fingerprint images, matches the uniqueness of each print read by the sensor and compares it to the one stored in its module or local system database.

It consists of optical fingerprint sensor, high performance DSP processor and Flash. It boasts of functions such as fingerprint enrollment, fingerprint deletion, fingerprint verification, fingerprint upload, fingerprint download, etc.

3.5.4 Applications

- Computer peripherals – improves security and convenience
- Transportation systems – validation of operators, drivers and inspectors
- Medical equipment – authorization of operator or technician
- Physical access systems – approval for entry
- Kiosks and vending machines – confirmation of person receiving the selection
- Point of Sale terminals – authentication of tellers and cashiers

3.5.5 Features

- Rugged, solid-state optical fingerprint sensor
- High resolution 500 DPI imager
- Adapts to wet/dry fingers
- Simple Interfacing protocol

Fig:3.7 Fingerprint sensor

3.5.6 Specifications of Sensor

- Fingerprint enrollment time <250ms
- Fingerprint search time <1s（100 fingerprint, average value in test） Resolutions 500 DPI
- Security level 5, Adjustable Capacity 768 Templates
- FAR <0.0001%

- FRR <0.01%
- Power Supply 4.3V to 6V Working Current <80mA Peak Current <90mA Communication Interface TTL
- Communication Baud Rate 57600 bps Working Temperature -10 deg C to +40 deg C
- Working Humidity 40% RH to 85% TH (no dew) Module Dimensions 60x21x25 mm (LxWxH)

3.6 BUZZER:

3.6.1 Types of Buzzer

Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

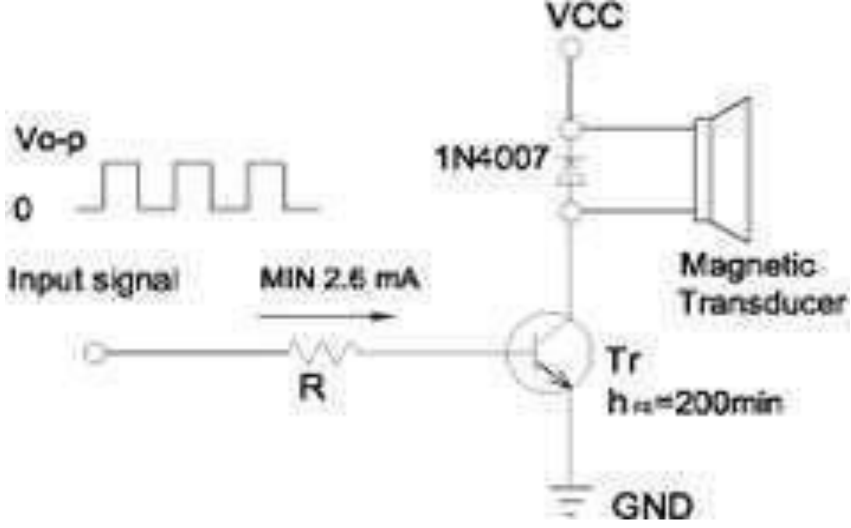

Fig:3.8 Driving Circuit for Magnetic Transducer

3.6.2 Specifications of buzzer:

- **Rated Voltage**: A magnetic buzzer is driven by 1/2 square waves (V o-p). **Operating Voltage**: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
- **Consumption Current**: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
- **Direct Current Resistance**: The direct current resistance is measured by ammeter directly. **Sound Output**: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
- **Rated Frequency**: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
- **Operating Temp**: Keep working well between -30°C and +70°C.
- **Driving methods**: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.
- **Dimension**: Dimension affects frequency, small size result in high frequency.
- **Voltage**: Depend on V o-p (1/2 square waves)
- **Fixed methods**: From the highest cost to the lowest- DIP, wires/ connector, SMD.

3.6.3 How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer starts to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer needs to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of silicon.

Fig:3.9 Buzzer

3.7 Switches

A switch is an electrical component that can break an electrical circuit, interrupting the current or diverting it from one conductor to another. The most familiar form of switch is a manually operated electromechanical device with one or more sets of electrical contacts. Each set of contacts can be in one of two states: either 'closed' meaning the contacts are touching and electricity can flow between them, or 'open', meaning the contacts are separated and non-conducting.

Fig:3.11 Switches in a row

Switches with larger numbers of poles or throws can be described by replacing the "S" or "D" with a number or in some cases the letter "T" (for "triple"). In the rest of this article the terms *SPST*, SPDT and intermediate will be used to avoid the ambiguity in the use of the word "way".

3.7.1 Working of Switch

A pair of contacts is said to be "closed" when current can flow from one to the other. When the contacts are separated by an insulating air gap, an air space, they are said to be "open", and no current can flow at typical voltages.

Switches are classified according to the arrangement of their contacts in electronics. Electricians installing building wiring use different nomenclature, such as "one-way", "two- way", "three-way" and "four-way" switches

In a push-button type switch, in which the contacts remain in one state unless actuated, the contacts can either be normally open (abbreviated "no." or "no") until closed by operation of the switch, or normally closed (″n.c. or "nc″) and opened by the switch action. A switch with both types of contact is called a changeover switch. These may be "make-before- break" which momentarily connect both circuits, or may be "break-before-make" which interrupts one circuit before closing the other

3.7.2 APPLICATIONS

- They are used for the given instructions to the required device like robot, driving the motor, etc.
- Switches can arrange in the matrix from or in the required from according to the application.
- **Reset circuit of the controller, motor also has the switches for its particular functioning.**

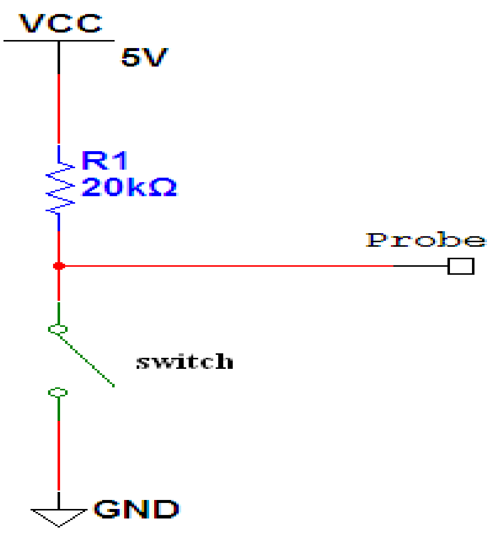

Fig:3.12 Circuit of Switch

From the above circuit it explains the working of the switch when supply is given to the circuit the resistor takes the current and oppose to the certain extend until the switch is pressed. These switches can be connected parallel or serial in required manner.

We can have resistor, capacitor, light resistor diode etc. as the combination of the switch. For example, w the reset circuit in which we the resistor and capacitor as the combination.

From the above circuit it explains the working of the switch when supply is given to the circuit the resistor takes the current and the oppose to the certain extend until the switch is pressed. These switches can be connected parallel or serial in required manner.

CHAPTER 4
PROJECTIMPLEMENTATION

4.0 IMPLEMENTATION STAGES:

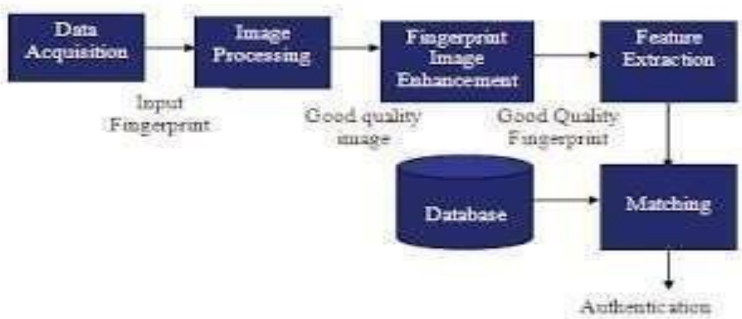

Fig:4.1 Implementation of Finger print based exam hall authentication

1. Algorithm of Fingerprint Based Voting System:
Step 1: Start

Step 2: Users can register by giving their fingerprints. We use a microcontroller to store them.

Step 3: Scan your finger

Step 4: If match found go to step 5 else return to step3

Step 5: user checks their detail

Step 6: enrolled

Step 7: cast your fingerprint

Step 8: verified

Step 9: Stop

2. Fingerprint Identification and Matching:

Fundamentally, we utilize advanced imaging innovation in securing, putting away, and dissecting the unique mark information.

1. Acquiring Images:

In the image identification process, the first step is to obtain an image as, without it, we cannot perform further steps. To acquire an image of a fingerprint, the person needs to place their finger on the sensor. Once the voter places their finger, on one end of the prism, the total internal reflection occurs through which we can capture the image using the image sensor and lens from another end of the prism. But the image extracted in this step is unprocessed.

The position and placement of the finger play a prominent role in the process of capturing an impression. For intensifying the total internal reflection and capture a fingerprint of good quality with the image sensor, we need to make sure that the finger is placed correctly on the module.

2. Storing the images:

The unprocessed image acquired in the previous step is now processed using image segmentation.

Image Segmentation: The captured images may contain some redundant data and noise along with required data, so we use image segmentation in which we divide the image into many segments called pixels to remove the irrelevant data. To ease the process of image analysis, we use image segmentation.

We use the normalization of an image to get even pixels. Once the pixels are uniform, it results in the formation of an image, and then to reduce or remove the noise present in it, we use the Gabor filter. The thresholding technique is implemented on the filtered image to change it into a binary image, then we compare threshold values and pixel values, if the value is higher than the threshold value then we set the pixel value to 1 else 0. Next, to remove some pixels from the foreground, we implement the thinning process. Finally, all the segments form a single image.

3. Analyzing the Image:

Finally, it shows to whom the user cast the vote.

Using image analysis, we can retrieve all related data from the image for further use. Mostly some electrical machines are used to collect the required data. According to this project, the electrical machine is a fingerprint module through which we capture the fingerprint. The retrieved data from the image can be compared with data stored in different storage devices for identification, authentication, etc.

4.1 WORKING FLOW OF THE PROJECT:

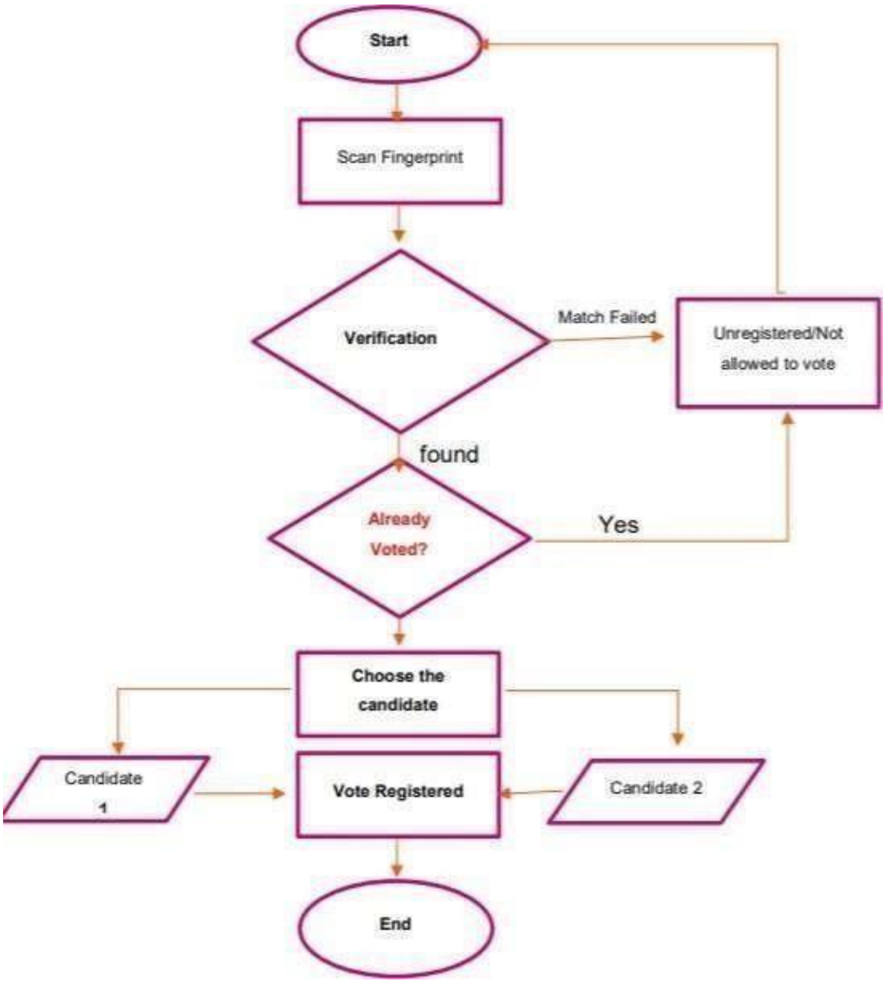

Fig:4.2 Working flow of Finger Print Based Exam Hall Authentication

4.2 EXPERIMENTAL RESULTS:

By simulating this project one will see the display on the LCD, the system writing the name of the project "Fingerprint based exam hall Authentication", few seconds later it will display the following message: "PUT YOUR FINGER" this is just to tell the subject (student) to be authenticated to put her/his finger on the fingerprint scanner for it to be able to read his/her fingerprints, after that if the student is authentic then the following message will be displayed: "ENTER YOUR PASSKEY", this is a password that every registered student got during registration/enrolment phase.

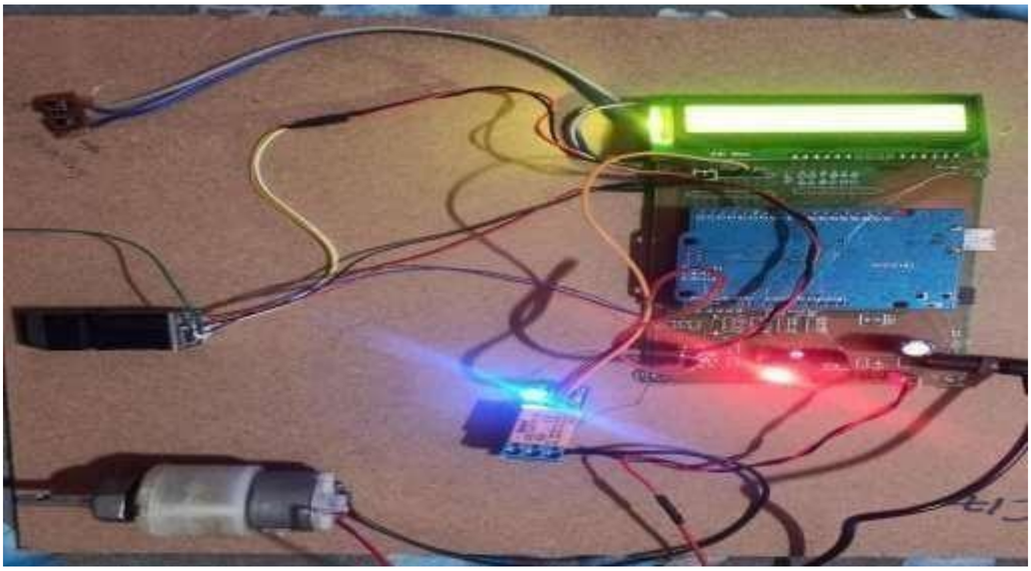

Fig 4.3:Overall design

4.2.1 INTERPRETING EXPERIMENTAL RESULTS:

Fig:4.4 Displays Commands in LCD

Fig 4.5 Finger print Scanner

Fig:4.6 Displayed on LCD “User not authorized”

Fig:4.7 It shows the result obtained after authentication

CHAPTER 5
ADVANTAGES AND LIMITATIONS

5.0 ADVANTAGES

Some advantages of using this system are discussed below:

- Safe: It is an utmost important that the process be secure and no one should be able to tamper with the result before, during authentication process. Since the system is not connected to internet, no online external influence can occur. Also, it is very easy for security personnel to secure the device if needed.
- Cost: The conventional paper system used in Nepal is very expensive because of papers and printings, transportation, staff expenses and it takes several days to count the votes. On the other hand, the biometric fingerprint system is cheap, compact and can store any amount of data with proper upgrade.
- Accuracy and Reliability: There is a very slim chance of errors happening from electronic system so, people can rely on results to be accurate.
- Time Saving: It takes weeks to organize the authentication. This time frame is not peaceful for that area so it is ideal to get result as soon as possible. With electronic device results can be produced is minutes rather than days or weeks

5.1 LIMITATIONS

- The collection of fingerprints of all students is little difficult.
- The personal details of the students does not verifying in this system other than fingerprint.
- Only fingerprints of the student is identified instead of identifying the person.

5.2 APPLICATIONS

This project can be used as authentication and it is a very simple and efficient way to organize a system.

1. Fingerprint is used to save time and get accurate results.
2. This system is trustable and very efficient.
3. This system is very useful in emergency cases.

CHAPTER 6
CONCLUSION AND FUTURE SCOPE

6.0 CONCLUSION

The project Biometric Model for Examination impersonation and Biometric Access is a better substitute for the use of Identity card in verifying users ‘identity Experience has shown the porosity of Identity cards in uniquely identifying individual in the face of sophisticated Forgery technology. The naturalness in the use of fingerprint makes it a reliable access control technique. The fact that a user no longer needs to carry identity cards and other documents for identification explain the ease of use. The Exam hall authentication system using fingerprints. The implemented minutiae extraction is much more accurate and faster than our previous feature-extraction. In our proposed system accurately verify the fingerprint is valid user or not. If valid user then it allow attending the exam else not allowed. In this experimental result shows the proposed method is suitable for all the authentication based application and also it robust.

6.1 FUTURE SCOPE

- Number of active forging may decrease.
- It could be interfaced with the computer and results can be displayed quickly and easily or the result can be stored in the central server whose data can be stored in the backend servers.
- It could be interfaced with the printer so that the hardcopy of the data can be taken.
- It could make the results available at any corner of the world in minimum time.

ACKNOWLEDGMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

We extended our deep sense of gratitude to Principal**, Dr. P. SANTOSH KUMAR PATRA**, St. Martin's Engineering College, Dhulapally, for permitting us to undertake this project.

We are also thankful to **Dr. B. Hari Krishna, Head & Professor**, of the department Electronics and Communication Engineering, St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project and as well as our **Project Coordinator** , **Dr. K. Nishakar**, **Professor** in Electronics and Communication Engineering, for his valuable support.

We would like to express our sincere gratitude and indebtedness to our **Project Supervisor, Ms. P. Pushpa**, **Assistant Professor**, Electronics and Communication Engineering , St. Martin's Engineering College, Dhulapally, for her support and guidance throughout our project.

Finally, we express thanks to all those who have helped us successfully to completing this project. Furthermore, we would like to thank our family and friends for their moral support and encouragement.

We express thanks to all those who have helped us in successfully completing the project.**.**

ABSTRACT

This project IOT Liquid Level Monitoring system is a very innovative system which will inform the users about the level of liquid and will prevent it from overflowing. To demonstrate this the system makes use of 4 containers. For this the system uses ultrasonic sensors placed over the containers to detect the liquid level and compare it with the container's depth. The system makes use of AVR family microcontroller, LCD screen, WiFi modem for sending data and a buzzer. The system is powered by a 12V transformer. The LCD screen is used to display the status of the level of liquid in the containers. Whereas a web page is built to show the status to the user monitoring it. The web page gives a graphical view of the containers and highlights the liquid level in color in order to show the level of liquid. The LCD screen shows the status of the liquid level. The system puts on the buzzer when the level of liquid collected crosses the set limit. Thus this system helps to prevent the wastage of water by informing about the liquid levels of the containers by providing graphical image of the containers via a web page.

CHAPTER 1

INTRODUCTION

INTRODUCTION:

Imagine the usefulness of being able to switch on the air conditioner system ten minutes before you get home on a hot afternoon. How about security system to detect smoke, burglary attempts alerted to you. These imaginations build the idea of Water/Liquid Level Monitoring that has no end. The sophisticated liquid Level Monitoring systems of course record the usage of liquid. Technology nowadays has become an integrated part of people's lives. It has, and continues to influence many aspects of daily life and has allowed better social interaction, ease of transportation,

From the time of its introduction, the number of people that use mobile phones and the internet to communicate with other people has increased dramatically to become one of the major means of communication. People with the help of smart phones can now connect to the internet with out the need for a computer, while still offering the same functionality but through different means.With the introduction of advanced software and hardware devices, smart phones are now powerful devices and have become an important part of people’s daily lives. A major aspect is how the Smartphone is able to connect and communicate with other devices.

A field that is recently gaining popularity is Liquid Level Monitoring which can also use smart phones as information or functionality hubs. The present invention relates to the field of Internet of things (IOT) in Liquid Level Monitoring. The goal of this research is to develop a smart device for estimating accurately the liquid level and prevent overflowing and leakage. The recent advancements in the area of IoT has provided solutions to measure the quantity and level of liquid in liquid transmission system using sensor based wireless technology.

1.1 OBJECTIVE OF THE PROJECT

The main aim of this system is to monitor the liquid level at industrial areas so that they help in detecting the wastage of water and measures can be taken to avoid unnecessary overflowing of water in the areas where monitoring is a difficult task.

1.2 AIM OF THE PROJECT

The primary aim for doing our project is to present a handy module consisting of sensors and micro systems which will inform the users about the level of liquid and will prevent it from overflowing. To achieve this, the following objectives have to be completed.

- Studying the components and its working.
- Develop a kit with the all the components needed for its functioning.
- Studying the articles of various publishers.
- Designing and developing a system which can communicate to the server.
- Testing and maintaining the implemented system.

1.3 MOTIVATION OF THE PROJECT

Many essential liquids need to be measured and monitored as its leakage and overflowing might result in accidents and most probably disasters. So few industrial liquids are to be carefully monitored as they are costly, imported and requires high maintenance to avoid any liquid loss. This has motivated to develop Liquid Level Monitoring System Using Internet of Things. Nowadays, liquid level monitoring system plays a vital role in water, oil, automotive and also gas industries.Many industrial and process control applications involve the monitoring of the level of a liquid in a vessel, or storage tank.

1.4 EXISTENCE METHOD

Water Monitoring System has ultrasonic sensor and it is used to detect the level of the water. The level of the water can be measured by means of centimetre. The processor process the data from the level of water and send it to the Arduino and display the level using LCD display.

Ultrasonic sensor detects the level of water and displays the level on the LCD. When the detected level is indicated as “FULL” the buzzer will produce sound. This project saves time and money. Helps in preventing accidents that occur at railway bridges. The input to the Arduino is ultrasonic sensor. Water level will be detected by ultrasonic sensor. The outputs are buzzer and LCD.

1.5 PROPOSED METHOD

This project IOT Liquid Level Monitoring system is a very innovative system which will inform the users about the level of liquid and will prevent it from overflowing. To demonstrate this the system makes use of 4 containers. For this the system uses ultrasonic sensors placed over the containers to detect the liquid level and compare it with the container’s depth. The system makes use of AVR family microcontroller, LCD screen, WiFi modem for sending data and a buzzer. The system is powered by a 12V transformer. The LCD screen is used to display the status of the level of liquid in the containers. Whereas a web page is built to show the status to the user monitoring it. The web page gives a graphical view of the containers and highlights the liquid level in color in order to show the level of liquid. The LCD screen shows the status of the liquid level. The system puts on the buzzer when the level of liquid collected crosses the set limit.

1.6 LITERATURE SURVEY

Liquid Level Monitoring can be found in many areas since before.

Various types of Liquid Level Monitoring system based on the control are:

1. Individual systems: This is a very popular type of systems. Here the whole model is implemented on a targeted single source system.

2. Large control systems: Here the liquid level is implemented on a very large scale basis and huge amounts of sensors are used.

3. Central Control systems: Computerized systems programmed to handle all the functions of multiple utilities like air conditioning system or home entertainment systems, refrigerators all at the same instant regardless of your presence. Control system can be accessed through telephone or internet from any corner of the world.

Based on the method of automation various types are as follows:

1. Bluetooth based Liquid Level Monitoring: Here Bluetooth plays a major role in alerting the anomalies.

2. Remote Liquid Level Monitoring: In this, the system is controlled remotely.

3.Automatic Liquid Level Monitoring: The system is programmed to automatically perform some defined actions.

1.7 ORGANIZATIONAL THESIS

In this project, firstly we learn about the block diagram part to implement this application. This gives a very clear idea about the further procedure. Then we put forward towards the schematics of each and every module in the project. After having clear overview about the project with the help of schematics and block diagram, we go through the hardware modules in the project one after the other. Firstly, micro controller is the base module of the project. We interface other hardware modules with the help of micro controller only. Ultrasonic sensors are used for the identification of distance between the sensor and object, depth of the object, etc . In this project WiFi module is used to transfer the updated result to the server. LCD is used for the displaying of the data regarding the level of water identified . The distance of the water level is displayed on the LCD. When the level of the water identified is “FULL” the buzzer sets “ON”. Now, the software implementation is done using Arduino IDE. The results are followed by the conclusion, applications and future scope of the project.

CHAPTER 2

BLOCK DIAGRAM

2.1 BLOCK DIAGRAM

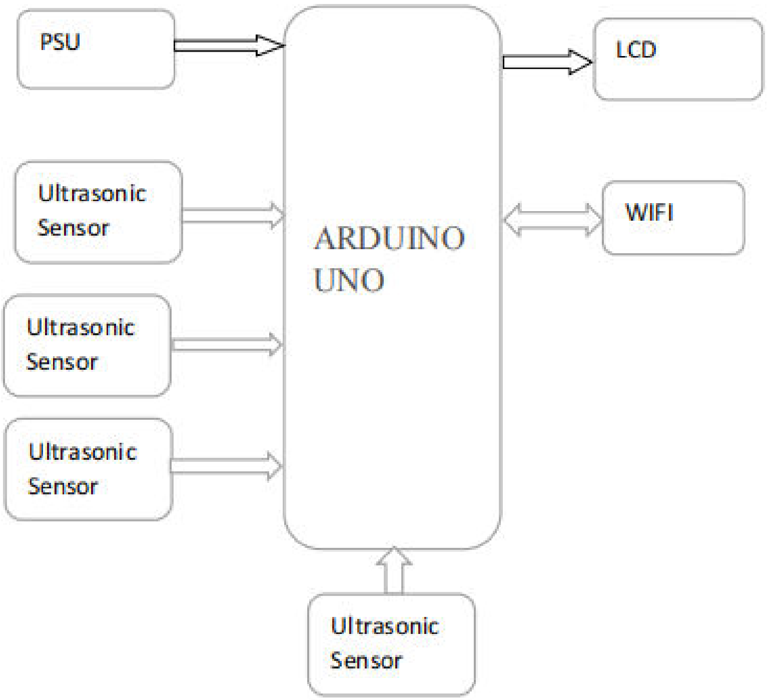

Figure:2.1 Block Diagram

MICROCONTROLLER

Arduino is open source software. Arduino UNO is a micro-controller, ATmega328P contain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

WIFI MODULE

The ESP8266 WiFi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

ULTRA SONIC SENSOR

Ultrasonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal.Ultrasonic waves travel faster than the speed of audible sound (i.e. the sound that humans can hear). Ultrasonic sensors have two main components: the transmitter (which emits the sound using piezoelectric crystals) and the receiver (which encounters the sound after it has travelled to and from the target).In order to calculate the distance between the sensor and the object, the sensor measures the time it takes between the emission of the sound by the transmitter to its contact with the receiver. The formula for this calculation is **D = ½ T x C** (where D is the distance, T is the time, and C is the speed of sound ~ 343 meters/second)

LIQUID CRYSTAL DISPLAY(LCD)

Liquid-crystal display (**LCD**) is a flat panel display, electronic visual display that uses the light modulation properties of liquid crystals. Liquid crystals do not emit light directly. LCD’s are available to display arbitrary images or fixed images which can be displayed or hidden, such as preset words, digits, and 7-segment displays as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger element.

POWER SUPPLY

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage stabilizer, AC to DC converter, DC to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems' based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply, so the AC 230V needs to be converted into 5V DC using the step-down converter in their power supply circuit. Power supply circuit, the name itself indicates that this circuit is used to supply the power to other electrical and electronic circuits or devices. There are different types of power supply circuits based on the power they are used to provide for devices. For example, the micro-controller based circuits, usually the 5V DC regulated power supply circuits, are used, which can be designed using different techniques for converting the available 230V AC power to 5V DC power. Generally the converters with output voltage less than the input voltage are called as step-down converters.

BUZZER

A buzzer or beeper is an audio signaling device, which may be mechanical, electromechanical, or piezoelectric. Typical uses of buzzers and beepers include alarm devices, timers and confirmation of user input such as a mouse click or keystroke. Nowadays, it is more popular to use a ceramic-based piezoelectric sounder like a Son alert which makes a high-pitched tone. Usually these were hooked up to "driver" circuits, which varied the pitch of the sound or pulsed the sound on and off.

2.2 SCHEMATIC DIAGRAM

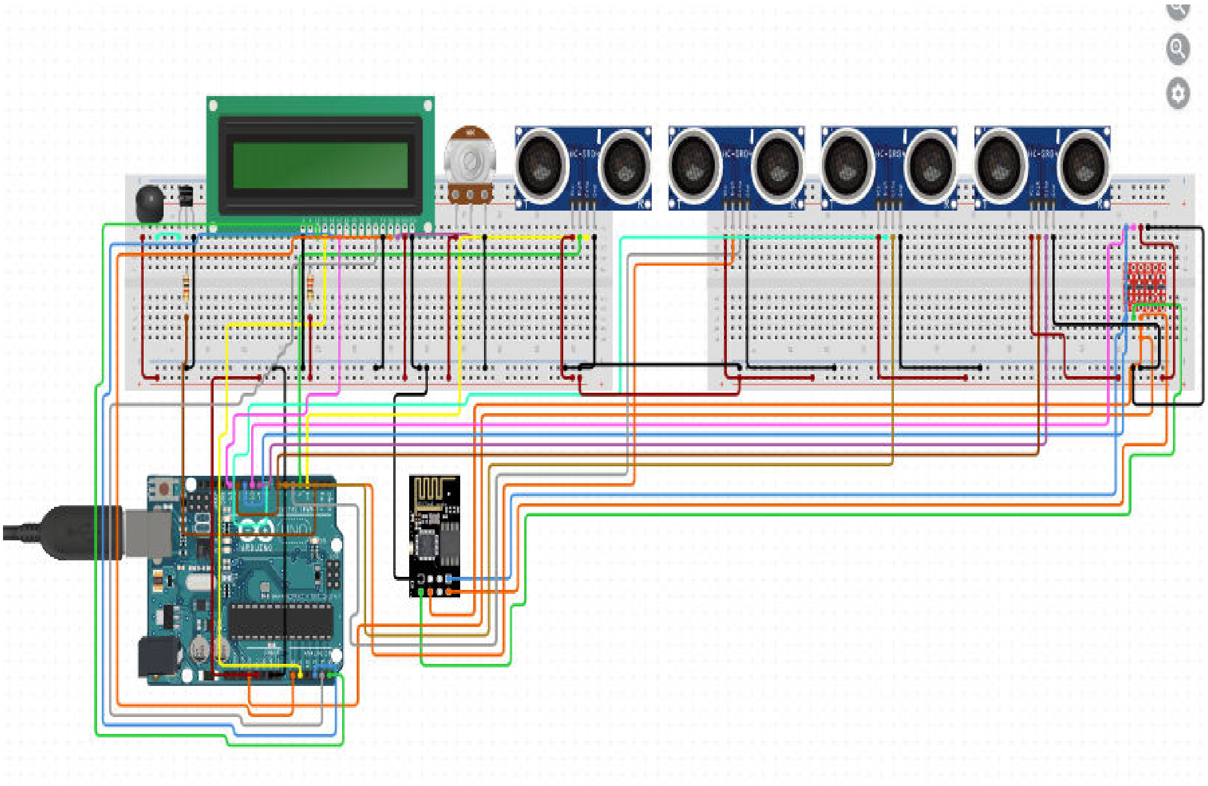

Figure : 2.2 Schematic Diagram

SCHEMATIC DIAGRAM DESCRIPTION

In this project, we are going to make a Liquid level monitoring system which uses the ultrasonic sensor to monitor the level of water. We have used Arduino UNO as the heart of the circuit. All the hardware required such as WIFI Module, ultrasonic sensor, Buzzer, LED, LCD display are connected to the Arduino UNO by using the GPIO pins present on the Arduino UNO board. LCD display shows HIGH level whenever the water is full. The buzzer connected to Arduino also sets “ON”. The microcontroller collects the data and displays on the LCD display. The WIFI Module is an ESP2866 microcontroller which transfers the information to the Think speak server. The project will use Arduino UNO with AtmegaP328 microcontroller as heart of the circuit. ATmega328P has 28 pins. The Power requirement of LPC2148 Microcontroller is 5VDC and VSS ground. In this project, we have microcontroller which collects the data and displays it on to the LCD display as well as on any system that has internet access. Firstly, connect all the components to the Arduino UNO and turn on the UNO board by using 5V supply given from USB or LAN port. Switch on the WIFI in order to transfer the information to server. To check the output switch on the power supply. Now place an object in front of sensor until the ultrasonic sensor senses the level. The level is detected and can be viewed graphically as well as digitally on any system by login to the think speak portal. The buzzer starts buzzing as the level is high and the LED glows indicating the water is full. As the buzzer and LED are set high the output of Arduino Uno also becomes high. This process continues till the water level is controlled.

The hardware modules are interfaced to the micro controller as follows:

LCD is interfaced from 8^{th} to 13^{th} pin of the Arduino.

The ultrasonic sensor1 is given to the 4^{th} pin of the Arduino.

The ultrasonic sensor1 is given to the 5^{th} pin of the Arduino.

The ultrasonic sensor2 is given to the 6^{th} pin of the Arduino.

The ultrasonic sensor2 is given to the 7^{th} pin of the Arduino.

The ultrasonic sensor3 trig pin is given to analog pin A4.

The ultrasonic sensor3 echo pin is given to analog pin A5.

The ultrasonic sensor4 trig pin is given to analog pin A1.

The ultrasonic sensor4 echo pin is given to analog pin A2.

The Buzzer is given to the 7^{th} pin of the Arduino.

CHAPTER 3

HARDWARE DESCRIPTION

HARDWARE MODULE

The hardware and software components used for the implementation of Water Level Monitoring System at Railway Bridges are

1. Arduino UNO.

2. WIFI Module

3. Regulated Power Supply

4. LCD display.

5. Ultrasonic Sensor.

6. Buzzer.

7. LED indicator.

8. Voltage Regulator

3.1 ARDUINO UNO

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message and turn it into an output activating a motor, turning on an led, publishing as it reached a wider community, the Arduino board started something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based Wiring), the Arduino Software (IDE), based on Processing. Arduino was born at the area Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming wearable, 3dprinting, and embedded environments. All Arduino boards are completely open-source, empowering from everyday objects to complex scientific instruments. Professional gathered around open-source plat form, The software too is open-source, it is growing through the contributions of users worldwide, the Arduino board is shown in below figure.

Figure 3.1 Arduino UNO board

WHY ARDUINO?

Arduino UNO is inexpensive. Arduino is cross platform, its IDE can run on multiple Operating Systems such as Windows, Macintosh, Linux and many more. It has simple and clear programming environment. Its software and hardware are open-source and extensible, that is, Arduino programming can be expanded through C++ libraries and can also leap to AVR 'C' language programming. It is simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove the chemistry and physics principles or to get started with programming and robotics.

Designers and the architects build interactive prototypes, musicians, artists use it for installations and to experiment with new musical instruments. Makers of course use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers can start tinkering just following the step by step instructions of a kit or sharing ideas online with other members of the Arduino community.

There many other microcontrollers platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Fidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems.

INEXPENSIVE

Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50

SIMPLE, CLEAR PROGRAMMING ENVIRONMENT

The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

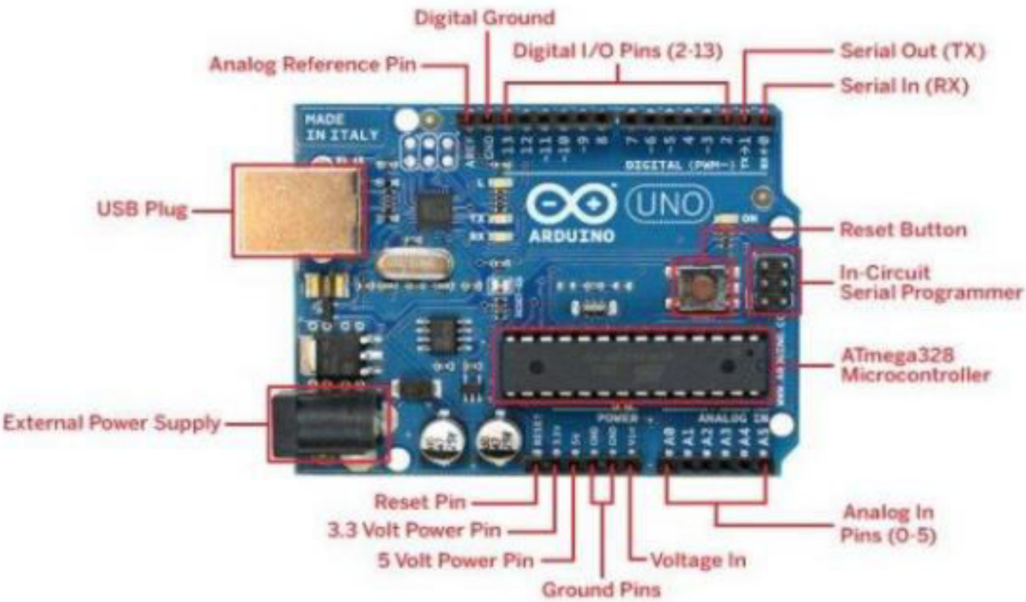

Figure 3.2 Arduino Board Description

OPEN SOURCE AND EXTENSIBLE SOFTWARE

The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

OPEN SOURCE AND EXTENSIBLE HARDWARE

The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money and the parts of Arduino board is shown below.

FEATURES OF ARDUINO UNO

Micro controller	Atmega328
Operating voltage	5V
Input Voltage(recommended)	7-12V
Input Voltage	6-20V
Digital I/O	14(of which 6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 Ma
DC Current for 3.3V Pin	50 Ma
Flash Memory	32 KB(Atmega328 of which 0.5 KB used by bootloader)
SRAM	2 KB (ATmega32)
EEPROM	1 KB(ATmeha328)
Clock Speed	16 MHz

Table 3.1 : Features of Arduino

ADVANTAGES

1. Inexpensive -Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50.
2. Cross-platform - The Arduino software runs on Windows, Macintosh OSX, and the Linux operating systems. Most microcontroller systems are limited to Windows.

3.Simple programming environment- Here the Arduino programming environment is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with the look and feel of Arduino.

4. Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

4. Open source and extensible hardware - The Arduino is based on Atmel's ATMEGA8 and ATMEGA168 microcontrollers. The plans for the modules are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users that can build the breadboard version of the module in order to understand how it works and save money.

APPLICATIONS OF ARDUINO

- It is an easy USB interface. This allows interface with USB as this is like a serial device.

- The chip on the board plugs straight into your USB port and supports on your computer as a virtual serial port. The benefit of this setup is that serial communication is an extremely easy protocol which is time-tested and USB makes connection with modern computers and makes it comfortable.

• It is easy-to-find the microcontroller brain which is the ATmega328 chip. It has more number of hardware features like timers, external and internal interrupts, PWM pins and multiple sleep modes.

• It is an open source design and there is an advantage of being open source is that it has a large community of people using and troubleshooting it. This makes easy to help in debugging projects.

• It is 16MHz clock which is fast enough for most applications and does not speeds up the microcontroller.

• It is very convenient to manage power inside it and it had a feature of built-in voltage regulation. This also be powered directly off a USB port without any external power. You can connect an external power source of up to 12v and this regulates it to both 5v and 3.3v.

• 13 digital pins and 6 analog pins. This sort of pins allows you to connect hardware to your Arduino Uno board externally. These pins are used as a key for extending the computing capability of the Arduino Uno into the real world.

This has an ICSP connector for bypassing the USB port and interfacing the Arduino directly as a serial device. This port is necessary to re-boot load your chip if it corrupts and can no longer used to your computer.

• It has a 32 KB of flash memory for storing your code.

• An on-board led is attached to digital pin 13 to make fast the debugging of code and to make the debug process easy finally it has the button to reset.

POWER

The Arduino Uno can be powered via through USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an AC-to-DC adapter (wall-wart) or battery. The adapter can be connected by plugging a 2.1mm center-positive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and Vin pin headers of the POWER connector. The board can operate on an external supply of 6 to 20 volts. If supplied with less than 7V, however, the 5V pin may supply less than five volts and the board may be unstable. If using more than 12V, the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts. the power pins are as follows.

- **VIN.** The input voltage to the Arduino board when it's using an external power source (as opposed to 5 volts from the USB connection or other regulated power source). You can supply voltage through this pin, or, if supplying voltage via the power jack, access it through this pin.

- **5V.** The regulated power supply used to power the microcontroller and other components on the board. This can come either from VIN via an on-board regulator, or be supplied by USB or another regulated 5V supply.

- **3V3.** A 3.3 volt supply generated by the on-board regulator. Maximum current draw is 50 mA.

- **GND.** Ground pins.

INTRODUCTION TO ATMEGA328

ATMEGA328 is an eight (8) bit Microcontroller. It can handle the data sized of up to eight (8) bits. It is an AVR based micro-controller. Its built in internal memory is around 32KB. It operates ranging from 3.3V to 5V. It has an ability to store the data even when the electrical supply is removed from its biasing terminals. it is the excellent features include the cost efficiency and low power dissipation, programming lock for security purposes, real timer counter with the separate oscillator and It is generally or normally used in Embedded Systems applications. ATmega-328 is shown in the figure given below.

Figure 3.3 ATMega328 Microcontroller

ARDUINO UNO ATMEGA328

The Arduino UNO is a micro controller board based on the ATMega. UNP means one in Italian and is named to mark the upcoming release of the given Arduino 1.0 . It has digital input/output pins, 6 analog inputs, 16MHz ceramic resonator. A USB connection. A power jack, An ICSP header and a reset button.it contains information everything needed to support the microcontroller. simply connect it to a computer with a USB cable or power it with a ac-to-dc adapter or battery to get started. The UNO differs from all preceding boards in that it does not use the FTDI USB-to serial driver chip.

ARCHITECTURE AND WORKING OF ARDUINO UNO

The Arduino UNO can be also powered via the USB connection or with an external power supply.the power source is selected automatically.External (non-USB) power can come either from an AC-to-DC adapter or battery. The adapter can connected by plugging a 2.1mm center positive plug into the board's power jack. Leads from a battery can be inserted in the Gnd and Vin pin headers of the power connector. The board can operate on an external supply of 6to 20 volts. If supplied with less than 7v however, the 5v pin may supply less than five volts and the board may be unstable. If using more than 12v.the voltage regulator may overheat and damage the board.the 21recommended range is 7 to 12 volts. The processor of the Arduino board uses the Harvard architecture where the program code and program data have separate memory. It consists of two memories such as program memory and data memory. Where in the data is stored in data memory and the code is stored in the flash program memory. The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM 1kb of EPROM and operates with a 16MHz clock speed. Architecture of Atmega328 is shown below.

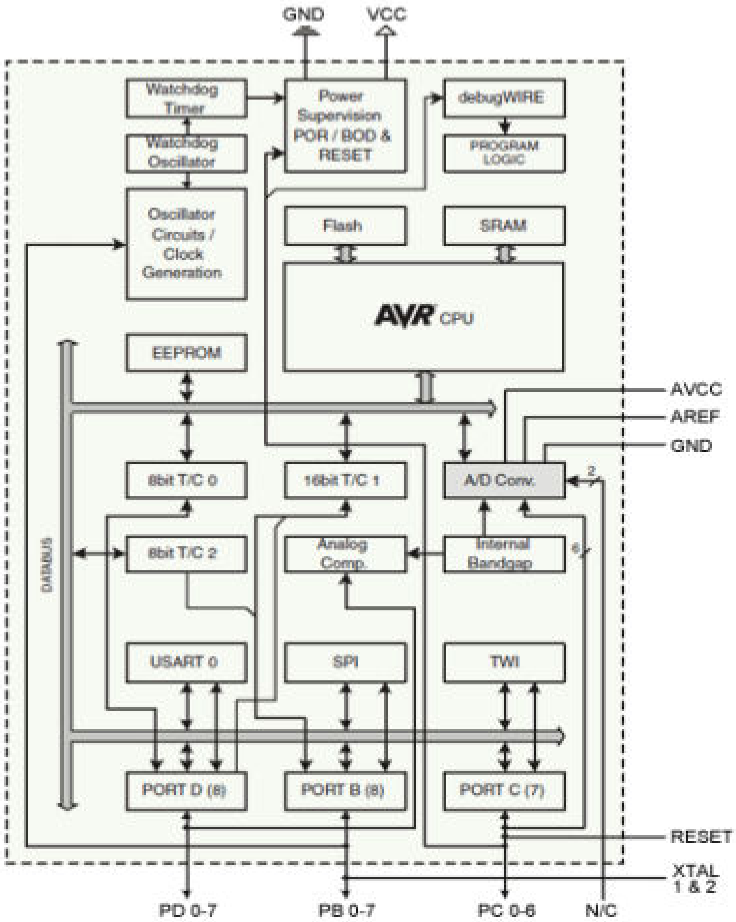

Figure 3.4 ATMega328 Architecture

ATMEGA328 PINS DESCRIPTION

Functions associated with the pins must be known in order to use the device appropriately.ATmega-328 pins are divided into different ports which are given in detail below.

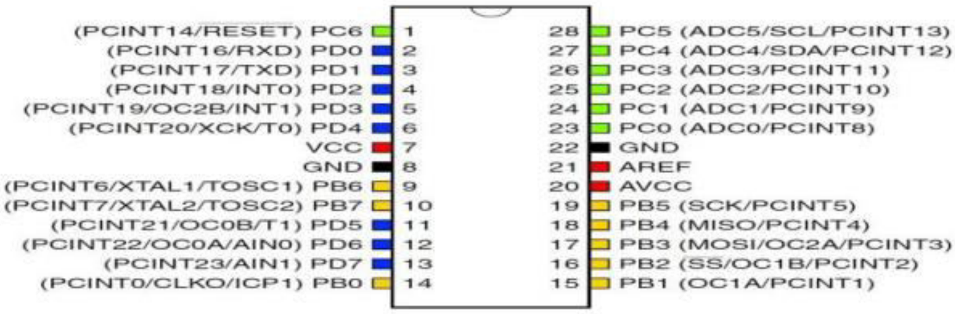

Figure 3.5 ATMega328 ports

AVCC is a supply voltage pin for analog to digital converter.

VCC is a digital voltage supply.

GND denotes Ground and it has a 0V.

Port A consists of the pins from **PA0** to **PA7.** These pins serve as analog input to analog to digital converters. If analog to digital converter is not used, **port A** acts as an eight (8) bit bidirectional input/output port.

Port B consists of the pins from **PB0** to **PB7.** This port is an 8 bit bidirectional port having an internal pull-up resistor.

Port C consists of the pins from **PC0** to **PC7.** The output buffers of **port C**

Port D consists of the pins from **PD0** to **PD7.** It is also an 8 bit input/output port having an internal pull-up resistor.All of the AVR ports are shown in figure given below.

3.2 WIFI MODULE

The ESP8266 is a low-cost Wi-Fi microchip, with a full TCP/IP stack and microcontroller capability, produced by Espressif Systems[1] in Shanghai, China The ESP8285 is an ESP8266 with 1 MiB of built-in flash, allowing the building of single-chip devices capable of connecting to Wi-Fi.

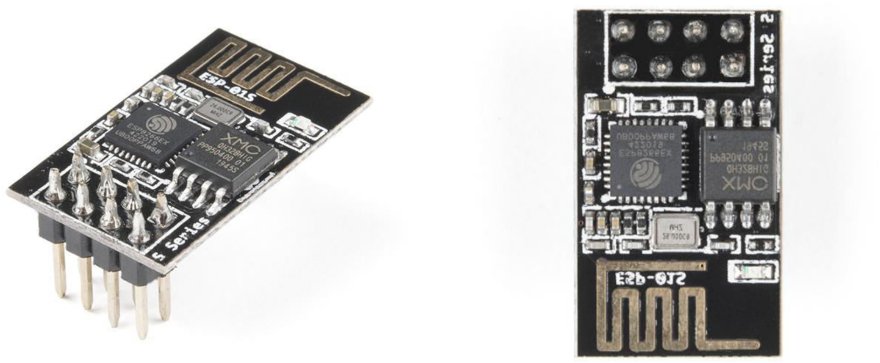

Figure 3.6 ESP8266 WIFI Module

This small module allows microcontrollers to connect to a Wi-Fi network and make simple TCP/IP connections using Hayes-style commands. The very low price and the fact that there were very few external components on the module, which suggested that it could eventually be very inexpensive in volume, attracted many hackers to explore the module, the chip, and the software on it.

These microcontroller chips have been succeeded by the ESP32 family of devices, including the pin-compatible ESP32-C3.

Processor: L106 32-bit RISC microprocessor core based on the Tensilica Xtensa Diamond Standard 106Micro running at 80 MHz[5]

Memory:[*citation needed*]

32 KiB instruction RAM

32 KiB instruction cache RAM

80 KiB user-data RAM

16 KiB ETS system-data RAM

External QSPI flash: up to 16 MiB is supported (512 KiB to 4 MiB typically included)

The pin out is as follows for the common ESP-01 module:

1. GND, Ground (0 V)
2. GPIO 2, General-purpose input/output No. 2
3. GPIO 0, General-purpose input/output No. 0

4. RX, Receive data in, also GPIO3
5. VCC, Voltage (+3.3 V; can handle up to 3.6 V)
6. RST, Reset
7. CH_PD, Chip power-down
8. TX, Transmit data out, also GPIO1

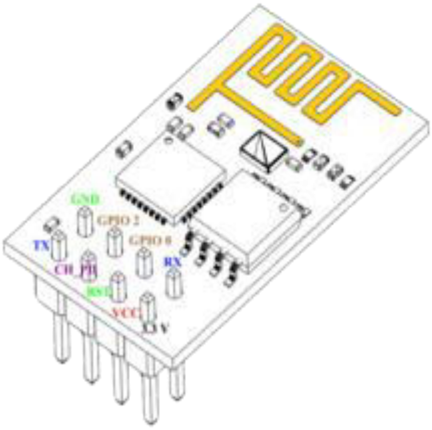

Figure 3.7 ESP8266 pin configuration

The ESP8266 WiFi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existence interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution!

Note: The ESP8266 Module is not capable of 5-3V logic shifting and will require an external Logic Level Converter. Should not power it directly from 5V developed board.

3.3 REGULATED POWER SUPPLY

A variable regulated power supply, also called a variable bench power supply, is one where you can continuously adjust the output voltage to your requirements. Varying the output of the power supply is the recommended way to test a project after having double checked parts placement against circuit drawings and the parts placement guide.

This type of regulation is ideal for having a simple variable bench power supply. Actually this is quite important because one of the first projects a hobbyist should undertake is the construction of a variable regulated power supply. While a dedicated supply is quite handy, it's much handier to have a variable supply on hand, especially for testing.

Mainly the microcontroller needs 5 volt power supply. To use these parts we need to build a regulated 5 volt source. Usually you start with an unregulated power To make a 5 volt power supply, we use a 7805 voltage regulator IC (Integrated Circuit).

V_{out} range	1.25V – 37V
V_{in} – V_{out} difference	3V – 40V
Operation ambient temperature	0 – 125°C
Output I_{max}	<1.5A
Minimum Load $Current_{max}$	10Ma

Table:3.2 Circuit features

Block Diagram

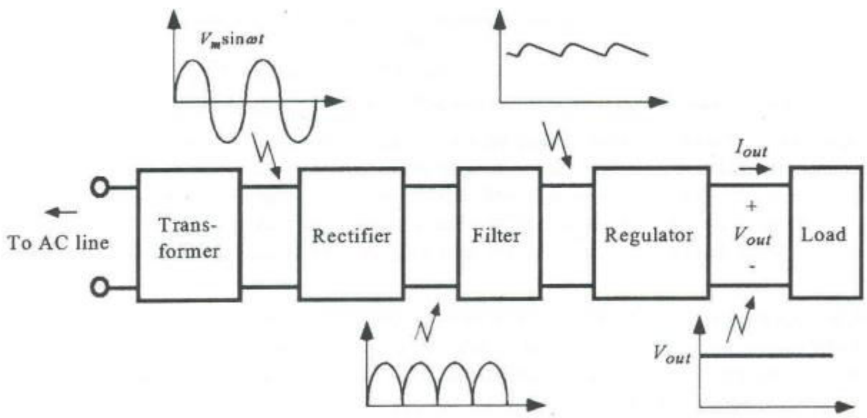

Figure 3.8 Block diagram of RPS

Power supply

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage stabilizer, AC to DC converter, DC to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems' based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply, so the AC 230V needs to be converted into 5V DC using the step-down converter in their power supply circuit.

Power supply circuit, the name itself indicates that this circuit is used to supply the power to other electrical and electronic circuits or devices. There are different types of power supply circuits based on the power they are used to provide for devices. For example, the micro-controller based circuits, usually the 5V DC regulated power supply circuits, are used, which can be designed using different techniques for converting the available 230V AC power to 5V DC power. Generally the converters with output voltage less than the input voltage are called as step-down converters.

Step Down the Voltage Level

The step-down converters are used for converting the high voltage into low voltage. The converter with output voltage less than the input voltage is called as a step-down converter, and the converter with output voltage greater than the input voltage is called as step-up converter. There are step-up and step-down transformers which are used to step up or step down the voltage levels. 230V AC is converted into 12V AC using a step-down transformer. 12V output of step down transformer is an RMS value and its peak value is given by the product of square root of two with RMS value, which is approximately 17V.

Figure 3.9 Step-down Transformer

Step-down transformer consists of two winding's, namely primary and secondary winding's where primary can be designed using a less-gauge wire with more number of turns as it is used for carrying low-current high-voltage power, and the secondary winding using a high-gauge wire with less number of turns as it is used for carrying high-current low-voltage power. Transformers works on the principle of Faraday's laws of electromagnetic induction.

Convert AC to DC

230V AC power is converted into 12V AC (12V RMS value wherein the peak value is around 17V), but the required power is 5V DC; for this purpose, 17V AC power must be primarily converted into DC power then it can be stepped down to the 5V DC.

But first and foremost, we must know how to convert AC to DC? AC power can be converted into DC using one of the power electronic converters called as Rectifier. There are different types of rectifiers, such as half-wave rectifier, full-wave rectifier and bridge rectifier. Due to the advantages of the bridge rectifier over the half and full wave rectifier, the bridge rectifier is frequently used for converting AC to DC.

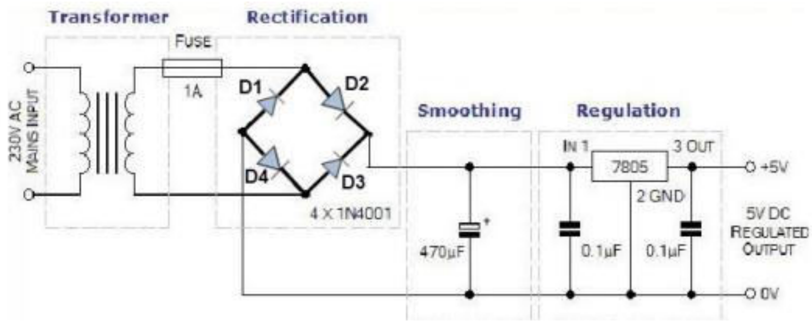

Figure 3.10 AC to DC converter

Bridge rectifier consists of four diodes which are connected in the form a bridge. We know that the diode is an uncontrolled rectifier which will conduct only forward bias and will not conduct during the reverse bias. If the diode anode voltage is greater than the cathode voltage then the diode is said to be in forward bias. During positive half cycle, diodes D2 and D4 will conduct and during negative half cycle diodes D1 and D3 will conduct. Thus, AC is converted into DC; here the obtained is not a pure DC as it consists of pulses. Hence, it is called as pulsating DC power. But voltage drop across the diodes is (2*0.7V) 1.4V; therefore, the peak voltage at the output of this rectifier circuit is 15V (17-1.4) approx.

Smoothing the Ripples using Filter

15V DC can be regulated into 5V DC using a step-down converter, but before this, it is required to obtain pure DC power. The output of the diode bridge is a DC consisting of ripples also called as pulsating DC. This pulsating DC can be filtered using an inductor filter or a capacitor filter or a resistor-capacitor-coupled filter for removing the ripples. Consider a capacitor filter which is frequently used in most cases for smoothing.

Figure 3.11 Filter

We know that a capacitor is an energy storing element. In the circuit, capacitor stores energy while the input increases from zero to a peak value and, while the supply voltage decreases from peak value to zero, capacitor starts discharging. This charging and discharging of the capacitor will make the pulsating DC into pure DC, as shown in figure.

REGULATING 12V DC INTO 5V DC USING VOLTAGE REGULATOR

15V DC voltage can be stepped down to 5V DC voltage using a DC step-down converter called as voltage regulator IC7805. The first two digits ‘78’ of IC7805 voltage regulator represent positive series voltage regulators and the last two digits ‘05’ represents the output voltage of the voltage regulator.

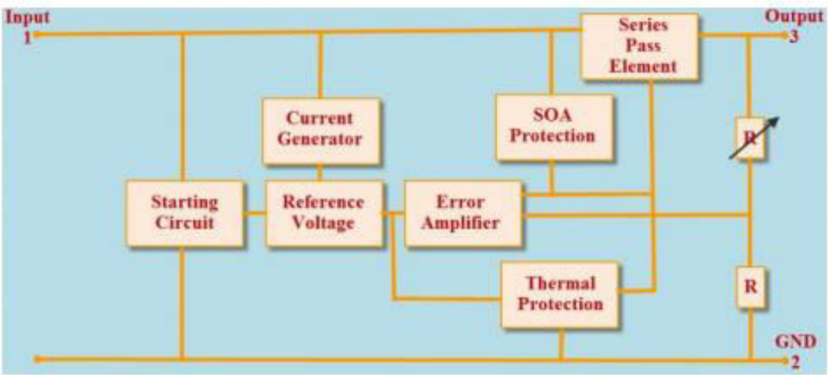

Figure 3.12 Voltage Regulator

The block diagram of IC7805 voltage regulator is shown in the figure consists of an operating amplifier acting as error amplifier, zener diode used for providing voltage reference, as shown in the figure.

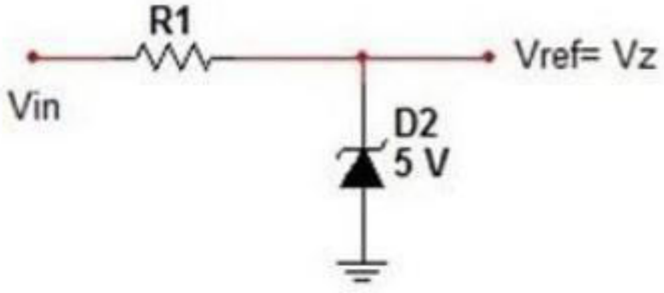

Figure 3.13 Zener Diode as Voltage Reference

Transistor as a series pass element used for dissipating extra energy as heat; SOA protection (Safe Operating Area) and heat sink are used for thermal protection in case of excessive supply voltages. In general, an IC7805 regulator can withstand voltage ranging from 7.2V to 35V and gives maximum efficiency of 7.2V voltage and if the voltage exceeds 7.2V, then there is loss of energy in the form of heat. To protect the regulator from over heat, thermal protection is provided using a heat sink. Thus, a 5V DC is obtained from 230V AC power.

3.4 LCD DISPALY (16x2)

Figure: 3.14 LCD Display

LIQUID CRYSTAL DISPLAY

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCD’s connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

FEATURES:

(1) Interface with either 4-bit or 8-bit microprocessor.

(2) Display data RAM

(3) 80x□8 bits (80 characters).

(4) Character generator ROM

(5) 160 different 5 x7 dot-matrix character patterns.

(6) Character generator RAM

(7) 8 different user programmed 5x7 dot-matrix patterns.

(8) Display data RAM and character generator RAM may be accessed by the microprocessor.

(9) Numerous instructions

(10) Clear Display, Cursor Home, Display ON/OFF, Cursor ON/OFF, Blink Character, Cursor Shift, Display Shift.

(11) Built-in reset circuit is triggered at power ON.

(12) Built-in oscillator.

DESCRIPTION OF 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

SCHEMATIC DIAGRAM:

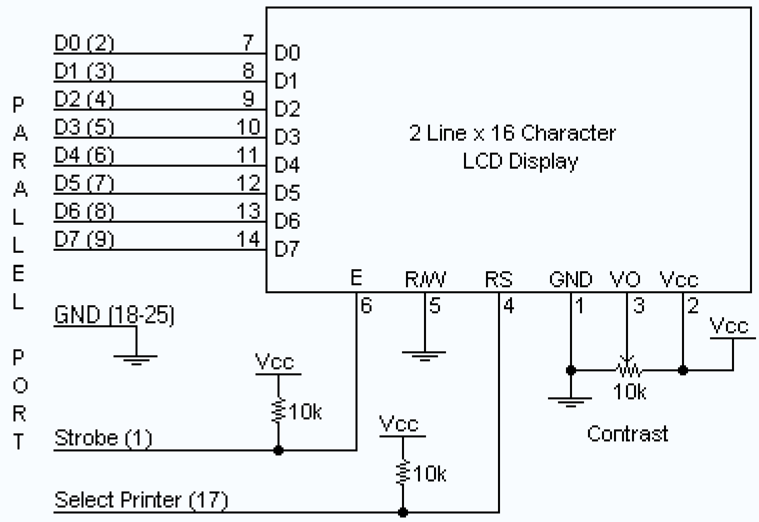

Figure:3.15 Schematic Diagram of LCD

Above is the quite simple schematic. The LCD to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780. The one I used to test this circuit was a Power tip PC-1602F and an old Philips LTN211F-10 which was extracted from a Poker Machine! The diagram to the right, shows the pin numbers for these devices. When viewed from the front, the left pin is pin 14 and the right pin is pin 1

16 x 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 ALPHANUMERIC LCD MODULE SPECIFICATIONS:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)

6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

Table 3.3 Specifications of LCD

FEATURES:

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address Locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Table: 3.4 Address Locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.Several different LC technologies exists. “super-twist” types, for example, offer Improved contrast and viewing angle over the older “twisted pneumatic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

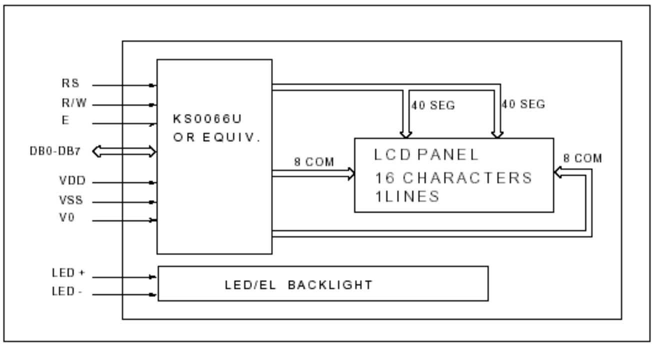

Figure: 3.16 Electrical Block Diagram

POWER SUPPLY FOR LCD DRIVING:

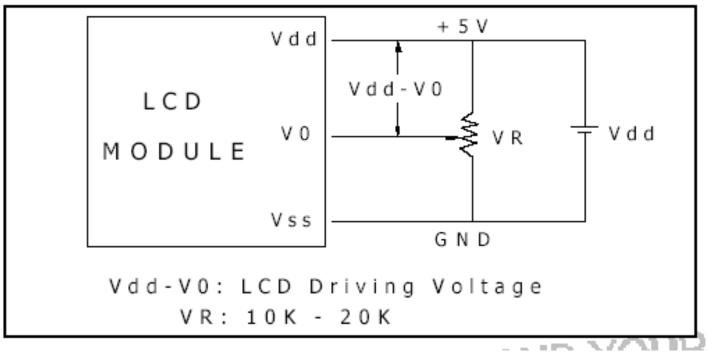

Figure: 3.17 : Power Supply for LCD

PIN DESCRIPTION:

Most LCD's with 1 controller has 14 Pins and LCD's with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

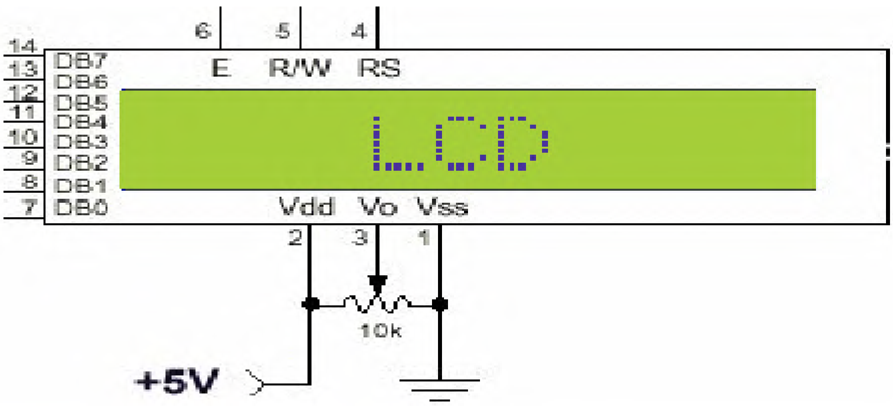

Figure 3.18: Pin Diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table: 3.5 Pin Specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD data sheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low.

Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

E - 0 Access to LCD disabled- 1 Access to LCD enabled R/W - 0 Writing data to LCD 1 Reading data from LCD RS - 0 Instructions-1 Character

Writing data to the LCD:

1) Set R/W bit to low
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high
2) Set RS bit to logic 0 or 1 (instruction or character)
3) Set data to data lines (if it is writing)
4) Set E line to high
5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

SWITCHES:

The switches must be the type where On = 0, so that when they are turned to the zero position, all four outputs are shorted to the common pin, and in position “F”, all four outputs are open circuit. All the available characters that are built into the module are shown in Table 3. Studying the table, you will see that codes associated with the characters are quoted in binary and hexadecimal, most significant bits (“left-hand” four bits) across the top, and least significant bits (“right-hand” four bits) down the left. Most of the characters conform to the ASCII standard, although the Japanese and

Greek characters (and a few other things) are obvious exceptions. Since these intelligent modules were designed in the "Land of the Rising Sun," it seems only fair that their Katakana phonetic symbols should also be incorporated. The more extensive Kanji character set, which the Japanese share with the Chinese, consisting of several thousand different characters, is not included! Using the switches, of whatever type, and referring to Table 3, enter a few characters onto the display, both letters and numbers. The RS switch (S10) must be "up" (logic 1) when sending the characters, and switch E (S9) must be pressed for each of them. Thus the operational order is: set RS high, enter character, trigger E, leave RS high, enter another character, trigger E, and so on. The first 16 codes in Table 3, 00000000 to 00001111, ($00 to $0F) refer to the CGRAM. This is the Character Generator RAM (random access memory), which can be used to hold user-defined graphics characters. This is where these modules really start to show their potential, offering such capabilities as bar graphs, flashing symbols, even animated characters. Before the user-defined characters are set up, these codes will just bring up strange looking symbols. Codes 00010000 to 00011111 ($10 to $1F) are not used and just display blank characters. ASCII codes "proper" start at 00100000 ($20) and end with 01111111 ($7F). Codes 10000000 to 10011111 ($80 to $9F) are not used, and 10100000 to 11011111 ($A0 to $DF) are the Japanese characters.

Table: 3.6 Character details in LCD

Initialization by Instructions:

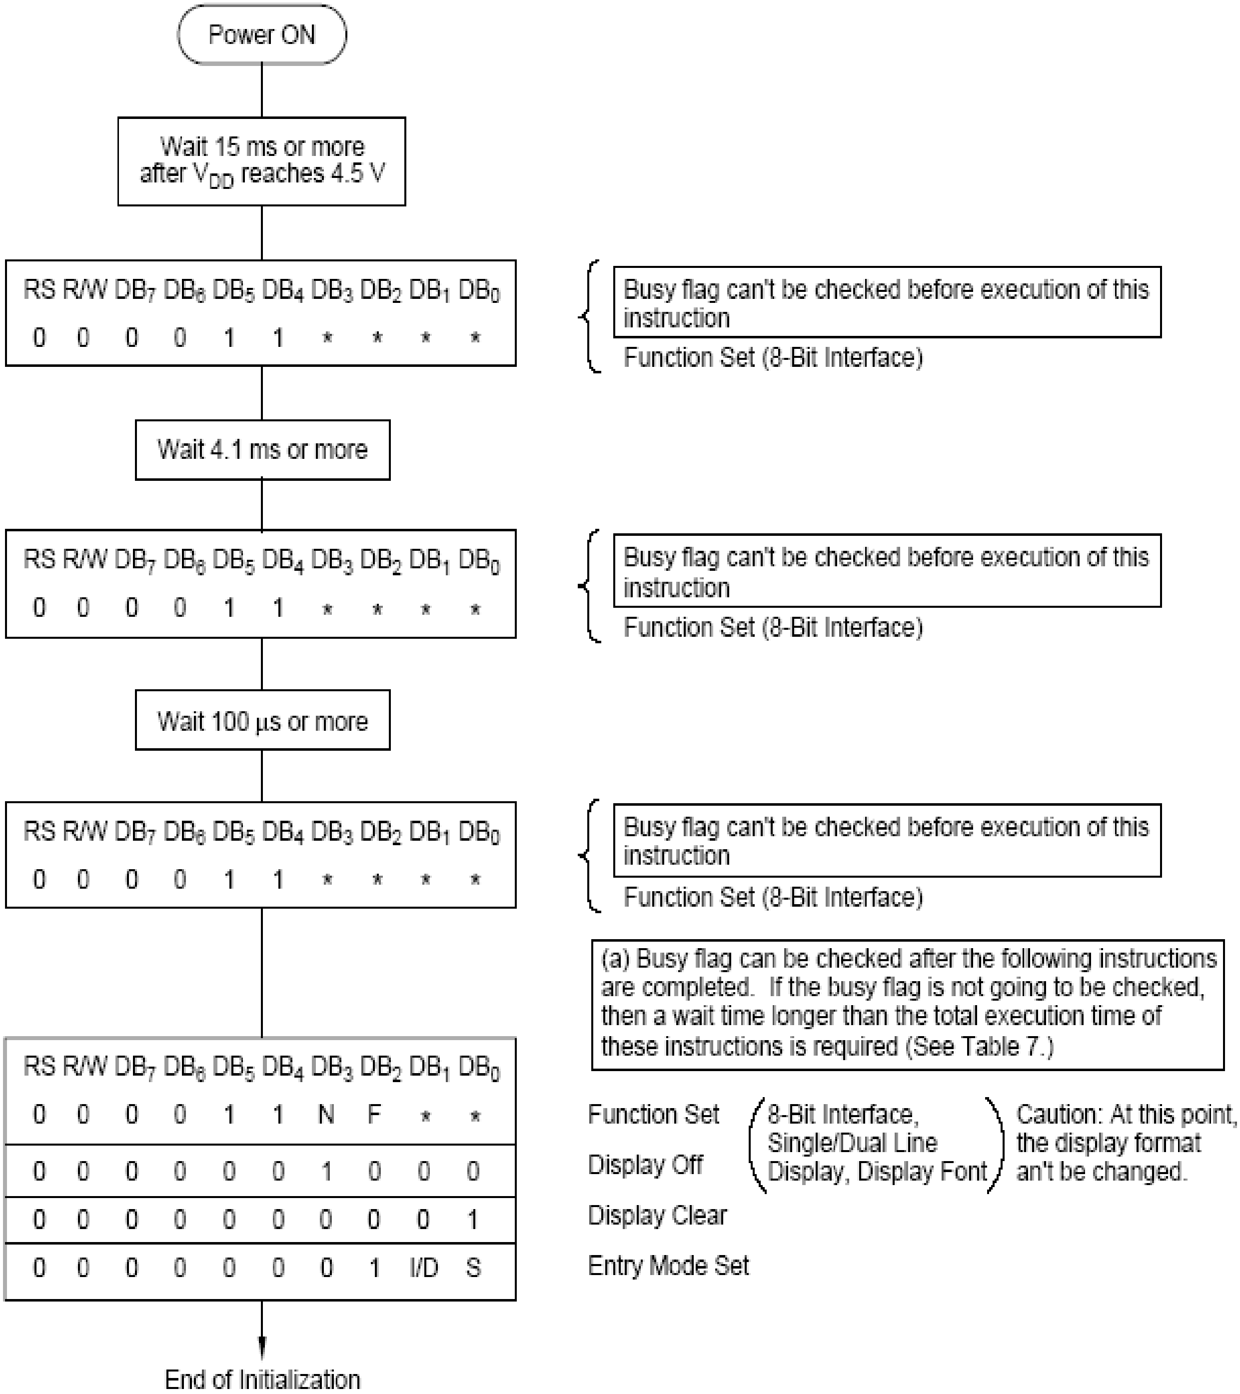

Figure 3.19: Flow Chart of LCD

If the power conditions for the normal operation of the internal reset circuit are not satisfied, then executing a series of instructions must initialize LCD unit. The procedure for this initialization process is as above show.

LCD COMMANDS:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table: 3.7 Commands

3.5 ULTRA SONIC SENSOR

ULTRASONC PRINCIPLE:

Ultrasonic sensors emit short, high-frequency sound pulses at regular intervals. These propagate in the air at the velocity of sound. If they strike an object, then they are reflected back as echo signals to the sensor, which itself computes the distance to the target based on the time-span between emitting the signal and receiving the echo. As the distance to an object is determined by measuring the time of flight and not by the intensity of the sound, ultrasonic sensors are excellent at suppressing background interference. Virtually all materials which reflect sound can be detected, regardless of their color. Even transparent materials or thin foils represent no problem for an ultrasonic sensor.Micro sonic ultrasonic sensors are suitable for target distances from 30 mm to 10 m and as they measure the time of flight they can ascertain a measurement with pinpoint accuracy. Some of our sensors can even resolve the signal to an accuracy of less than 0.18 mm. Ultrasonic sensors can see through dust-laden air and ink mists. Even thin deposits on the sensor membrane do not impair its function. Sensors with a blind zone of just 30 mm and an extremely narrow beam spread are finding totally new applications these days: measuring levels in yogurt pots and test tubes as well as scanning small bottles in the packaging sector - no trouble for our sensors. Even thin wires are reliably detected.

Figure 3.20 Ultrasonic Sensor Module

SPECIFICATION:

The ultrasonic range sensor detects objects in it’s path and can be used to calculate the range to the object. It is sensitive enough to detect a 3cm diameter broom handle at a distance of over 2m.

Voltage - 5v

Current - 30mA Type. 50mA Max.

Frequency - 40 KHz

Max Range - 3 m

Min Range - 3 cm

Sensitivity - Detect 3cm diameter broom handle at > 2 m

Input Trigger - 10uS Min. TTL level pulse

Echo Pulse - Positive TTL level signal, width proportional to range.

Small Size - 43mm x 20mm x 17mm height

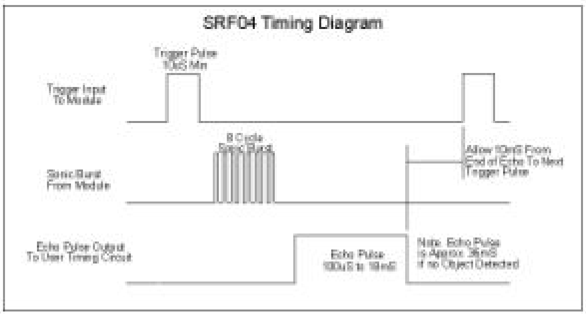

Figure 3.21 Ultrasonic Sensor Timing Diagram

ELECTRIC CONNECTION:

The SRF004 ultrasonic range finder has 5 connections pins. The power supply is connected to the 5V and 0V ground connections on the SRF004. (Note that BOTH the ‘Mode’ (hole 4) and ‘0V Ground’ (hole 5) connections MUST be connected to 0V for correct operation with the PICAXE system). Take care not to overheat, and therefore damage, the solder connection pads whilst making connections.The SRF004 Trigger Input is connected to a PICAXE output pin.The SRF004 Echo Output is connected to a PICAXE input pin.Ultrasonic sensors have set new standards in automation

Figure 3.22 Pin configuration of Ultrasonic Sensor Module

CONNECTION:

The SRF004 must be mounted above the buggy (e.g. by using a small home-made aluminum bracket (not supplied)). The SRF004 has five solder connections which must be connected via wires to the solder joints on the bottom of the buggy PCB.

1. Hole 1 – 5v Supply – to PIC chip leg 14 (V+ Supply)

2. Hole 2 – Echo Output – to PIC chip leg 15 (input 6)

3. Hole 3 – Trigger Input – to PIC chip leg 9 (output 3)

4. Hole 5 – 0V Ground – to PIC chip leg 5 (0V Ground)

3.6 BUZZER

A buzzer or beeper is an audio signaling device, which may be mechanical, electromechanical, or piezoelectric (piezo for short). Typical uses of buzzers and beepers include alarm devices, timers, and confirmation of user input such as a mouse click or keystroke.

Figure 3.23:Buzzer

.

Mechanical

A joy buzzer is an example of a purely mechanical buzzer and they require drivers. Other examples of them are doorbells.

Piezoelectric

Nowadays, it is more popular to use a ceramic-based piezoelectric sounder like a Son alert which makes a high-pitched tone. Usually these were hooked up to "driver" circuits, which varied the pitch of the sound or pulsed the sound on and off.

Figure 3.24 Piezoelectric Buzzer

A piezoelectric element may be driven by an oscillating electronic circuit or other audio signal source, driven with a piezoelectric audio amplifier. Sounds commonly used to indicate that a button has been pressed are a click, a ring or a beep. Piezo buzzer is an electronic device commonly used to produce sound. Light weight, simple construction and low price make it usable in various applications like car/truck reversing indicator, computers, call bells etc. Basically, the sound source of a piezoelectric sound component is a piezoelectric diaphragm as shown in fig(1). A piezoelectric diaphragm consists of a piezoelectric ceramic plate which has electrodes on both sides and a metal plate (brass or stainless steel, etc.). A piezoelectric ceramic plate is attached to a metal plate with adhesives. Applying D.C. voltage between electrodes of a piezoelectric diaphragm causes mechanical distortion due to the piezoelectric effect. For a misshaped piezoelectric element, the distortion of the piezoelectric element expands in a radial direction. And the piezoelectric diaphragm bends toward the direction. The metal plate bonded to the piezoelectric element does not expand. Conversely, when the piezoelectric element shrinks, the piezoelectric diaphragm bends in the direction Thus, when AC voltage is applied across electrodes, the bending is repeated, producing sound waves in the air. Buzzers typically provide a user with an alert when a given condition within the circuit has occurred. Normally man's audible frequency range is 20Hz to 20kHz , but we can hear up to frequency ranges from 2kHz to 4kHz .

To interface a buzzer the standard transistor interfacing circuit is used(Fig 2). Note that if a different power supply is used for the buzzer, the 0V rails of each power supply must be connected to provide a common reference. If a battery is used as the power supply, it is worth remembering that piezo sounders draw much less current than buzzers. Buzzers also just have one 'tone', whereas a piezo sounder is able to create sounds of many different tones. Here transistor acts as a switch.

To switch on buzzer -high 1

To switch off buzzer -low 1

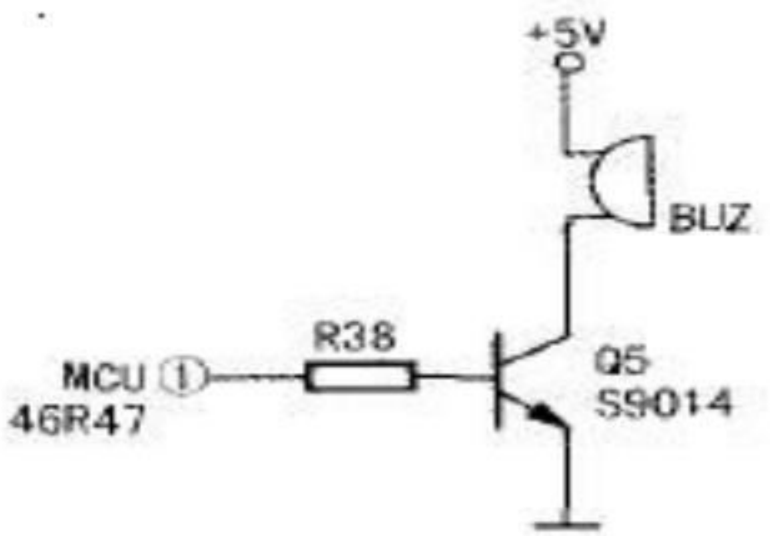

Figure 3.25 Buzzer with Transistor Interfacing Circuit

Notice (Handling) In Using Self Drive Method:

1) When the piezoelectric buzzer is set to produce intermittent sounds, sound may be heard continuously even when the self drive circuit is turned ON / OFF at the "X" point as shown. This is because of the failure of turning off the feedback voltage.

2) Build a circuit of the piezoelectric sounder exactly as per the recommended circuit shown in the catalog. Life of the transistor and circuit constants is designed to ensure stable oscillation of the piezoelectric sounder.

3) Design switching which ensures direct power switching.

4) The self drive circuit is already contained in the piezoelectric buzzer. So there is no need to prepare another circuit to drive the piezoelectric buzzer.

5) Rated voltage (3.0 to 20Vdc) must be maintained. Products which can operate with voltage higher than 20Vdc are also available.

6) Do not place resistors in series with the power source, as this may cause abnormal oscillation. If a resistor is essential to adjust sound pressure, place a capacitor (about 1μF) in parallel with the piezo buzzer.

7) Do not close the sound emitting hole on the front side of casing.

8) Carefully install the piezo buzzer so that no obstacle is placed within 15mm from the sound release hole on the front side of the casing.

MODERN APPLICATIONS

While technological advancements have caused buzzers to be impractical and undesirable, there are still instances in which buzzers and similar circuits may be used. Present day applications include:

- Novelty uses
- Judging panels
- Educational purposes
- Annunciator panels
- Electronic metronomes
- Game show lock-out device
- Microwave ovens and other household appliances

- Sporting events such as basketball games
- Electrical alarms
- Joy buzzer (mechanical buzzer used for pranks)

3.7 VOLTAGE REGULATOR

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

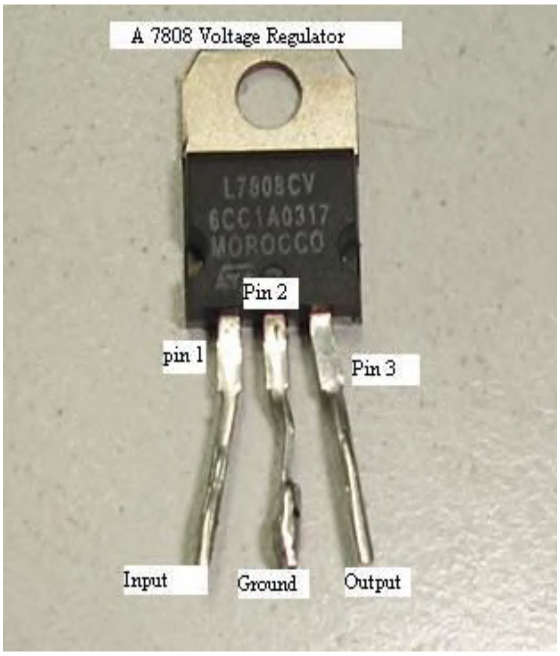

Figure: 3.26 Regulator

3.8 LIGHT EMITTING DIODE (LED)

The Light emitting diode is a two-lead semiconductor light is a special type of diode and they have similar electrical characteristics of a PN junction diode. Hence the led allows the flow of current in the forward direction and blocks the current in the reverse direction. The led occupies the small area which is less than that of the 1mm2 here the led figure is shown below.

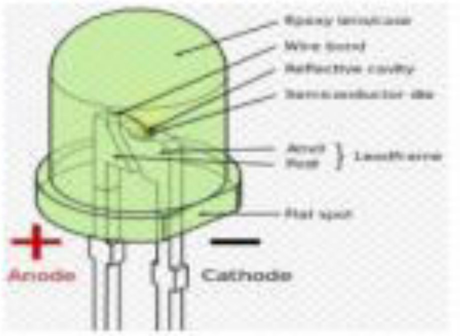

Figure: 3.27 Light Emitting Diode

WORKING OF LED

The light emitting diode simply, we know as a diode. When the diode is forward biased, then the electrons & holes are moving fast across the junction and they are combining constantly, removing one another out. Soon after the electrons are moving from the n-type to the p-type silicon, it combines with the holes, then it disappears. Hence it makes the complete atom & more stable and it gives the little burst of energy in the form of a tiny packet or photon of light.

CHAPTER 4

SOFTWARE DESCRIPTION

4.1 SOFTWARE DESIGN

ARDUINO IDE

The Arduino Integrated Development Environment (IDE) is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++[2]. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.[3]The source code for the IDE is released under the GNU General Public License, version 2.[4] The Arduino IDE supports the languages C and C++ using special rules of code structuring.[5] The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution.[6] The Arduino IDE employs the program to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.[7]

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]
Repository	github.com/arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux

Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

Table 4.1 Features of Arduino IDE

PROGRAMMING

The Arduino Uno can be programmed with the Arduino Software (IDE). Select Arduino Uno from the Tools Board After your code is compiled using Arduino IDE, it should be uploaded to the main microcontroller of the Arduino UNO using a USB connection.

Because the main microcontroller doesn't have a USB transceiver, you need a bridge to convert signals between the serial interface (UART interface) of the microcontroller and the host USB signals. The ATmega328 on the Arduino Uno comes pre programmed with a boot loader that allows you to upload new code to it without the use of an external hardware programmer. It communicates using the original STK500 protocol.

You can also bypass the boot loader and program the microcontroller through the ICSP (In-Circuit Serial Programming) header using Arduino are similar. The ATmega16U2 (or 8U2 in the rev1&rev2 boards) firmware source code is available in the Arduino repository.

The ATmega16U2 or 8U2 is loaded with a DFU boot loader, which can be activated by On Rev1 boards connecting the solder jumper on the back of the board and then resetting the 8U2. On Rev2 or later boards there is a resistor that pulling the 8U2 or 16U2 HWB line to ground, making it easier to put into DFU mode. You can then use Atmel's FLIP software (Windows) or the DFU programmer (MacOS X and Linux) to load a new firmware. Or you can use the ISP header with an external programmer (overwriting the DFU boot loader)**.** Arduino is an open-source hardware platform that is being used by people around the globe for building electronics projects. It is an integrated platform which contains both the physical and programmable circuit otherwise known as microcontroller and a software (or IDE) that you can run on your computer to write and upload the code onto the physical board.

Arduino Board is quite popular among many people who want to get started with electronics, and unlike other embedded system boards Arduino does not require any additional hardware to upload the code (generally known as programmer). The Arduino Program can be written and uploaded using the Arduino IDE that needs just an USB cable to connect. Since the interface is simple and are less complicated. Arduino is preferred by most of the aspiring engineers.

Here we will try to understand about the Arduino Architecture and its functionalities. The processor of the Arduino Board uses Harvard Architecture for which the program code and program data have separate memory. The memory of it is divided into two namely program memory and data memory. The data will be stored in the data memory whereas the 17program code will be stored in the flash program memory. For ex: The Atmega328 microcontroller has 32kb of flash memory, 2kb of SRAM, 1kb of EPROM and operates at 16MHz clock speed. Some of the other basic functions of Arduino are.

Digital write pin is used to write the digital value of the given pin.

Pin mode pin is used to set the pin to I/O mode.

Analog read pin reads and returns the value.

Analog write pin writes the value of the pin

Serial. Begins pin sets the beginning of serial communication by setting the rate of bit

Digital read pin reads the digital value of given pin

4.2 PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

ABOUT PROTEUS:

It is a software suite containing schematic, simulation as well as PCB designing.
ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.The designer can also develop 2D drawings for the product.

FEATURES:

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.
ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

STARTING NEW DESIGN

Step 1: Open ISIS software and select New design in File menu

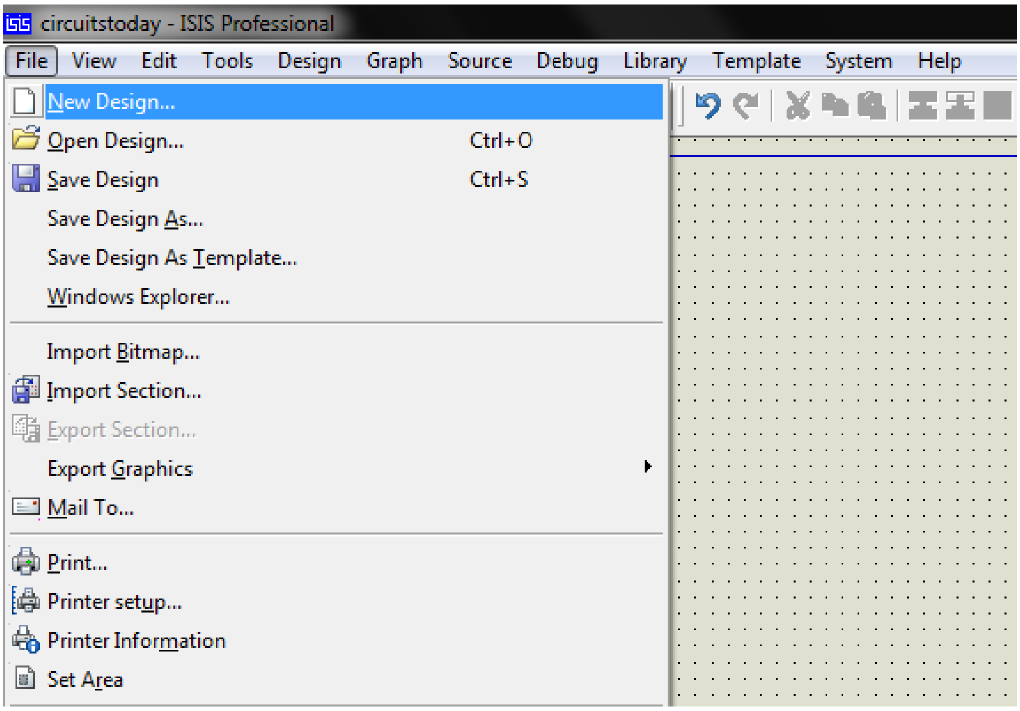

Figure 4.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the project size while printing. For now, select default or according to the layout size of the circuit.

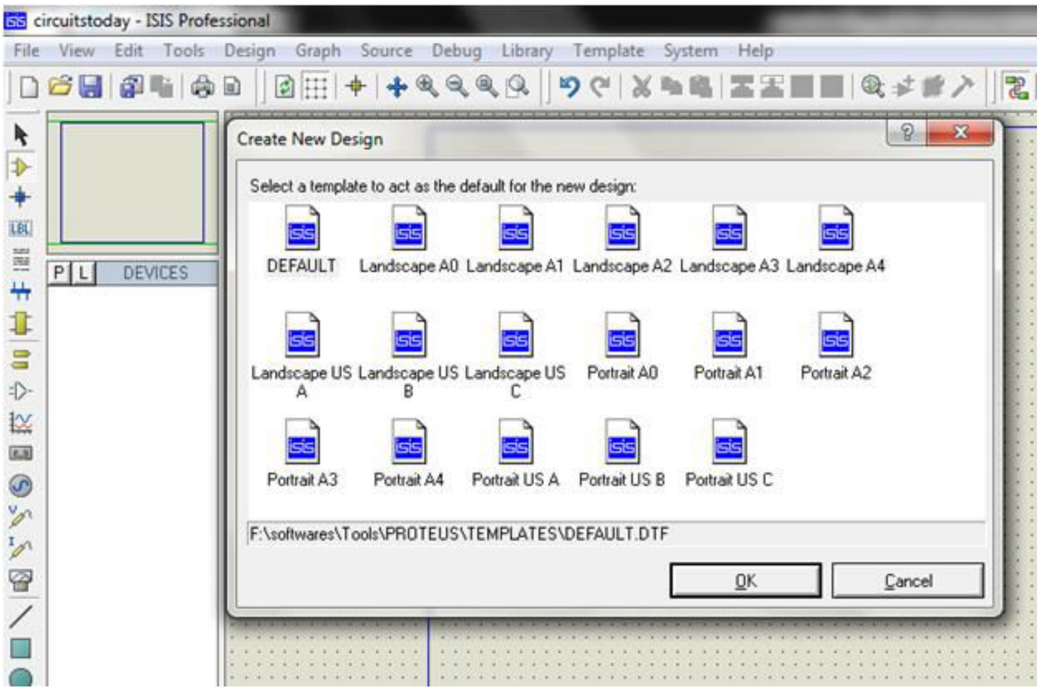

Figure 4.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

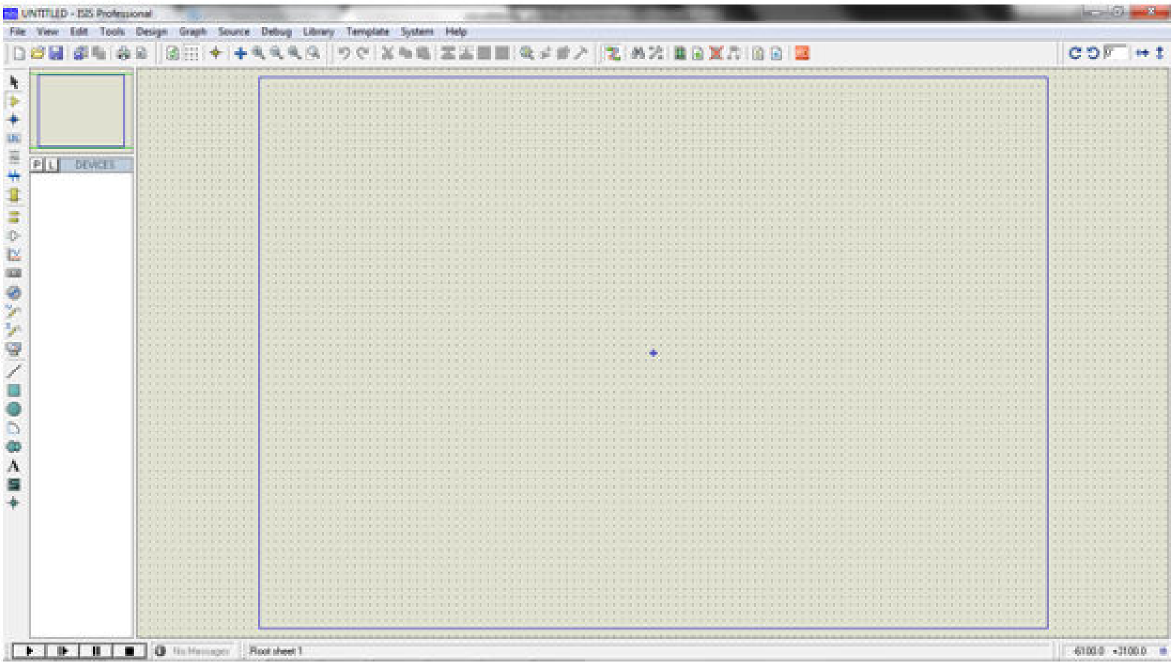

Figure 4.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

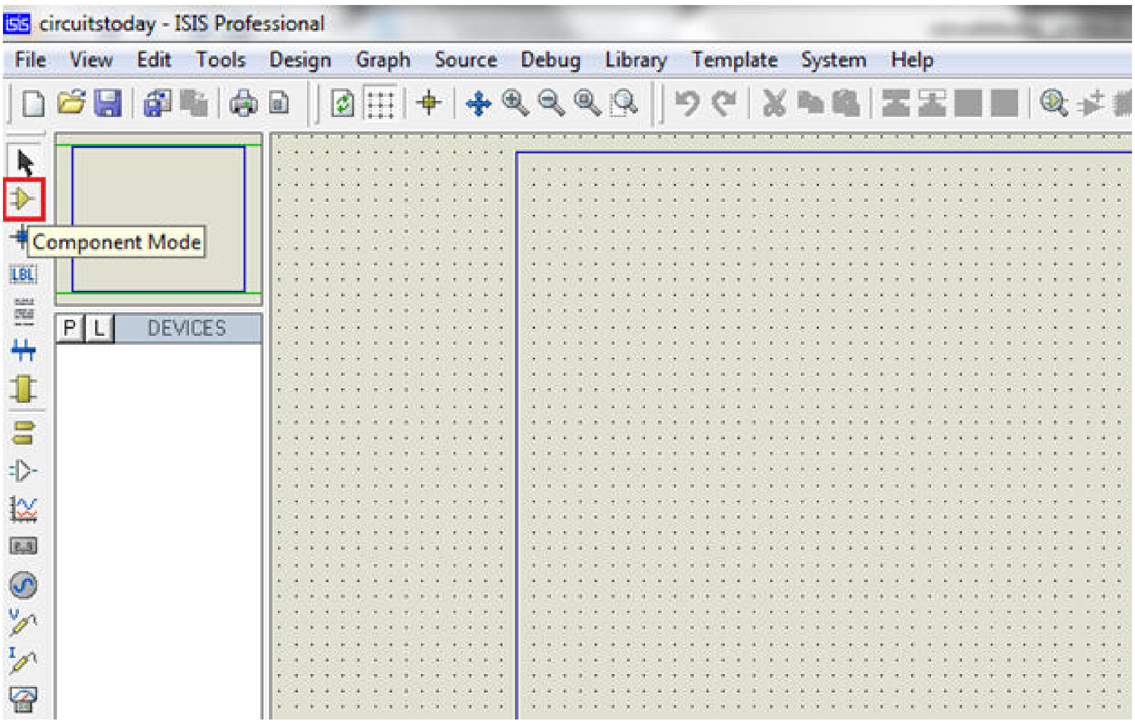

Figure 4.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

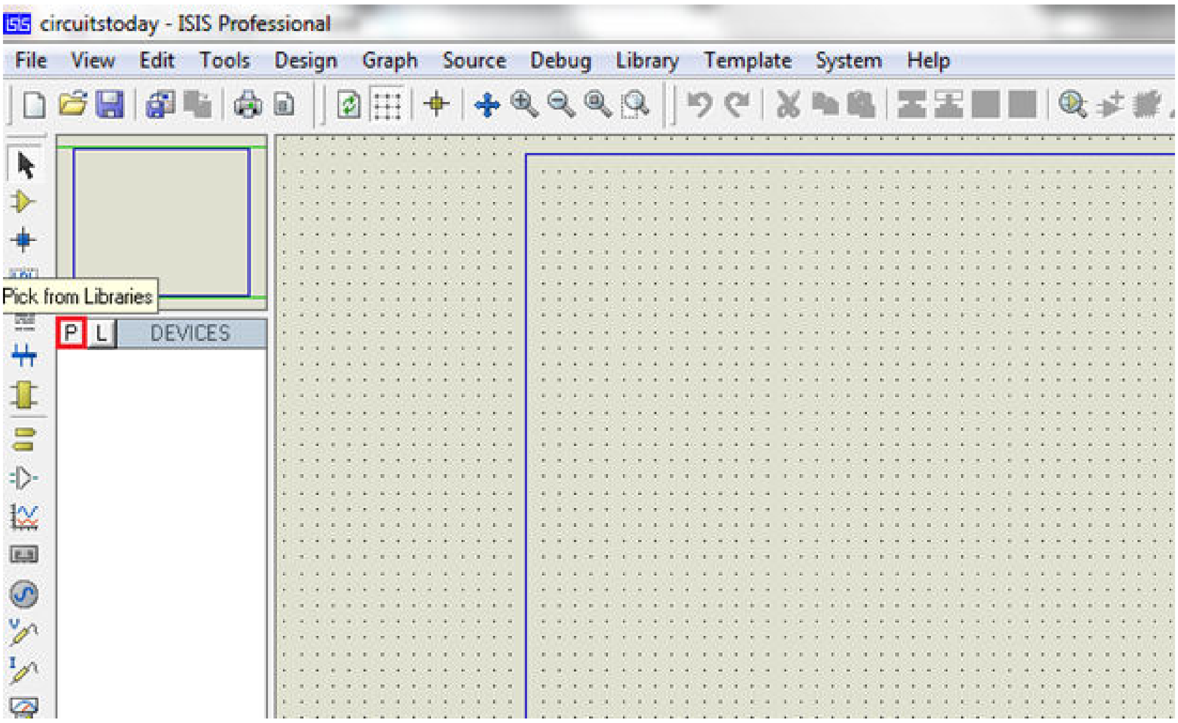

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

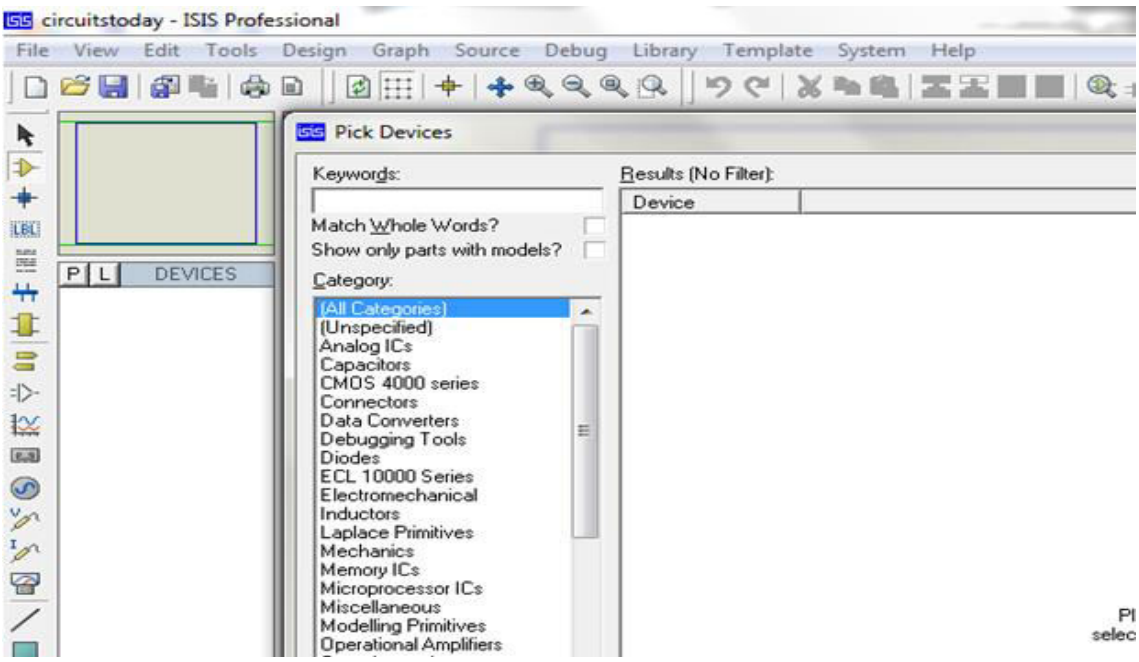

Figure 4.6 Keywords Text box

Example shows selection of push button. Select the components accordingly.

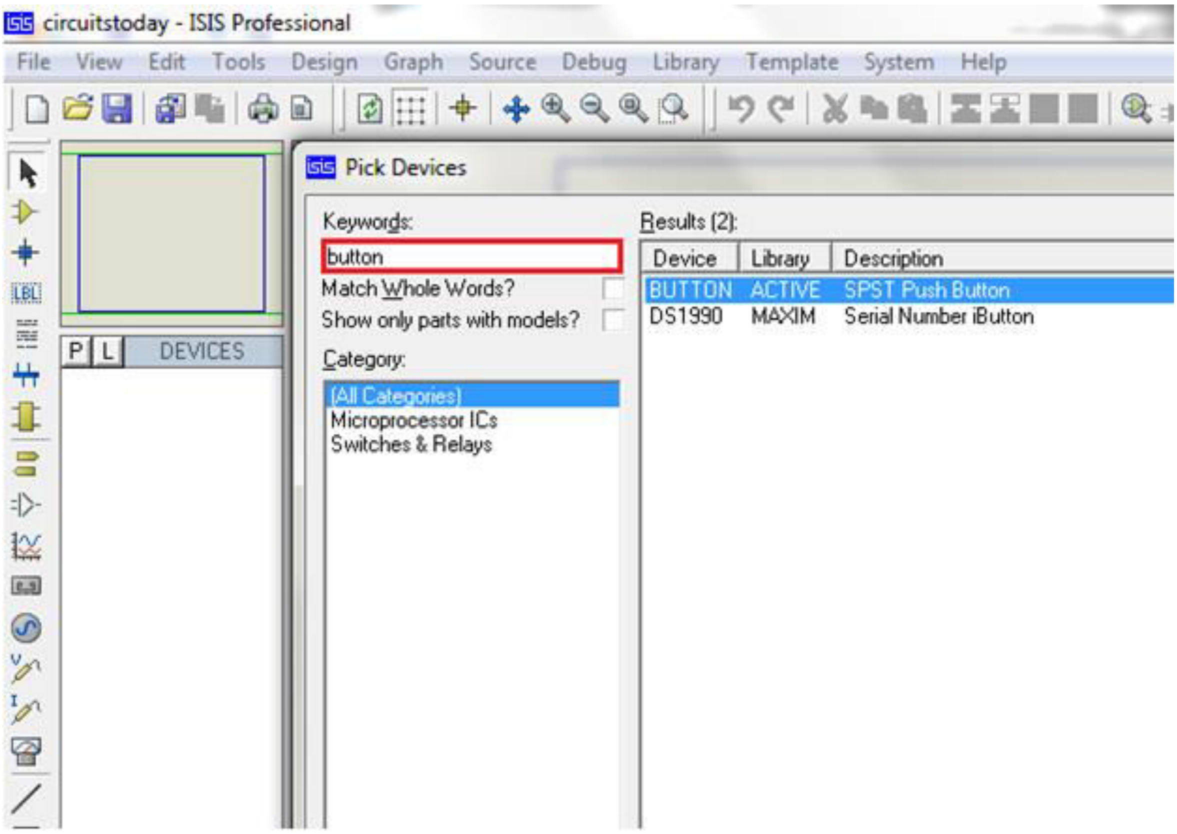

Figure 4.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

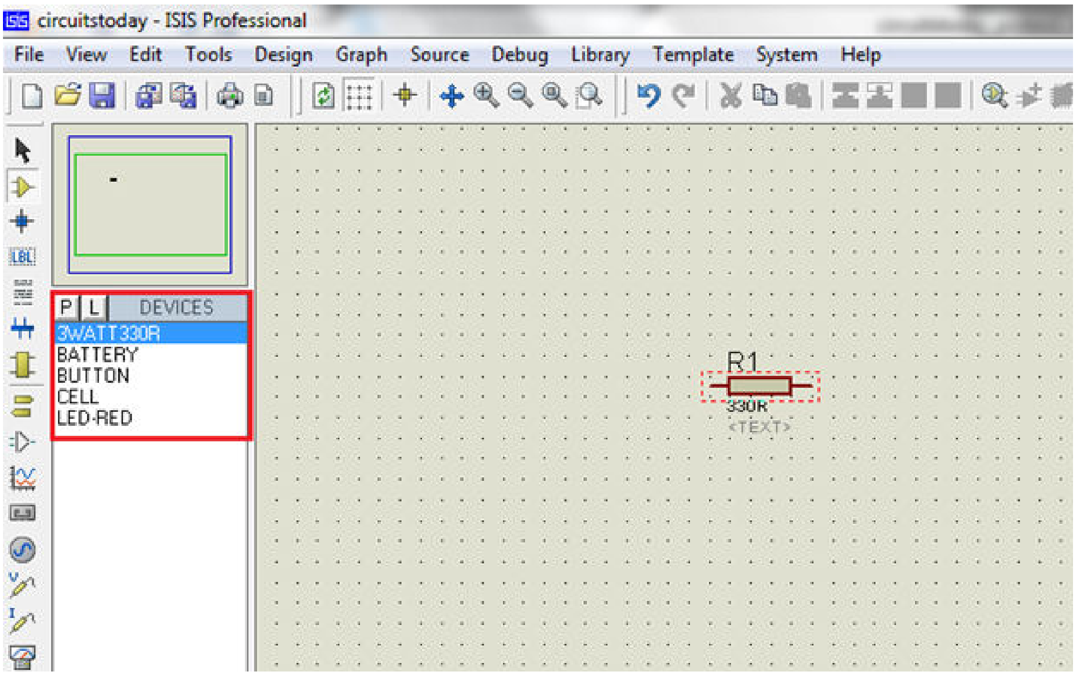

Figure 4.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

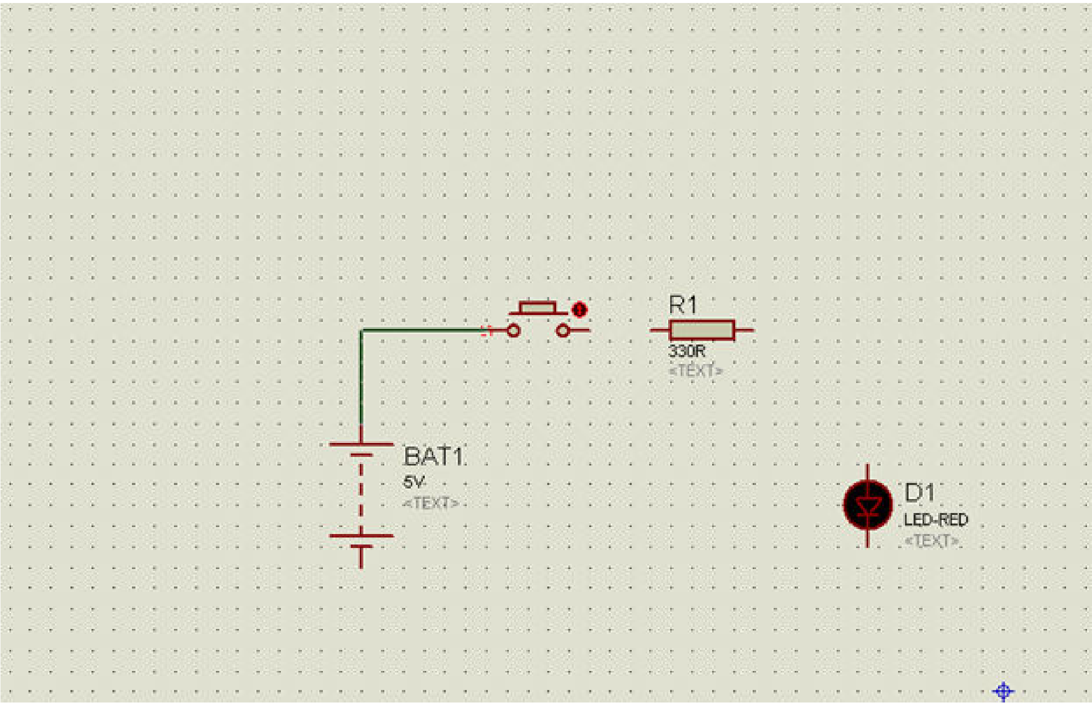

Figure 4.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on OK.

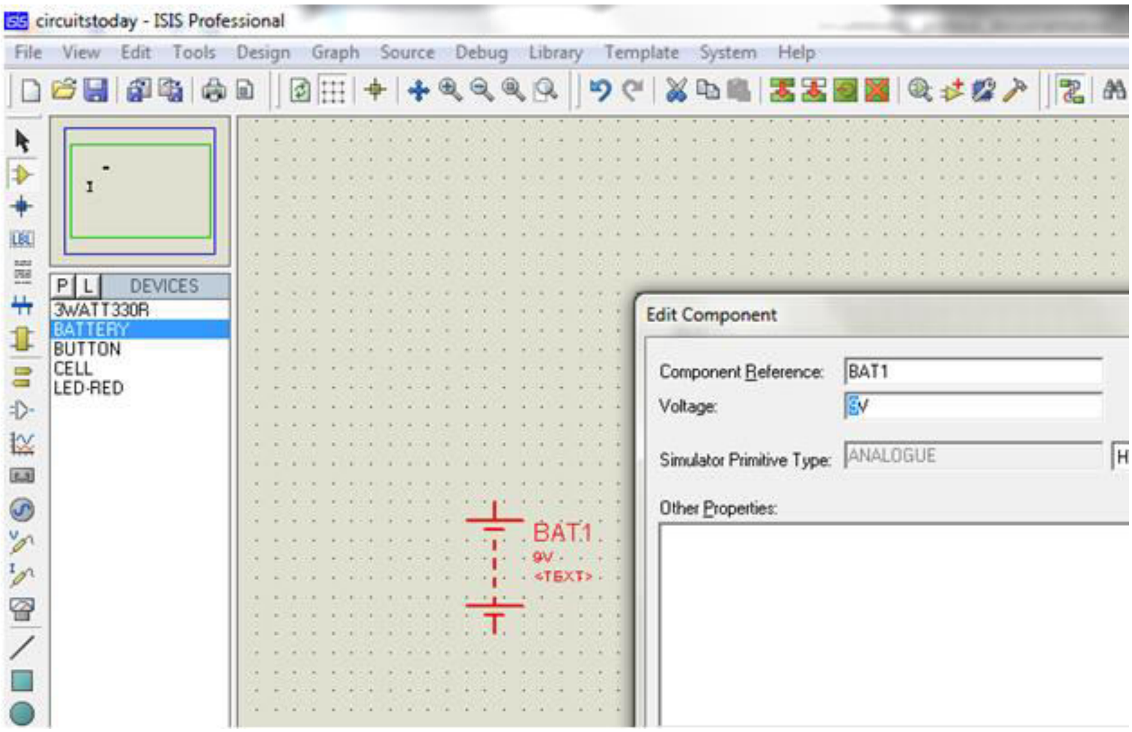

Figure 4.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

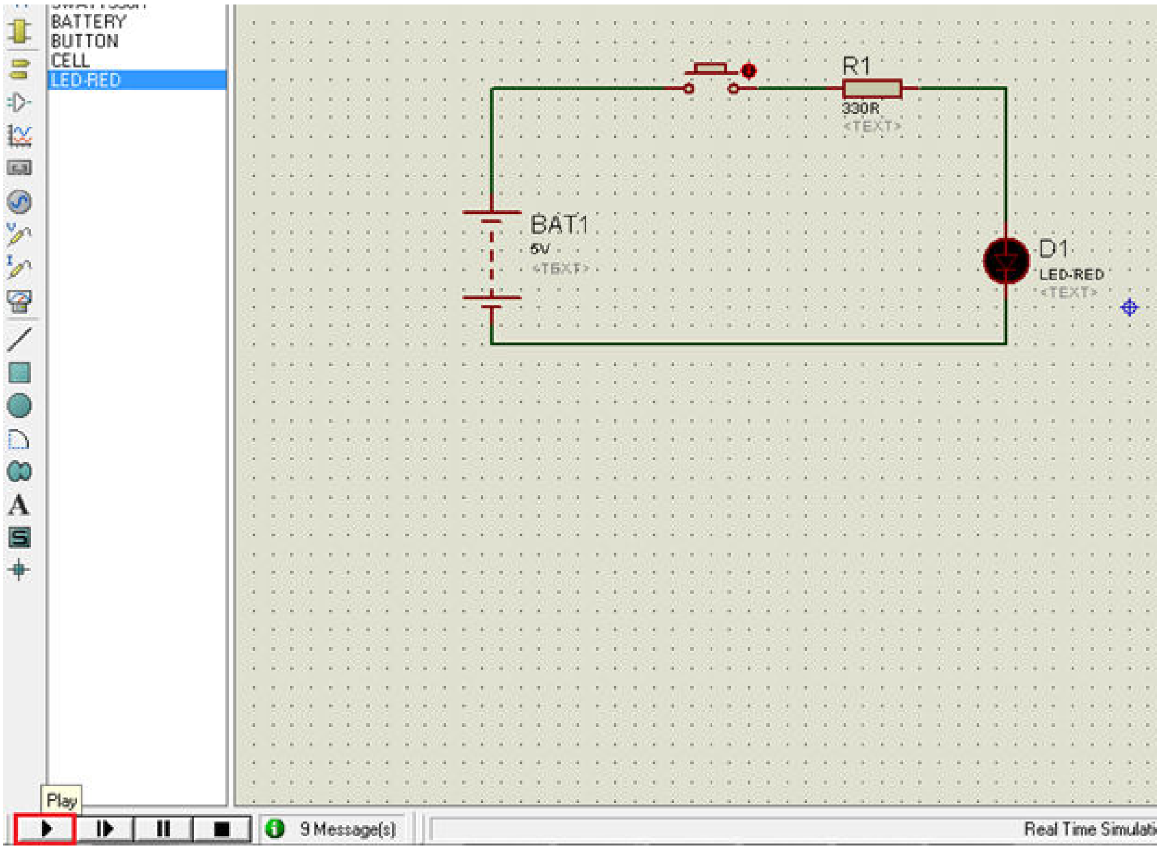

Figure 4.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

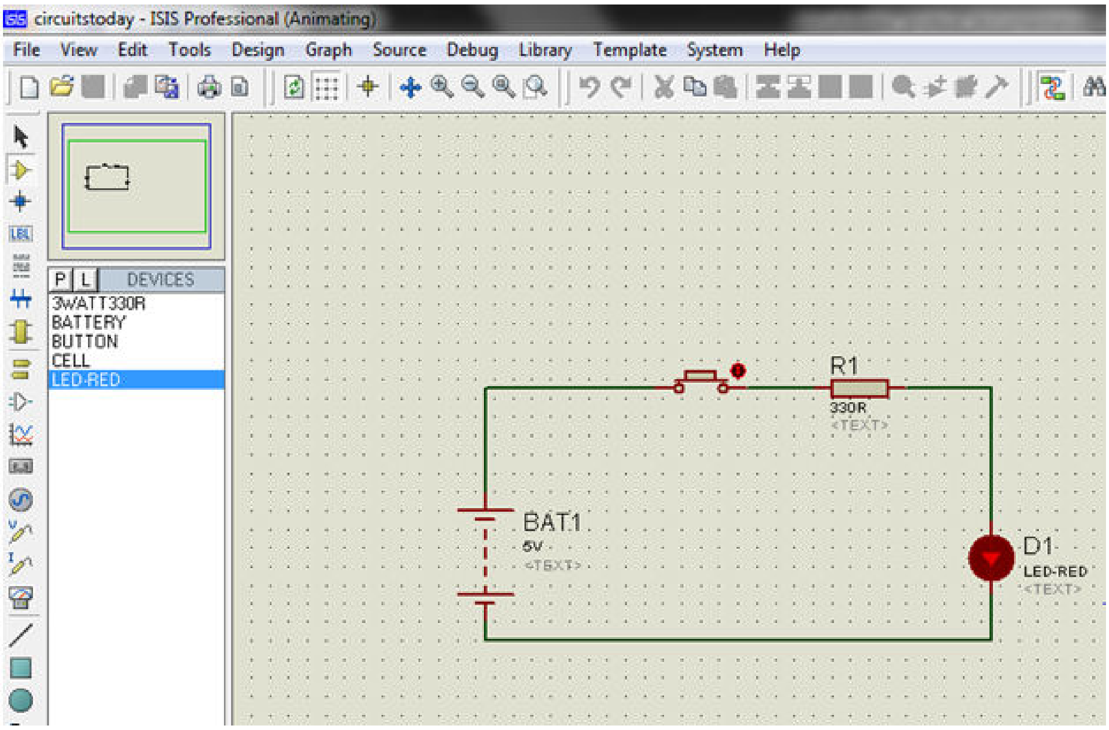

Figure 4.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

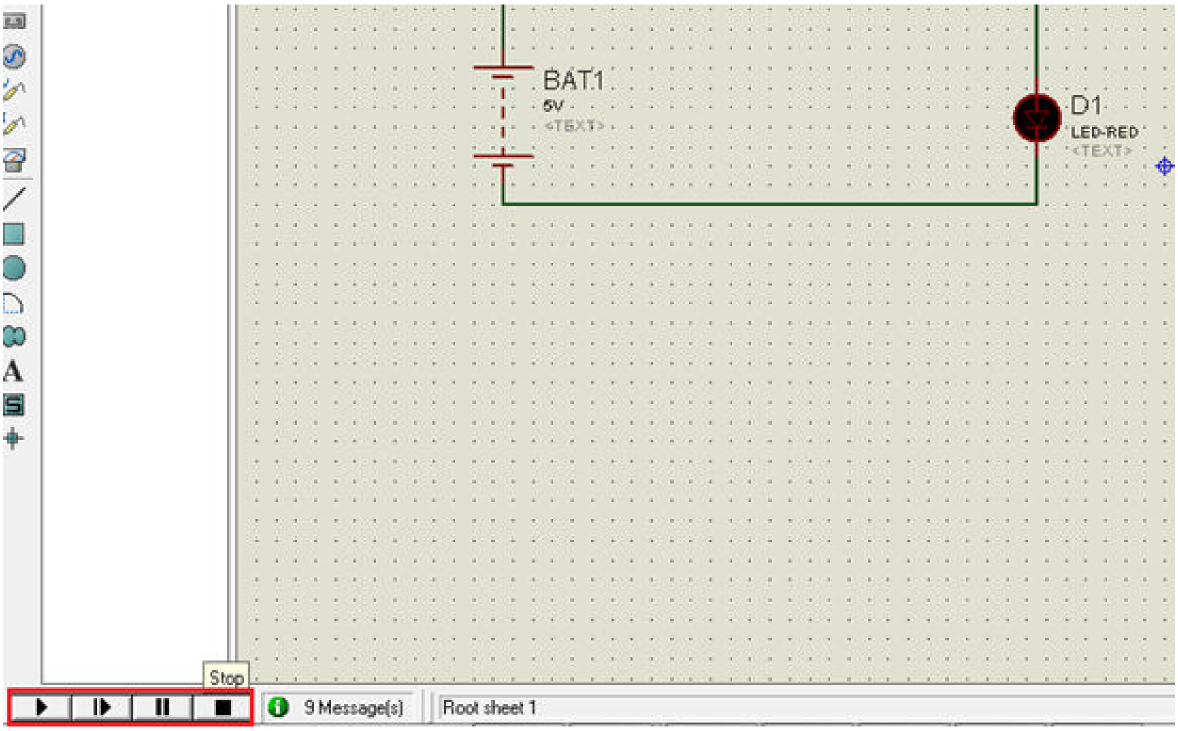

Figure 4.13 Simulation Step-Pause-Stop Buttons

4.3 THINK SPEAK PLATFORM

ThingSpeak is an IoT cloud platform service that allows you to aggregate, visualize and analyze live data streams in the cloud. ThingSpeak provides instant visualizations of data posted by your devices to ThingSpeak.You can send data to ThingSpeak from your devices, create instant visualization of live data, and send alerts.ThingSpeak is IoT Cloud platform where you can send sensor data to the cloud. You can also analyze and visualize your data with MATLAB or other software, including making your own applications.

ThingSpeak enables sensors, instruments, and websites to send data to the cloud where it is stored in either a private or a public channel. ThingSpeak stores data in private channels by default, but public channels can be used to share data with others.A channel is where you send your data to store. Each channel includes 8 fields for any type of data, 3 location fields, and 1 status field. Once you have a ThingSpeak Channel you publish data to the channel, have ThingSpeak process the data, then have your application retrieve the data.

In order to retrieve data from Think speak cloud, below steps are to be followed

1. On the ThingSpeak.com website, select Channels > My Channels.
2. Under the channel that you created for this target hardware, click Settings.
3. Click the API Keys tab.
4. Copy the key from Read API Key parameter.
5. Open the ThingSpeak Read block in your model and paste the copied API key.

THING SPEAK ACCOUNT CREATION

1. Visit www.thingspeak.com.

2. Click "Sign Up".

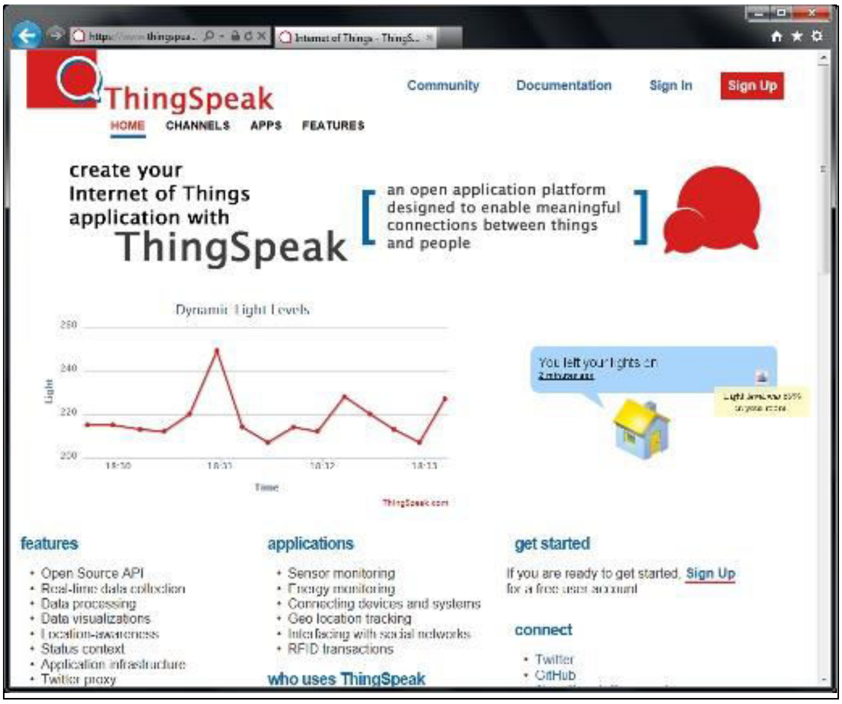

Figure 4.14 Sign up

3. Fill the following mandatory fields: User ID, E-mail, Time Zone, Password and Password Confirmation.

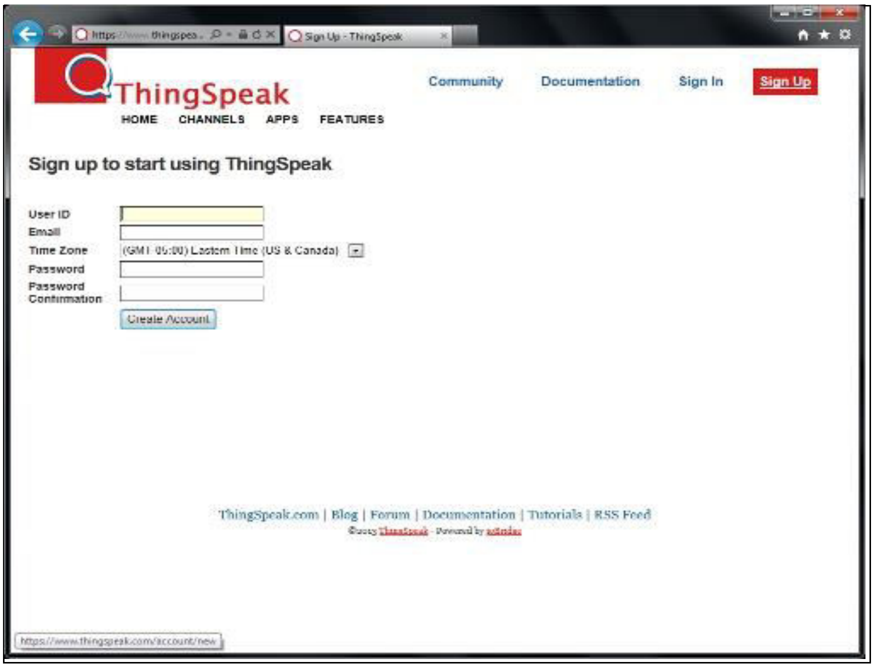

Figure 4.15 Filling the mandatory fields

4. .Click"CreateAccount".

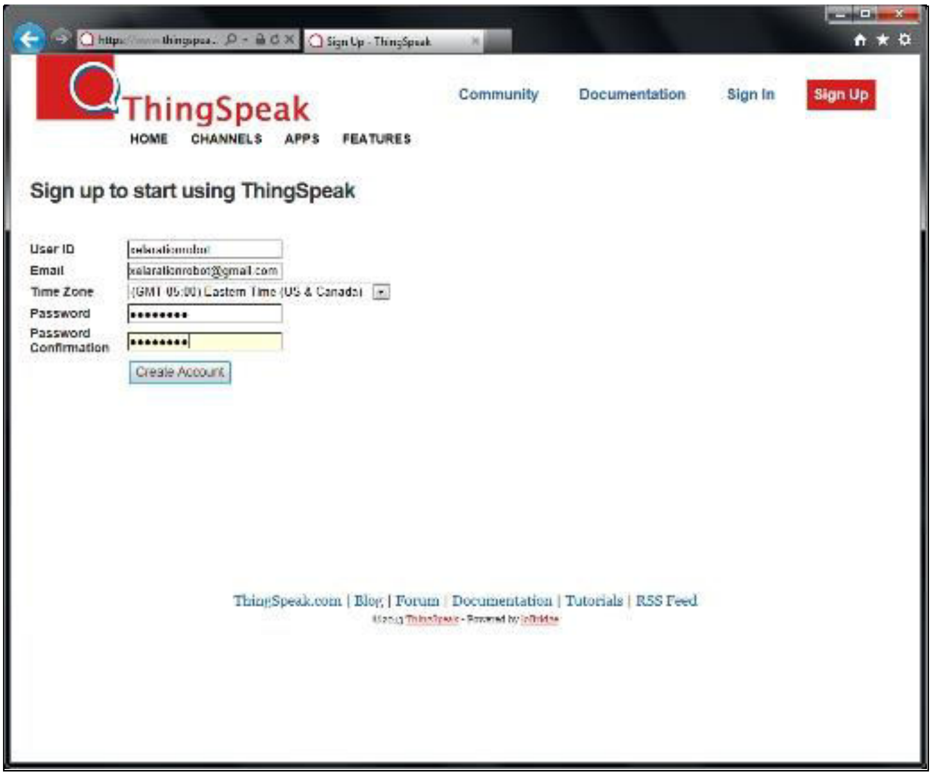

Figure 4.16 Creating account

5. Click "Create New Channel".

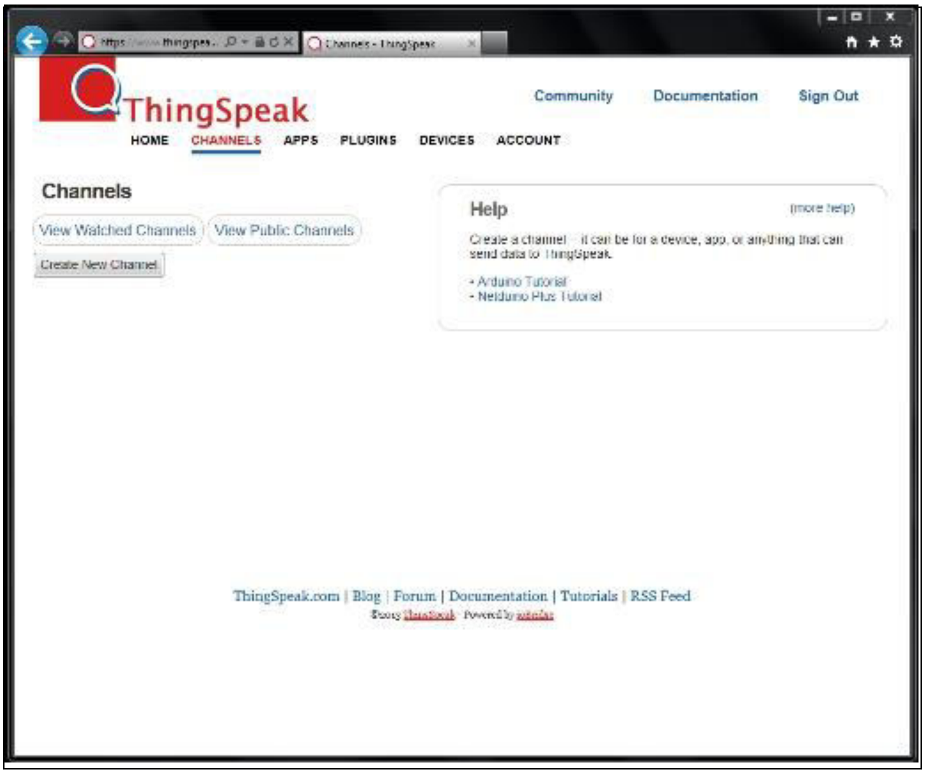

Figure 4.17 Creating new channel

6.

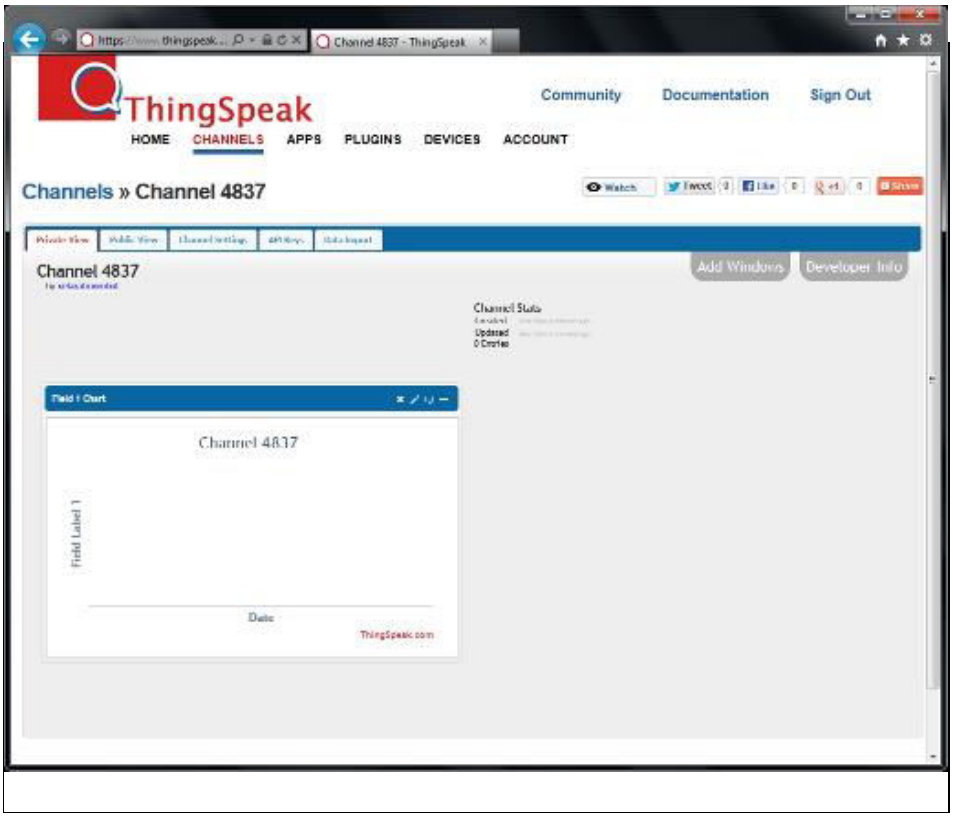

Figure 4.18 Channel settings

7. Fill Fields 1 to 6 with the following values: Left Wheel, Right Wheel, Vacuum, Bumper, Cliff and Battery.

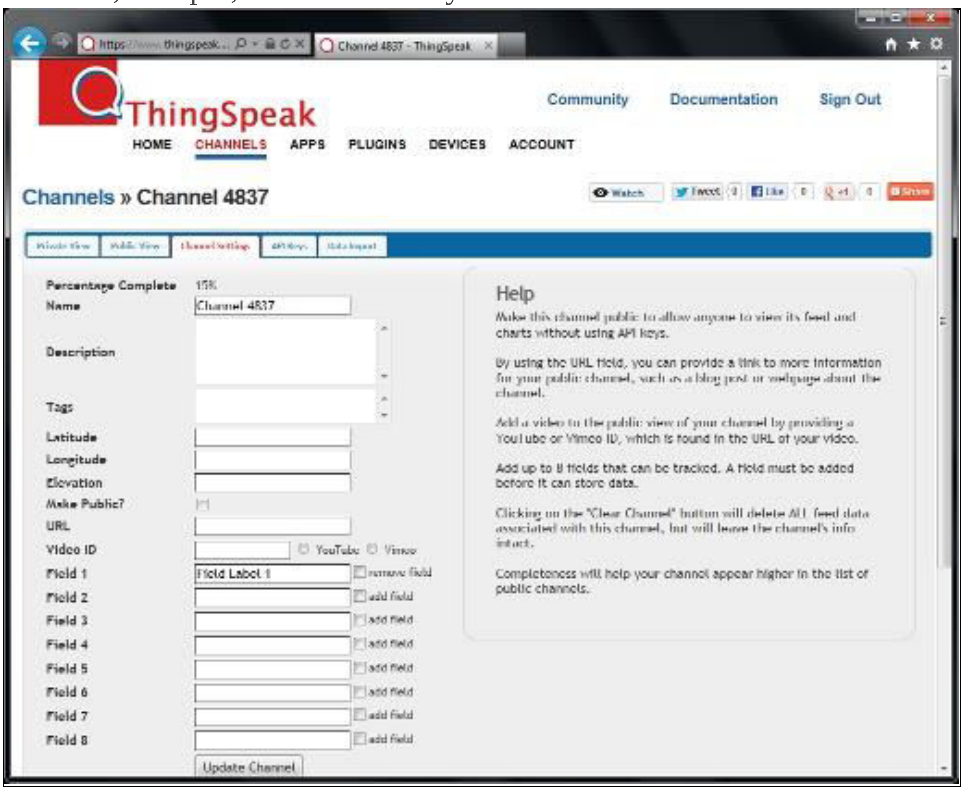

Figure 4.19 Filling the fields related to the project

8.

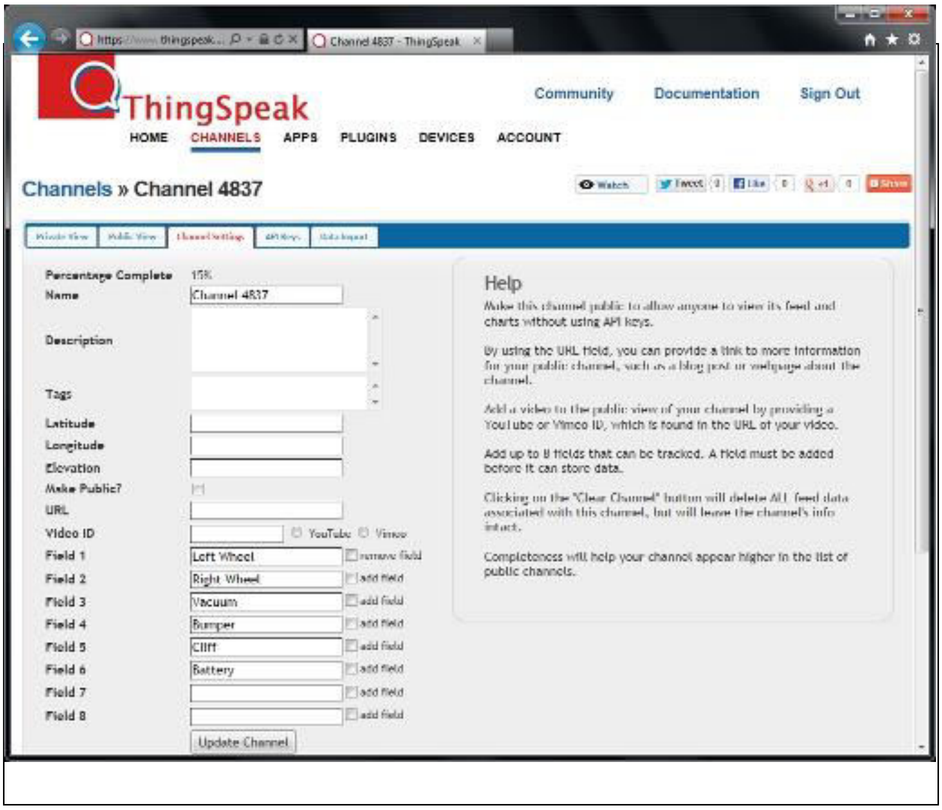

Figure 4.20 Update channel

9. Click the "API Key" tab to get the API key required by the installer.

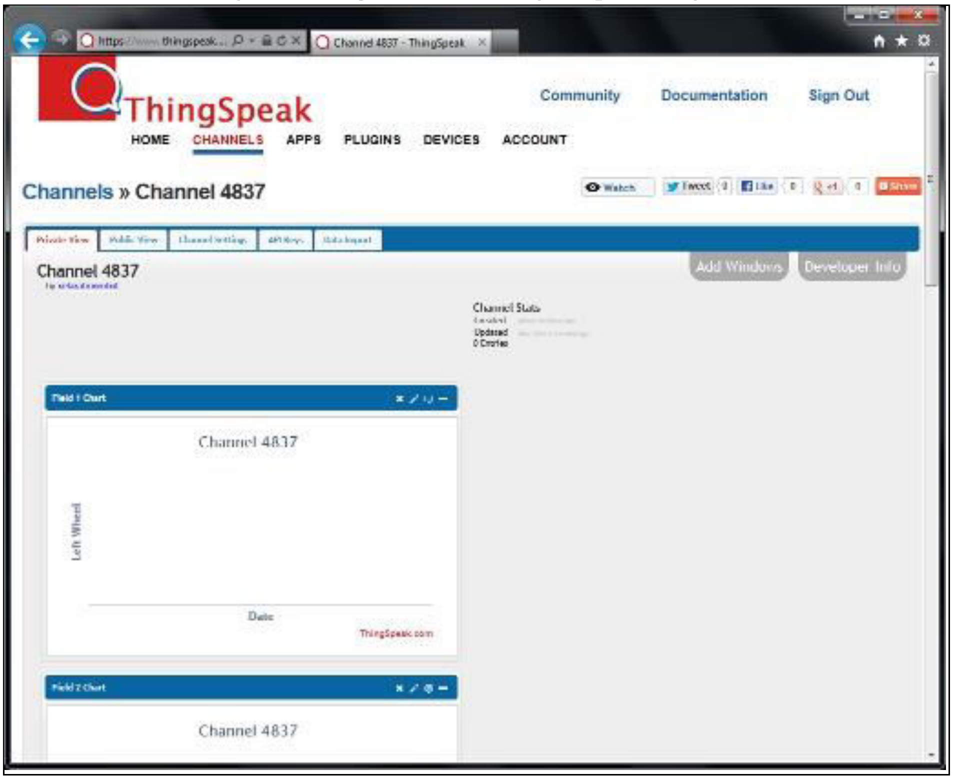

Figure 4.21 API Key generated

CHAPTER 5

RESULT

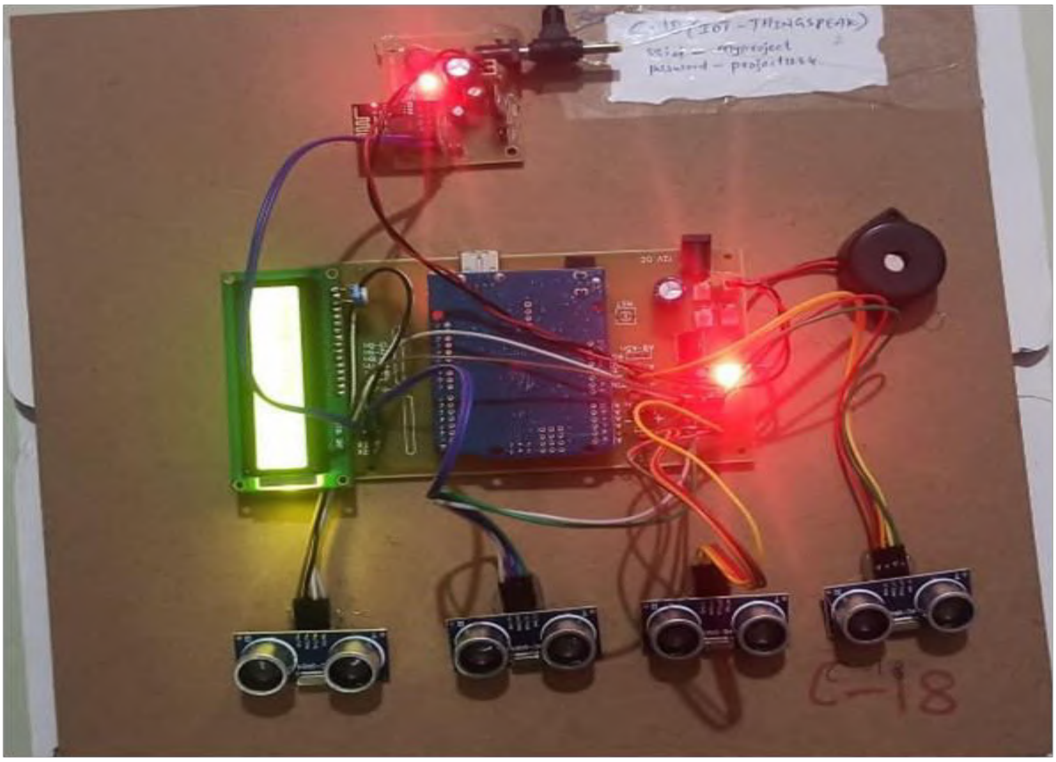

Figure: 5.1 Outlook of the project

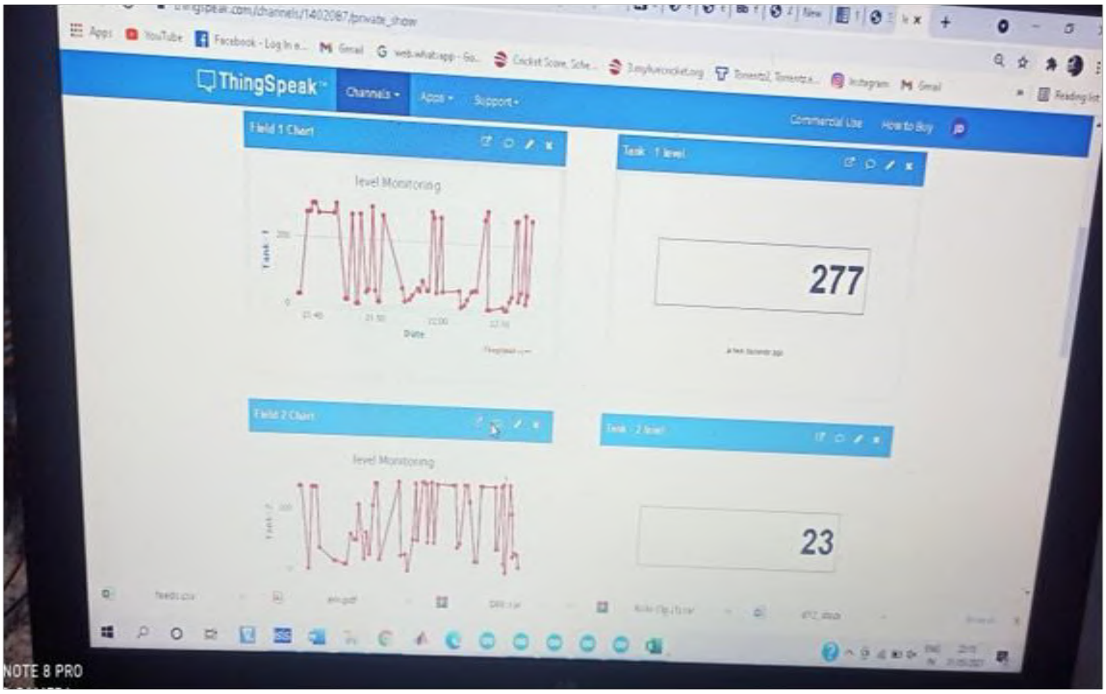
Figure: 5.2 Output of the system on LCD screen



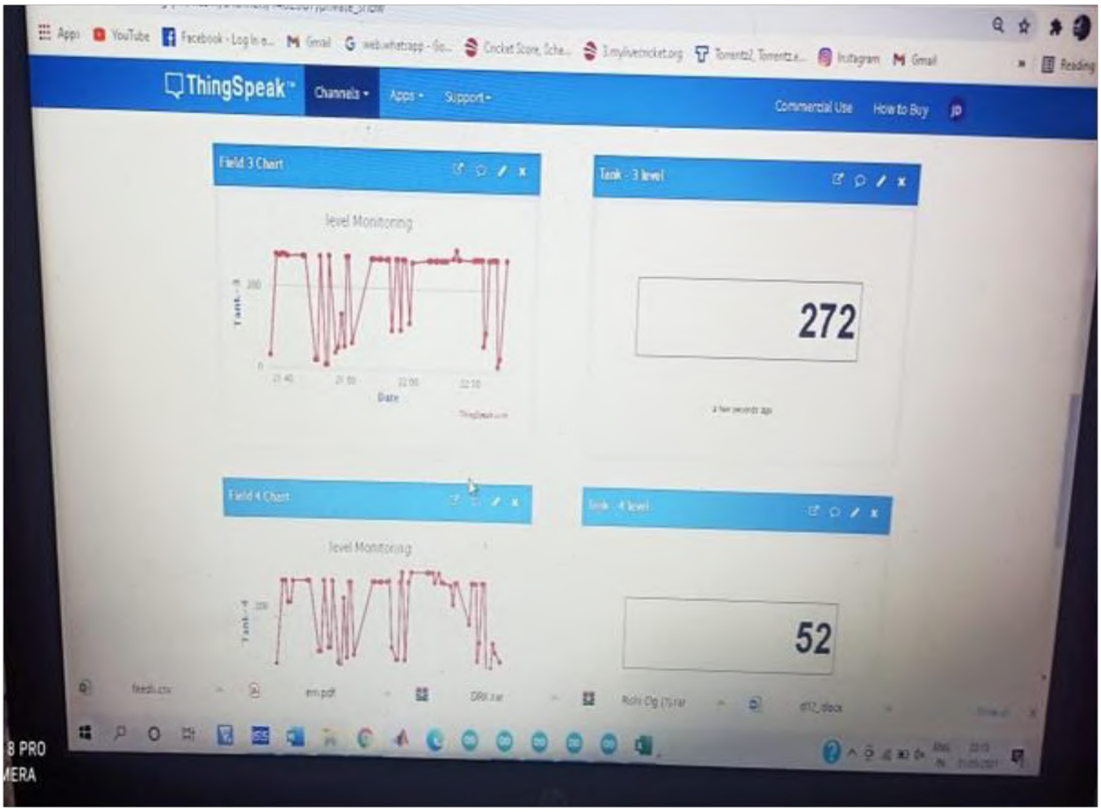


Figure:5.3 graphical and digital view of the 4 tank levels at cloud server

CHAPTER 6

CONCLUSION AND FUTURE SCOPE

6.1 CONCLUSION

Finally the project has been successfully implemented and tested. I am proud to express my delight as the project I embarked upon is successfully finished in such a short span of time.The project proposes a simple liquid level monitoring system with different levels indicated. It also signifies when the water level is below and above then the requirement. Then users can manage the liquid resource and reduce the liquid wastage.

The most important feature of the system is that the users can see the liquid level and its status from anywhere. Thereby especially the industrial firms can manage the liquids effectively. The project gave us more confidence that we will be able to put it in practice, whatever the theoretical knowledge we gained during the course of study till now. It really persuades us to do more and more perhaps better way in future.

6.2 ADVANTAGES

1. This IOT liquid level monitoring system could be installed in that chemical industries which have different chemicals in liquid form and store these chemicals in a separate tank.
2. This IOT based system could be installed in mineral water industries to control the water level in a tank.
3. This system is less costly, more compact, more efficient and more reliable as
4. compared to other liquid level monitoring systems.
5. With IoT, Wireless Water Level Monitoring Becomes Cost-Effective
6. With IoT Human Error Could Be Eliminated
7. IoT Enables Efficient Water Tank Level Monitoring
8. Improved Production Planning with Level Monitoring
9. Leak Detection and Structural Integrity Control
10. Thefts and Tampering Protection

6.3 APPLICATIONS OF LIQUID LEVEL MONITORING SYSTEM

1. Oil Tank Level Monitoring
2. Water Tank Level Monitoring
3. Oil Tanker Monitoring
4. Weather Forecasting & Modelling
5. Diesel Fuel Tank Level Monitoring
6. Petrochemical Plants Monitoring
7. Flood Management
8. Smart Irrigation

6.4 FUTURE SCOPE

Future Work can involve the analysis of water level in a particular area so that the wastage of water is prevented. In future, the proposed system can be used to monitor and analyze water usage of the specific water source thus require developing such logic for the application.

We can also include the GSM-based system where the message will be sent to the particular person to prevent any kind of leakage.The system can also be used to recover the leakage liquid with the help of an electric valve. It opens after getting the information from the controller and the liquid gets stored in a reserved tank.

CHAPTER 1

INTRODUCTION TO IMAGE PROCESSING

INTRODUCTION

1.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

The image is two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

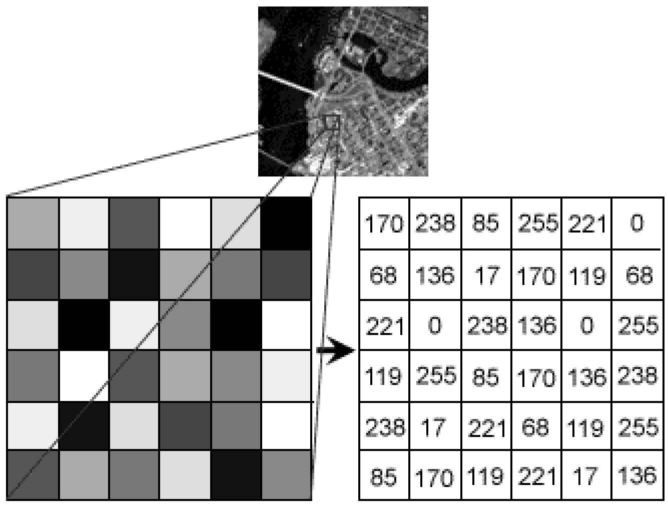

Fig 1.1 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

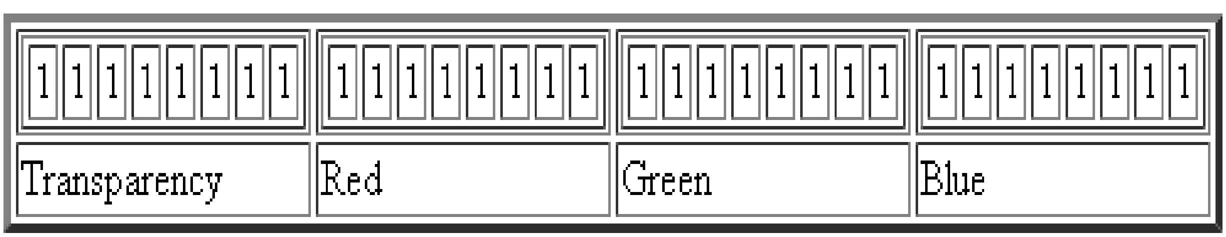

Fig1.2 Transparency image

1.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High-resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 mega-pixels (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

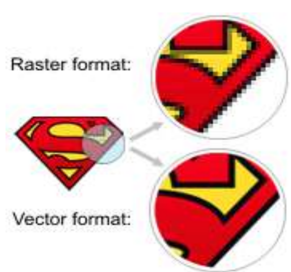

Fig1.3 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

1.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pix-maps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata is recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, the name of the camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

1.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields suffers from myths, miss-connect ions, misunderstandings and misinformation. It is the vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor plowed with imprecise jargon.

Several factors combines to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low-cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

1.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

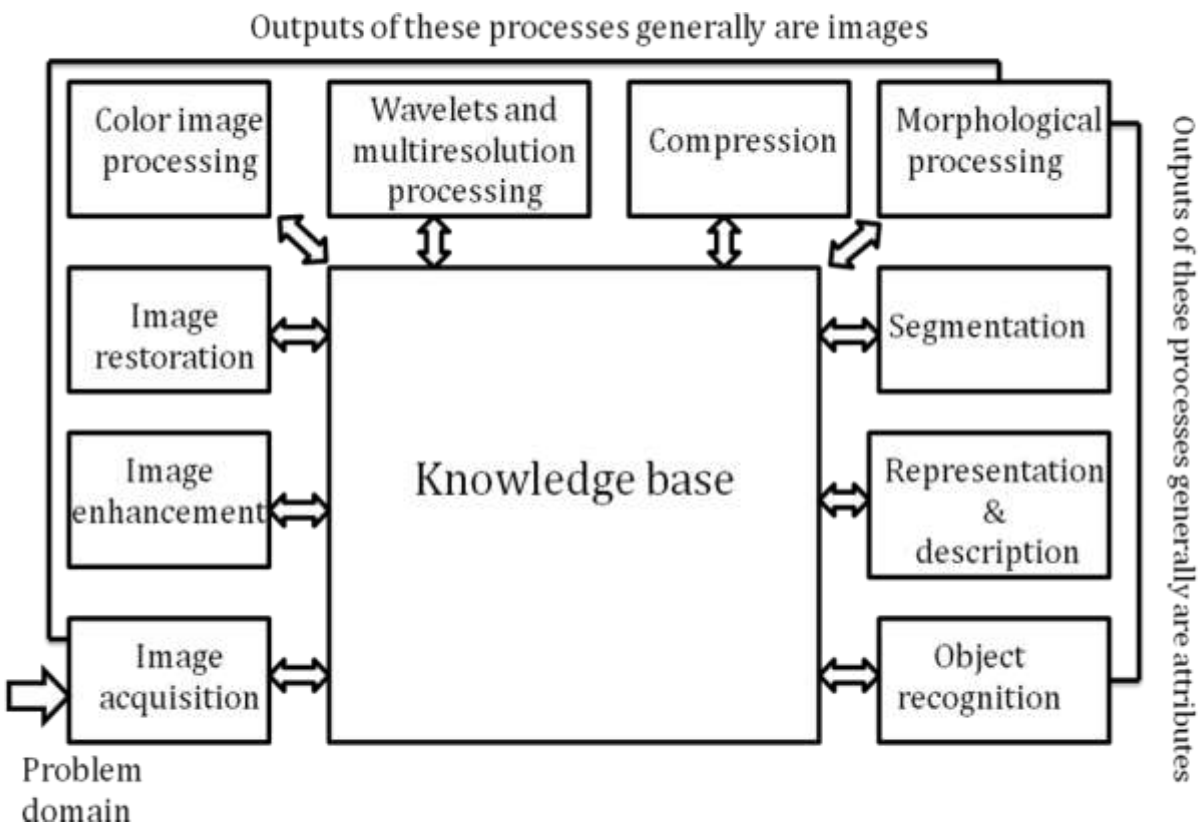

Fig 1.5 Image fundamental

1.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.5.1 Digital camera image

The scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.5.2 digital camera cell

1.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.5.3 Image enhancement

1.5.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

1.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.5.5 Color & Gray scale image

1.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform-based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

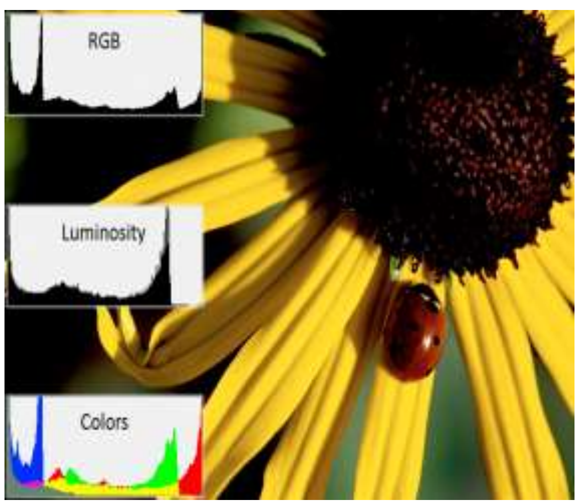

Fig 1.5.6 RGB histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub-band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.5.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which is characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

1.5.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.5.7 Blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.5.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward a successful solution of imaging problems that require objects to be identified individually.

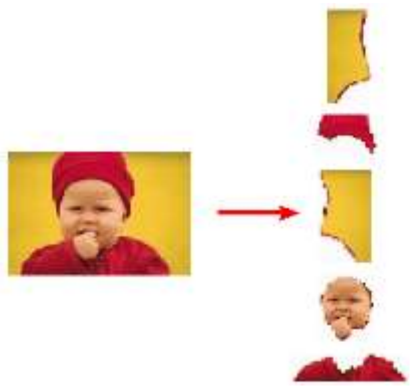

Fig 1.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

1.5.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

1.5.10 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

1.5.11 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an interrelated to list of all major possible defects in a materials inspection problem or an image database containing high-resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

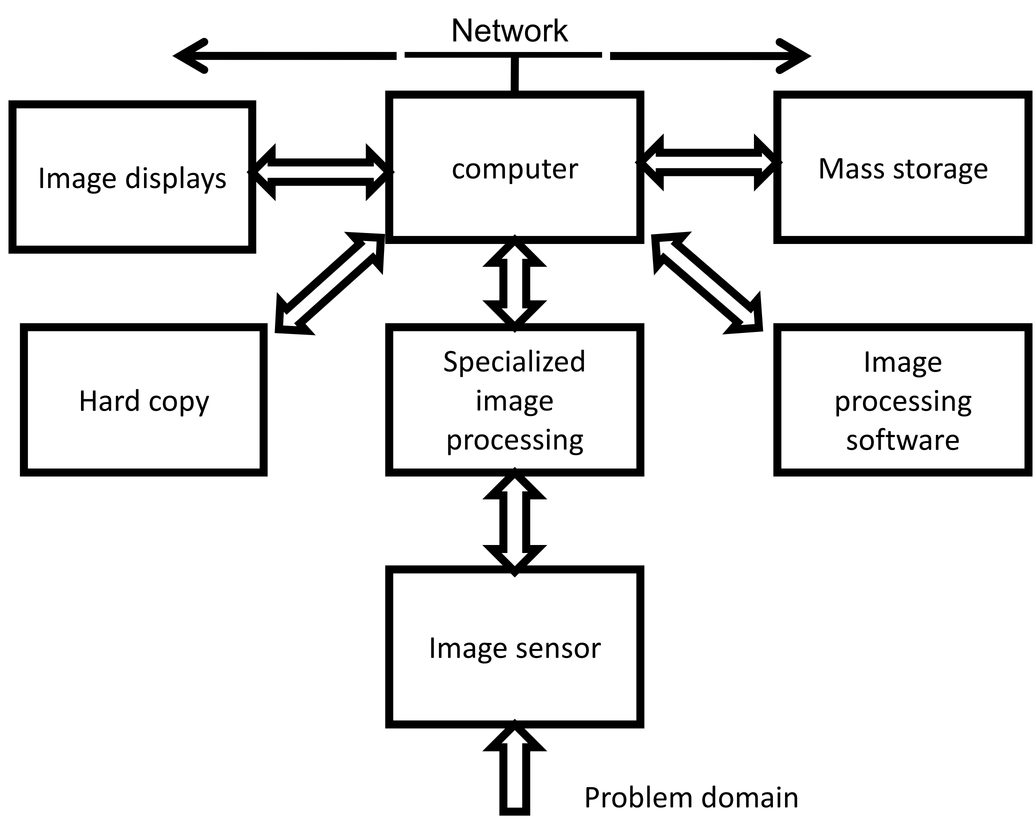

Fig 1.6 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sense, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications falls into three principal categories: (1) short-term storage for use during processing, (2) online storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), G-bytes (meaning gigs, or one billion, bytes), and T-bytes (meaning term, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as a scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing online storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but the infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are their requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. The film provides the highest possible resolution, but the paper is the obvious medium of choice for the written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of a large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of the optical fiber and other broadband technologies.

CCM:

In music

- Contemporary Christian music, a genre of popular music which is lyrically focused on matters concerned with the Christian faith
    - *CCM Magazine*, a magazine that covers Contemporary Christian music
- University of Cincinnati College-Conservatory of Music, the performing arts college of the University of Cincinnati

- Cincinnati Conservatory of Music, a conservatory formed in 1867 as part of a girls' finishing school which later became part of the University of Cincinnati College-Conservatory of Music.
- Contemporary Commercial Music
- In the context of MIDI: control change message.

In cryptography

- CCM mode, a mode of operation for cryptographic block ciphers
- Combined Cipher Machine, a common cipher machine system for securing Allied communications during World War II

In medicine

- Cerebral cavernous malformation, a vascular disorder of the central nervous system that may appear either sporadically or exhibit autosomal dominant inheritance
- Classical Chinese medicine, a medicine that developed from germ theory
- Comprehensive Care Management, a member of the Beth Abraham Family of Health Services
- *Critical Care Medicine*, a peer-reviewed medical journal in the field of critical care medicine

In politics

- Chama Cha Mapinduzi, the ruling political party of Tanzania
- Crown Council of Monaco, a seven-member administrative body which meets at least twice annually to advise the Prince of Monaco on various domestic and international affairs
- Convention on Cluster Munitions is an international treaty that prohibits the use of cluster bombs, a type of explosive weapon which scatters submunitions ("bomblets") over an area.
- Coalition for a Conservative Majority, a nonprofit, political advocacy group organized by Tom DeLay and Kenneth Blackwell

In religion

- Catholic Campus Ministry, a Catholic student organization on many college campuses
- Council of Churches of Malaysia, an ecumenical body in Malaysia comprising mainline Protestant churches and Oriental Orthodox Church
- Christ Church Manchester, otherwise known as CCM is a church in Manchester that meets in numerous locations
- Christian Compassion Ministries, a mission organization in the Philippines

In sports

- CCM (The Hockey Company), a manufacturing company of Canada
- CCM (cycle), a manufacturing company of Canada
- Central Coast Mariners FC, an Australian professional football (soccer) team based on the Central Coast of New South Wales, Australia

In technology

- Continuous Controls Monitoring describes techniques of continuously monitoring and auditing an IT system
- Continuous Current Mode, operational mode of DC-DC converters
- Cisco CallManager, a Cisco product
- Cloud Computing Manifesto
- Configuration & Change Management
- CORBA Component Model, a portion of the CORBA standard for software componentry
- A deprecated abbreviation for the cubic centimeter unit of volume measurement

In transportation

- CCM (cycle), a cycle manufacturer
- CCM Airlines, a regional airline based in Ajaccio, Corsica, France

- Clews Competition Motorcycles, a British motorcycle manufacturer based in Blackburn, England
- Cabin Crew Member, another name for flight attendant

In education

- County College of Morris, a two-year, public community college located off of Route 10 on Center Grove Road in Randolph Township, New Jersey
- City College Manchester, a Further Education college in the United Kingdom.
- City College of Manila, in the Philippines.

In military

- Center for Countermeasures, a United States military center based at White Sands Missile Range, New Mexico
- Command Chief Master Sergeant, a position in the United States Air Force

In other fields

- Corn cob mix, a kind of silage consisting of corn cobs and kernels.
- El Centro Cultural de Mexico, an alternative space in Santa Ana, Orange County, California
- Cerberus Capital Management, a large privately owned hedge fund
- Certified Consulting Meteorologist, a person designated by the American Meteorological Society to possess attributes as they pertain to the field of meteorology
- Crime Classification Manual, FBI produced text for a standardized system to investigate and classify violent crimes.
- Cervecería Cuauhtémoc Moctezuma, a major brewery in Mexico that produces brands such as Dos Equis and Tecate.

Color and texture are two low-level features widely used for image classification, indexing, and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures the global distribution of color in an image One of the main drawbacks of the histogram- based approaches are that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that has a particular grayscale combination. Let I am an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and GL denotes the individual gray levels, where, GL $\in$ {0,., GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \mathbf{Pr}((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i, j))$$

Jim(i, j) is the number of times the gray level of a pixel p denoted by glp equals I, and the gray level of its neighbor Np denoted by glop equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is I, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three-dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation. Many image databases often contain both colors as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where a color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation, and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights. One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U, and V are considered independently. In the Multichannel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU, and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(i; j) = Pr((up; vNp) = (i; j))$$

$$mcmLU(i; j) = Pr((lp; uNp) = (i; j))$$

$$mcmLV(i; j) = Pr((lp; vNp) = (i; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals I, and the V chromaticity value of its neighbor Np denoted by VPN equals j, as a fraction of the total number of pixels in the image. Similarly, mcm(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JPEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second-order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view of both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use the ICICM feature in an image retrieval application from large image databases.

The Early result of this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically, there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Tertiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal number of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the tertiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drop just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexa-cone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON-INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H, S, V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity are divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

G = Qs*Qv*H+Qv*s+V

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 & if \quad h \in [316,20] \\ 1 & if \quad h \in [21,40] \\ 2 & if \quad h \in [41,75] \\ 3 & if \quad h \in [76,155] \\ 4 & if \quad h \in [156,190] \\ 5 & if \quad h \in [191,270] \\ 6 & if \quad h \in [271,295] \\ 7 & if \quad h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 & if \quad s \in [0,0.2) \\ 1 & if \quad s \in [0.2,0.7) \\ 2 & if \quad s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 & if \quad v \in [0,0.2) \\ 1 & if \quad v \in [0.2,0.7) \\ 2 & if \quad v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, which quantize the whole color space for the 72 kinds of the main colors. We can handle 72 bins of one-dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc.

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real-world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented to differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:

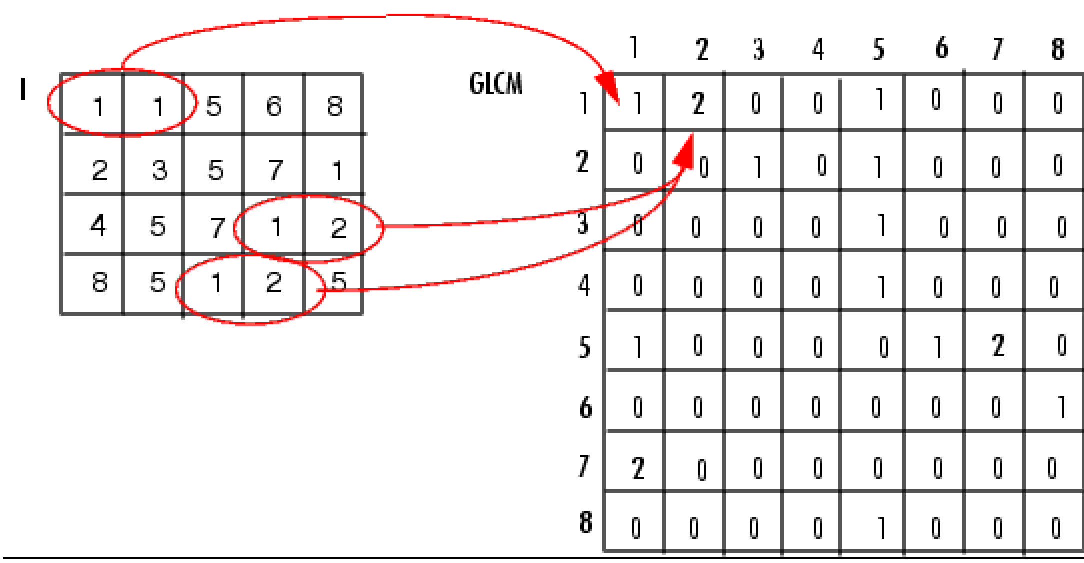

Fig 1.7 Over-view of texture

CHAPTER 2

REVIEW OF RELATED LITERATURE

2.1 Literature Review

This part summarizes some recent methods related to image forgery detection as an overview and also references from which the researchers have new ideas and solutions. For copy move detection, the searching of similar regions is the main purpose in almost all methods while the searching of inconsistencies of features is considered the solution in splicing detection. Although there are numerous related methods published, most of them solve problems of copy-move or splicing separately and only few papers can solve problems of both copy-move and splicing in the same image. Therefore, developing an algorithm to detect any forgery regions, not limited to copy-move or forgery, is still a challenge for scientists in the field of image forensics.

A. Copy-Move Forgery Detection For copy-move detection, a survey in [3] covers and evaluates methods published until 2012 in which the duplicated regions are confirmed based on feature vectors comparisons. Feature vectors can be extracted directly from tested images or after applying a transformation such as DWT and DCT. The difference on feature extractions and the way to compare feature vectors comprise the variety in methods. After that, a new method to extract the image features by describing the spatial structure of the gray image texture called Local Binary Pattern (LBP) was introduced by Leida Li et al. [4] in 2013. In the case of color image, it should be first converted to gray image by using $I=0.299R+0.587G+0.114B$ and low pass filter should be applied to obtain the low-frequency features which is more stable than the high-frequency ones. As the previous methods, the feature matching is defined based on the threshold. Moreover, the post-processing including a special designed filter and morphological operations is also considered in the process of detection. The method is robust to JPEG compression, noise contamination, blurring, rotation and flipping. However, it is difficult to detect the rotated regions with general angles. Investigation of invariant block features and appropriate selection of the dimension of features are suggested to improve the random rotation. Using Undecimated Dyadic Wavelet Transform (UDWT) and Zernike moments is proposed as a new method to detect the forgery in copy-move images by Jiyun Yang [5] in 2013. In this paper, the applying UDWT is firstly used to collect the low frequencies (LL) components. Traditional ZMs is then computed to produce feature vectors of overlapping blocks on LL and find the copied regions from these vectors. Lexicographical sorting, correlation coefficients with a threshold value are used to find the similar vectors and limit the exact forged blocks from the groups of similar vectors obtained in lexicographical sorting step, respectively. Blur invariants are also used to produce feature vectors in copy-move image forgery detection [6]. Based on this idea, the LL sub-band from DWT of an image using Harr basis is divided into small overlapping blocks whose features are then represented by blur moment invariants. Each block feature vector consists of 24 blur invariants in case of grayscale images and 72 ones in the RGB and is reduced dimension by applying PCA. The block similarity analysis will detect the duplicated regions by considering the Euclidean distances and a user defined threshold. This is applied to image with noise, blur and contrast changes. The applying other basis or DCT is suggested in the coming research. In [7], an image is decomposed into four sub-bands using DWT in which the LL sub-band is considered for the coming steps. The proposed algorithm uses SIFT on each small overlapping block divided from LL sub-band to extract feature vector. These feature vectors are used to create a descriptor vector and compared to detect if there is a copy-move manipulation in the image. This method is checked with MICC-F200 database with high accuracy, less time, robust to scale and rotation. The authors of this algorithm developed SUFT (Speed-Up Robust Feature) to extract the features of image block instead of using SIFT as in [7]. The combination of SUFT and DWT, DyWT are also presented. With the results obtained from the proposed method, SUFT is proved faster than SIFT while SIFT is mostly used to select the invariant features [8]. B. Splicing Forgery Detection Splicing is more complex than copy-move, not only in the forgery manipulation but also in detection. The key idea of many splicing detection methods is searching regions being inconsistent with camera characteristics or image features. Regions which are resampled, double compressed, and those with blur discrepancies or sharpness differences can be considered traces of splicing. However, because of the variety of splicing, more and more algorithms have been developed in recent years. Conditional Co-occurrence Probability Matrix (CCPM) is used to detect the splicing in image based on the third order statistical features [9]. CCPM contains the discriminative information which are included in higher order statistical features and independent to the image features. However, the higher dimensionality of features is, the more complex computation is. Therefore, principal Component Analysis (PCA) is also used to improve the computational complexity of the proposed method which is robust and better than Markov features both in spatial domain and block discrete cosine transform (BDCT) domain. Rescaling and its factor are used to detect the forgery caused by splicing [10]. A region copied from an image will be resized or scaled before pasting to the destination image. Scaling makes the pasted portion resampled and inconsistent. In addition, properties of the zero-crossing of the second difference are considered to calculate the scaling factor with different interpolation schemes. The algorithm of rescale detection and estimation proposed clearly in five steps including pre-processing to convert the RGB to grayscale and extract Y component from YCbCr conversion; calculate the second difference, their zero-crossing and Discrete Fourier Transform (DFT) before searching for the periodicity and peak detection. Differences of JPEG compression in an image can be caused by the splicing [11]. JPEG forgery detection based on 8x8 block Discrete Cosine Transform (DCT) transform to detect the shift of DCT block alignment. The splicing detection was proposed by analyzing and suggesting solutions for cases making the differences in compression history including detections of Aligned Double JPEG, non-aligned Double JPEG, Primary Quantization Table, JPEG ghost. Illumination inconsistencies and intrinsic resampling properties are also parameters to detect the splicing [12]. The first requires an input image and a database for training. The algorithm begins with 30x30 blocks which will be transformed into an opponent color space HSV before extracting features of contrast and mean. The contrast is calculated from the standard deviation while the mean is obtained by computing the average grey level. These features will decide suitable algorithm. Illumination color estimation, illumination map creation, Wavelet-based features extraction and classifier are the following steps of the proposed method by illumination differences detection. The second solution in this paper proposes a resampling detection scheme to detect forgery in which second difference in horizontal or vertical, Radon transform, FFT of covariance, high-pass filtering, feature extraction and classifier are included. C. Forgery Detection for both Copy-Move and Splicing An integrated technique, which combines DCT and Speeded Up Robust Features (SURF), to detect the image forgery in term of copy-move or splicing was proposed in 2011 [13]. This means the tested images can be optional, not classified in copy-move or splicing in advance. The paper finds new traces based on recompression to detect the counterfeit of recompressed images. Periodicity analysis with double compression effect in both spatial and DCT domain is applied before using SURF descriptor to against the variation of rotation and scaling. The proposed method located the forgery regions efficiently for both copy-move and splicing image, especially, discriminated the positions of original and forged regions. At the EUROCON 2013 in Croatia, a method can detect both copy-move and splicing in image using a multi-resolution Web Law Descriptor (WLD) was presented [14]. The algorithm firstly converts a RGB image into YCbCr so that the WLD can extract the features from chrominance components which are less sensitive than luminance. To extract the features effectively, WDM are expressed by two components of differential excitation and orientation, which based on Weber' law. The multi-resolution WLD histogram is comprised of the histogram of three neighbors of (8,1), (16,2), and (24,3) where the first argument is the number of neighboring pixels and the second is the radius of the neighbors from the center pixel. A support vector machine, which involves to training and testing image, is used for classification purpose.

CHAPTER 3

SOFTWARE INTRODUCTION

3.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension.fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

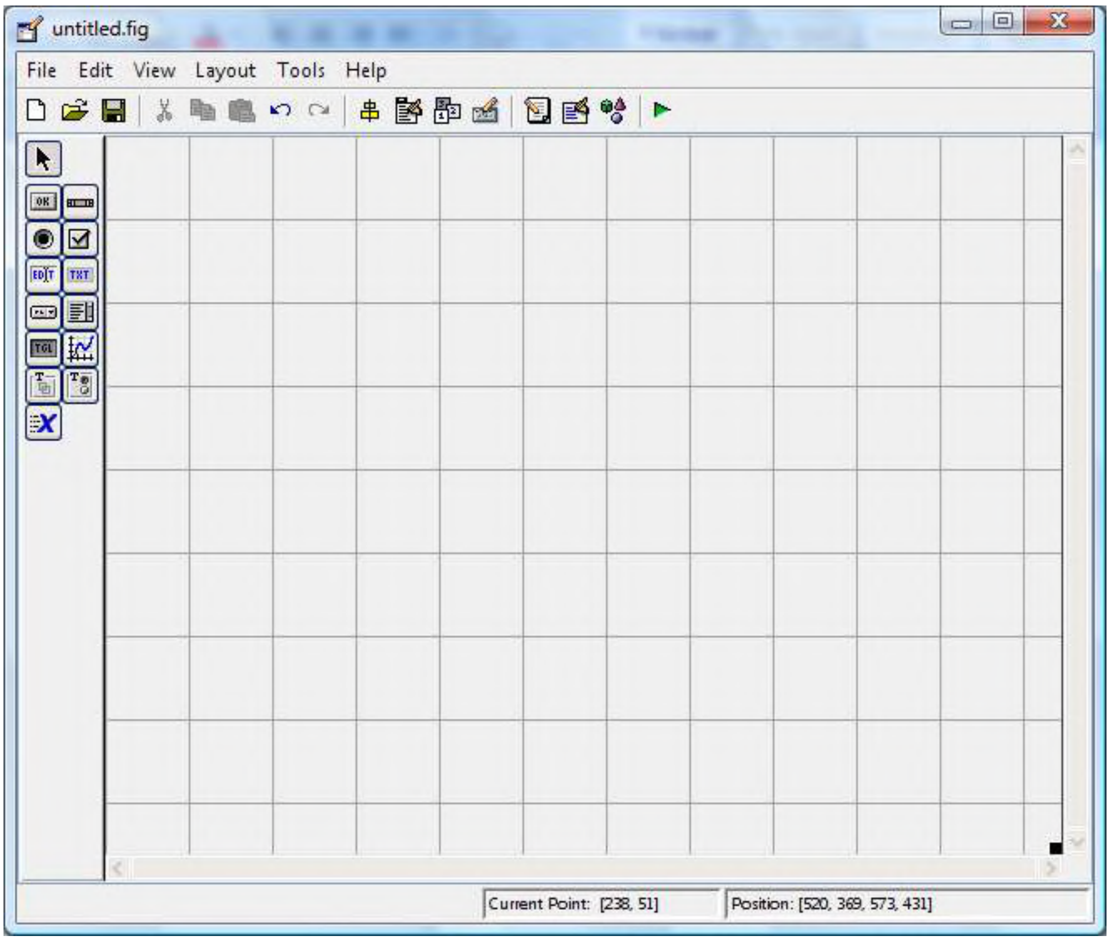

Fig 3.3 MATLAB window

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.4.1 Introduction - describes the components of the MATLAB system.

3.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

3.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.5 DEVELOPMENT ENVIRONMENT

3.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.on a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Content tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorite's tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

3.6 MANIPULATING MATRICES

3.6.1 **Entering Matrices**

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

    16     3     2    13

     5    10    11     8

     9     6     7    12

     4    15    14     1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

3.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 1: Arithmetic Operators

3.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, for a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 2: MATLAB Functions

3.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

3.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (ui-controls and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

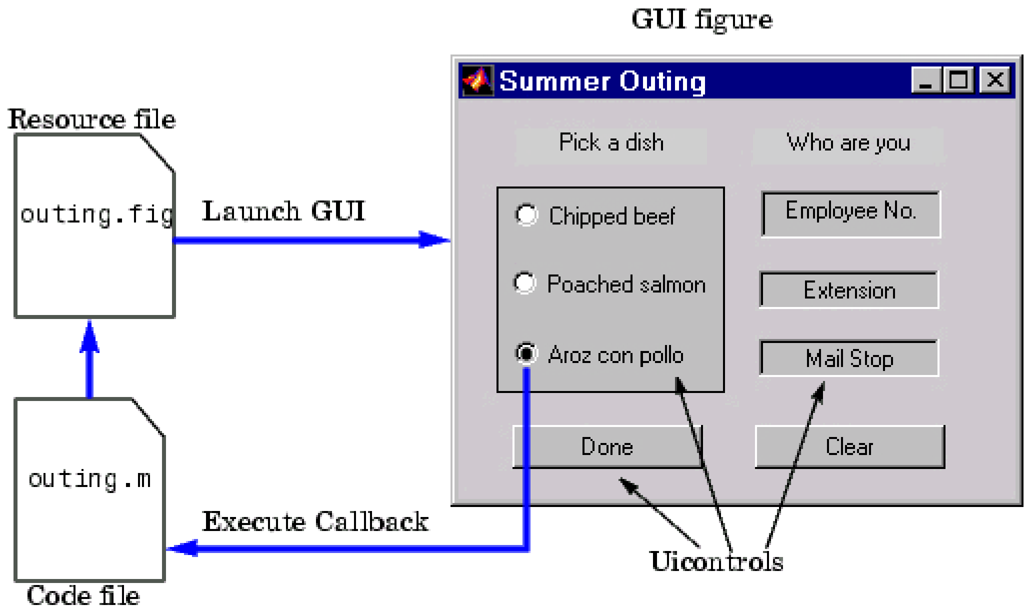

FIG 3.7.2 graphical user blocks

3.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

3.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a true-color image. For example, the array a defines 16-by-128 true-color image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

 .

 .

 .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menu-bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu-bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls display lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non-integer values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item. This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for an example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 5

CONCLUSION AND FUTURE ENHANCEMENT

5.1 CONCLUSION

In this work, a CMFD technique consisting of oriented FAST and rotated BRIEF (ORB) as the feature extraction method and 2NN with HAC as the feature matching method is proposed. The ORB parameters, namely the number of features to retain and patch size are optimized using PSO. The optimization is essential in obtaining a balance between performance and runtime. Evaluation of the proposed CMFD technique is performed on images which suffers from various geometrical attacks. An overall accuracy rate of 84.33% and 82.79% was obtained for evaluation carried out with images from the MICCF600 and MICC-F2000 database. When evaluation is carried out on tampered images with different geometric attacks, the proposed CMFD technique performs accurately for tampered images with object translation, different degree of rotation and enlargement.

5.2 FUTURE ENHANCEMENT

Digital image forgery is a growing field of research. Although limitations are there in the existing methods, still it promises the improvement in detection methods.

The major concern of this field is that the method should achieve better performance than existing methods in terms of true positive rate and false alarms.

The other challenge is the robustness of existing methods to various malicious operations. Every method should be designed only after consulting with the image forensic experts and after receiving the feedback from them to implement the changes. Another future scope is that till date there is no unified algorithm for image forgery detection which can identify every type of forgery.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics and communication engineering', session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **PLANT SOIL AND pH SENSING ALRAM** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

A. Naveen Kumar (18K85A0433)
G. Durga Mahesh (18K85A0428)
A. Ramesh kumar (17K81A04G8)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

We extended our deep sense of gratitude to Principal**, Dr. P. SANTOSH KUMAR PATRA**, St. Martin's Engineering College, Dhulapally, for permitting us to undertake this project.

We are also thankful to **Dr.B.HARI KRISHNA**, Head of the Department, ECE , St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project and as well as our project coordinator **Dr.A.ANAND** professor in ECE, for his valuable support.

We would like to express our sincere gratitude and indebtedness to our project supervisor **Mr,K.NISHAKAR** Associate professor in ECE, St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project.

Finally, we express thanks to all those who have helped us successfully to completing this project. Furthermore, we would like to thank our family and friends for their moral support and encouragement.

We express thanks to all those who have helped us in successfully completing the project.

A. Naveen Kumar (18K85A0433)

G. Durga Mahesh (18K85A0428)

A. Ramesh kumar (17K81A04G8)

ABSTRACT

Plants need water as well as good soil (pH rich) to ensure proper plant growth. It becomes difficult to monitor these things manually each time to ensure proper growth and any ignorance may lead to bad plant health or plant decay/death. Here we propose an Arduino microcontroller base system that makes use of soil moisture sensor along with pH value sensor to constantly check for these values. The system microcontroller ensures the plant gets proper moisture and pH by continuously monitoring for it. It also displays this on a display screen for user to monitor.

LIST OF FIGURES

CHAPTER-1

INTRODUCTION

1.1. Project Overview:

India is a developing nation with a very large population. Due to increasing population, the basic need such as food and water is increasing day by day. Thus, there is a need of saving these resources and utilize them in an efficient manner. Since water is one of the most important elements in our daily life, thus we must use efficient ways to utilize water and save it for future generations. One of method is efficient irrigation management practices for fields. Irrigation water management practices could greatly benefit by the knowledge of moisture in the soil. To determine the soil moisture, we have designed and developed a nickel probes based soil moisture sensor and a response monitoring system. By knowing the moisture value, we can estimate when to water and how much to water the fields so that there is no over- watering or wilting of crops. These practices will increase crop yield, improve quality of crops, conserve water resources, save energy, and decrease fertilizer supplies.

1.2 Objective of The Project:

The objective of this project is to provide a combination of manual supervision and partial automation. It is similar to manual set up in most respects but it reduces the labour involved in terms of irrigation design is simple. Easy to install microcontroller-based circuit to monitor and record the values of temperature and soil moisture.

CHAPTER-2

INTRODUCTION ABOUT EMBEDDED SYSTEMS

2.1 Introduction:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.
The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.
The simplest devices consist of a single microprocessor (often called a "chip"), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware.

2.2 Block Diagram of Embedded System:

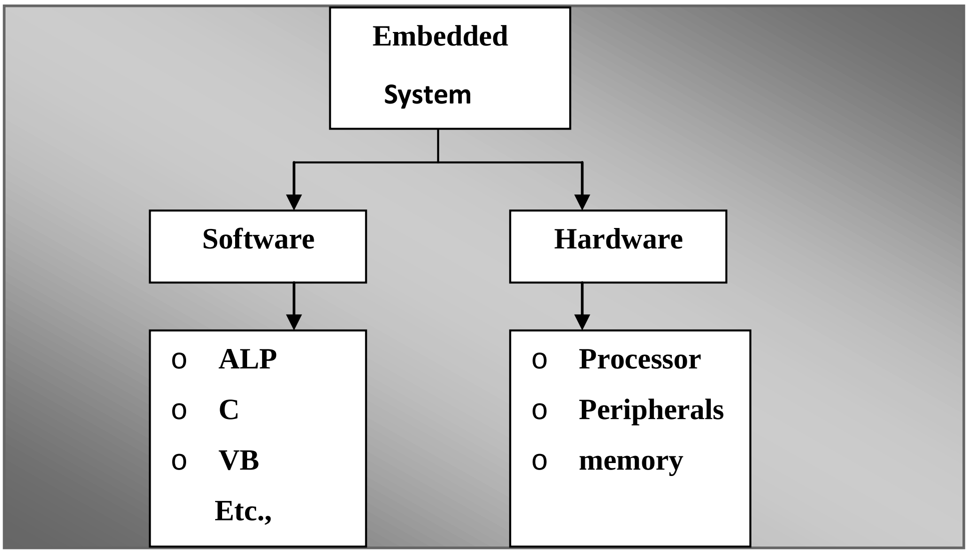

Fig.2.1: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

2.3 Applications of Embedded Systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

2.4 Micro Processor (μp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

2.5 Three Basic Elements of a Microprocessor:

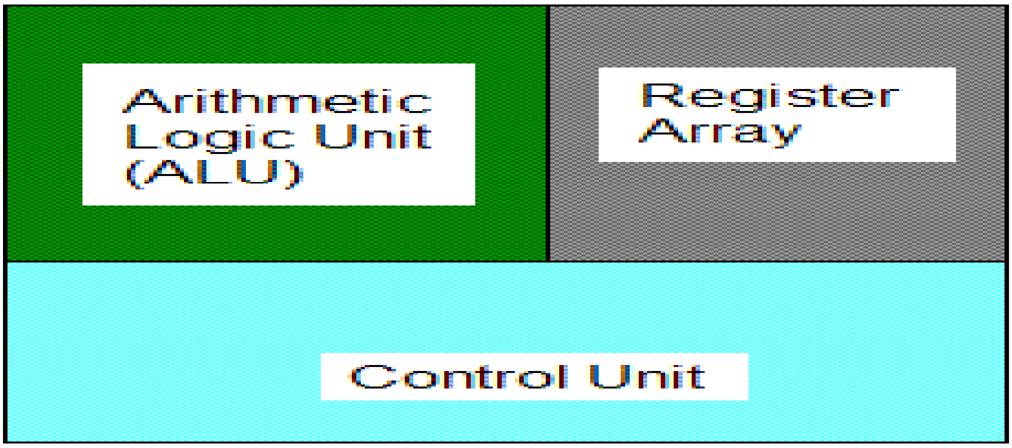

Fig.2.2: Three basic elements of a microprocessor

2.6 Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

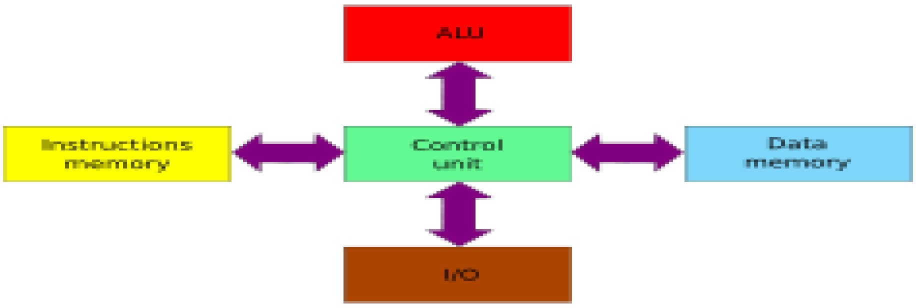

Fig.2.3: Harvard Architecture

2.6.1 Uses of the Harvard architecture*:*

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.6.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

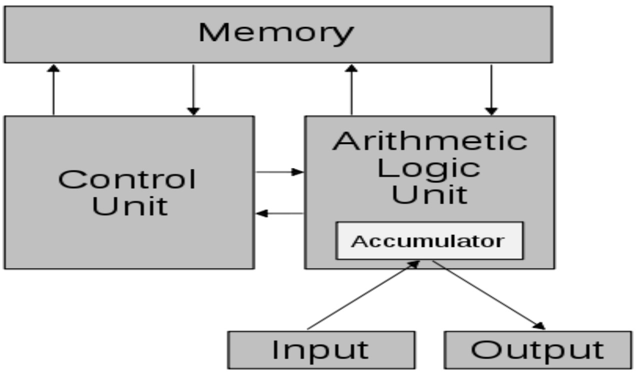

Fig.2.3.1: Schematic of the Von-Neumann Architecture.

CHAPTER-3

MICRO CONTROLLER UNIT

3.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Table 3.1: Atmega328 specifications

Microcontroller	ATmega328P – 8-bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

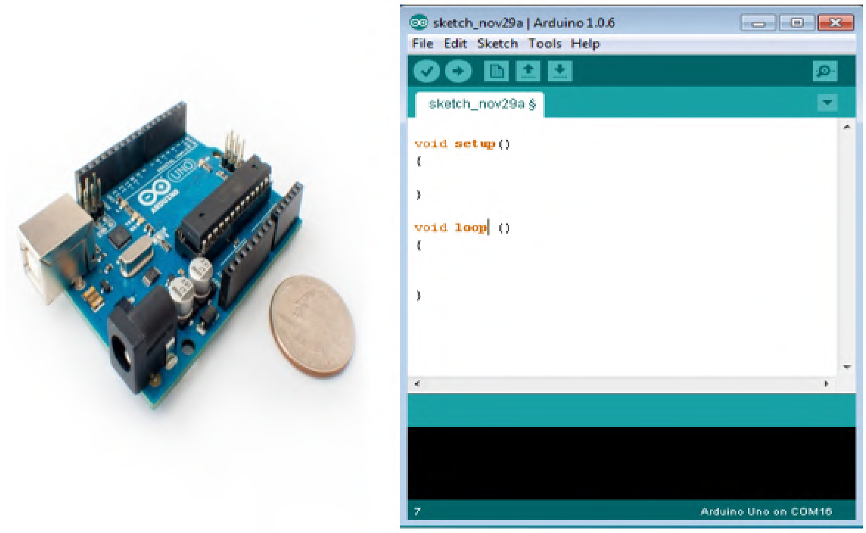

Fig 3.1 Arduino Uno

3.2 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16 U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16 U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini-3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fios	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Lilypad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible

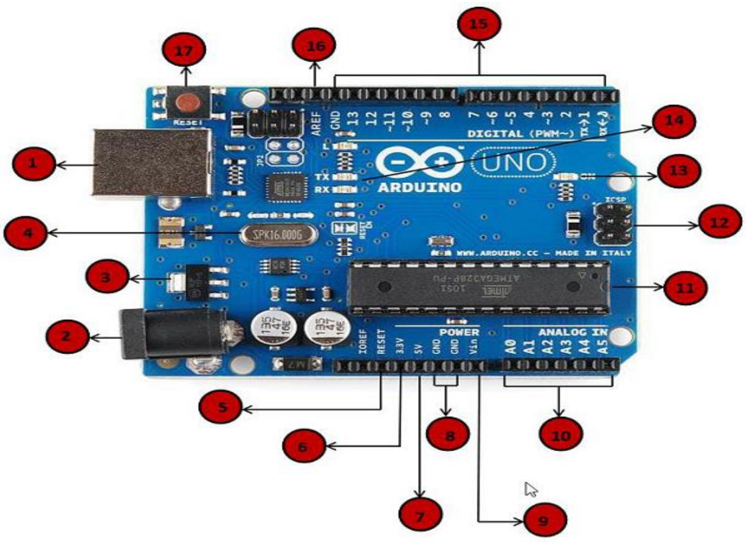
3.2.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. • GND (8) (Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different

	from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labelled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.3 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

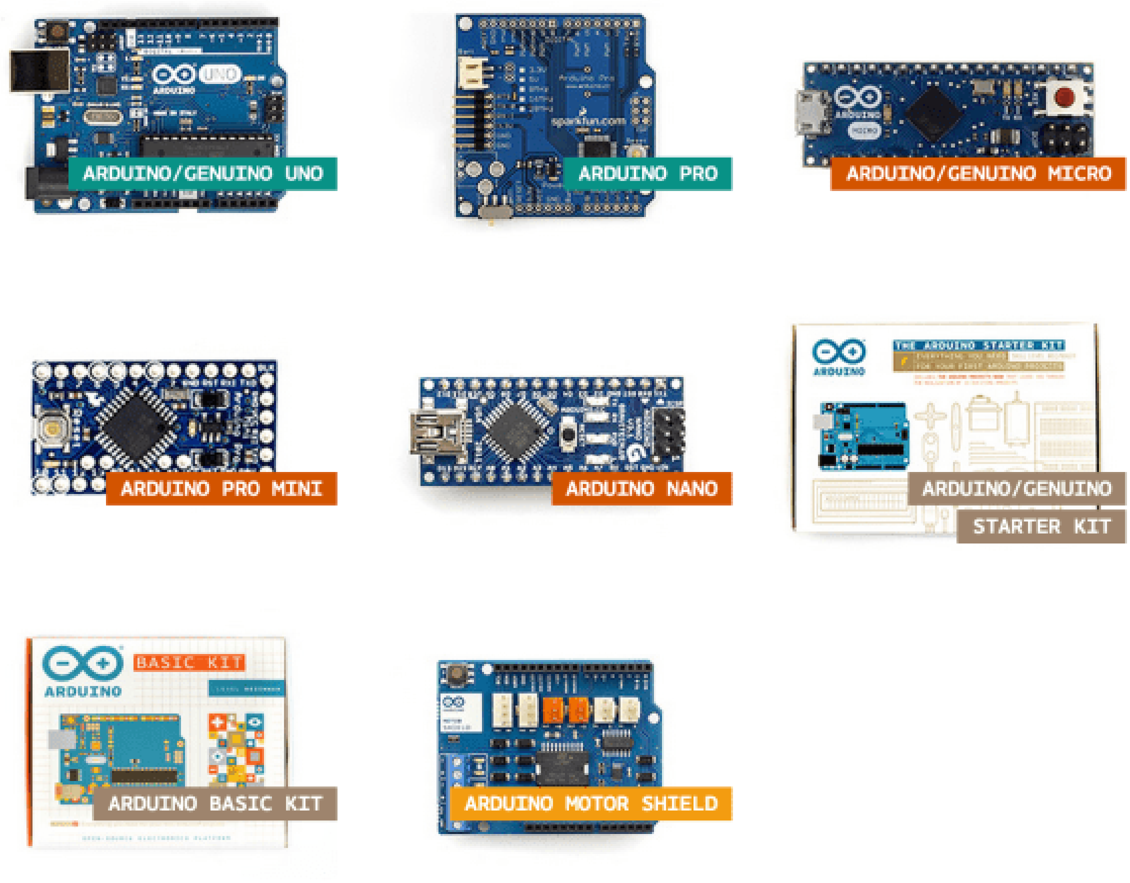


Fig.3.3: Arduino Family

3.4 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

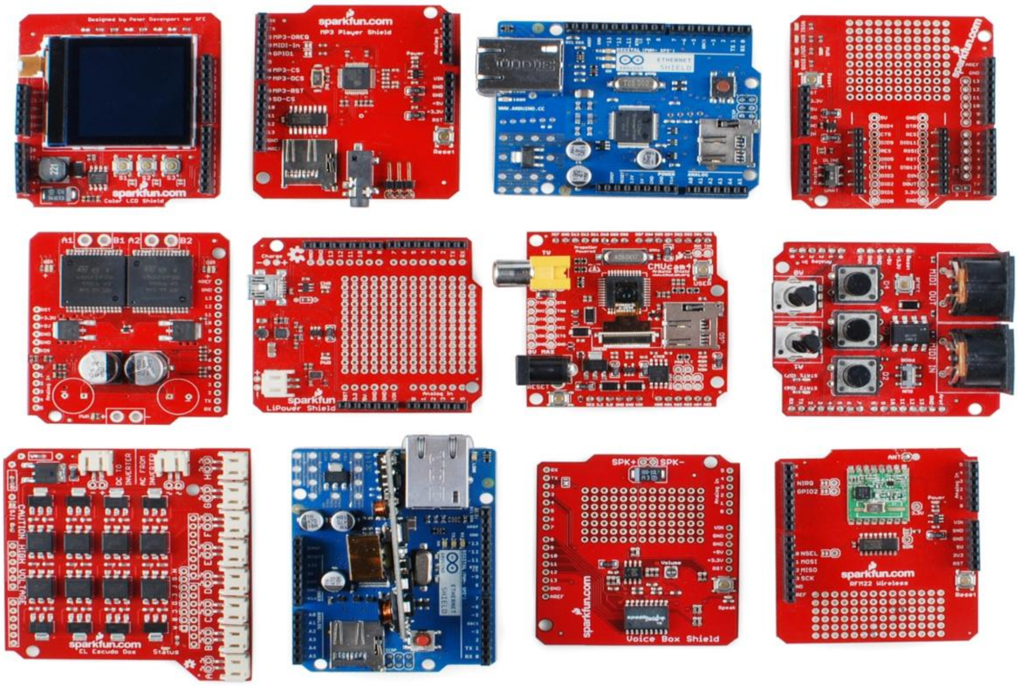

Fig.3.4: Arduino Shields

3.5 PIN DESCRIPTION OF ATMEGA328

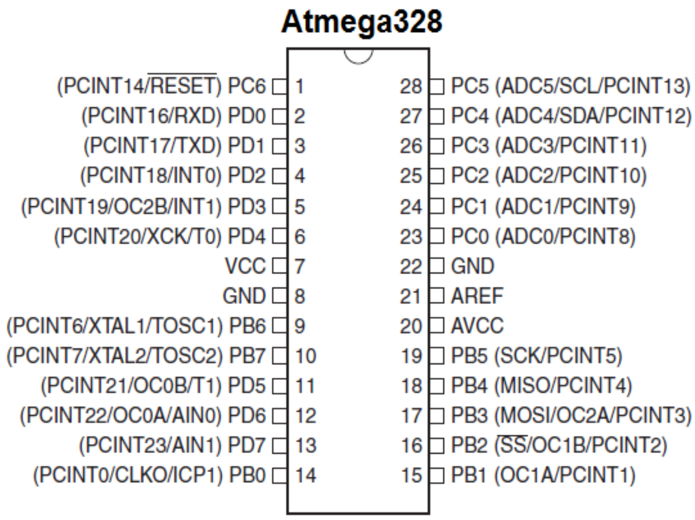

Fig.3.5: Pin description of ATMEGA328

3.6 Advantages Of Arduino:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

3.7 Applications:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

CHAPTER-4

POWER SUPPLY UNIT

4.1 Introduction:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as "Regulated D.C Power Supply".

4.1.1 Block Diagram of Power Supply:

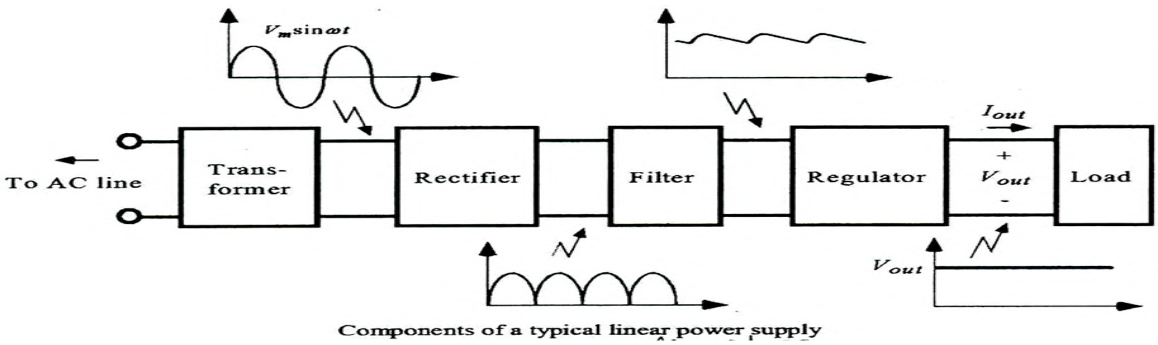

Fig.4.1.1: Block Diagram of Power Supply

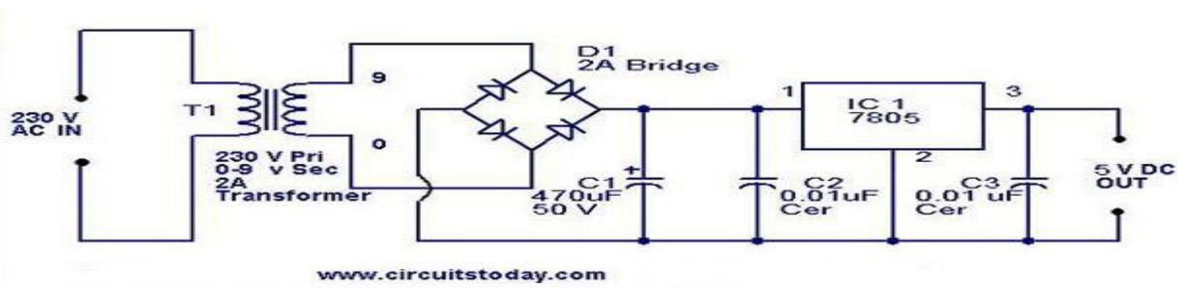

Fig.4.1.1(A): Schematic Diagram of Power Supply

4.1.2 Description of Power Supply:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.2 Transformer:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

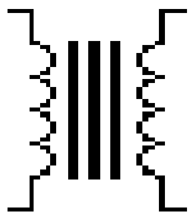

Fig.4.2: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

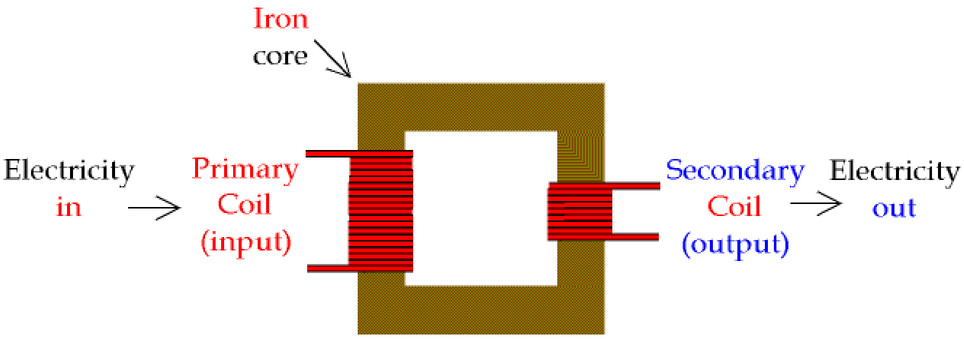

Fig.4.2(A): Transformer

4.2.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

4.2.2 Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

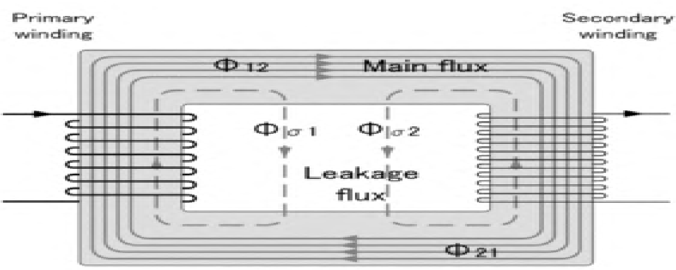

Fig.4.2.2: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

4.2.3 Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers is designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step-down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

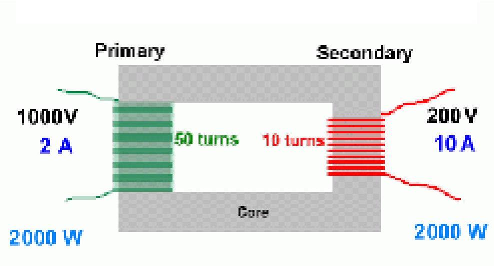

Fig.4.2.2: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts, then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step-down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

4.2.2 Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step-up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step-up transformer is needed to use a 220v product in a country with a 110v supply. A step-up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So, a step-up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step-up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, Nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

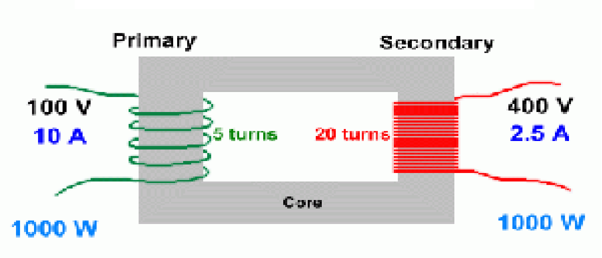

Fig.4.2.2(a): Step-Up Transformer

4.3 Diodes:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

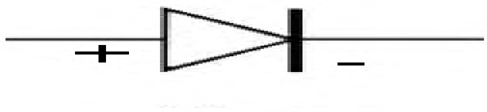

Fig.4.3: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

4.4 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

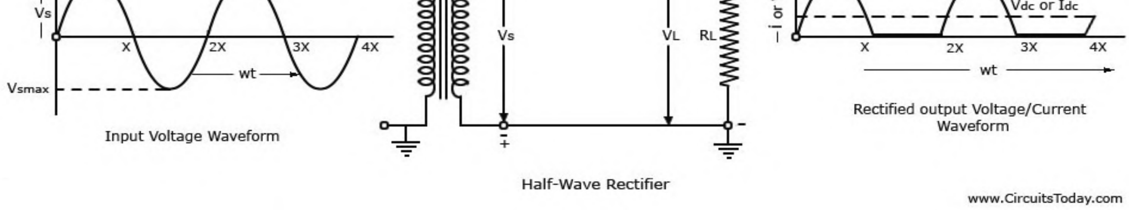

Fig.4.4(a): Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

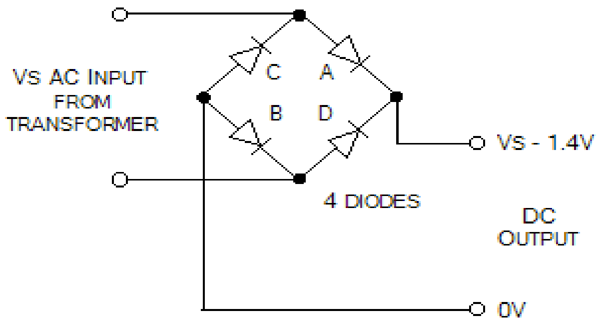

Fig.4.4(b): Full-Wave Rectifier

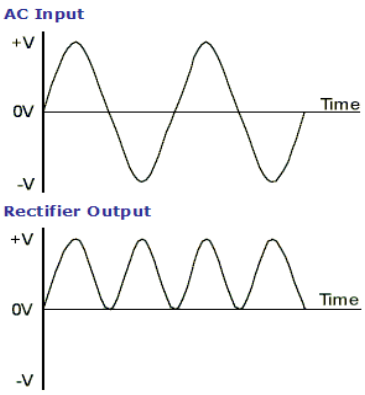

Fig.4.4(c): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12AC in, you will 10.6V DC out.

4.5 Capacitor Filter:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

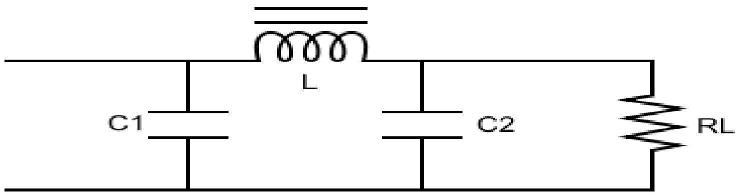

Fig.4.5: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result, the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

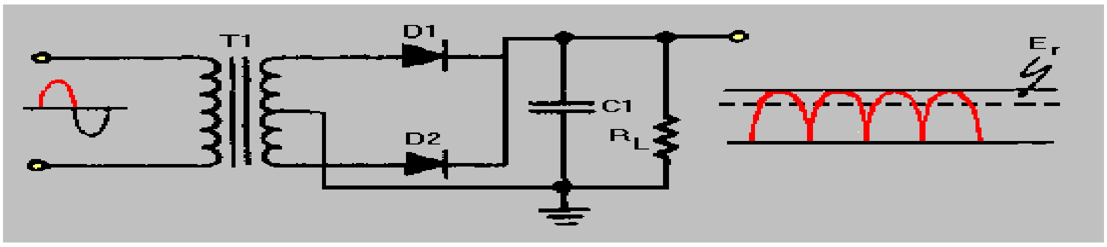

Fig.4.5(A): Centered Tapped Full-Wave Rectifier with a Capacitor Filter

4.6 Voltage Regulator:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulators are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:’78’ indicate the positive series and ‘xx’ indicates the voltage rating. Suppose 7805 produces the maximum 5V.’05’indicates the regulator output is 5V.

79xx:’78’ indicate the negative series and ‘xx’ indicates the voltage rating. Suppose 7905 produces the maximum -5V.’05’indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

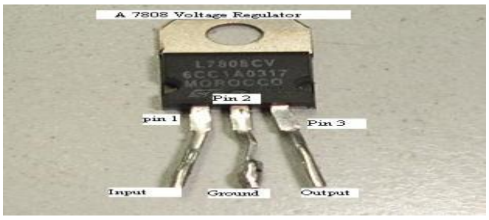

Fig.4.6: Regulator

CHAPTER-5

PROJECT DISCRIPTION

5.1 Hardware Requirement:

- Arduino uno
- LCD
- Power Supply
- Soil Moisture Sensor
- PH Sensor
- ESP-01
- Relay
- AC Pump

Software Components:

- Arduino IDE
- Proteous

5.2 Block Diagram of Project:

Wi-Fi Module:

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IoT devices. We've featured several projects using this module, such as **How To Make Smart Home Electronics: A Smart Mailbox** and **How To Read Your Arduino's Mind: Building A Childproof Lock**. This tutorial will walk you through setting up ESP8266 Wi-Fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

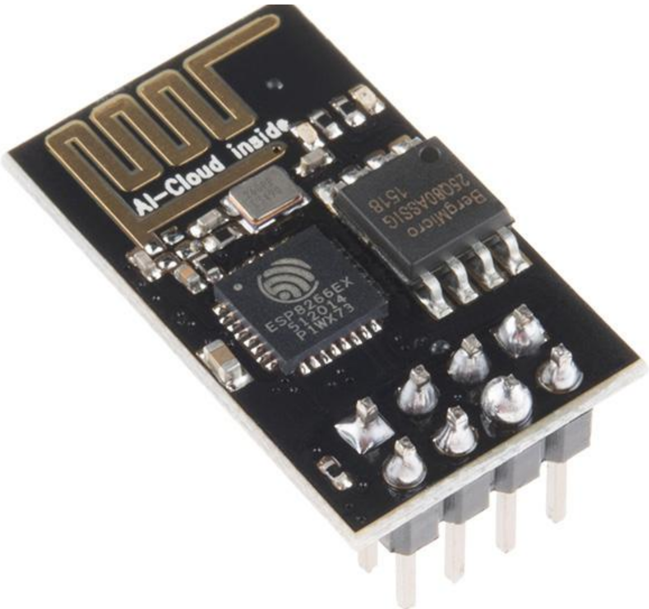

Figure 1. ESP8266 ESP-01 module / ©Sparkfun

ESP-01 Features – Sparkfun**:**

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms

- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266's pins is according to the following diagram:

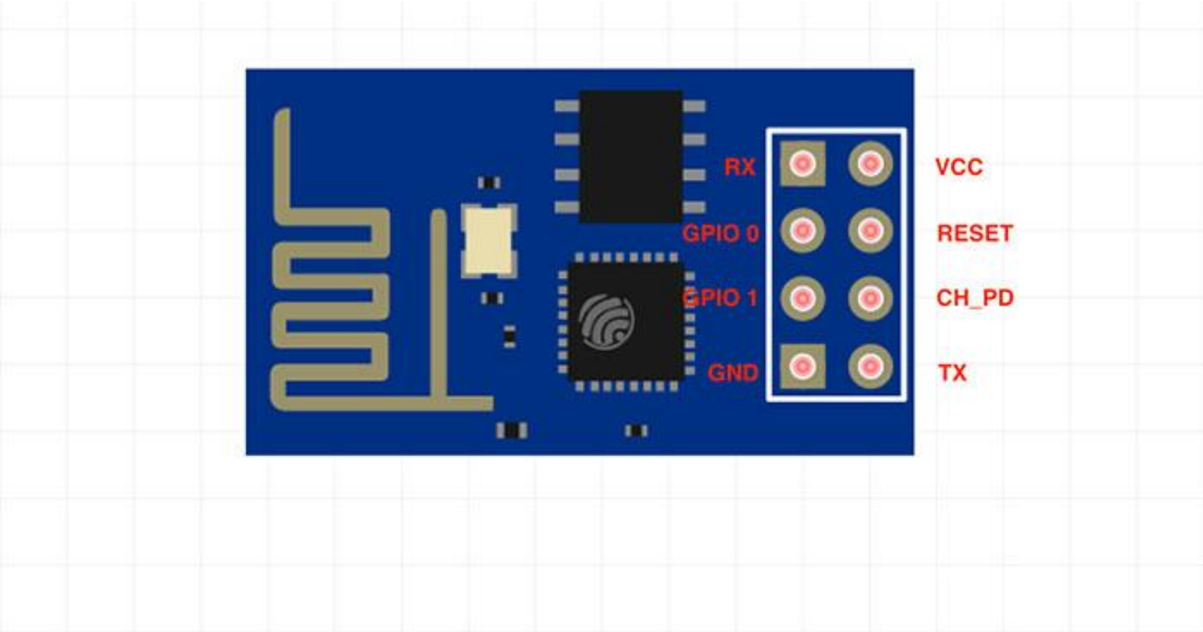

Figure 2. ESP8266 Pinout / ©Github.com/ydonnelly

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the Wi-

Fi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

Use the following diagram to connect the ESP8266 module to the Arduino:

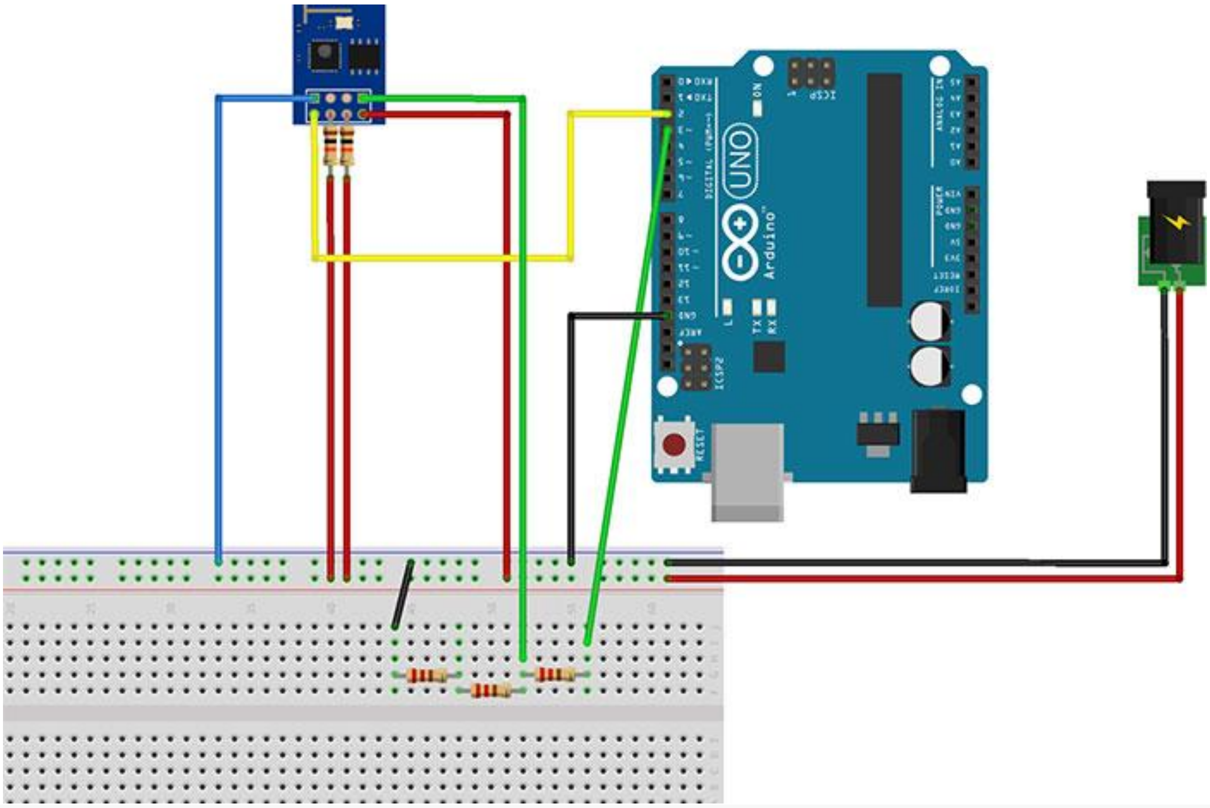

Figure 3. Connection between ESP8266 and Arduino Uno

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
    - You can use something like this: https://www.sparkfun.com/products/114
- Breadboard and jumper wires

A couple of features of this circuit stand out immediately.

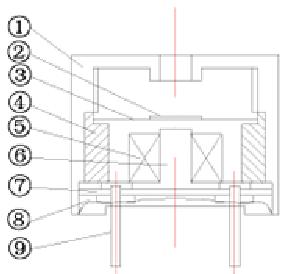
First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the Vcc and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

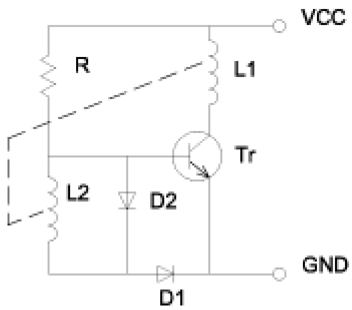
Buzzer:

1. Magnetic Transducer



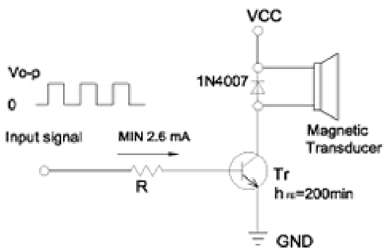
Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field.

When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.



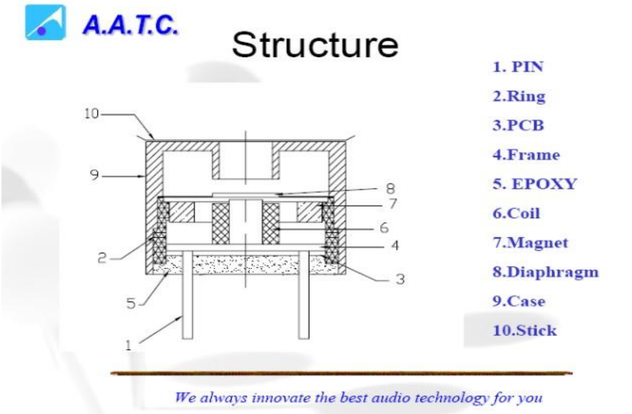
2. Magnetic Buzzer (Sounder)

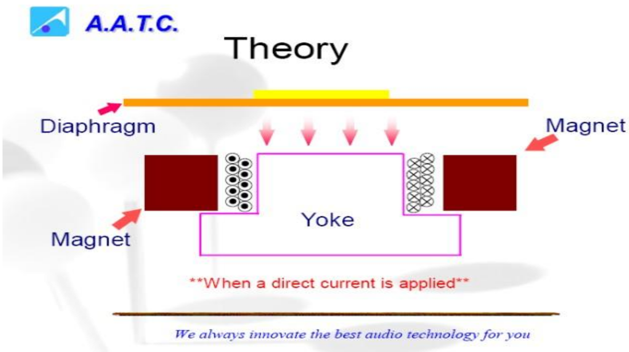
Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

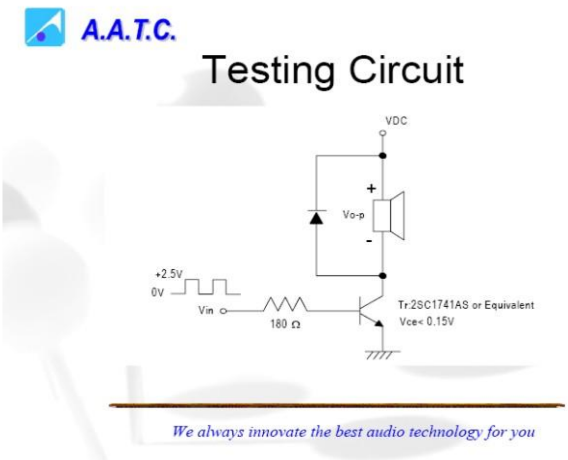


Recommended Driving Circuit for Magnetic Transducer

Introduction of Magnetic Buzzer (Transducer)







Specifications:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Direct Current Resistance: The direct current resistance is measured by ammeter directly.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and

1/2 square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

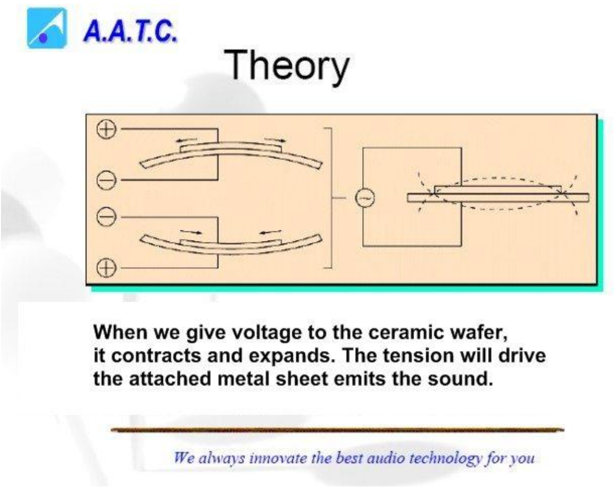
Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

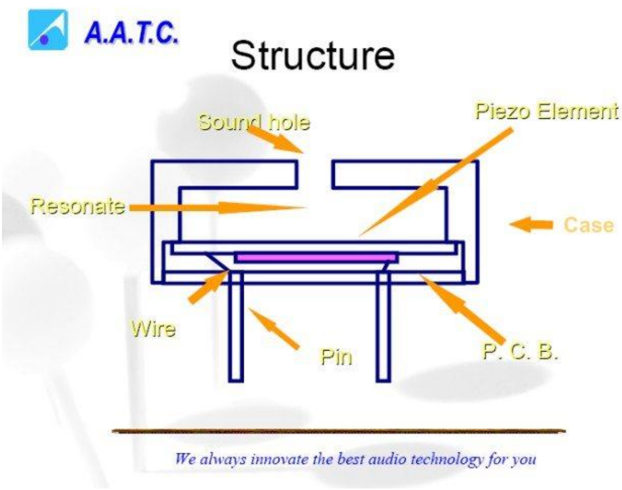
Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

Introduction of Piezo Buzzer





Specifications:
Rated Voltage: A piezo buzzer is driven by square waves (V p-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes

more electricity.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

How to choose:

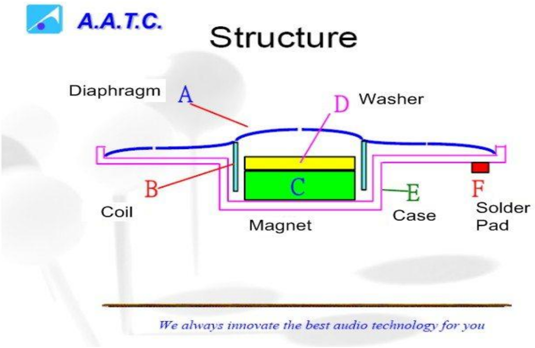
Driving methods: AZ-XX's-x series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current. Besides, there are different tone nature for you to choose, such as continuous, fast pulse, and slow pulse.

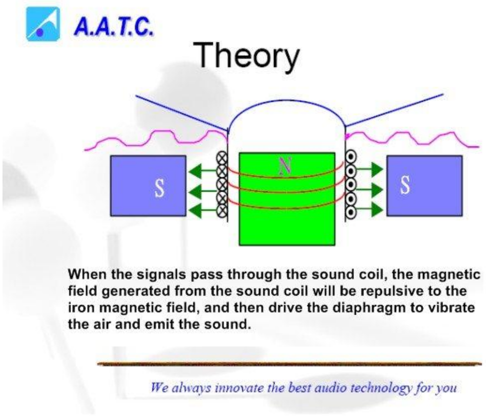
Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Driven by square waves (V p-p), the higher voltage results in the higher SPL.

Pin Pitch: The numerous spec. for the piezo buzzers lead to the difficulty in finding a spec. in facsimile, therefore we suggest that you can firstly choose a spec. with the same pitch and similar frequency.

Introduction of Micro Speaker:





How to choose:

The factors which affect the SPL: the square measure of diaphragm, the amplitude of vibration, magnetic field intensity, power, impedance, resonant chamber, the pattern and the thickness of diaphragm, and the holes.

Power vs. SPL: Suppose all the conditions are the same, increasing the power does not mean the SPL will increase as well. We need to revise the diaphragm and the sound coil to load the higher power, but it leads to lower SPL instead.

Dimension vs. SPL: A larger speaker can vibrate more air; therefore, it provides higher SPL. In addition, the thicker speaker can give wider amplitude of vibration which also leads to higher SPL.

Acoustics: What we request most is how much SPL a micro speaker can output.

Matching: It will be better to provide the power slightly higher than the rated power for the enlarged circuit.

Question for mechanism:

The volume of the resonant chamber: The general problem of the consuming products is that the resonant chambers are not big enough. We can only try to find space to enlarge the volume of the resonant chamber.

Sound Hole: Must be more than 1/8 of the diaphragm's area at least.

Airtight: The front and back sound fields of the speaker should be separated to avoid neutralization.

Shock absorber: When a speaker works the vibration will also happen at the same time. In order to reduce interference, it will do good to have some material between speaker and case to absorb the shock.

Mounting: The speakers are usually fixed on the case. Firmly fixed is important especially for the iron housing or the large size to avoid separating in the drop test.

How to choose the speaker

Dimension: To the micro speaker, size has decisive influence on its volume. 5mm difference of diameter might result in double or half area of diaphragm, therefore the SPL is quite different. Besides, the thicker speaker has more space to vibrate the air, and usually has bigger magnet, so it will be more powerful to push the air and emit louder sound.

Power: Mainly refer to how much power can a speaker bear, there is no direct relation to the SPL. The speaker with larger power needs to use thicker diaphragm and sound coil to bear larger power, which will lead to lower efficiency (SPL). Therefore, according to the mechanical design, try to select a larger speaker which matches the outputting power from the amplified circuit, then the best SPL would be emitted.

Impedance: Higher impedance can save more electricity; however, the SPL and the loaded power will go down. The reason is that we have to use thinner wire or to coil more, the front makes the power lower, and the after leads to heaviness and low efficiency.

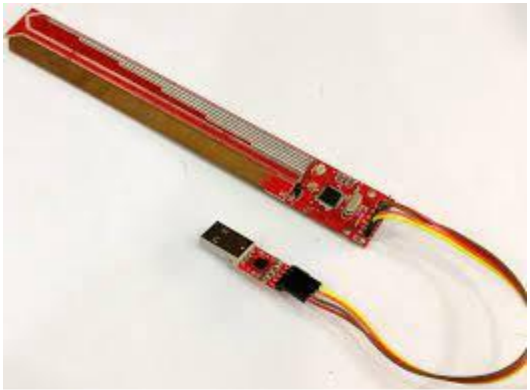
The material of diaphragm: Most speakers (diameter less than 50mm) use mylar diaphragms, which are easily finished, cheaper and waterproof. However, mylar diaphragm is not good at heatproof and the sound is stiff.

The patterns of diaphragm: The speaker with concentric circles diaphragm is good for the speech sounds. Generally, the SPL is good at the frequency before 5-6 KHz, but will dramatically decrease after 6 KHz. On the other hand, the speaker with radiate diaphragm has average frequency response. Supposing other conditions are all the same, the SPL of radiate diaphragm will lower than the concentric circles one at the frequency before 6 KHz.

PH SENSOR:

In nearly every industrial and scientific application, pH is determined by measuring the voltage of an electrochemical cell. Figure 2-1 shows a simplified diagram of a pH cell. The cell consists of a measuring electrode, a reference electrode, a temperature sensing element, and the liquid being measured. The voltage of the cell is directly proportional to the pH of the liquid. The pH meter measures the voltage and uses a temperature-dependent factor to convert the voltage to pH. Because the cell has high internal resistance, the pH meter must have a very high input impedance. Figure 2-1 shows separate measuring and reference electrodes. In most process sensors, the electrodes and the temperature element are combined into a single body. Such sensors are often called combination electrodes. The cell voltage is the algebraic sum of the potentials of the measuring electrode, the reference electrode, and the liquid junction. The potential of the measuring electrode depends only on the pH of the solution. The potential of the reference electrode is unaffected by pH, so it provides a stable reference voltage. The liquid junction potential depends in a complex way on the identity and concentration of the ions in the sample. It is always present, but if the sensor is properly

designed, the liquid junction potential is usually small and relatively constant. All three potentials depend on temperature. The construction of the electrodes and the electrical potentials associated with them are discussed in Sections 2.2 and 2.3. THEORY AND PRACTICE OF pH MEASUREMENT SECTION 2.0 CELLS FOR MEASURING pH SECTION 2.0 CELLS FOR MEASURING pH 2.1 GENERAL 2.2 MEASURING ELECTRODE 2.3 REFERENCE ELECTRODE 2.4 LIQUID JUNCTION POTENTIAL 2.5 DOUBLE JUNCTION REFERENCE ELECTRODES FIGURE
2-1. pH Measurement Cell. The cell consists of a measuring and reference electrode. The voltage between the electrodes is directly proportional to the pH of the test solution. The proportionality constant depends on temperature, so a temperature sensor is also necessary. A 100 Ω platinum RTD is commonly used, although 1000 Ω platinum RTDs, 3 kΩ Balco RTDs, and thermistors are also used.



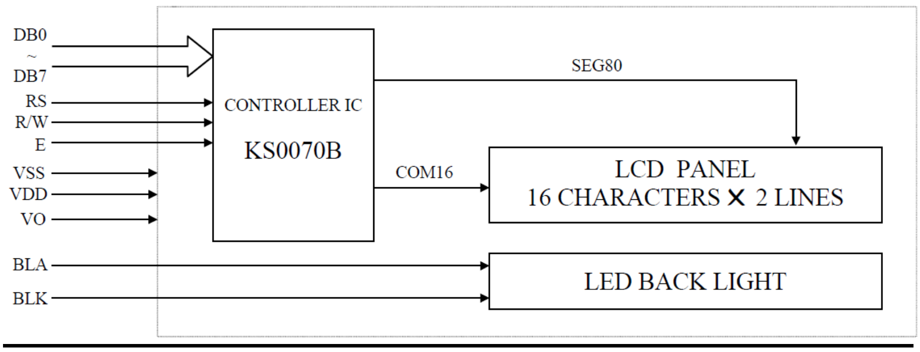
MEASURING ELECTRODE Figure 2-2 shows the internals of the measuring electrode. The heart of the electrode is a thin piece of pH-sensitive glass, which is blown onto the end of a length of glass tubing. The pH-sensitive glass, usually called a glass membrane, gives the electrode its common name: glass electrode. Sealed inside the electrode is a solution of potassium chloride buffered at pH 7. A piece of silver wire plated with silver chloride contacts the solution. The silver wire-silver chloride combination in contact with the filling solution constitutes an internal reference electrode. Its potential depends solely on the chloride concentration in the filling solution. Because the chloride concentration is fixed, the electrode potential is constant. See Appendix A for a more detailed discussion of how the chloride concentration determines the electrode potential. As Figure 2-2 shows, the outside surface of the glass membrane contacts the liquid being measured, and the inside surface contacts the filling solution. Through a complex mechanism, an electrical potential directly proportional to pH develops at each glass-liquid interface. Because the pH of the filling solution is fixed, the potential at the inside surface is constant. The potential at the outside surface, however, depends on the pH of the test solution. The overall potential of the measuring electrode equals the potential of the internal reference electrode plus the potentials at the glass membrane surfaces. Because the potentials inside the electrode are constant, the overall electrode potential depends solely on the pH of the test solution. The potential of the measuring electrode also depends on temperature. If the pH of the sample remains constant but the temperature changes, the electrode potential will change. Compensating for changes in glass electrode potential with temperature is an important part of the pH measurement. Figure 2-3 shows a cross-section through the pH glass. pH sensitive glasses absorb water. Although the water does not penetrate more than about 50 nanometers (5 x 10-8 m) into the glass, the hydrated layer must be present for the glass to respond to pH changes. An ion exchange mechanism involving alkali metals and hydrogen ions in the hydrated layer is responsible for the pH response of the glass. The layer of glass between the two hydrated layers remains dry. The dry layer makes the glass a poor conductor of electricity and causes the high internal resistance (several hundred megohms) typical of glass electrodes.

16 * 2 Alphanumeric LCD

Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

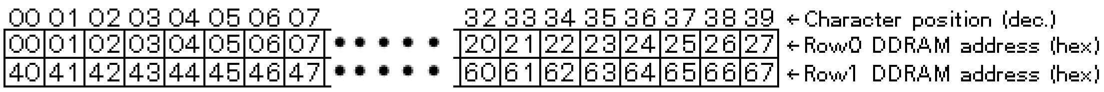
Block Diagram



Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So, whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

Busy Flag

Busy Flag is a status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

Instruction Register (IR) and Data Register (DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g., LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 x 2 Alphanumeric LCD Module Features

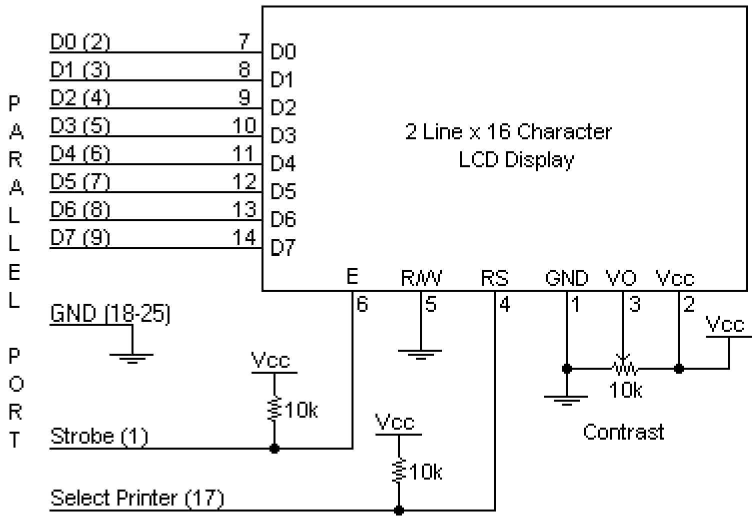
- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

Schematic

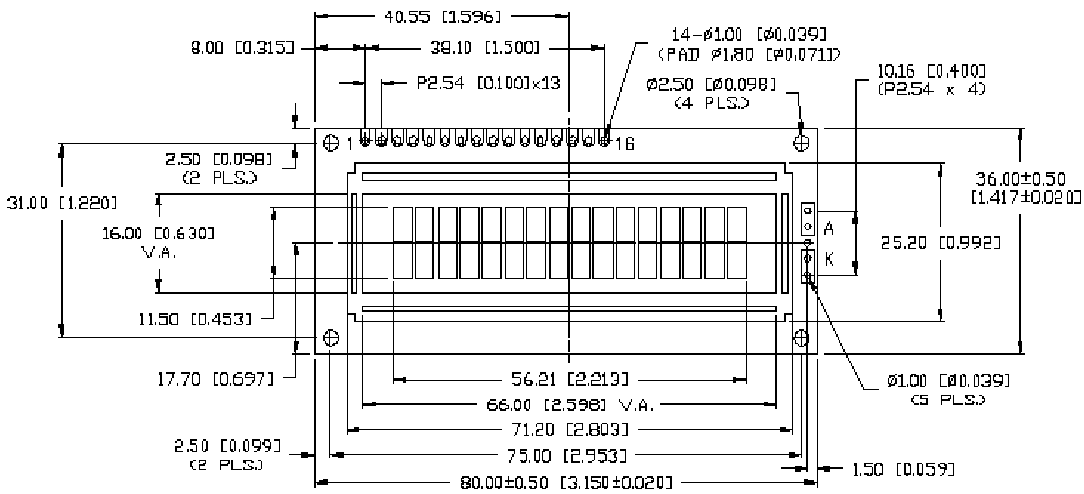
Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.



Specifications



Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16-character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

Soil Moisture Sensor:

Soil moisture sensors measure the water content in soil. A soil moisture probe is made up of multiple soil moisture sensors. One common type of soil moisture sensors in commercial use is a Frequency domain sensor such as a capacitance sensor. Another sensor, the neutron moisture gauge, utilize the moderator properties of water for neutrons. Cheaper sensors - often for home use- are based on two electrodes measuring the resistance of the soil. Sometimes this simply consists of two bare (galvanized) wires, but there are also probes with wires embedded in gypsum

Agriculture

Measuring soil moisture is important in agriculture to help farmers manage their irrigation systems more efficiently. Not only are farmers able to generally use less water to grow a crop, they are able to increase yields and the quality of the crop by better management of soil moisture during critical plant growth stages.

Besides agriculture, there are many other disciplines using soil moisture sensors. Golf courses are now using sensors to increase the efficiencies of their irrigation systems to prevent over watering and leaching of fertilizers and other chemicals offsite.

Landscape irrigation

In urban and suburban areas, landscapes and residential lawns are using soil moisture sensors to interface with an irrigation controller. Connecting a soil moisture sensor to a simple

irrigation clock will convert it into a "smart" irrigation controller that prevents an irrigation cycle when the soil is wet.

Submersive Motor:

A submersible motor is an electric motor which can operate while being submerged in water. This sealed motor is typically found in use on pumps. Both sump pumps and water wells use a submersible motor to power the pumping mechanism used in the system. Due to the submersion in water, it is critical that all electrical connections be made water-tight to prevent damage to the motor as well as to anyone working on the unit.

The typical water well relies on a submersible motor to pump the water out of the well. The motor is attached to a pump and lowered down through the well casing. Many well contractors attach a small cable to the pump unit to lower it down, while many simply lower the pump unit down by the electrical cord. In either case, the pump and the submersible motor rest at the bottom of the casing suspended in the water. A hose fitted to the nipple on the pump sends the water up and out of the well when the submersible motor turns on.

This design is critical with an electric pump due to the advantage of pushing rather than pulling liquid. A pump is able to push a much greater amount of liquid than it is able to pull, thereby requiring the submersible motor to place the pump at the source of the liquid. Used in this manner, a pump is able to work effectively with a much smaller motor. This results in less electrical power used, a cooler running pump motor as well as a pump that is able to move a great quantity of liquid in a short time.

The typical submersible motor is contained within a rubber sock which maintains the pump's dryness. The sock is removed when servicing the pump or motor and replaced once the service is complete. This allows the pump to operate for a greater length of time without becoming damaged by the water. Many submersible motors offer years of uninterrupted use.

Relay

A relay is used to isolate one electrical circuit from another. It allows a low current control circuit to make or break an electrically isolated high current circuit path. The basic relay consists of a coil and a set of contacts. The most common relay coil is a length of magnet wire wrapped around a metal core. When voltage is applied to the coil, current passes through the wire and creates a magnetic field. This magnetic field pulls the contacts together and holds them there until the current flow in the coil has stopped. The diagram below shows the parts of a simple relay.

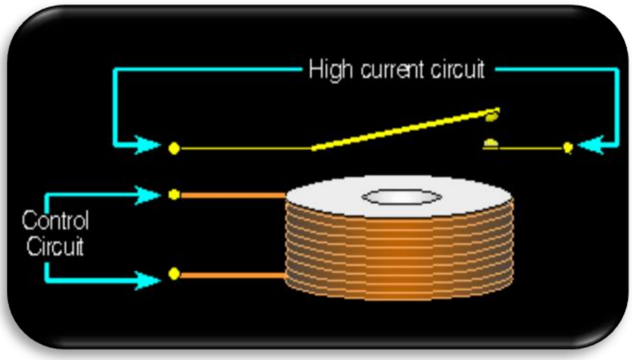


Figure: Relay

Operation:

When a current flow through the coil, the resulting magnetic field attracts an armature that is mechanically linked to a moving contact. The movement either makes or breaks a connection with a fixed contact. When the current is switched off, the armature is usually returned by a spring to its resting position shown in figure 6.6(b). Latching relays exist that require operation of a second coil to reset the contact position.

By analogy with the functions of the original electromagnetic device, a solid-state relay operates a thyristor or other solid-state switching device with a transformer or light-emitting diode to trigger it.

dwq

Pole and throw

SPST

SPST relay stands for Single Pole Single Throw relay. Current will only flow through the contacts when the relay coil is energized.

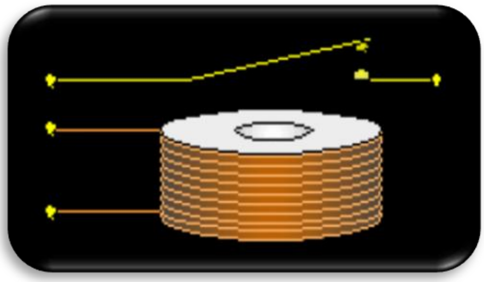

Figure: SPST Relay

SPDT Relay

SPDT Relay stands for Single Pole Double Throw relay. Current will flow between the movable contact and one fixed contact when the coil is De-energized and between the movable contact and the alternate fixed contact when the relay coil is energized. The most commonly used relay in car audio, the Bosch relay, is a SPDT relay.

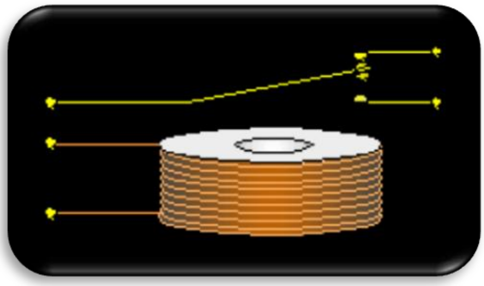

Figure: SPDT Relay

DPST Relay

DPST relay stands for Double Pole Single Throw relay. When the relay coil is energized, two separate and electrically isolated sets of contacts are pulled down to make contact with their stationary counterparts. There is no complete circuit path when the relay is De-energized.

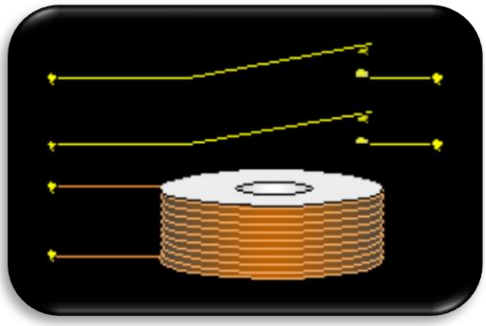

Figure: DPST Relay

DPDT Relay:

DPDT relay stands for Double Pole Double Throw relay. It operates like the SPDT relay but has twice as many contacts. There are two completely isolated sets of contacts.

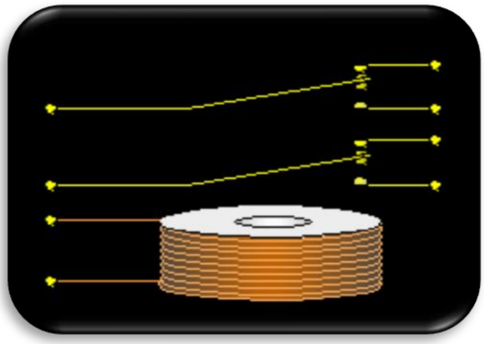

Figure: DPDT Relay

This is a 4 Pole Double Throw relay. It operates like the SPDT relay but it has 4 sets of isolated contacts.

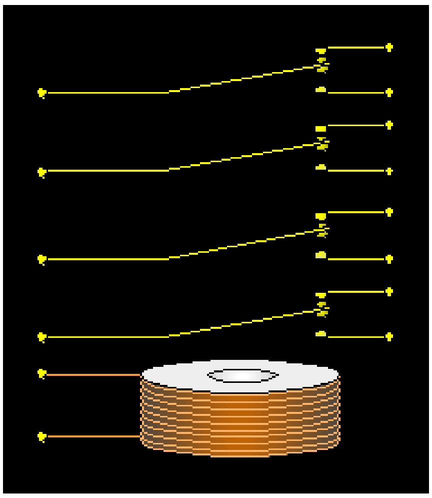

Figure: 4 Pole Double Throw relay

Types of relays:

1. Latching Relay
2. Reed Relay
3. Mercury Wetted Relay
4. Machine Tool Relay
5. Solid State Relay (SSR)

Latching relay

Latching relay, dust cover removed, showing pawl and ratchet mechanism. The ratchet operates a cam, which raises and lowers the moving contact arm, seen edge-on just below it. The moving and fixed contacts are visible at the left side of the image.

A **latching relay** has two relaxed states (bi-stable). These are also called "impulse", "keep", or "stay" relays. When the current is switched off, the relay remains in its last state. This is achieved with a solenoid operating a ratchet and cam mechanism, or by having two opposing coils with an over-centre spring or permanent magnet to hold the armature and contacts in position while the coil is relaxed, or with a remanent core. In the ratchet and cam example, the first pulse to the coil turns the relay on and the second pulse turns it off. In the two-coil example, a pulse to one coil turns the relay on and a pulse to the opposite coil turns the relay off. This type of relay has the advantage that it consumes power only for an instant, while it is being switched, and it retains its last setting across a power outage. A remanent core latching relay requires a current pulse of opposite polarity to make it change state.

Figure: Latching relay

Reed relay

A reed relay has a set of contacts inside a vacuum or inert gas filled glass tube, which protects the contacts against atmospheric corrosion. The contacts are closed by a magnetic field generated when current passes through a coil around the glass tube. Reed relays are capable of faster switching speeds than larger types of relays, but have low switch current and voltage ratings.

Mercury-wetted relay

A **mercury-wetted reed relay** is a form of reed relay in which the contacts are wetted with mercury. Such relays are used to switch low-voltage signals (one volt or less) because of their low contact resistance, or for high-speed counting and timing applications where the mercury eliminates contact bounce. Mercury wetted relays are position-sensitive and must be mounted vertically to work properly. Because of the toxicity and expense of liquid mercury, these relays are rarely specified for new equipment. See also mercury switch.

Machine tool relay

A **machine tool relay** is a type standardized for industrial control of machine tools, transfer machines, and other sequential control. They are characterized by a large number of contacts (sometimes extendable in the field) which are easily converted from normally-open to normally-closed status, easily replaceable coils, and a form factor that allows compactly installing many relays in a control panel. Although such relays once were the backbone of automation in such industries as automobile assembly, the programmable logic controller (PLC) mostly displaced the machine tool relay from sequential control applications.

Solid-state relay

A solid state relay (SSR) is a solid state electronic component that provides a similar function to an electromechanical relay but does not have any moving components, increasing long-term reliability. With early SSR's, the tradeoff came from the fact that every transistor has a small voltage drop across it. This voltage drop limited the amount of current a given SSR could handle. As transistors improved, higher current SSR's, able to handle 100 to 1,200 Amperes, have become commercially available. Compared to electromagnetic relays, they may be falsely triggered by transients.

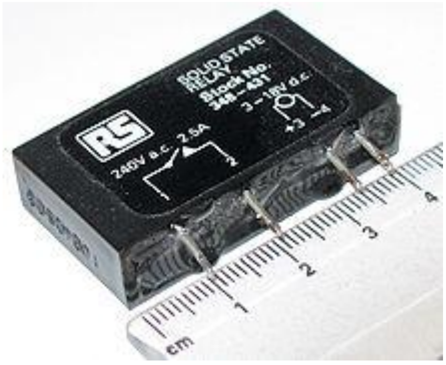

Figure: Solid relay, which has no moving parts

Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old-style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialling the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current
- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

Applications

Relays are used: To control a high-voltage circuit with a low-voltage signal, as in some types of modems,

- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,
- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low

voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,

- To perform logic functions. For example, the Boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.
- To perform time delay functions. Relays can be used to act as an mechanical time delay device by controlling the release time by using the effect of residual magnetism by means of a inserting copper disk between the armature and moving blade assembly.

CHAPTER -6

SOFTWARE EXPLINATION

6.1 Software Requirements

- Proteus simulation
- Arduino software
- Programming language

6.1.1 Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux.

Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

…This explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software (IDE)
- ✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

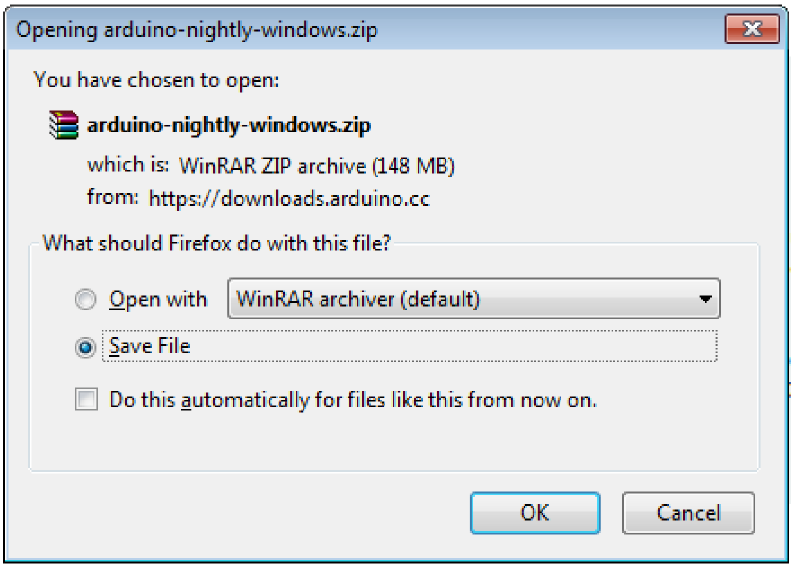
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



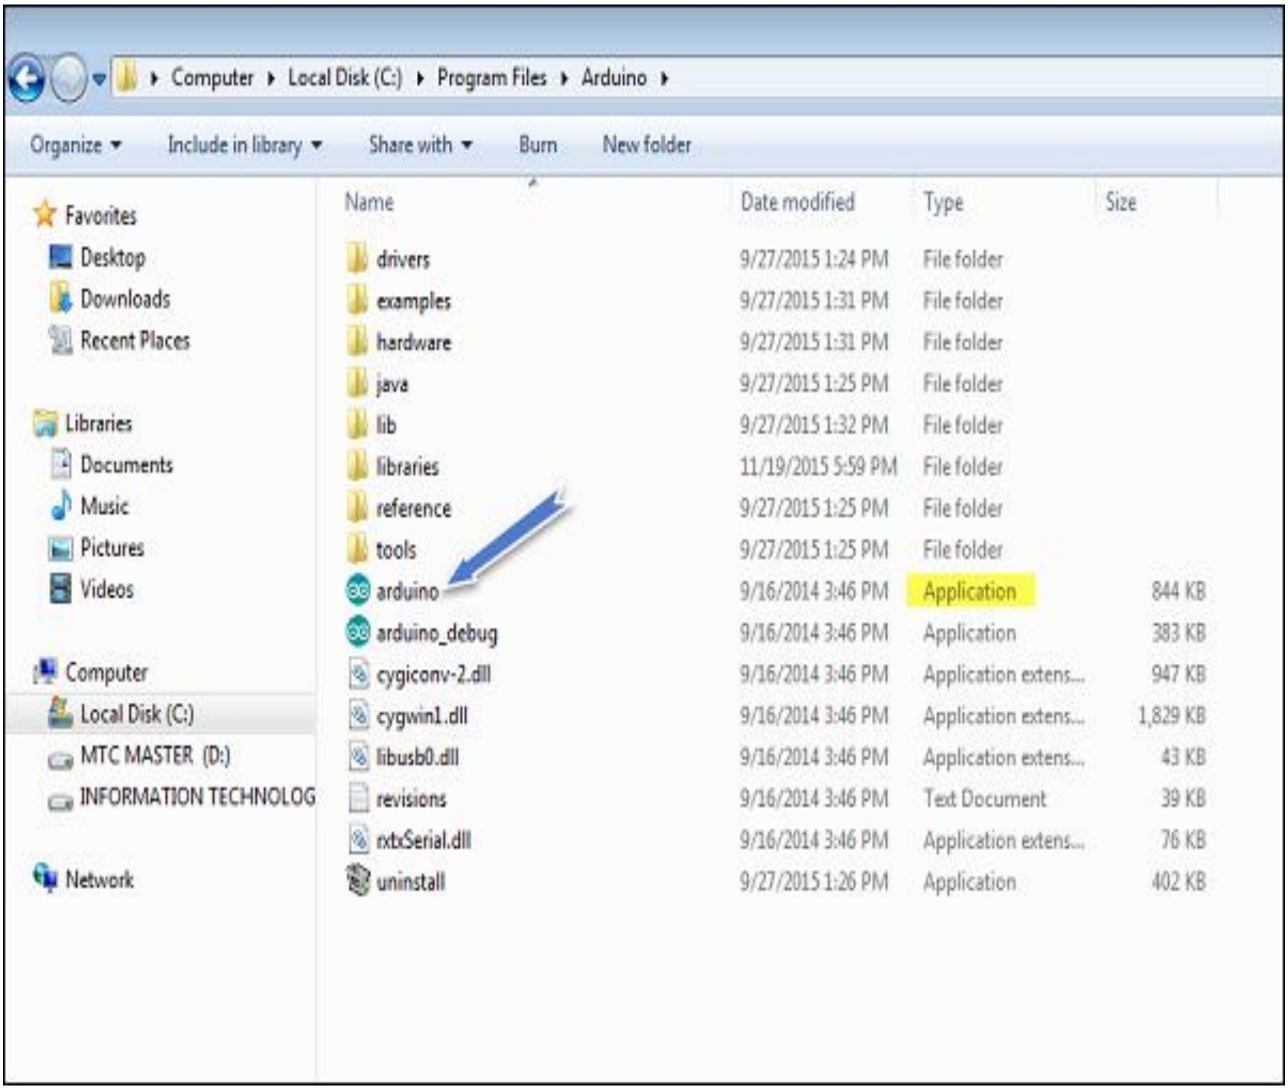
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

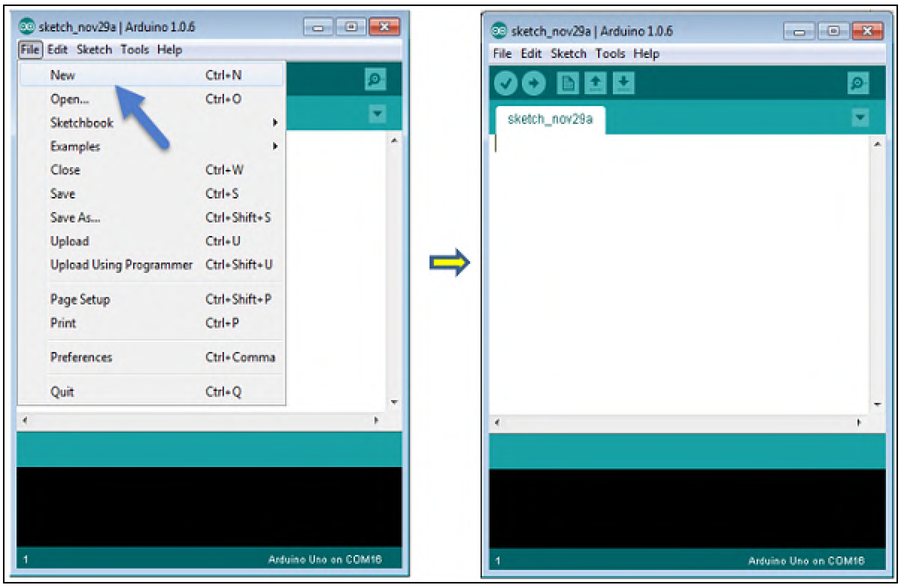


Step 5 − Open your first project.

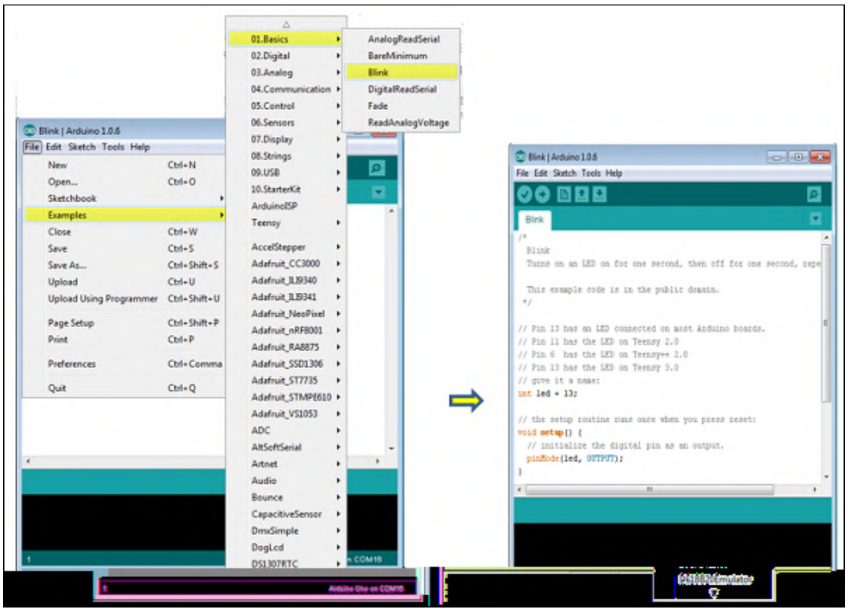
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

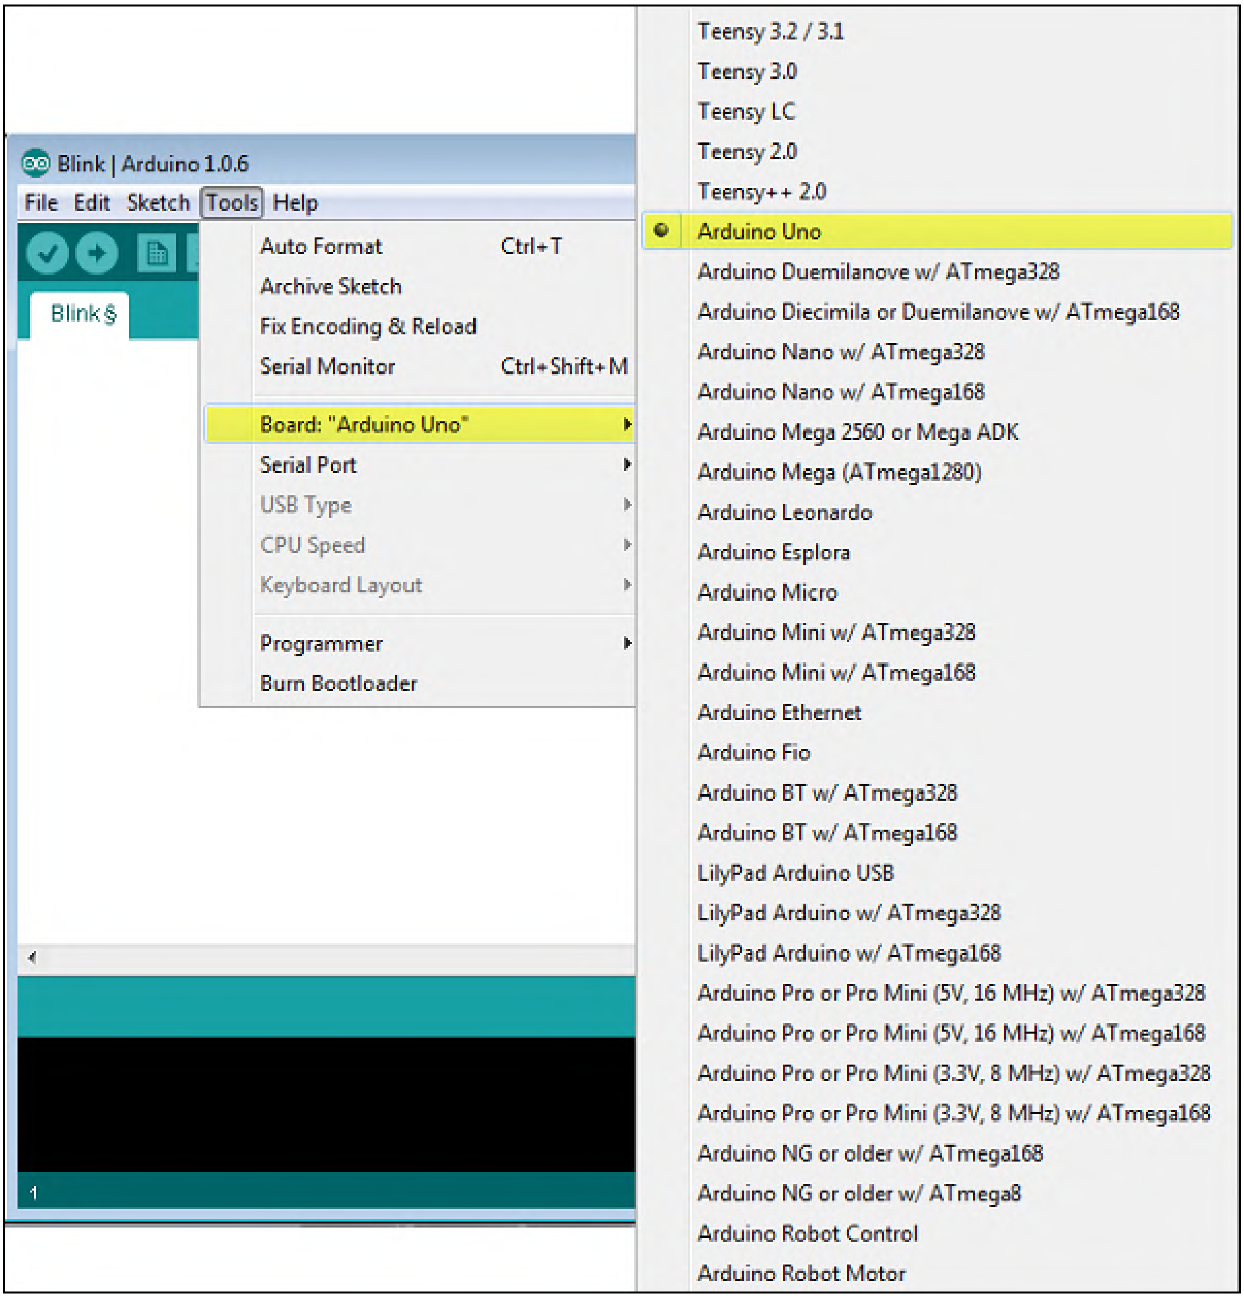


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

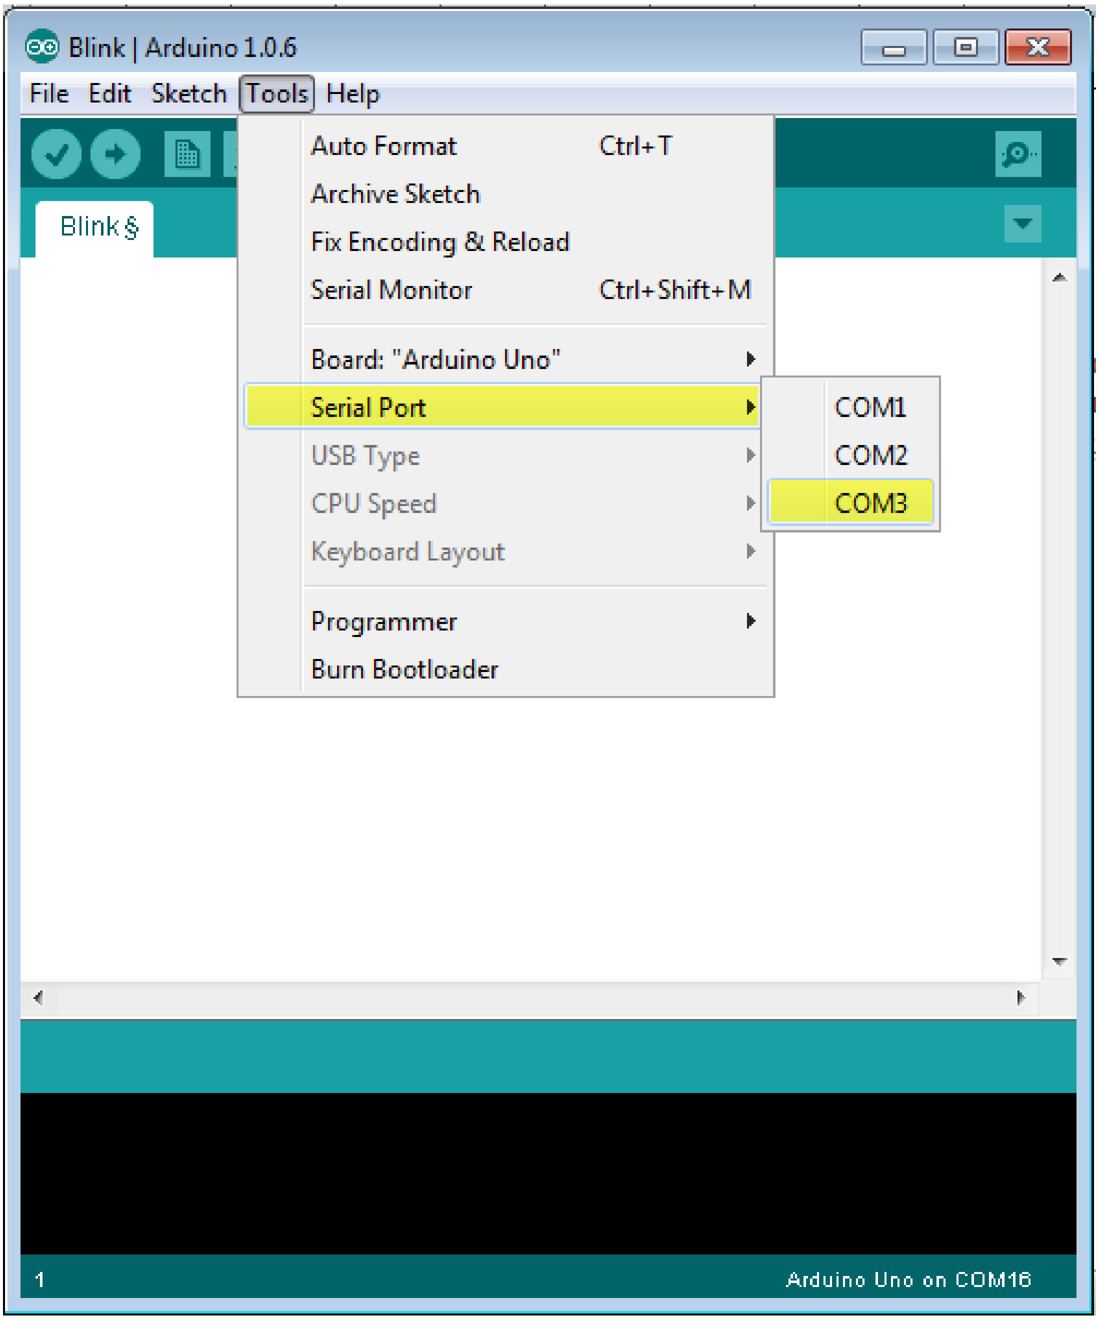
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

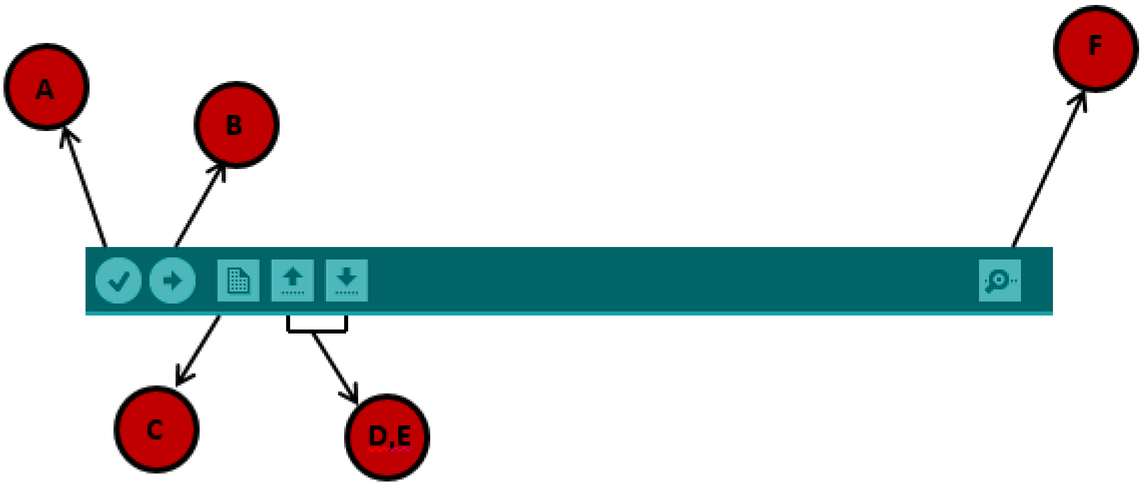
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient.

While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

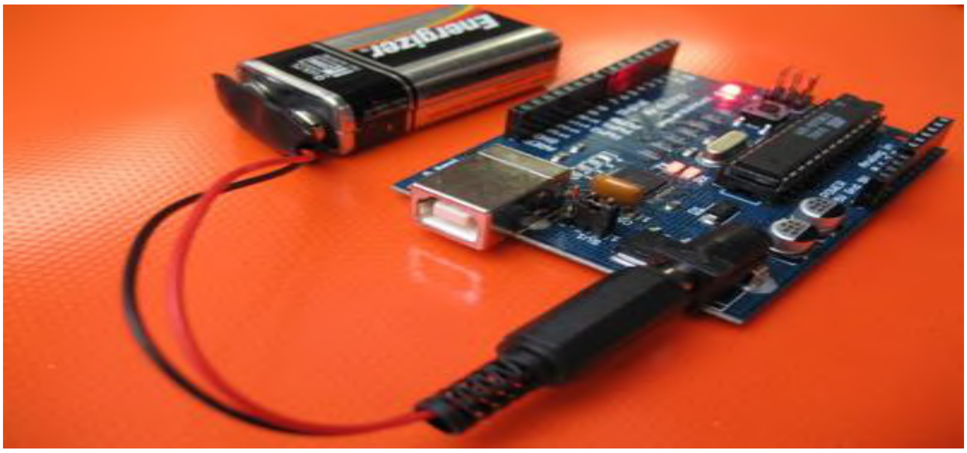


Fig.6.1: Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
```

}

void loop() {}

6.2 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

6.3 Proteus:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select new design in File menu

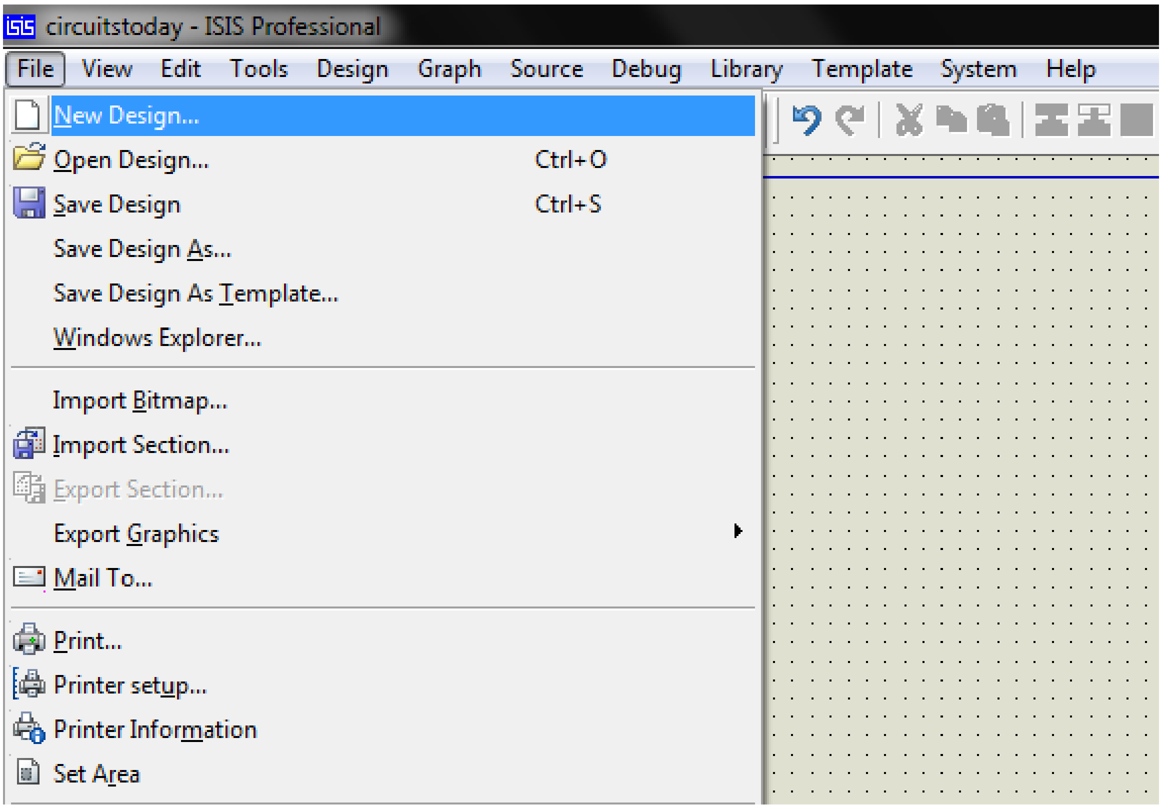

Fig Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

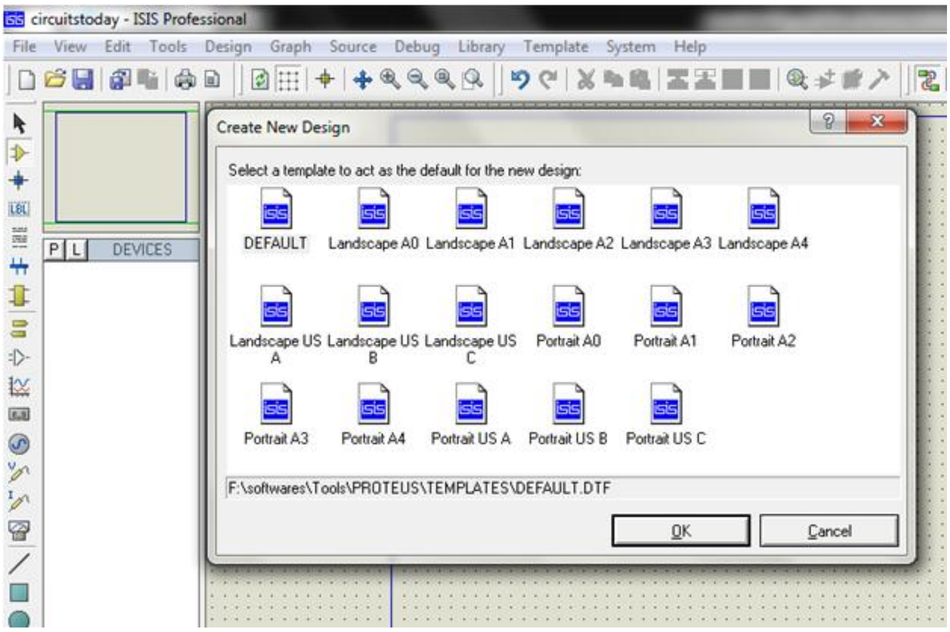

Fig Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

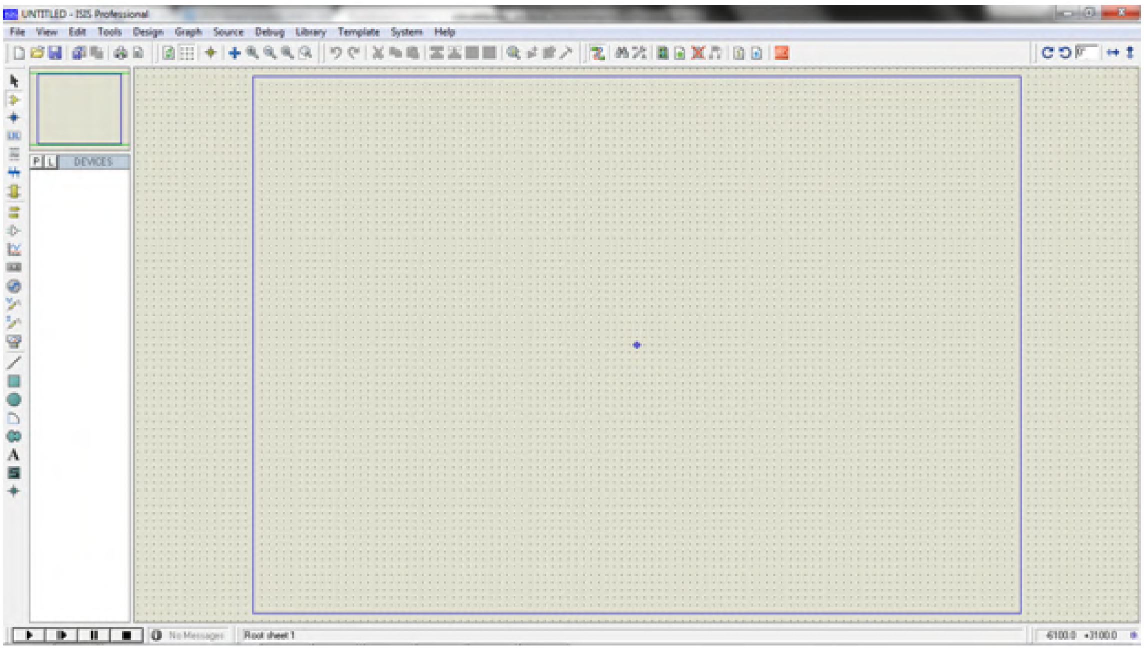

Fig Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

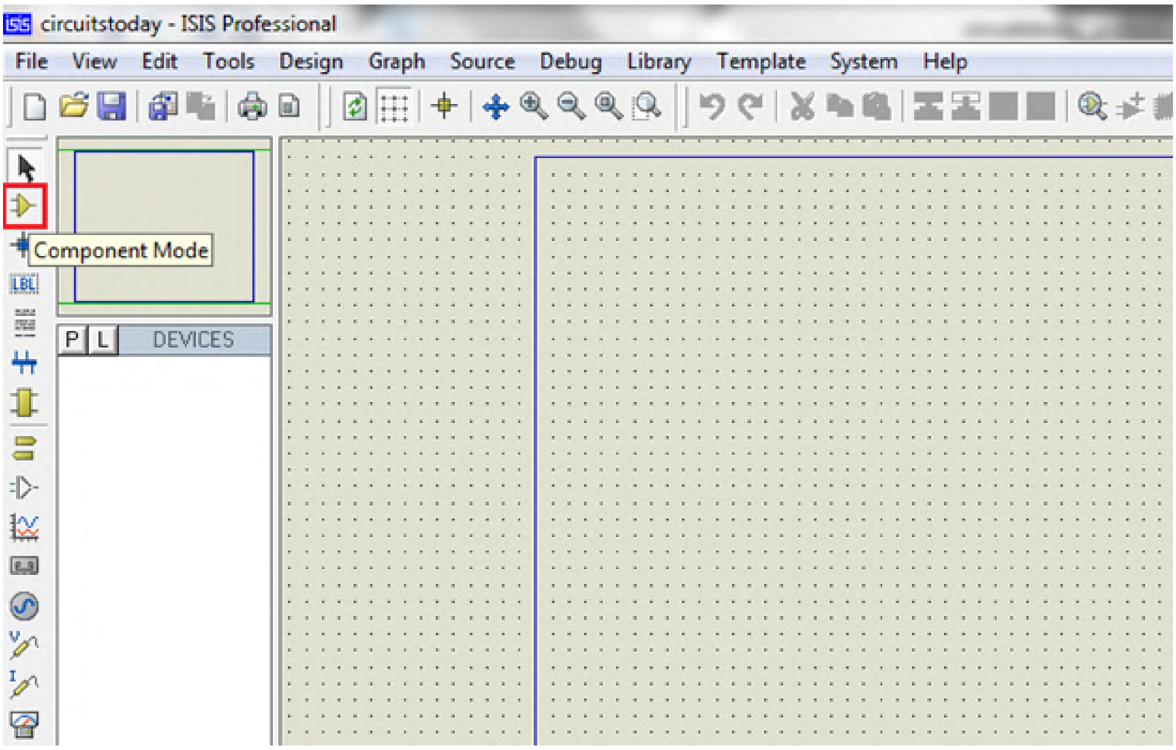

Fig Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

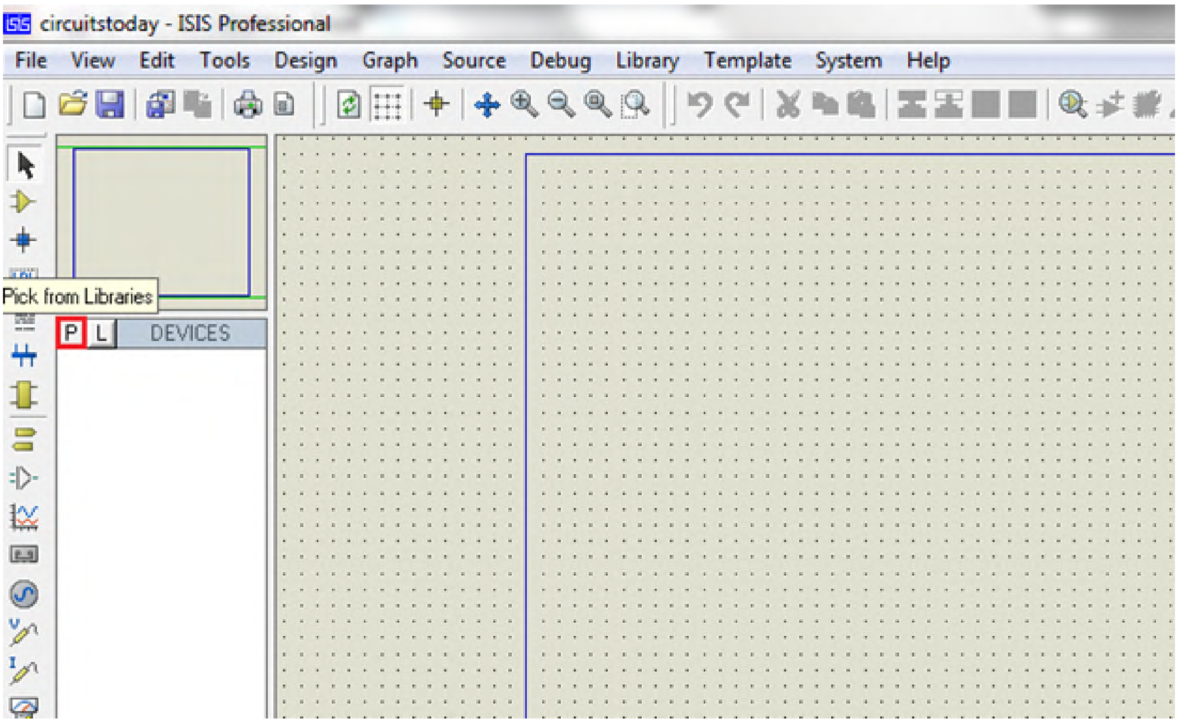

Fig Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

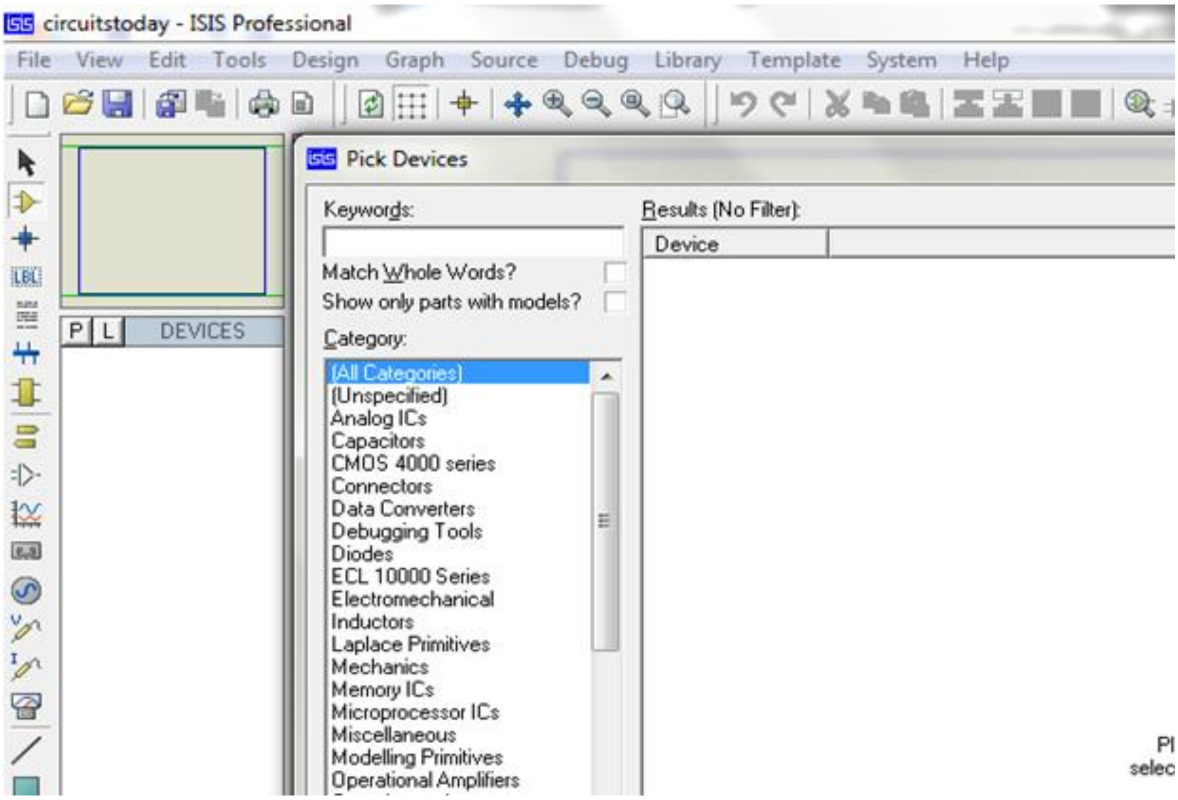

Fig Keywords Textbox

Example shows selection of push button. Select the components accordingly.

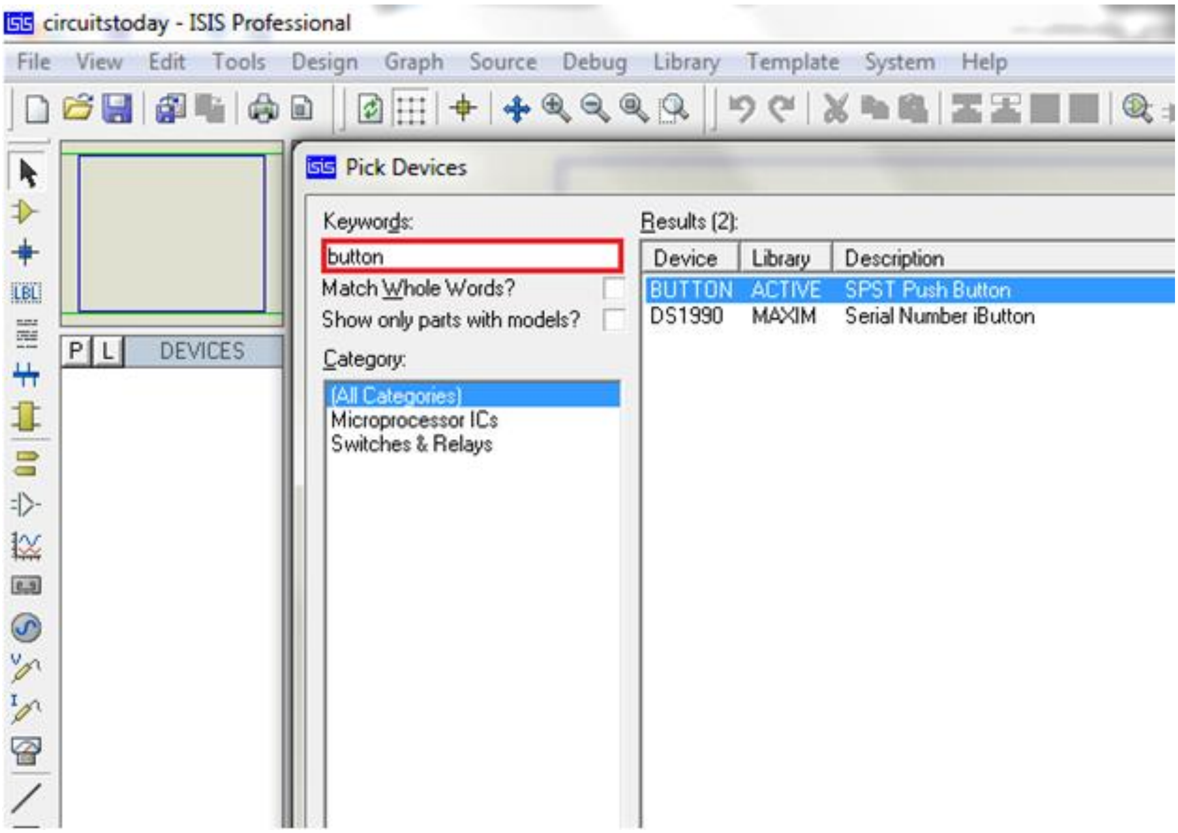

Fig Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

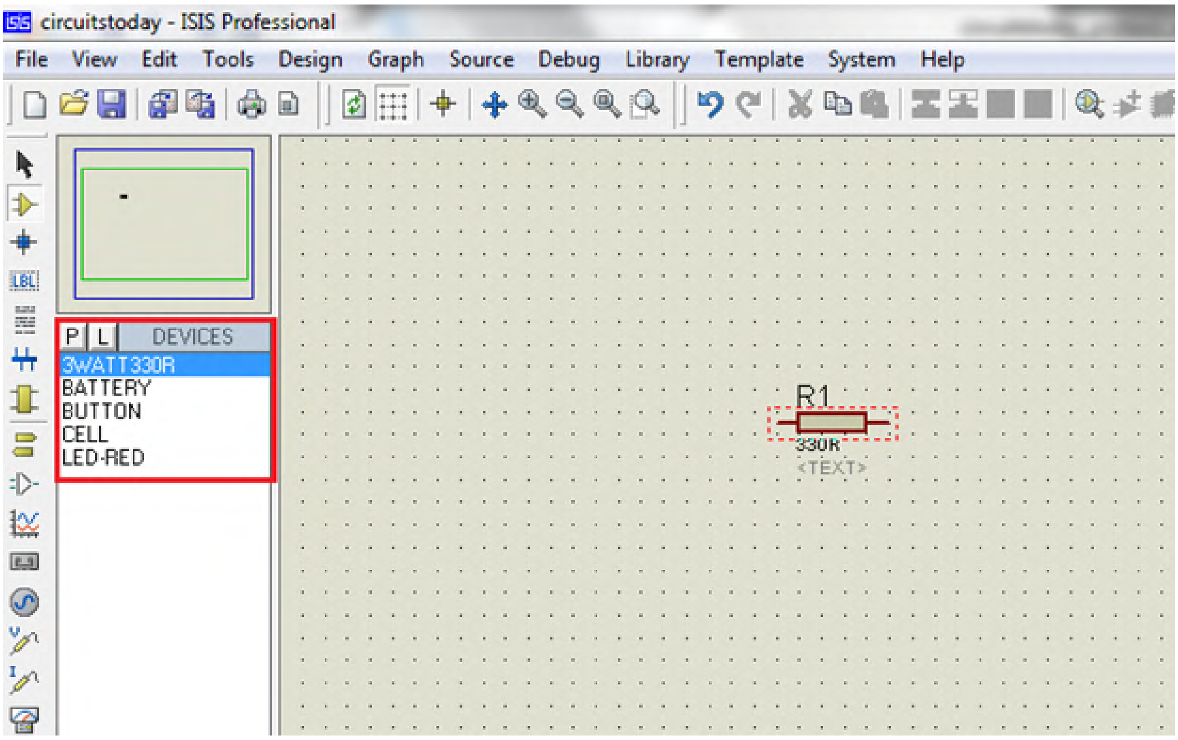

Fig Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

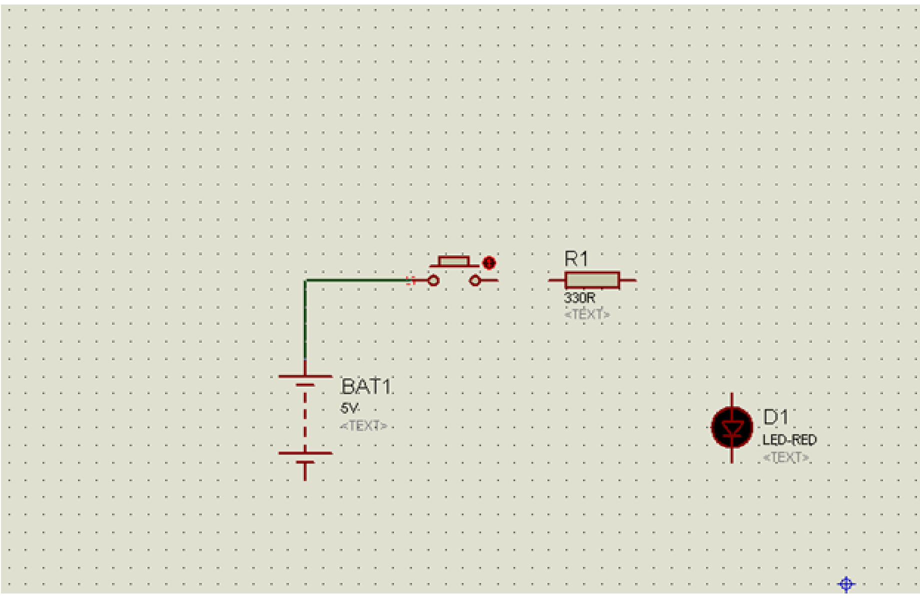

Fig Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

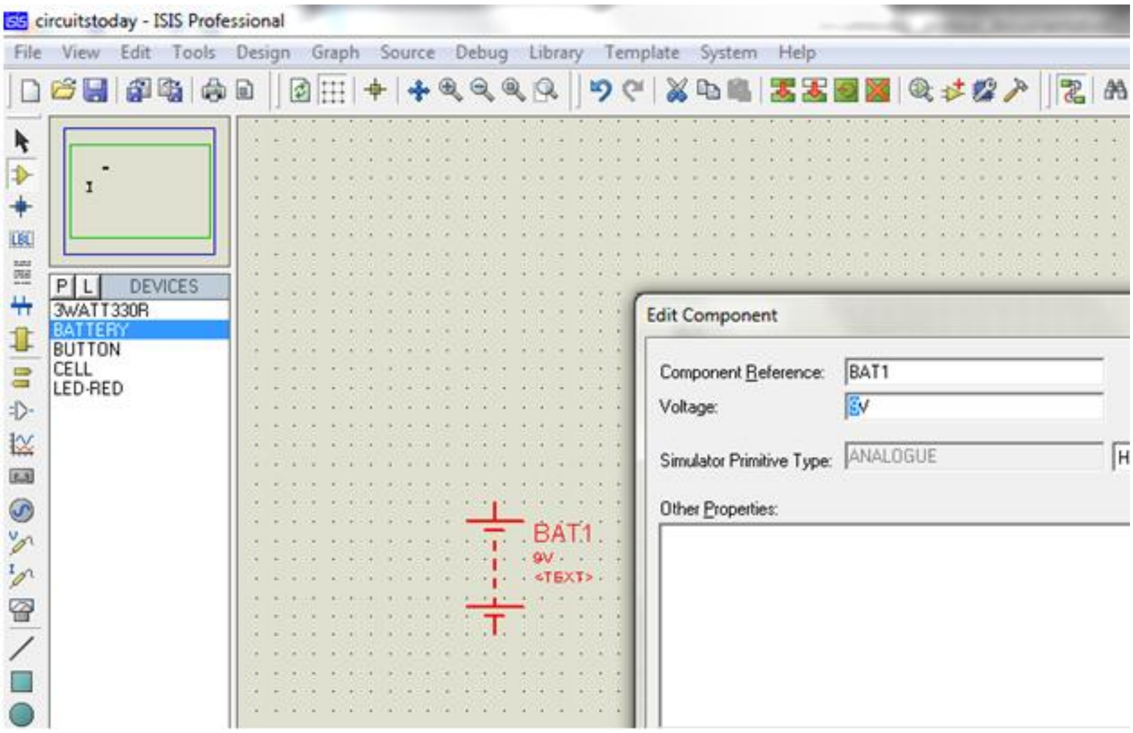

Fig Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

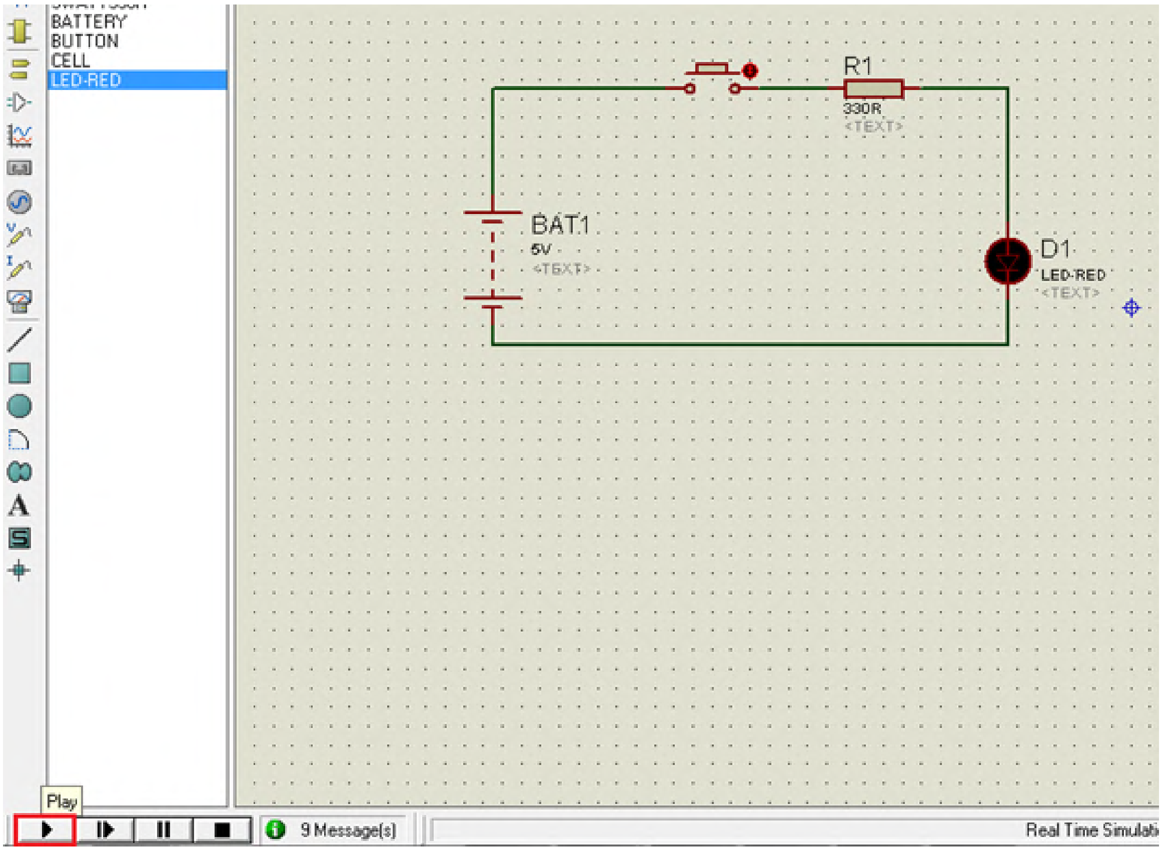

Fig Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

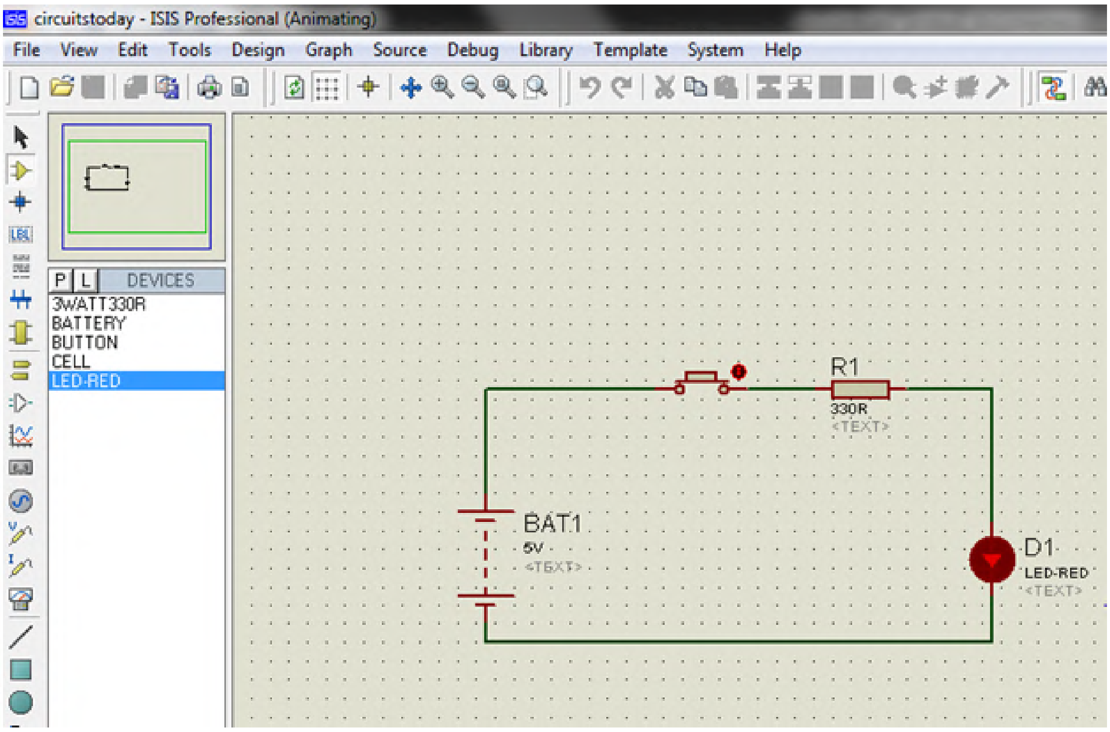

Fig Simulation Animating

Simulation can be stepped, paused or stopped at any time.

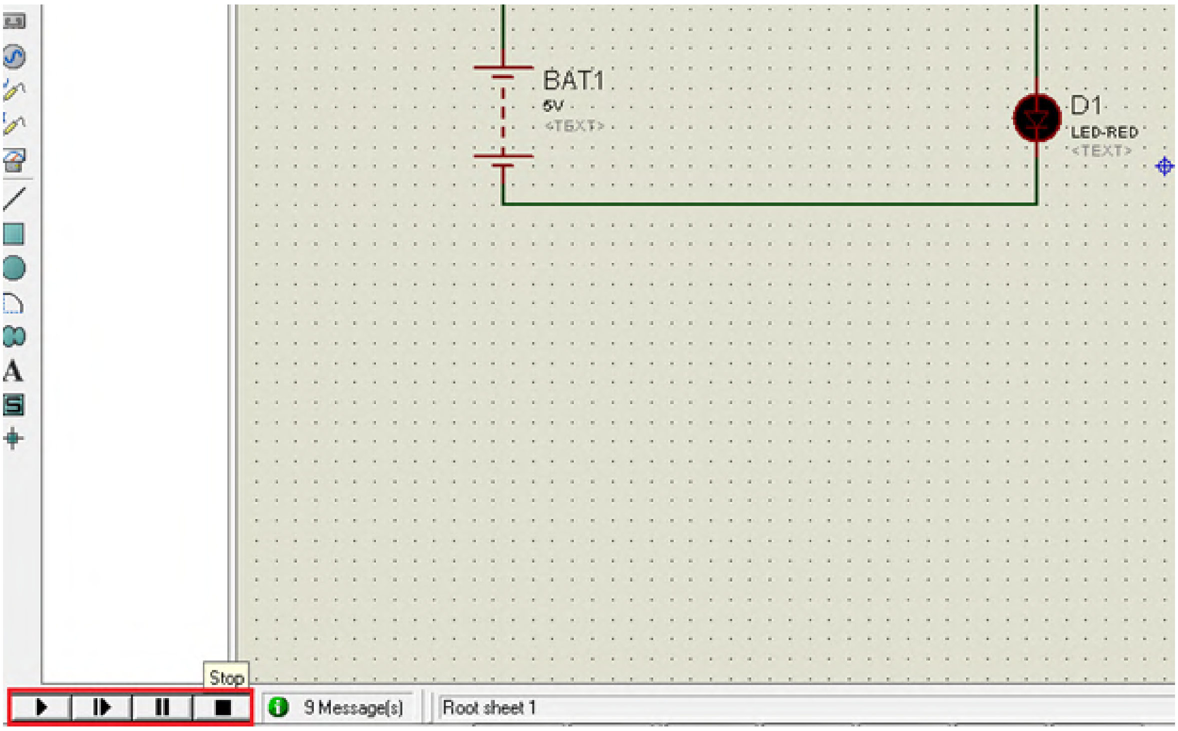

Fig Simulation Step-Pause-Stop Buttons

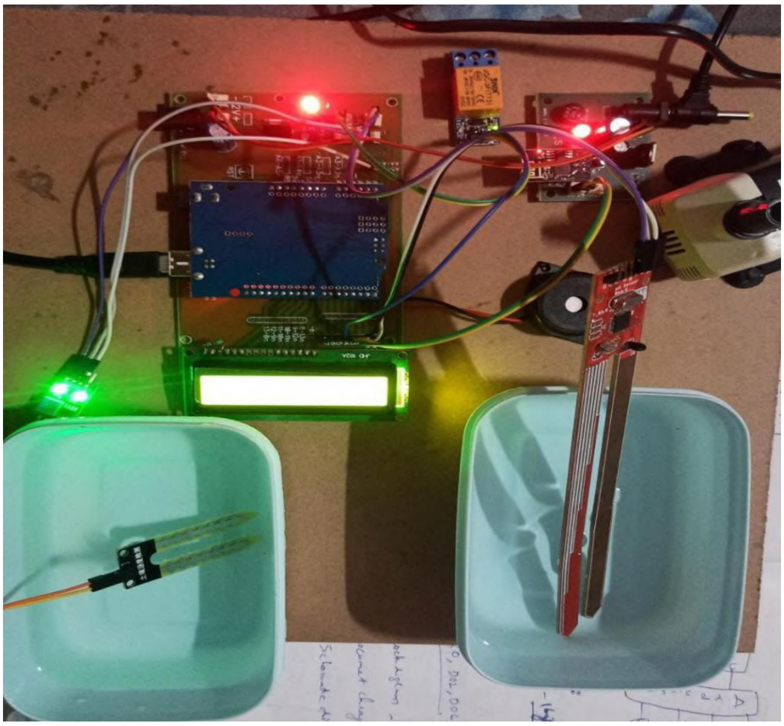
CHAPTER-7

RESULT & CONCLUSION

7.1 Experimental Result:



Project Code:

```
#include <LiquidCrystal.h>
 LiquidCrystal lcd (13,12,11,10,9,8);
 #include <SoftwareSerial.h>
 SoftwareSerial mySerial (2,3);
  //adc
 int temp = A0, soil = A5, water = A2, relay=4, buz=7;
char res [130];
 //pins

////////////////////

```

7.2 Conclusion:

In present days especially farmers are facing major problems in watering their agriculture fields, it’s because they have no proper idea about when the power is available so that they can pump water. Even after then they need to wait until the field is properly watered, which makes them to stop doing other activities. Here is an idea which helps not only formers even for watering the gardens also, which senses the soil moisture and switches the pump automatically when the power is ON.

7.3 Further Enhancement:

The working of project is basically dependent on the output of the humidity sensor. Whenever there is need of excess water in the desired field (RICE crops) then it will not be possible by using sensor technology. By using this we will be able to irrigate the desired fields and in desired amount.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P. Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come

We would like to express our gratitude to **our dept. project coordinator** Mr.M.Govind Raj for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

We dedicate this thesis to almighty

1. Mr. Kevin Martin (17K81A04F0)
2. Mr. Shaik Nazar Basha (17K81A04H1)

ABSTRACT

In next generation mobile communication environment, a huge number of smart devices will require a large amount of data traffic. To accommodate these, 5G mobile communication systems using millimeter-wave bands are being studied, and the new radio access is standardized by 3rd Generation Partnership Project (3GPP). This paper investigates a 5G NR based uplink millimeter-wave massive multiple-input multiple-output (MIMO) system. The spectral efficiency is analyzed in a 3GPP spatial channel model scenario, urban micro cell.

CHAPTER 1

INTRODUCTION

With the advent of the Internet of Things, the number of smart devices requiring wireless communication has exploded. They require a large amount of data traffic. To accommodate this, 5G mobile communication systems are being studied in many countries around the world. 5G mobile telecommunication businesses aim to increase frequency efficiency, increase density of user's connection, decrease delay speed, and increase network capacity more than 4G. To meet the requirements of 5G mobile communication, 3rd Generation Partnership Project (3GPP) standardized the New Radio Access (NR) that supports millimetre-wave bands above 6 GHz, in December 2017 [9]. Millimetre based mobile telecommunication technology is being studied as a key 5G technology to accommodate the growing traffic of mobile telecommunication.

Design a 5G NR transmission frame and the uplink millimetre-wave massive multiple-input multiple output (MIMO) system based on 5G NR considering multi users in the urban micro cell scenario. In addition, a spatial multiplexing technique is applied to support streams with high spectral efficiency, and the performance of the system is evaluated through spectral efficiency analysis.. we describe the millimeter-wave channel model. The 5G NR based uplink millimeter-wave massive MIMO system is described .

Multiple-Input Multiple-Output (MIMO) technology is a wireless technology that uses multiple transmitters and receivers to transfer more data at the same time. MIMO technology takes advantage of a radio-wave phenomenon called multipath where transmitted information bounces off walls, ceilings, and other objects, reaching the receiving antenna multiple times via different angles and at slightly different times

Figure 1.1 : MIMO Technology uses multiple radios to transfer more data at the same time

MIMO, is a radio communications technology or RF technology that is being mentioned and used in many new technologies these days. Wi-Fi, LTE; Long Term Evolution, and many other radio, wireless and RF technologies are using the new MIMO wireless technology to provide increased link capacity and spectral efficiency combined with improved link reliability using what were previously seen as interference paths.

Even now many there are many MIMO wireless routers on the market, and as this RF technology is becoming more widespread, more MIMO routers and other items of wireless MIMO equipment will be seen.

MIMO technology leverages multipath behavior by using multiple, “smart” transmitters and receivers with an added “spatial” dimension to dramatically increase performance and range. MIMO allows multiple antennas to send and receive multiple spatial streams at the same time.

MIMO makes antennas work smarter by enabling them to combine data streams arriving from different paths and at different times to effectively increase receiver signal-capturing power. Smart antennas use spatial diversity technology, which puts surplus antennas to good use. If there are more antennas than spatial streams, the additional antennas can add receiver diversity and increase range.

MIMO -Multiple Input Multiple Output basics:

As a result of the use of multiple antennas, MIMO wireless technology is able to considerably increase the capacity of a given channel. By increasing the number of receive and transmit antennas it is possible to linearly increase the throughput of the channel with every pair of antennas added to the system. This makes MIMO wireless technology one of the most important wireless techniques to be employed in recent years. As spectral bandwidth is becoming an ever more valuable commodity for radio communications systems, techniques are needed to use the available bandwidth more effectively. MIMO wireless technology is one of these techniques. MIMO is effectively a radio antenna technology as it uses multiple antennas at the transmitter and receiver to enable a variety of signal paths to carry the data, choosing separate paths for each antenna to enable multiple signal paths to be used.

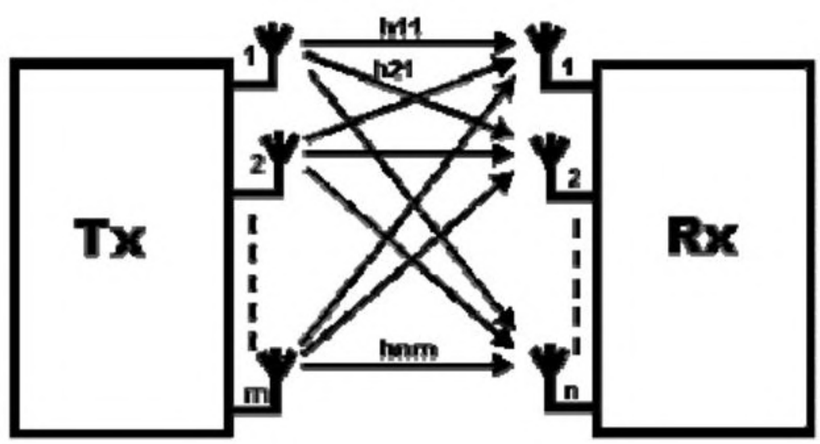

Figure 1.2 : MIMO Block Diagram

One of the core ideas behind MIMO wireless systems space-time signal processing in which time is complemented with the spatial dimension inherent in the use of multiple spatially distributed antennas, i.e. the use of multiple antennas located at different points. Accordingly MIMO wireless systems can be viewed as a logical extension to the smart antennas that have been used for many years to improve wireless. It is found between a transmitter and a receiver, the signal can take many paths. Additionally by moving the antennas even a small distance the paths used will change. The variety of paths available occurs as a result of the number of objects that appear to the side or even in the direct path between the transmitter and receiver. Previously these multiple paths only served to introduce interference. By using MIMO, these additional paths can be used to advantage. They can be used to provide additional robustness to the radio link by improving the signal to noise ratio, or by increasing the link data capacity.

One of the key advantages of MIMO spatial multiplexing is the fact that it is able to provide additional data capacity. MIMO spatial multiplexing achieves this by utilising the multiple paths and effectively using them as additional "channels" to carry data. The maximum amount of data that can be carried by a radio channel is limited by the physical boundaries defined under Shannon's Law. Multiple-input, multiple-output (MIMO) antenna systems are used in modern wireless standards, including in IEEE 802.11n, 3GPP LTE, and mobile WiMAX systems. The technique supports enhanced data throughput even under conditions of interference, signal fading, and multipath. The demand for higher data rates over longer distances has been one of the primary motivations behind the development of MIMO orthogonal- frequency-division-multiplexing (OFDM) communications systems. Shannon's law defines the maximum rate at which error free data can be transmitted over a given bandwidth in the presence of noise. It is usually expressed in the form:

$$\text{Capacity} = BW \log2(1 + SNR) \text{ ---- Eq. 1}$$

Where C is the channel capacity in bits per second, BW is the bandwidth in Hertz, and SNR is Signal to Noise Ratio.

The above Eq.1 shows, an increase in a channel's SNR results in marginal gains in channel throughput. As a result, the traditional way to achieve higher data rates is by increasing the signal bandwidth. Unfortunately, increasing the signal bandwidth of a communications channel by increasing the symbol rate of a modulated carrier increases its susceptibility to multipath fading. For wide bandwidth channels, one partial solution to solving the multipath challenge is to use a series of narrowband overlapping subcarriers.

Not only does the use of overlapping OFDM subcarriers improve spectral efficiency, but the lower symbol rates used by narrowband subcarriers reduces the impact of multipath signal products. MIMO communications channels provide an interesting solution to the multipath challenge by requiring multiple signal paths. In effect, MIMO systems use a combination of multiple antennas and multiple signal paths to gain knowledge of the communications channel. By using the spatial dimension of a communications link, MIMO systems can achieve significantly higher data rates than traditional single-input, single-output (SISO) channels.

In a 2 x 2 MIMO system, signals propagate along multiple paths from the transmitter to the receiver antennas. Using this channel knowledge, a receiver can recover independent streams from each of the transmitter's antennas. A 2 x 2 MIMO system produces two spatial streams to effectively double the maximum data rate of what might be achieved in a traditional 1 x 1 SISO communications channel. The maximum channel capacity of a MIMO system, the channel capacity can be estimated as a function of N spatial streams. A basic approximation of MIMO channel capacity is a function of spatial streams, bandwidth, and signal-to-noise ratio (SNR) and is shown in the following Eq. :

$$\text{Capacity} = N\ BW \log_2 (1 + SNR) \text{ --- Eq. 2}$$

Given the equation for MIMO channel capacity, it is possible to investigate the relationship between the number of spatial streams and the throughput of various implementations of SISO and MIMO configurations. As an example, the IEEE 802.11g specs prescribe that a wireless-local-area network (WLAN) channel uses a SISO configuration. With this standard, the maximum coded data rate of 54 Mb/s requires use of a 64-QAM modulation scheme and a code rate of 3/4. As a result, the un-coded bit rate is 72 Mb/s (4/3 x 54 Mb/s). With minimum transmitter error vector magnitude (EVM) at -25 dB, an SNR of 25 dB can be estimated as the requirement for a 64-state quadrature amplitude- modulation (64QAM) scheme. While EVM and SNR are not equivalent in all cases, we can assume that the magnitude error of a symbol will dominate the signal error as the SNR approaches its lower limit. The maximum data rate of IEEE 802.11g maps closely with the maximum channel capacity dictated by the Shannon- Hartley theorem. According to this theorem, a Gaussian channel with an SNR of 25 dB should produce an un coded data rate of 94 Mb/s in a 20-MHz channel bandwidth. By contrast, Eq. 2 would suggest that a MIMO channel with four spatial streams should be capable of four times the capacity of the SISO channel. 20-MHz channel with a signal-to-noise ratio (SNR) of 25 dB and four spatial streams should have an un coded bit rate of 4 x 94 Mb/s = 376 Mb/s.

This estimation maps closely with the expected data rates of the draft IEEE 802.11n physical layer specs. IEEE 802.11n is designed to support MIMO configurations with as many as four spatial streams. At the highest data rate, bursts using a 64QAM modulation scheme with a 5/6 channel code rate produce a data rate of 288.9Mb/s and an uncoded bit rate of 346.68 Mb/s. At the highest data rate, the IEEE 802.11n channel with four spatial streams produces a data rate that is comparable to the theoretical limit of 376 Mb/s. It can be observed that the bit rate of a 4 x 4 (four spatial stream) MIMO configuration exceeds that of the Shannon- Hartley limit at all data rates, making MIMO systems attractive for higher data throughput. While MIMO systems provide users with clear benefits at the application level, the design and test of MIMO devices is not without significant challenges. MIMO systems are a natural extension of developments in antenna array communication. While the advantages of multiple receive antennas, such as gain and spatial diversity, have been known and exploited for some time the use of transmit diversity has only been investigated recently .

The advantages of MIMO communication, which exploits the physical channel between many transmit and receive antennas, are currently receiving significant attention. While the channel can be so nonstationary that it cannot be estimated in any useful sense , in this article we assume the channel is quasi static. MIMO systems provide a number of advantages over single-antenna-to-single-antenna communication. Sensitivity to fading is reduced by the spatial diversity provided by multiple spatial paths. Under certain environmental conditions, the power requirements associated with high spectral-efficiency communication can be significantly reduced by avoiding the compressive region of the information-theoretic capacity bound. Here, spectral efficiency is defined as the total number of information bits per second per Hertz transmitted from one array to the other.

After an introductory section, we describe the concept of MIMO information-theoretic capacity bounds. Because the phenomenology of the channel is important for capacity, we discuss this phenomenology and associated parameterization techniques, followed by examples of space-time codes and their respective receivers and decoders. We performed experiments to investigate channel phenomenology and to test coding and receiver techniques. Capacity We discuss MIMO information-theoretic performance bounds in more detail in the next section. Capacity increases linearly with signal-to-noise ratio (SNR) at low SNR, but increases logarithmically with SNR at high SNR. In a MIMO system, a given total transmit power can be divided among multiple spatial paths (or modes), driving the capacity closer to the linear regime for each mode, thus increasing the aggregate spectral efficiency. As seen in Figure 1, which assumes an optimal high spectral-efficiency MIMO channel (a channel matrix with a flat singular-value distribution), MIMO systems enable high spectral efficiency at much lower required energy per information bit

A channel may be affected by fading and this will impact the signal to noise ratio. In turn this will impact the error rate, assuming digital data is being transmitted. The principle of diversity is to provide the receiver with multiple versions of the same signal. If these can be made to be affected in different ways by the signal path, the probability that they will all be affected at the same time is consid erably reduced. Accordingly, diversity helps to stabilise a link and improves performance, reducing error rate.

Several different diversity modes are available and provide a number of advantages:

- **Time diversity:** Using time diversity, a message may be transmitted at different times, e.g. using different timeslots and channel coding.
- **Frequency diversity:** This form of diversity uses different frequencies. It may be in the form of using different channels, or technologies such as spread spectrum / OFDM.
- **Space diversity:** Space diversity used in the broadest sense of the definition is used as the basis for MIMO. It uses antennas located in different positions to take advantage of the different radio paths that exist in a typical terrestrial environment.

MIMO is effectively a radio antenna technology as it uses multiple antennas at the transmitter and receiver to enable a variety of signal paths to carry the data, choosing separate paths for each antenna to enable multiple signal paths to be used.

One of the core ideas behind MIMO wireless systems space-time signal processing in which time (the natural dimension of digital communication data) is complemented with the spatial dimension inherent in the use of multiple spatially distributed antennas, i.e. the use of multiple antennas located at different points. Accordingly MIMO wireless systems can be viewed as a logical extension to the smart antennas that have been used for many years to improve wireless.

It is found between a transmitter and a receiver, the signal can take many paths. Additionally by moving the antennas even a small distance the paths used will change. The variety of paths available occurs as a result of the number of objects that appear to the side or even in the direct path between the transmitter and receiver. Previously these multiple paths only served to introduce interference. By using MIMO, these additional paths can be used to advantage. They can be used to provide additional robustness to the radio link by improving the signal to noise ratio, or by increasing the link data capacity.

The two main formats for MIMO are given below:

- **Spatial diversity:** Spatial diversity used in this narrower sense often refers to transmit and receive diversity. These two methodologies are used to provide improvements in the signal to noise ratio and they are characterized by improving the reliability of the system with respect to the various forms of fading.
- **Spatial multiplexing:** This form of MIMO is used to provide additional data capacity by utilizing the different paths to carry additional traffic, i.e. increasing the data throughput capability.

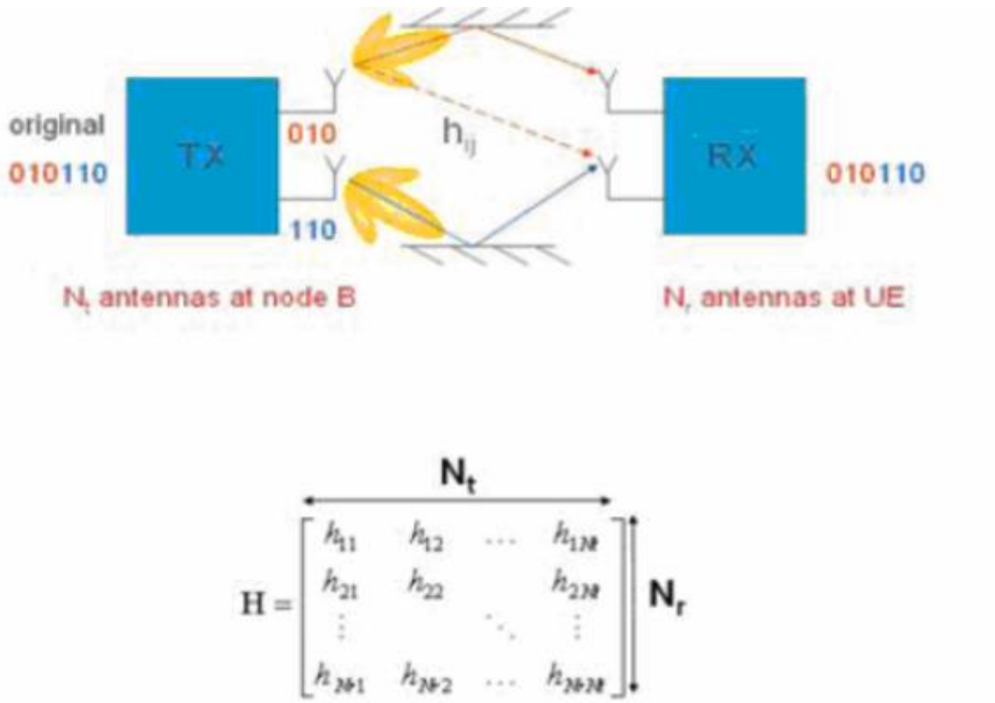

Figure 1.3 : Spatial multiplexing

Each transmit antenna transmits a different data stream. Each receive antenna may receive the data streams from all transmit antennas. The channel (for a specific delay) can thus be described by the following channel matrix H: As above figure. In this general description, Nt is the number of transmit antennas, Nr is the number of receive antennas, resulting in a 2x2 matrix for the baseline LTE scenario. The coefficients hij of this matrix are called channel coefficients from transmit antenna i to receive antenna j, thus describing all possible paths between transmitter and receiver side. The number of data streams that can be transmitted in parallel over the MIMO channel is given by min {Nt, Nr} and is limited by the rank of the matrix H. The transmission quality degrades significantly in case the singular values of matrix H are not sufficiently strong.

This can happen in case the 2 antennas are not sufficiently de-correlated, for example in an environment with little scattering or when antennas are too closely spaced. In LTE, up to 2 code words can be mapped onto different so-called layers. The number of layers for transmission is equal to the rank of the matrix H. There is a fixed mapping between code words to layers.

Figure 1.4 below describes how precoding on transmitter side is used to support spatial multiplexing. This is achieved by applying a precoding matrix W to the signal before transmission.

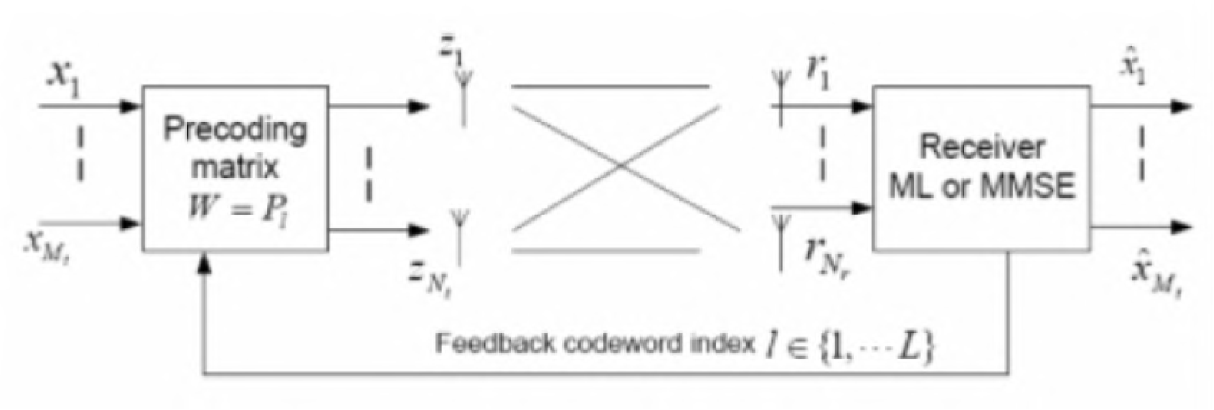

Figure 1.4: Pre-coding principle

As a result of the use multiple antennas, MIMO wireless technology is able to considerably increase the capacity of a given channel while still obeying Shannon's law. By increasing the number of receive and transmit antennas it is possible to linearly increase the throughput of the channel with every pair of antennas added to the system. This makes MIMO wireless technology one of the most important wireless techniques to be employed in recent years. As spectral bandwidth is becoming an ever more valuable commodity for radio communications systems, techniques are needed to use the available bandwidth more effectively. MIMO wireless technology is one of these techniques.

1.2 Benefits Of MIMO Technology

(1) Multiple antenna configurations can be used to overcome the detrimental effects of multi-path and fading when trying to achieve high data throughput in limited-bandwidth channels.

Multiple-input, multiple-output (MIMO) antenna systems are used in modern wireless standards, including in IEEE 802.11n, 3GPP LTE, and mobile WiMAX systems. The technique supports enhanced data throughput even under conditions of interference, multi-path and fading. The demand for higher data rates over longer distances has been one of the primary motivations behind the development of MIMO orthogonal- frequency-division-multiplexing (OFDM) communications systems.

(2) Superior Data Rates, Range and Reliability

Systems with multiple antennas at the transmitter and receiver – also referred to as Multiple Input Multiple Output (MIMO) systems – offer superior data rates, range and reliability without requiring additional bandwidth or transmit power. By using several antennas at both the transmitter and receiver, MIMO systems create multiple independent channels for sending multiple data streams.

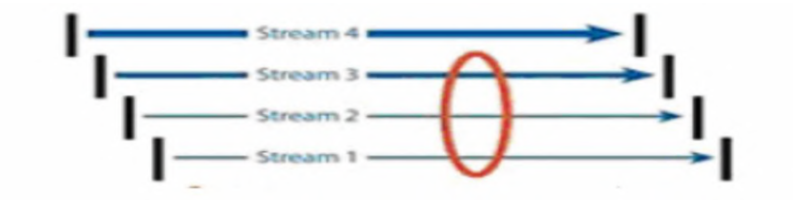

Figure 1.5: Stream combining for enhanced reliability

4x4 MIMO system supports up to four independent data streams. These streams can be combined through dynamic digital beamforming and MIMO receiver processing (in the red oval) to increase reliability and range. The number of independent channels and associated data streams that can be supported over a MIMO channel is equivalent to the minimum number of

antennas at the transmitter or receiver. Thus, a 2x2 system can support at most two streams, a 3x3 system can support three streams and a 4x4 system can support four streams. Some of the independent streams can be combined through dynamic digital beamforming and MIMO receiver processing, as shown in the red oval, which results in increased reliability and range.

LTE MIMO Concepts

MIMO systems form an essential part of LTE in order to achieve the ambitious requirements for throughput and spectral efficiency. MIMO refers to the use of multiple antennas at transmitter and receiver side.

Downlink MIMO

For the LTE downlink, a 2x2 configuration for MIMO is assumed as baseline configuration, i.e. 2 transmit antennas at the base station and 2 receive antennas at the terminal side. Configurations with 4 antennas are also being considered. Different MIMO modes are envisaged. It has to be differentiated between spatial multiplexing and transmit diversity, and it depends on the channel condition which scheme to select. The optimum pre-coding matrix W is selected from a predefined "codebook" which is known at eNodeB and UE side. Unitary pre-coding is used, i.e. the precoding matrices are unitary: WHW= I. The UE estimates the radio channel and selects the optimum pre-coding matrix. The optimum pre-coding matrix is the one which offers maximum capacity. The UE provides feedback on the uplink control channel regarding the preferred pre-coding matrix (pre-coding vector as a special case). Ideally, this information is made available per resource block or at least group of resource blocks, since the optimum pre-coding matrix varies between resource blocks.

Transmit Diversity:

Instead of increasing data rate or capacity, MIMO can be used to exploit diversity. Transmit diversity schemes are already known from WCDMA release 99 and will also form part of LTE as one MIMO mode. In case the channel conditions do not allow spatial multiplexing, a transmit diversity scheme will be used instead, so switching between these two MIMO modes is possible depending on channel conditions. Transmit diversity is used when the selected number of streams (rank) is one.

Uplink MIMO:

Uplink MIMO schemes for LTE will differ from downlink MIMO schemes to take into account terminal complexity issues. For the uplink, MU-MIMO can be used. Multiple user terminals may transmit simultaneously on the same resource block. This is also referred to as spatial domain multiple access (SDMA). The scheme requires only one transmit antenna at UE side which is a big advantage. The UEs sharing the same resource block have to apply mutually orthogonal pilot patterns.

To exploit the benefit of two or more transmit antennas but still keep the UE cost low, antenna subset selection can be used. In the beginning, this technique will be used, e.g. a UE will have two transmit antennas but only one transmit chain and amplifier. A switch will then choose the antenna that provides the best channel to the eNodeB. Multiple-input multiple-output, or MIMO, is a radio communications technology or RF technology that is being mentioned and used in many new technologies these days. Wi-Fi, LTE (3G long term evolution) and many other radio, wireless and RF technologies are using the new MIMO wireless technology to provide increased link capacity and spectral efficiency combined with improved link reliability using what were previously seen as interference paths.

The multiple input multiple output channel technology is aimed to increase the capacity in the wireless communication network. With the invention of MIMO, the technology seems to gain popularity as it is being implemented in the current commercial wireless products and networks such as broadband wireless access systems, wireless local area networks (WLAN), 3G networks, etc. The main idea behind MIMO is that, the sampled signals in spatial domain at both the transmitter and receiver end are combined so that they form effective multiple parallel spatial data streams which increase the data rate. The occurrence of diversity also improves the quality that is the bit-error rate (BER) of the communication.

Single Input Single Output versus MIMO channel capacity In communication systems, input discrete source symbols are mapped into a sequence of channel symbols which are then transmitted through the wireless channel. The transmission of channel symbols through the wireless channel is by nature random and random noise is added to the channel symbols. The measure of how much information that can be transmitted and received with minimum probability of error is called the channel capacity. A Single Input Single Output system involves the use of one antenna both at the transmitter and receiver end. To a telecommunications engineer, there exit a limit at which reliable transmission of information is not possible for a given transmission bandwidth and power. These limits where discovered by Claude Shannon in 1948 when he established the principles of information and communication theory on his various publications. Shannon also established the conditions that enable the transmission of information over a noisy channel at a given rate, for a given power of the signal and noise. These limiting factors are the finite bandwidth and the S/N of the channel.

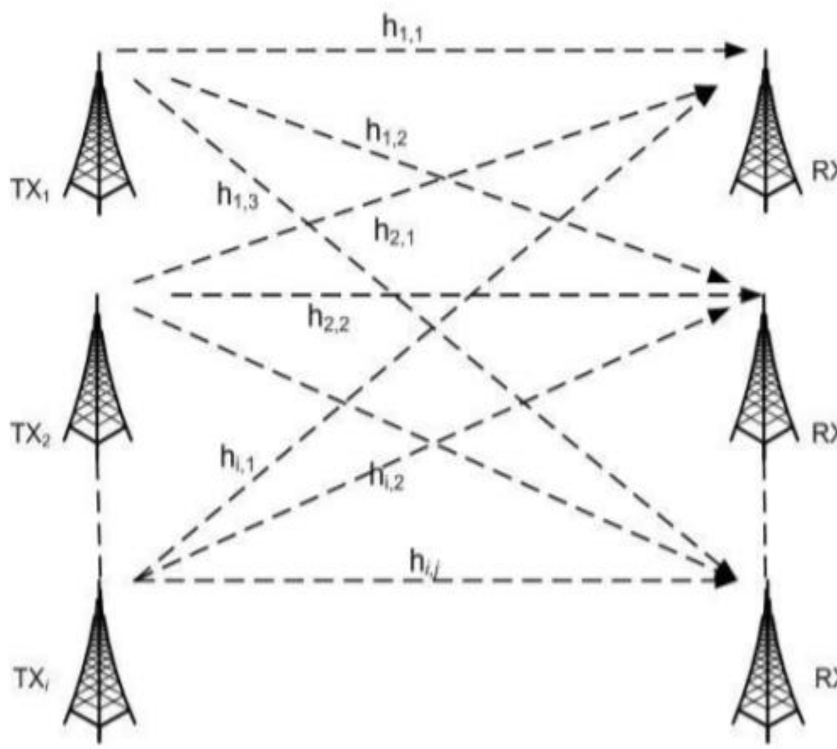

Figure 1.6 : A generalized MIMO wireless communication system.

This is because for a communication channel to accommodate the signal spectrum, enough transmission bandwidth is needed otherwise there will be distortion. ”The higher data rate is to be transmitted, the shorter digital pulses must be used and the shorter digital pulses are used for transmission, the wider bandwidth is required”. For a deterministic channel with a bandwidth (B) with additive noise, Shannon proved that information with a rate of r bits per second (bps) can be transmitted with a small error probability provided that the bit rate is less than the capacity of the channel $r < C$ where S/N, the signal-to-noise ratio and B the bandwidth of the transmission channel. Assuming we have a channel with additive noise N and that we have some freedom of choosing the average transmission power S, to set up a reliable transmission link to send r bits per second. From the Shannon theorem, the data rate r cannot exceed capacity C, $r < C$, but we still have one degree of freedom in the choice of bandwidth B and power S. It can be realized that, for a given signal-to-noise ratio S/N, if we wish to double C, we have to double the bandwidth B. On the other hand, if we double C, for a given B we have to evaluate the S/N.

Representation of MIMO channel :

A 2 x 2 MIMO channel model The first channel model to be considered in this project will be a 2 x 2 MIMO system that is a system with 2 transmits (TX) and 2 receive (RX) antennas where different independent data streams are transmitted from multiple antennas to multiple receive antennas. This channel model will be extended to a 3 x 3 MIMO system and even more to illustrate the channel characteristics in relation to the increase in the number of antennas. The signals considered in the MIMO systems of this project are baseband signals ignoring modulation processes and concentrating on the up and down frequency conversion. Therefore the signals on the i-th transmit antenna will be denoted x□ while the received signal on the j-th receive antenna denoted as y. Figure 2 shows the antenna set-up and the various unknown channel coefficients.

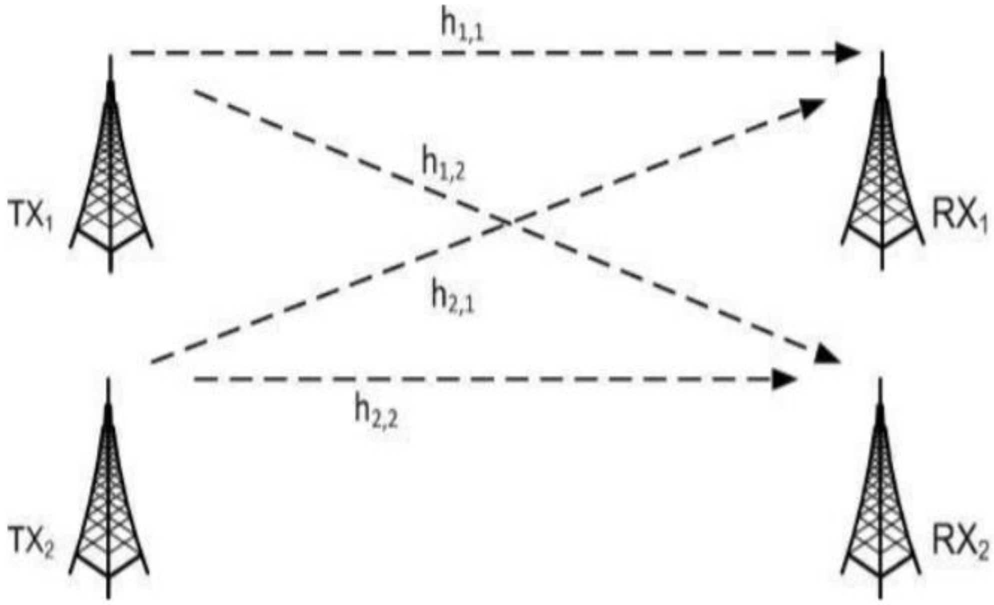

Figure 1.7 : Channel characteristic of a 2 x 2 MIMO wireless communication system.

Since the coefficient of the unknown in the channel matrix Wc and the number of transmitted signal X is equal to the number of received signal Y, the equation can be solved if the channel Wc is inversed which in this case a 2 x 2 matrix inversion.

Channel estimation procedure

Channel characteristics estimation In order to estimate the channel characteristics, we expand each transmitted and received signals in time and write into signal matrix columns K discrete samples in time. The signals matrixes get K rows and as many columns as we have antennas, N or M. In general a MIMO system involves multiple antennas at the transmitting end and multiple receivers at the receiving end. Figure 4 show a general representation of a 3 x 3 general MIMO system.

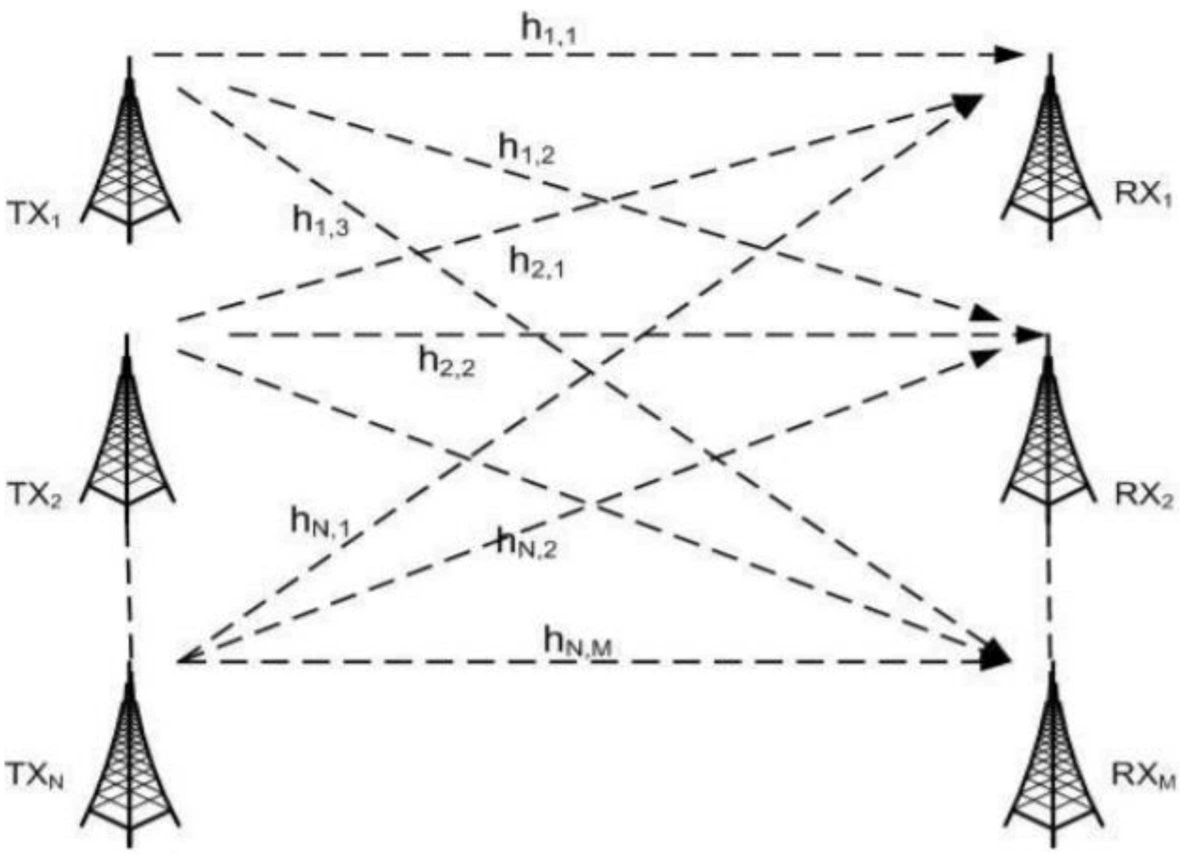

Figure1.8 : General 3 x 3 MIMO system with unknown channel characteristics.

In order to determine the characteristic of the channel, both the transmitted signal X and the received signal Y have to be known. If the transmitted and received signals are of the form

$$\mathbf{X} = [\mathbf{x}_1, \mathbf{x}_2, \dots \mathbf{x}_N] = \begin{pmatrix} x_{1,1} & \cdots & x_{1,N} \\ \vdots & \ddots & \vdots \\ x_{K,1} & \cdots & x_{K,N} \end{pmatrix}$$

$$\mathbf{Y} = [\mathbf{y}_1, \mathbf{y}_2, \dots \mathbf{y}_M] = \begin{pmatrix} y_{1,1} & \cdots & y_{1,M} \\ \vdots & \ddots & \vdots \\ y_{K,1} & \cdots & y_{K,M} \end{pmatrix}$$

If the channel transfer matrix Wc can be determine, then it means the transmitted signals can also be determine because the received signal Y is known. We may write the expression between these vector signals as

$$Y = X\ Wc$$

Orthonormal space concept

Orthonormal basis of transmitted signal:

Orthonormal basis is a coordination system where we can present as many dimensions as is the maximum number of antennas of the transmitted and received signals. The main reason why we need the orthonormal base is to have a common coordinated system in order to combine the transmitted signal X and the received signal Y. The number of dimension of the orthonormal base matrix depends on the maximum number of antennas at both the transmitted and the receiver end of the MIMO system. It does not actually matter what kind of signal (X or Y) used in generating the orthonormal space but it is most convenient to use the transmitted training signal X which is defined to contain linearly independent column signals. Suppose K = 3 time samples per transmitted signal X and per received signal Y respectively of a 3 x 3 channel transmission system were observed. Figure 6 shows a Line of Sight (LOS) MIMO system made up of three transmitters and three receivers.

In figure, N = 3 transmitted signals and M = 3 received signals, the format of the unknown channel transfer matrix Ŏc would be 3 x 3. Assume that all signals are real valued and the transmitted signals and received signals are observed as signal matrices. Then we need the orthonormal basis matrix Ux to solve for an estimated channel transfer matrix Ŏc. It is easier to calculate the orthonormal base matrix Ux of a square matrix; therefore in the next section we estimate the channel model by calculating first the orthonormal basis matrix Ux of a simple 2 x 2 MIMO system and then proceed to a more complex 3 x 3 MIMO system.

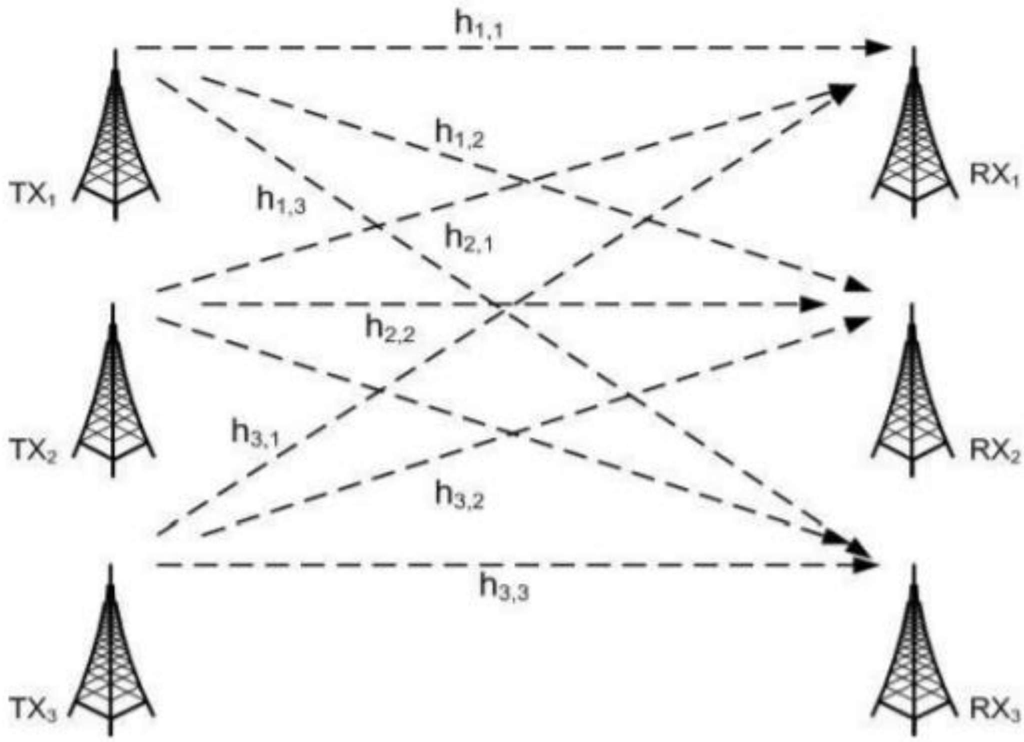

Figure 1.9 : 3 x 3 MIMO wireless communication system.

This is a form of antenna diversity, which uses multiple antennas to improve signal quality and strength of an RF link. The data is split into multiple data streams at the transmission point and recombined on the receive side by another MIMO radio configured with the same number of antennas. The receiver is designed to take into account the slight time difference between receptions of each signal, any additional noise or interference, and even lost signals. By transmitting the same data on multiple streams, the MIMO radios introduce redundancy into data transmission that classic single antenna setups (SISO: Single In, Single Out) can’t provide. This gives MIMO systems several advantages over typical SISO configurations:

- MIMO radios can utilize the bounced and reflected RF transmissions (known as multipath propagation) to actually improve signal strength even without clear line-of-site, since MIMO radios receive and combine multiple streams of the same data that are received at slightly different time intervals. This is particularly useful in urban environments, where signal degradation between single antennas without clear line-of-site is a major issue. Urban environments provide plenty of reflection paths for MIMO signals to take between the transmit and receive radios.
- Overall throughput can be improved, allowing for greater quality and quantity of video or other data to be sent over the network.
- By utilizing multiple data streams, issues such as fading caused lost or dropped data packets can be reduced, resulting in better video or audio quality.

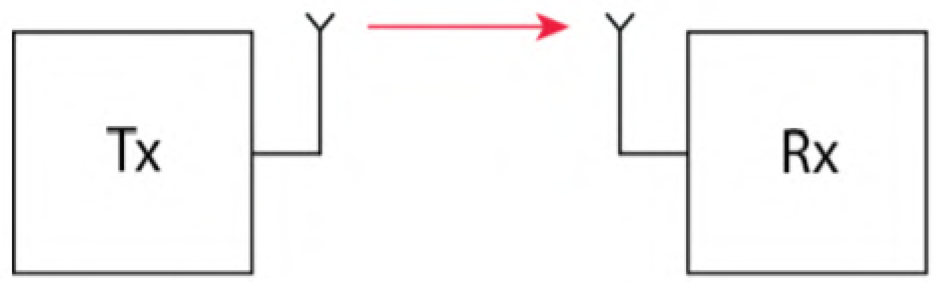

Figure 1.10 :Example of SISO system, where one antenna is used on each side of the RF

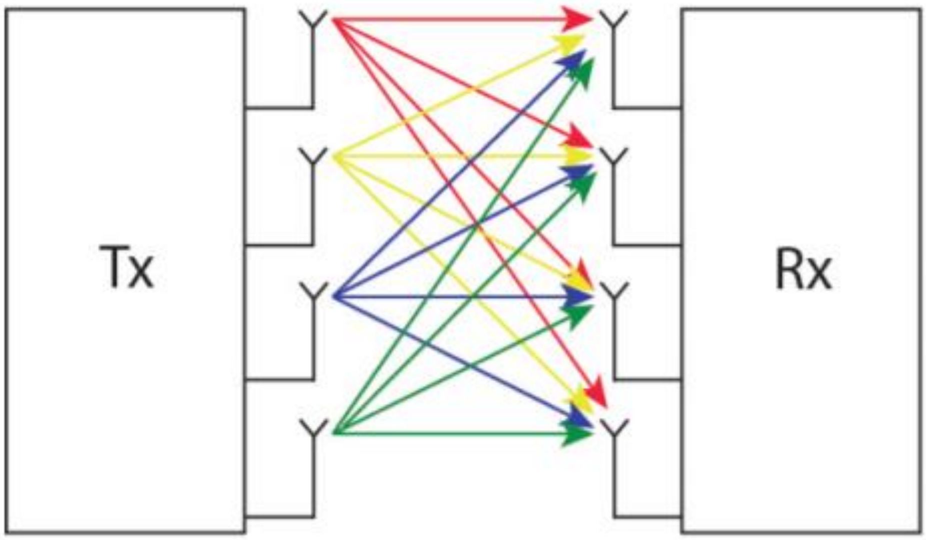

Figure 1.11 : Example of a 4X4 MIMO system

where four antennas from the transmit radio communicate with four antennas on the receive radio to improve link connection strength and bandwidth. Some MIMO radio systems also offer Ad-Hoc networking capability, where individual user nodes (such as a person with hand-held radio or vehicle with on-board MIMO radio and antennas installed) can enter or leave the MIMO network at any time, and automatically forward data from other node users through the network, creating a self-forming, self-healing mesh network that doesn't rely on a central architecture to operate.

This is similar to how scalable MANET radio systems work. The ability to take advantage of this type of networking opens up MIMO radio systems to new groups of users who need reliable, scalable network coverage. These systems are more practical than ever as MIMO radio systems continue to decrease in size and can be packaged into familiar hand-held radio form factors. Base stations and network repeaters can also be quickly deployed for short-term events that need a larger coverage area, without the hassle of permanent installation. A few example of users groups who are taking advantage of MIMO systems:

• First responders who often operate in chaotic, changing situations and can't rely on cellular networks or other existing fixed infrastructure to be operational when needed due to natural disasters, power outages, overloaded networks, or other issues.

• Broadcast television production, such as live sports or news broadcasts, where the story may change during broadcast and video transmission locations have to move without notice, or where the shoot might involve multiple, simultaneous areas of interest. Eliminating long, expensive cable runs is another major advantage for this market.

• Law enforcement or military users who need to operate their own separate communication networks on dedicated radio bands. This includes intra-team communication among small groups, as well as larger networks that include ground vehicles, UAV / UGV systems, and more

.

Figure 1.12 : Example of a Silvus MIMO radio with two gooseneck antennas being used to transmit HD video at the Indianapolis 500.

Standard MIMO Configurations MIMO radio systems utilize multiple antennas in order to send and receive multiple data streams at once. The number of antennas needed is defined by the radio manufacturer based on what they determine will work for optimal transmission and reception with their particular hardware and software. Typical configurations are:

• 2X2 MIMO (two transmit antennas, two receive antennas)

• 3X3 MIMO (three transmit antennas, three receive antennas)

•4X4 MIMO (four transmit antennas, four receive antennas)

• 8X8 MIMO (eight transmit antennas, eight receive antennas) Understanding the Basics of MIMO Communication Technology Generally speaking, the more antennas a system has the more simultaneous data streams can be transmitted at once, improving the radio link. However individual system setups, current physical and RF environmental conditions, and advances in radio technology means that more antennas doesn’t always equal better system performance.

Antenna Choices for MIMO Radios:

There are many antenna choices for MIMO radios, depending on how the user wishes to configure their radio system based on the unique needs of their application. Broadly speaking, antennas for MIMO use can be broken down the following categories:

1. **Traditional vertically polarized dipole antennas.** These are the same antennas used on SISO systems, the only difference being that the MIMO system will utilize two or more of the same antenna. In practice almost any omni directional antenna can be used as long as it meets the frequency band requirements, gain, RF power handling, and other parameters for the system being specified.

Figure 1.13 : Examples of two vertically polarized omni-directional antennas that can utilized in matched pairs on MIMO systems.

2. Multi-antenna products contained within a single radome. These antennas contain two or more RF connectors, which each connect to a different antenna within the radome. These are often designed with a slant left and slant right polarization, with each element offset 90 degrees (orthogonally) from the other, providing additional antenna polarization diversity for busy RF environments without increasing system installation complexity for the end user.

Each product features multiple RF connectors, each connected to a discrete antenna within the product’s radome. These are often cross-polarized for additional polarization and spatial diversity. Just as with SISO systems, MIMO systems can utilize omni-directional antennas or directional panels and sector antennas for different communication scenarios and coverage needs.

CHAPTER 2

CHANNEL MODEL

In order to accommodate the recent surge in mobile traffic, millimeter-wave frequencies above 6 GHz are being considered for the new mobile communication system . The millimeter-wave supports wide bandwidth, and the short wavelength of it enables the miniaturization of antennas. Therefore, millimeter-wave based mobile communication systems can be equipped with more antennas in the same space as long-term evolution (LTE) base stations. However, short wavelengths can cause high path loss and low signalto-noise radio (SNR).

3GPP TR 38.901, a millimeter-wave channel model of 3GPP technical report [10], is considered. This millimeter-wave channel model covers the frequency range from 0.5 GHz to 100 GHz. Thisfollows the frame work of WINNERII/WINNER+ and was modeled considering the radio propagation characteristics of the horizontal and vertical dimension. There are three scenarios, urban micro cell (UMi), urban macro cell (UMa), and indoor-office cell, in 3GPP TR 38.901, and this paper considers an UMi scenario. In UMi scenario, user equipment (UE) can be located randomly between 1.5 m and 22.5 m. The transmit antenna of the base station is located below the roof of the building where the UE can be located. The scenario has the environment with characteristics the line-ofsight (LOS) and the non-line-of-sight (NLOS) for outdoor and indoor areas between a base station (BS) and UEs. Detailedscenario parameters are described in Table 1.

TABLE I. MILLIMETER-WAVE CHANNEL MODEL: UMI SCENARIO

Parameters		Value
ISD		200m
BS antenna height		10m
UE location	Outdoor/Indoor	Outdoor and indoor
	LOS/NLOS	LOS and NLOS
UE height (h_{UE})	general equation	$h_{UE}=3(n_{fl}-1)+1.5$
	n_{fl} for outdoor UEs	1
	n_{fl} for indoor UEs	$n_{fl} \sim$ uniform$(1, N_{fl})$ where $N_{fl} \sim$ uniform$(4,8)$
Indoor UE ratio		80%
UE distribution (horizontal)		Uniform

CHAPTER 3

ORTHOGONAL FREQUENCY DIVISION MULTIPLEXING

Orthogonal frequency division multiplexing (OFDM) is a technique, method or scheme for digital multi-carrier modulation using many closely spaced subcarriers a previously modulated signal modulated into another signal of higher frequency and bandwidth. Each of these subcarriers contains numbers of parallel data streams or channels and is modulated conventionally at a low symbol rate; these are groups of bits of data related to (but not the same as) gross bitrate, which is expressed in bits/second.This term is also known as coded OFDM (COFDM) and discrete multi-tone modulation (DMT), used for both wireless and physical communication mediums.

The term "orthogonal” is actually an adjective describing two things acting independently or in an uncorrelated manner; in this case, any two signals of an OFDM-based product operating without dependence on, or interference with, one another.OFDM is used for wideband digital communication, which is commonly used for digital television and audio broadcasting (radio) as well as broadband Internet access and wireless networking. OFDM is very similar to FDM (frequency division multiplexing) but with technology purposely emphasizing the minimization of crosstalk or signal interference from other nearby signal carrying communication mediums. OFDM uses many narrow band signals as opposed to a signal modulated at a high symbol rate and a large bandwidth.

OFDM-based products include:

- Certain types of broadband access through POTS (plain old telephone service) copper wiring
- Power line communication (PLC)
- Multimedia over Coax Alliance (MoCA) home networking
- Some digital radio systems
- Some digital TV systems
- Some mobile TV systems

The idea of multi-carrier transmission has surfaced recently to be used forcombating the hostility of wireless channel and providing high data rate communications. OFDM is a special form of multi-carrier transmission where all the subcarriersare orthogonal to each other. OFDM promises a high user data rate transmissioncapability at a reasonable complexity and precision.

At high data rates, the channel distortion to the data is very significant, and it issomewhat impossible to recover the transmitted data with a simple receiver. A verycomplex receiver structure is needed which makes use of computationally expensiveequalization and channel estimation algorithms to correctly estimate the channel, sothat the estimations can be used with the received data to recover the originallytransmitted data. OFDM can drastically simplify the equalization problem by turningthe frequency-selective channel into a flat channel. A simple one-tap equalizeris needed to estimate the channel and recover the data. Future telecommunication systems must be spectrally efficient to support a numberof high data rate users. OFDM uses the available spectrum very efficiently whichis very useful for multimedia communications. For all of the above reasons, OFDM has already been accepted by many of the future generation systems

OFDM Overview:

- The Orthogonal Frequency Division Multiplexing (OFDM) transmission scheme is the optimum version of the multicarrier transmission scheme. In the past, as well as in thepresent, the OFDM is referred in the literature Multi-carrier, Multi-tone and FourierTransform.
- The concept of using parallel data transmission and frequency multiplexing was published in the mid 1960s. After more than thirty years of research and development,OFDM has been widely implemented in high speed digital communications. Due torecent advances of digital signal Processing (DSP) and Very Large Scale Integratedcircuit (VLSI) technologies, the initial obstacles of OFDM implementation such asmassive complex computation, and high speed memory do not exist anymore.
- The use of Fast Fourier Transform (FFT) algorithms eliminates arrays of sinusoidal generators and coherent demodulation required in parallel data systems and makes the implementation of the technology cost effective .
- The OFDM concept is based on spreading the data to be transmitted over a large number

of carriers, each being modulated at a low rate.

- In contrast to conventional Frequency Division Multiplexing, the spectral overlapping among sub-carriers are allowed in OFDM since orthogonality will ensure the subcarrierseparation at the receiver, providing better spectral efficiency and the use of steep band pass filter was eliminated.
- OFDM transmission system offers possibilities for alleviating many of the problems encountered with single carrier systems. It has the advantage of spreading out a frequencyselective fade over many symbols. This effectively randomizes burst errors caused byfading or impulse interference so that instead of several adjacent symbols beingcompletely destroyed, many symbols are only slightly distorted.
- This allows successful reconstruction of majority of them even without forward error correction. Because of dividing an entire signal bandwidth into many narrow sub bands, the frequency response over individual sub bands is relatively flat due to sub band are smaller than coherence bandwidth of the channel. Thus, equalization is potentiallysimpler than in a single carrier system and even equalization may be avoided altogether ifdifferential encoding is implemented.
- The orthoganality of sub channles in OFDM can be maintained and individual sub channels can be completely separated by the FFT at the receiver when there are no inter symbol interference (ISI) and intercarrier interference (ICI) introduced by the transmission channel distortion.
- Since the spectra of an OFDM signal is not strictly band limited, linear distortions such asmultipath propagation causes each subchannel to spread energy into the adjacentchannels and consequently cause ISI.
- One way to prevent ISI is to create a cyclically extended guard interval, where eachOFDM symbol is preceded by a periodic extension of the signal itself. When the guardinterval is longer than the channel impulse response or multipath delay, the ISI can be eliminated.
- By using time and frequency diversity, OFDM provides a means to transmit data in a frequency selective channel. However, it does not suppress fading itself. Depending on their position in the frequency domain, individual subchannels could be affected by fading.

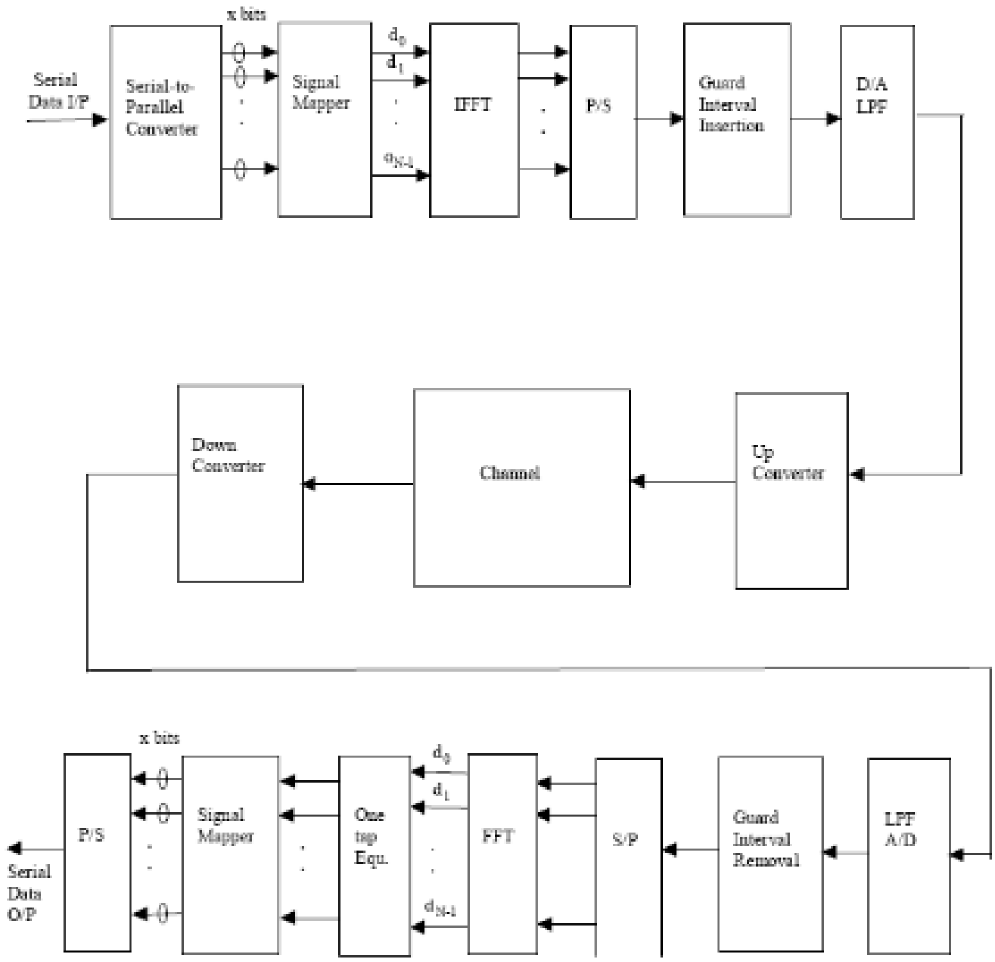

Figure 3.1: General OFDM System

OFDM Transceiver Systems:

A complete OFDM transceiver system is described in Fig. 2 In this model, forwarderror control/correction(FEC) coding and interleaving are added in the systemto obtain the robustness needed to protect against burst errors. An OFDM systemwith addition of channel coding and interleaving is referred to as coded OFDM(COFDM).

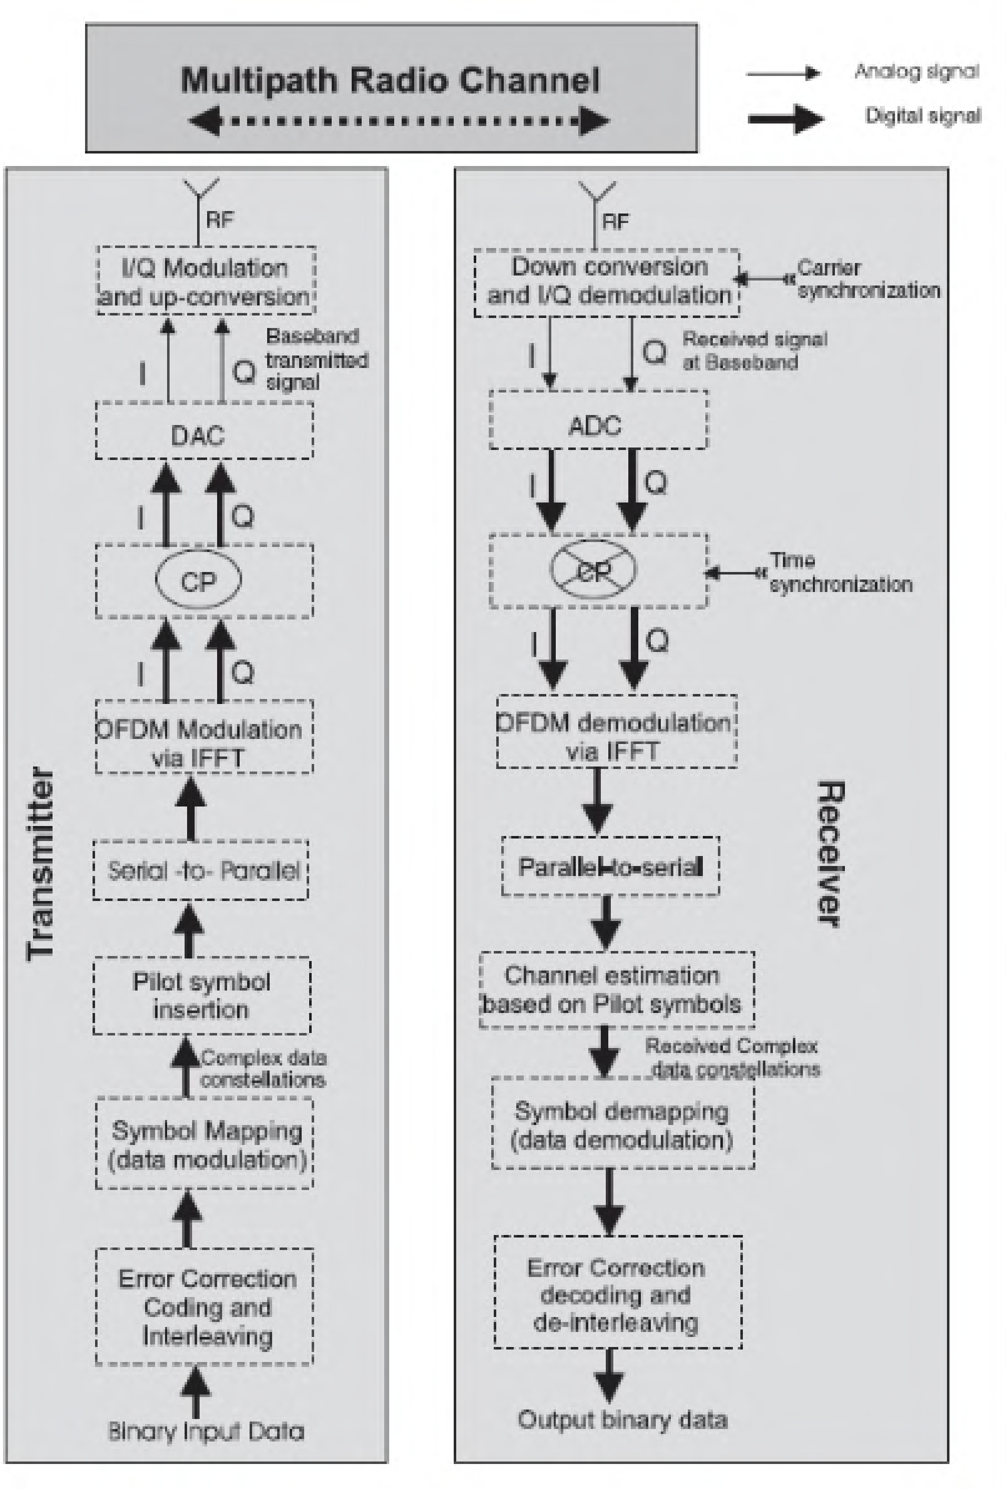

Figure 3.2: OFDM transceiver model

OFDM in Cellular Mobile System:

Severe multipath propagation, arising from multiple scattering by buildings and otherstructures in the vicinity of a mobile unit, makes the design of a mobile communicationchannel very challenging.· The scattering produces rapid random amplitude and phase variations in the receivedsignal as the vehicle moves in the multipath field. In addition, the whole motionintroduces a Doppler shift, which causes a broadening of the signal spectrum.· Since OFDM has the property of robustness to multipath propagation and other favorableproperties, it is likely to be considered for mobile communication systems. Cimini(1985) proposed a cellular mobile radio system based on OFDM.

OFDM combined with CDMA and TDMA is being investigated by many researchers. Various Multicarrier (MC) transmission schemes have been recently introduced intoDirect Sequence- Code Division Multiple Access(DS-CDMA) systems to acquirebenefits such as higher rate data transmission, bandwidth efficiency, frequency diversityand interference reduction.

Synchronization:

Synchronization is a big hurdle in OFDM. Synchronization usually consists of three parts:

1. Frame detection
2. Carrier frequency offset estimation and correction
3. Sampling error correction.

Frame detection is used to determine the symbol boundary so that correct samples for a symbol frame can be taken. Due to the carrier frequency difference of the transmitter and receiver, each signal sample at time t contains an unknown phase factor

e j2pDf ct

where c Df is the unknown carrier frequency offset. This unknown phase factor must be estimated and compensated for each sample before FFT at the receiver since otherwise the orthogonality between subcarriers are lost. For example, when the carrier is at 5GHz, an 100ppm crystal offset corresponding to a frequency offset of 50kHz. For a symbol period of T = 3.2 ms, DfcT = 1.6 . Because the sampling clock difference between the transmitter and receiver, each signal sample is off from its correct sampling time by a small amount which is linearly increasing with the index of the sample. For example, for 100ppm crystal offset, it will be off by 1 sample after 10000 samples. If a symbol contains 100 samples, then within each symbol the maximum offset will be 1% of a sample. Although this may cause the orthogonality degration between the sub-carriers, it can usually be ignored. If sampling error must be corrected, then interpolation filter must be used to construct the signal at correct sampling time

Channel estimation:

For burst communication system, training symbols are used at the beginning of each burst. Since theburst is short, the channel is assumed static over a whole burst so that once the channel is estimated, theinverse of the estimated channel response will be used to compensate the signal for the whole burst.Assuming the received signal after FFT isY(k) = C(k)X (k) + Z(k)where k is sub-carrier index, C is the channel, X is the pilot data, and Z is the noise. The simplest way toestimate the channel is then by

$$\hat{C}(k) = \frac{Y(k)}{X(k)}$$

i.e. dividing the received signal by the known pilot. Without noise, this gives the correct estimation. Whennoise is present, there could be error.

Analytical Model of OFDM System:

In this section, an analytical time-domain model of an OFDM transmitter andreceiver, as well as a channel model, is derived.

Transmitter:

The sth OFDM symbol is found using the sth subcarrier block, Xs[k]. In practice,the OFDM signal is generated using an inverse DFT. In the following model, thetransmitter is assumed to be ideal, i.e., sampling or filtering do not affect the signalat the transmitter side. Therefore, a continuous transmitter output signal may beconstructed directly using a Fourier series representation within each OFDM symbolinterval.

Receiver:

The signal at the receiver side consists of multiple echoes of the transmitted signal,as well as thermal (white gaussian) noise and interference. The RF signal received by the uth user is written as

$$r(t) = \Re e\left\{(\tilde{s}(t) * \tilde{h}_{u,s}(t))e^{j2\pi f_c[s]t}\right\} + \nu(t), \qquad sT_s \le t < (s+1)T_s,$$

where ν(t) is a real-valued, passband signal combining additive noise and interference.The receiver now has to recreate the transmitted signal. Aside from noise andmultipath effects, other imperfections in the receiver may also affect this process:

Timing error:

In order to demodulate the signal, the receiver must establish thecorrect timing. This means that the receiver must estimate which time instantcorresponds to t = 0 in the received signal (as seen from the transmitted signal point of view). As there are different uncertainties involved, a timing error of δtis assumed.

• Frequency error:

Similarly, the local oscillator of the receiver may oscillate atan angular frequency that is different from the angular frequency of the incoming signal. This difference is denoted as δω= 2πδf.The shifted timescale in the receiver is denoted as t_ = t − δt. Furthermore, dueto the angular frequency error δω, the down-converted signal spectrum is shifted infrequency. The down-converted signal is therefore written as

$$\tilde{r}(t) = (\tilde{s}(t') * \tilde{h}_{u,s}(t))e^{j\delta\omega t} + \tilde{\nu}(t'), \qquad sT_s \le t < (s+1)T_s,$$

Sampling:

Although the receiver may be modeled in the continuous time domain, an OFDMreceiver uses discrete signal processing to obtain the estimate of the transmittedsubcarriers.When the received signal is modeled as a Dirac impulse train, i.e., an ideallysampled signal, (2.17) is instead written as

$$\tilde{y}_{s,d}(t) = \sum_{n=0}^{N-1} \tilde{y}_s[n]\delta_c(t - nT),$$

ADVANTAGES OF OFDM:

1. The beauty of OFDM lies in its simplicity. One trick of the trade that makesOFDM transmitters low cost is the ability to implement the mapping of bits tounique carriers via the use of IFFT.
2. Unlike CDMA, OFDM receiver collects signal energy in frequency domain,thus it is able to protect energy loss at frequency domain.
3. In a relatively slow time-varying channel, it is possible to significantly enhancethe capacity by adapting the data rate per subcarrier according to SNR of thatparticular subcarrier.
4. OFDM is more resistant to frequency-selective fading than single-carrier systems.
5. The OFDM transmitter simplifies the channel effect, thus a simpler receiverstructure is enough for recovering transmitted data. If we use coherent modulationschemes, then very simple channel estimation (and/or equalization) isneeded, on the other hand, we need no channel estimator if differential modulationschemes are used.

6. The orthogonality preservation procedures in OFDM are much simpler comparedto CDMA or TDMA techniques even in very severe multipath conditions.
7. It is possible to use maximum likelihood detection with reasonable complexity.
8. OFDM can be used for high-speed multimedia applications with low servicecost.
9. OFDM can support dynamic packet access.
10. Single-frequency networks are possible in OFDM, which is especially attractivefor broadcast applications.
11. Smart antennas can be integrated with OFDM. MIMO systems and space–timecoding can be realized on OFDM and all the benefits of MIMO systems can beobtained easily. Adaptive modulation and tone/power allocation are also realizableon OFDM.

Disadvantages of OFDM System:

a) **Strict synchronization requirement:**

OFDM is highly sensitive to time and frequency synchronization errors, and especiallyat frequency synchronization errors, everything can go wrong . Indeed,demodulation of an OFDM signal with an offset in the frequency can lead to a highbit error rate.The source of frequency synchronization errors is two: first one being the differencebetween local oscillator frequencies in transmitter and receiver, second beingrelative motion between the transmitter and receiver that gives Doppler spread. Localoscillator frequencies at both transmitter and receiver must match as closelyas they can. For higher number of subchannels, the matching should be even better.Motion of transmitter and receiver causes the other frequency error. So, OFDM mayshow significant performance degradation at high-speed moving vehicles.To optimize the performance of an OFDM link, accurate synchronization is ofprime importance. Synchronization needs to be done in three factors: symbol, carrierfrequency, and sampling frequency synchronization. A good description of synchronizationprocedures is given.

b) Peak-to-Average Power Ratio (PAPR):

Peak-to-average power ratio (PAPR) is proportional to the number of subcarriersused for OFDM systems. An OFDM system with large number of subcarriers willthus have a very large PAPR when the subcarriers add up coherently. Large PAPRof a system makes the implementation of digital-to-analog converter (DAC) andanalog-to-digital converter (ADC) extremely difficult. The design of RF amplifieralso becomes increasingly difficult as the PAPR increases.

The clipping and windowingtechnique reduces PAPR by non-linear distortionof the OFDM signal. It thus introduces self-interference as the maximum amplitudelevel is limited to a fixed level. It also increases the out-of-band radiation, but this isthe simplest method to reduce the PAPR. To reduce the error rate, additional forwarderror correcting codes can be used in conjunction with the clipping and windowingmethod.Another technique called linear peak cancelationcan also be used to reduce thePAPR. In this method, time-shifted and time-scaled reference function is subtractedfrom the signal, such that each subtracted reference function reduces the peak powerof at least one signal sample. By selecting an appropriate reference function withapproximately the same bandwidth as the transmitted function, it can be assured thatthe peak power reduction does not cause out-of-band interference. One example of
a suitable reference function is a raised cosine window. Detailed discussion aboutcoding methods to reduce PAPR can be found.

C) Co-channel Interference in Cellular OFDM:

In cellular communication systems, CCI is combated by combining adaptive antennatechniques, such as sectorization, directive antenna, antenna arrays. UsingOFDM in cellular systems will give rise to CCI. Similarly with the traditional techniques,with the aid of beam steering, it is possible to focus the base station's antennabeam on the served user, while attenuating the co-channel interferers.

- **OFDM System Design Issues:**

System design always needs a complete and comprehensive understanding and considerationof critical parameters. OFDM system design is of no exception, as it dealswith some critical, and often conflicting parameters. Basic OFDM philosophy is todecrease data rate at the subcarriers, so that the symbol duration increases, thus themultipaths are effectively removed. This poses a challenging problem, as highervalue for CP interval will give better result, but it will increase the loss of energydue to insertion of CP. Thus, a trade-off must be obtained for a reasonable design.

- **OFDM System Design Requirements**

• **Available bandwidth**: Bandwidth is always the scarce resource, so the mother of the system design should be the available bandwidth for operation. The amount of bandwidth will play a significant role in determining number of subcarriers, because with a large bandwidth, we can easily fit in a large number of subcarriers with reasonable guard space.

• **Required bit rate**: The overall system should be able to support the data rate required by the users. For example, to support broadband wireless multimedia communication, the system should operate at more than 10 Mbps at least.

• Tolerable delay spread: Tolerable delay spread will depend on the user environment. Measurements show that indoor environment experiences maximum delayspread of few hundreds of ns at most, whereas outdoor environment can experienceup to 10 µs. So the length of CP should be determined according to thetolerable delay spread.

• **Doppler values**: Users on a high-speed vehicle will experience higher Dopplershift, whereas pedestrians will experience smaller Doppler shift. These considerationsmust be taken into account.

OFDM System Design Parameters:

The design parameters are derived according to the system requirements. Followingare the design parameters for an OFDM system:

• Number of subcarriers: Increasing number of subcarriers will reduce the data rate via each subcarrier, which will make sure that the relative amount of dispersion in time caused by multipath delay will be decreased . But when there are large numbers of subcarriers, the synchronization at the receiver side will be extremely difficult.

• Guard time (CP interval) and symbol duration: A good ratio between the CPinterval and symbol duration should be found, so that all multipaths are resolvedand not significant amount of energy is lost due to CP. As a thumbrule, the CP interval must be two to four times larger than the root mean square (RMS) delay spread. Symbol duration should be much larger than the guard timeto minimize the loss of SNR, but within reasonable amount. It cannot be arbitrarilylarge, because larger symbol time means that more subcarriers can fit withinthe symbol time. More subcarriers increase the signal processing load at boththe transmitter and receiver, increasing the cost and complexity of the resultingdevice.

• Subcarrier spacing: Subcarrier spacing must be kept at a level so that synchronization is achievable. This parameter will largely depend on available bandwidth and the required number of subchannels.

• Modulation type per subcarrier: This is trivial, because different modulation schemes will give different performances. Adaptive modulation and bit loading may be needed depending on the performance requirement. It is interesting to note that the performance of OFDM systems with differential modulation compares quite well with systems using non-differential and coherent demodulation. Furthermore, the computation complexity in the demodulation process is quite low for differential modulations.

OFDM has several significant benefits over single carrier QAM modulation which has lead to its adoption in many of the modern wireless standards, including ADSL, European Digital Video Broadcast, IEEE 802.11a/g/n (WiFi), WiMax, and 3GPP Long Term Evolution (LTE). First of all, OFDM enables easy equalization, solving many of the equalization complexity issues we encountered for single carrier QAM by working instead in the frequency domain. Second of all, the ability to control the size of the constellation on each subcarrier in OFDM also allows it to mimic the "waterfilling" construction which maximizes the amount of information which can be reliably transmitted over the channel: subcarriers (frequencies) with better channel gains can utilize higher order modulations and coding rates. A final significant benefit that we will encounter later in the course is that OFDM allows for an especially easy to implement and understand multiple access strategy OFDMA, in which different subcarriers (frequencies) are allocated to different users at different times. To understand how OFDM modems work, we must first revisit several properties of the discrete Fourier Transform, and its efficient implementation the Fast Fourier Transform.

Orthogonal Frequency Division Multiplexing (OFDM) is special form of multi-carrier modulation, patented in 1970. It is particularly suited for transmission over a dispersive channel. (See further discussion of MCM over wireless channel.)

In a multipath channel, most conventional modulation techniques are sensitive to intersymbol interference unless the channel symbol rate is small compared to the delay spread of the channel. OFDM is significantly less sensitive to intersymbol interference, because a special set of signals is used to build the composite transmitted signal. The basic idea is that each bit occupies a frequency-time window which ensures little or no distortion of the waveform. In practice, it means that bits are transmitted in parallel over a number of frequency-nonselective channels. Applications of OFDM are found in

- Digital Audio Broadcasting (DAB) and
- Digital Video Broadcasting over the terrestrial network: Digital Terrestrial Television Broadcasting (DTTB). In the DTTB OFDM transmission standard, about 2,000 to 8,000 subcarriers are used.
- UMTS. The UMTS Forum is selecting an appropriate radio solution for the third generation mobile standard, as a successor to GSM. OFDM is one of the five competing proposals.

- Wireless LANs. OFDM is used in HIPERLAN Phase II, which supports 20 Mbit/s in propagation environments with delay spreads up to 1 msecond.

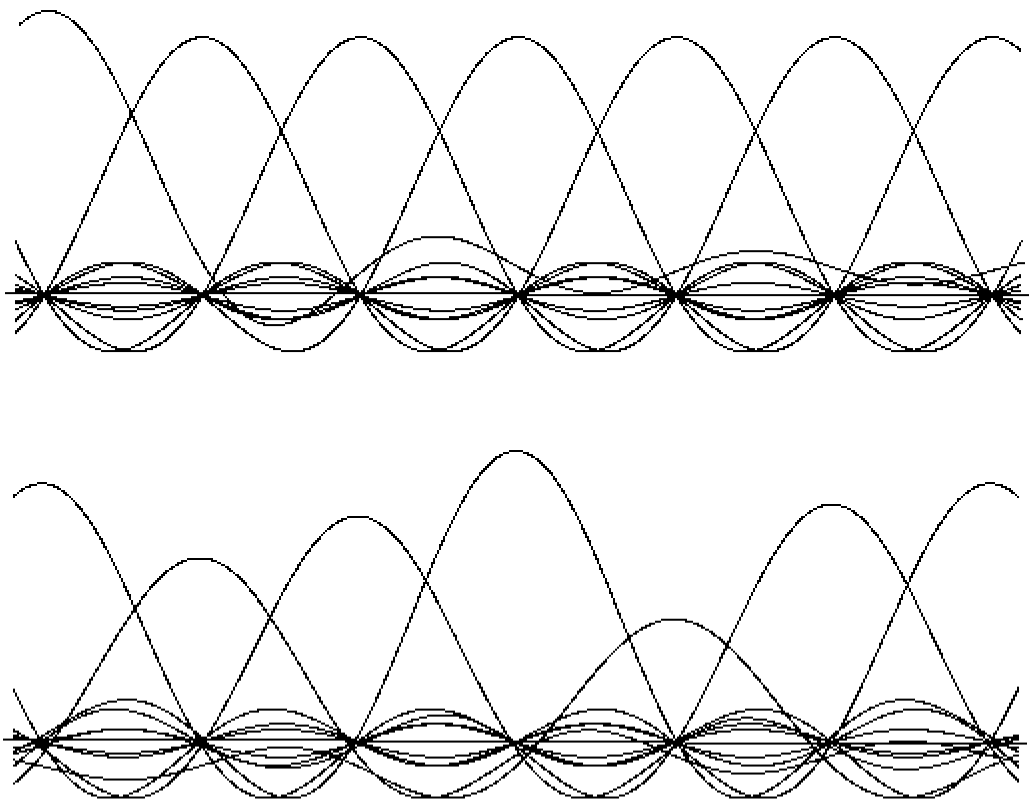

Figure 3.3: Signal spectrum of an OFDM signal.

The effect of multipath scattering on OFDM differs from what happens to other forms of modulation. A qualitative description and mathematical description of OFDM is presented by Dusan Matic. Jean-Paul Linnartz reviews the effects of a Doppler spread and the associated rapid channel variations. Dusan Matic also studied the system design aspects of OFDM at mm-wavelengths.

Coded OFDM

Multi-Carrier Modulation on its own is not the solution to the problems of communication over unreliable multipath channels. The channel time dispersion will excessively attenuate some subcarriers such that the throughput on these sub-channels would be unacceptable small. Only if the joint signal of many subcarriers is processed appropriately, the diversity advantages of MCM can be exploited. The need for coding across subcarriers was addressed by Sari et al. warning against overly enthusiastic pursuit of MCM. The advantages of frequency-domain implementations of equalizers (using an FFT) should not be mistaken for an "inherent" diversity gain of OFDM, which may not exist.

In an OFDM transmitter, blocks of k incoming bits are encoded into n channel bits. Before transmission, an n-point Inverse-FFT operation is performed. When the signals at the I-FFT output are transmitted sequentially, each of the n channel bits appears at a different (subcarrier) frequency. Such coding across subcarriers is necessary. If one subcarrier experiences deep fading, this leads to erasure of the bit on this subcarrier.

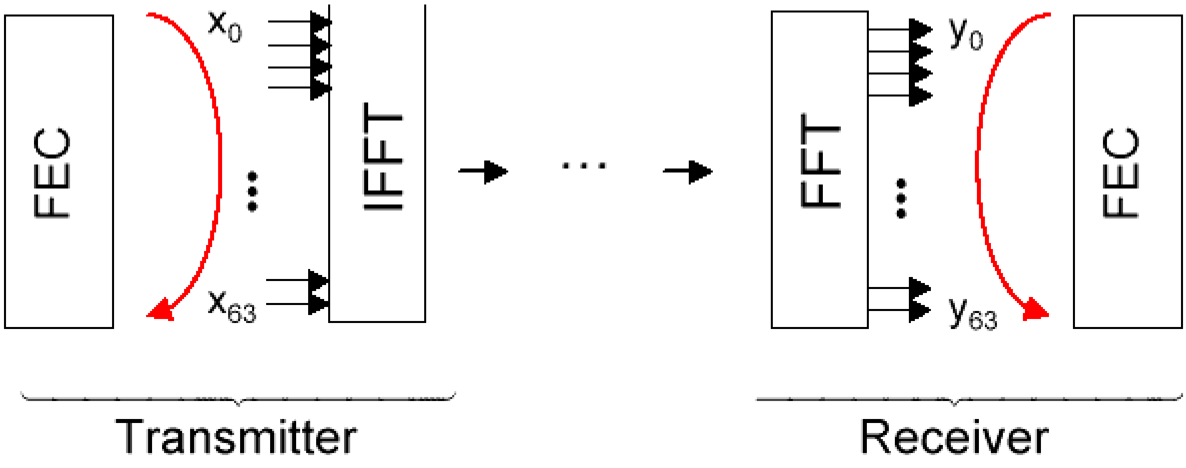

Figure 3.4: Transmitter and Receiver

But of course coding across subcarriers is not the only mechanism that can be invoked to combat dispersion or to exploit diversity. Other possibilities are

- Interleaving in frequency or time domain with coding in the other domain,
- The use of different signal constellations at different frequencies, i.e., adapting the subcarrier bit rate to the channel state,
- Signal spreading over various subcarriers, e.g., according to a linear matrix operation, as is proposed in Orthogonal Multi-Carrier Code Division Multiplexing.

If in a point-to-point MCM link, the receiver and the transmitter can cooperate by adaptively distributing of their power budget over the individual subcarriers. For instance, the signal-to-noise ratios selected according to Gallager's water-pouring theorem can (under certain conditions) be proved to be optimum. Efficient loading of the various subcarriers can for instance significantly enhance the performance of MCM over twisted pair telephone subscriber loops with crosstalk from other nearby copper pairs.

Implementational Aspects:

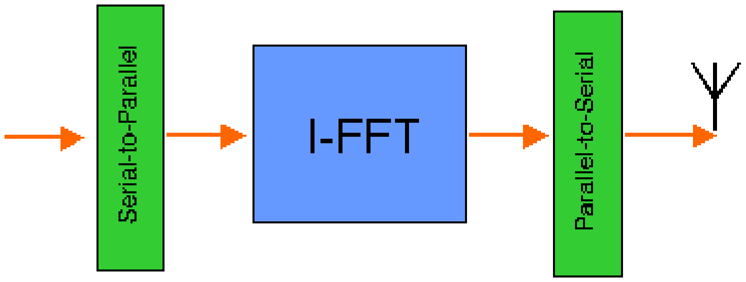

Figure 3.5: OFDM transmitter using an (inverse) Fast Fourier Transform (FFT).

- OFDM is not a constant-envelope modulation method. Therefore transmit power amplifiers must be highly linear.
- OFDM receiver performance is very sensitive to phase noise.
- Synchronization to an OFDM signal also requires frame synchronization, to support an FFT operation at the receiver.

What is OFDM?

OFDM is a form of multicarrier modulation. An OFDM signal consists of a number of closely spaced modulated carriers. When modulation of any form - voice, data, etc. is applied to a carrier, then sidebands spread out either side. It is necessary for a receiver to be able to receive the whole signal to be able to successfully demodulate the data. As a result when signals are transmitted close to one another they must be spaced so that the receiver can separate them using a filter and there must be a guard band between them. This is not the case with OFDM. Although the sidebands from each carrier overlap, they can still be received without the interference that might be expected because they are orthogonal to each another. This is achieved by having the carrier spacing equal to the reciprocal of the symbol period.

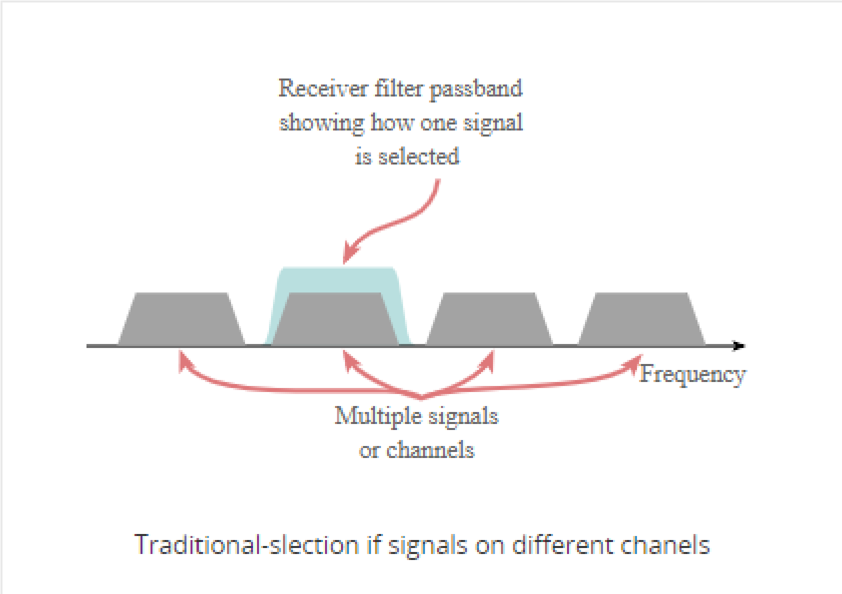

Figure 3.6: Signal at the Receiver End.

To see how OFDM works, it is necessary to look at the receiver. This acts as a bank of demodulators, translating each carrier down to DC. The resulting signal is integrated over the symbol period to regenerate the data from that carrier. The same demodulator also demodulates the other carriers. As the carrier spacing equal to the reciprocal of the symbol period means that they will have a whole number of cycles in the symbol period and their contribution will sum to zero - in other words there is no interference contribution.

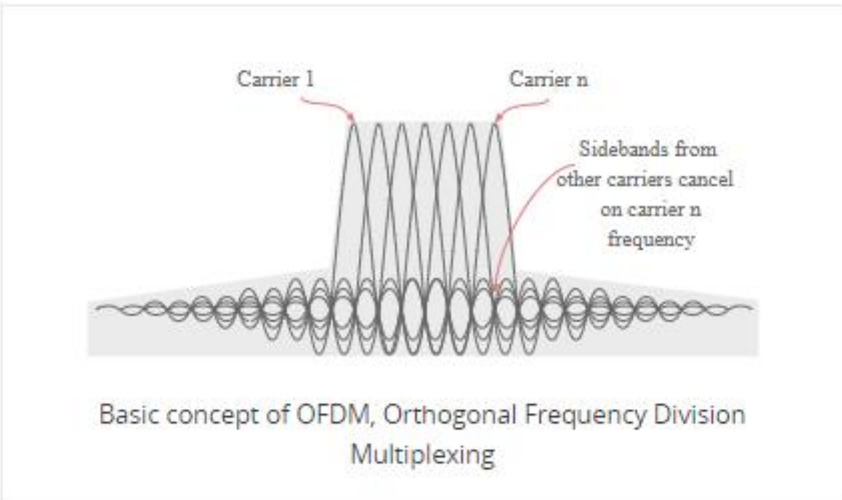

Figure 3.7: Basic concept of OFDM.

One requirement of the OFDM transmitting and receiving systems is that they must be linear. Any non-linearity will cause interference between the carriers as a result of inter-modulation distortion. This will introduce unwanted signals that would cause interference and impair the orthogonality of the transmission.

In terms of the equipment to be used the high peak to average ratio of multi-carrier systems such as OFDM requires the RF final amplifier on the output of the transmitter to be able to handle the peaks whilst the average power is much lower and this leads to inefficiency. In some systems the peaks are limited. Although this introduces distortion that results in a higher level of data errors, the system can rely on the error correction to remove them.

Data on OFDM:

The data to be transmitted on an OFDM signal is spread across the carriers of the signal, each carrier taking part of the payload. This reduces the data rate taken by each carrier. The lower data rate has the advantage that interference from reflections is much less critical. This is achieved by adding a guard band time or guard interval into the system. This ensures that the data is only sampled when the signal is stable and no new delayed signals arrive that would alter the timing and phase of the signal.

Guard interval on OFDM signals:

The distribution of the data across a large number of carriers in the OFDM signal has some further advantages. Nulls caused by multi-path effects or interference on a given frequency only affect a small number of the carriers, the remaining ones being received correctly. By using error-coding techniques, which does mean adding further data to the transmitted signal, it enables many or all of the corrupted data to be reconstructed within the receiver. This can be done because the error correction code is transmitted in a different part of the signal.

Key features of OFDM

The OFDM scheme differs from traditional FDM in the following interrelated ways:

- Multiple carriers (called subcarriers) carry the information stream
- The subcarriers are orthogonal to each other.

- A guard interval is added to each symbol to minimize the channel delay spread and intersymbol interference.

Frequency offset OFDM synchronization:

- It is particularly important that the demodulator in an OFDM receiver is able to synchronize accurately with the carriers within the OFDM signal. Offsets may arise for a number of reasons including any frequency errors between the transmitter and the receiver and also as a result of Doppler shifts if there is movement between the transmitter and receiver.
- If the frequency synchronisation is impaired, then the orthogonality of the carriers is reduced within the demodulation process and error rates increase. Accordingly it is essential to maintain orthogonality to reduce errors and maintain the performance of the link.
- First look at the way that sampling should occur. With the demodulator in synchronisation, all the contributions from the other carriers sum to zero as shown. On this way all the carriers are orthogonal and the error rate is at its minimum.
- OFDM demodulation showing how the interference from other carriers is minimised at the centre of the carrier frequency
- If a situation is encountered where the OFDM synchronisation for the frequency aspects are poor, then the demodulator will centre its samples away from the peak of the signal, and also at a point where the contributions from the other signals do not sum to zero. This will lead to a degradation of the signal which could in turn lead to an increase in the number of bit errors.
- OFDM demodulation where interference is high due to poor frequency synchronisation
- Clock offset OFDM synchronization
- It is also necessary to maintain OFDM synchronization in terms of the clock. Gain if the clock synchronisation is not accurate, sampling will be offset and again orthogonality will be reduced, and data errors will increase.

- When looking at OFDM synchronization with regard to the clock offset, the carrier spacing used within the receiver for sampling the received signal will be based upon the internal clock rate. If this differs from that used within the transmitter, it will be found that even if the first carrier within the multiplex is correct, then there will be a growing discrepancy with each carrier away from the first one. Even small levels of discrepancy will cause the error rate to increase.
- OFDM demodulation with clock synchronization misalignment : When using OFDM it is necessary to ensure that the synchronisation for both timing and frequency is accurate. By ensuring accurate synchronisation, it is possible to perform the optimum demodulation of the signal. Any misalignment causes the receiver to start to pick up the unwanted interference signals. Fortunately it is relatively easy to obtain accurate synchronisation signals as these are available from the network, and short term synchronisation can be generated internally.
- In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a method of encoding digital data on multiple carrierfrequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G mobile communications.
- In coded orthogonal frequency-division multiplexing (COFDM), forward error correction (convolutional coding) and time/frequency interleaving are applied to the signal being transmitted. This is done to overcome errors in mobile communication channels affected by multipath propagation and Doppler effects. COFDM was introduced by Alard in 1986 [1] [2][3] for Digital Audio Broadcasting for Eureka Project 147. In practice, OFDM has become used in combination with such coding and interleaving, so that the terms COFDM and OFDM co-apply to common applications.[4]
- OFDM is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. OFDM was introduced by Chang of Bell Labs in 1966.[5][6][7] Numerous closely spaced orthogonal sub-carrier signals with overlapping spectra are emitted to carry data.[8] Demodulation is based on Fast Fourier Transform algorithms. OFDM was improved by Weinstein and

Ebert in 1971 with the introduction of a guard interval, providing better orthogonality in transmission channels affected by multipath propagation.[9] Each sub-carrier (signal) is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate. This maintains total data rates similar to conventional single-carrier modulation schemes in the same bandwidth.

- The main advantage of OFDM over single-carrier schemes is its ability to cope with severe channel conditions (for example, attenuation of high frequencies in a long copper wire, narrowband interference and frequency-selective fading due to multipath) without complex equalization filters. Channel equalization is simplified because OFDM may be viewed as using many slowly modulated narrowband signals rather than one rapidly modulated wideband signal. The low symbol rate makes the use of a guard interval between symbols affordable, making it possible to eliminate intersymbol interference (ISI) and use echoes and time-spreading (in analog television visible as ghosting and blurring, respectively) to achieve a diversity gain, i.e. a signal-to-noise ratio improvement. This mechanism also facilitates the design of single frequency networks (SFNs) where several adjacent transmitters send the same signal simultaneously at the same frequency, as the signals from multiple distant transmitters may be re-combined constructively, sparing interference of a traditional single-carrier system.

Orthogonality:

- Conceptually, OFDM is a specialized frequency-division multiplexing (FDM) method, with the additional constraint that all subcarrier signals within a communication channel are orthogonal to one another.
- In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that cross-talk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

- The orthogonality requires that the sub-carrier spacing is Hertz, where T_U seconds is the useful symbol duration (the receiver-side window size), and k is a positive integer, typically equal to 1. This stipulates that each carrier frequency undergoes k more complete cycles per symbol period than the previous carrier. Therefore, with N sub-carriers, the total passband bandwidth will be B = N*Δf (Hz).
- The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e. near half the Nyquist rate for the double-side band physical passband signal). Almost the whole available frequency band can be used. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users.
- A simple example: A useful symbol duration T_U = 1 ms would require a sub-carrier spacing of (or an integer multiple of that) for orthogonality. N = 1,000 sub-carriers would result in a total passband bandwidth of NΔf = 1 MHz. For this symbol time, the required bandwidth in theory according to Nyquist is (half of the achieved bandwidth required by our scheme), where R is the bit rate and where N = 1,000 samples per symbol by FFT. If a guard interval is applied (see below), Nyquist bandwidth requirement would be even lower. The FFT would result in N = 1,000 samples per symbol. If no guard interval was applied, this would result in a base band complex valued signal with a sample rate of 1 MHz, which would require a baseband bandwidth of 0.5 MHz according to Nyquist. However, the passband RF signal is produced by multiplying the baseband signal with a carrier waveform (i.e., double-sideband quadrature amplitude-modulation) resulting in a passband bandwidth of 1 MHz. A single-side band (SSB) or vestigial sideband (VSB) modulation scheme would achieve almost half that bandwidth for the same symbol rate (i.e., twice as high spectral efficiency for the same symbol alphabet length). It is however more sensitive to multipath interference.
- OFDM requires very accurate frequency synchronization between the receiver and the transmitter; with frequency deviation the sub-carriers will no longer be orthogonal, causing inter-carrier interference (ICI) (i.e., cross-talk between the sub-carriers). Frequency offsets are typically caused by mismatched transmitter

and receiver oscillators, or by Doppler shift due to movement. While Doppler shift alone may be compensated for by the receiver, the situation is worsened when combined with multipath, as reflections will appear at various frequency offsets, which is much harder to correct. This effect typically worsens as speed increases, and is an important factor limiting the use of OFDM in high-speed vehicles. In order to mitigate ICI in such scenarios, one can shape each sub-carrier in order to minimize the interference resulting in a non-orthogonal subcarriers overlapping. For example, a low-complexity scheme referred to as WCP-OFDM (Weighted Cyclic Prefix Orthogonal Frequency-Division Multiplexing) consists of using short filters at the transmitter output in order to perform a potentially non-rectangular pulse shaping and a near perfect reconstruction using a single-tap per subcarrier equalization. Other ICI suppression techniques usually increase drastically the receiver complexity.

CHAPTER 4

5G NR BASED SYSTEM MODEL

5G NR Transmission Frame:

When comparing 4G LTE with 5G NR, the most significant change is in frequency domain. NR supports frequencies above 6 GHz as well as frequencies below 6 GHz, and supports various subcarrier spacing (SCS) according to OFDM Numerology. OFDM Numerology is a newly designed concept to utilize the wide bandwidth of the millimeter-wave, and SCS of 30 kHz, 60 kHz, 120 kHz, and 240 kHz, including the existing 15 kHz are supported according to that. For each SCS, the number of slots and the number of OFDM symbols is determined in a frame. This paper considers SCS of 60 kHz for millimeter-wave MIMO systems. A subframe consists of four slots, each consisting of 14 OFDM symbols. When the system bandwidth is 100 MHz, the number of resource blocks (RBs) is 125 and the number of resource elements (REs) is 84000 in a subframe. Table 2 shows the NR transmission frame configuration. The Fig. 1 shows the RBs assigned to 10 UEs by proportional fair (PF) scheduling. Wireless mobile communication channels with wide bandwidth have frequency selective fading characteristics, so each UE is allocated suitable sections among 100 MHz

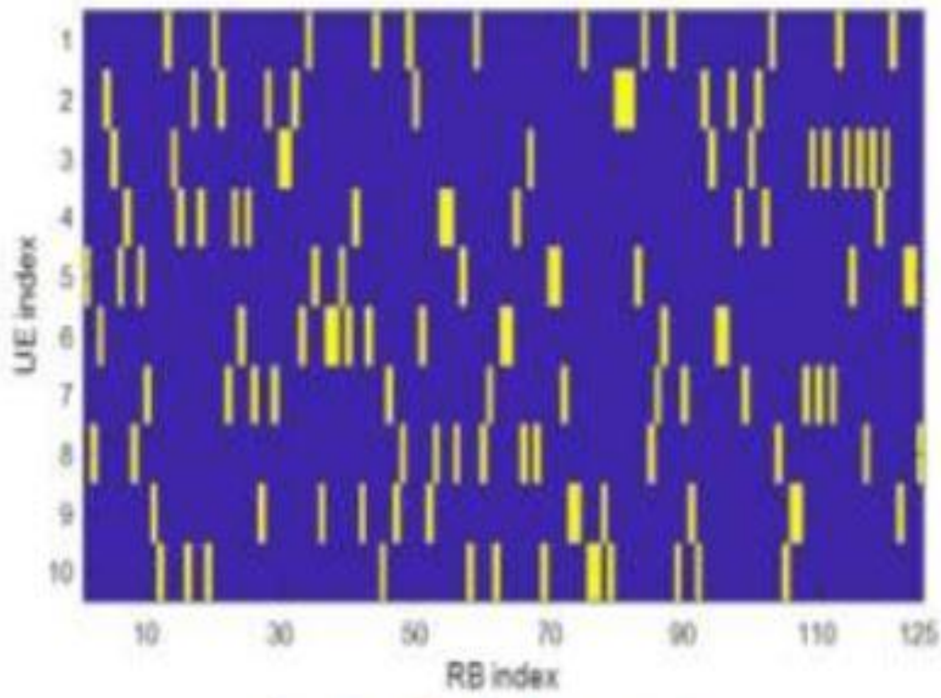

Figure 1. Scheduled RBs per UE

Figure 4.1: Scheduled RBs per UE

TABLE II. NR FRAME CONFIGURATION

Parameter	Value
SCS [kHz]	60
The number of SCs per RB	12
RB bandwidth [kHz]	720
System bandwidth [MHz]	100
The total number of SCs	1500
The total number of RBs	125
The number of slots	4
The number of symbols per slot	14

Spatial Multiplexing MIMO System Model This paper considers an uplink massive MIMO system based on 3GPP NR in the millimeter-wave channel. One BS equipped with uniform rectangular array (URA) having r v h N N N = · antennas and K UEs equipped with uniform linear array (ULA), N 1 t · , are considered, as shown in Fig. 2. This paper assumes that the number of antennas in base stations is greater than that of UE. Each UE can transmit L data streams to the base station at the same time. L is the number of data streams, and this paper considers L Nδ t . That is, the total number of data streams N s is K L· . The transmit signal k x by k-th UE can be expressed as follows:

$$x_k = \sqrt{p} H_k S_k + N_k \qquad (1)$$

Where p is the average transmit power. Nk is denotes Gaussian noise. N N t H C k · □ is the channel matrix from k-th UE to BS. It is expressed as follows:

$$H_k = \begin{bmatrix} h_{1,1}^k & h_{1,2}^k & \cdots & h_{1,N_r}^k \\ h_{2,1}^k & h_{2,2}^k & \cdots & h_{2,N_r}^k \\ \vdots & \vdots & \vdots & \vdots \\ h_{N_t,1}^k & h_{N_t,2}^k & \cdots & h_{N_t,N_r}^k \end{bmatrix} \qquad (2)$$

h is the channel impulse response (CIR) for a NLOS case or a LOS case. NLOS CIR and LOS CIR are given by:

$$h_{u,s}^{NLOS}(\tau,t) = \sum_{n=1}^{2}\sum_{i=1}^{3}\sum_{m\in R_i} h_{u,s}^{NLOS}(t)\delta(\Delta\tau) + \sum_{n=3}^{N} h_{u,s,n}^{NLOS}(t)\delta(\Delta\tau) \qquad (3)$$

$$h_{u,s}^{LOS}(\tau,t) = \sqrt{\frac{1}{K_R+1}} h_{u,s}^{NLOS}(\tau,t) + \sqrt{\frac{K_R}{K_R+1}} h_{u,s,l}^{LOS}(t)\delta(\Delta\tau) \qquad (4)$$

h and , ,LOS are the channel coefficients obtained by 12 step procedure. The field patterns of receive antenna element u and the field patterns of transmit antenna element s are considered. For the vertical and horizontal dimensions, azimuth angle of arrival, zenith angle of arrival, azimuth angle of departure, and zenith angle of departure are considered. The detailed step can be found in [10]. k S is data streams, 1 2 [, ,..., ,]T k L S s s s = , and l s is the transmit symbol. L is determined by the channel rank. An BS reports on the calculated rank indicator and channel quality indicator (CQI) to indicate a suitable uplink transmission data rate towards each UE.

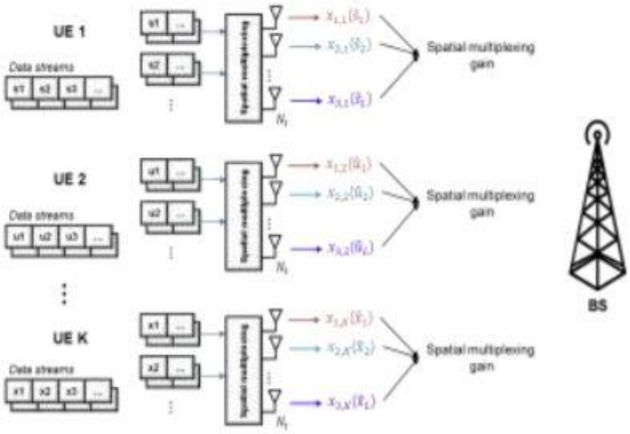

Figure 4.2: System model in uplink

CHAPTER 5

Software Introduction:

5.1. Introduction to MATLAB:

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn

and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

5.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

  This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

  This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

  This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

- **Graphics:**

  MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

5.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.

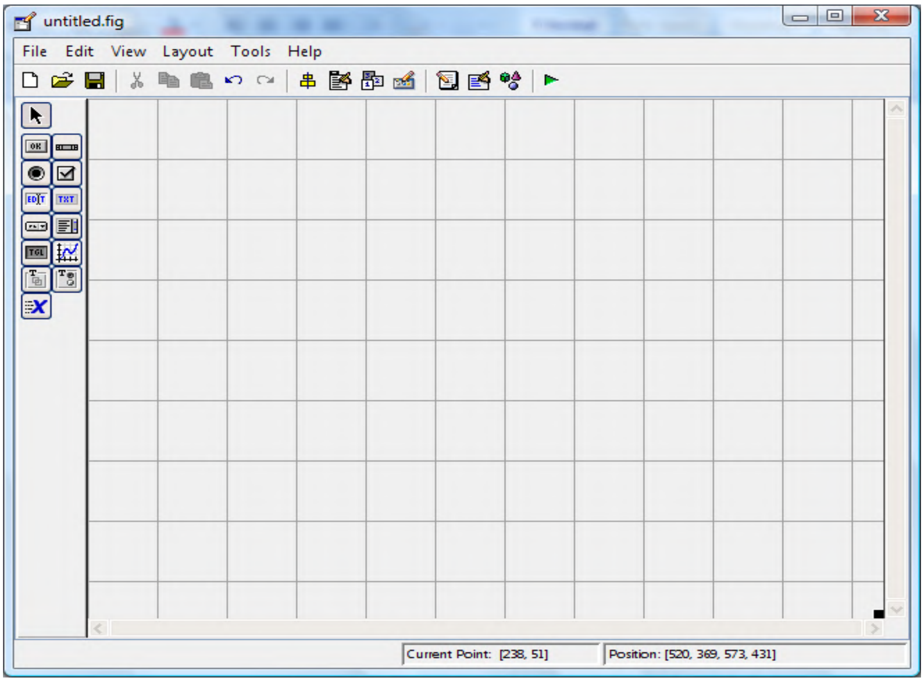

Figure 5.1: GUI(Graphical User Interface)

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

5.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

5.4.1 Introduction - describes the components of the MATLAB system.

5.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

5.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

5.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

5.5 DEVELOPMENT ENVIRONMENT

5.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

5.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

5.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

5.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

5.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window

- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window.In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane - After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

5.6 MANIPULATING MATRICES

5.6.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A = 16     3     2    13

     5    10    11     8

     9     6     7    12
```

4   15   14   1

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

5.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

5.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

5.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

5.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

5.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

5.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

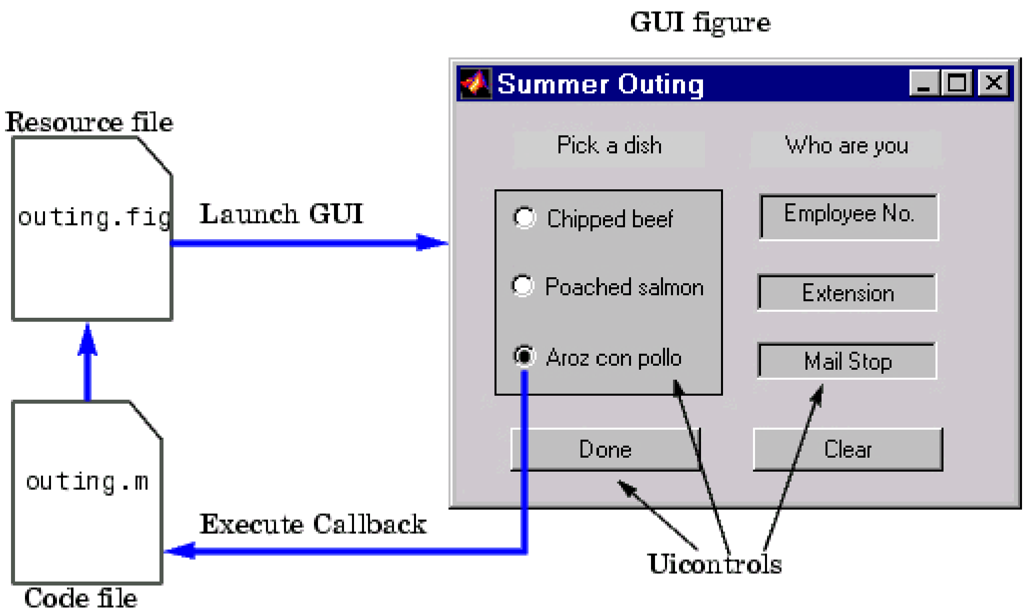
While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of itschildren (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and thecallbacks, which are defined as subfunctions. This M-file is referred to as theapplication M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.



5.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

5.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

5.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)
off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
mutual_exclude(off)
% Continue with callback
  .
  .
  .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
  % then checkbox is checked-take approriate action
else
```

```
    % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
    errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

```
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

Chapter 7

CONCLUSION

5G NR transmission frame and investigates the uplink millimeter-wave massive MIMO system under UMi scenario. The effect on the system performance according to the separation distance is investigated, and the system performance considering the number of transmit and receive antennas is also investigated. The simulation results show that high spectral efficiency can be obtained in a case where the separation distance between BS and UE is close. Also, as the number of transmit and receive antennas increases, the spectral efficiency that can be acquired increases by the spatial multiplexing MIMO technique. Based on the results of this study, further studies will be carried out to effectively estimate the millimeter wave channel and to reduce the excessive feedback overhead of the massive MIMO systems.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "IOT BASED TOLL BOOTH MANAGER SYSTEM" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1) Ms. K. Poojitha(17K81A04L2)

2) Mr. Kanduri Karthik Reddy(17K81A04L3)

3) Mr. Karnam Thanoj Kumar(17K81A04L4)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to our College Management for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. SANTOSH KUMAR PATRA**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr. A. ANAND, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We take it as privilege to thank our Project Coordinator, **Ms. P. PUSHPA**, **Assistant Professor**, Department of ECE for the ideas that led to complete the Project work and we also thank her for her continuous guidance, support and unfailing patience, throughout the course of this work.

Finally, we are highly grateful and obliged to our project guide **Mr. S. P.MANIKANTA, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work.

ABSTRACT

Managing multiple toll booths is a very complicated task. We here propose a smart card based toll booth system that is monitored over IOT. The Internet server maintains all the data of user accounts and also their balance. All vehicle owners would possess a rfid based card that stores their account number. Our system at toll booths will monitor the cards scanned when a car arrives at the toll booth. The system now connects to the online server to check if the card is valid and if valid what is the balance. If user balance is sufficient, the user balance is deducted online and web system sends signal back to the card scanner system that the user has been billed. On receiving this signal, the system operates a motor to open the toll gate for that car. The system is controlled by a microcontroller to achieve this purpose. The microcontroller uses wifi connection to connect to the internet through which system interacts with web server to perform the online verification process. Also, system allows to store data of all the vehicles passed at particular time intervals for later reference and surveillance. This system thus automates the entire toll booth collection and monitoring process with ease using RFid plus IOT based system.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

GLOSSARY OF COMMONLY USED TERMS:

Active Tag – An RFID tag that uses a battery to power its microchip and communicate with a reader. Active tags can transmit over the greatest distances (100+ feet). Typically, they can cost $20.00 or more and are used to track high value goods like vehicles and large containers of merchandise.

Agile Reader – A reader that can read different types of RFID tags – either made by different manufacturers or operating on different frequencies.

Antenna – A device for sending or receiving electromagnetic waves.

Anti-Collision – A feature of RFID systems that enables a batch of tags to be read in one reader field by preventing the radio waves from interfering with one another. It also prevents individual tags from being read more than once.

Automatic Data Capture (ADC) – Methods of collecting data and entering it directly into a computer system without human intervention. Automatic Identification (Auto-ID) Refers to any technologies for capturing and processing data into a computer system without using a keyboard. Includes bar coding, RFID and voice recognition.

Auto-ID Center – A group of potential RFID end users, technology companies and academia. The Auto-ID center began at the Massachusetts Institute of Technology (MIT) and is now a global entity. It is focused on driving the commercialization of ultra-low cost RFID solutions that use Internet like infrastructure for tracking goods throughout the global supply chain. The Auto-ID Center organization is now EPC global.

Electronic Product Code (EPC)

A standard format for a 96-bit code that was developed by the Auto-ID Center. It is designed to enable identification of products down to the unique item level. EPC's have memory allocated for the product manufacturer, product category and the individual item. The benefit of EPC's over traditional bar codes is their ability to be read without line of sight and their ability to track down to the individual item versus at the SKU level.

EPC global – The association of companies that are working together to set standards for RFID in the retail supply chain. EPC global is a joint venture between EAN International and the Uniform Code Council, Inc.

Radio Frequency Identification (RFID)

A method of identifying items uniquely using radio waves. Radio waves do not require line of site and can pass through materials like cardboard and plastic but not metals and some liquids.

Read Range

The distance from which a reader can communicate with a tag. Several factors including frequency used orientation of the tag, power of the reader and design of the antenna affect range.

Reader

Also called an interrogator. The RFID reader communicates via radio waves with the RFID tag and passes information in digital form to the computer system. Readers can be configured with antennas in many formats including handheld devices, portals or conveyor mounted.

Read Only Tags

Tags that contain data that cannot be changed. Read only chips are less expensive than read-write chips

Read-Write Tags

RFID chips that can be read and written multiple times. Read/Write tags can accept data at various points along the distribution cycle. This may include transaction data at the retail point of sale. They are typically more expensive than read only tags but offer more flexibility.

RFID Transponder

Another name for a RFID tag. Typically refers to a microchip that is attached to an antenna, which communicates with a reader via radio waves. RFID tags contain serial numbers that are permanently encoded, and which allow them to be uniquely id

"WORM" Chip (Write Once Read Many) and then becomes "Read only" afterward

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

With the growth in the number of vehicles the need for expansive roads catering to thousands of vehicles moving across India has become inevitable. However, considering the present situation the current toll system has several drawbacks. Due to the limited number of toll booths and slow collection process, the average waiting time per vehicle is 10 minutes. This results in losses worth thousands of crores of Rupees in terms of fuel wastage. This long wait time often results in drivers getting irritated resulting in verbal spats and physical fights among people and the toll attendants. Several such incidents have been reported in the press with some of these fights even resulting in the death of the toll plaza attendants. In addition, there are numerous cases of toll plaza accidents which happen due to the sudden lane changing by drivers for faster clearance. The major reason behind this is that, the security at the tolls is insufficient and it is beyond the traffic polices control to manage the vast number of vehicles. We keep hearing of many such incidents at toll plazas which mostly occur due to negligence either on the people's side or due to lack of control from the government agencies including the police. In case of events, where lives are lost, such losses are a life shattering experience.

As is well known, in such a scenario, the general public is a little hesitant in taking responsibilities of any such incident. Hence the government has to come up with an effective plan which bridges the gap between the toll management and the public expectation of the service that they experience. Introduction of an elective toll plaza operation plan by the government, its strict implementation and monitoring which would result in a more efficient and a more responsive and efficient system could be a good option for easing the challenges associated with the existing tolling process.

The requirements for new web applications supporting different types of devices an purposes are continuously growing. The main advantages of web application development as well as popular development features covering integration with different technologies are considered. Integration and possibilities of application of cloud-based web applications in real scenarios with different embedded Internet of Things (IoT) devices are considered and described. The design and implementation of a cloud-based web application supporting vehicle toll payment system using IoT device is presented and described. The development framework as well as featured and popular technologies used to realize a vehicle toll payment by IoT device are described. The concept of vehicle toll payment over an online payment system is also described. Processing, monitoring and control in the cloud-based web application of such payments using IoT devices are described and presented. Also, system allows to store data of all the vehicles passed at particular time intervals for later reference and surveillance. This system thus automates the entire toll booth collection and monitoring process with ease using RFID plus IoT based system.

1.2 OBJECTIVES OF THE STUDY:

The use of automated toll collection system in many metropolitan cities would be an efficient step towards the overcrowding of the city highways in heavy congestion of traffic. As we all know, transportation is the strength of our country's economy. There are various implementation, protocols in wireless sensor network and components such as RFID thus enabling reduction in operation costs and motivating cashless transactions. In case of manual toll collection system time consumption is much far worse as well as fuel depletion and most important is the environment, the amount of air pollution that is created at the toll booth site is at high level, so our developed system will reduce time wastage and not only reduce air pollution but also conserve fuel. The sole purpose of this paper is to reduce the hardships caused by manual toll collection system and pass the subject's vehicle through toll barrier in a matter of few seconds without halt.

Each and every day more and more vehicles are increasing rapidly and the graph of the rate of buying vehicles is exponential, which has become a major problem at the site of toll booths due to heavy traffic causing endless number of problems such as high petrol/diesel consumption leading to depletion of hydrocarbon deposits below earth's crust and also death causalities due to heavy traffic. The sole purpose of this paper is to motivate cashless transactions by installing automated e-toll collection system and the technology that we used is the use of RFID readers/tags. Basically to tackle this problem, the use of RFID tags that must be uniquely fixed onto subject's vehicle and RFID reader module must be fixed at e-toll tooth. When a subject's vehicle passes through the gate, the reader will detect an incoming frequency of 125 kHz of the RFID tag and read a unique no that has been assigned by govt. authority and the toll fee will be deducted from linked bank a/c or the e-wallet of system. This system is capable of saving time as well as fuel conservation which can save a lot of individual's economy. This particular system is far much better and very efficient towards people as they will not stay in a long and lengthy queue thus automated e-toll system will eliminate the hardships of people parking vehicles in a long queue. RFID has the potential of eliminating corruption at local level and also reduce operational costs as well as errors in human operations. WSN's i.e. wireless sensor networks are basically used in different scenarios such as home, office, healthcare, agriculture and also at toll collection plaza which can capture and transmit data from all incoming vehicles and outgoing vehicles because of their consistent and distinctive properties.

1.3 SCOPE OF THE STUDY:

- **IOT (internet of things)** based toll booth manager system is such type of a system that provides the automatic toll collection process with the help of internet resources and RFID (radio frequency identification) technology.

- If we talk about accountability, then manually toll collection process is very complicated because it is not so much easy to manage hundred and thousands of vehicles at same time.

- It required more man power as well as with more toll collection booth, which could be so much costly and difficult for toll collection department.

- On other hand, so much time is wasted by the vehicle owners when they are stand in so much long toll collection row.

- To manage all these above situations and to facilitate the vehicles owners, so many toll booth manager systems are available in market but that one's are so much costly as well as they are not so much efficient, reliable, precise and friendly to use.

- Here we have proposed a system that is called IOT based toll booth manager system which is so much efficient, reliable and friendly to use. In this system every vehicle owner possess a RFID based card, which would be scanned this card during pass through toll collection both.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- LCD
- Power Supply
- RFID
- Buzzer
- WIFI
- L293D
- Motor

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop andbefore assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the toll booth system with better efficiency, with less time delay and the results were also satisfactory and we successfully got the output in mobile telnet app and LCD screen. We would like to improve the project in future for further developments.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

The ATC system in the paper "A review on automated toll collection system" the two types of study were compared namely the RFID based study and Leach-C based study showed promising and efficient way to develop the system but it also showed us lack of a point where the Leach-C system worked on digital image processing where the number plate of subject's vehicle was scanned using high-tech camera. Using the RFID based implementation and eliminating the DIP based implementation to make system better time efficient. The survey done in the paper named "A 5.8 GHz ISM band Microstrip antenna for RFID applications" showed us the path using and developing RFID antenna for scanning the details of subject's vehicles from a handy distance thus enhancing the distance of vehicle and RFID reader would cover a large area. Smart Toll Collection System based on IoT (IJSTE/ Volume 3 / Issue 12 / 002) All rights reserved by www.ijste.org 10 The review was done of the paper "Automated toll collection system using RFID" Enlighted us the various components that can used while developing our own system in time saving and in efficient way so as to make a hybrid system that is mentioned in the paper "A review on automated toll collection system". "A Survey in Image Mining" showed a path towards machine learning and data mining concepts and helped us in mining databases in the form of people's feedback.

2.2 REVIEW ON RELATED LITERATURE:

The first person to propose electronic toll system was William Vickrey. He proposed this system for Washington Metropolitan Area. He was also the recipient of Nobel Economics prize in 1959 [5] The transponder and reader technology spread all around Norway. The system was broached in the Bergen (1986). World"s first completely automated electronic toll collection system was introduced in Trondheim (1991). Norway too has electronic fee collection EFC. [5] In different places in the United States like California, Pennsylvania, Texas, Delaware and Florida, vehicles can pass through electronic toll collecting booths directly. For the same no of cars, operations in electronic toll booths take place faster as the users are preregistered. Toll collecting gates are usually broader than the original width of the road but this made it possible to fit them into smaller narrower roads. Although these limitations are present, if the time taken for operation at the toll booth is reduced, then the speed of operation can be increased. The greater the speed of operation, less number of total lanes was required and as more number of lanes started getting automated, there was a reduction in the overall short term cost of the project. Also if the long term cost of the project is considered, larger number of vehicles started using electronic toll and vehicles using manual toll reduced. [5] According to references, the methodology proposes use of Infrared sensors to gather real time data from the waste bins and that of the microcontroller board to communicate this information to the waste managers.

These sensors collect information about the objects, their surroundings and communicate this information to other stations, linked through wired or wireless networks. The system will check using the IR sensors when the bin becomes full and will notify the waste managers upon filling up of the bins and will provide an optimal and effective collection route. [10] According to reference, The initial technical realization of IoT was achieved by utilizing RFID (Radio Frequency Identification) technology, which was limited to identification, object tracking and extracting information of specific objects. However, The implemented IoT based system performs sensing, actuating, data gathering, storing, and processing by connecting physical or virtual devices to the Internet. [10] According to reference, To facilitate vehicle monitoring, toll collection and faithful vehicle authentication on the highways and to have an efficient usage of communication link between RF Modems over a wireless channel, a module is proposed. There are two types of implementation modules-the Vehicle Module (Active RFID Tag) and the Base Module. Microcontroller contains user-specific information associated with vehicle, such as the owners information with his billing address, vehicle engine number and vehicle registration number. The base module allows the base module to check the activities of vehicles in range, including the vehicles in range, their status, and the detailed information about any registered vehicle.[6] According to reference, Open Road Tolling uses video evidence to identify vehicle usage of a toll facility without the use of toll booths for toll collection without having to stop or even slow down to pay the toll.

The application, for Open Road Tolling, utilizes pattern recognition and image processing methods. This paper presents Open Road Tolling (ORT) using number plate recognition. The proposed Number Plate Recognition (NPR) techniques consist of mainly two modules: histogram based number plate localization and number plate recognition using template matching, thus making it simple & faster. AVI technology uses Laser or Radio Frequency (RF) method. Laser systems uses barcode attached to the vehicle & read by vehicle scanner as the vehicle passes through the toll lane. [7] According to reference, The German Federal Ministry of Transport had conducted a fee collection experiment on German motorways called ChipTicket systems. The ChipTicket system assumes that vehicles are equipped with a chip card, and an in-vehicle unit. The in-vehicle unit contains transmitting and receiving facilities for communication with the toll stations - the so-called charge collection stations. The chip card is a plastic card contains an integrated microprocessor. When a driver passes a charge collection station, payment is made automatically by the vehicle the chip ticket is made and the fee is registered and stored in the station computer.[8]

A microcontroller has been programmed to operate a remotely operated positioning system of a satellite. Earlier, if we wanted to get an exact angle of the satellite, it needed manual adjustment. To overcome this drawback, this paper was aimed at developing a system to remotely operate the satellite. The IR signal from the remote (Transmitter) is sent and is received by the IR sensor (Receiver) which has been interfaced with the main microcontroller. The data from the transmitter is sent in an encoded format which is received by the receiver sensor and is the suitably sent to the main microcontroller. Corresponding signal is sent by the microcontroller to the motor driver which in turn rotates the motor and thereby the satellite accordingly. [9] According to reference, the ESP826 is a Wi-Fi module that has very efficient on chip storage and processing capabilities with lower cost and higher quality. ESP is based on IEEE 802.11 Wi-Fi protocol and it supports various network protocols. For connecting the machine to server a level shifter is used. [12]

This system on chip (SOC) design has been provided with a TCP/IP protocol stack which is used to provide Wi-Fi connection to any microcontroller that has been used by the system. There are three different methods to implement ESP8266. Using AT commands for communication is the simplest way that can be used. AT commands can be sent via the computer through a USB to serial adapter cable to the controller for setup and testing purposes. The second way is peripheral mode by interfacing compatible microcontroller with the module. The third method can be implemented by directly programming the GPIO pins of the module and interfacing them with external peripherals and sensors. An ESP8266 device can be used as an access point or as a station or both at the same time. Usually the access point also has a network data connection.

Therefore itcan act as a bridge between the wireless network and the TCP/IP network which is the internet. Once it has been finalized which mode the device will be used in, then we set a global mode which indicates the state in which the device will be used (As an access point or a station or both). Wi-Fi module is connected to the controller through this level shifter and have used SPI protocol.. Here considering the need for consistency of data we have utilized TCP/IP network protocol for communicating with the server [11] The ESP8266 is designed to occupy minimal PCB area, without compromising on providing maximum inbuilt features. Cost Effective - Among the major advantages of the module include its price. You can get a module at lower than $5. Power - The power saving architecture operates in 3 modes: active mode, sleep mode and deep sleep mode, thus yielding very power efficient system. Ease of Interfacing - Module can be easily calibrated when required by reprogramming it for interfacing wide range of sensors.[13]

There are various of protocol is used in IoT (Internet of Things) devices. One of the most useful protocols is MQTT (Message Queuing Telemetry Transport). Second basic protocol is TCP. MQTT is broker based publishing/subscribing messaging protocol. It is open, lightweight, and very easy to implement. Moreover it has low bandwidth protocol.[14] The ATmega328 is the microcontroller used for this project. It shows important specifications like 14 digital input/output pins, 6 analog inputs, a USB connection, a 16 MHz ceramic resonator, an ICSP header, a power jack, and a reset button. The Arduino can be powered via the USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an ACto-DC adapter (wall-wart) or battery. The board can operate on an external supply of 6 to 20 volts. However it suffers form possibilities of overheating which may damage the board. The recommended range is 7 to 12 volts.[21] Controller –ATmega328 controller has been used which is an 8-bit microcontroller based on AVR. It has built-in communication protocol like I2C and UART and many other essential features. Real Time Clock-RTC module of DS1307 is connected to ATmega328 through two wire interface for reading the on and off time of the machine. Level shifter: MOSFET based level shifter is needed to drop down voltage in between, as ATmega328 operate on 5V and ESP-12 on 3.3V.[12]

2.3 CONCLUSION ON REVIEWS:

The ATC system in the paper “A review on automated toll collection system” the two types of study were compared namely the RFID based study and Leach-C based study showed promising and efficient way to develop the system but it also showed us lack of a point where the Leach-C system worked on digital image processing where the number plate of subject’s vehicle was scanned using high-tech camera. Using the RFID based implementation and eliminating the DIP based implementation to make system better time efficient. The survey done in the paper named “A 5.8 GHz ISM band Microstrip antenna for RFID applications” showed us the path using and developing RFID antenna for scanning the details of subject's vehicles from a handy distance thus enhancing the distance of vehicle and RFID reader would cover a large area.

The review was done of the paper "Automated toll collection system using RFID" Enlighted us the various components that can used while developing our own system in time saving and in efficient way so as to make a hybrid system that is mentioned in the paper "A review on automated toll collection system". "A Survey in Image Mining" showed a path towards machine learning and data mining concepts and helped us in mining databases in the form of people's feedback. The survey done in the paper named ATC turned out to be good step for developing ATC as we tried the best option in choosing the components in terms of reducing operation costs, time saving, flexible and also added the theft detection module in our system enabling security on high alert and detecting of stolen vehicles. During the period of learning and reviewing we also tried in improving and eliminating the costs of GSM kits embedded on the micro-controller board by replacing by use of private SMS gateway or govt. running GSM Company, which has reduced the operation cost much and has made our system more independent of using GSM kit.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

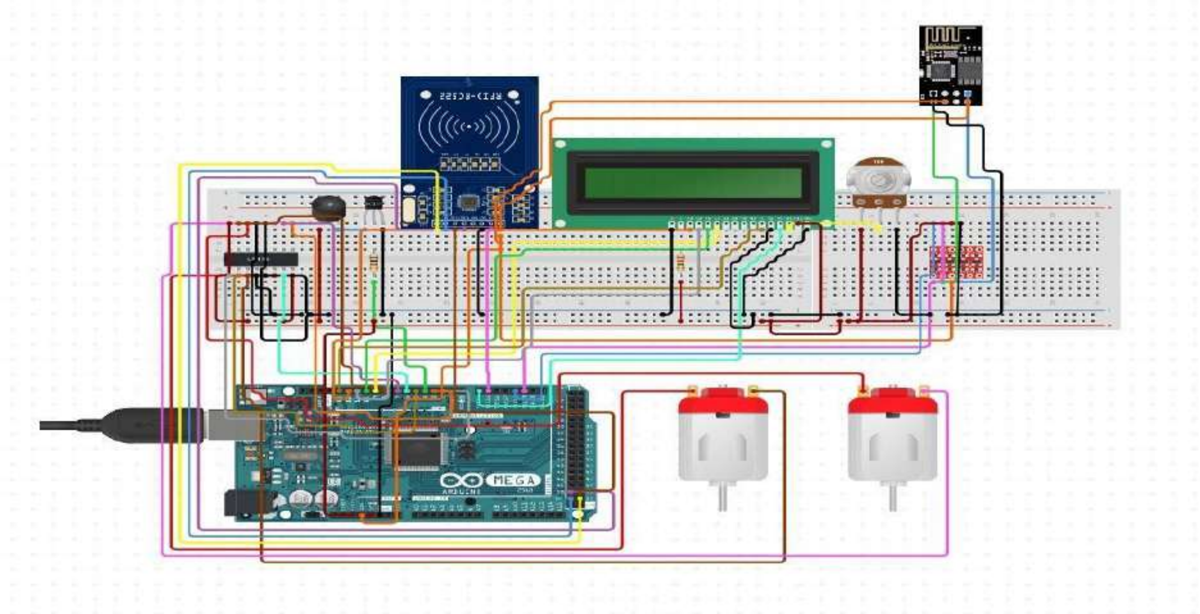

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

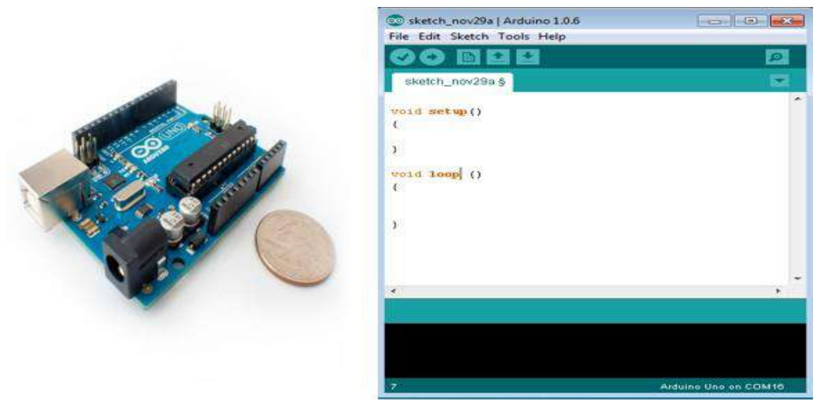

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini-05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini-3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Lilypad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Lilypad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

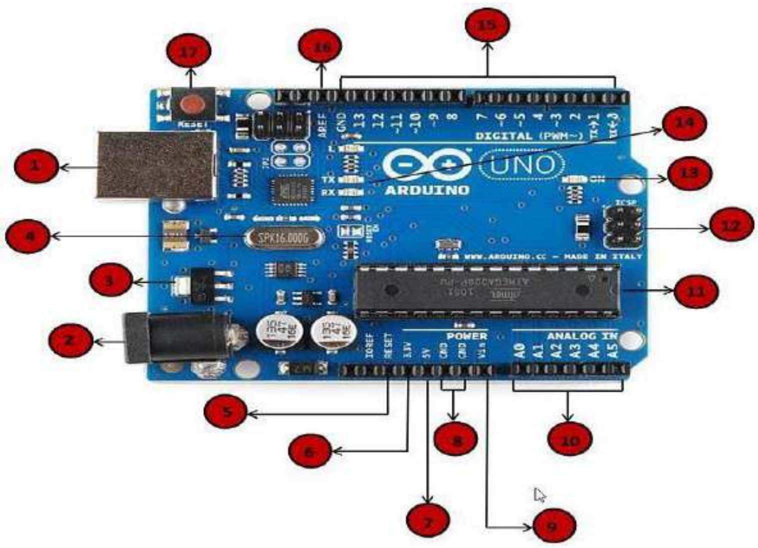

Fig.3.2.1.3 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.

5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator**

	This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 3.2.1.3 Board description of Arduino UNO

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.4: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

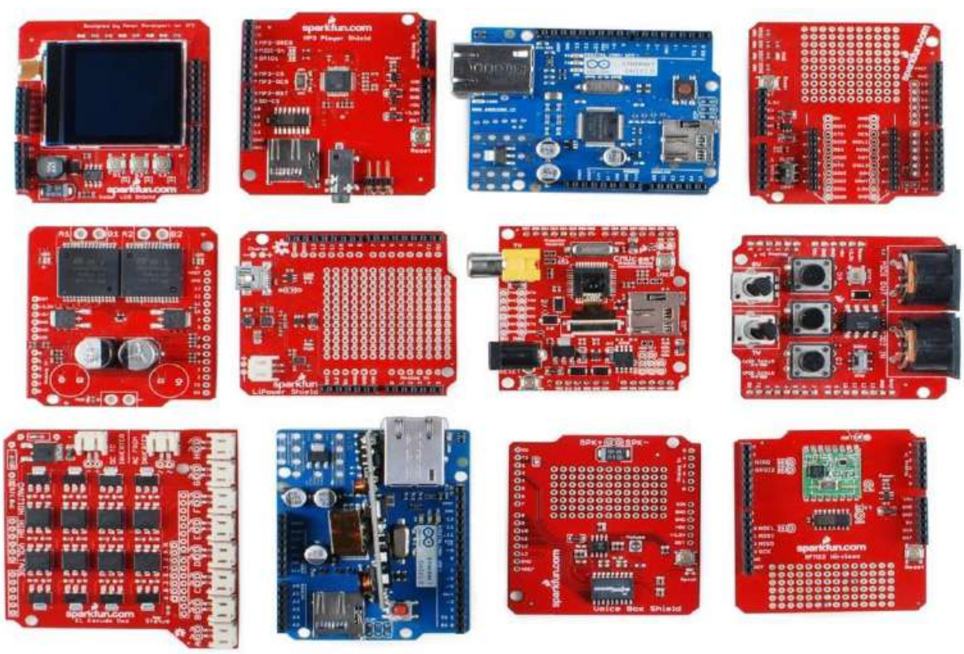

Fig.3.2.1.5: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

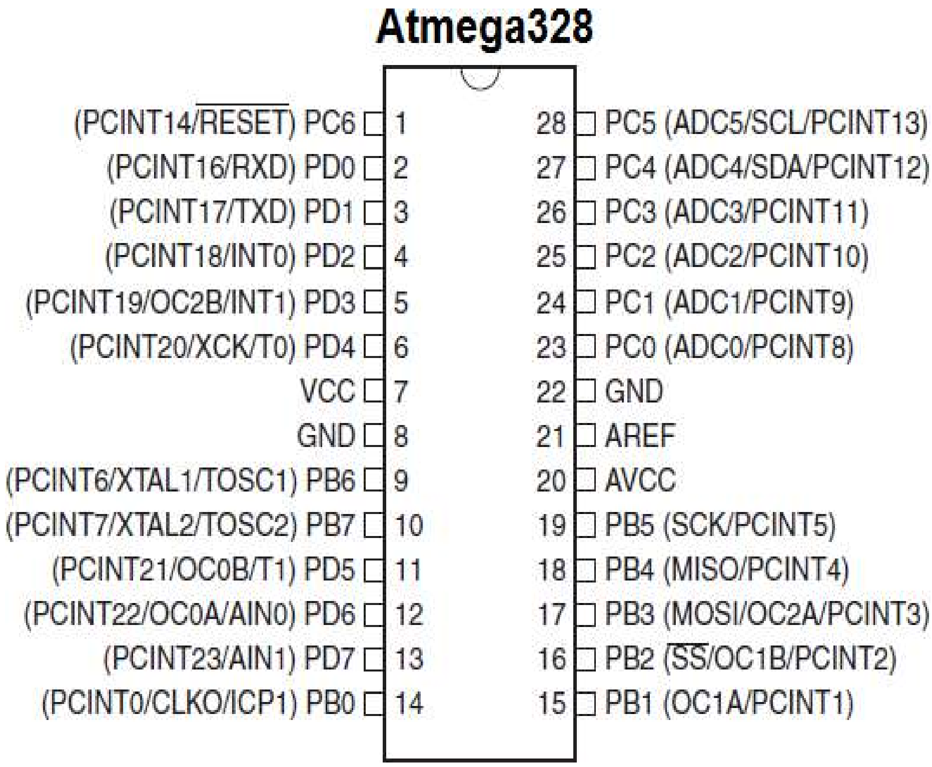

Fig.3.2.1.6 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

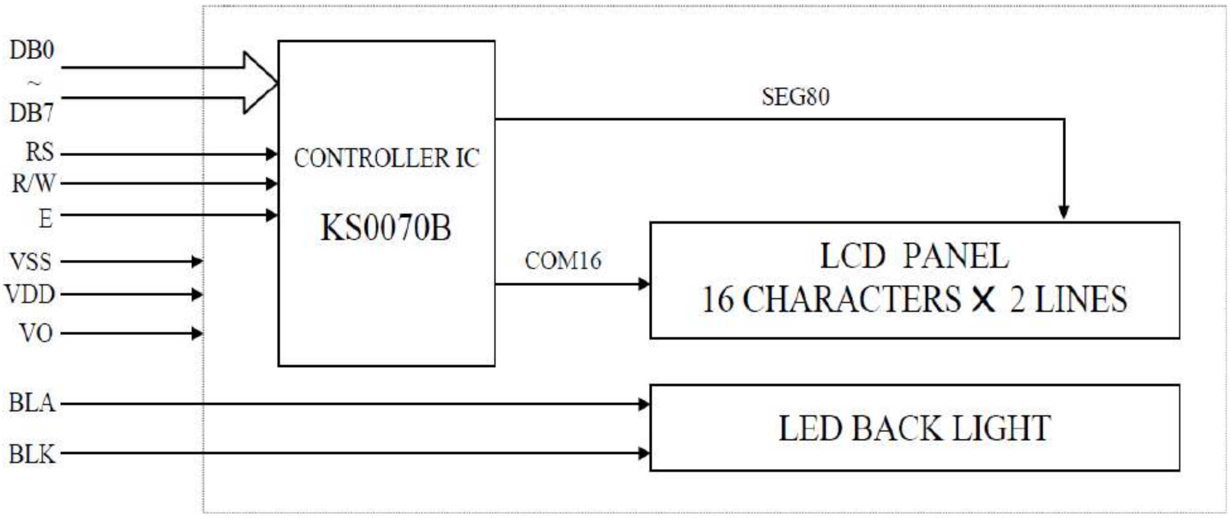

fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user. Figure below will show you the DDRAM addresses of 2 Line LCD.

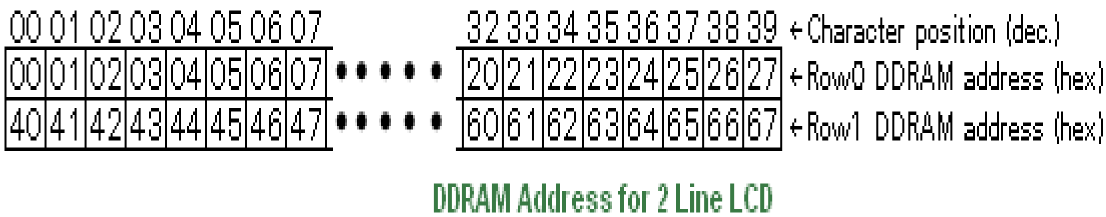

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 BUZZER

3.2.3.1 MAGNETIC TRANSDUCER

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

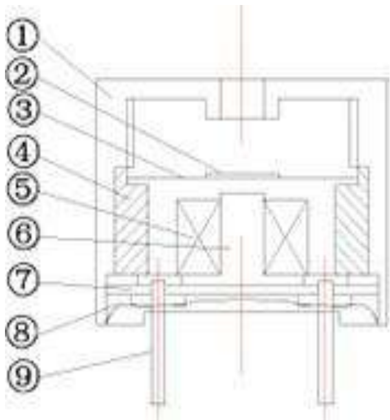

Fig.3.2.3.1 Magnetic Transducer

3.2.3.2 MAGNETIC BUZZER(SOUNDER)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

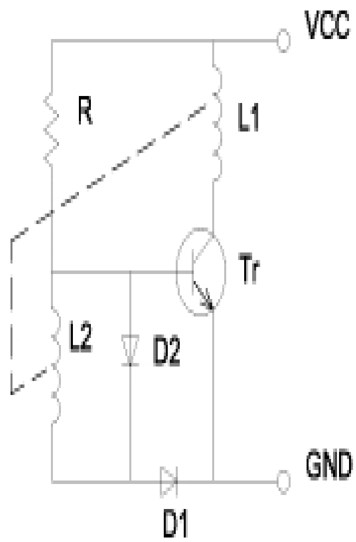

Fig.3.2.3.2 Magnetic Buzzer

3.2.3.3 SPECIFICATIONS:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Direct Current Resistance: The direct current resistance is measured by ammeter directly.
Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating Temp. : Keep working well between -30℃ and +70℃.
How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

3.2.3.4 HOW TO CHOOSE A BUZZER:

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.5 INTRODUCTION OF PIEZO BUZZER:

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

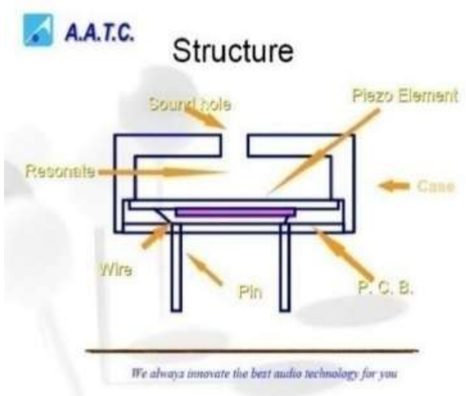

Fig.3.2.3.5 piezo buzzer

3.2.3.6 SPECIFICATIONS:

Rated Voltage: A piezo buzzer is driven by square waves(Vp-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

Sound Output: The sound output is measured by decibel meter.

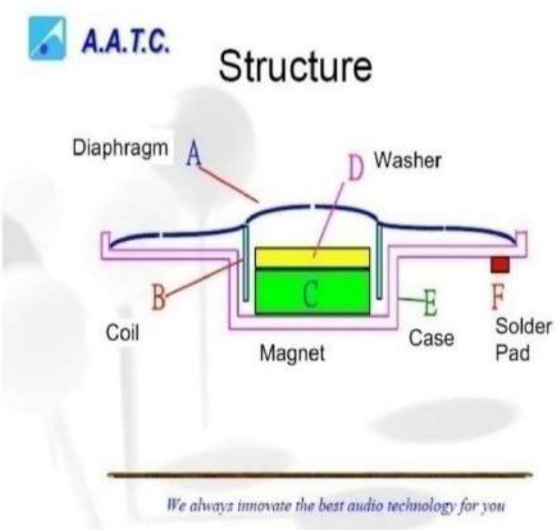

Fig. 3.2.3.6 structure of piezo buzzer

Applying rated voltage and square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating Temp.: Keep working well between -30℃ and +70℃.

3.2.4 L293D

3.2.4.1 INTRODUCTION

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.
L293D is basically a motor driver or controller. It has two built-in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g. stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc. Its common real-life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

Fig. 3.2.4.1 L293D Motor Driver

3.2.4.2 L293D PINS:

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

3.2.4.3 L293D PIN FUNCTIONS:

- L 293D each pin has different tasks to perform when they are in working condition.

- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

Table 3.2.4.3 L293D Pin Functions

3.2.4.4 L293D PINOUT:

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.

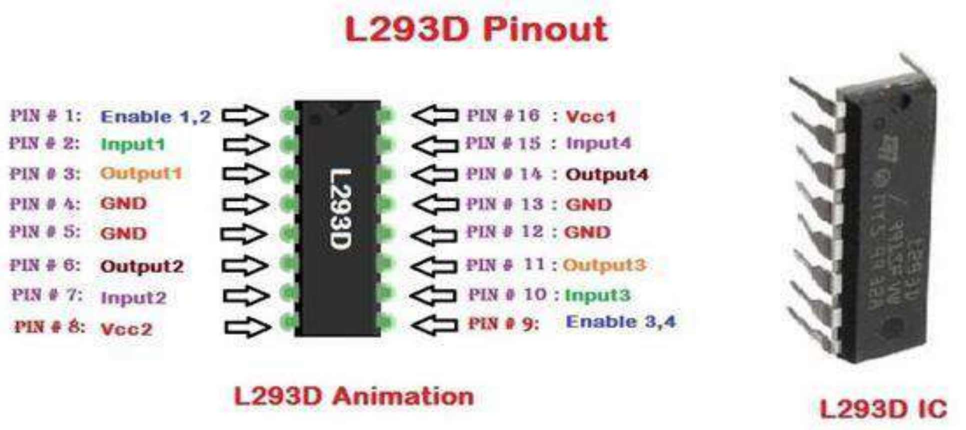

Fig. 3.2.4.4 L293D Pinout

3.2.5 MOTOR

Motors usually operates on this higher current. L-293D has to built-in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g., relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

3.2.6 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.6.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are
completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and
wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers,

it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under

a Creative Commons license, so experienced circuit designers can make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-
This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.
When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

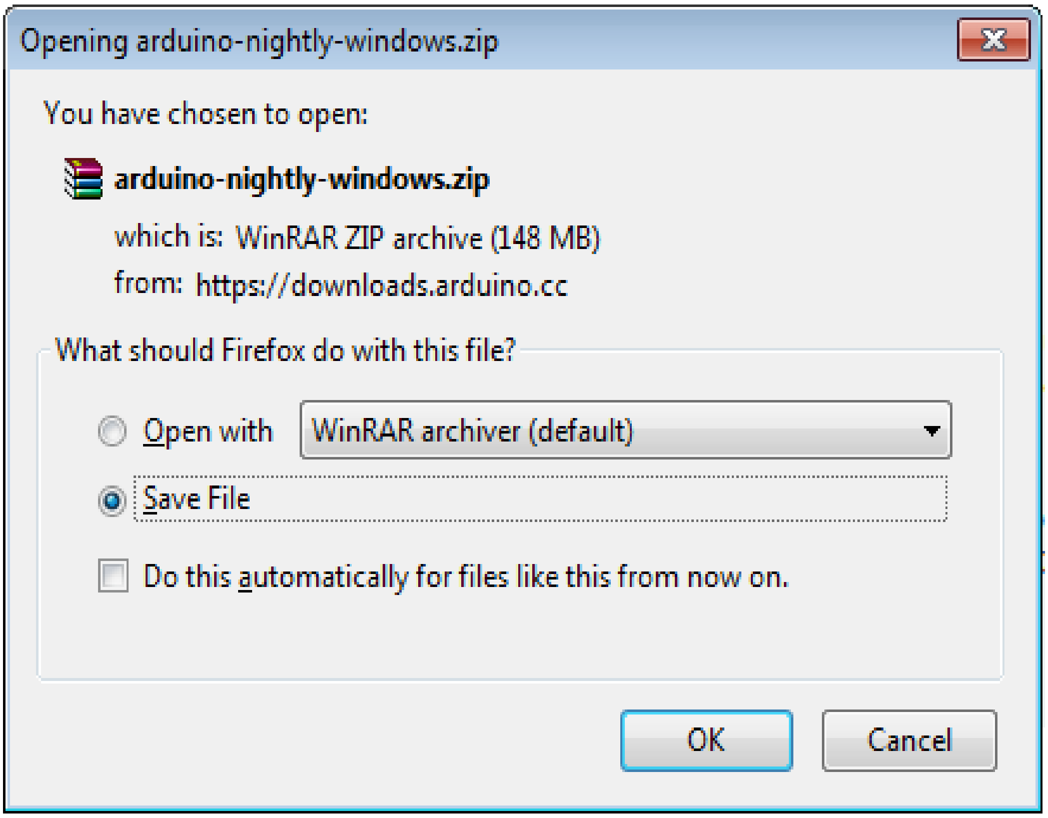

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

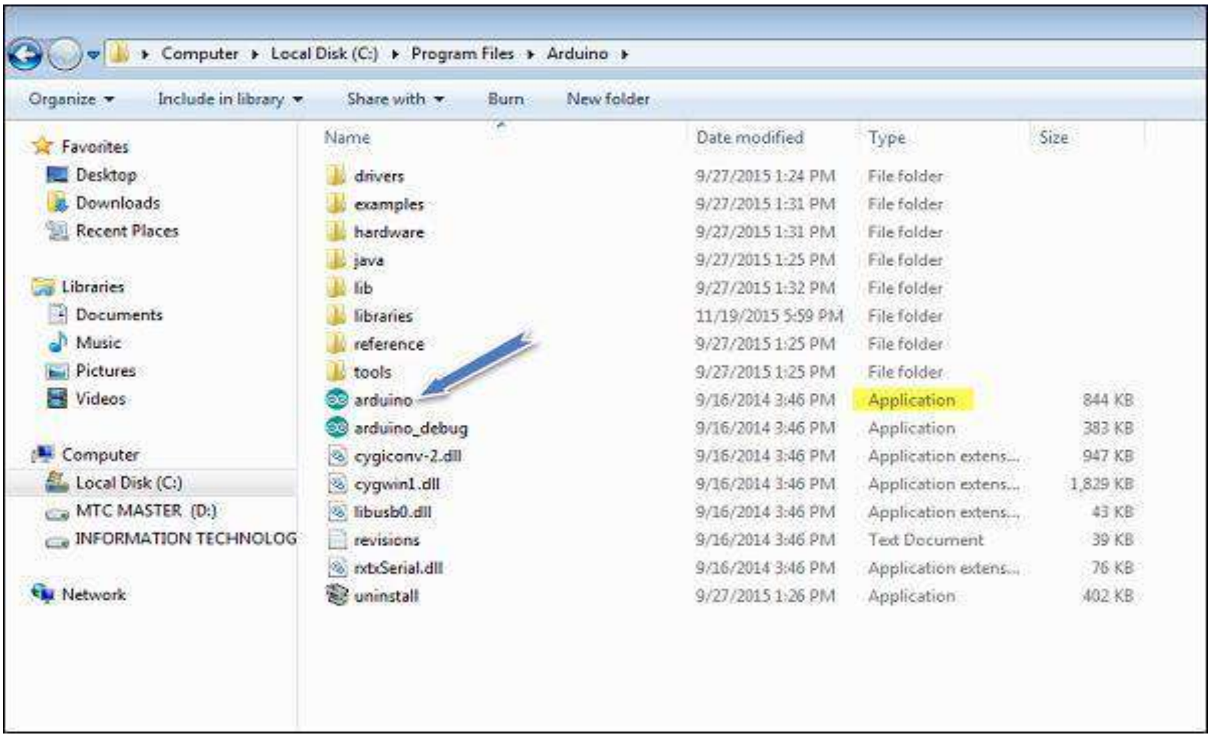

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

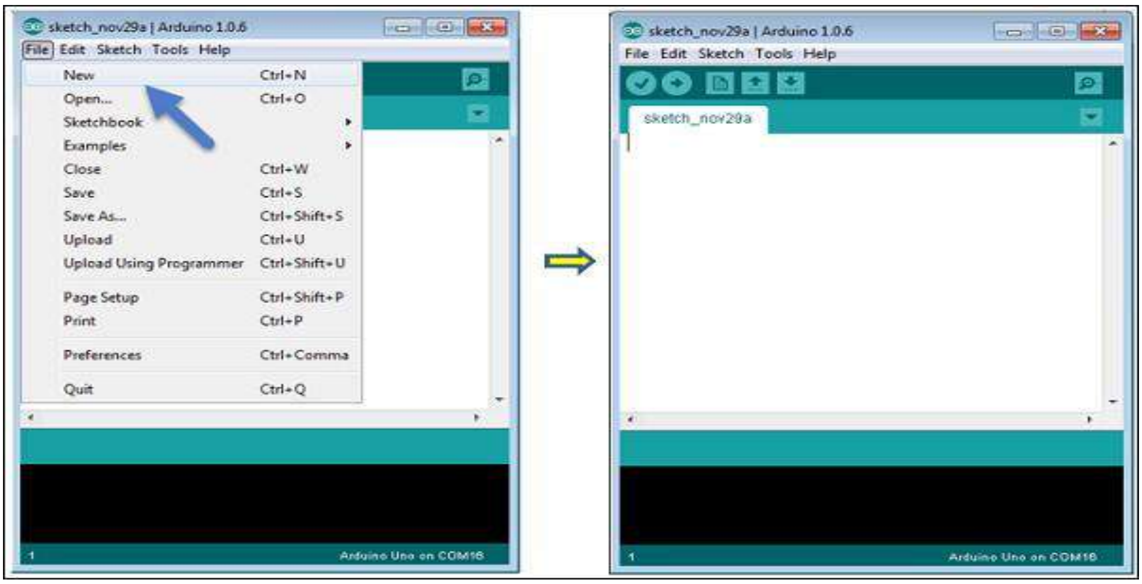

Fig. 3.2.6.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

.

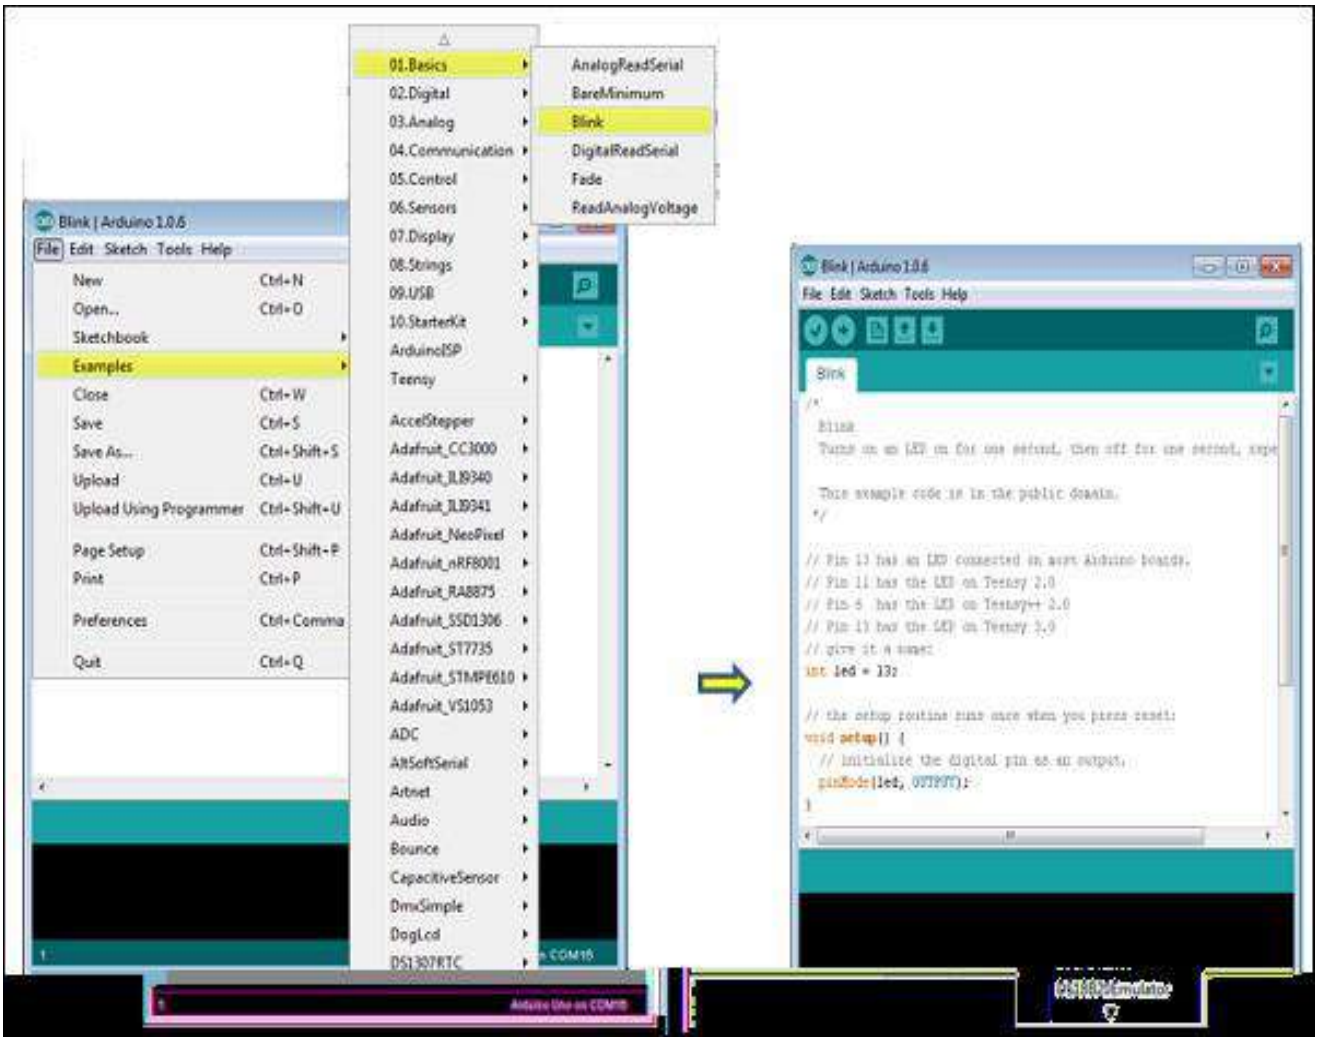

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

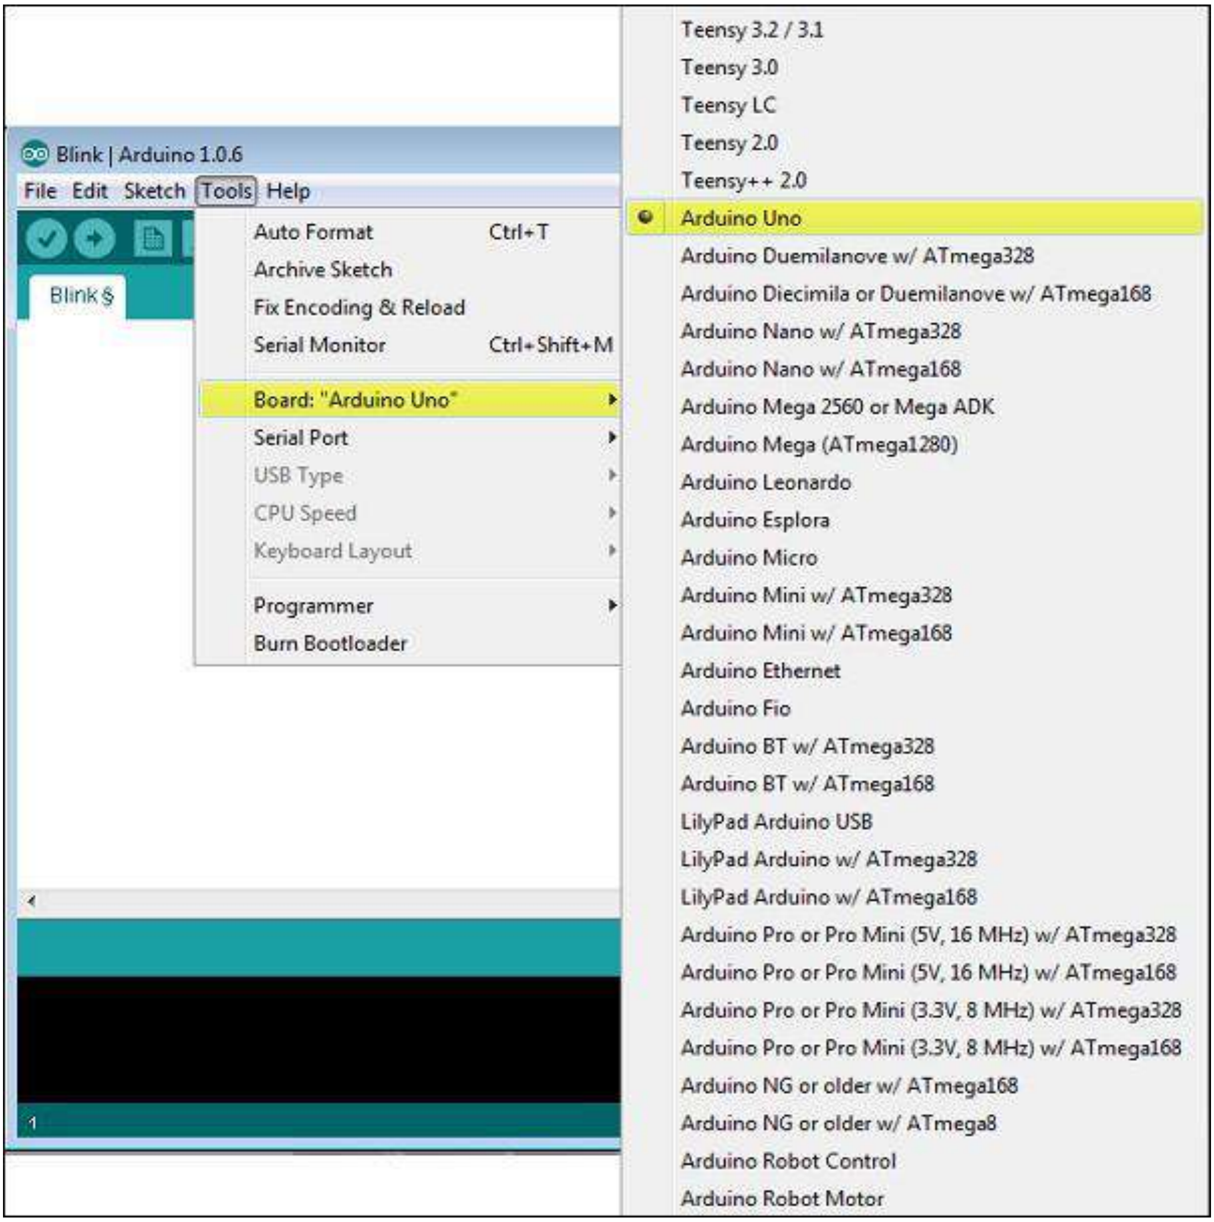

Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

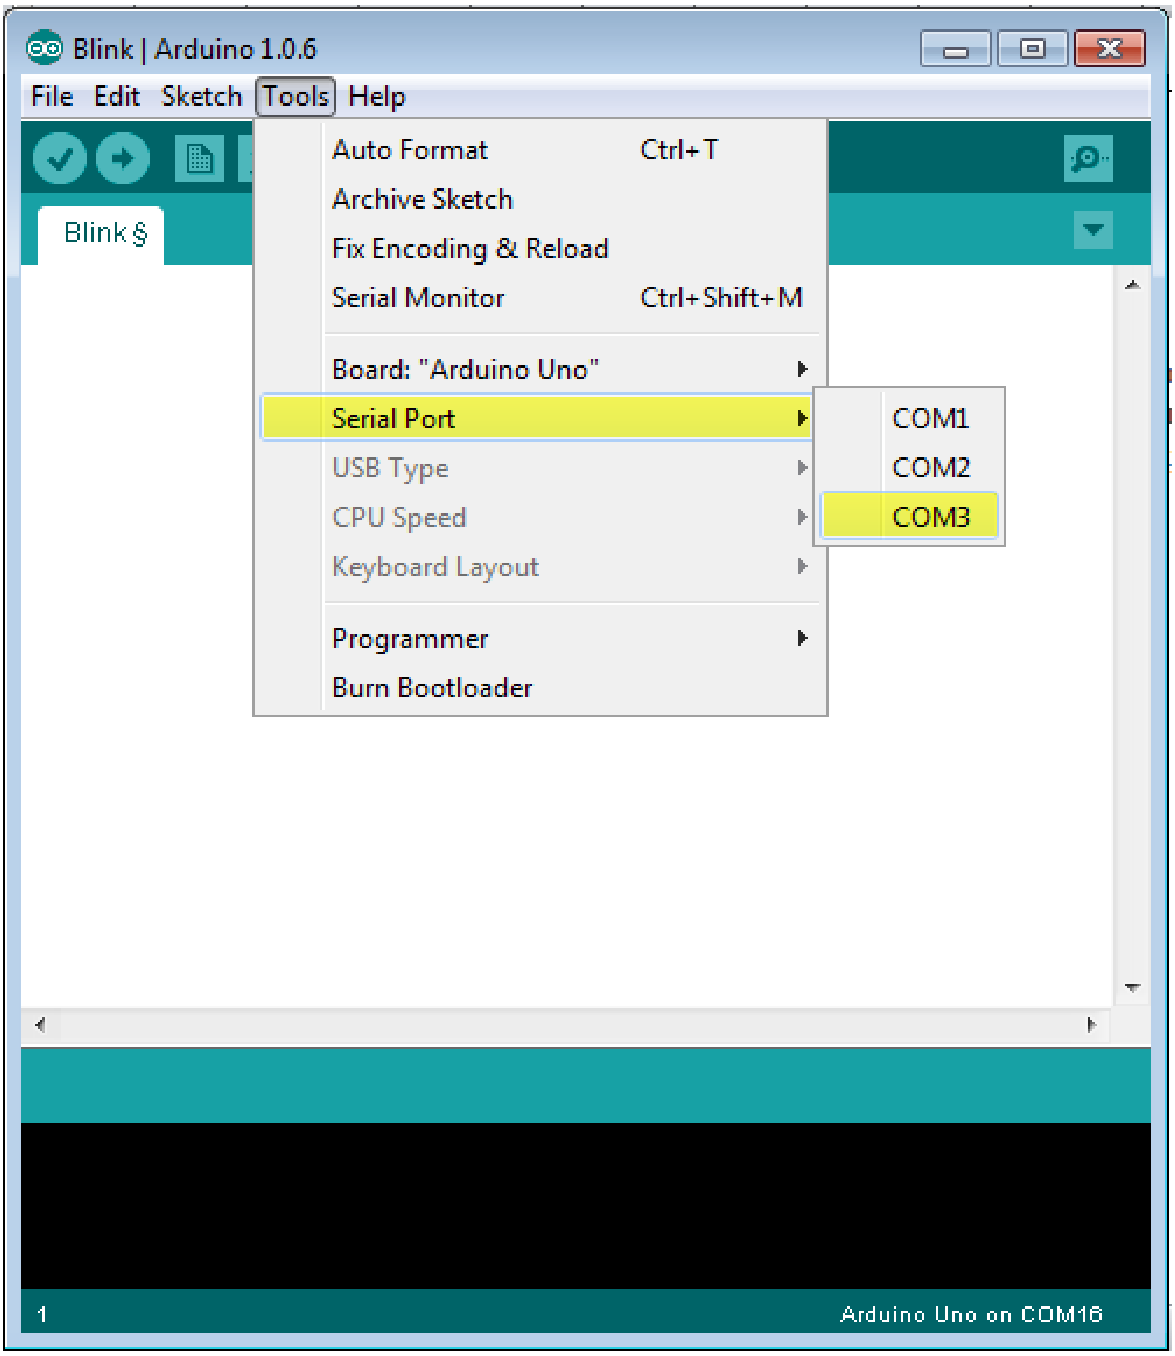

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

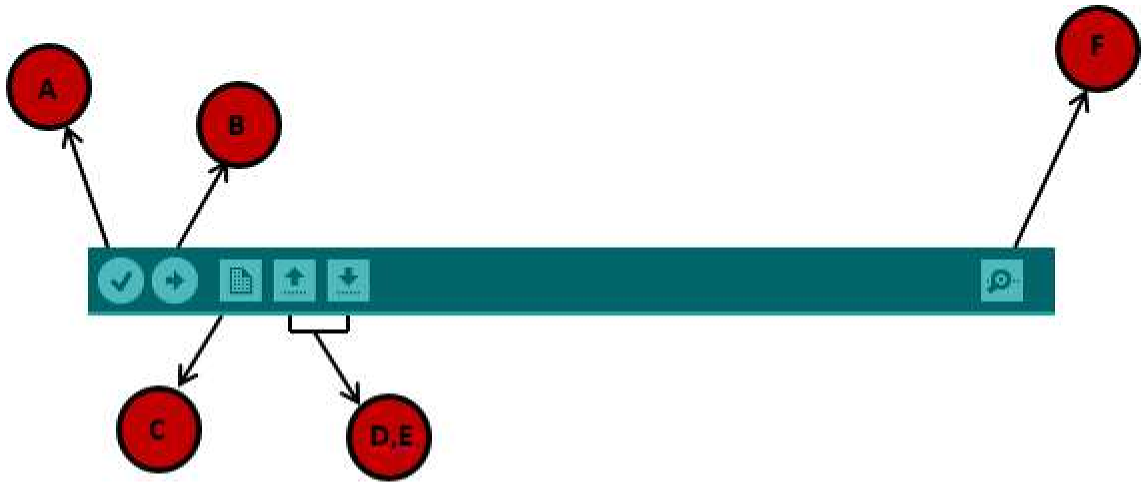

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

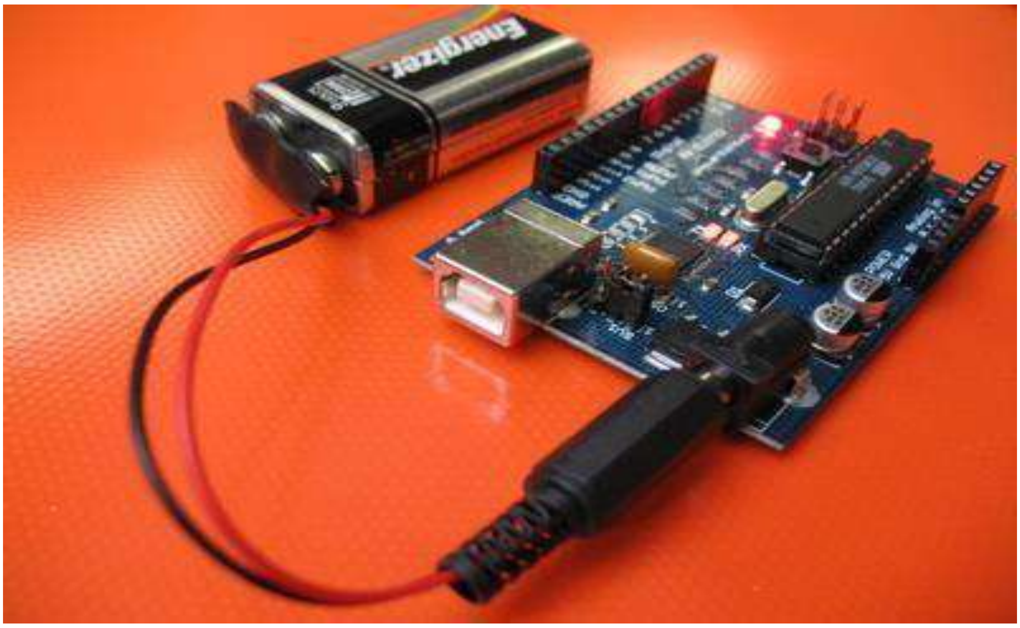

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

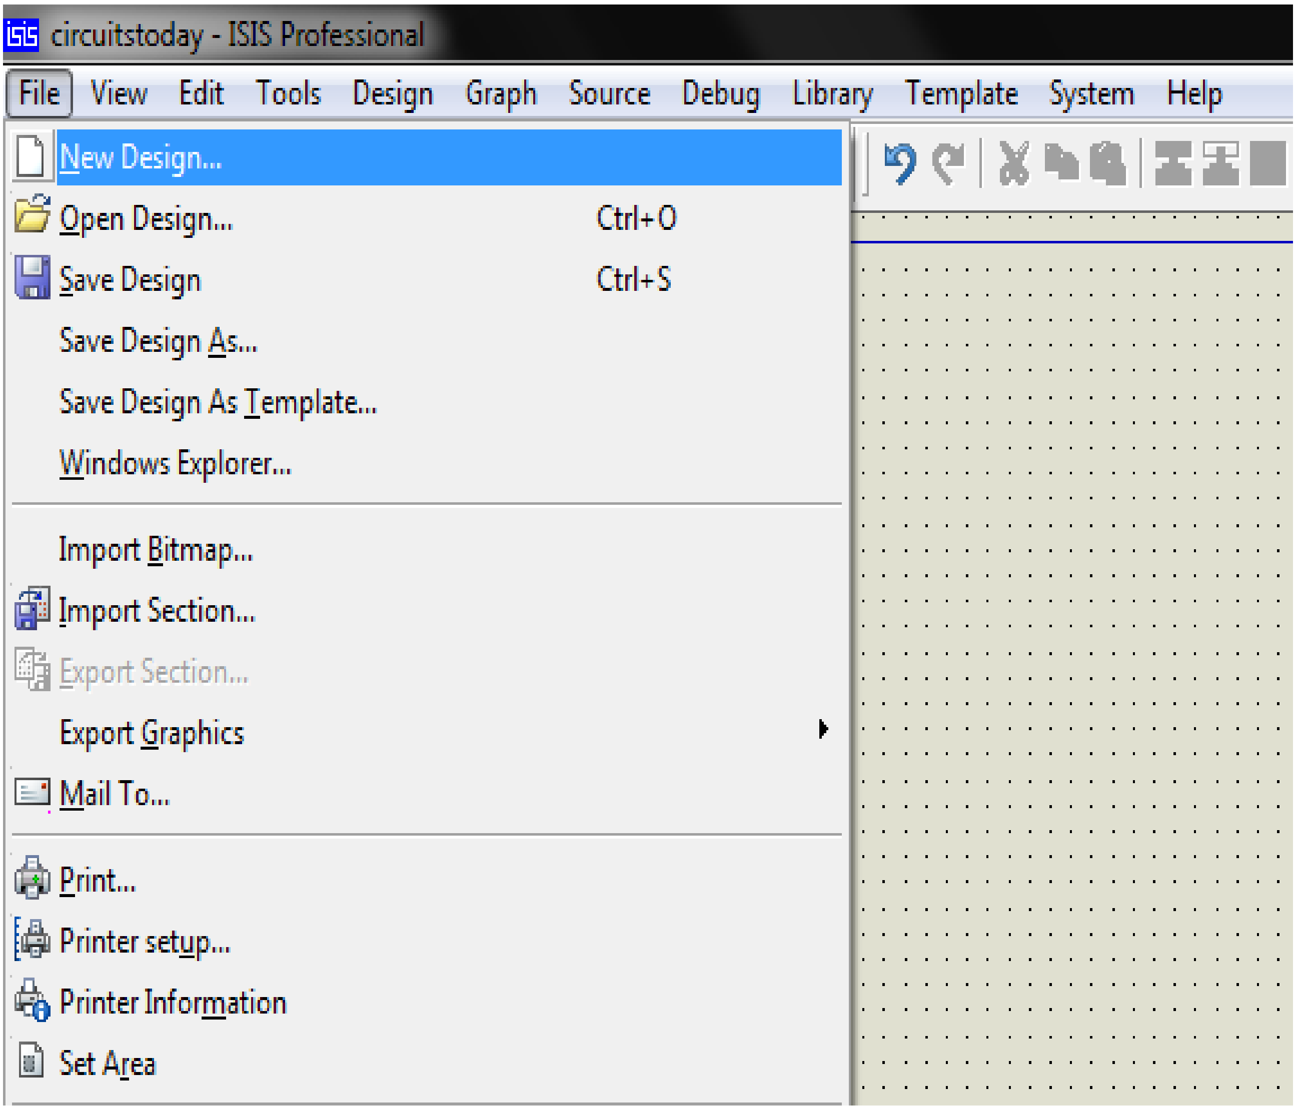

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

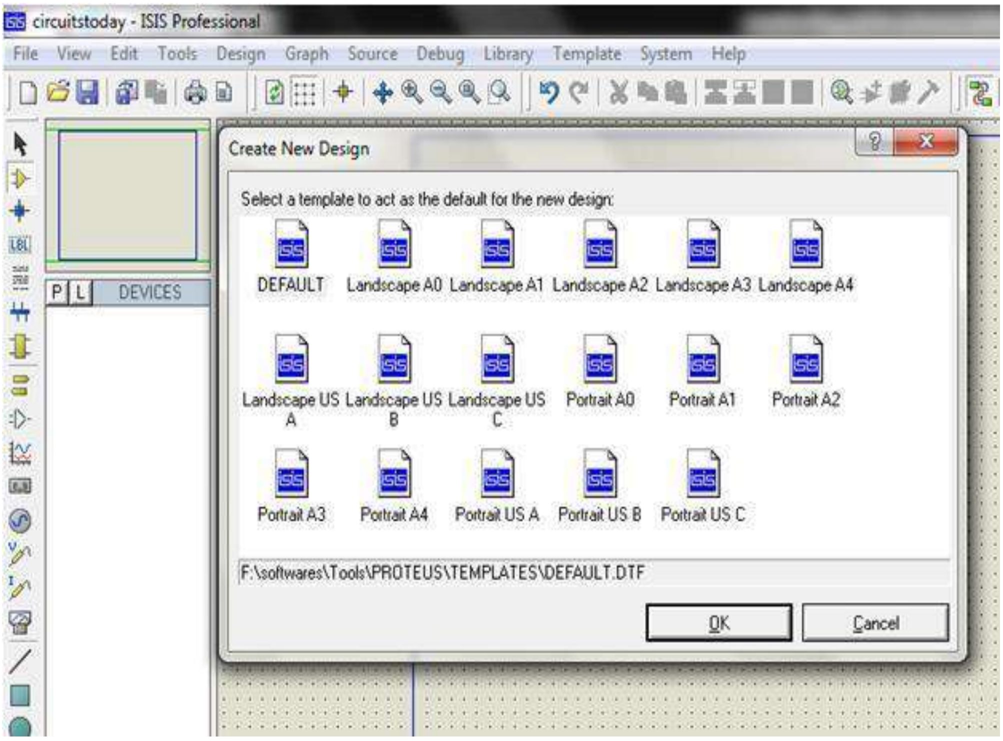

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

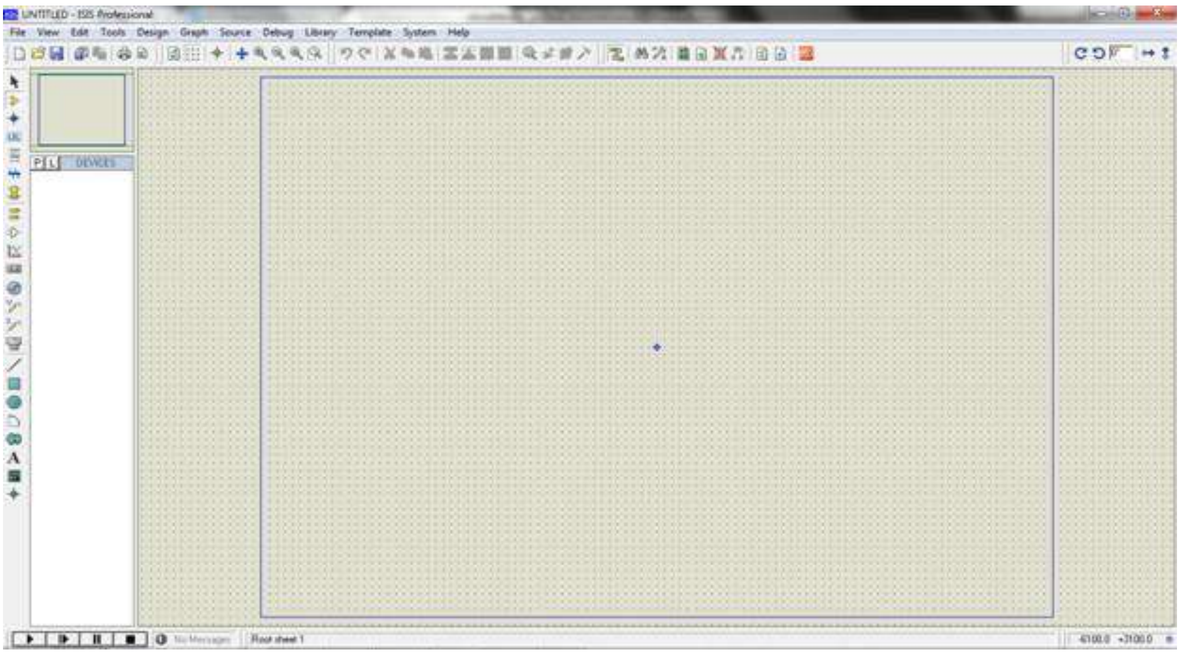

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

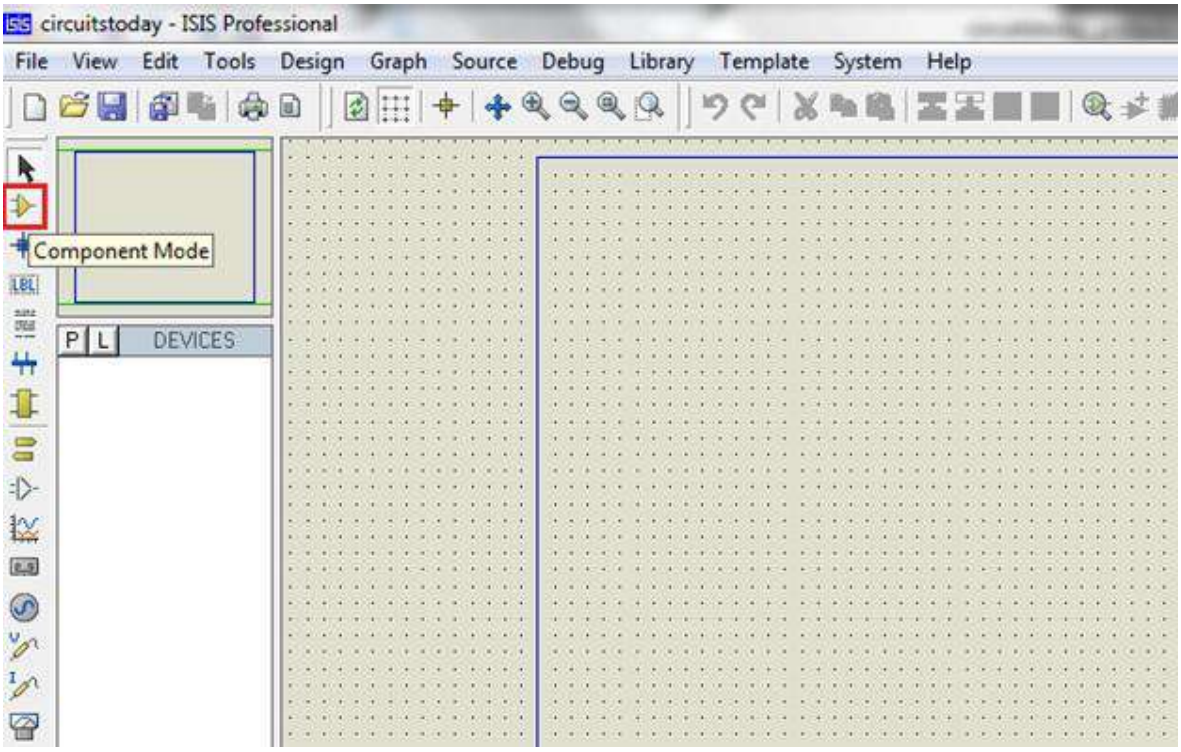

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

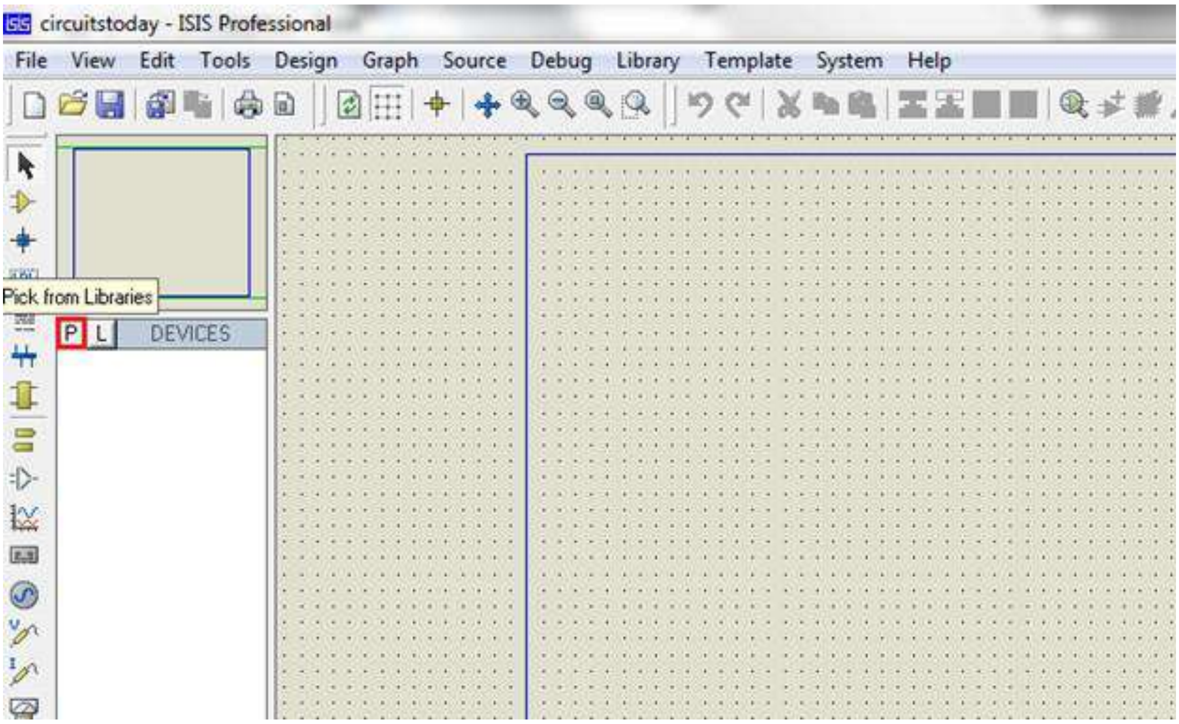

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

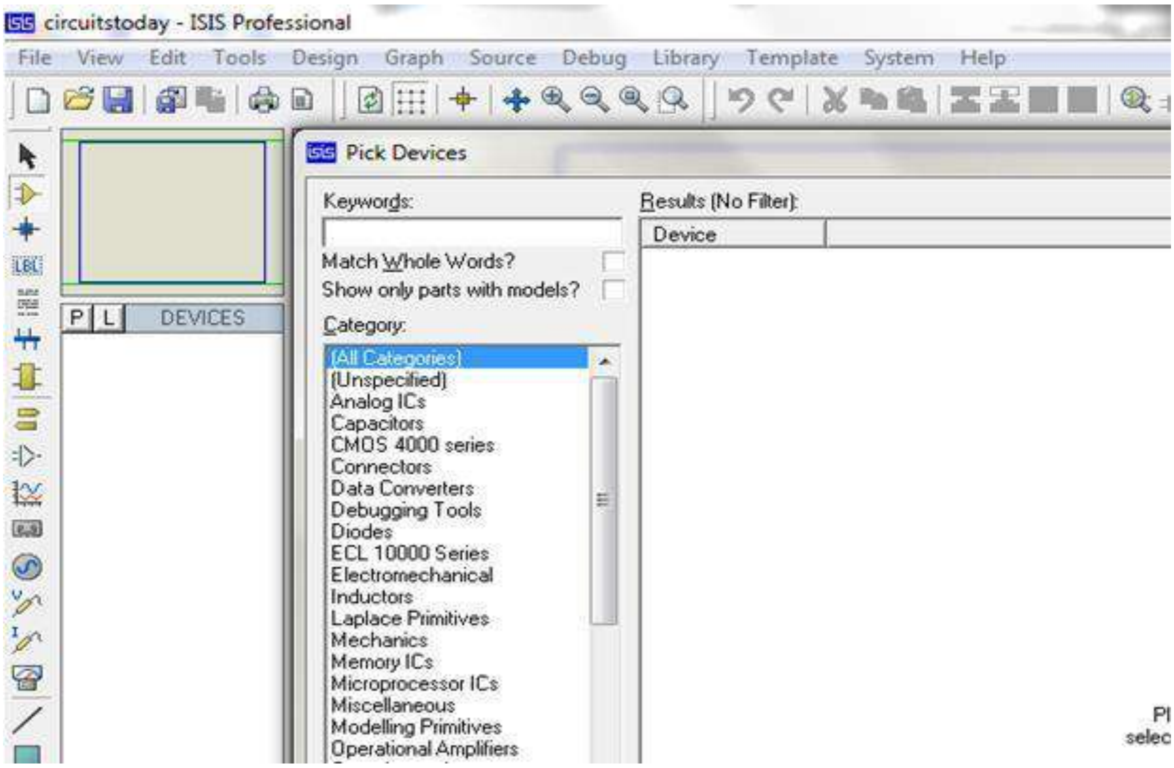

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

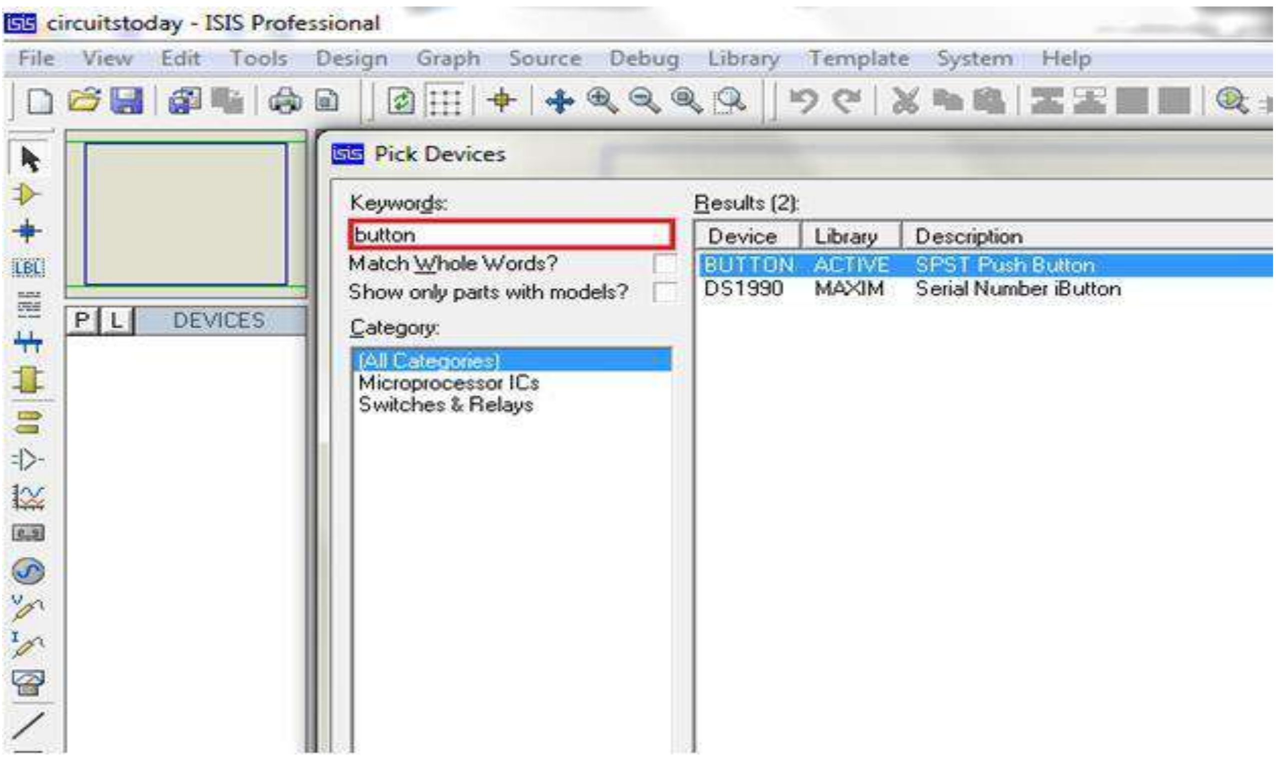

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

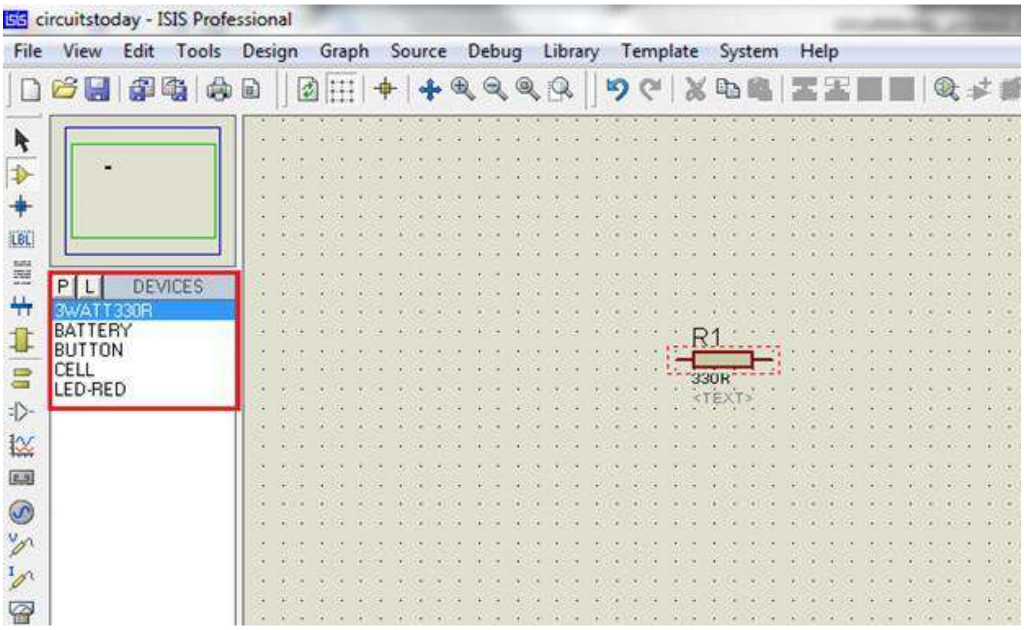

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

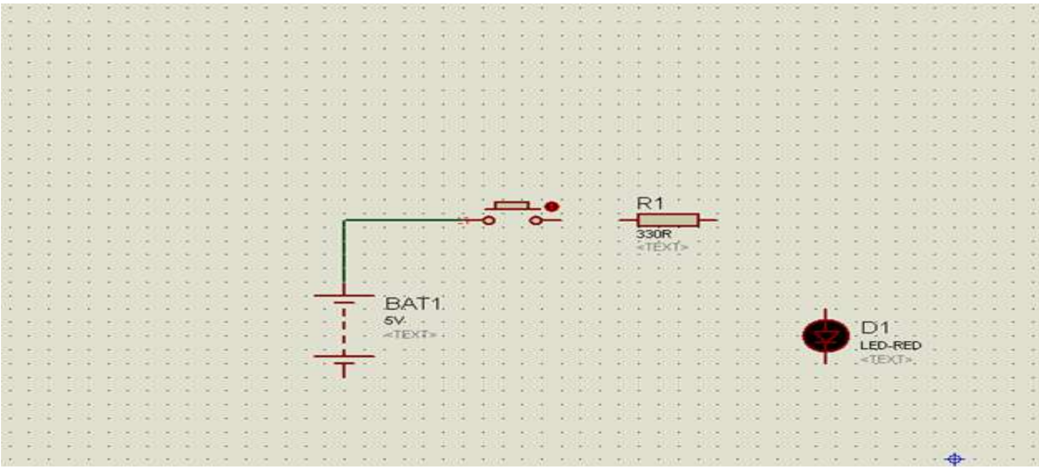

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

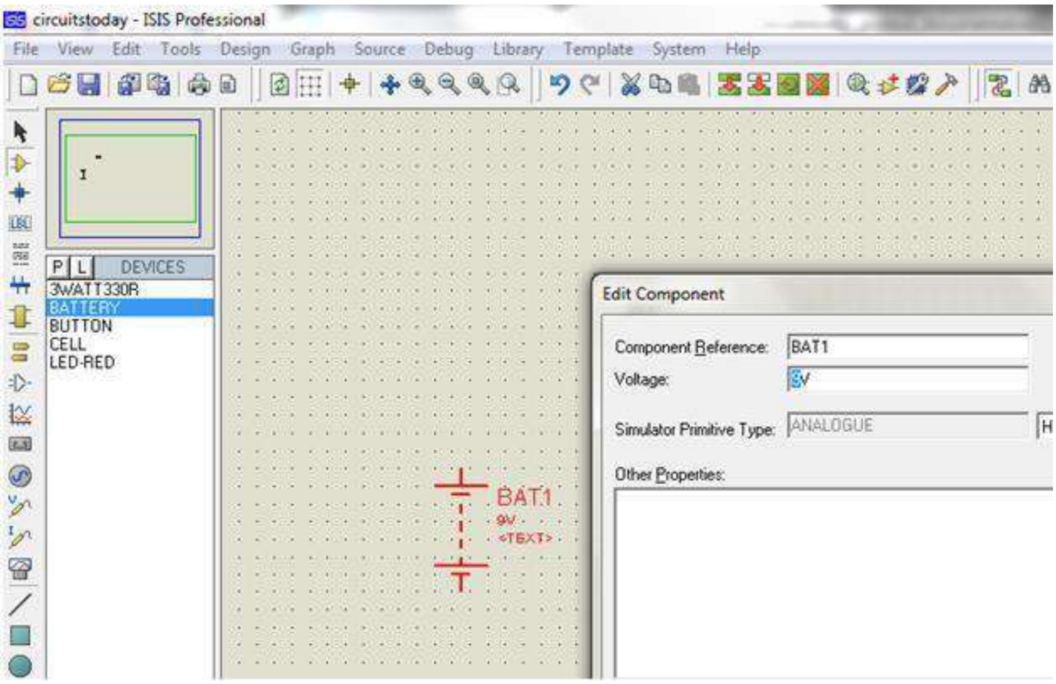

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

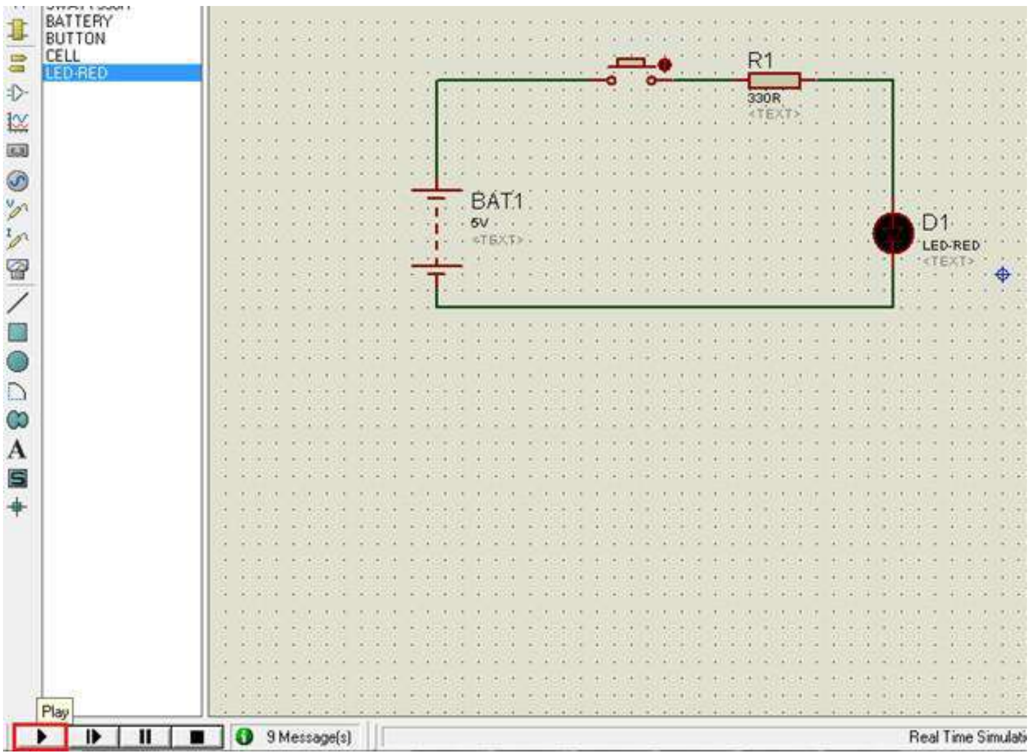

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

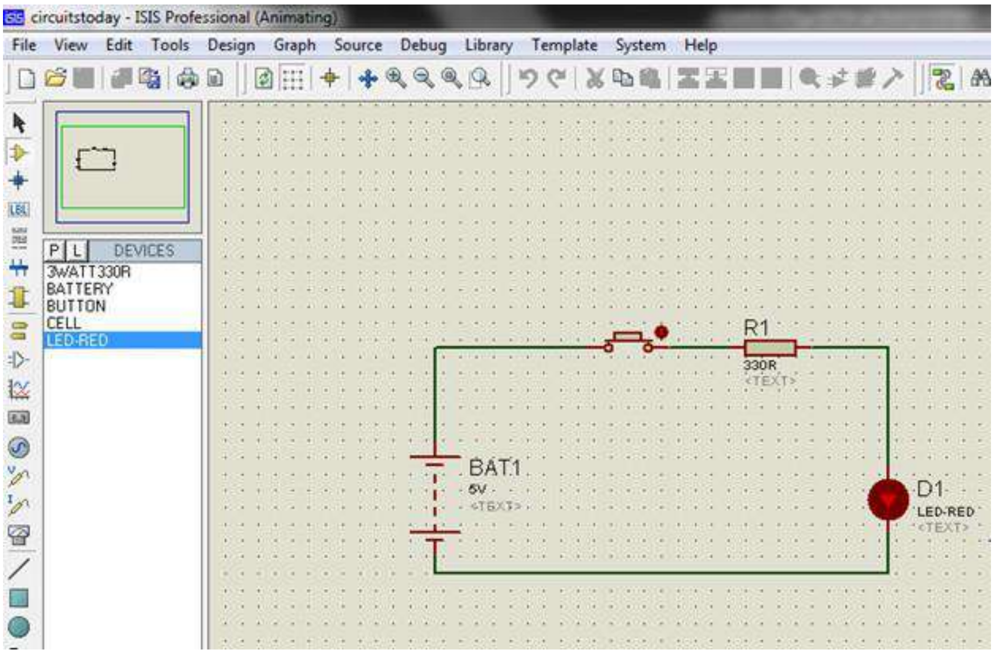

Fig . 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

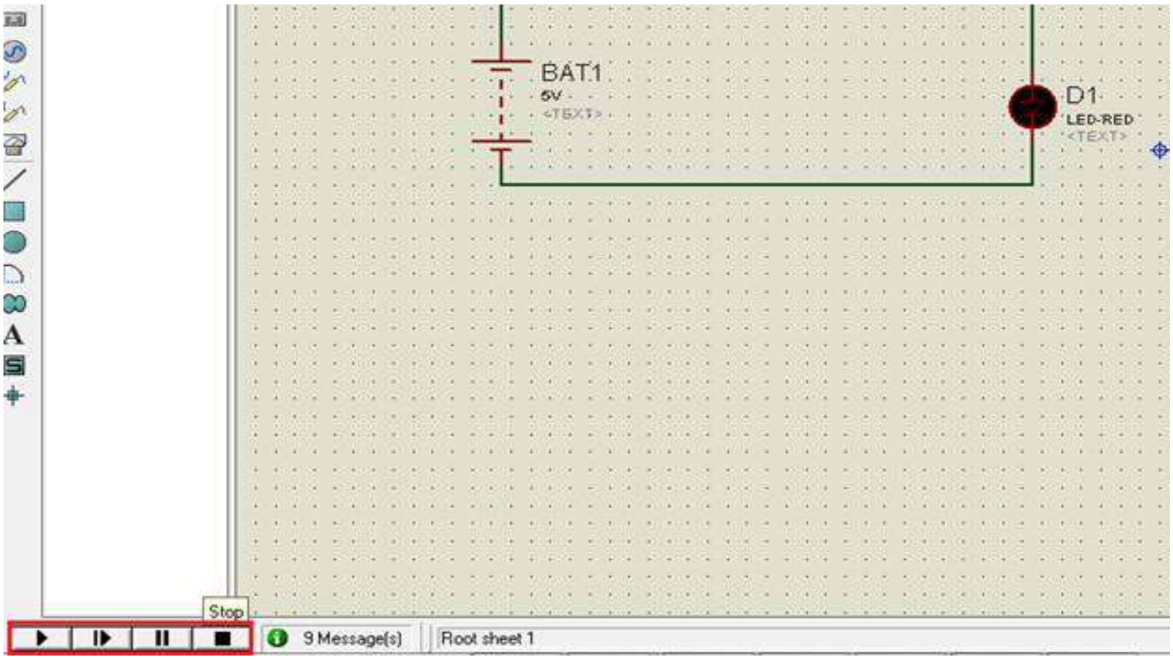

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.2.8 TELNET MOBILE APP:

Telnet is a client-server protocol, based on a reliable connection-oriented transport. Typically, this protocol is used to establish a connection to Transmission Control Protocol (TCP) port number 23, where a Telnet server application (telnetd) is listening. Telnet, however, predates TCP/IP and was originally run over Network Control Program (NCP) protocols.

Even though Telnet was an ad hoc protocol with no official definition until March 5, 1973,[3] the name actually referred to Teletype Over Network Protocol as the RFC 206 (NIC 7176) on Telnet makes the connection clear:[4]

The TELNET protocol is based upon the notion of a virtual teletype, employing a 7-bit ASCII character set. The primary function of a User TELNET, then, is to provide the means by which its users can 'hit' all the keys on that virtual teletype.[5]

Essentially, it used an 8-bit channel to exchange 7-bit ASCII data. Any byte with the high bit set was a special Telnet character. On March 5, 1973, a Telnet protocol standard was defined at UCLA[6] with the publication of two NIC documents: Telnet Protocol Specification, NIC 15372, and Telnet Option Specifications, NIC 15373.

Many extensions were made for Telnet because of its negotiable options protocol architecture. Some of these extensions have been adopted as Internet standards, IETF documents STD 27 through STD 32. Some extensions have been widely implemented and others are proposed standards on the IETF standards track (see below) Telnet is best understood in the context of a user with a simple terminal using the local Telnet program (known as the client program) to run a logon session on a remote computer where the user's communications needs are handled by a Telnet server program.

When Telnet was initially developed in 1969, most users of networked computers were in the computer departments of academic institutions, or at large private and government research facilities. In this environment, security was not nearly as much a concern as it became after the bandwidth explosion of the 1990s. The rise in the number of people with access to the Internet, and by extension the number of people attempting to hack other people's servers, made encrypted alternatives necessary.

3.3 DEFINE THE MODULES:

3.3.1 RFID (RADIO FREQUENCY IDENTIFICATION) MODULE

3.3.1.1 INTRODUCTION:

Radio Frequency Identification (RFID) technology has been attracting considerable attention with the expectation of improved supply chain visibility for both suppliers and retailers. It will also improve the consumer shopping experience by making it more likely that the products they want to purchase are available.

Recent announcements from some key retailers have brought the interest in RFID to the forefront. This guide is an attempt to familiarize the reader with RFID technology so that they can be asking the right questions when considering the technology.

3.3.1.2 WHAT IS RFID?

RFID (Radio Frequency Identification) is a method of identifying unique items using radio waves. Typical RFID systems are made up of 2 major components: readers and tags. The reader, sometimes called the interrogator, sends and receives RF data to and from the tag via antennas. A reader may have multiple antennas that are responsible for sending and receiving the radio waves. The tag, or transponder, is made up of the microchip that stores the data, an antenna, and a carrier to which the chip and antenna are mounted.

RFID technology is used today in many applications, including security and access control, transportation and supply chain tracking. It is a technology that works well for collecting multiple pieces of data on items for tracking and counting purposes in a cooperative environment.

3.3.1.3 THREE PRIMARY FREQUENCY BANDS HAVE BEEN ALLOCATED FOR RFID USE.

Low Frequency (125/134 KHz):

Most commonly used for access control and asset tracking.

Mid-Frequency (13.56 MHz):

Used where medium data rate and read ranges are required.

Ultra-High-Frequency (850 MHz to 950 MHz and 2.4 GHz to 2.5 GHz): offer the longest read ranges and high reading speeds.

Applications for RFID within the supply chain can be found at multiple frequencies and different RFID solutions may be required to meet the varying needs of the marketplace. Many of today's RFID technologies cannot reliably cover areas wider than 4 to 5 feet, making them unsuitable for wide openings that are the norm in manufacturing, distribution and stor receiving dock environments. Since UHF (Ultra High Frequency) can cover portals up to 9 feet wide it is gaining industry support as the choice bandwidth for inventory tracking applications including pallets and cases.

Technology providers are developing readers that work with multiple system protocols and frequencies so that users will be able to choose the RFID products that work best for their market and products.

3.3.1.4 RFID TAGS ARE FURTHER BROKEN DOWN INTO TWO CATEGORIES:

Active RFID Tags are battery powered. They broadcast a signal to the reader and can transmit over the greatest Distances (100+ feet). Typically, they can cost $4.00 - $20.00 or more and are used to track high value goods like vehicles and large containers of goods. Shipboard containers are a good example of an active RFID tag application

Passive RFID Tags do not contain a battery. Instead, they draw their power from the reader. The reader transmits a low power radio signal through its antenna to the tag, which in turn receives it through its own antenna to power the integrated circuit (chip). The tag will briefly converse with the reader for verification and the exchange of data. As a result, passive tags can transmit information over shorter distances (typically 10 feet or less) than active tags. They have a smaller memory capacity and are considerably lower in cost ($1.00 or less) making them ideal for tracking lower cost items

There are two basic types of chips available on RFID tags, Read-Only and **Read-Write**. Read only chips are programmed with unique information stored on them during the manufacturing process. The information on read-only chips can never be changed.
With Read-Write chips, the user can add information to the tag or write over existing information when the tag is within range of the reader. Read-Write chips are more expensive that Read Only chips. Another method used is something called a "WORM" chip (Write Once Read Many). It can be written once and then becomes "Read only" afterwards. This is a desirable format since companies will be able to write an EPC (electronic product code) to the tag when the product is produced and packaged.

3.3.1.5 HOW WILL RFID AFFECT OUR INDUSTRY?

RFID is expected to provide huge advantages to manufacturers by offering the tools to better plan production and respond more quickly to market demand. It will facilitate automation of inventory counts and speed shipping and receiving at the distribution level. For retailers, it will help to reduce stock-outs, enable product tracking and potentially reduce theft and streamline the POS function. RFID will also open other merchandising opportunities and help with the overall consumer buying experience.

Due to the current cost of the technology (both tags and infrastructure), the initial phase of adoption for retailers is at carton and pallet marking applications. The current technology being adopted for carton and pallet labelling is passive UHF tags (850 MHz – 950 MHz). As the cost of tags and readers comes down, a wider adoption at the item marking level will develop.
In order for RFID to grow quickly, it is important that standards be developed so that the technology providers are working toward a common goal of providing low cost and

compatible technologies. Not only will it drive down costs, but standards will also help users to reap the greatest benefit from their investment by providing value throughout the whole supply chain.

3.3.1.6 ORGANIZATIONS FOCUSED ON DEVELOPING RFID STANDARDS:

EPC global, Inc., a division of the Uniform Code Council, and its sponsors are working to standardize a new Electronic Product Code (EPC) as the next standard for identifying products. Their goal is not to replace existing bar code standards but to expand the information available down to unique identifiers for each marked item, and to enable more automatic reading. EPC utilizes the basic structure of the Global Trade Item Number (GTIN).

EPC global, Inc. has proposed open standards for tags and readers with the intention of bringing the costs down to a level where RFID tags could be applied to individual items. The work may lead to the creation of a new global Internet network that would allow companies to track items and enable end users to access the full benefits of RFID.

EPC global, Inc. has developed a specification for RFID tags to be used in the retail sector. The specification does not mandate what type of tag to be used but is intended to provide guidelines on data structure and how the tags should perform so that they can be used over a common platform.The specification requires that the chip contain an Electronic Product Code (EPC). The chip must be able to communicate according to an open standard and meet some minimum requirements so that it can be read by reading devices anywhere.

3.3.1.7 THE ELECTRONIC PRODUCT CODE (EPC):

The EPC is a number made up of a header and 3 sets of data as shown in the figure below. The header identifies the EPC version number – which will allow for different lengths or types of EPC later on. The second part of the number identifies the EPC manager – typically this would be the manufacturer of the item the EPC is attached to. The third part is called object class and refers to the exact type of product– most often the stock-keeping unit (SKU). The fourth series of numbers is the serial number that is unique to the item. (The second and third sets of data are similar in function to the numbers in UPC barcodes.)

ELECTRONIC PRODUCT CODE TYPE 1			
01.0000A89.00016F.000169DCO			
Header	EPC Manager	Object Class	Serial Number
8-bits	28-bits	24-bits	36-bits

Table 3.3.1.7 The Electronic Product Code (EPC)

Above is an example of a 96-bit EPC. It will allow sufficient capacity for 268 million companies. Each manufacturer will have the ability to create up to 16 million object classes with 68 billion serial numbers in each class. This should provide sufficient capacity to cover all products manufactured in the world for many years to come. As an interim step, the Auto-ID center is also proposing a 64-bit tag in order to minimize cost in the near term.

Potential Issues That Need Consideration When Choosing the Type of RFID and Method for Application to Your Products or Packaging.

Enthusiasm within the RFID industry has resulted in much hype about the technology over the past several years. As a result, it is important to embrace the technology with a bit of caution. The following are some of the issues that require close scrutiny when investigating RFID:

Tag Cost – This should not to be confused with chip cost. Although the goal is to bring the cost of the tag (chip and antenna) down to 5 cents, this goal is in the future since it both assumes manufacturing breakthroughs and is predicated on consumption in the billions of tags per year. Today, the cost is closer to "less than 50 cents" for a read/write solution in high (millions) volume. Ultimate tag cost will also be very much dependent on the type of chip required (read only versus read/write), size of the antenna needed and how it is packaged to meet a specific application.

Tag Size – Tag size is dependent on the read range desired. Although the chips are very tiny, they will not operate without being mounted to an antenna. The size of the antenna will determine the read distance performance of the tag so understanding the size of the antenna needed for the application is more important than the size of the chip alone.

Infrastructure Cost – Much focus appears to be placed on the tag cost since it is a recurring expenditure. Reader cost and infrastructure costs for implementing RFID must also be looked at very closely as well. Both the software systems requirements and physical environment, in which RFID is intended to be used, are critical to the ultimate performance of a system and may require changes to accommodate using it effectively. As an example, RFID chips cannot be read through metal objects. Other forms of electromagnetic interference may also impede performance of he technology and require changes to the physical environment where RFID will be used. The number and types of readers will also be a major expenditure depending on your application.

Read Distances – Read distances for RFID are very much dependent on the frequency chosen for the application. Tag orientation also affects the read range as the range diminishes as the tag is rotated from being perpendicular to the path to the reader. Reading reliability is quite good when labels are alone in a reader field like cases on a conveyor line, but less certain when the labels are randomly oriented as with labelled cases on a skid. The antenna size (both on the tag and the readers) will also be a determining factor. Hand held readers are not capable of using as much power as stationary readers and as result provide shorter read distances.

Government Regulation – Governments around the world regulate the use of the frequency spectrum. Different countries have already assigned certain parts of the spectrum for other uses and as a result, there is virtually no part of the spectrum that is available everywhere in the world for use by RFID. This means that a RFID tag may not work in all countries. As an example if you choose the Ultra High Frequency (UHF) frequency that Operates at 915MHz in the U.S. and you ship your product to Europe, they may not be able to be read it since Europe operates in the UHF spectrum at 869 MHz. This is an important consideration when operating in a global environment.

Anti-Collision – This is an important feature of RFID chips/readers since it will allow multiple tags to be read while grouped in one reader field. It is not available on all RFID tags but is an important feature if you are planning to use RFID for inventory counts, shipping and receiving where multiple tags need to be read at the same time.

Privacy Issues – Consumer groups have expressed concern over the potential (real or imagined) privacy invasion that might result with widespread RFID item marking. These groups are pushing for legislation that will require manufacturers to advise consumers that the products contain RFID devices and must provide a means so that the devices can be disabled at point of purchase. These issues are most prevalent at the item marking level and will have little impact on the implementation of carton and pallet labelling.

3.3.2 ESP8266 WIFI MODULE

3.3.2.1 INTRODUCTION

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

3.3.2.2 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I^2C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I^2S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

3.3.2.3 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring
- Natural Language-based voice assistants.

3.3.2.4 STRUCTURE AND CONFIGURATION:

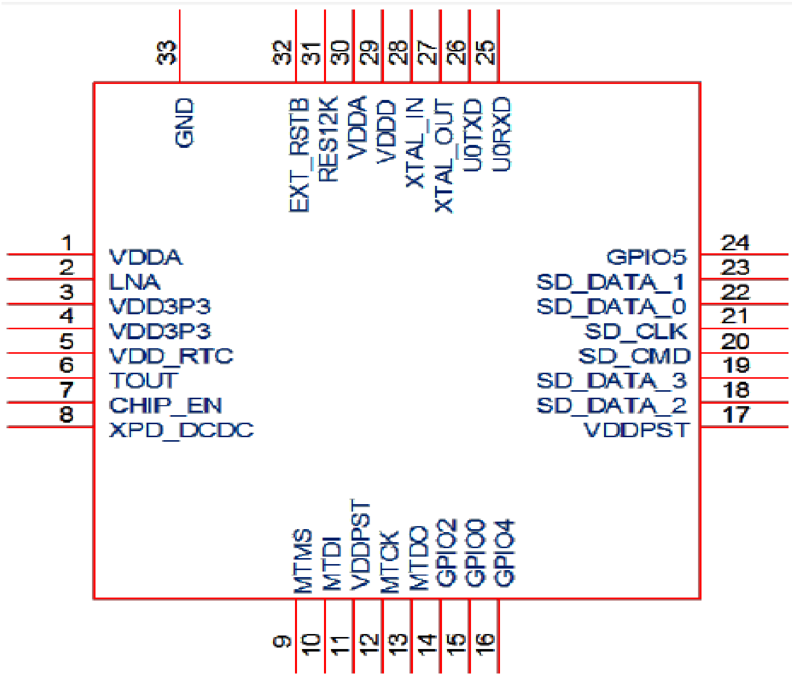

Fig.3.3.2.4 Structure and configuration

3.4 MODULE FUNCTIONALITIES:

3.4.1 RFID MODULE

3.4.1.1 Functionality of Radio Frequency Identification: The Transponder

The RFID transmitter is called a **transponder**, sometimes also a tag or simply a radio tag. It consists of an antenna (often a coil), a computer chip and a carrier material or housing. The chip is equipped with analog and digital circuits, and it also has a memory that can sometimes be written to several times. In some cases, the transponder is a semiconductor chip. Tags differ in several factors. Among other things, they have different sizes, lifetimes, clock frequencies, memory sizes or ranges.

The chips have a unique identity in the form of a **serial number** so that they can be clearly identified. The identity cannot be changed, which can prevent abuse. If it is a rewritable memory, the identity can be extended continuously and fully automatically by additional information (Auto-ID). In this respect, for example, previous locations of goods are interesting. RFID technology is also essential when it comes to choosing the right order picking procedure.

Tags usually do not have their **own energy supply**. In this case, the transponder is called passive. The reader delivers the necessary energy for data transmission to the tag. The antenna must be a coil that charges a capacitor by induction. Exceptions called active transponders have their own battery. Their use is worth it if the tag is to have a long range and various additional functions.

Transponders can be attached to or in the object to be marked. For example, they are stuck on (e.g. on pallets or cartons), embedded directly in objects (e.g. in screws, shoe soles, banknotes or documents) and even implanted in living beings (in pets behind the ear, in people's hands). Successful research and development have made it possible to use temperature-resistant transponders since 2006. Since then, they can even be cast in metals, which has various advantages: the risk of damage, wear and tear or loss is minimised and they are also invisible.

3.4.1.2 Functionality of Radio Frequency Identification: The Reader

A reader that must be in close range reads the tag's data using an alternating electromagnetic field or high-frequency radio waves. The receiver is also known as a **reader**. In addition to purely readout readers, there are also readers that can **write new information to the transponder's memory**. The transmitted radio waves are influenced by the tag because it reflects part of the energy. First, the unique identity and any other requested information are transmitted. In addition, different things can be stored.

The reader is a **combination of hardware and specially programmed software**. The **more range a reader should have, the more energy in the form of electrical current must be used for its use**. Typical ranges are between a few centimeters and a few meters. The smaller the range, the more precisely selected transponders can be addressed.

A longer range can be chosen, for example, if two objects should not be too close together. This is the case, for example, with containers containing flammable liquids and spark spraying equipment. Readers for radio frequency identification are available as handheld versions for manual operation, but can also take on various other forms, for example in the form of a gate through which goods flows.

3.4.2 ESP8266 WIFI MODULE

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost-effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution!

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

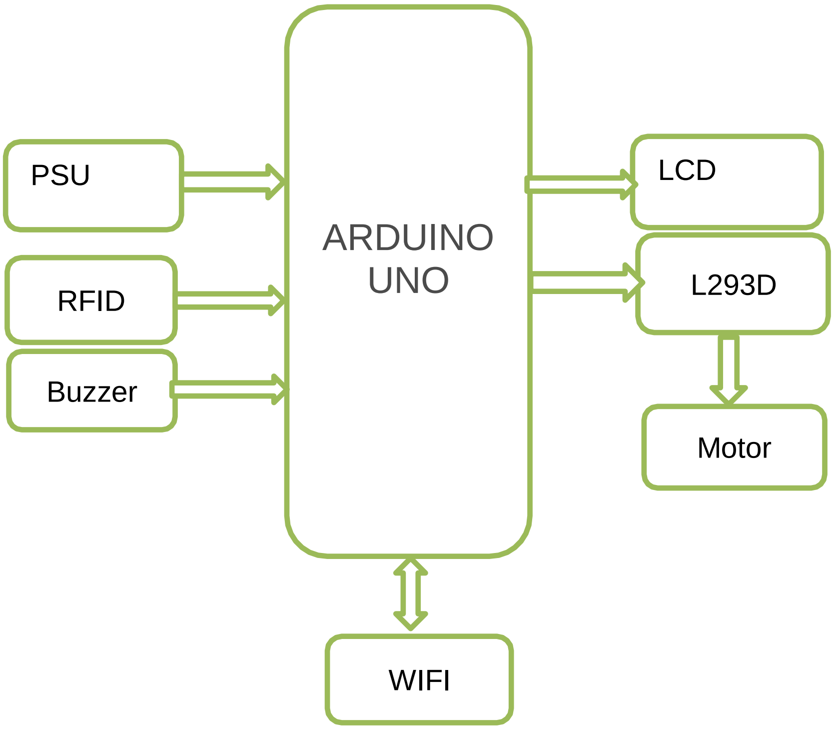

Fig.4.1: Block diagram of the project

4.2 FLOW CHART

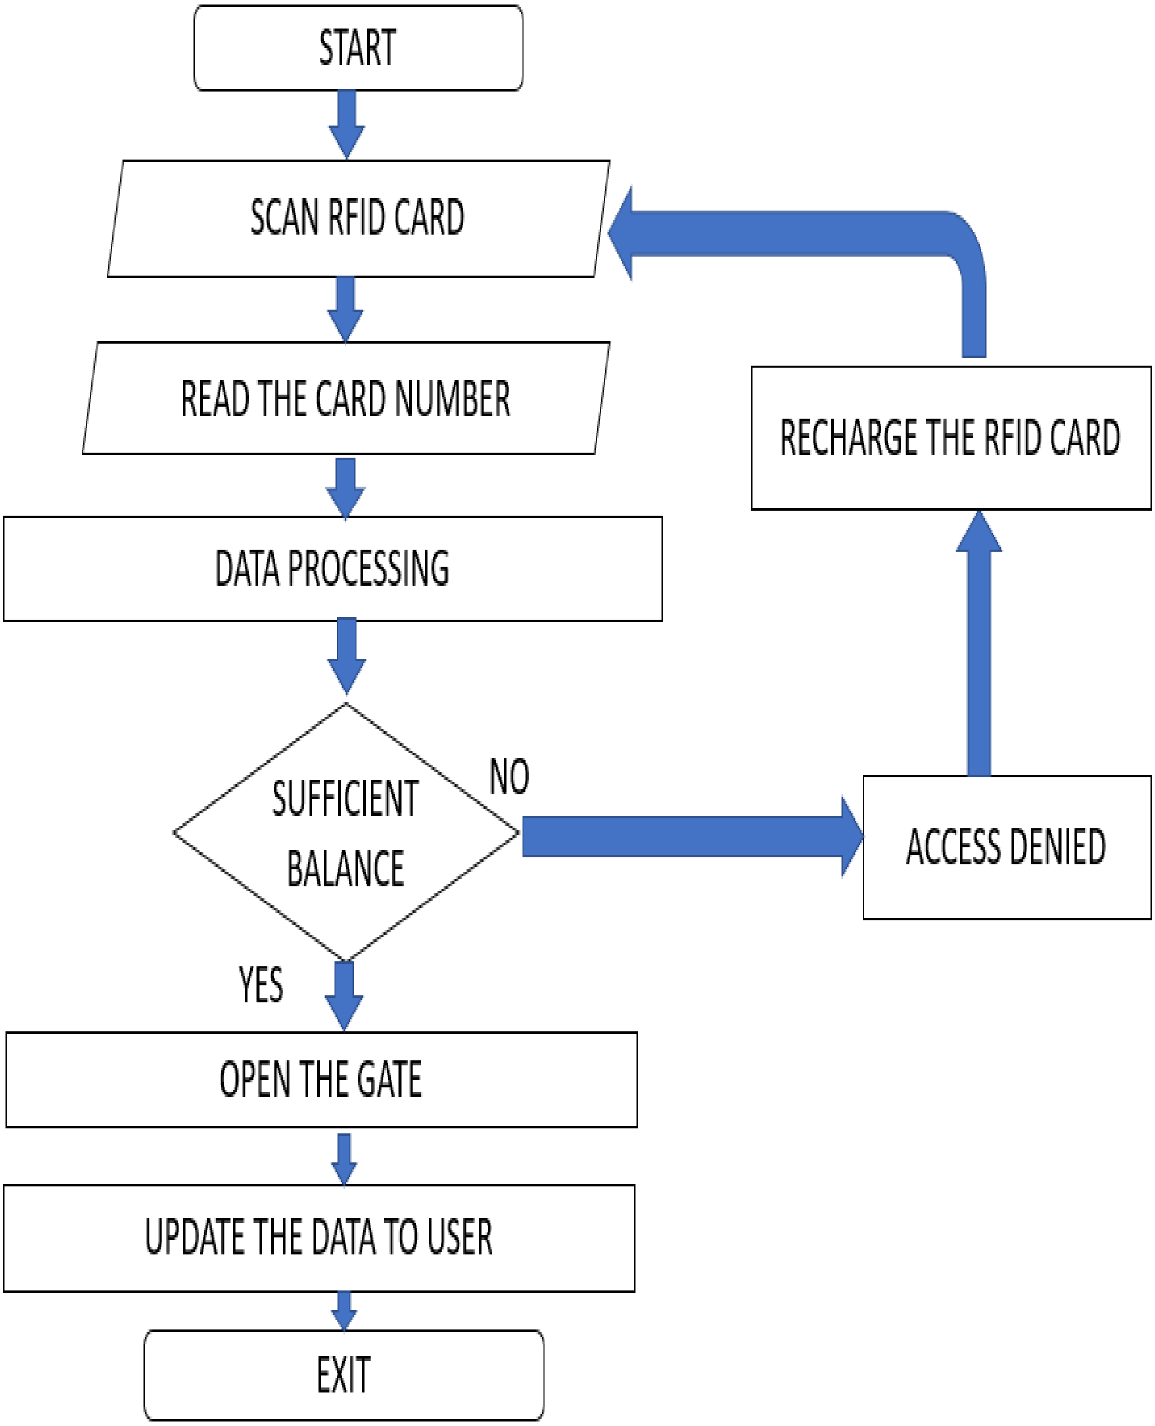

Fig.4.2 Flow Chart

4.3 IMPLEMENTATION STAGES

Stage-1: First on lcd we will get a message displaying waiting for link that indicates the wifi is not yet connected.

Fig.4.3.1 WAITING FOR LINK

Stage-2: In Mobile Telnet App, we will get a message like welcome when the wifi is connected to ESP8266 WIFI Module.

Fig.4.3.2 WELCOME

Stage-3: After the wifi is connected,we will get a message on LCD displaying Please Scan UR Card.

Fig.4.3.3 Please Scan UR Card

Stage-4: When we scan the card, if sufficient amount is available, we will get a message access granted for person and remaining balance will be displayed on LCD.

Fig.4.3.4 Access Granted

Stage-5: When we scan the card, if sufficient amount is not available, we will get a message access denied for person and balance will be displayed on LCD.

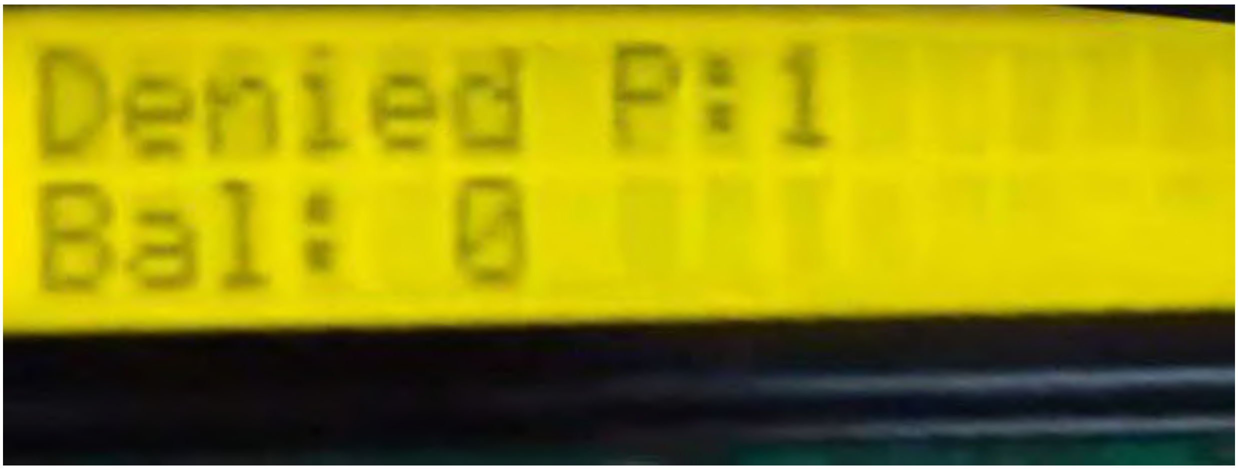

Fig.4.3.5 Access Denied

Stage-6: When card is recharged, amount will be added to card and display's person recharge done on LCD Screen.

Fig.4.3.6 Recharge Done

4.5 RESULTS

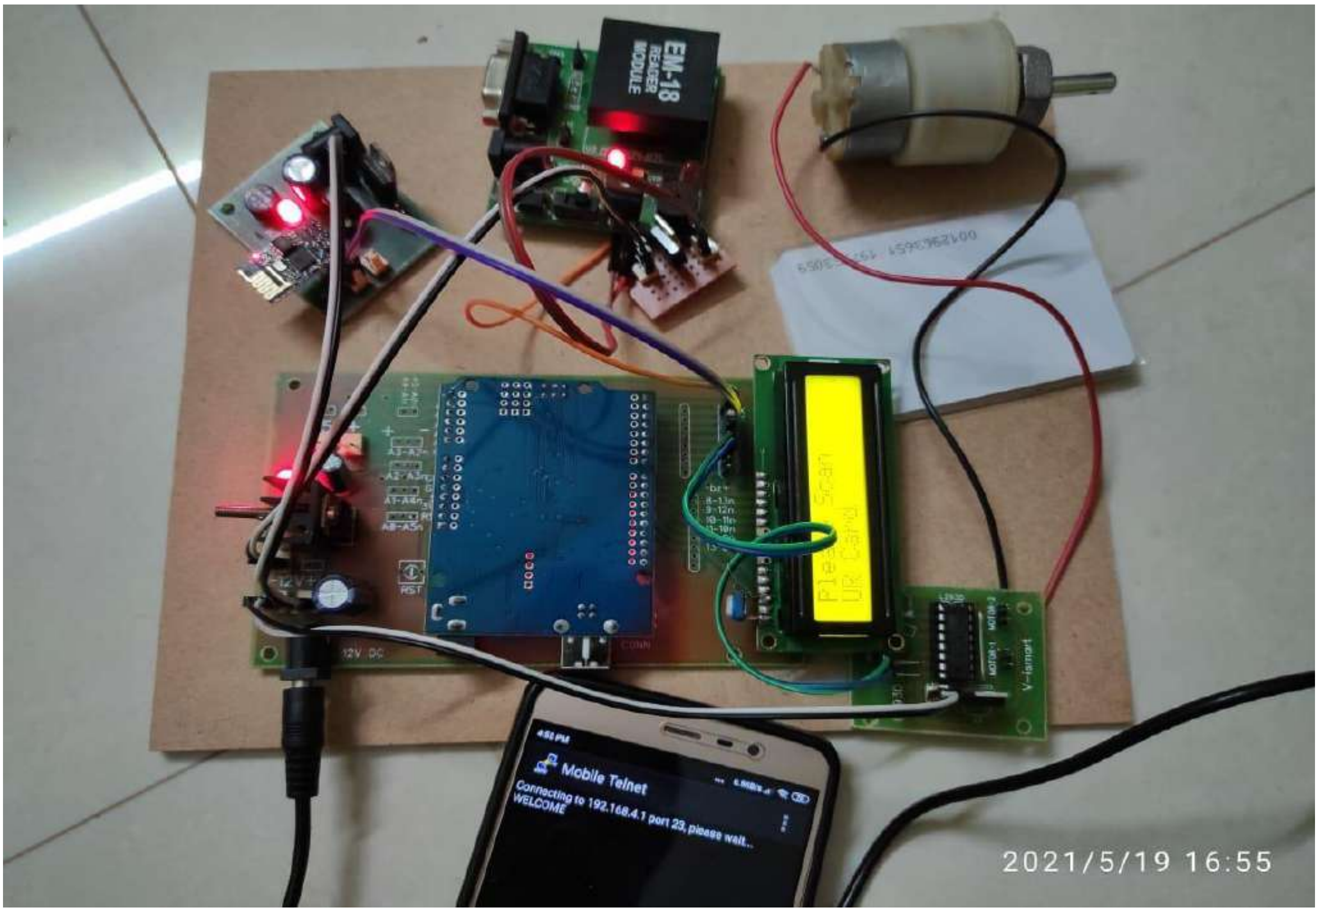

Fig.4.5 Final Output

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Today, governments want to take these ETC solutions one step further, with more sophisticated systems that not only eliminate the need for toll booths, but also enable governments to charge for road usage based on a variety of factors, including time of day, vehicle weight, distance driven, type of road and the pollution produced by the vehicle. These new systems enable governments to implement programs that charge tolls that better reflect the vehicle’s impact on road infrastructure, traffic and the environment, helping them:

- Reduce congestion during peak periods of the day by lowering tolls during low-traffic periods;
- Reduce congestion in specific areas by lowering tolls on specific roads;
- Encourage individuals and companies to purchase low-carbon-emission vehicles by charging higher tolls for vehicles that pollute more; and
- Transition the source of revenue financing road infrastructure from fuel-based taxes to toll on road usage, which will include any type of vehicle (from electric vehicles with small tolls to high-gas-consumption vehicles with high tolls).

Security: IoT is a combination of physical objects (“things”), sensors, embedded software and keeps a goal of effective connectivity and faithful data exchange. The current graphs imply that IoT market growing at remarkable rate. However, some of these devices suffer from limited memory, power consumption and processing power. These issues may cause IoT to become penetrable and hence security is at utmost priority to IoT domain.

As stated in a 2015 report by Hewlett-Packard on IoT research [3]:
1. Per 100, 70 devices still use un-encrypted network services
2. Per 100, 90 devices collected at least one piece of personally identifiable information (via device, cloud or mobile app)
3. Per 100, 70 devices (with cloud and mobile app components) enabled an attacker to identify valid user accounts through enumeration.

4. 80% of devices (with cloud and mobile app components) failed to require passwords of sufficient complexity

5.Behind every 10 device every 6 devices user interfaces (UI) were vulnerable

Following are the vulnerabilities of the IoT as per The Open Web Application Security Project (OWASP)

1) Insufficient protection compositions.

2) Dubiously secured Software/Firmware

3) Doubtful Network Services

4) Doubtful Web Interface

5) Worst Physical Security

6) Doubtful Cloud Interface

7) Doubtful Mobile Interface

8) Privacy Concerns

9) Doubtful Authentication/Authorization

10) Inadequate Transport Encryption Ongoing approaches to secure IoT have attempted to put a grip on communication protocol-based mechanisms, such as encryption for data-at-rest or in-transit.

But this itself is doubtful if the respective endpoints themselves are capable of being modified either by local access or remote connections. Gartner claims that by year 2020 more than 25% of identified attacks in a particular company will be on IoT devices or systems, even though IoT will only contribute to less than 10% of IT security budgets.

The testing methods of our project that is iot based toll booth manager system The requirements for testing this project is mobile app, wifi connection. First on lcd we will get a message displaying waiting for link that indicates the wifi is not yet connected. In Mobile Telnet App, we will get a message like welcome when the wifi is connected to ESP8266 WIFI Module.After the wifi is connected, we will get a message on LCD displaying Please Scan UR Card.When we scan the card, if sufficient amount is available, we will get a message access granted for person and remaining balance will be displayed on LCD. When we scan the card, if sufficient amount is not available, we will get a message access denied for person and balance will be displayed on LCD. When card is recharged, amount will be added to card and display's person recharge done on LCD Screen.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

- The sole purpose of this project was to promote cashless transactions under Digital India initialization. Smooth trafficking at the toll plaza site corruption less transactions as well as reducing air pollution, stagnant long queue traffic will be reduced.

- The system has successfully overcome the drawbacks of the existing system by reducing the man power at the toll booth. It provides easy way of toll collection and maintenance of the information in a reliable and efficient manner.

- We aim to show that Toll booth can be completely managed by „Internet of Things" technology with the help of RFID reader. We present a related literature and market survey to show need of such design. We now discuss the potential directions for improving the design presented in this paper.

- **High data rates**: While the data rates of transmission and reception of data by Wi-Fi module and RFID reader are sufficient for our target application scenarios, we believe that with better access to the hardware functionality of RFID sensors, one can achieve higher data rates.

6.2 FUTURE ENHANCEMENT

- We can add GPS to our project to know live location, if anyone skips the toll booth.

- Voice System can be added in this project to indicate if the card is invalid or has insufficient balance.

- Cloud data can be handled using android application. Person will be granted permissions to register, recharge and renew toll account with the help of android application. Moreover, security system needs to be integrated within this module. Thus, when module is implemented on a greater level, it will result in cost reduction and increase in reliability.

PUBLICATION

Submitted Paper in the Conference ICISECT - 21 with Paper ID (ICISECT21-0003) and got Acceptance for the Paper.

APPENDICES

This project shows, that the functionalities of the Toll booth can be completely managed using the 'Internet of Things' concept based on the RFID technology. In reference to survey of annual toll collection on toll plazas, conducted by government of Maharashtra in year 2010, we examine and report on the conditions of total time spent, for money transaction on toll plaza, by a particular vehicle and further evaluate total fuel wastage as well as human errors involvement, while doing so. Finally, to provide an optimal solution, we consent with the idea of making toll plazas completely automated, with assistance of IoT technology.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "IOT BASED MONITORING SYSTEM FOR COMATOSE PATIENT USING ARDUINO" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1) **Mr. D. BHAVISH (17K81A04J8)**
2) **Mr. MARTHA VAMSHI KRISHNA(17K81A04M5)**
3) **Mr. PAMPARI UMESH CHANDRA(17K81A04N5)**

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr B. HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr A. Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our project internal guide, **Mr. P. Pavan Kumar, Assistant Professor,** Department of ECE and our class project coordinator **Ms. P. Pushpa**, **Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr Maalyadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

Coma is a state of unconsciousness where the patient fails to respond. These patients need utmost care and 24*7 observations. This paper presents a continuous monitoring and recording of patient data without human intervention. If there is any sudden changes occur in the normal range of body parameters such as body temp falls or rise, blood pressure (B. P.) increases or decreases causing high or low B.P. where both are not stable conditions for better health, then it has facility to automatically alert the medical person. The development sensor identifies the patient development and furthermore produces an alarm message to the clinical individual.

One main area of research that has seen an adoption of the technology is the healthcare sector. The people in need of healthcare services find it very expensive this is particularly truein developing countries. As a result, this project is an attempt to solve a healthcare problem currently society is facing. The main objective of the project was to design a remote healthcare system. It's comprised of two main parts. The first part being, detection of patient's vitals using sensors, second for sending data to cloud storage. Remote viewing of the data enables a doctor or guardian to monitor a patient's health progress away from hospital premises. The Internet of Things (IoT) concepts have been widely used to interconnect the available medical resources and offer smart, reliable, and effective health care service to the patients. Health monitoring for coma living is one of the paradigms that can use the IoT advantages to improve the patient's lifestyle.

CHAPTER 1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Health is a fundamental right of humans. Large number of people across the world are dying daily due to diseases. One major reason for this large number of deaths is the absence of timely and effective assistance. Continuous monitoring of coma patients can save lives considerably through the timely check-up. So, it very much needed that a system would be developed which would monitor the patients continuously and effectively.

The monitoring system is based on wireless sensor nodes. Failure of the node is mainly distributed to the system in the form of IoT, which still makes the system intentional. The use of the IoT protocol allows the integration of third - party application and devices. Advances in telecommunication and IT sector have given birth to Internet of Things (IoT). In today's world, the effective use of IoT technologies provided convenience to the physicians as well as patients, as they can be applied to various medical areas (such as real-time monitoring, patient information management, and healthcare management). The body sensor network (BSN) technology is one from the core technologies of IoT developments in healthcare system, in which a patient can be monitored by collection of tiny powered and lightweight wireless sensor nodes. To grab the benefit of emerged IoT in the field of healthcare, the consumers, physicians and patients need to think of some innovative and reliable methods. Due to the emergence of help of IoT's potential these people now can collect real-time raw data from unlimited number of patients for a continuous period of time through smart devices connected on an interconnected network. In last decades health issues are raising day to day life at very high speed every day. One of the major health issues is a coma. Coma is a deep state of persistent sleep in which a person cannot be awakened; he fails to respond normally too painful stimuli, light, or sound; lacks a normal wake-sleep cycle; and does not initiate voluntary actions. Comatose are not able to knowingly feel, speak or move. Comas can be caused by various things such as- a severe injury to the head that hurts the brain, infections in the brain, brain damage due to lack of oxygen for too long, taking too much medicine (overdose) or other drugs, may be due to chemical imbalances in the body from other illnesses. Sometimes the person in a coma state can respond to the external environment by voluntary movements such as he may open his eyes in response to external impulse. Even though an individual in a coma state appears normal but they could not respond to the external commands. Since the physical motion of persistent vegetative state individual are rare, there is a need for regular attention and care. Technology will always make things simpler and the human life much easier to survive. It affects the many zones of life; one of the important regions is medical field. Internet of Medical Things (IoMT) is an extension of the internet of things into the healthcare domain. Then IoMT is an ecosystem of interconnected sensors, wearable devices, medical devices, and clinical systems and applications that can connect to health care information technology systems using networking technologies.

It enables various healthcare applications to reduce healthcare costs, provide timely medical responses, and improves the quality of medical treatment. There are many applications of IoMT but one of the popular Example of IoMT is remote patient monitoring (RPM). The comatose health history will be perceived and studied at any time at any place and by doctor with the help of wireless technology. With the help of technology, we can permanently store patient health information on the server. This paper delivers a health status assisting system that identifies human body parameters such as blood pressure, body temperature, body movement and more information on the IoT server through Thing Speak. In emergency situations, this system automatically sent an alert SMS to the patient's caregivers, doctors if any strange data detected. Various sensors such as BP, temperature, acceleration and ultrasonic sensor, are used for a few seconds to collect body health parameter information for the proper treatment.

1.2 OBJECTIVES OF THE STUDY:

A health observing system comprises of variety of sensors connected to the patient and they communicate that data via the processing Things speak. In this project, ARDUINO is acts as a data junction node as well as a processor. The patient and doctor smart phone or computers are used as a monitoring device. The sensors are used to measure the health parameters of patient after these parameters are acts as readings and finally converted into signals. These signals are provided for processing to ARDUINO. Then ARDUINO displays the information on a monitor and also stores the information over the cloud with the help of IoT. This information can be accessed by the doctor on his phone/computer and get the notification. Also there is facility provided to send an alert message to the doctor or patient care giver if any abnormal data is detected. The workflow of the project is as- the sensors value are read and displayed on the monitor and stored in the cloud for future use. The proposed health monitoring system consists of different sensors which are divided into two categories. One is used for monitoring vitals of the comatose and second is used for detecting any physical changes occur in the comatose. Here, temperature and blood pressure are the two vitals recorded and monitored to understand health status of a comatose. The other sensors is PIR sensor which are used for detecting any physical changes that occurring comatose. These sign switch gives data are recorded and checked consistently to comprehend the body working. In the event that the arrangements of these detected signs which are outside ordinary ranges normally suggest the requirement for some consideration or conceivable departure to a more elevated level of treatment during which we alert the doctor.

1.3 SCOPE OF THE STUDY:

- IOT Monitoring proves really helpful when we need to monitor & record and keep track of changes in the health parameters of the patient over a period of time. So with the IOT health monitoring, we can have the database of these changes in the health parameters.
- Patient health parameter data is stored over the cloud. So it is more beneficial than maintaining the records on printed papers kept in the files. Or even the digital records which are kept in a particular computer or laptop or memory device like a pen- drive. Because there are chances that these devices can get corrupt and data might be lost. Whereas, in the case of IOT, cloud storage is more reliable and does have minimal chances of data loss.
- This system is powered by the Arduino-UNO it includes a blood pressure monitoring unit and an ultrasonic sensor to check urine, temperature sensor, motion sensor, and an LCD display.
- When we turn the system on, it gets connected to the website using WIFI, System monitor shows four signs namely heart rate, temperature, humidity, and urine output.
- In case if the patient regains consciousness and attempts to move, the sensor will detect the motion and update it over IOT and LCD. In this way, our system monitors the comatose patients.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino UNO
- Ultrasonic (US) sensor
- Liquid Cristal Display
- WIFI Module
- DHT11–Temperature and Humidity Sensor
- Blood Pressure Sensor
- PIR Sensor

1.4.2 SOFTWARE REQUIREMENT:

- ARDUINO IDE
- PROTEUS SOFTWARE

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro- controller; we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software.

Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way.

We calculated and got all health vital information of coma patient's and displayed on LCD and also updated on Server. So, doctor can check and track the patient's health status from any- where in the world

CHAPTER-2
LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

IoT based monitoring system for comatose patients using Arduino provides better healthcare service by improving the availability and transparency of the health data. However, it also poses serious threats to data security and privacy. This project aim to developing a system which gives body temperature and blood pressure using LM35 and blood pressure sensor respectively. These sensors interfaced with controller Arduino Uno board. Wireless data transmission done by Arduino through Wi-Fi module. This project proposes an internet so things (IOT) based real time patient monitoring system that is able to guarantee the integrity of the real time parameters.

The internet of things (IOT) has already changed the world and it influences both the way we live and work. The internet is gradually becoming a necessary and important tool in our everyday lives. The number of nodes connected to internet are increasing day by day and this burst amount of connections give rise to an emerging technology named as internet of things (IOT). It is consisting of smart devices connected to internet and embedded with processors and sensors. These sensors collect the data and send through Wi-Fi module where collected data is analyzed. This system also can be expanded by adding more e-health sensors to collect various health parameters. Research on reducing the jitter delay and eliminating the noise signal are also required to improve the performance of the proposed system. High blood pressure is a serious condition that can cause to damage heart and other organs and increase the risk of heart attack and stroke. It would be helpful to have a convenient way to automatically take many blood pressure readings throughout the day and over time to see how often one's blood pressure is high. temperature sensor is used for measurement of body temperature. Sensor is put in touch with body and it senses body temperature. It is calibrated linearly in Celsius. It has low self-heating capability.

2.2 REVIEW OF RELATED LITERATURE:

In the existing system, we use active network technology to network various sensors to a Patient. Various critical parameters are continuously monitored via sensors and reported to the

Doctors or Nurses in attendance for timely response in case of critical situations. The sensors are attached to the body of the patients without causing any discomfort to them. In this project we monitor the important physical parameters like body temperature, ECG, heart beat rate and blood pressure using the sensors which are readily available. Thus, the analog values that are sensed by the different sensors are then given to a microcontroller attached to it. The microcontroller processes these analog signal values of health parameters separately and converts it to digital values using ADC converter. Now, the digitalized values from more than one microcontroller are sent to the Central PMS. Each of the sensors attached microcontroller with a transceiver will act as a module which has its own unique ID. Each module transmits the data wirelessly to the gateway attached to the PC of the Central PMS.

The gateway is attached to the PC i.e. Central PMS which is situated in the medical center, is capable for selecting different patient IDs and allowing the gateway to receive different physical parameter values the patient specified by the ID. The software designed using Graphical User Interface (GUI) can operate on different physical parameters of each patient, consecutively with a specified time interval for each patient. The Existing framework gives the solution for just three well being parameters of the trance like state patients. This existing work utilizes the results of heartbeat sensor, Temperature sensor and body development sensor for detecting the health parameters suchas heartbeat rate, internal heat level, patient's body temperature and movements of the trance like state patients. In the event there is discover any variations from the results of health parameters of the patient suddenly the microcontroller sends an alarm message through the GSM device. It sends that information to the mobile number of the patients in charge person and guardian. Further- more in this framework LCD (Liquid Crystal Display) used to show the readings which are taken from the sensors. It has the accompanying drawbacks, for example, utilizing constrained detecting parameters, one of the chances that any irregular condition the message alert send through GSM module to the cell phone as SMS and also it showed in LCD board. These drawbacks could be overwhelmed by the proposed framework.

2.3 CONCLUSION ON REVIEWS:

To overcome all the problems in the existing system in monitoring health of the coma patients in the proposed system we introduced IoT based health monitoring system for coma patient's using Arduino.

Proposed system, consists of mainly two units- in the first unit, we connect all the sensors to coma patient's body and get all the vital health information from the sensors and Arduino UNO micro-controller will calculates all those information.

In the second unit, after calculating all the information by the Arduino UNO. It will display's all the health status of coma patients on the LCD and also updates all information in the Sever.

So, doctor can check the patient's health status from any part of the world.

- Blood Pressure Sensor

3.4 ARDUINO UNO

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Table 3.4: Atmega328 specifications

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency (Clock Speed)	16 MHz

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read Analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloudand many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.

3.4.1 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

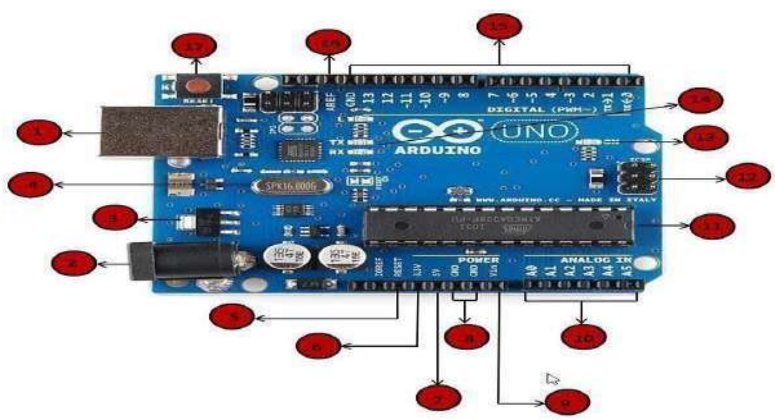

Fig 3.4.1 Board Description

TABLE 3.4.1 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit.

	• Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The

	TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.4.2 PIN DESCRIPTION OF ATMEGA328:

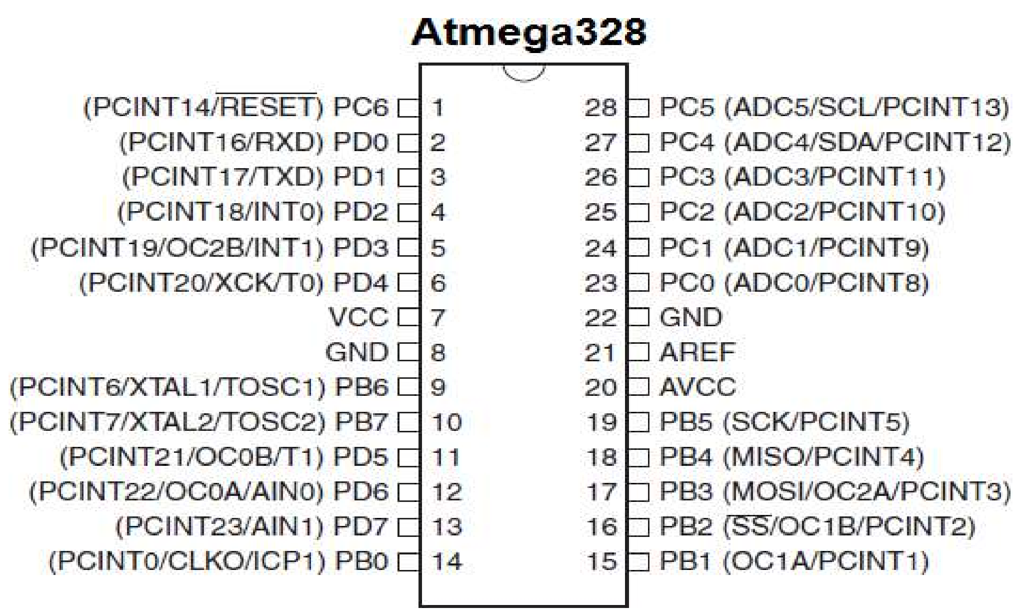

Fig 3.4.2 Pin description pf ATMEGA328

3.4.3 ADVANTAGES OF ARDUINO:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

3.4.4 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.5 WI-FI MODULE:

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IoT devices. This will walk you through setting up ESP8266 Wi-fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We'll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

3.5.1 What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

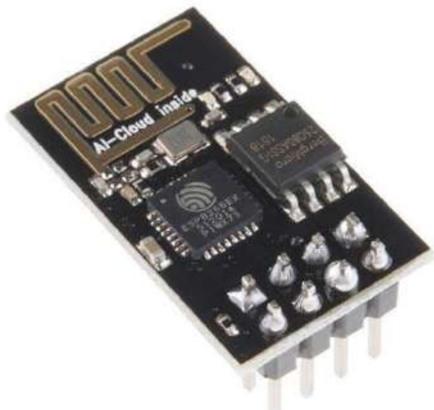

Fig 3.5.1 ESP8266 Wi-Fi Module

3.5.2 FEATURES OF ESP8266

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

3.5.3 STRUCTURE AND PIN CONFIGURATION

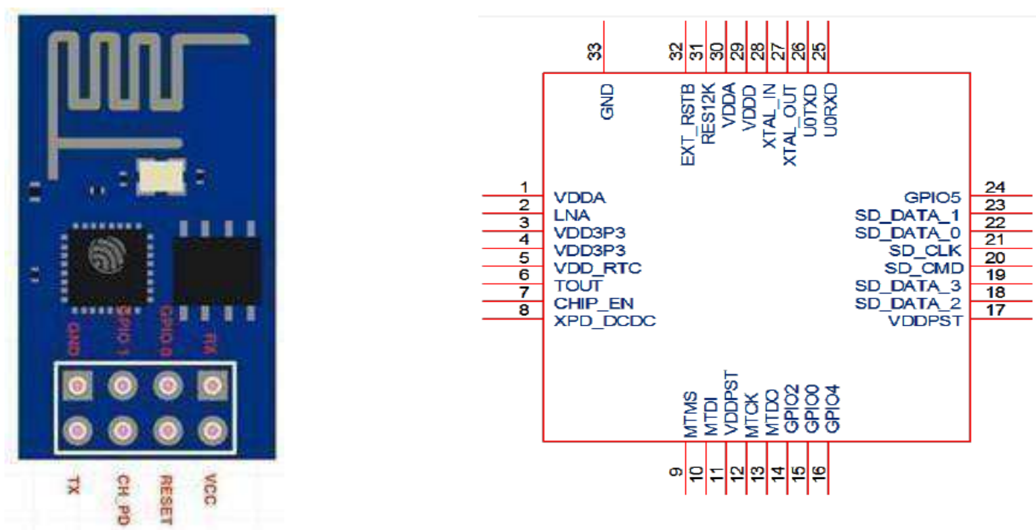

Fig 3.5.3 structure and pin configuration

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V VCC (VCC cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to aserial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wi-fi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

3.5.4 HOW TO CONNECT ESP8266 WI-FI MODULE

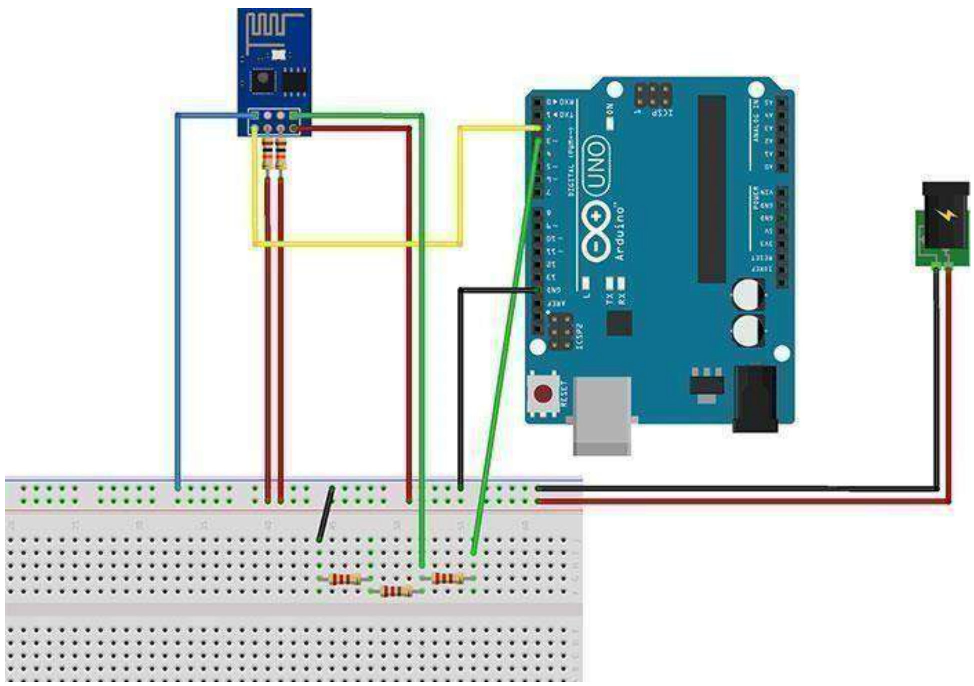

Fig.3.5.4 connection of Fig ESP8266 wi-fi module

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up

- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
- Breadboard and jumper wires

A couple of features of this circuit stand out immediately.

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the VCC and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digitalhigh and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

3.5.5 APPLICATIONS

- IOT Projects
- Access Point Portals
- Wireless Data logging
- Smart Home Automation

- Learn basics of networking
- Portable Electronics
- Smart bulbs and Sockets

3.6 16 * 2 ALPHANUMERIC LCD

3.6.1 WHAT IS LCD

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

3.6.2 BLOCK DIAGRAM:

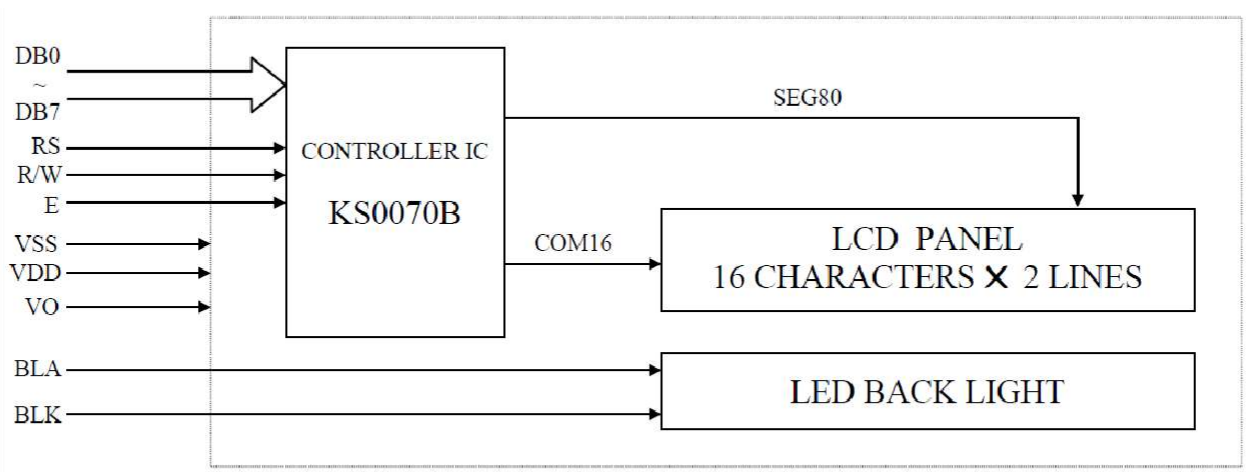

Fig 3.6.2 Block diagram of 16*2 LCD

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

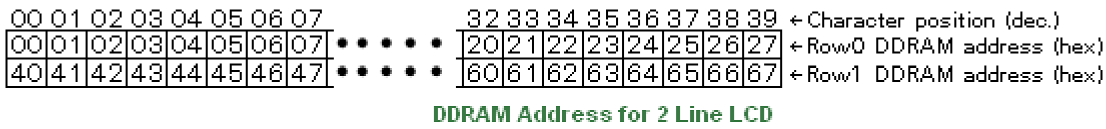

Fig.3.6.3 DDRAM addresses of 2 Line LCD

3.6.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.6.4 BUSY FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.6.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.6.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.6.7 SCHEMATIC DIAGRAM:

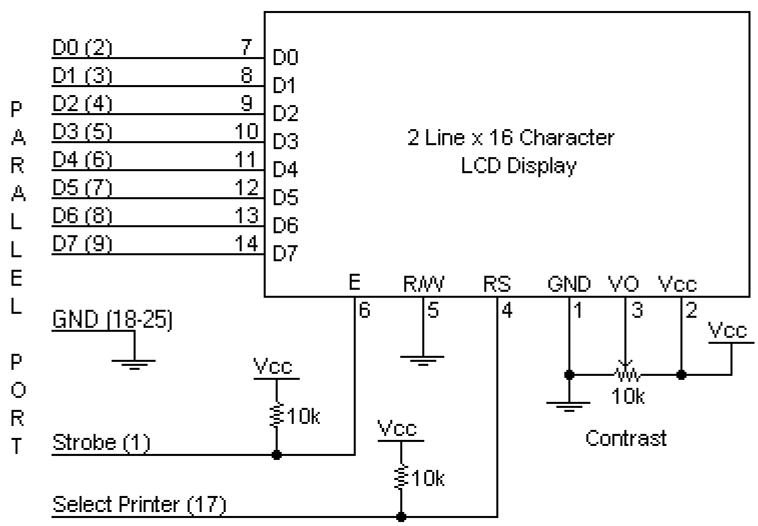

Fig 3.6.7 Schematic Diagram of LCD

3.6.8 SPECIFICATIONS:

Table 3.6.8 Specifications of 16*2 LCD Display

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a "1" on the back of the PCB. Do not get confused by this.

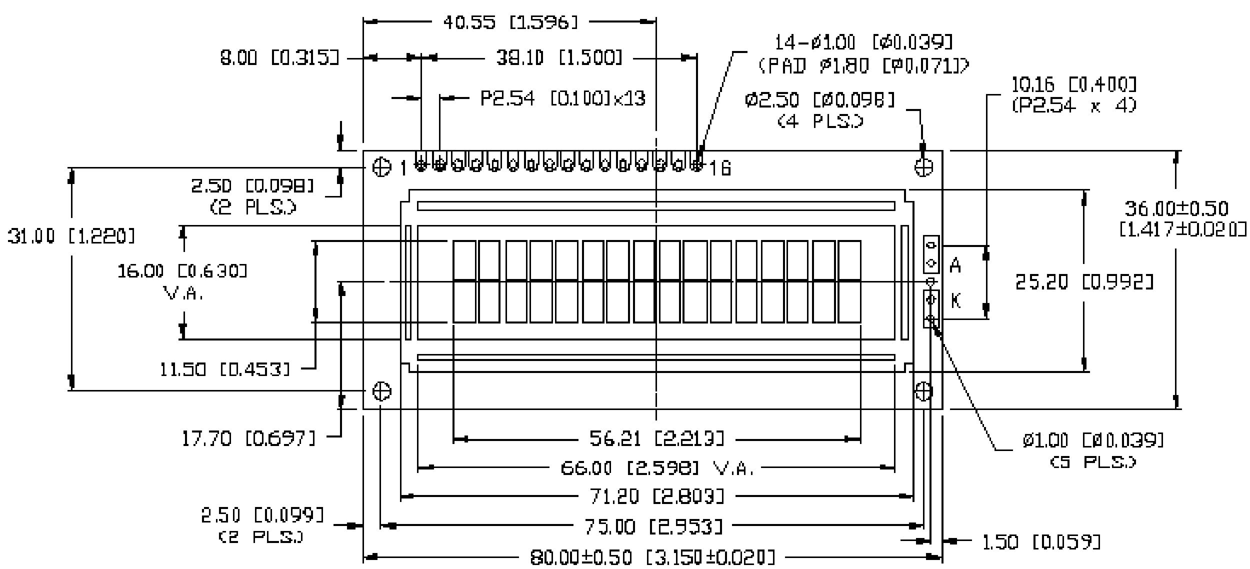

Fig.3.6.9 Connector pin diagram

3.6.9 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16-character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.6.10 APPLICATIONS

- In most of the applications that's have only small values to show, uses the LCD.
- Most of the commercial meters use this module to represent the data output.
- In the toys and developing projects, it is still vastly in use.
- In black and white printers, it helps to show the printer settings and status.

3.7 ULTRASONIC SENSOR

3.7.1 WHAT IS ULTRA SONIC SENSOR?

An ultrasonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal.

Fig 3.7.1 Ultrasonic sensor

3.7.2 WORKING PRINCIPLE

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4pin module, whose pin names are VCC, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications, where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver.

The sensor works with the simple high school formula that

Distance = Speed × Time

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

Fig 3.7.2 Ultrasonic sensor working principle

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic-wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

3.7.3 PIN CONFIGURATION

Fig 3.7.3 Pin Configuration

Table 3.7.3 Pin Configuration of Ultrasonic Sensor

Pin Number	Pin Name	Description
1	VCC	The VCC pin powers the sensor, typically with +5V
2	Trigger	TriggerpinisanInputpin.Thispinhastobekepthighfor10usto initialize measurement by sending US wave.
3	Echo	EchopinisanOutputpin.Thispingoeshighforaperiodoftimewhich willbeequaltothetime takenfortheUSwavetoreturnbacktothe sensor.
4	Ground	This pin is connected to the Ground of the system.

3.7.4 HOW TO USE THE HC-SR04 ULTRASONIC SENSOR

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

Power the Sensor using a regulated +5V through the VCC ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to bemade high for 10uS and then turned off. This action will trigger an ultrasonic wave at frequency of40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information, the distance is measured as explained in the above heading.

3.7.5 SPECIFICATIONS

- Operating voltage: +5V
- Theoretical Measuring Distance: 2cm to 450cm
- Practical Measuring Distance: 2cm to 80cm
- Accuracy: 3mm
- Measuring angle covered: <15°
- Operating Current: <15mA
- Operating Frequency: 40Hz

3.7.6 APPLICATIONS

- Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot path finding robot etc.
- Medical ultrasonography.

- Burglar Alarms.
- Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water

3.8 DHT11 TEMPERATURE AND HUMIDITY SENSOR

3.8.1 WHAT IS DHT11 SENSOR?

DHT11 is a low-cost digital sensor for sensing temperature and humidity. This sensor can be easily interfaced with any micro-controller such as Arduino, Raspberry Pi etc… to measurehumidity and temperature instantaneously. DHT11 humidity and temperature sensor is availableas a sensor and as a module

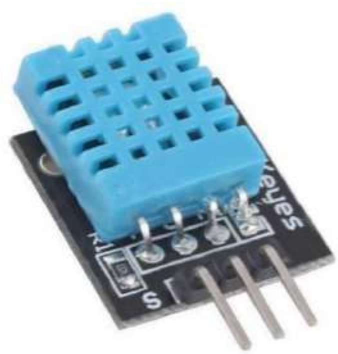

Fig 3.7.1 DHT11 Sensor

3.8.2 WORKING PRINCIPLE

DHT11 sensor consists of a capacitive humidity sensing element and a thermistor for sensing temperature. The humidity sensing capacitor has two electrodes with a moisture holding substrate as a dielectric between them. Change in the capacitance value occurs with the change in humidity levels.

The IC measure, process this changed resistance values and change them into digital form. For measuring temperature this sensor uses a Negative Temperature coefficient thermistor, which causes a decrease in its resistance value with increase in temperature. To get larger resistance value even for the smallest change in temperature, this sensor is usually made up of semiconductor ceramics or polymers. The temperature range of DHT11 is from 0 to 50 degree Celsius with a 2-degree accuracy.

Humidity range of this sensor is from 20 to 80% with 5% accuracy. The sampling rate of this sensor is 1Hz.i.e., it gives one reading for every second. DHT11 is small in size with operating voltage from 3 to 5 volts. The maximum current used while measuring is 2.5mA.

DHT11 sensor has four pins- VCC, GND, Data Pin and a not connected pin. A pull-up resistor of 5k to 10k ohms is provided for communication between sensor and micro-controller.

3.8.3 PIN CONFIGURATION

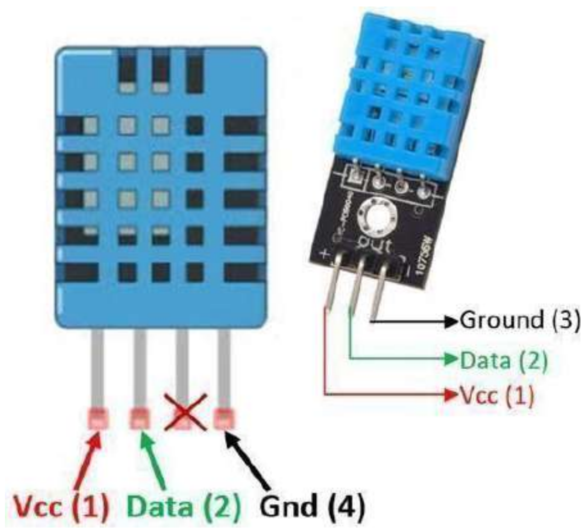

Fig 3.8.3 Pin Configuration

Table 3.8.3 Pin Configuration of DTH11 Sensor

No:	Pin Name	Description
For DHT11 Sensor		
1	VCC	Power supply 3.5V to 5.5V
2	Data	Outputs both Temperature and Humidity through serial Data
3	NC	No Connection and hence not used
4	Ground	Connected to the ground of the circuit
For DHT11 Sensor module		
1	VCC	Power supply 3.5V to 5.5V

2	Data	Outputs both Temperature and Humidity through serial Data
3	Ground	Connected to the ground of the circuit

3.8.4 HOW TO USE

The DHT11 Sensor is factory calibrated and outputs serial data and hence it is highly easy to set it up. The connection diagram for this sensor is shown below.

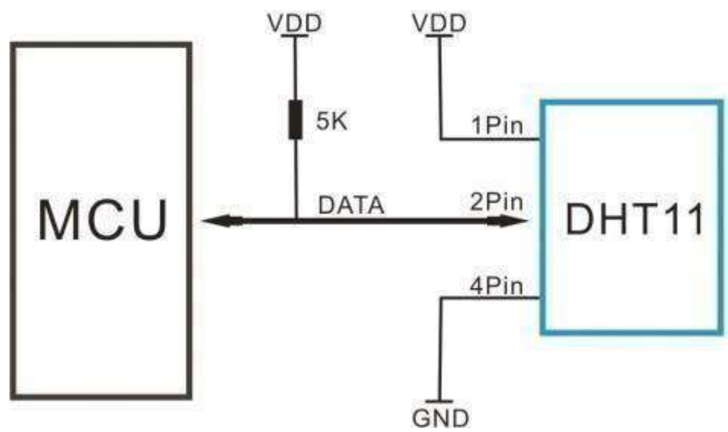

Fig 3.8.4 Connection of DHT11 Sensor

As you can see the data pin is connected to an I/O pin of the MCU and a 5K pull-up resistor is used. This data pin outputs the value of both temperature and humidity as serial data. If you are trying to interface DHT11 with Arduino then there are ready-made libraries for it which will give you a quick start.

If you are trying to interface it with some other MCU then the datasheet given below will come in handy. The output given out by the data pin will be in the order of 8bit humidity integer data + 8bit the Humidity decimal data +8bit temperature integer data + 8bit fractional temperature data +8bit parity bit. To request the DHT11 module to send these data the I/O pin has to be momentarily made low and then held high as shown in the timing diagram below.

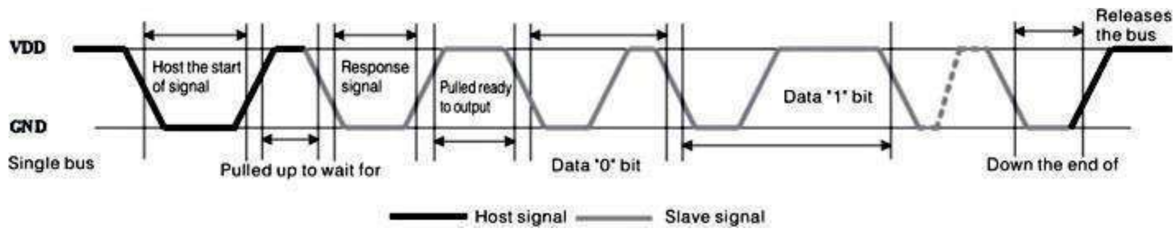

Fig 3.8.4 Timing Diagram of DHT11 Sensor

3.8.5 SPECIFICATIONS

- Operating Voltage: 3.5V to 5.5V
- Operating current: 0.3mA (measuring) 60uA (standby)
- Output: Serial data
- Temperature Range: 0°C to 50°C
- Humidity Range: 20% to 90%
- Resolution: Temperature and Humidity both are 16-bit
- Accuracy: ±1°C and ±1%

3.8.6 APPLICATIONS

- Measure temperature and humidity
- Local Weather station
- Automatic climate control
- Environment monitoring

3.9 PIR SENSOR

3.9.1 WHAT IS PIR SENSOR?

PIR is a short name for PASSIVE INFRA RED Sensor. PIR sensor is used to detect the motion of humans or any particular movement of a particle with up to distance of 10meters at an angle of+150 to -150 degrees.

Fig 3.9.1 PIR Sensor

3.9.2 WORKING PRINCIPLE

The PIR sensors are more complicated than the other sensors as they consist of two slots. These slots are made of a special material which is sensitive to IR. The Fresnel lens is used to see that the two slots of the PIR can see out past some distance. When the sensor is inactive, then the two slots sense the same amount of IR. The ambient amount radiates from the outdoors, walls or room etc.

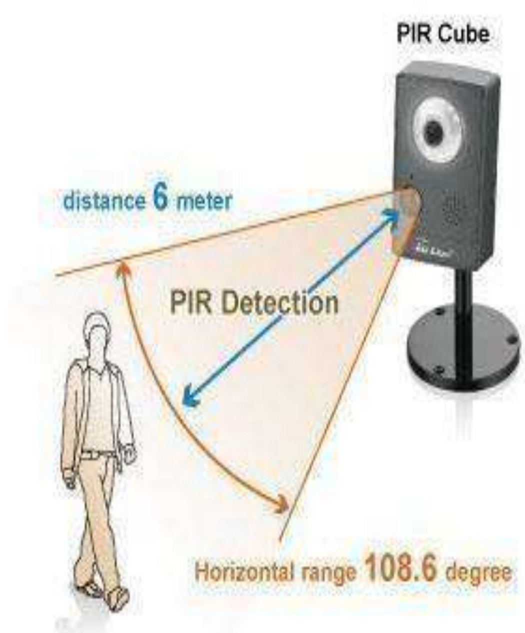

Fig 3.9.2.1 Working principle of PIR sensor

When a human body or any animal passes by, then it intercepts the first slot of the PIR sensor. This causes a positive differential change between the two bisects. When a human body leaves the sensing area, the sensor generates a negative differential change between the two bisects. The infrared sensor itself is housed in a hermetically sealed metal to improve humidity/temperature/noise/immunity. There is a window which is made of typically coated silicon material to protect the sensing element.

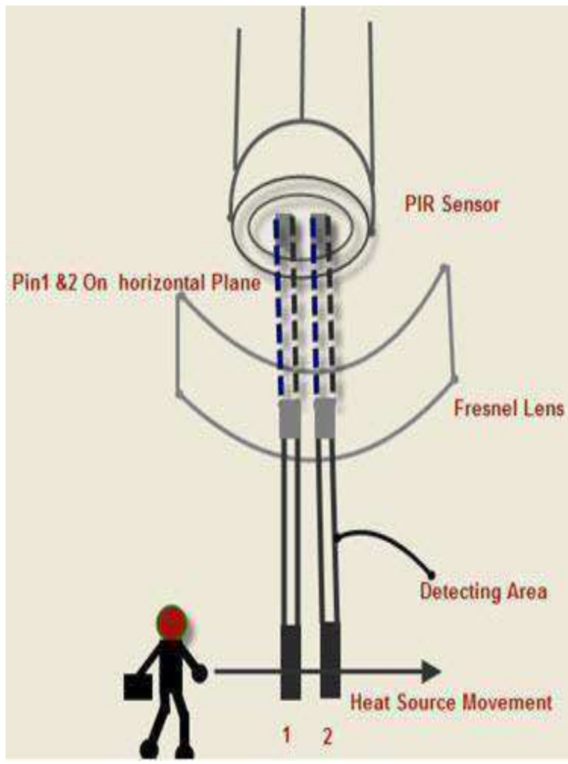

Fig 3.9.2.2 Working principle of PIR sensor

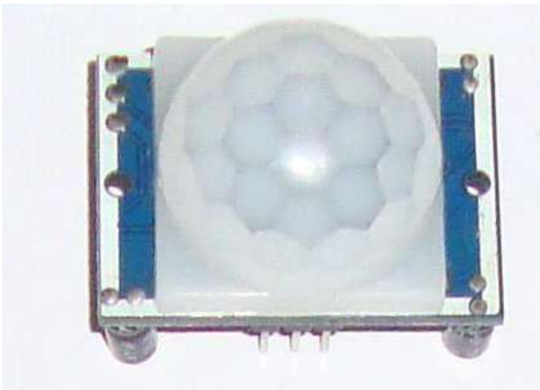
Basically, motion detection use light sensors to detect either the presence of infrared light emitted from a warm object or absence of infrared light when a object interrupts a beam emitted by another part of the device.

A PIR sensor detects the infrared light radiated by a warm object. It consists of pyro electric sensors which introduce changes in their temperature (due to incident infrared radiation) into electric signal. When infrared light strikes a crystal, it generates an electrical charge. Thus a PIR sensor can be used to detect presence of human beings within a detection area of approximately 14 meters

3.9.3 PIN CONFIGURATION



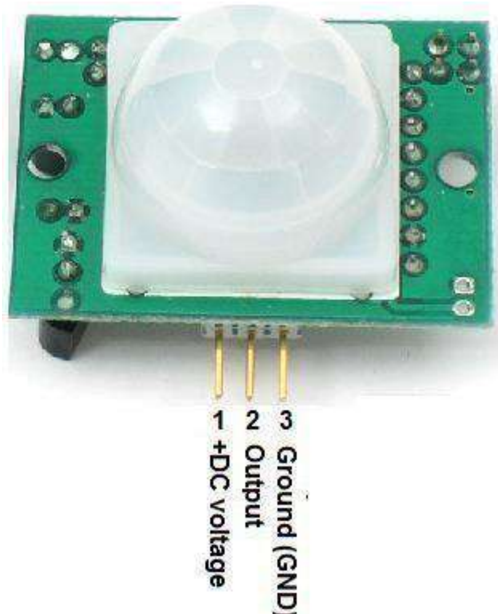


Fig 3.9.3 Pin Configuration

Table 3.9.3 Pin Configuration of PIR Sensor

Pin Number	Pin Name	Description
1	VCC	Inputvoltageis+5Vfortypicalapplications.Canrangefrom 4.5V-12V
2	High/Low Output (Dout)	Digital pulse high (3.3V) when triggered (motion detected) digital low(0V) when idle(no motion detected)
3	Ground	Connected to ground of circuit

3.9.4 SPECIFIACTIONS

- Complete with PIR, Motion Detection.
- Dual Element Sensor with Low Noise and High Sensitivity.
- Supply Voltage – 5V.
- Delay Time Adjustable.
- Standard TTL Output.

3.9.5 APPLICATIONS

- All outdoor Lights
- Lift Lobby
- Multi Apartment Complexes
- Common staircases
- For Basement or Covered Parking Area
- Shopping Malls
- For garden lights

3.10 BLOOD PRESSURE SENSOR

3.10.1 WHAT IS BLOOD PRESSURE SENSOR?

The Blood Pressure Sensor is a non-invasive sensor designed to measure human blood pressure.

Fig 3.10.1 Blood Pressure Sensor

It measures systolic, diastolic and mean arterial pressure utilizing the oscillometric method. Pulse rate is also reported.

3.10.2 WORKING PRINCIPLE

3.10.2.1 Using manual Machine:

Usually, pressure cuff linked to a mercury column is used to measure the blood pressure. Here, the doctor manually pumps the cuff to increase the pressure on the artery. Then using stethoscope, the noise of the blood rushing through the artery.

Fig 3.10.2 Manual BP Machine

3.10.2.2 Using Automated Machine

In automatic Blood Pressure measurement system, instead of mercury a pressure sensor is used to detect the pressure in the artery and give output. This digital output is displayed on the monitor. This monitor has an onboard processor to process the output given by pressure sensor, record results and display them on the digital read-out screen.

Fig 3.10.2.2 Automated BP Machine

3.10.3 SPECIFICATIONS

- Pressure range: 0 mmHg to 258 mmHg
- Maximum pressure without permanent damage: 1550 mmHg
- Typical accuracy: ±1 mmHg
- Temperature compensated: -20°C to 85°C
- Sensing element: SSCMRRN005PGAA5
- Combined linearity and hysteresis: typical ±0.25%
- Response time: 1 millisecond

CHAPTER-4
SOFTWARE DESCRIPTION

4.1 SOFTWARE EXPLANATION:

SOFTWARE REQUIREMENTS:

- Arduino software
- Programming language
- Proteus simulation

4.1.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments.

A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon asit reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments.

All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

4.1.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows, wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

Open source and extensible hardware - The plans of the Arduino boards are published under

- a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software (IDE)
- ✓ Proceed with board specific instructions.

4.1.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

4.1.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.4.1.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.4.1.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

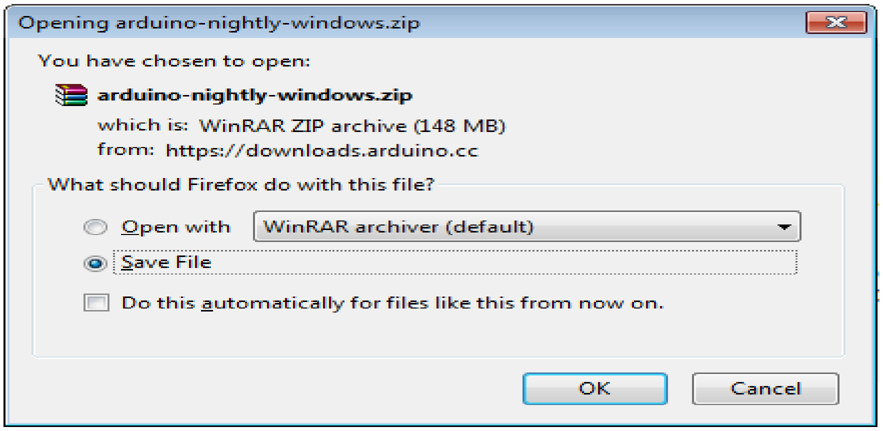

Fig.4.1.4.3 Download Arduino IDE SoftwareStep 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

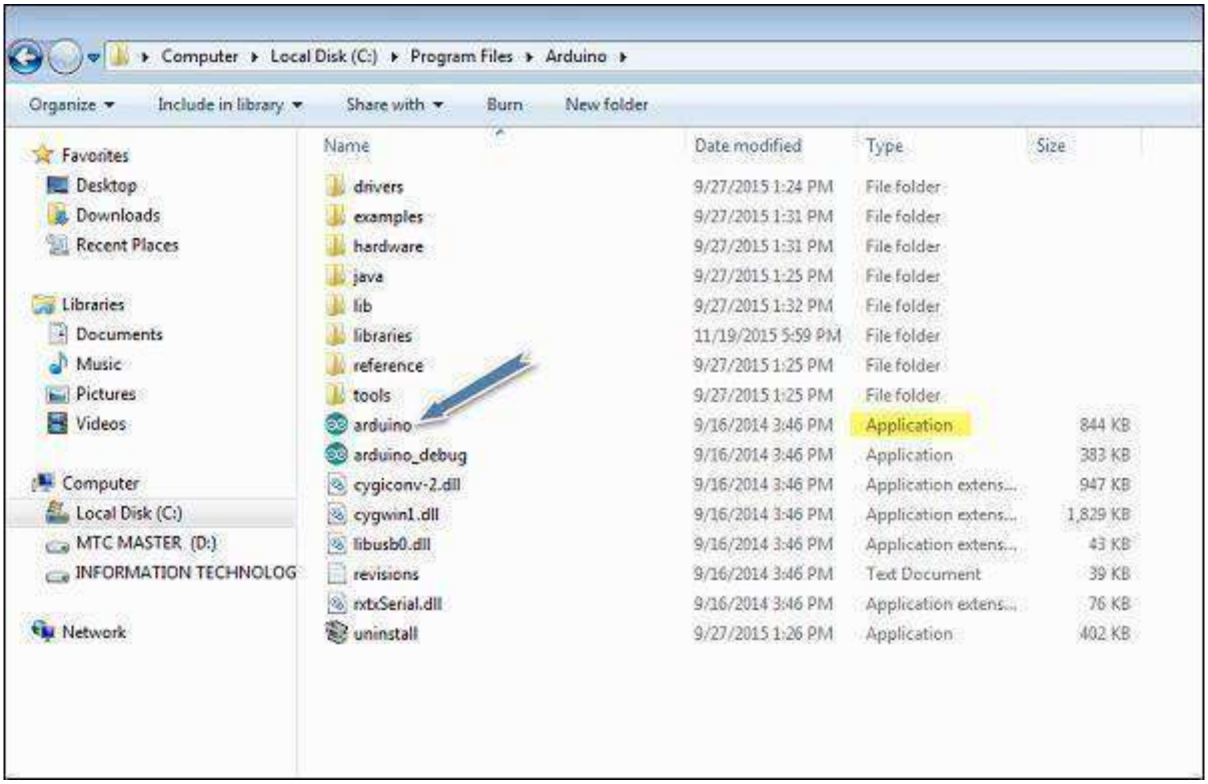

Fig.4.1.4.4 Launch Arduino IDEStep 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File →**New**

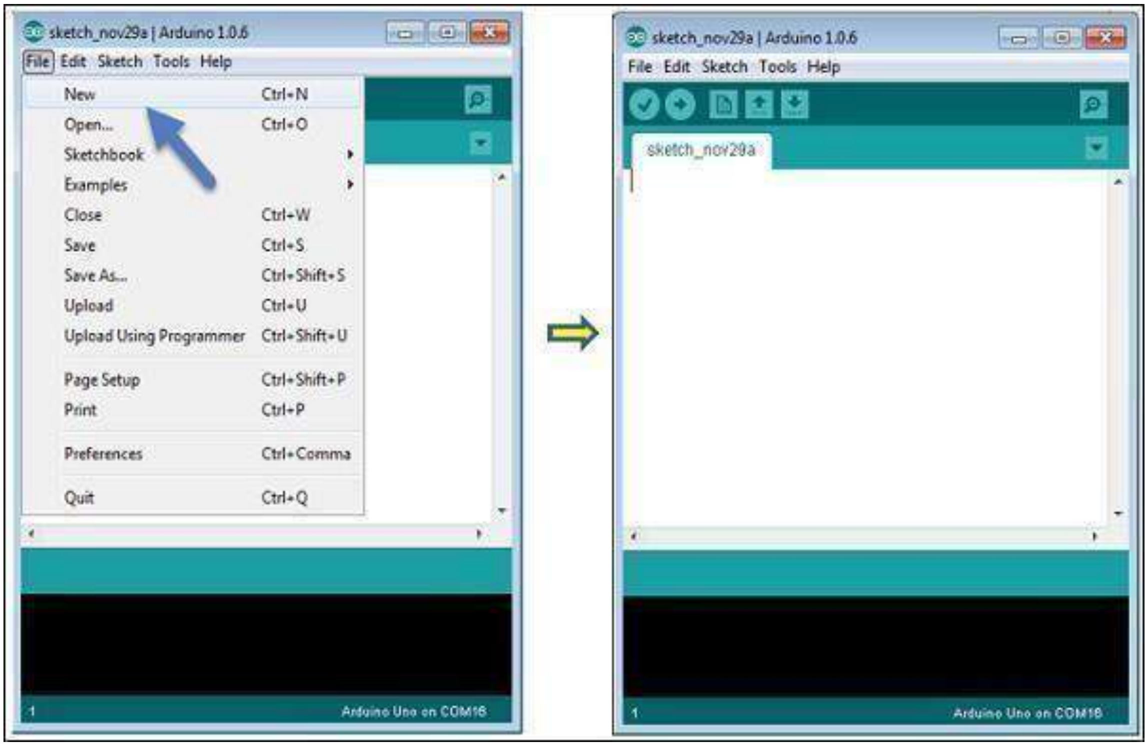

Fig.4.1.4.5 Open your first project.

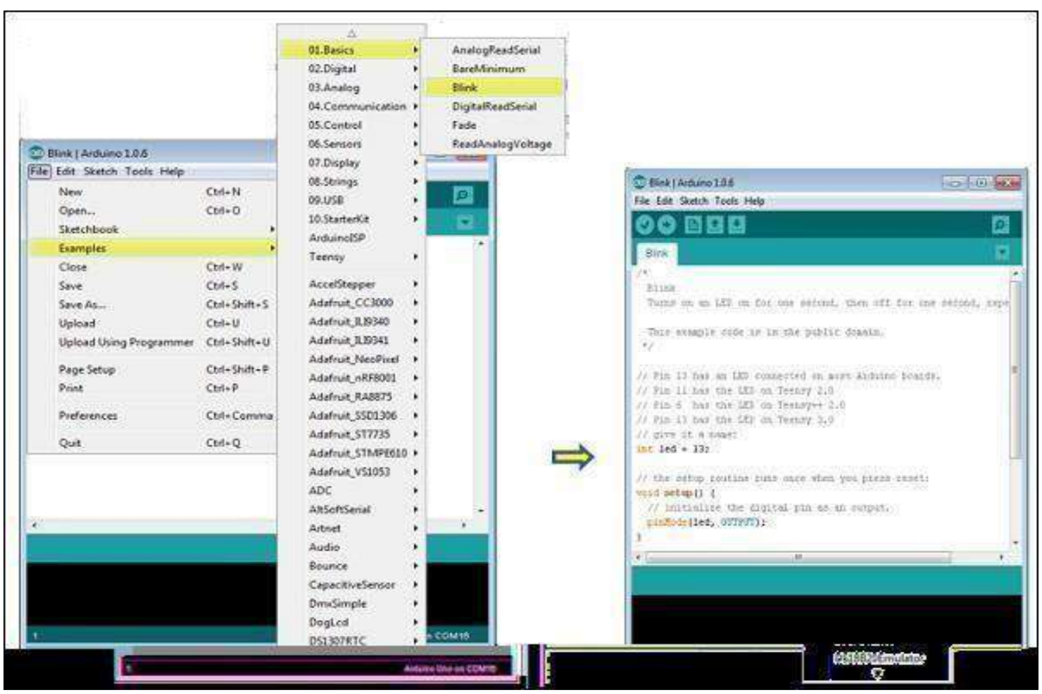
To open an existing project example, select File → Example → Basics → Blink.



.

Fig.4.1.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

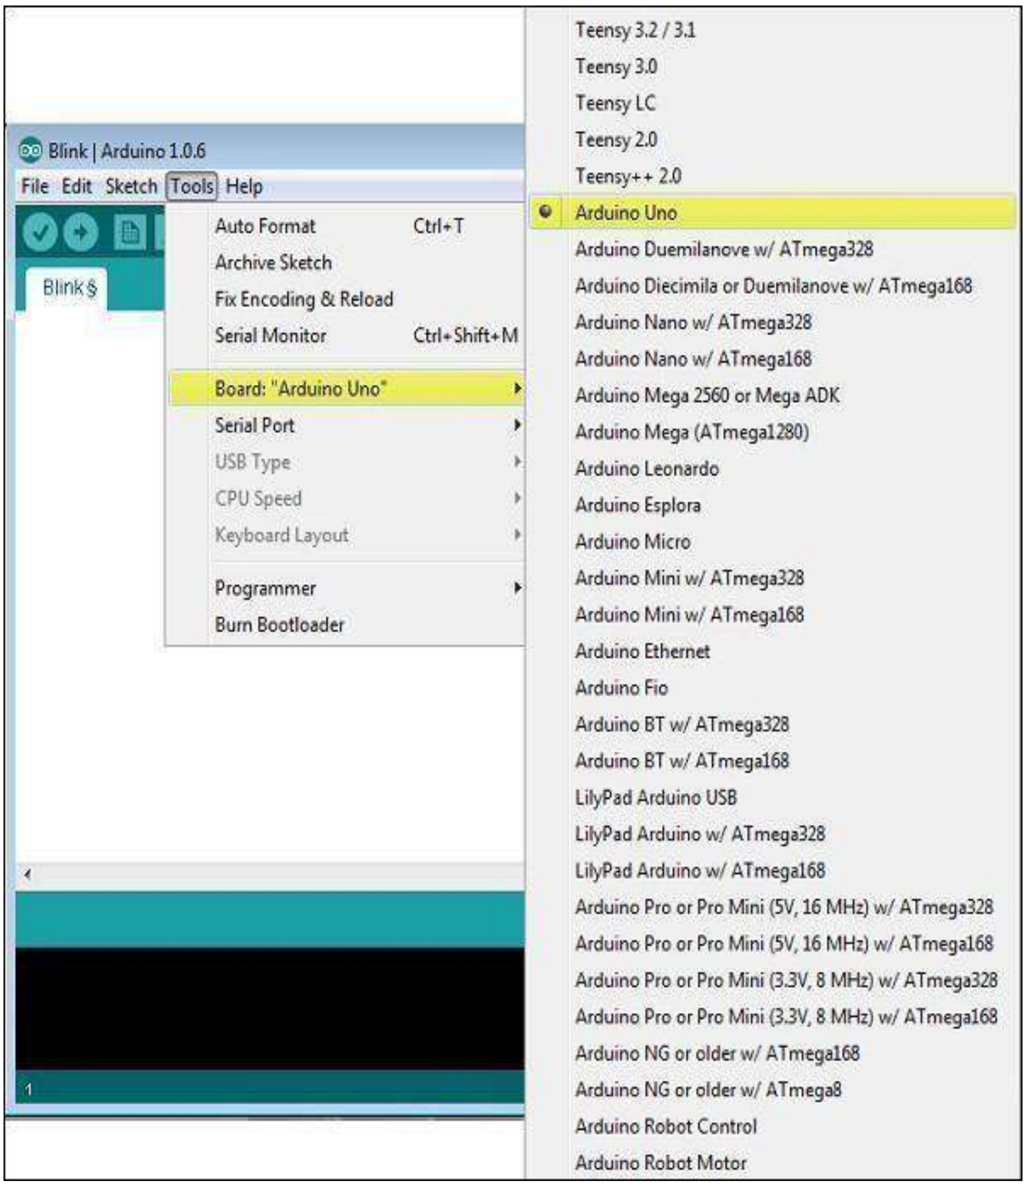


Fig.4.1.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports).To find out, you can disconnect your Arduino board and re-open the menu, the entry thatdisappears should be of the Arduino board. Reconnect the board and select that serial port.

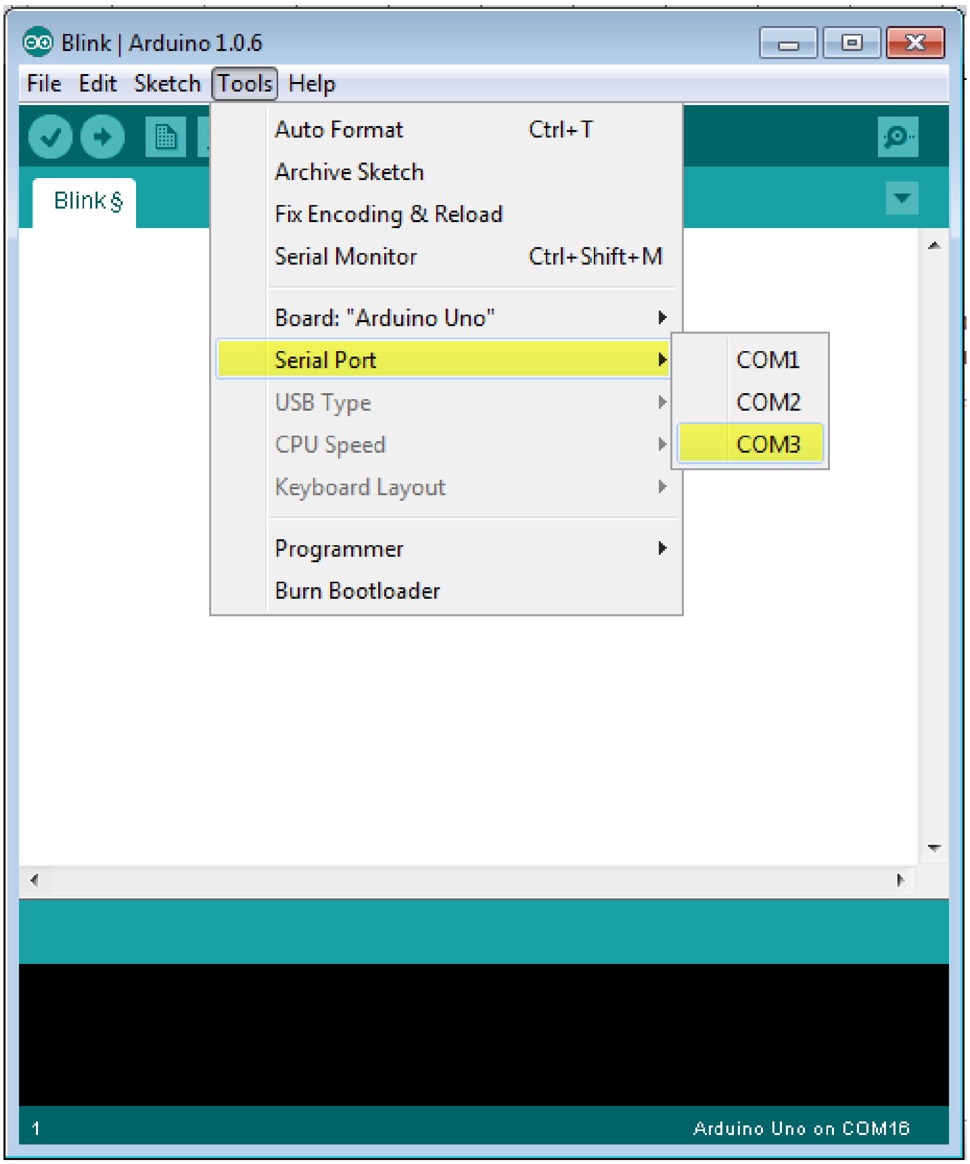

Fig.4.1.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

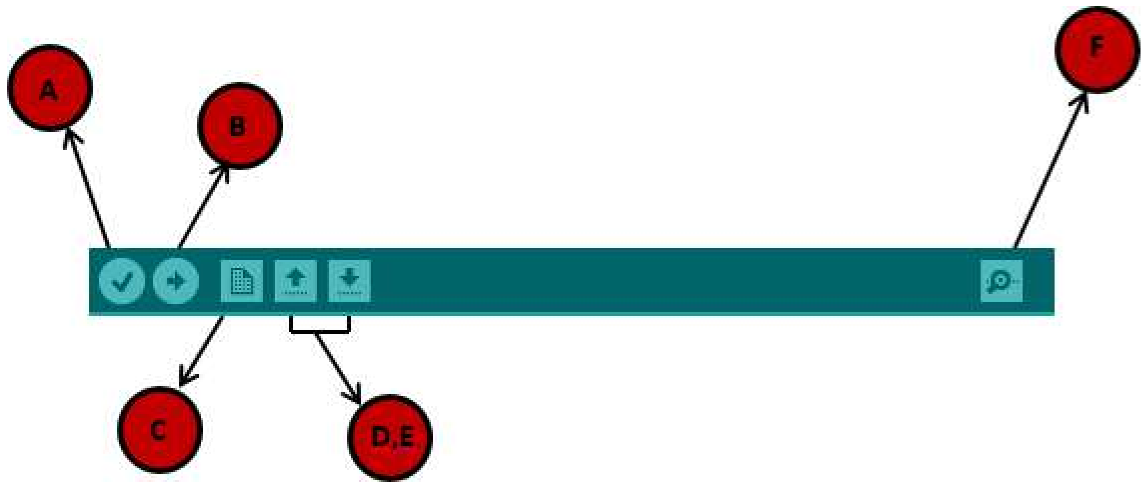

Fig.4.1.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and GND connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

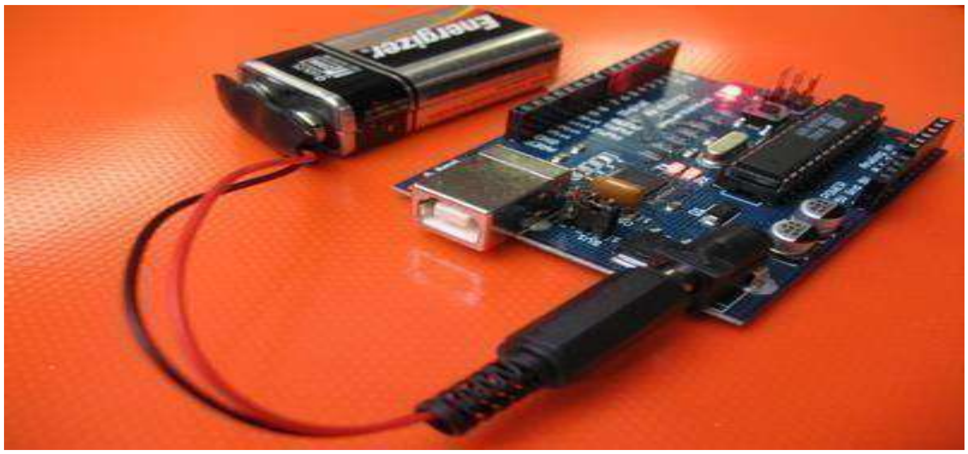

Fig.4.1.4.10 Connecting a Battery

.

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig.4.1.4.11 Example Program

4.1.5 MC PROGRAMMING LANGUAGE: EMBEDDED C :

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

4.2 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab Centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integratedcircuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

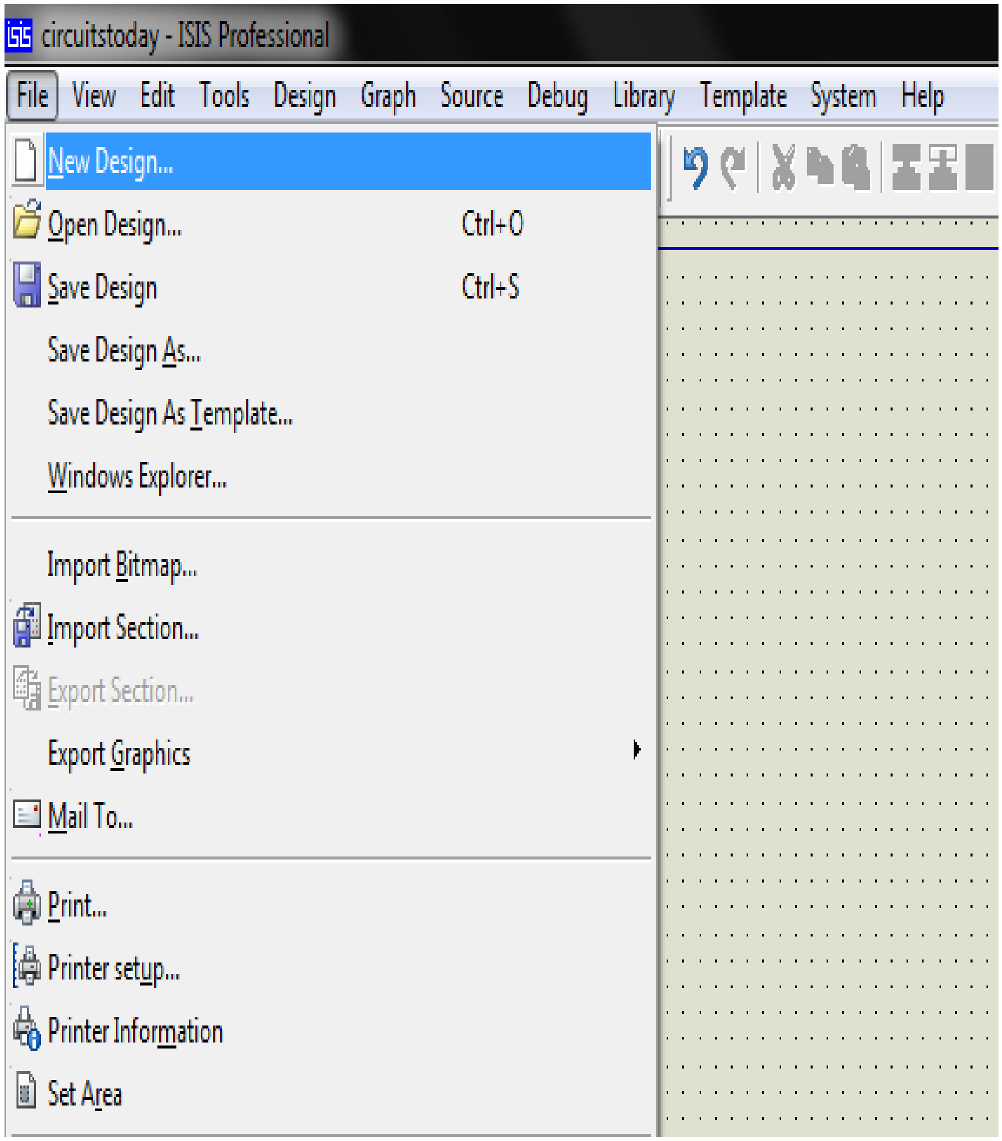

Fig.4.2.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

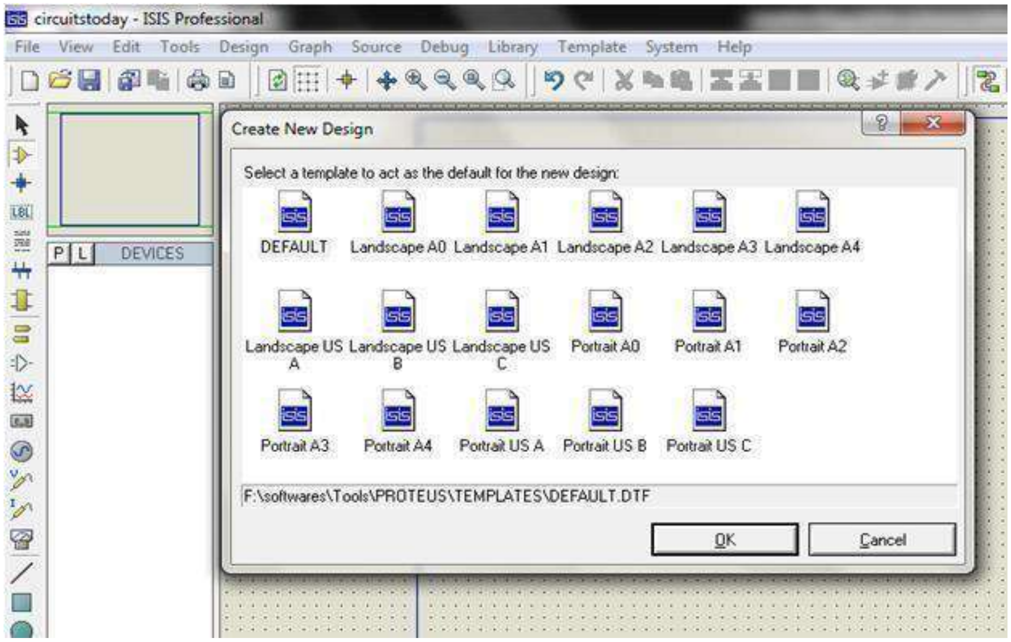

Fig.4.2.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

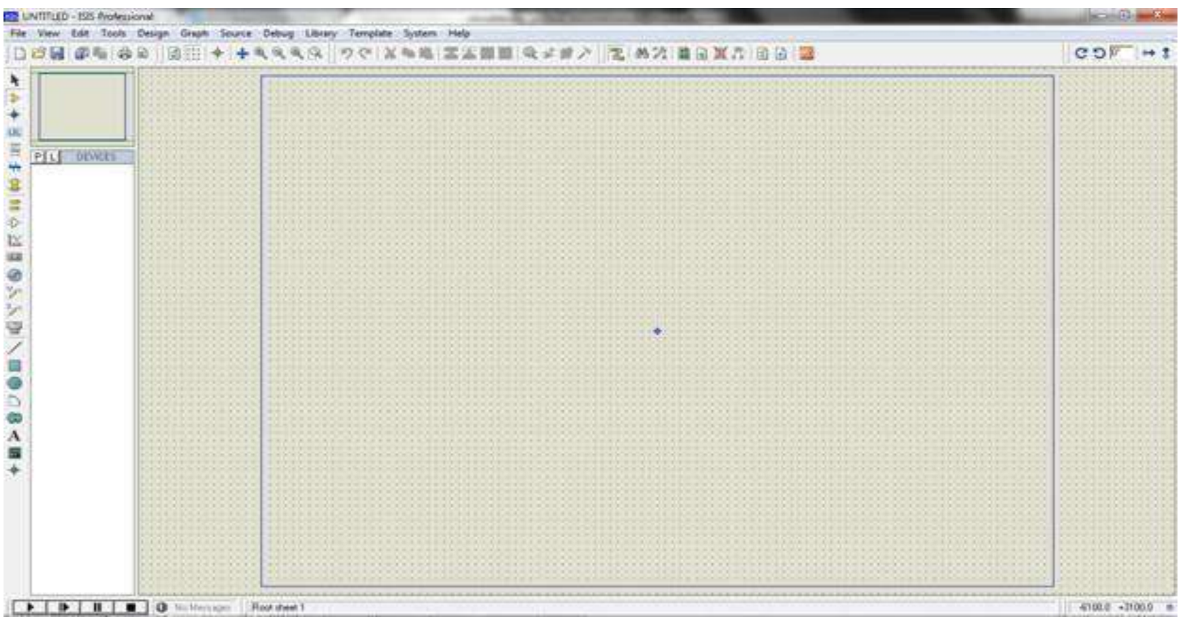

Fig.4.2.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

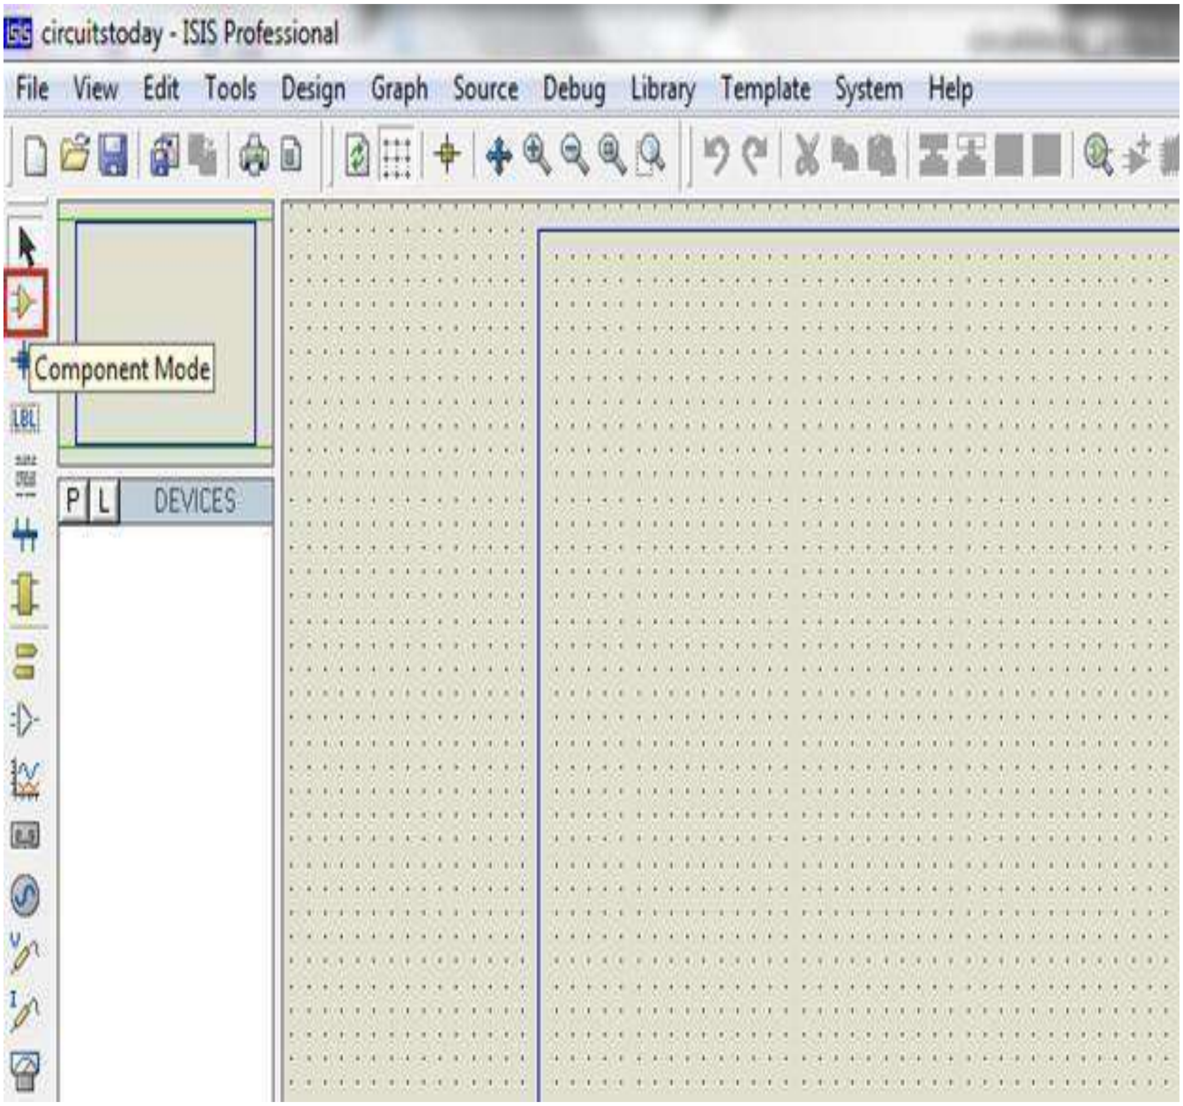

Fig.4.2.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

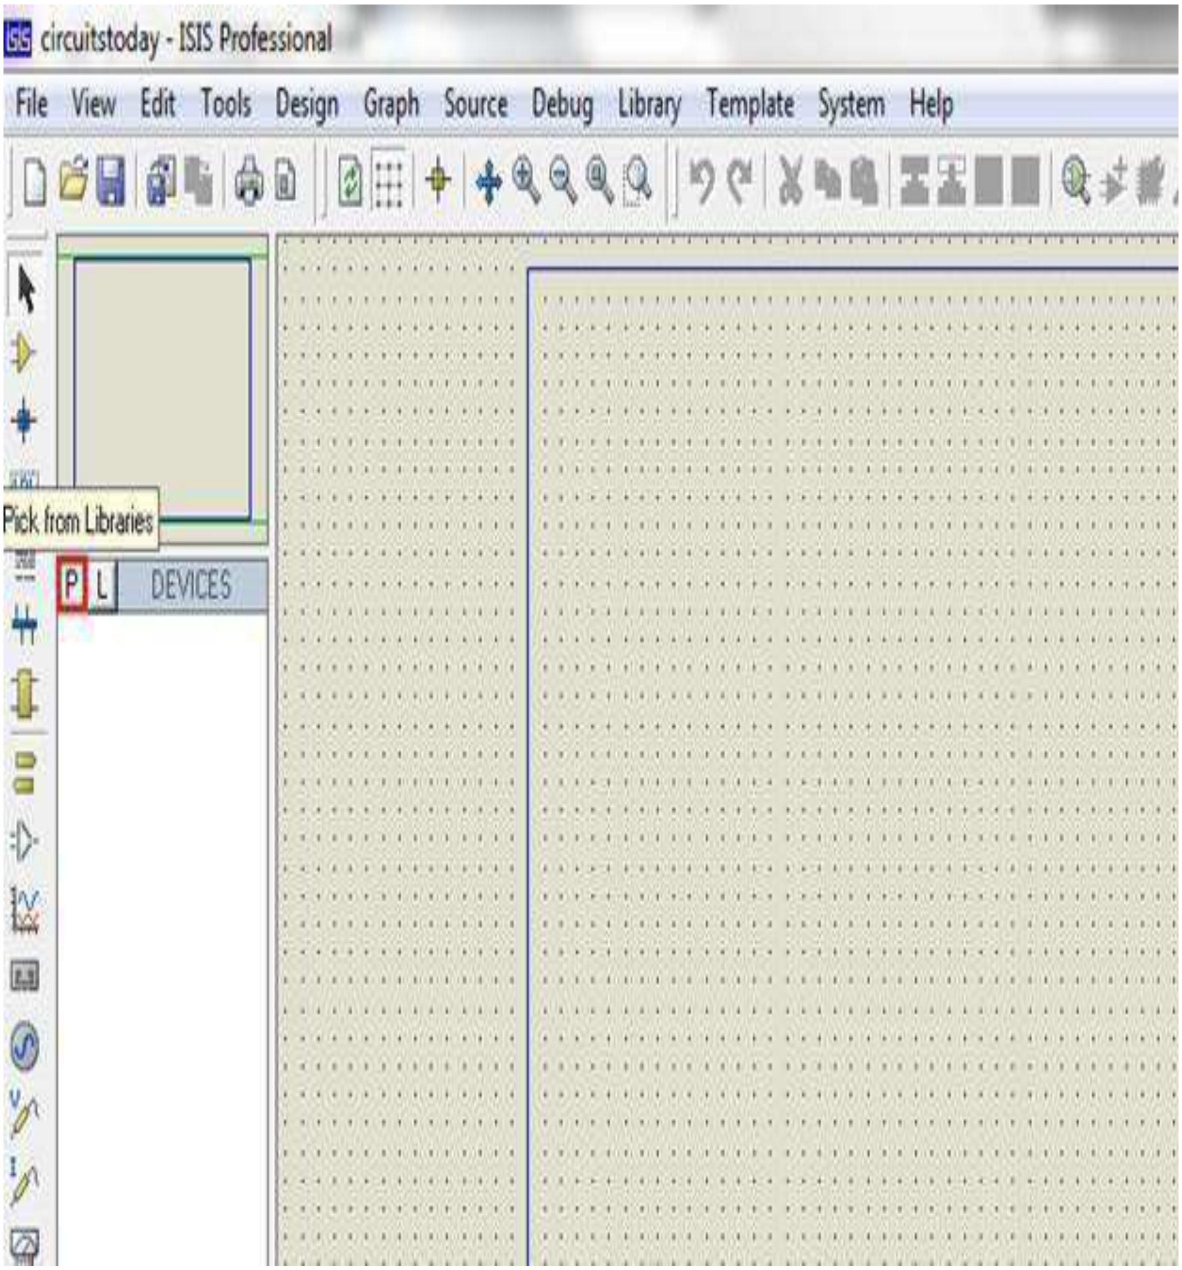

Fig.4.2.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

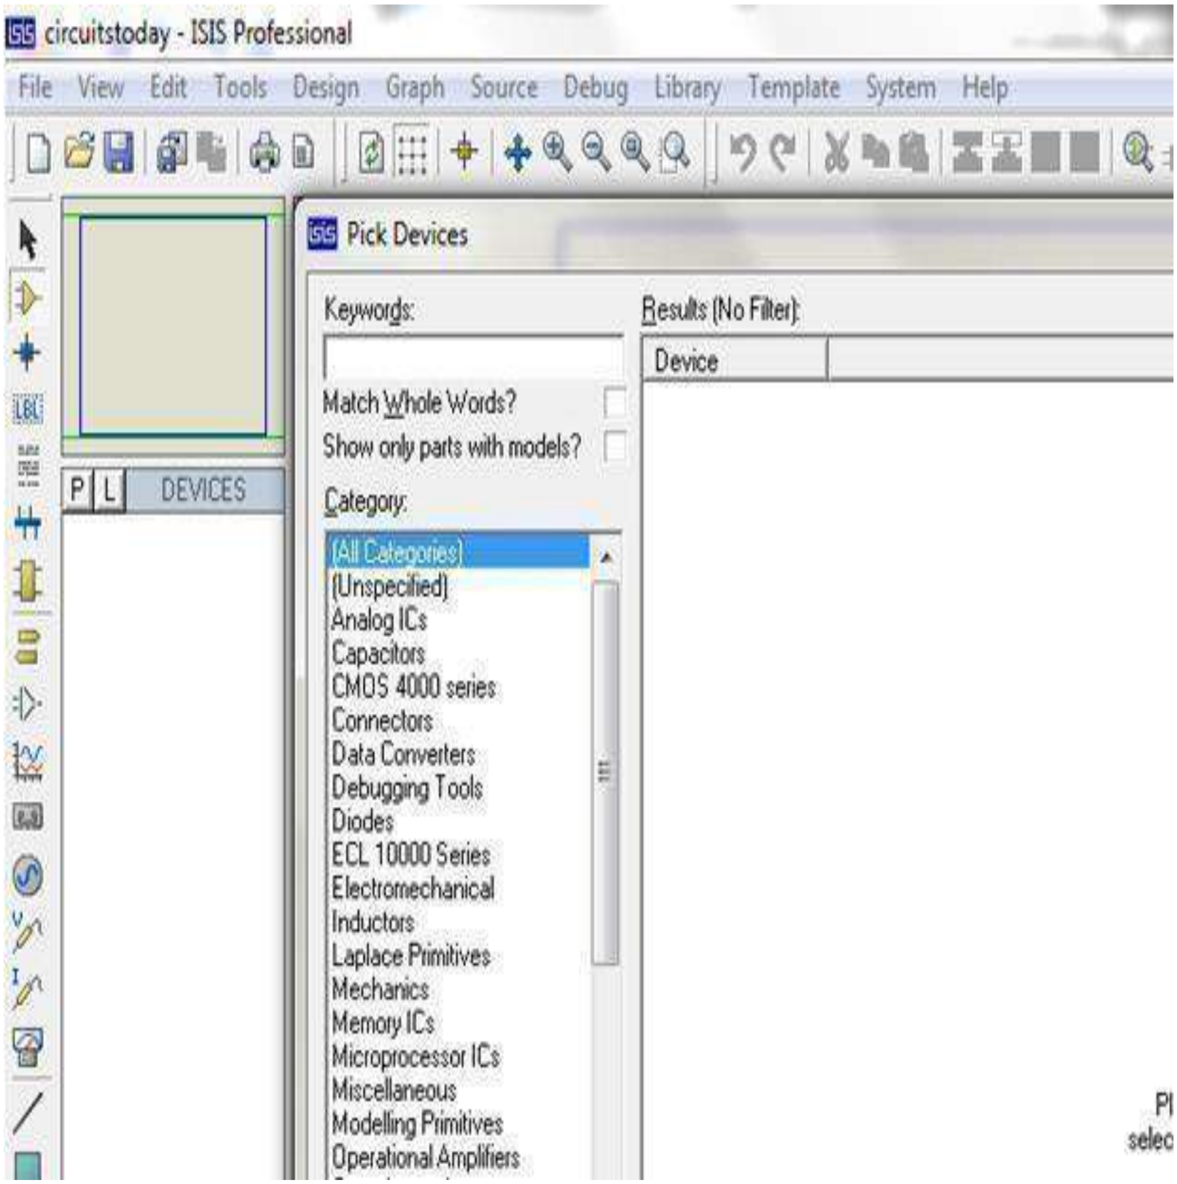

Fig.4.2.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

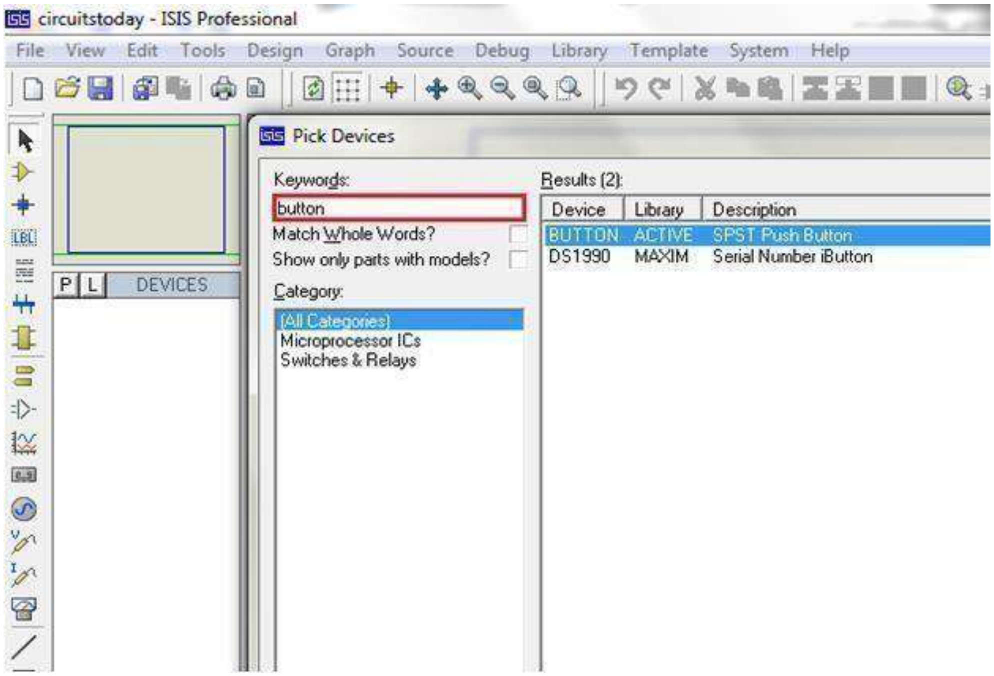

Fig4.2.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

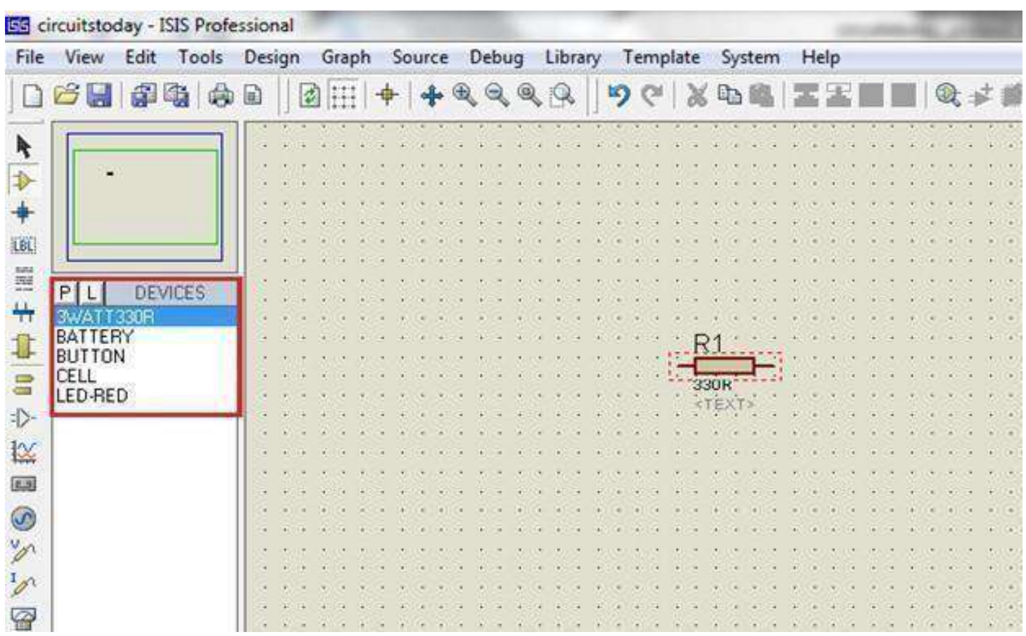

Fig.4.2.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

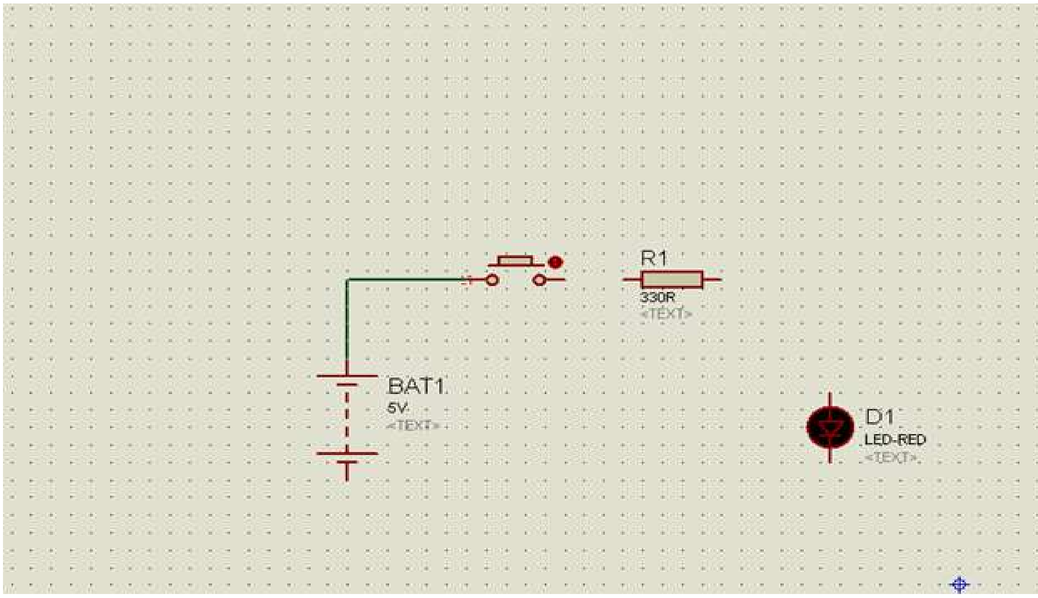

Fig.4.2.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

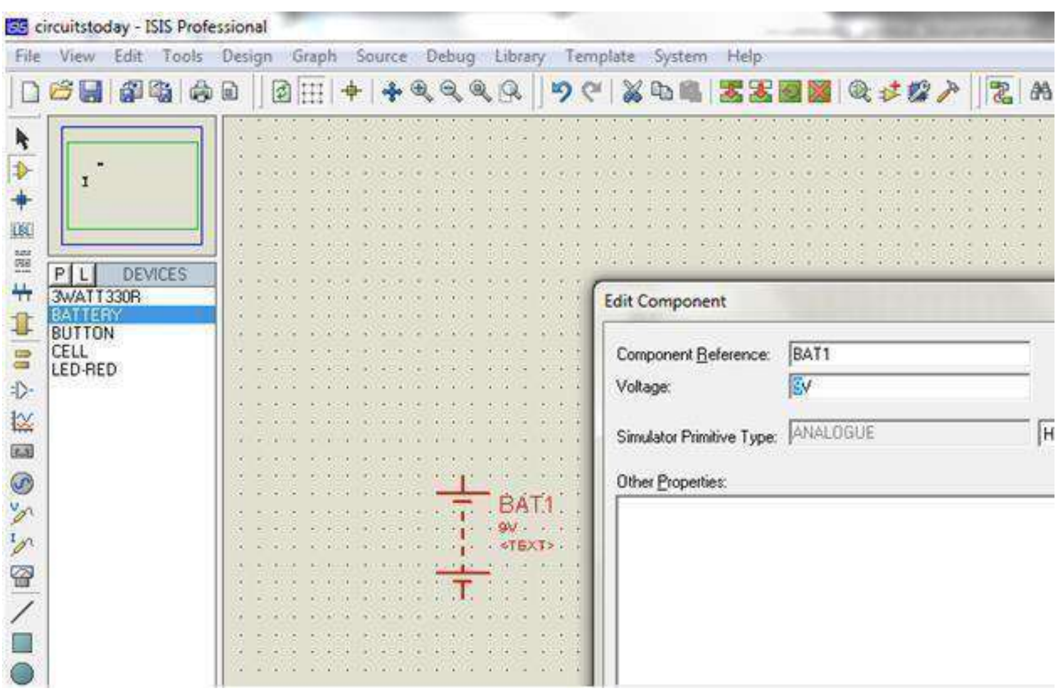

Fig.4.2.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

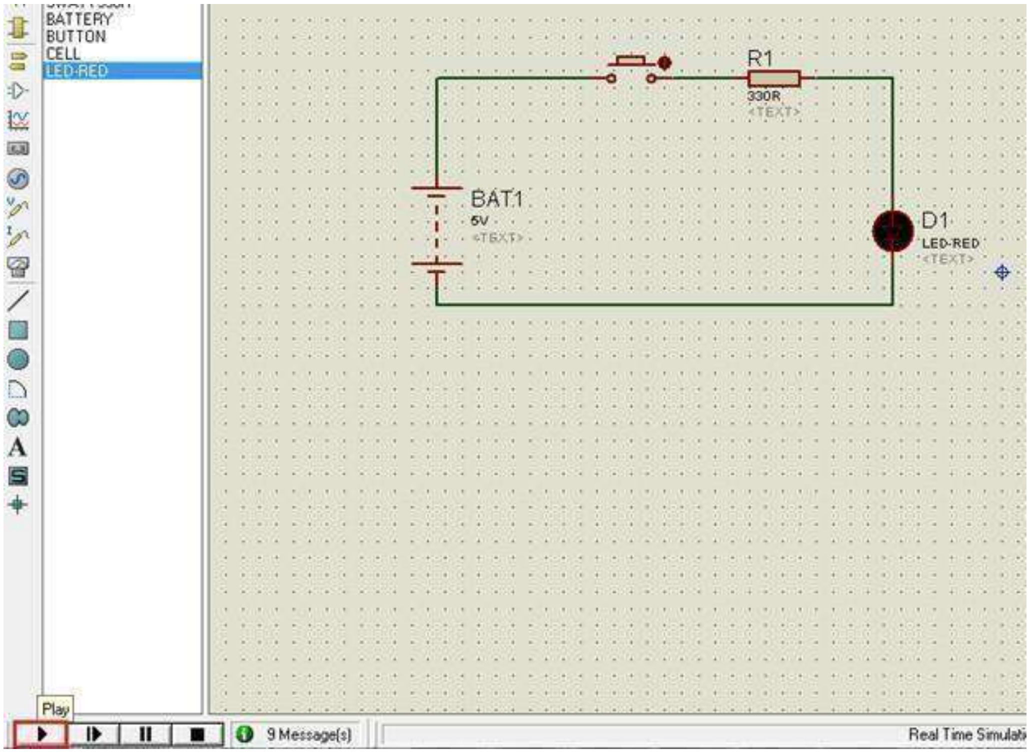

Fig.4.2.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

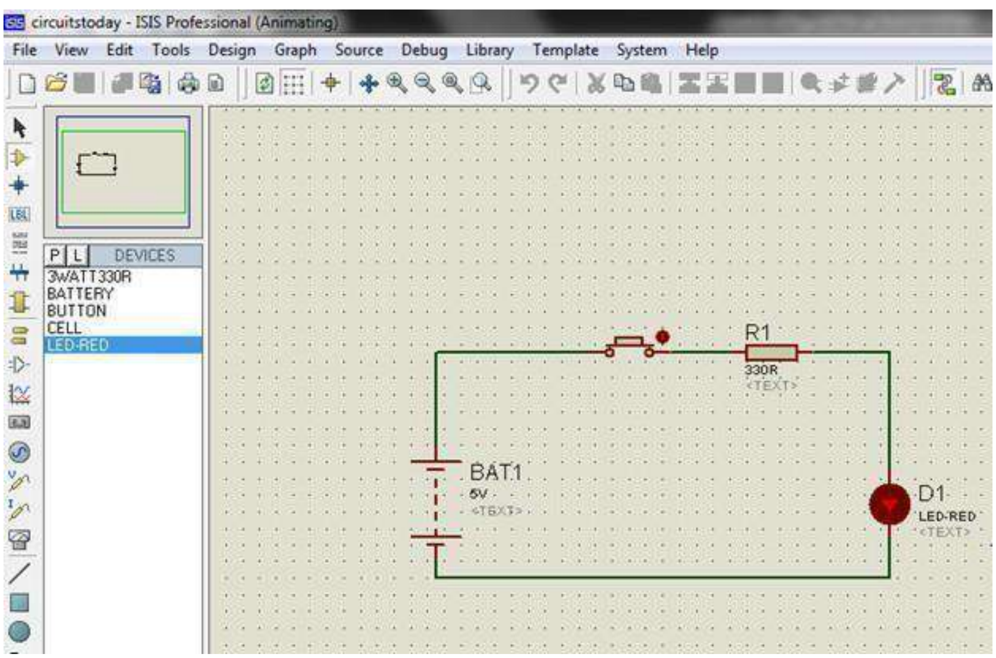

Fig4.2.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

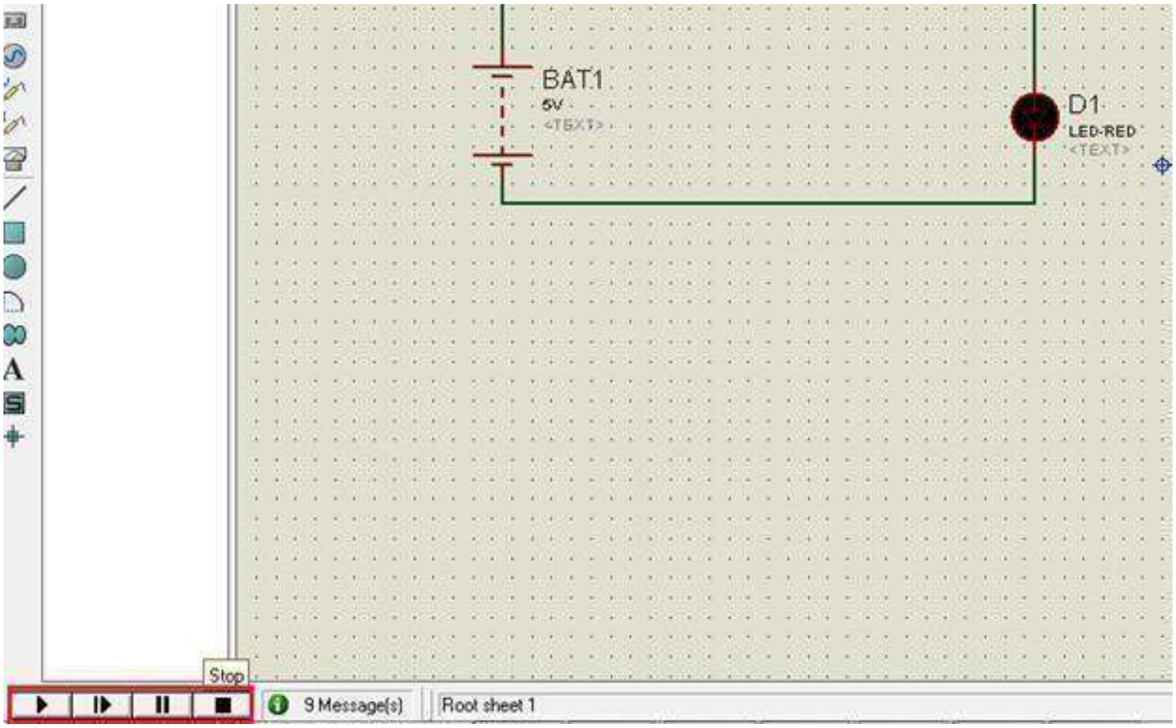

Fig.4.2.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by IoT Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyze and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citationneeded].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

- Create a free MathWorks account or sign into Things Speak using an existing account.
- Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.
- Record the following for the selected channel:
- Channel ID, which is listed at the top of the channel view.
- Write API key, which can be found on the API Keys tab of your channel view.

CHAPTER – 5
SOFTWARE TESTING AND CODE IMPLEMENTATION

5.1 SOFTWARE TESTING

Software Testing is a process of executing the application with an intent to find anysoftware bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

5.2 TESTING LEVELS

There are various testing levels based on the specificity of test.

- **Unit testing**: Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.

- **Integration Testing**: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.

- **System Testing**: System testing tests a completely integrated system to verify that the system meets its requirements.

- **Acceptance testing**: Acceptance testing tests the readiness of application, satisfying all requirements.

- **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

5.3 SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

5.4 CODE IMPLEMENTATION

5.4.1 PROJECT CODE

```
#include <SoftwareSerial.h>
SoftwareSerial mySerial(2,3);

#include <LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);

String readvoice;
char buff[200],k=0;
char c=0,c1=0;
 unsigned char rec = 0,buf[120],buf1[120],buf3[120];
 unsigned int count=0,ik=0,ct=0,value=0;
void upload1(unsigned char *chr,unsigned char *chr1,unsigned char *chr2,unsigned char *chr3);
 char res[130];
char check(char* ex,int timeout)
{
  int i=0;

CHAPTER-6
PROJECTIMPELEMENTATION

6.1 FLOW CHART

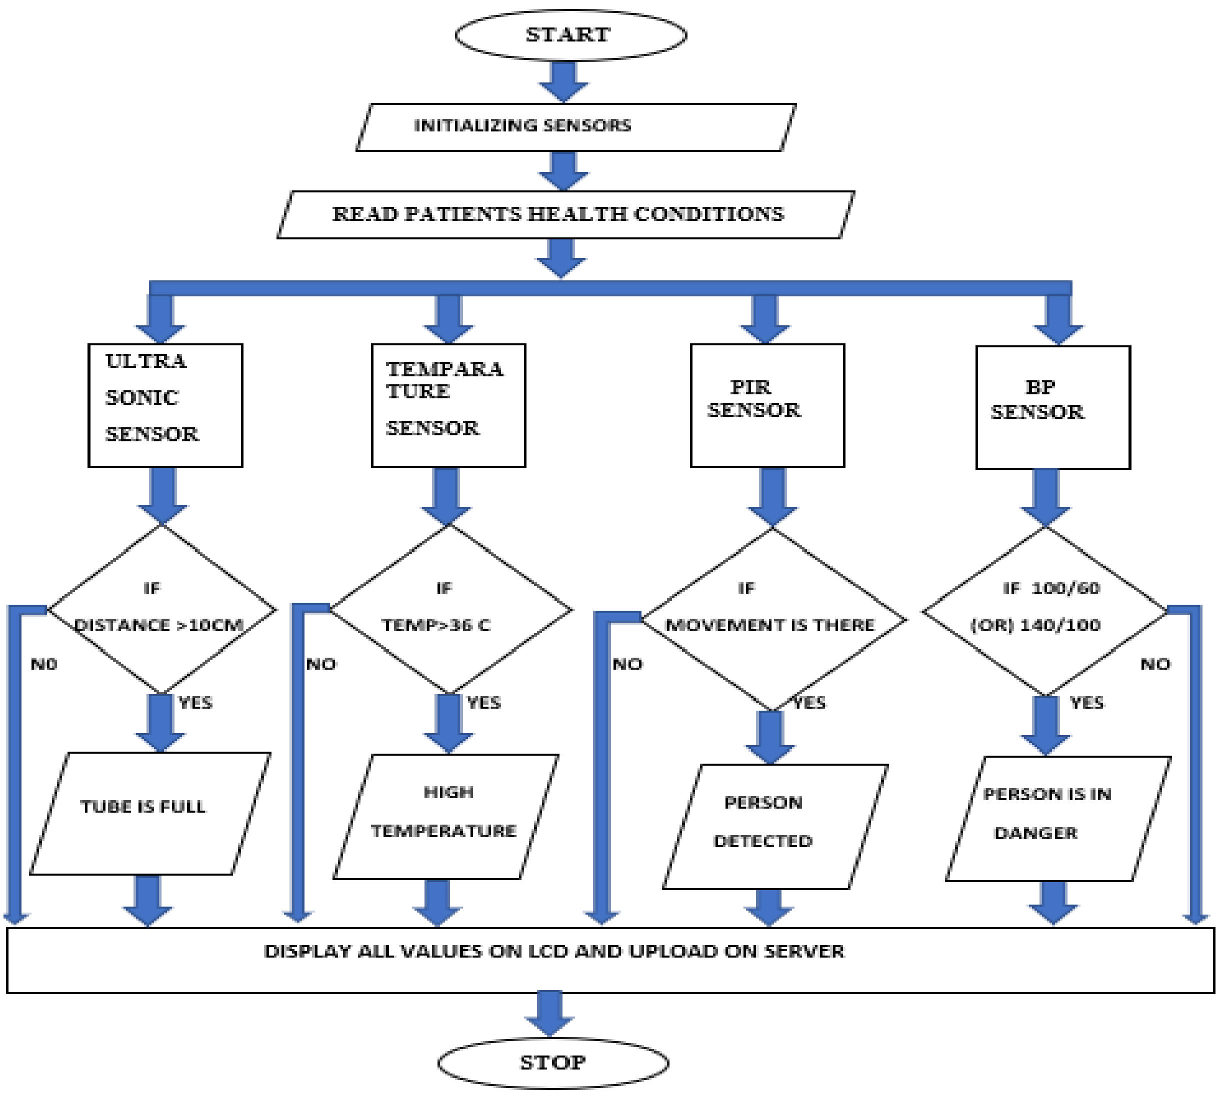

Fig 6.1 Flow Chart

6.2 IMPLEMENTATION STAGES

Stage 1:

When we switch on the power supply, the circuit will be activated and LCD displays as WELCOME.

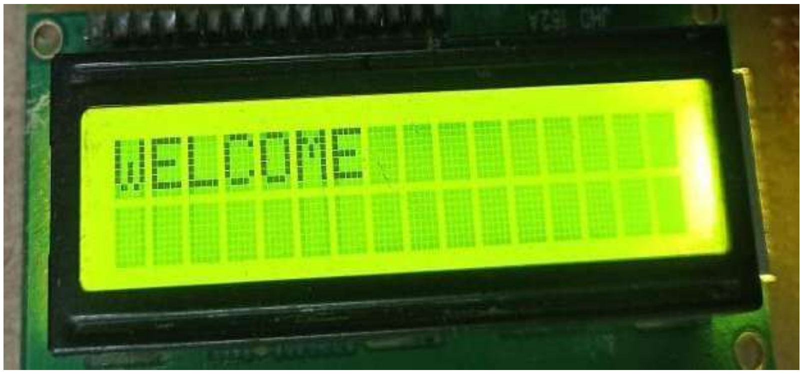

Fig 6.2.1 Starting of the operation

Stage 2:

To connect to wi-fi, we need to enter Required SSID name and its password in order establish internet connection to the system.

Fig 6.2.2.1 Status of the internet connection as connecting

After entering correct required SSID name and its password, the status of the internet connection will be displayed as CONNECTED on LCD.

Fig 6.2.2.2 Status of internet connection as connected

Stage 3:

In this stage, Sensors like temperature sensor, ultrasonic sensor, pir sensor and blood pressure sensor calculates the coma patient's vital health parameters and sends that information to Arduino and displays status on LCD.

Fig 6.2.3 Ultrasonic Sensor

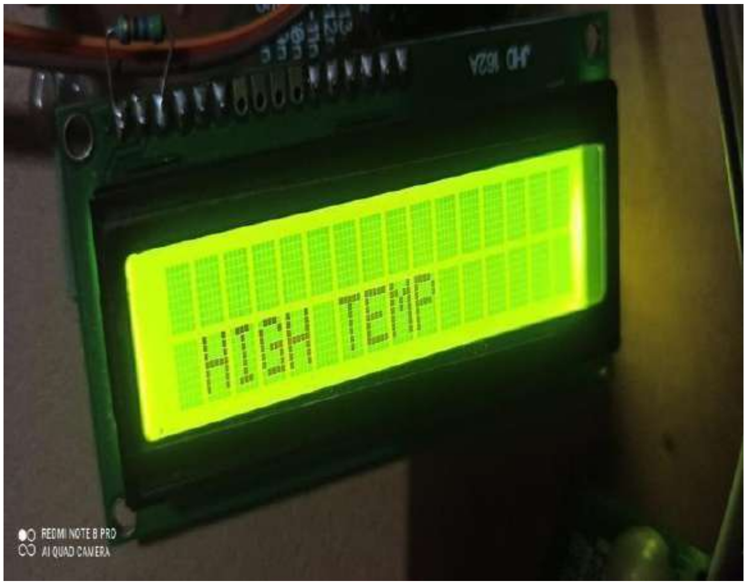

Fig 6.2.4 Temperature Sensor

Fig 6.2.5 PIR Sensor

Stage 4

After calculating all vital health parameters, these values are also uploaded into the server and that status is displays on LCD

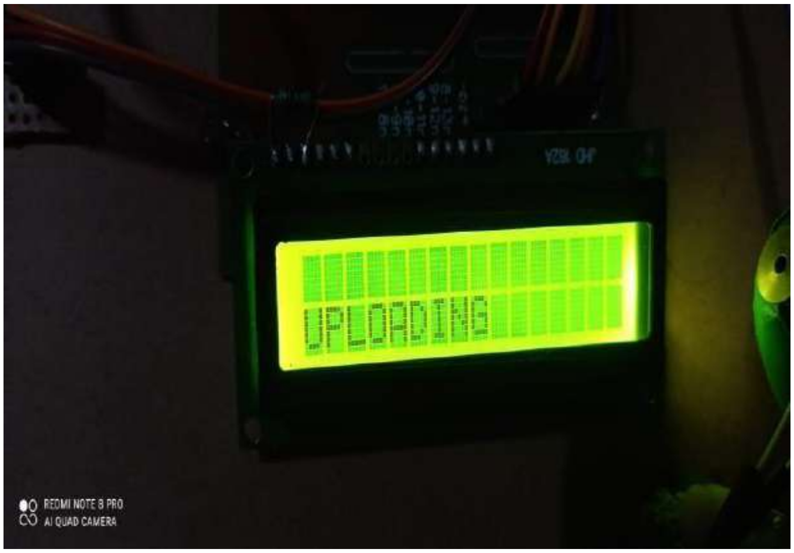

Fig6.2.6 Server Conformation

In this way, all the vital health parameter is calculated and also all calculated information is also uploaded in the things Speak Server. So that doctor can check and analyze patients health condition and can give any prescription to patient from anywhere in the world.

CHAPTER-7
APPLICATIONS AND ADVANTAGES

7.1 APPLICATION OF THE PROJECT:

- IoT has applications in healthcare that benefit patients, families, physicians, hospitals and insurance companies. IoT for Patients - Devices in the form of wearables like fitness bands and other wirelessly connected devices like blood pressure and heart rate monitoring cuffs, glucometer etc.
- IoT is undoubtedly transforming the healthcare industry by redefining the space of devices and people interaction in delivering healthcare solutions. IoT has applications in healthcare that benefit patients, families, physicians, hospitals and insurance companies.
- **IoT for Patients** - Devices in the form of wearables like fitness bands and other wirelessly connected devices like blood pressure and heart rate monitoring cuffs, glucometer etc. give patients access to personalized attention. These devices can be tuned to remind calorie count, exercise check, appointments, blood pressure variations and much more.
- IoT has changed people's lives, especially elderly patients, by enabling constant tracking of health conditions. This has a major impact on people living alone and their families. On any disturbance or changes in the routine activities of a person, alert mechanism sends signals to family members and concerned health providers.
- **IoT for Physicians -** By using wearables and other home monitoring equipment embedded with IoT, physicians can keep track of patients' health more effectively. They can track patients' adherence to treatment plans or any need for immediate medical attention. IoT enables healthcare professionals to be more watchful and connect with the patients proactively. Data collected from IoT devices can help physicians identify the best treatment process for patients and reach the expected outcomes.
- **IoT for Hospitals -** Apart from monitoring patients' health, there are many other areas where IoT devices are very useful in hospitals. IoT devices tagged with sensors are used for tracking real time location of medical equipment like wheelchairs, defibrillators, nebulizers,

Oxygen Pumps and other monitoring equipment. Deployment of medical staff at different locations can also be analyzed real time.

- The spread of infections is a major concern for patients in hospitals. IoT-enabled hygiene monitoring devices help in preventing patients from getting infected. IoT devices also help in asset management like pharmacy inventory control, and environmental monitoring, for instance, checking refrigerator temperature, and humidity and temperature control.

7. 2 ADVANTAGES OF THE PROJECT:

- This system is less costly more reliable and efficient as compared to other systems.
- 24 * 7 monitoring of coma patient.
- Continuous recording of patient data after particular time period.
- Power consumption less.
- No need of human attention for continuous observation of coma patient.
- High speed communication between doctor and patient through Things Speak cloud.

CHAPTER-8
CONCLUSION AND FUTURE ENCHANCEMENT

8.1 CONCLUSION:

The Internet of Things is considered now as one of the feasible solutions for any remote value tracking especially in the field of health monitoring. It facilitates that the individual prosperity parameter data is secured inside the cloud, stays in the hospital are reduced for conventional routine examinations and most important that the health can be monitored and disease diagnosed by any doctor at any distance.

8.2 FUTURE SCOPE:

- For further implementation, in emergency situations, this system can automatically send a warning message or call to alert the nearest hospital as well as to the ambulance if any abnormal data is identified in monitoring.
- The advanced development for the designed model is to add more parameters for monitoring the health status of patient.
- In future improvement to this designed model is to include MEDIBOX. This system can be used by the paralyzed patients by sending or giving reminder alert to take their medicines or dosage on time.
- Another extension to this system is to add web camera, after that anyone can monitor patient world-wide at any time.

PUBLICATION

Submitted Paper in the Conference ICSMEC – 21 with Paper ID (ICSMEC21-0081) and got Acceptance of paper.

DECLARATION

We, the student of Bachelor of Technology in Department of 'Electronics and Communications Engineering', session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "**DESIGN OF A LASER COMMUNICATION LINK BETWEEN SATELLITES IN A CONSTELLATION**" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Kushal Pooppal (17K81A04L8)
Amith Reddy Mosali (17K81A04N0)
Nikhil Mishra (17K81A04N4)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communications Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept. project coordinator Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide **Ms. Pushpa P**, **Assistant Professor,** Department of ECE and our class coordinator **Ms. Pushpa P, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinator **Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Satellites are the most important nodes in the global communication infrastructure on and off-earth. They have made communication in today's world more versatile. satellites helped in connecting stations and people from different parts of the globe. Despite it's popular applications, it's rarely available in rural areas. This can be solved by the use of Satellite Constellations which form a grid of networks in space, A satellite constellation is a group of artificial satellites working together as a system. Unlike a single satellite, a constellation can provide permanent global or near-global coverage. To facilitate high-bandwidth data transfer between satellites a novel Laser Communication Link needs to be designed that automatically acquires and tracks the signal to the next satellite ,thus allowing the data to be transferred within the constellation and then to the land to receive the data at high speeds. A laser communication link combined with satellite constellation grid will truly provide global high-speed internet access with future applications in LunarNet

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

LIST OF GRAPHS

GLOSSARY OF COMMONLY USED TERMS:

Satellite - An artificial body placed in orbit around the earth or moon or another planet in order to collect information or for communication.

Satellite constellation - A satellite constellation is a group of artificial satellites working together as a system. Unlike a single satellite, a constellation can provide permanent global or near-global coverage, such that at any time everywhere on Earth at least one satellite is visible.

Laser - A device that generates an intense beam of coherent monochromatic light (or other electromagnetic radiation) by stimulated emission of photons from excited atoms or molecules.

Acquisition - The process or technique of acquiring the required object within a particular range.

Tracking - The Process of following the acquired target for a particular period of time for a particular purpose.

LDR - It is a passive component that decreases resistance with respect to receiving luminosity on the component's sensitive surface.

Morse Code - An alphabet or code in which letters are represented by combinations of long and short light or sound signals

PWM - Pulse-width modulation, or pulse-duration modulation, is a method of reducing the average power delivered by an electrical signal, by effectively chopping it up into discrete parts, it is a technique for getting analog results with digital means.

Throughput - is the actual amount of data that is successfully sent/received over the communication link.

BPS - A measure of data transmission speeds, the amount of bits transferred in a single second.(Bits per second).

WPS - A measure of data transmission speeds, the amount of words transferred in a single second.(Words per second).

TX - Abbreviation for Transmitter

RX - Abbreviation for Receiver

I2C - I2C is a serial communication protocol, so data is transferred bit by bit along a single wire (the SDA line) and the other is SCL

LOS - Abbreviation for Line of Sight.

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

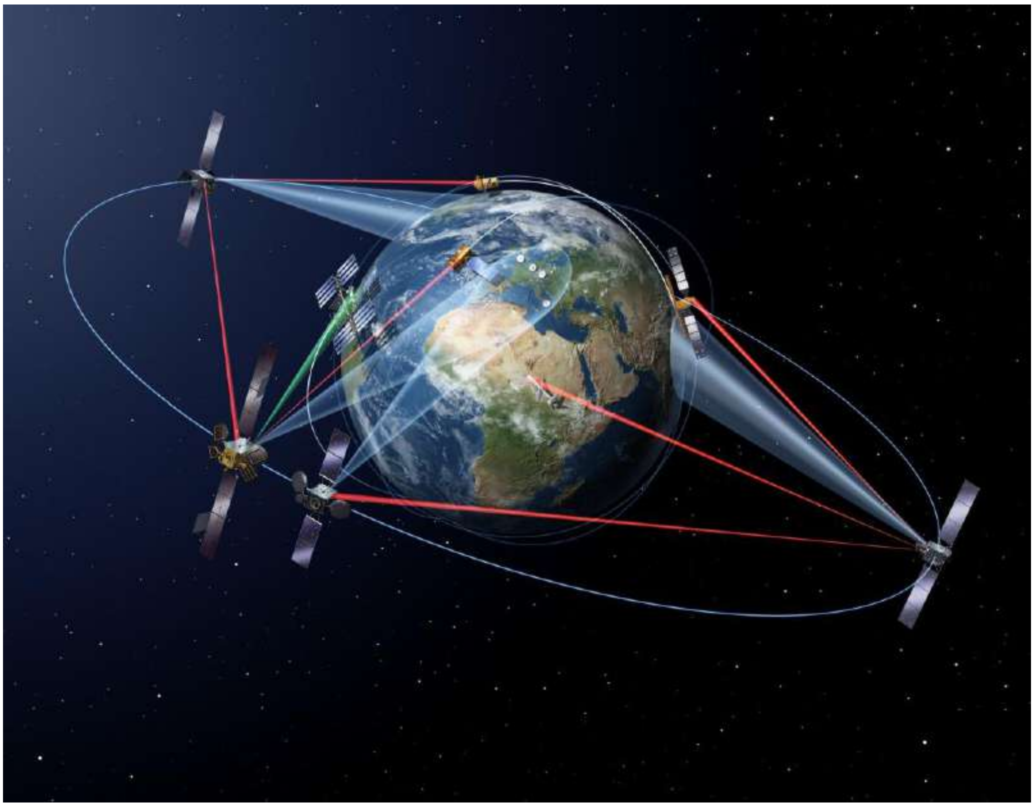

Fig 1.1: Global Space Segment of Communication

The demand for data—raw facts—and its successful evolution to information—arranged in context—is growing, arguably at an exponential rate. This is true for the civil, commercial, and security sectors (i.e., defense; specifically, the U.S. Department of Defense). Civil space activities include those to explore space and advance human understanding; commercial activities are those where private companies and industries provide services with the intent of making a profit [1]. During 1991's Operation DESERT STORM in Iraq, the U.S. Department of Defense had access to ninety-nine mega-bits per second of bandwidth. In 2003, access for Operations ENDURING FREEDOM in Afghanistan and IRAQI FREEDOM had grown to thirty-two-hundred mega-bits per second. In 2007, U.S. Department of Defense planners projected the need for sixteen giga-bits per second by 2010 [2]. A rudimentary analysis concludes that the U.S. Department of Defense requires an order of magnitude increase in bps every nine years. The U.S. Department of Defense's demand for data, information, and intelligence is exceeding its satellite communications capacity, whether owner-operator or contracted. Transitioning to laser-based satellite communications, in part due to its orders of magnitude greater throughput, is becoming necessary for the U.S. Department of Defense. Laser communications could provide from ten to one-hundred times better data rates than radio, due to the higher bandwidth [3]. This manuscript examines the technological maturation of employing lasers as the signal carrier for satellite communications linking terrestrial and space systems. The purpose of the manuscript is to inform the U.S. Department of Defense initial capabilities documents (ICDs) or key performance parameters (KPPs) for near-future satellite acquisition and development. By appreciating the history and technological challenges of employing lasers, rather than traditional radio frequency sources for satellite uplink and downlink signal carriers, this manuscript recommends ways for the U.S. Department of Defense to employ lasers to transmit and receive high bandwidth and large-throughput data from moving platforms that need to retain low probabilities of detection, intercept, and exploit (e.g., carrier battle group transiting to a hostile area of operations, unmanned aerial vehicle collecting over adversary areas). The manuscript also intends to identify commercial sector early-adopter fields and those fields likely to adapt to laser employment for transmission and receipt.

1.2 OBJECTIVES OF THE STUDY:

1. **Compare** existing system with Laser Comms
2. **Develop**: Signal Acquisition and Tracking for TX-RX
3. **Prototype**: Demonstrate LC between Sats using COTS
4. **Design**: An Implementation for Laser Comms in Satellite Constellation

1.3 SCOPE OF THE STUDY:

Satellites have made communication in today's world more versatile. A satellite constellation is a group of artificial satellites working together as a system. Unlike a single satellite, a constellation can provide permanent global or near-global coverage.

The present inter-sat communications is being carried out by RF(Radio Frequency) signals, which have its drawbacks in aspects like security, bandwidth, throughput, etc compared to laser communication.

To facilitate high-bandwidth data transfer between satellites a Laser Communication Link needs to be designed that automatically acquires and tracks the signal to the next satellite ,thus allowing the data to be transferred within the constellation and then to the land to receive the data at high speeds. A laser communication link combined with satellite constellation grid will truly provide global high-speed internet access with future applications in LunarNet.

The areas where the project focuses is in designing and developing techniques like Acquisition and tracking to successfully transmit data through laser using morse code and the chosen modulation techniques. These methods have to be followed to keep the satellites in Line of Sight throughout the period of communication for uninterrupted data transfer.

This project when implemented in the real world using viable equipment and technology can drastically improve the communication from the space segment.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino UNO - 2
- LASER Diode 650nm 5mw - 1
- Servos SG 90 - 2
- LDRs or Photoresistor - 3
- Perfboard
- Breadboard - 2
- Jumper Wires
- USB Type A Cable - 2

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino IDE
- MATLAB
- Visual Studio Code

1.4 PROCUREMENT OF EQUIPMENT:

All the equipment used in the project are Commercially available off the shelf parts(COTS) procured from tech stores.

The assembling is done on our own expertise and connections are made with great care following all safety precautions

The coding for the project, that is the code to be dumped in arduino, is developed using Arduino IDE and integrated into the project.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

This section begins with a quote succinctly introducing the history of laser employment, followed by chronological articulation before and through the twenty-first century. Following brief chronology, brief paragraphs introduce historical applications, finalizing the preparation for discussion of the results.

HISTORY OF LASER

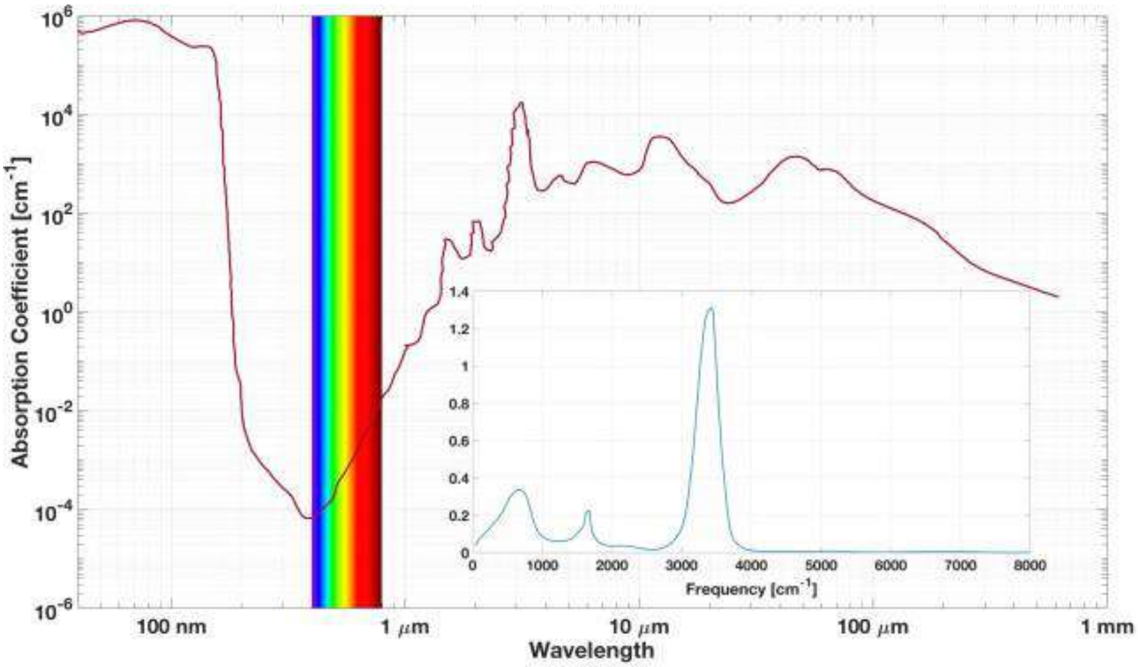

Fig 2.1: Attenuation of optical communication

Employment as Link Source Relevant laser applications have a long, interesting pedigree that harks back to the beginning of the space era. “The registered history of laser technologies for space application starts with the first laser echoes reflected off the Moon in 1962. Since then, photonic technologies have become very prominent in most technical development. Their presence has also dramatically increased in space applications thanks to the many advantages they present over traditional equivalent devices, such as the immunity against electromagnetic interference, as well as their efficiency and low power consumption. Lasers are one of the key components in most of those applications.” [4,5] The application of lasers for communications across great distances has an even longer pedigree, although the notions were not actualized until the last century.

Prior to the Twenty-First Century Shortly after WWII, Arthur C. Clarke wrote about employing light beams to transmit information [6]. His foresight was not realized until the 1960s with the development of the laser. Furthermore, it was not demonstrated as intended until the 1995 bidirectional ground-to-orbit laser communication demonstrations. The program successfully used lasers to uplink and downlink to the engineering test satellite-VI in elliptical geosynchronous transfer orbit, sending and receiving at a 1 mega-bits per second rate [7]. This unhurried pace (50 years between idea and demonstration: 30 years between technology development and adaptation) exemplifies the field of laser communications. Before considering lasers for uplinks and downlinks [8], lasers were employed for geodesy first [9–22] and also orbital determination [23–33]. The 1990s jump-started scientific examination of space and satellite laser communications [34–53]. Over roughly the next decade, the U.S. national air and space administration, and the European and Japanese space agencies, completed successful trials of space-based laser communications [34]. In 2001, the European space agency's semiconductor intersatellite link experiment and advanced relay and technology mission satellite received fifty mega-bits per second from hich is depicted in Figure 1. That same year, the geosynchronous lightweight technology experiment also successfully demonstrated bi-directional laser communications, and this time added an aircraft to the reception station list [35]. 2.1.2. Early Twenty-First Century Figure 1. satellite uplink and downlink with terrestrial stations from [8]: 0.6 m transmitter uplinking at 514.5 nanometers and 1.2 m receiver downlinking at 830 nanometers. The advanced relay and technology mission satellite laser communications capability was supplied by the optical payload laser experiment and the laser-utilizing communications equipment. Both systems provided source laser beams, at ten milli-watts and forty milli-watts, respectively. However, a lesson learned from the semiconductor intersatellite link experiment was that even with the laser-utilizing communications equipment beam's quadruple power, it failed to provide sufficient irradiance at ground-to-geosynchronous orbit ranges to perform initial acquisition [37]. However, the semiconductor intersatellite link experiment demonstrated a downlink bit error rate of 10-10 [37]. The semiconductor intersatellite link experiment did however reinforce a foundational advantage of laser communications over radio frequency communications: that laser communications requires less size, weight, and power for a given data rate [36]. Demonstrated years later, a two—point-five giga-bits per second communications link with a roughly three decibel link margin across a range of forty-two thousand kilometers, a capability that can be made using a two point-two meter antenna for Ka-band (weighing one-hundred fifty-three kilograms), a one-point nine meter antenna for a millimeter band (weighing one-hundred thirty-two kilograms), and a ten centimeters optical system for a one-point five-five micrometers wavelength (weighing sixty-five kilograms) [37]. In 2013, the U.S. national air and space administration began examining laser communications in earnest, focused in support of further exploration of Mars and beyond. That year the administration launched the lunar laser communications demonstrator [42,43], a high-rate demonstration of space laser communications [42]. “The Lunar Laser Communication Demonstration (LLCD) was conducted on NASA’s Lunar Atmosphere and Dust Environment Explorer (LADEE) satellite that launched in late 2013 [41]. The LLCD payload Figure 1. Satellite uplink and downlink with terrestrial stations from [8]: 0.6 m transmitter uplinking at 514.5 nanometers and 1.2 m receiver downlinking at 830 nanometers. 2.1.2. Early Twenty-First Century The advanced relay and technology mission satellite laser communications capability was supplied by the optical payload laser experiment and the laser-utilizing communications equipment. Both systems provided source laser beams, at ten milli-watts and forty milliwatts, respectively. However, a lesson learned from the semiconductor intersatellite link experiment was that even with the laser-utilizing communications equipment beam’s quadruple power, it failed to provide sufficient irradiance at ground-to-geosynchronous orbit ranges to perform initial acquisition [37]. However, the semiconductor intersatellite link experiment demonstrated a downlink bit error rate of 10−10 [37]. The semiconductor intersatellite link experiment did, however, reinforce a foundational advantage of laser communications over radio frequency communications: that laser communications requires less size, weight, and power for a given data rate [36]. Demonstrated years later was a 2.5 giga-bits per second communications link with a roughly three decibel link margin across a range of forty-two-thousand kilometers, a capability that can be made using a two-point-two meter antenna for Ka-band (weighing one-hundred fifty-three kilograms), a one-point nine meter antenna for a millimeter band (weighing one-hundred thirty-two kilograms), and a ten centimeter optical system for a 1.55 micrometer wavelength (weighing sixty-five kilograms) [37]. In 2013, the U.S. national air and space administration began examining laser communications in earnest, focused in support of the further exploration of Mars and beyond. That year, the administration launched the lunar laser communications demonstrator [42,43], a high-rate demonstration of space laser communications [42].

2.2 REVIEW ON RELATED LITERATURE:

Localization of underwater sensors is an important part of UOWNs for many applications such as resource exploration, surveillance, underwater environment monitoring, and disaster prevention. The large propagation delay of acoustic channels and high attenuation of RF/optical channels pose significant challenges for underwater localization. The major challenges for underwater localization are

Deployment of nodes: Most of the localization algorithms depend on the distribution of sensor nodes and the anchor nodes to form a network [44], [336]. • Mobility of the nodes: Due to the uncontrollable phenomena such as winds, turbulence, and current, the underwater sensor nodes inevitably drift from its position. The location of anchor nodes on the surface buoys can be accurately measured by using GPS but the location of the underwater nodes cannot be precisely measured.

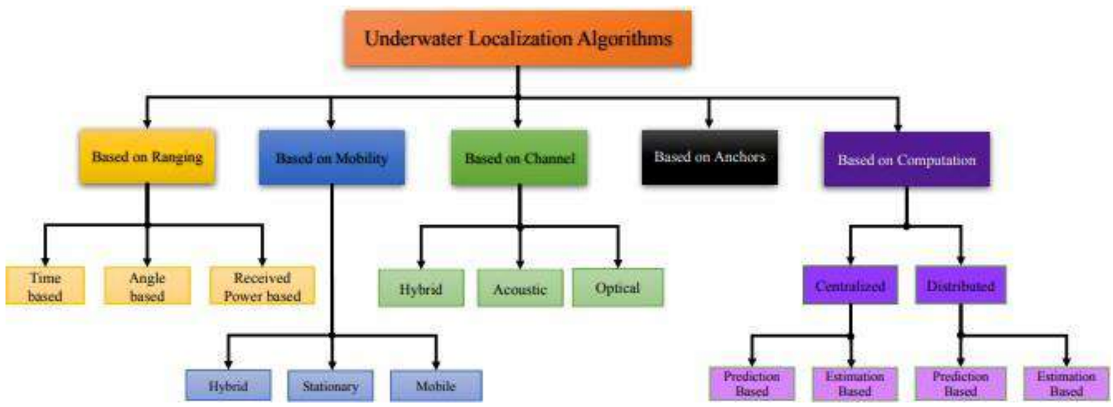

Fig 2.2: Taxonomy of underwater localization algorithms

Variations in the underwater wireless communication channel are very severe for all types of carrier waves. The effects of attenuation, absorption, reflection, scattering, and noise do not allow for accurate range measurements, thus reflecting large localization estimation error [45]. Synchronization: As the GPS signals are not available in the underwater environment, it is hard to achieve the time synchronization between the sensor nodes. Thus, if the time of arrival based ranging is used, this miss-synchronization will lead to large localization errors.

2.3 CONCLUSION ON REVIEWS:

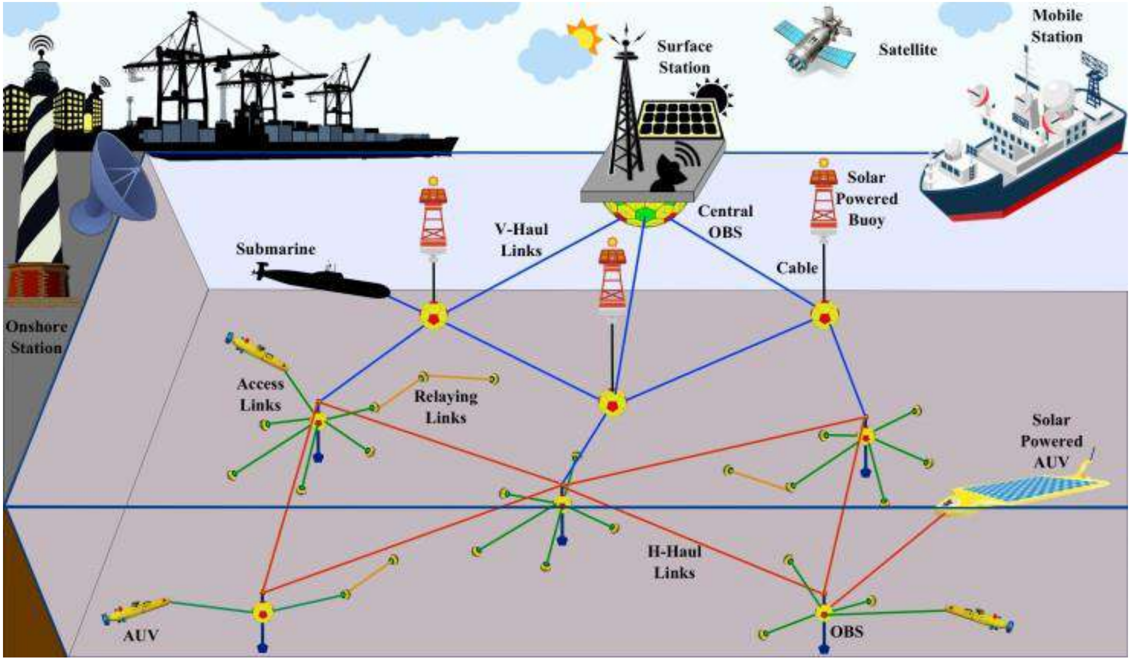

Fig 2.3 Illustration of underwater submarine optical comms

In this paper, we have presented a comprehensive survey of underwater optical wireless networks (UOWNs) research. This survey covers different aspects of cutting-edge UOWNs from a layer by layer perspective. Firstly, each layer of UOWNs such as physical, data link, networking, transport, and application layers are briefly presented and then localization techniques for UOWNs are surveyed. We started with defining different possible architectures for UOWNs and then the issues related to each layer are thoroughly discussed. Besides providing the technical background on UOWNs, we have also provided details on the challenges to design a practical UOWN. Additionally, localization is an important task where the location of the underwater optical sensor node can be used for node tracking, intruder detection, and data tagging. To reach this goal, communication, networking, and localization in UOWNs require more research efforts. In short, this survey can help the novice readers to get an insight of each layer and localization of UOWNs which can lead to the development of practical UOWNs.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

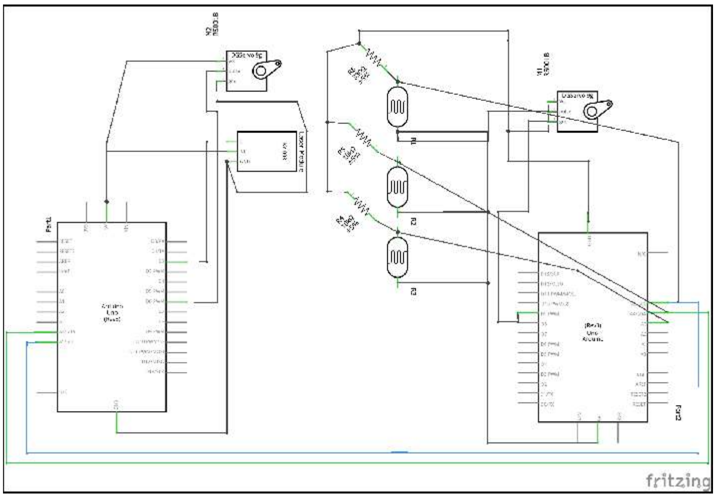

Fig 3.1 Schematic of the project

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION

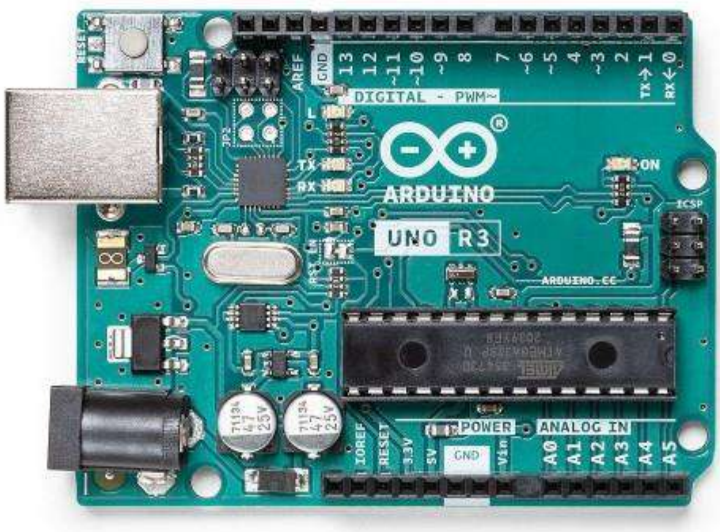

Fig 3.2 Arduino UNO Board Top View

Arduino is a prototype platform (open-source) based on easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connecting to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

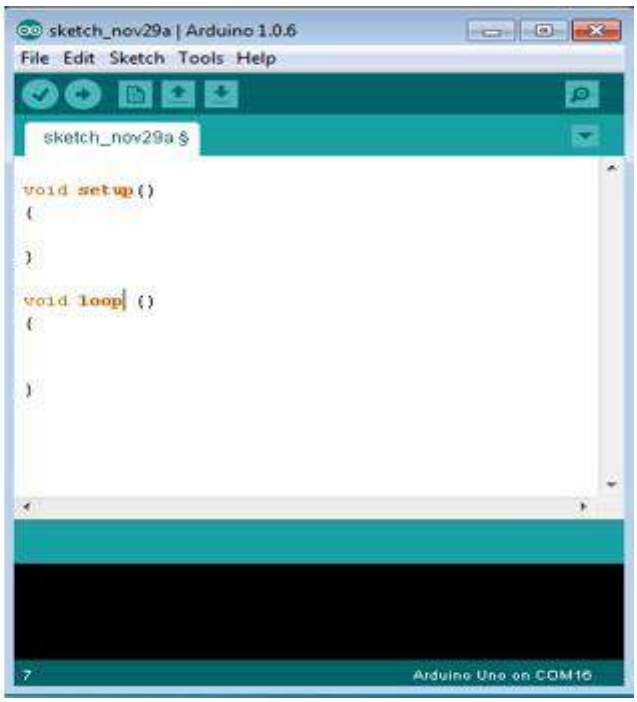

Fig 3.3 Arduino IDE View

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

Fig 3.4 Different Arduino Board Types

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Arduino boards based on ATMEGA328 microcontroller

Board Name	Op Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Arduino boards based on ATMEGA32u4 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

Arduino boards based on AT91SAM3X8E microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have the majority of these components in common.

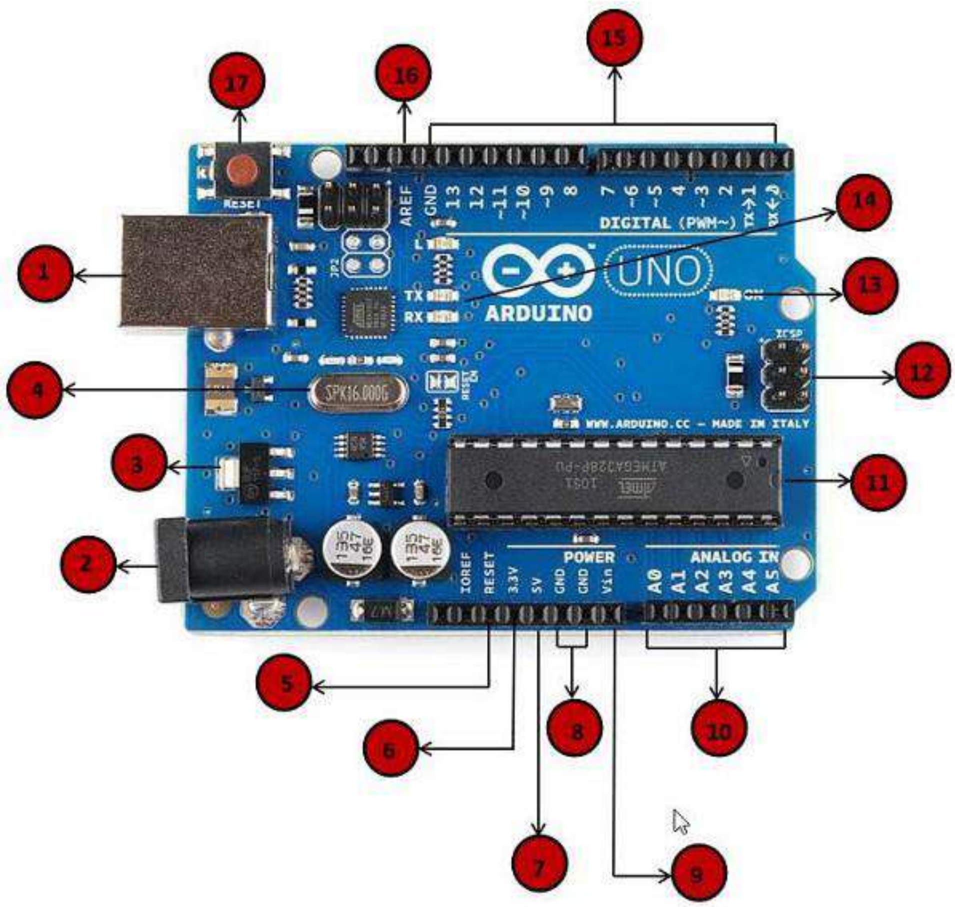

Fig 3.5 Arduino Pin Description

Table 4: Arduino Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the

	reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.

<table>
<tr><td>12</td><td>ICSP pin

Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.</td></tr>
<tr><td>13</td><td>Power LED indicator

This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.</td></tr>
<tr><td>14</td><td>TX and RX LEDs

On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.</td></tr>
<tr><td>15</td><td>Digital I/O

The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.</td></tr>
</table>

16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.5: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.6: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

Fig.3.7 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 LDR

A photo resistor is an electronic component whose resistance decreases with increasing incident light intensity. It can also be called a light-dependent resistor (LDR), or photoconductor.

Other light dependent resistors, or photo resistors have been made using materials including Cadmium Sulphide, Lead Sulphide and the more commonly used semiconductor materials including Ge ,Si and GaAs.

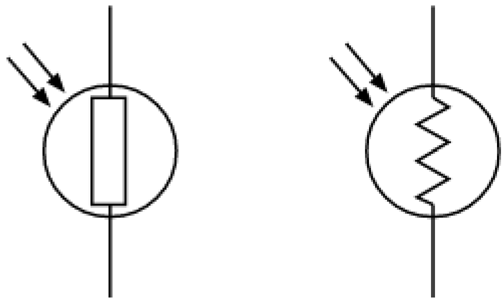

Fig 3.8: - Schematic Symbol of Photoresistor/LDR

The photoresistor, or Light Dependent Resistor, finds many uses as a low cost photosensitive element and was used for many years in photographic light meters as well as other applications.such as flame, smoke, and burglar detectors, card readers and lighting controls for street lamps. Units for the light intensity are Lux or Lumens.

1. **Basic structure:**

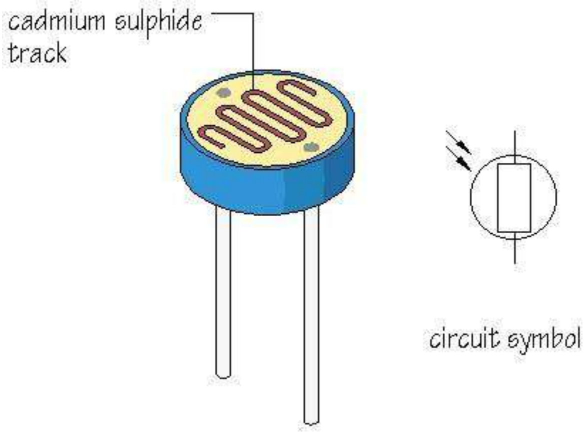

Fig 3.9 LDR Internal Layout

Although there are many ways in which LDR's or photo resistors can be manufactured, there are naturally a few more common methods that are seen. Essentially the LDR or photoresistor consists of a resistive material sensitive to light that is exposed to light. The photo resistive element comprises a section of material with contacts at either end. Although many of the materials used for light dependent resistors are semiconductors, when used as photo resistors, they are used only as a resistive element and there are no p-n junctions. Accordingly the devices are purely passive.

A typical structure for a Light Dependent Resistor uses an active semiconductor layer that is deposited on an insulating substrate. The semiconductor is normally lightly doped to enable it to have the required level of conductivity. Contacts then placed either side of the exposed area. In many instances the area between the contacts is in the form of zig zag, or inter digital pattern. This maximizes the exposed area and by keeping the distance between the contacts small it enhances the gain.

It is also possible to use a polycrystalline semiconductor that is deposited onto a substrate such as ceramic. This makes for a very low cost light dependent resistor.

2. Operation

Light Dependent Resistor made of a high resistance semiconductor, if light falling on the is of high enough efficiently, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, thereby lowering resistance.

In intrinsic devices, the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electrons across the entire band gap. Extrinsic devices have impurities added , which have a ground state energy closer to the conduction band, since the electrons don't have so far to jump, lower energy photons (i.e. longer wavelengths and lower frequencies) will suffice to trigger the device.

3. Characteristics of LDR:

The characteristics of LDR are shown below. Here the resistance variations are shown as a function of illumination. The resistance of LDR decreases with increasing incident light intensity.

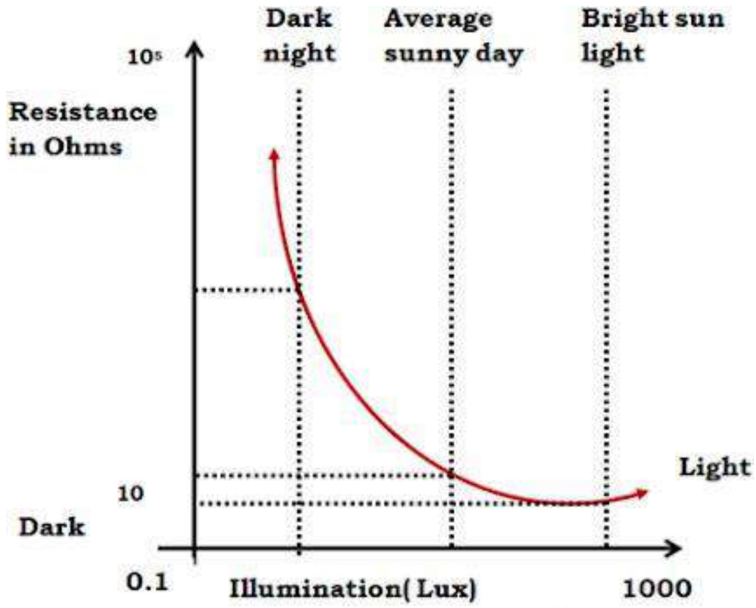

Fig 3.10: - Characteristics of LDR

4. LDR Applications:

Photoresistors come in many types. Inexpensive cadmium sulfide (CdS) cells can be found in many consumer items such as camera light meters, clock radios, alarm devices (as the detector for a light beam), nightlights, outdoor clocks, solar street lamps, and solar road studs, etc.Photoresistors can be placed in streetlights to control when the light is on. Ambient light falling on the photoresistor causes the streetlight to turn off. Thus energy is saved by ensuring the light is only on during hours of darkness.

Photoresistors or LDRs are also used in laser-based security systems to detect the change in the light intensity when a person/object passes through the laser beam.They are also used in some dynamic compressors together with a small incandescent or neon lamp, or light-emitting diode to control gain reduction. A common usage of this application can be found in many guitar amplifiers that incorporate an onboard tremolo effect, as the oscillating light patterns control the level of signal running through the amp circuit.The use of CdS and CdSe[3] photoresistors is severely restricted in Europe due to the RoHS ban on cadmium.

Lead sulfide (PbS) and indium antimonide (InSb) LDRs (light-dependent resistors) are used for the mid-infrared spectral region. Ge:Cu photoconductors are among the best far-infrared detectors available, and are used for infrared astronomy and infrared spectroscopy.

1. Camera light meters.
2. Clock radios.
3. Security alarms.
4. Optical switches.
5. Far infrared detector.
6. Streetlights.

5. **Testing Circuit of LDR:**

3.2.3 SERVO MOTOR

A **servo motor** is a type of motor that can rotate with great precision. Normally this type of motor consists of a control circuit that provides feedback on the current position of the motor shaft, this feedback allows the servo motors to rotate with great precision. If you want to rotate an object at some specific angles or distance, then you use a servo motor. It is just made up of a simple motor which runs through a **servo mechanism**. If a motor is powered by a DC power supply then it is called a DC servo motor, and if it is an AC-powered motor then it is called an AC servo motor. For this tutorial, we will be discussing only about the **DC servo motor working**. Apart from these major classifications, there are many other types of servo motors based on the type of gear arrangement and operating characteristics. A servo motor usually comes with a gear arrangement that allows us to get a very high torque servo motor in small and lightweight packages. Due to these features, they are being used in many applications like toy cars, RC helicopters and planes, Robotics, etc.

Servo motors are rated in kg/cm (kilogram per centimeter) most hobby servo motors are rated at 3kg/cm or 6kg/cm or 12kg/cm. This kg/cm tells you how much weight your servo motor can lift at a particular distance. For example: A 6kg/cm Servo motor should be able to lift 6kg if the load is suspended 1cm away from the motors shaft, the greater the distance the lesser the weight carrying capacity. The position of a servo motor is decided by electrical pulse and its circuitry is placed beside the motor.

Servo Motor Working Mechanism

It consists of three parts:

1. Controlled device
2. Output sensor
3. Feedback system

It is a closed-loop system where it uses a positive feedback system to control motion and the final position of the shaft. Here the device is controlled by a feedback signal generated by comparing output signal and reference input signal.

Here the reference input signal is compared to the reference output signal and the third signal is produced by the feedback system. And this third signal acts as an input signal to control the device. This signal is present as long as the feedback signal is generated or there is a difference between the reference input signal and reference output signal. So the main task of servomechanism is to maintain the output of a system at the desired value in the presence of noises.

Servo Motor Working Principle

A servo consists of a Motor (DC or AC), a potentiometer, gear assembly, and a controlling circuit. First of all, we use gear assembly to reduce RPM and to increase torque of the motor. Say at the initial position of the servo motor shaft, the position of the potentiometer knob is such that there is no electrical signal generated at the output port of the potentiometer. Now an electrical signal is given to another input terminal of the error detector amplifier. Now the difference between these two signals, one comes from the potentiometer and another comes from other sources, will be processed in a feedback mechanism and output will be provided in terms of error signal. This error signal acts as the input for the motor and motor starts rotating. Now the motor shaft is connected with the potentiometer and as the motor rotates so does the potentiometer and it will generate a signal. So as the potentiometer's angular position changes, its output feedback signal changes. After sometime the position of potentiometer reaches a position that the output of potentiometer is the same as the external signal provided. At this condition, there will be no output signal from the amplifier to the motor input as there is no difference between external applied signal and the signal generated at potentiometer, and in this situation the motor stops rotating.

Interfacing Servo Motors with Microcontrollers:

Interfacing hobby Servo motors like s90 servo motors with MCU is very easy. **Servos have three wires coming out of them**. Out of which two will be used for Supply (positive and negative) and one will be used for the signal that is to be sent from the MCU. An **MG995 Metal Gear Servo Motor** which is most commonly used for RC cars, humanoid robots etc. The picture of MG995 is shown below:

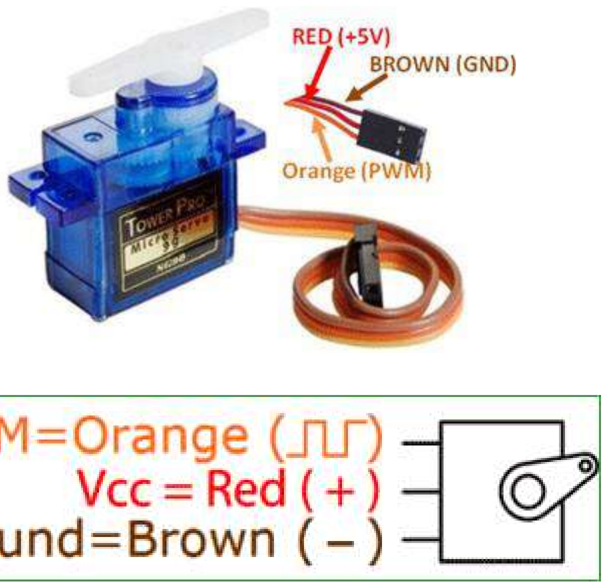

Fig 3.12 Servo Motor PWM Wiring

The color coding of your servo motor might differ hence check for your respective datasheet.

All servo motors work directly with your +5V supply rails but we have to be careful on the amount of current the motor would consume if you are planning to use more than two servo motors a proper servo shield should be designed.

Controlling Servo Motor:

All motors have three wires coming out of them. Out of which two will be used for Supply (positive and negative) and one will be used for the signal that is to be sent from the MCU.

Servo motor is controlled by PWM (Pulse width Modulation) which is provided by the control wires. There is a minimum pulse, a maximum pulse and a repetition rate. Servo motor can turn 90 degrees from either direction from its neutral position. The servo motor expects to see a pulse every 20 milliseconds (ms) and the length of the pulse will determine how far the motor turns. For example, a 1.5ms pulse will make the motor turn to the 90° position, such as if the pulse is shorter than 1.5ms the shaft moves to 0° and if it is longer than 1.5ms then it will turn the servo to 180°.

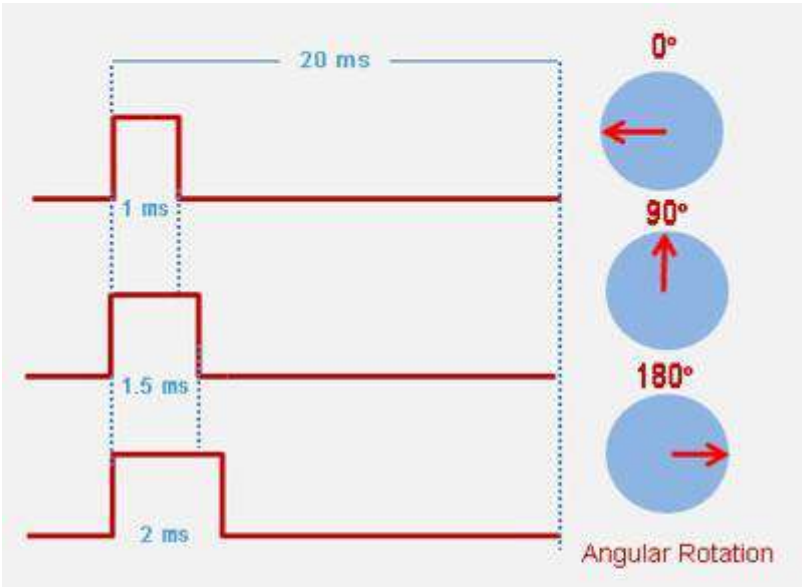

Fig 3.13: PWM Pulsing time series graph

Servo motor works on **PWM (Pulse width modulation)** principle, means its angle of rotation is controlled by the duration of applied pulse to its Control PIN. Basically, servo motor is made up of **DC motor which is controlled by a variable resistor (potentiometer) and some gears**. High speed force of the DC motor is converted into torque by Gears. We know that

WORK= FORCE X DISTANCE,

in DC motor Force is less and distance (speed) is high and in Servo, force is High and distance is less. The potentiometer is connected to the output shaft of the Servo, to calculate the angle and stop the DC motor on the required angle.

Servo motor can be rotated from 0 to 180 degrees, but it can go up to 210 degrees, depending on the manufacturing.

This degree of rotation can be controlled by applying the **Electrical Pulse** of proper width, to its Control pin. Servo checks the pulse every 20 milliseconds. The pulse of 1 ms (1 millisecond) width can rotate the servo to 0 degrees, 1.5ms can rotate to 90 degrees (neutral position) and 2 ms pulse can rotate it to 180 degree.

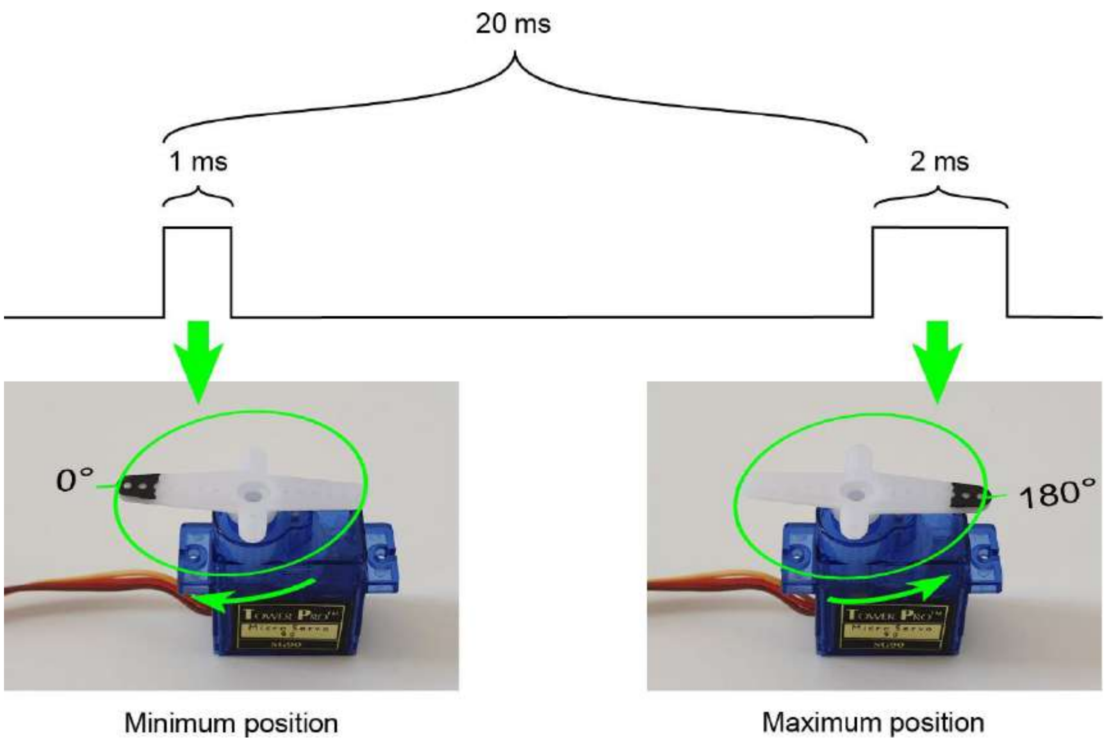

Fig 3.14 Servo Pulse Width with Angle

All servo motors work directly with your +5V supply rails but we have to be careful about the amount of current the motor would consume if you are planning to use more than two servo motors a proper servo shield should be designed.

3.2.3.2 SPECIFICATION

Dimensions & Specifications
A (mm) : 32
B (mm) : 23
C (mm) : 28.5
D (mm) : 12
E (mm) : 32
F (mm) : 19.5
Speed (sec) : 0.1
Torque (kg-cm) : 2.5
Weight (g) : 14.7
Voltage : 4.8 - 6

3.2.4 LASER DIODE

Fig 3.15: Laser Diode

A Laser Diode is a semiconductor device similar to a light-emitting diode (LED). It uses a p-n junction to emit coherent light in which all the waves are at the same frequency and phase. This coherent light is produced by the laser diode using a process termed as "Light Amplification by Stimulated Emission of Radiation", which is abbreviated as LASER. And since a p-n junction is used to produce laser light, this device is named as a laser diode. Before we learn more about the working process of a laser diode, let's look at how laser light is different from other types of light, and its advantages.

A laser diode is electrically a PIN diode. The active region of the laser diode is in the intrinsic (I) region, and the carriers (electrons and holes) are pumped into that region from the N and P regions respectively. While initial diode laser research was conducted on simple P-N diodes, all modern lasers use the double-hetero-structure implementation, where the carriers and the photons are confined in order to maximize their chances for recombination and light generation. Unlike a regular diode, the goal for a laser diode is to recombine all carriers in the I region, and produce light. Thus, laser diodes are fabricated using direct band-gap semiconductors. The laser diode epitaxial structure is grown using one of the crystal growth techniques, usually starting from an N doped substrate, and growing the I doped active layer, followed by the P doped cladding, and a contact layer. The active layer most often consists of quantum wells, which provide lower threshold current and higher efficiency

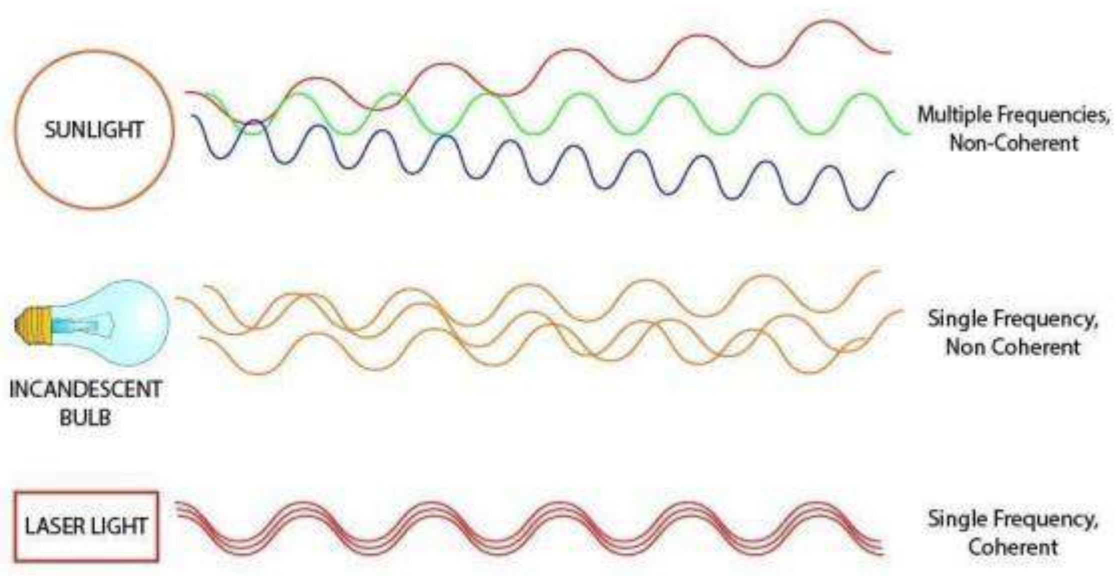

Fig 3.16 Coherency in Optical Waves

The light from sunlight or from most of the artificial light sources contains waves of multiple wavelengths and they are out of phase with each other. The light waves from monochromatic light sources like incandescent bulbs also are not in phase with each other. In contrast to the previous light sources, laser diodes produce a narrow beam of laser light in which all the light waves have similar wavelengths and they travel together with their peaks lined up. This is why laser beams are very bright, and can be focused over a very tiny spot.

Of all the devices that produce laser light, laser diodes or semiconductor lasers are the most efficient and they come in smaller packages. So they are widely used in various devices like laser printers, barcode readers, security systems, Autonomous vehicles (LIDAR), Fiber optic communications etc.

3.2.4.1 WORKING OF LASER DIODE

The working of a laser diode takes place in three main steps:

ENERGY ABSORPTION

The laser diode consists of a p-n junction where holes and electrons exist. (Here, a hole means the absence of an electron). When a certain voltage is applied at the p-n junction, the electrons absorb energy and they transition to a higher energy level.

Holes are formed at the original position of the excited electron. The electrons stay in this excited state without recombining with holes for a very small duration of time, termed as "recombination time" or "upper-state lifetime". The recombination time is about a nanosecond for most laser diodes.

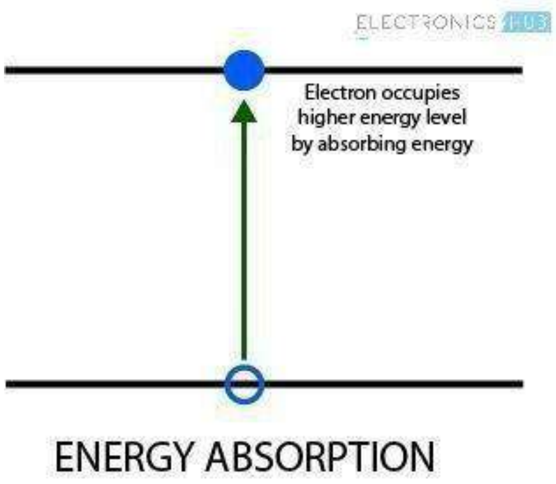

Fig 3.17 Energy Absorption

SPONTANEOUS EMISSION

After the upper-state lifetime of excited electrons, they recombine with holes. As the electrons fall from higher energy level to a lower energy level, the difference in energy is converted into photons or electromagnetic radiation. This same process is used to produce light in LEDs. The energy of the emitted photon is given by the difference between the two energy levels.

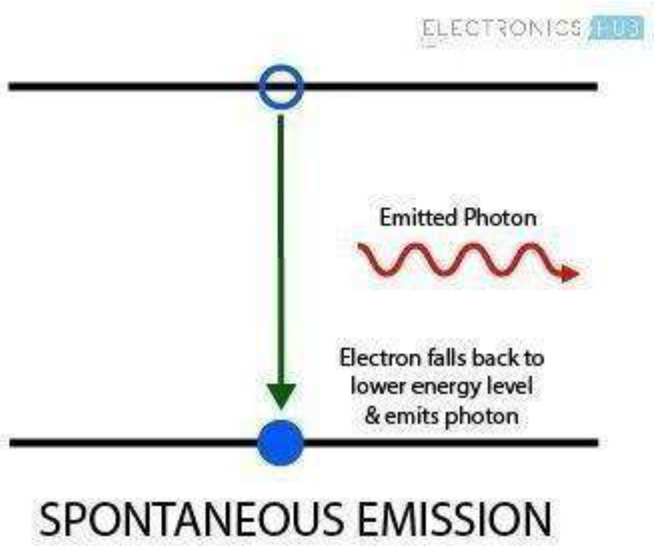

Fig 3.18 Spontaneous Emission

STIMULATED EMISSION

We need more coherent photons from the laser diode than the ones emitted through the process of spontaneous emission. A partially reflecting mirror is used on either side of the diode so that the photons released from spontaneous emission are trapped in the p-n junction until their concentration reaches a threshold value. These trapped photons stimulate the excited electrons to recombine with holes even before their recombination time. This results in the release of more photons that are in exact phase with the initial photons and so the output gets amplified. Once the photon concentration goes above a threshold, they escape from the partially reflecting mirrors, resulting in a bright monochromatic coherent light.

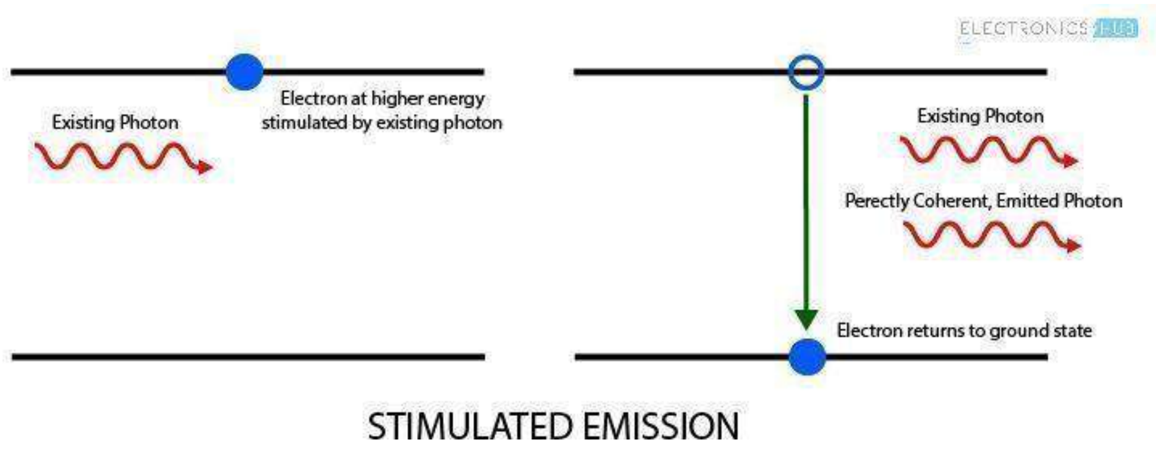

Fig 3.19 Stimulated Emission

CONSTRUCTION OF A LASER DIODE

A simple semiconductor laser diode is made up of the following parts in order:

- Metal Contact
- P-type Material
- Active/Intrinsic Region (N-type Material)
- N-type Material
- Metal Contact

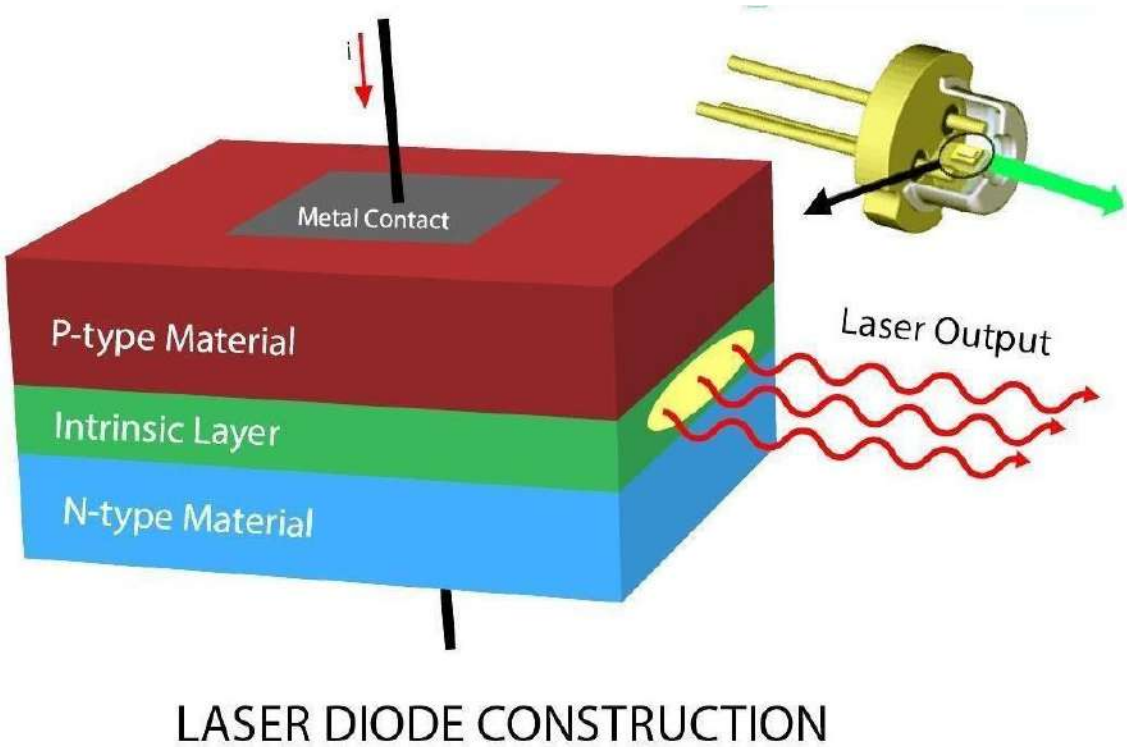

Fig 3.20 Laser Diode Construction

The input terminals are connected to metal plates which are sandwiched to the n-type and p-type layers. This type of laser diode is also called a “Homojunction Laser Diode”. The intrinsic region between the p-type and n-type material is used to increase the volume of the active region, so that more holes and electrons can accumulate at the junction. This allows more electrons to recombine with holes at any instant of time, resulting in better output power. The laser light is emitted from the elliptical region. This beam from the laser diode can be further focused using an optical lens. This entire PIN diode (P-type, Intrinsic, N-Type) arrangement is enclosed normally in a metal casing.

3.2.4.2 TYPES OF LASER DIODES

Double Heterostructure Laser Diode

In this type of laser diodes, an additional confinement layer of a different material is sandwiched between the two p-type and n-type materials. Each junction between different materials is called a heterostructure. Because of the presence of two heterostructures, this type of laser diode is named as a double heterostructure (DH) laser diode. The advantage of this DH laser diode is that the active region is confined to a thin layer which gives better optical amplification.

Quantum Well Laser Diode

The quantum well laser diode has a very thin middle layer, which acts as a quantum well. The electrons will be able to use quantum energy levels when transitioning from higher energy level to lower energy level. This gives a better efficiency for this type of laser diode.

Separate Confinement Heterostructure Laser Diode

The thin middle layer in the quantum well laser diode is very small for confining emitted light effectively. To compensate this, in the separate confinement heterostructure laser diode, another two layers are added over the three initial layers. These layers have a lower refractive index and help in confining the emitted light effectively.

Vertical Cavity Surface Emitting Laser Diode (VCSEL)

All the previously discussed laser diodes, the optical cavity is placed perpendicular to the current flow. In a vertical cavity surface emitting laser diodes, however, the optical cavity is along the axis of current flow. The partially reflecting mirrors are placed near the ends of the optical cavity.

Other Types

- Quantum Cascade Laser Diode
- Interband Cascade Laser Diode
- Distributed Bragg Reflector Laser Diode
- Distributed Feedback Laser Diode
- External Cavity Diode Laser
- Vertical External Cavity Surface Emitting Laser Diode (VCSEL)

3.2.4.3 Laser Diode P-I Characteristics

The diagram below is a graphical plot between output optical power on the y-axis and the current input to the laser diode on x-axis.

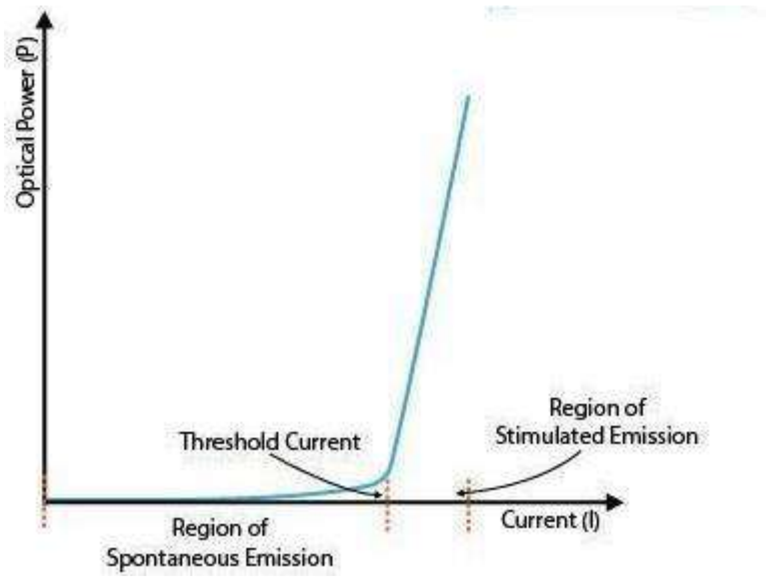

Fig 3.21 Laser Diode P-I Graph

As we increase the current flow to the laser diode, the optical power of output light gradually increases up to a certain threshold. Until this point, most of the light emitted is due to spontaneous emission. Above this threshold current, the process of stimulated emission increases. This causes the power of output light to increase a lot even for smaller increases in input current. The output optical power also depends on temperature and it reduces with decrease in temperature.

How to make a Laser Diode Driver Circuit?

Laser diodes require complex drive circuitries that involve feedback loops by measuring output optical power, temperature, voltage and input current. But for controlling a laser diode used in applications where high accuracy is not required, a simple laser diode driver circuit can be constructed using LM317 voltage regulator IC. Below is the diagram.

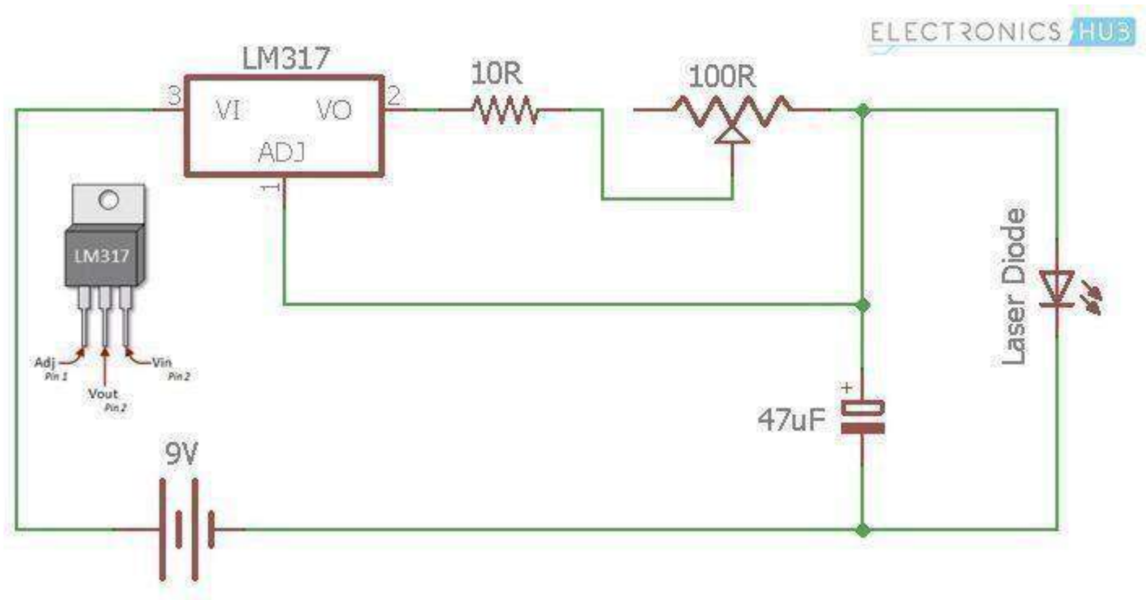

Fig 3.22 Laser Driver Circuit

The LM317 is configured to function as a constant current source. The output current depends on the value of resistance between Vout and Vadj of LM317 (Pin2 & Pin1). So adjusting the 100R potentiometer will change the output current that flows into the laser diode. The 10R resistor is used to prevent large currents from flowing when the value of 100R potentiometer is at zero. The 47uF capacitor is used to absorb any battery voltage spikes.

3.2.4.4 SPECIFICATION

Supply Voltage	5v
Power	5mW
Current	30mA
Wavelength	650 nm
Colour	Red
Module Size	15 x 24 x 9mm

Table: Laser Diode Specification

3.2.5 SOFTWARE EXPLANATION

3.2.5.1 Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

3.2.5.2 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

3.2.5.3 Features

ISIS has a wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semiconductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the footprints of different categories of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in ISIS can be directly transferred to ARES.

3.2.5.4 Starting New Design

Step 1: Open ISIS software and select New design in File menu

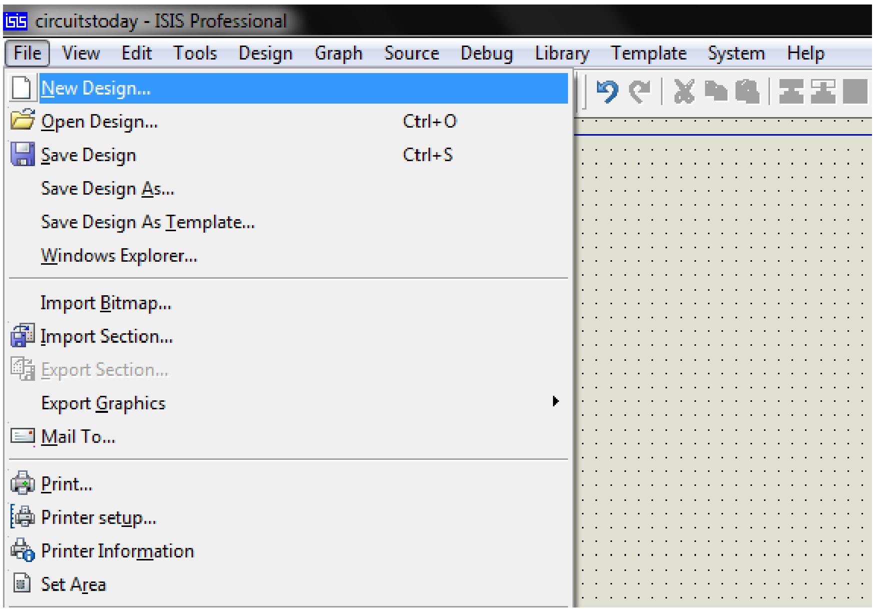

Figure 3.23 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

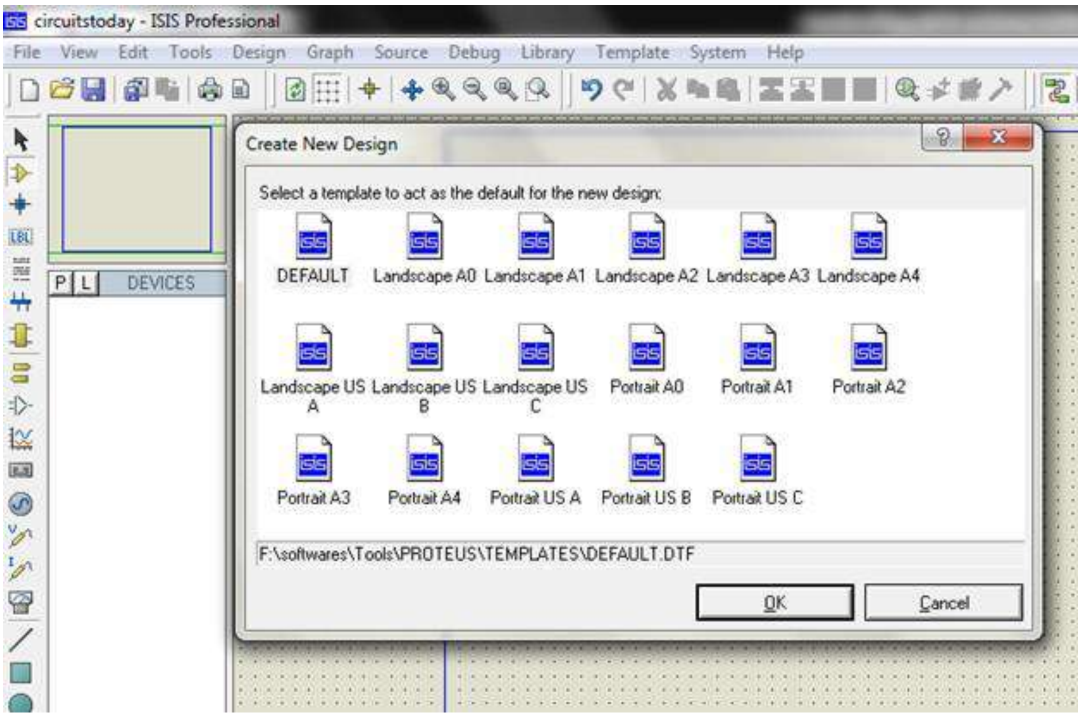

Figure3.24 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

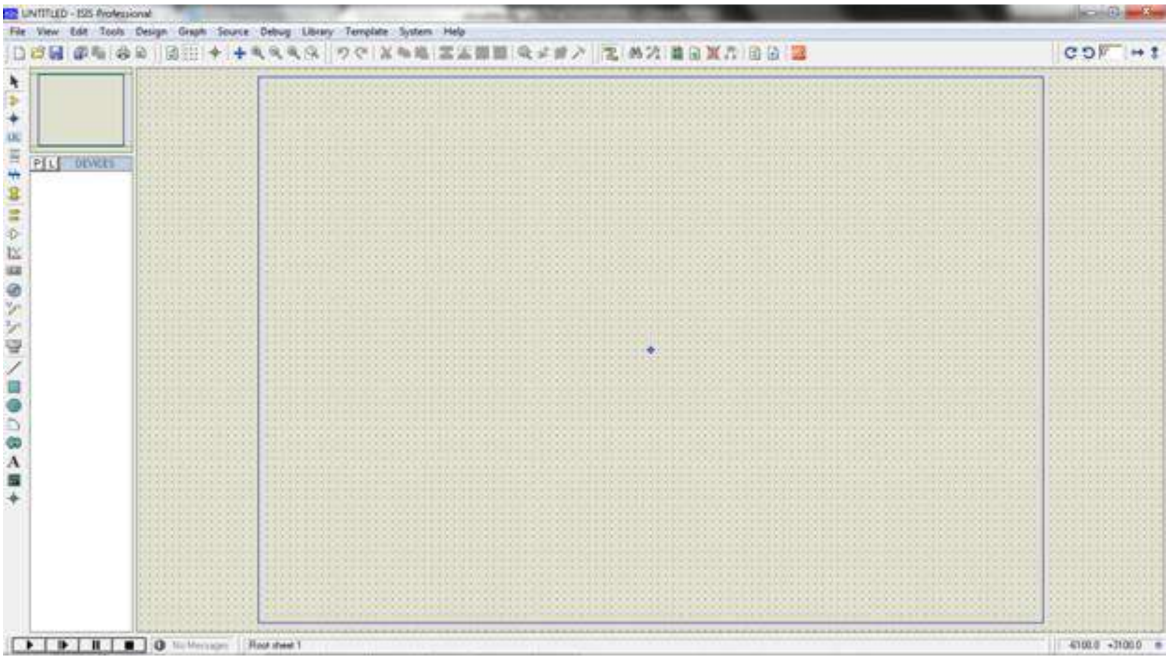

Figure 3.25 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

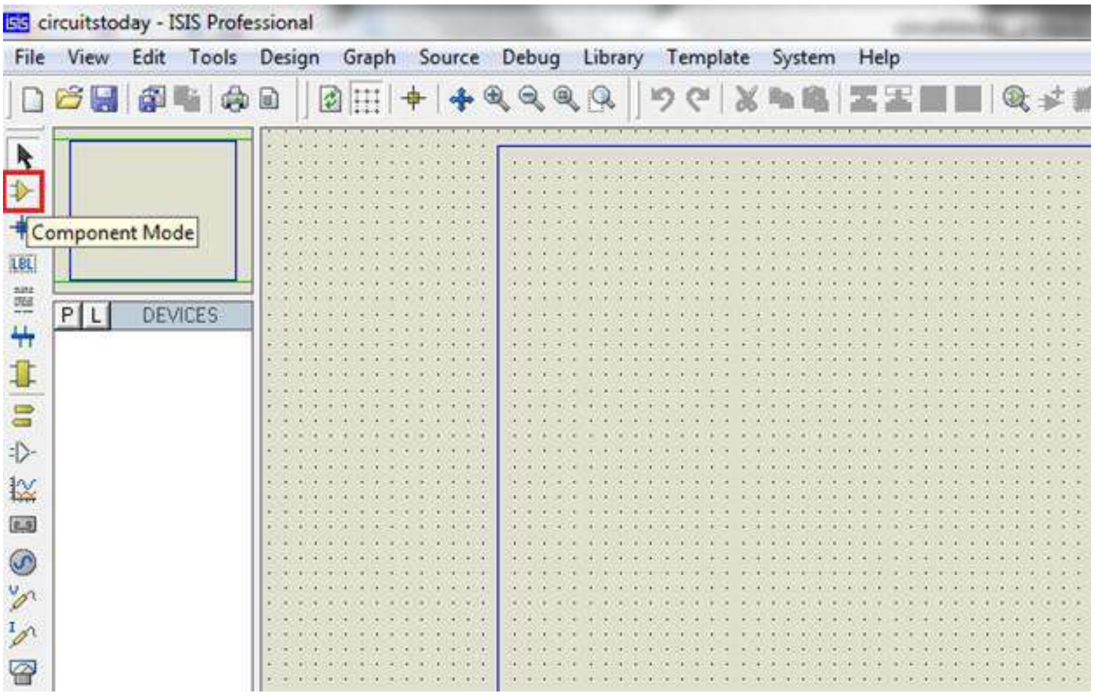

Figure 3.26 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

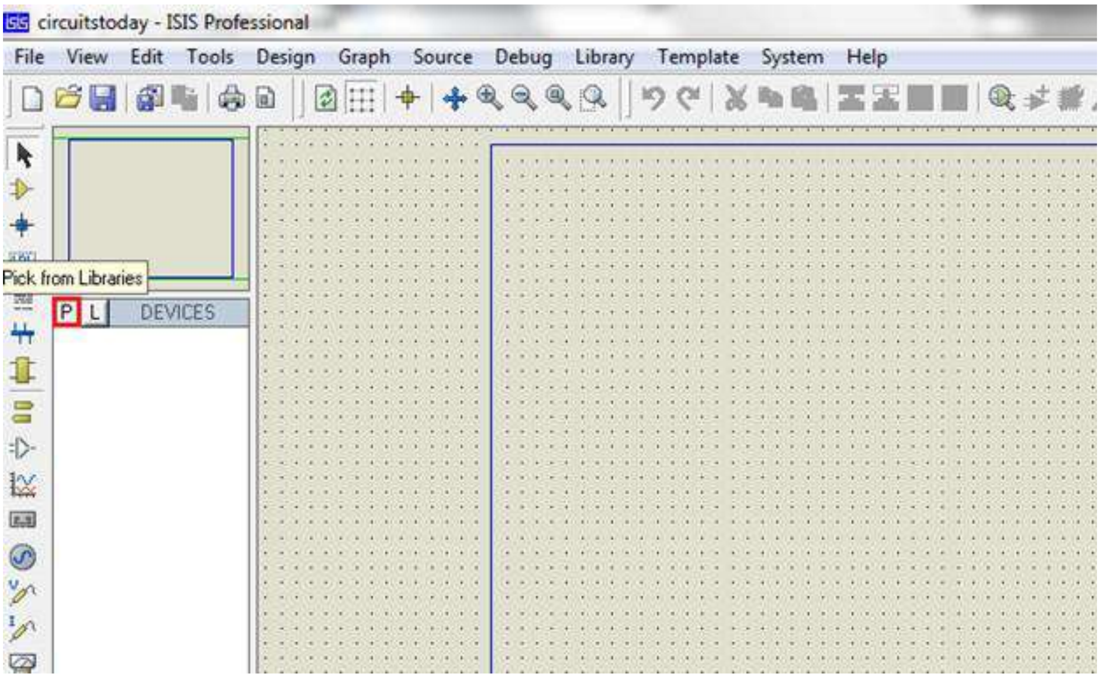

Figure 3.27 Pick from Libraries

Step 6: Select the components from categories or type the part name in the text box.

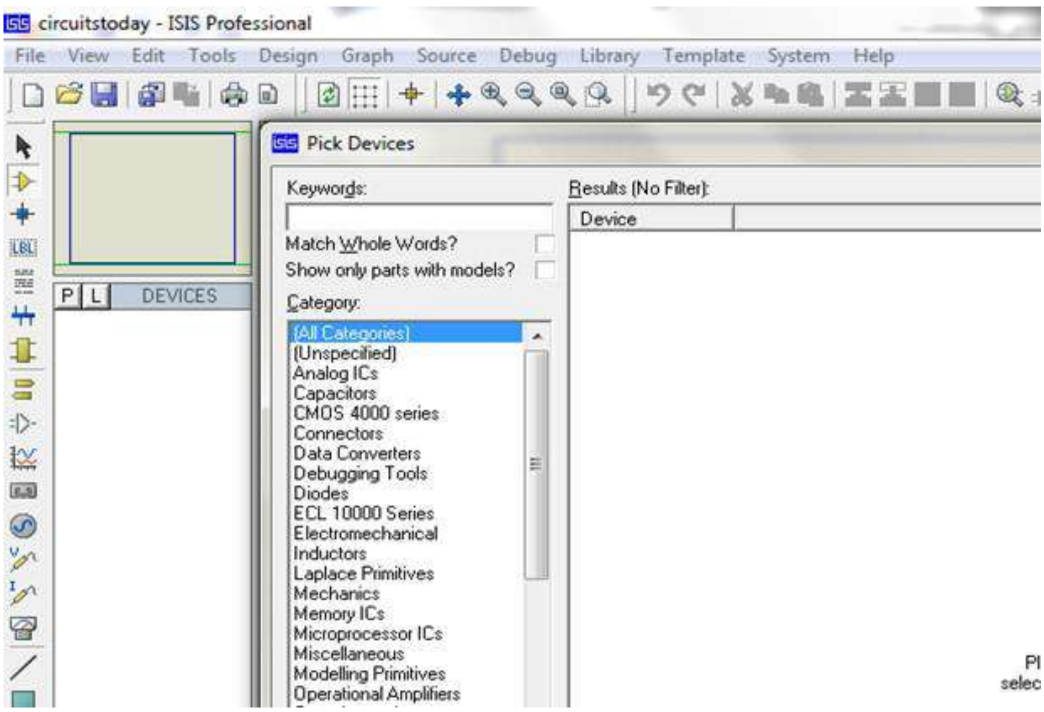

Figure 3.28 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

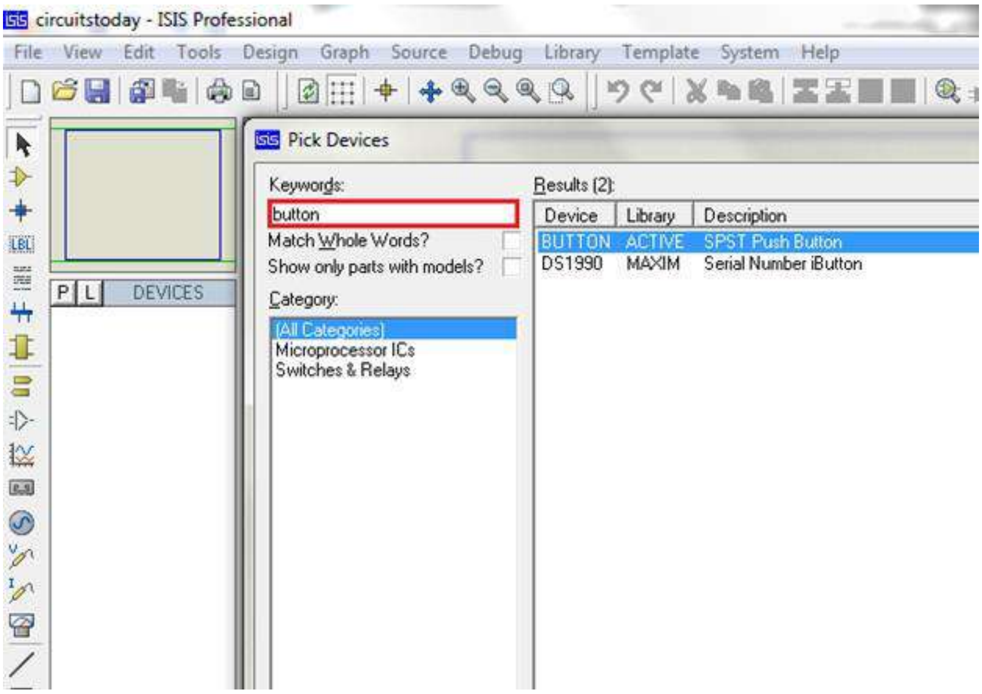

Figure 3.29 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

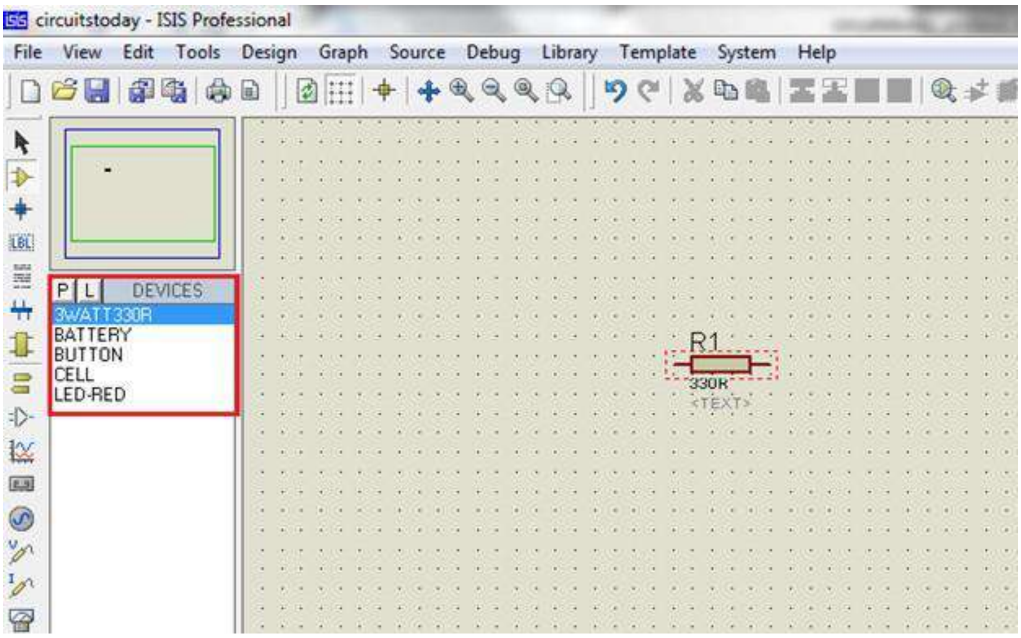

Figure 3.30 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows it to connect through wires. Left click from one terminal to another to make a connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

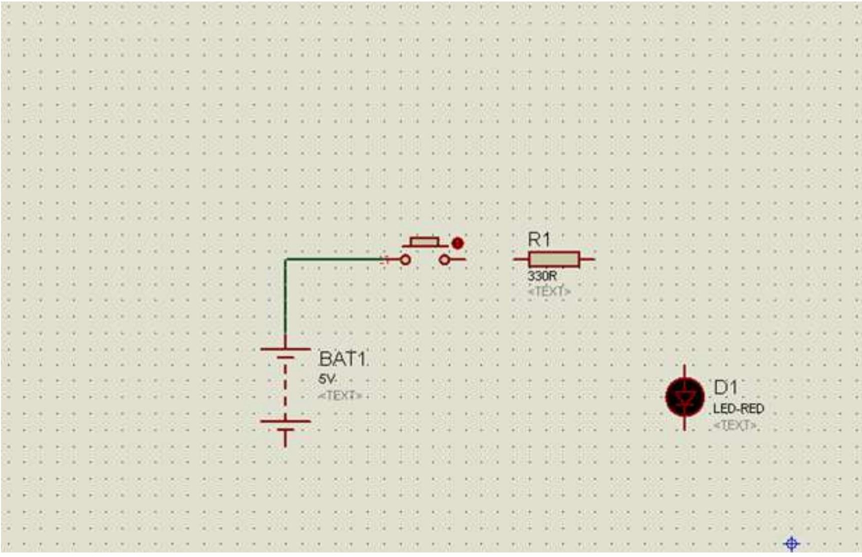

Figure 3.31 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok

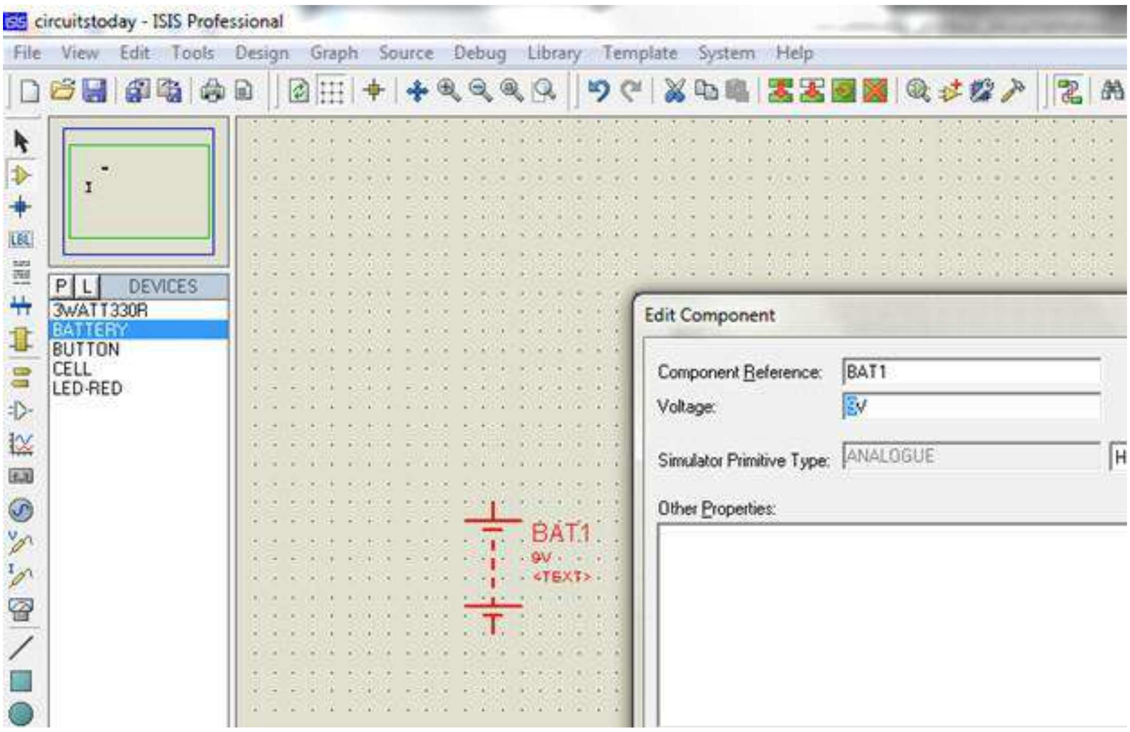

Figure 3.32 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

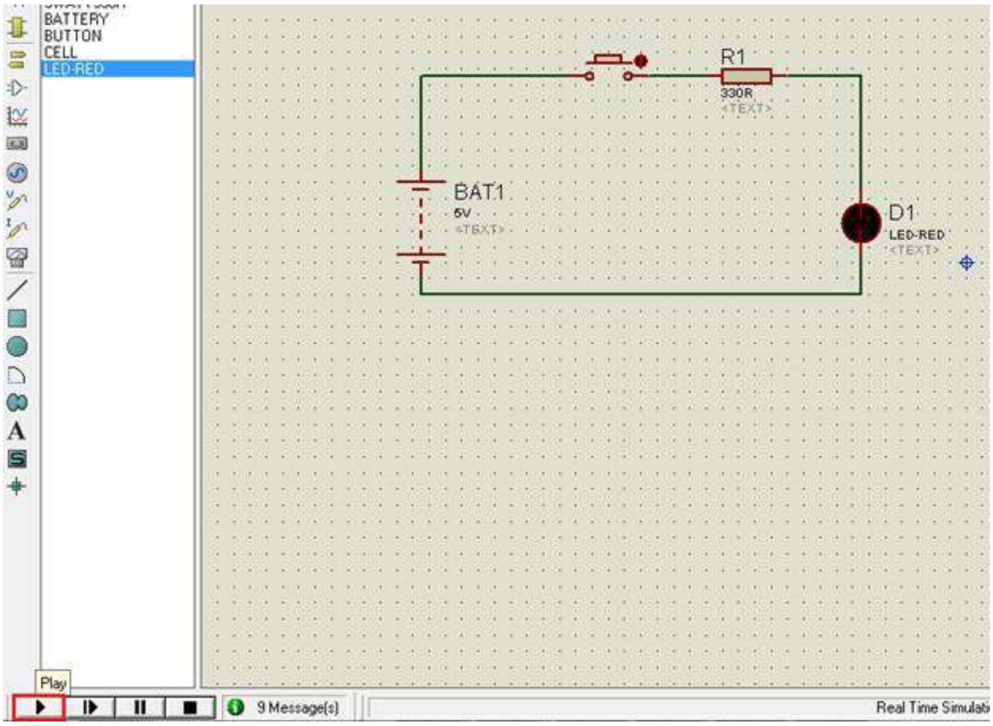

Figure 3.33 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make the LED glow.

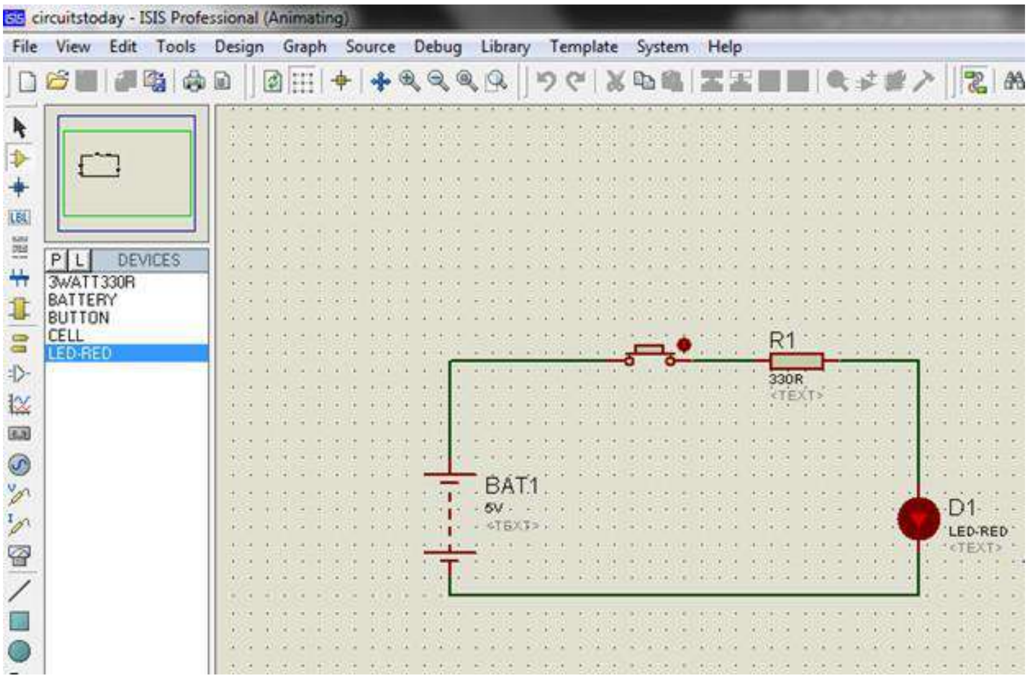

Figure 3.34 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

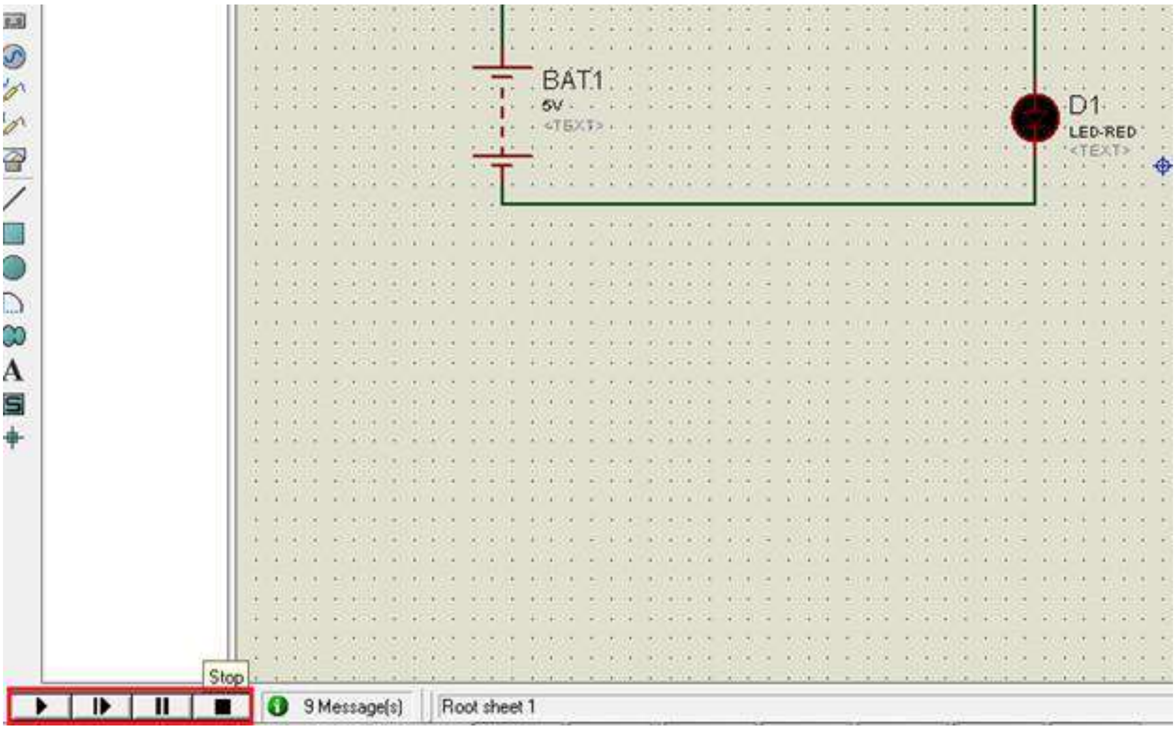

Figure 3.35 Simulation Step-Pause-Stop Buttons

3.2.5.2 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE

Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

4.3.1 Installation

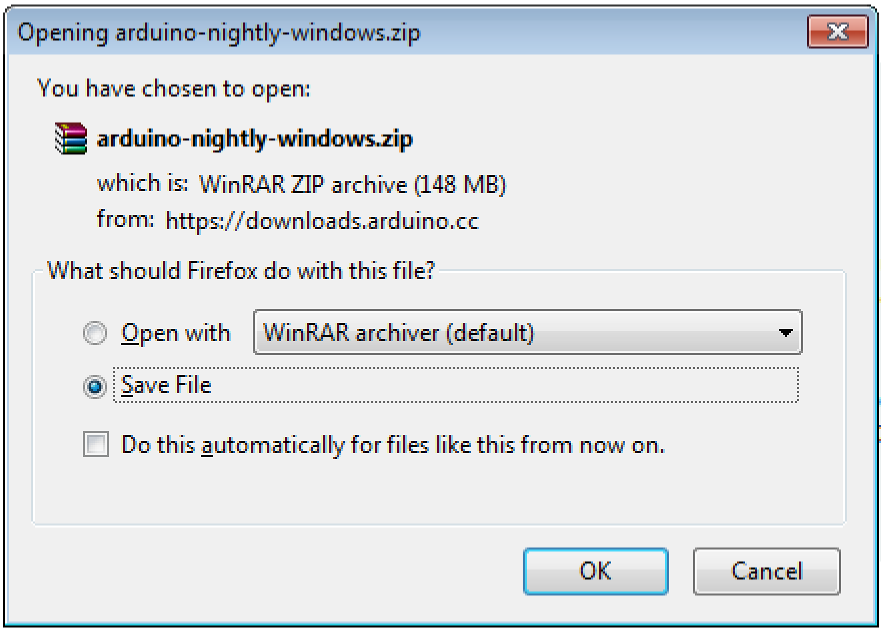
In this section, we will learn in easy steps how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



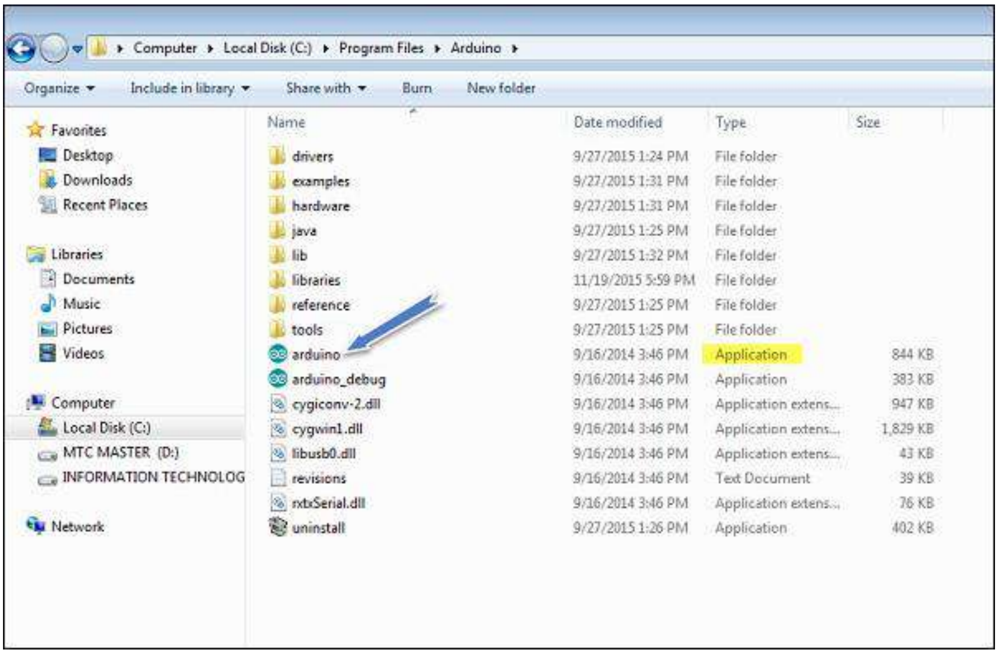
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

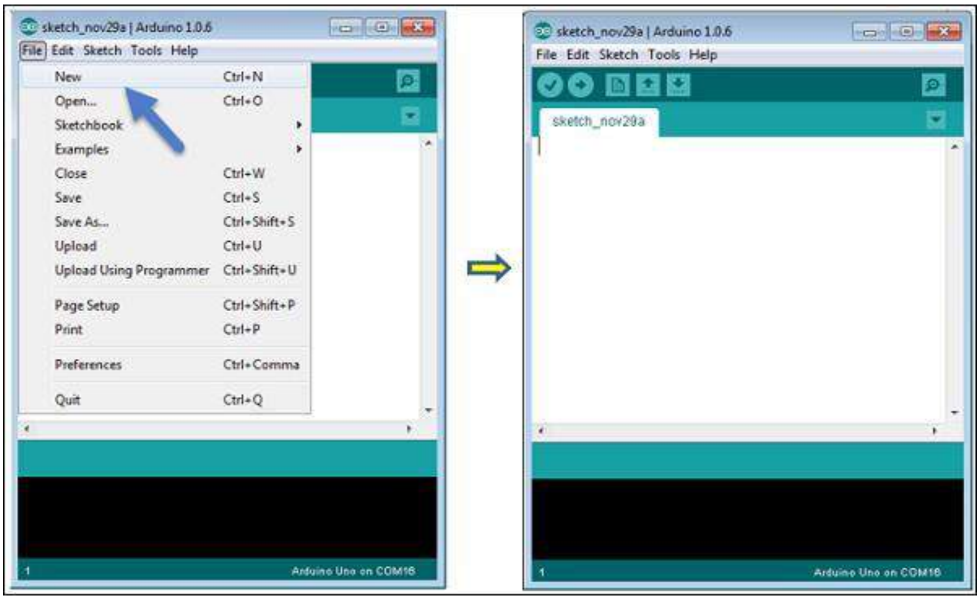


Step 5 − Open your first project.

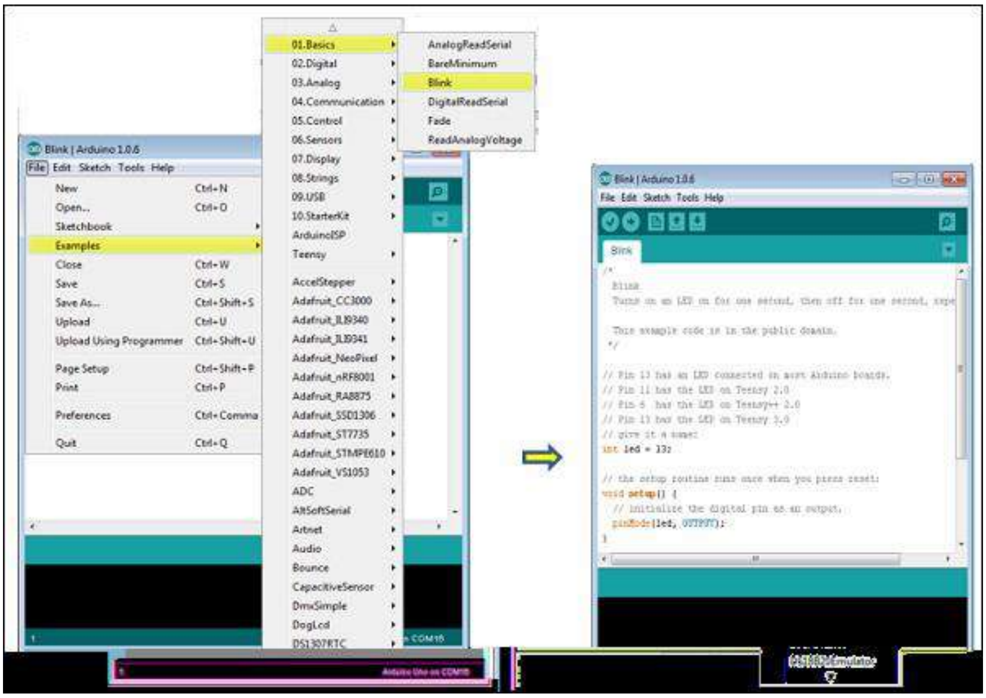
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



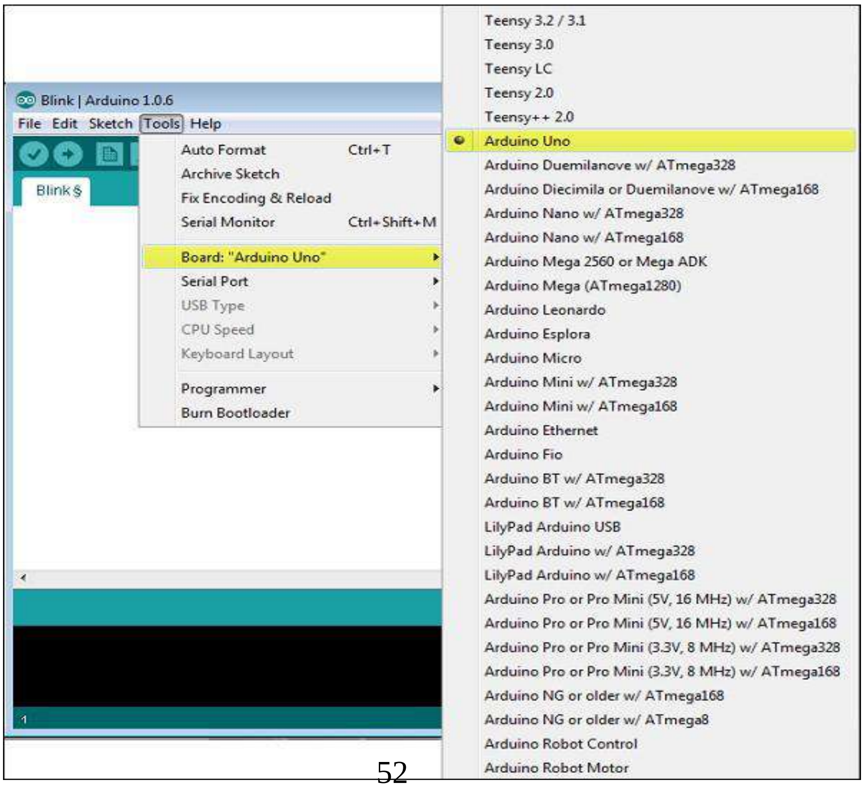
To open an existing project example, select File → Example → Basics → Blink.



Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

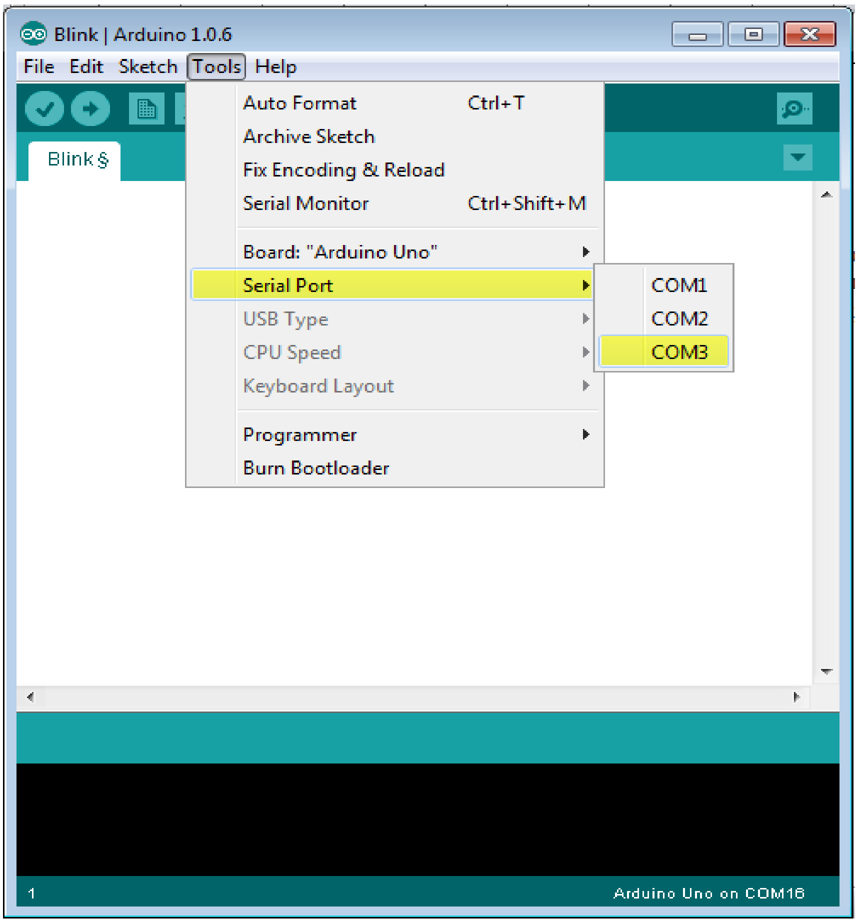
To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.Go to Tools → Board and select your board.



Here, we have selected the Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

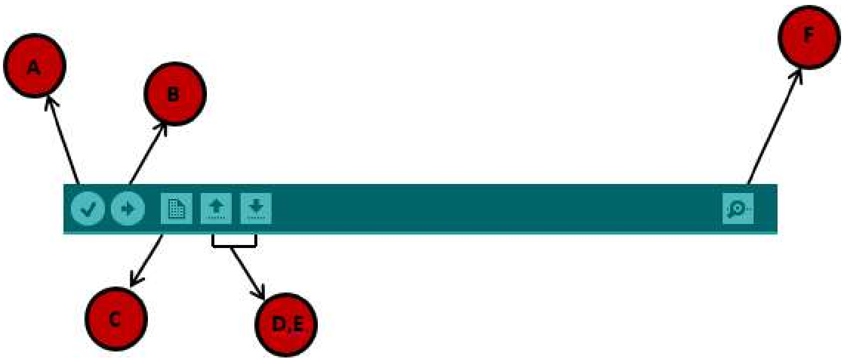
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT

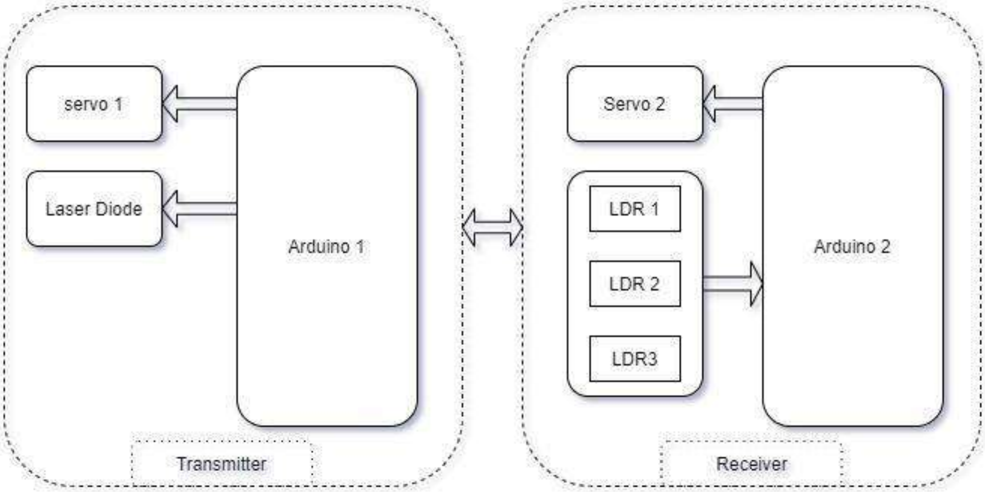


Fig 4.1 Block Diagram of Project

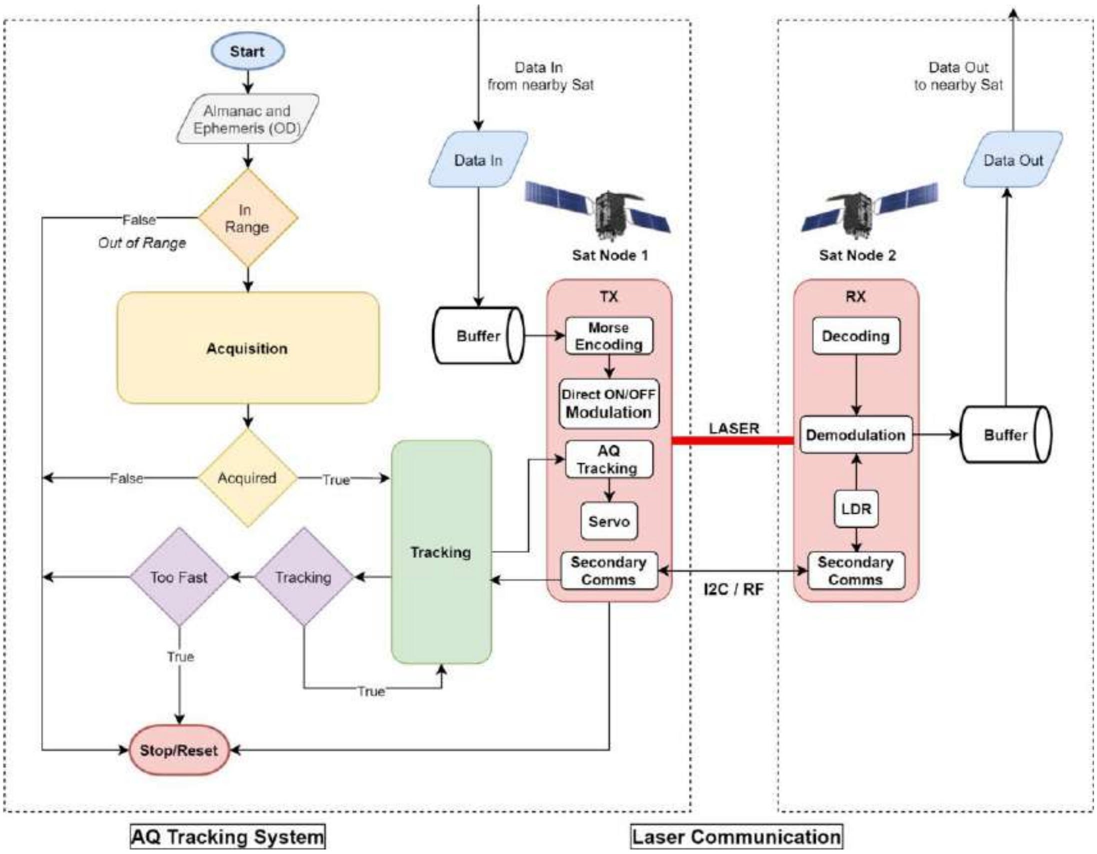
4.2 FLOW CHART



4.3 STATE FLOW DIAGRAM

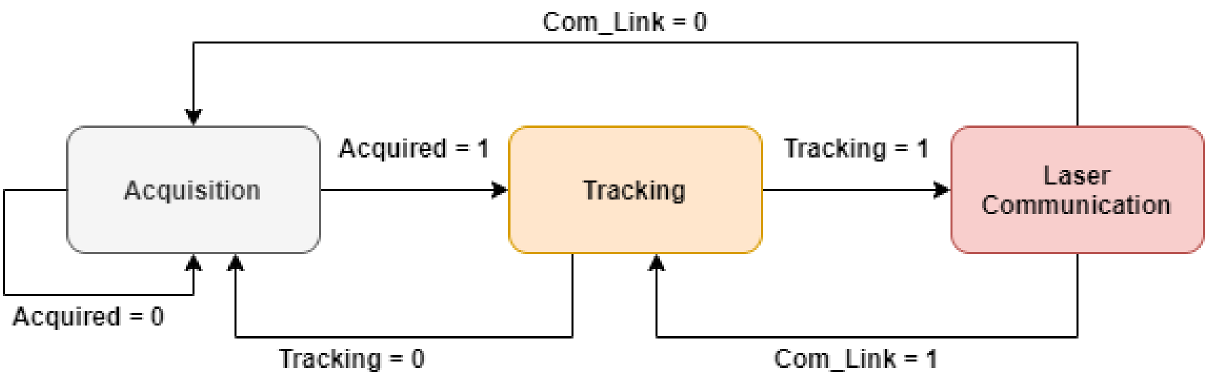


Fig 4.3 State Flow Diagram for Laser Com

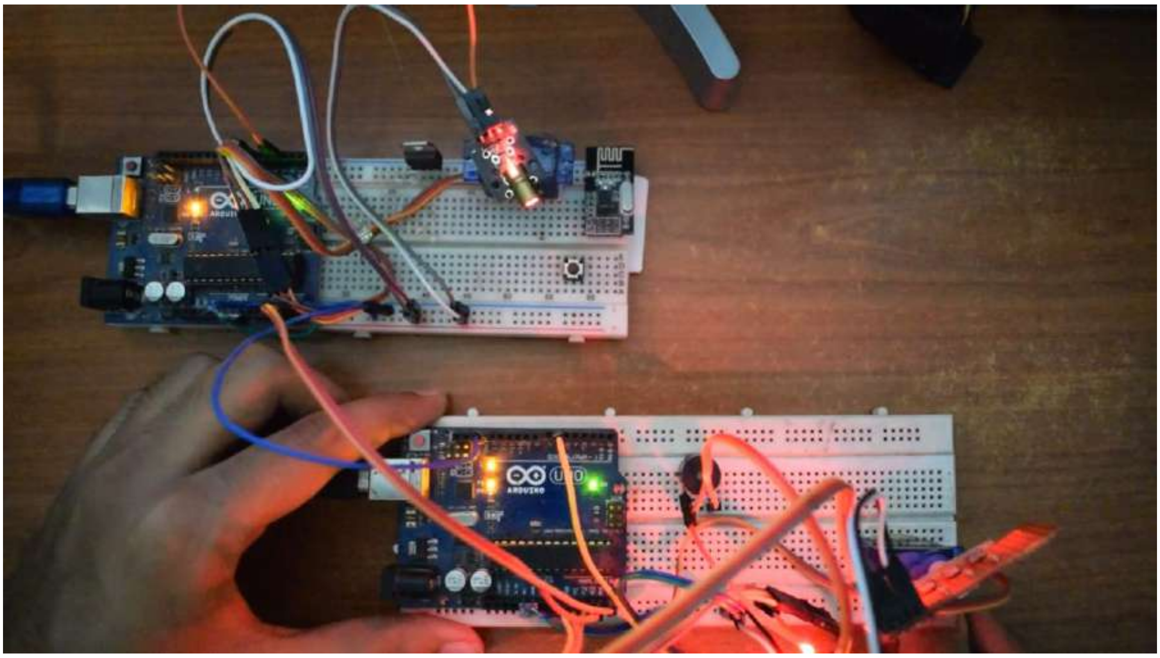
State	Laser Comm	Track	Acq	Status
1	0	0	0	Hold
2	0	0	1	AQ
3	0	1	0	-
4	0	1	1	AQ & T
5	1	0	0	error
6	1	0	1	error
7	1	1	0	error
8	1	1	1	Comms Est

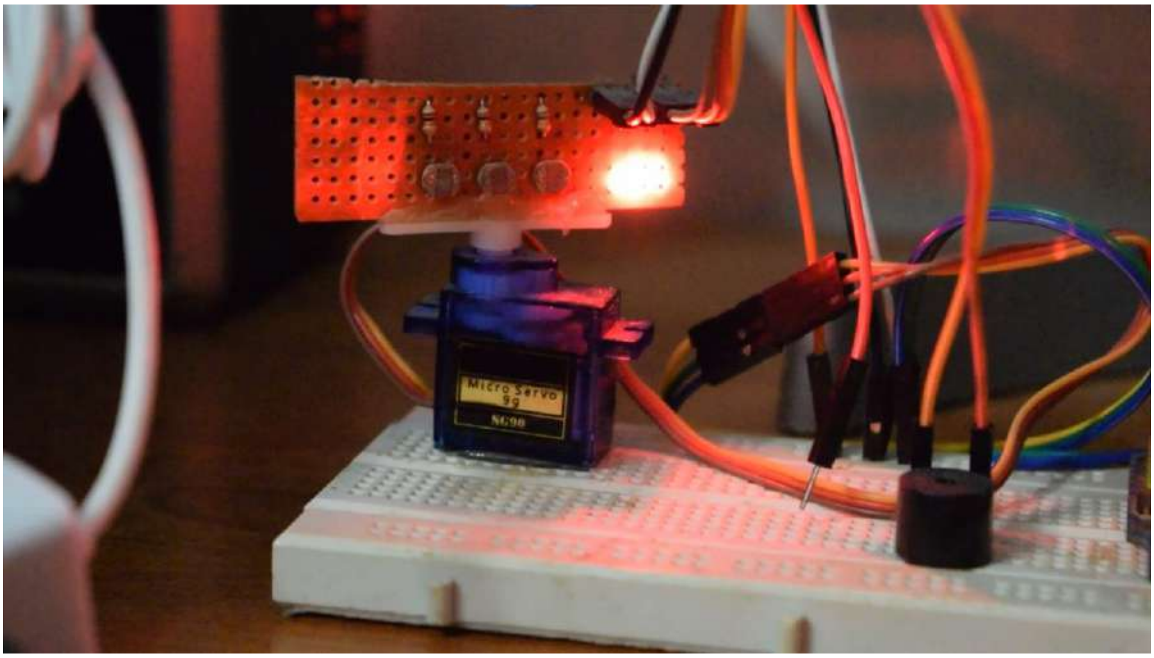
Table 7: State Flow Table

4.4 IMPLEMENTATION STAGES

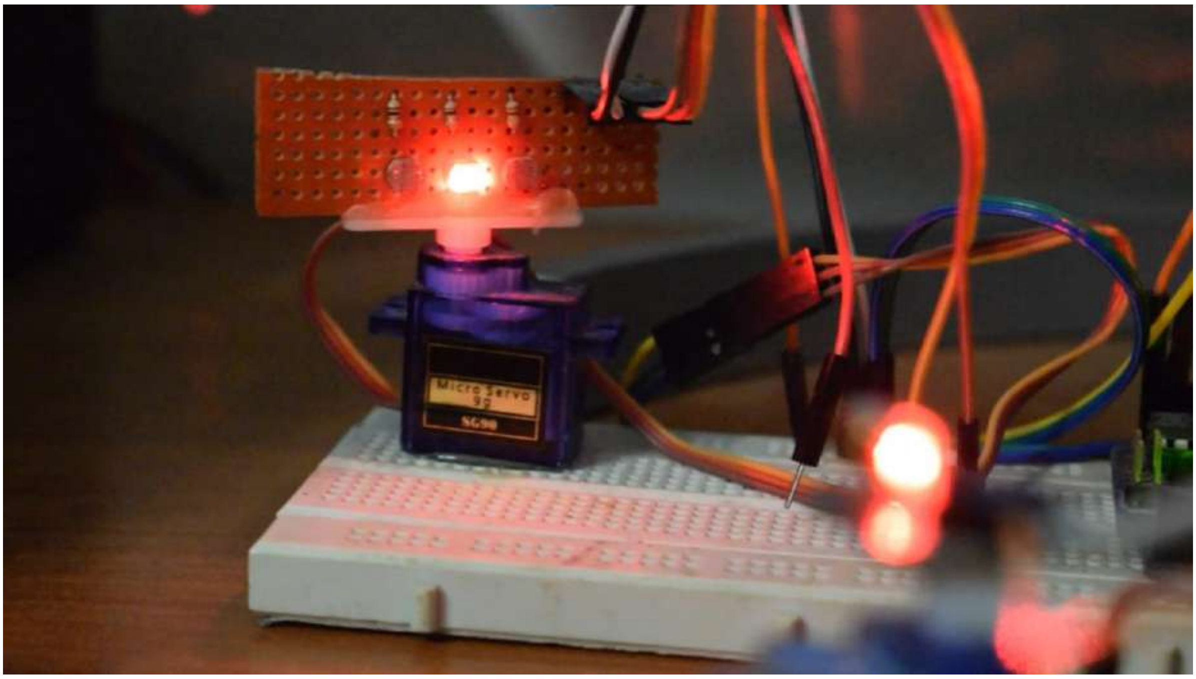
Stage 0: Pre-ARM Laser - This is the RESET stage.



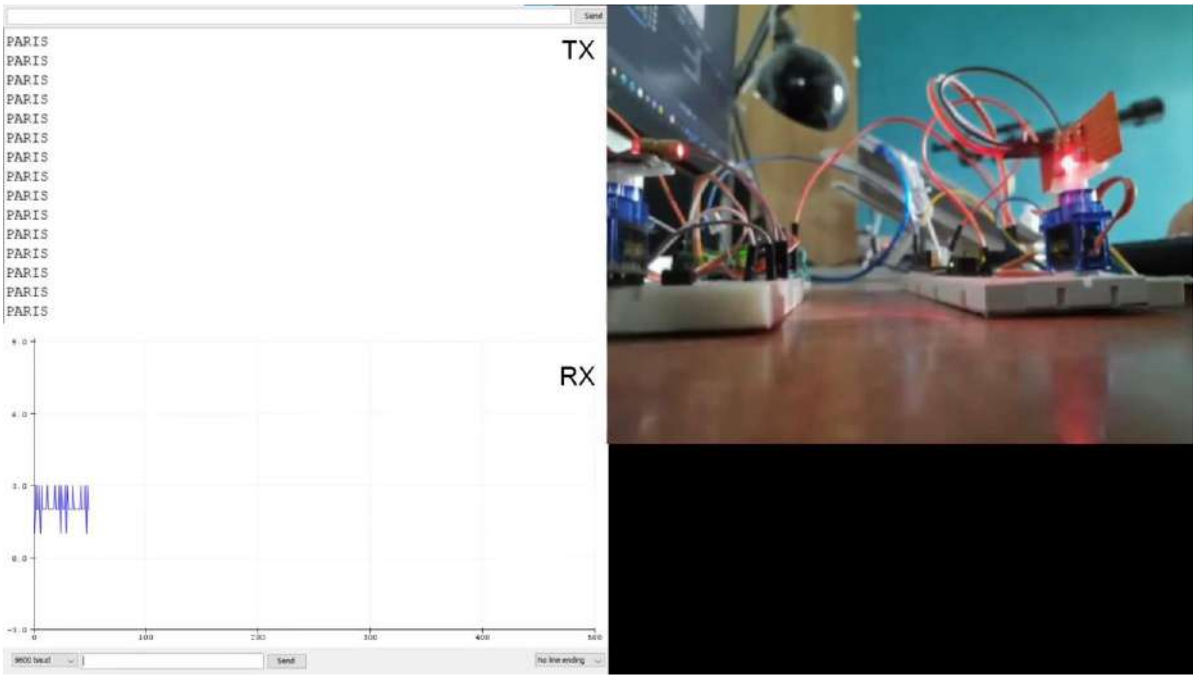
Stage 1: Acquisition- waiting for receiver to come into LOS and acquire it.



Stage 2: Tracking - The receiver is acquired and then tracking is done.



Stage 3: Laser Communication - Now laser communication is done between TX and RX using Morse code and Direct ON/OFF Modulation Method.



Stage 4: LOSS OF SIGNAL - when the TX and RX go out of sight the laser resets it's position and goes back to pre-arm stage

CHAPTER 5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

The following tests were conducted for the project:

1. Functional Test
2. Program Test
3. Speed Test
4. Debug Test
5. Error Testing

1. Functional Tests

Functional tests will test the functionality of various modules in the project, such as, LDR, Servos, Laser and others. The below graph represents the Intensity Characteristics of LASER Diode.

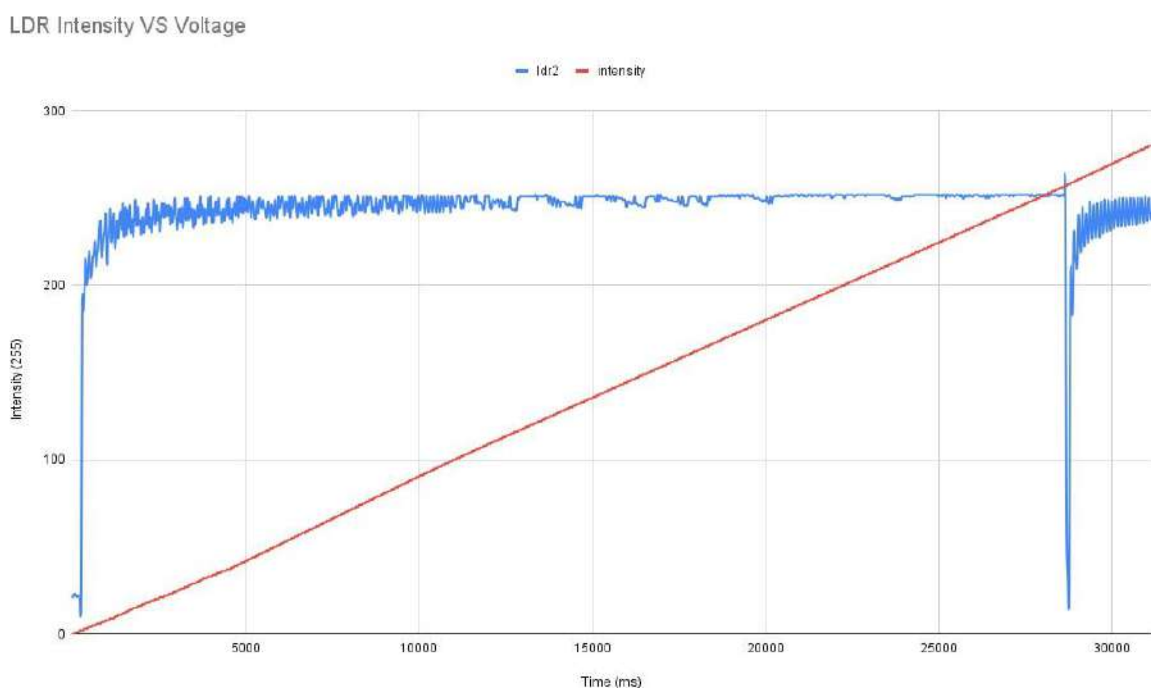

Fig 5.1 LDR Intensity graph

2. Program Tests

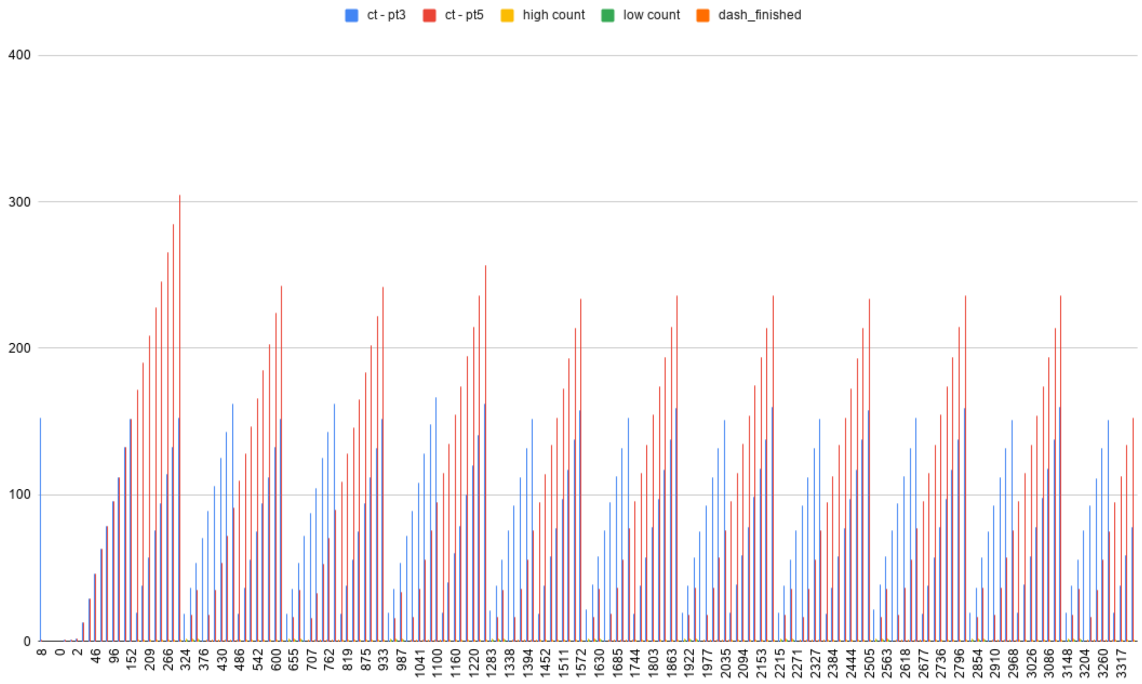

Fig 5.2 program test

3. Speed Test

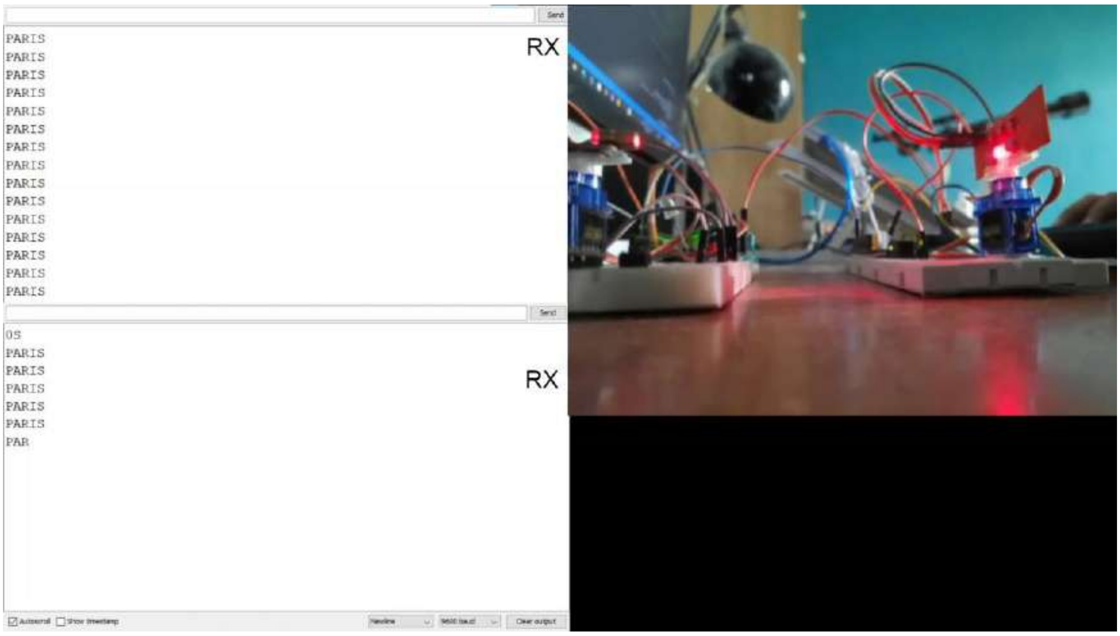

Fig 5.3 Speed test of morse code(WPM)

4. Debug Test:

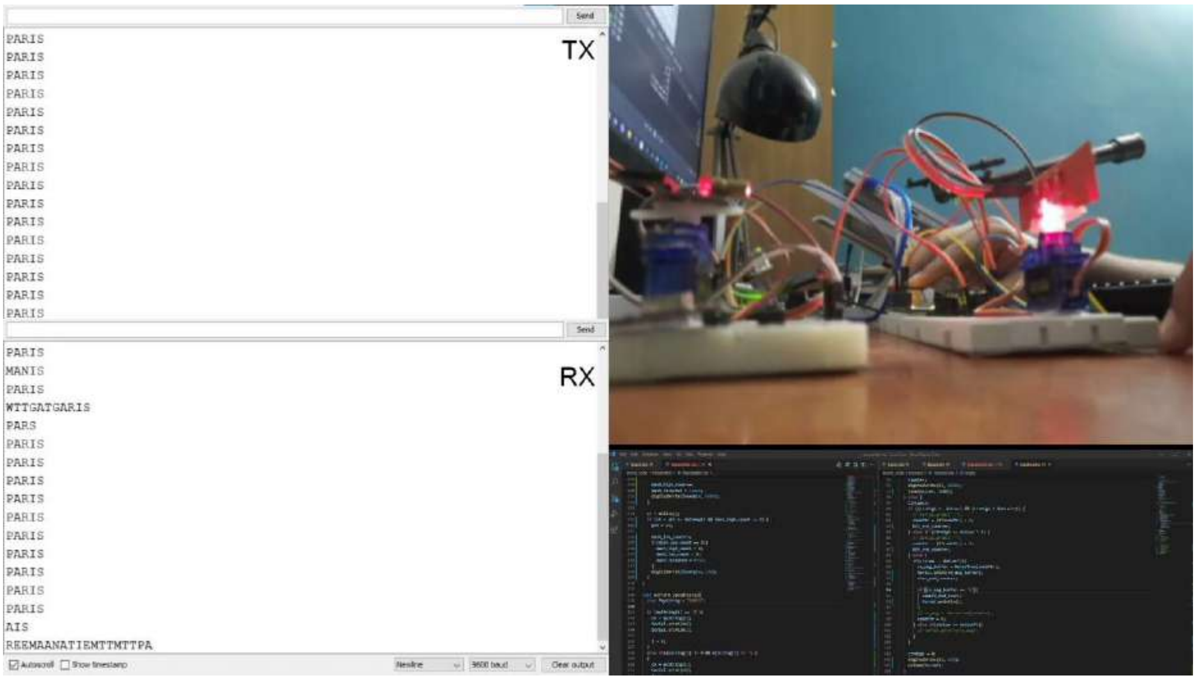

Fig 5.4 code debugging

5. Error Testing

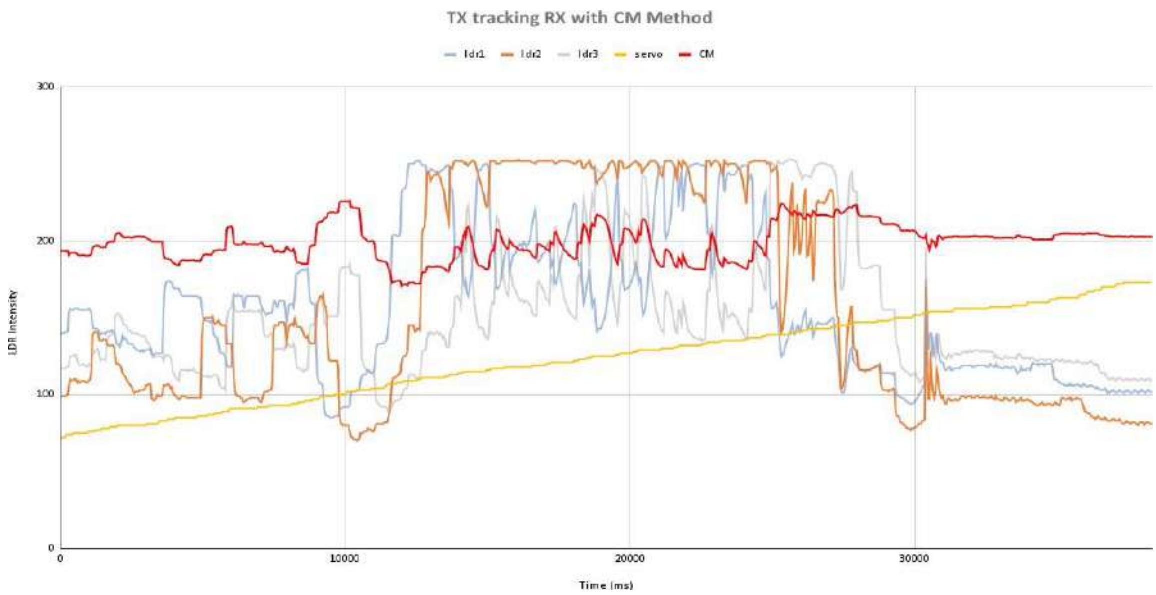

Fig 5.5 Tracking using CM method

The project testing was done in five parts:

1. **Acquisition** - Here how well the Tx is acquiring is tested by developing and testing multiple algorithms crossing down on which gives the better result.
2. **Tracking** - Here the ability of Tx and Rx to be in continuous LOS is tested by reading how uninterrupted the transmitted data is being received.
3. **Acquisition and Tracking** - Here the combination of both the methods is tested and how well they both work together for maintaining is LOS analysed.
4. **Laser Communication** - Here the implementation of laser comms using morse code is done and the data transmission and reception is tested by analysing the data error data speed in BPS and WPS.
5. **Complete Testing in 4 Stages** - a complete run of all the stages is done and performance is evaluated.

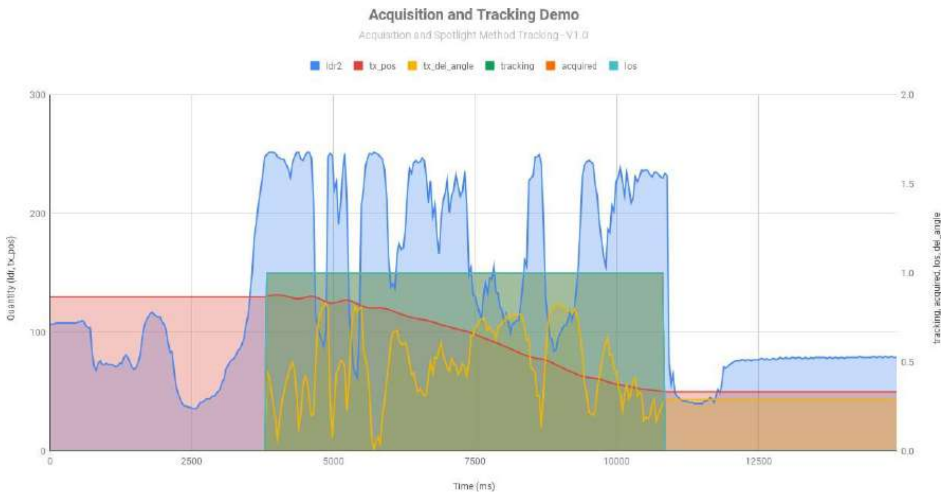

Fig 5.6 AQ and Tracking analysis

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

Laser crosslinks offer several benefits to current and near-future civil, commercial, and security sectors; the most obvious being highly secure, low error, high throughput data communications. Due to the protracted pace of laser crosslink development, melded with the lengthy lead-times for satcom development, compounded by the prolonged government procurement process, makes the time right for inclusive action now. Laser crosslinks technology is sufficiently mature to place payloads of small size, weight, and power on to-be-launched vehicles and follow in short order with the terrestrial legs—whether fixed, at sea, or in the air. The demand for data—raw facts—and its successful evolution to information—arranged in context—is growing, arguably at an exponential rate. The U.S. Department of Defense’s demand for data, information, and intelligence is exceeding its satellite communications capacity.

6.2 FUTURE ENHANCEMENT

- 3D Tracking Method for real time systems
- Develop Networking Topology
- Develop Routing Algorithm
- Build a Scalable Solution

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin‘s Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled –DRUNK DRIVING DETECTION USING CAR IGNITION LOCKING‖ is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1) Mr.M.Sharath Chandra(17K81A04M6)

2) Ms.A.Devi Sree(17K81A04J1)

3) Mr.Sri Datta(18K85A0442)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head & Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our **Dept. project coordinator Dr.A.Anand Kumar, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our project internal guide, **Mrs.CH.Swathi, Assistant Professor,** Department of ECE and our class project coordinator **Ms.P.Pushpa, Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

This study proposed an efficient technique for eradicating the upsurge in the number of cases of roads Accidents caused by excessive intake of alcohol. This study developed a prototype alcohol detection and Engine locking system by using an Arduino Uno microcontroller interfaced with an alcohol sensor along with an LCD screen and a DC motor to demonstrate the concept. The system uses MQ-3 alcohol sensor to Continuously monitor the blood alcohol content (BAC) to detect the existence of liquor in the exhalation of a driver. By placing the sensor on the steering wheel, our system has the capacity to continuously check alcohol level from the driver‘s breath. The ignition will fail to start if the sensors detects content of alcohol in the driver‘s breathe. In case the driver got drunk while driving, the sensor will still detect alcohol in his breath and stop the engine so that the car would not accelerate any further and the driver can park by the roadside. Results from testing the proposed system adequately matched the requirements for starting a car‘s engine once the level of alcohol detected in the breath of the driver is higher than the prescribed level permissible by law.

LIST OF TABLES

LIST OF FIGURES

Glossary of terms

***Approximation of Blood Alcohol Concentration (BAC)* :**

There are far variables involved to accurately estimate or predict a person‘s BAC simply based on gender. The data is so important for us to build an accurate project design. Blood alcohol content (BAC), also called blood alcohol concentration or blood alcohol level, is a measurement of alcohol intoxication used for legal or medical purposes.[1] A BAC of 0.10 (0.10% or one tenth of one percent) means that there is 0.10 g of alcohol for every 100 ml of blood, which is the same as 21.7 ml.

MQ-3 Alcohol Sensor Unit :

Gas Sensor(MQ3) module is useful for gas leakage detection (in home and industry). It is suitable for detecting Alcohol, Benzine, CH4, Hexane, LPG, CO. Due to its high sensitivity and fast response time, measurements can be taken as soon as possible. The sensitivity of the sensor can be adjusted by using the potentiometer. The output voltage from the Gas sensor increases when the concentration of gas increases. Sensitivity can be adjusted by varying the potentiometer.

Potentiometer:

A potentiometer sensor measures the distance or displacement of an object in a linear or rotary motion and converts it into an electrical signal. Our potentiometer sensors are qualified for various applications and industries. Custom linear and rotary potentiometers are designed for harsh environment aerospace applications including fin actuation, flight controls, and valve position measurement.

LCD display:

A liquid-crystal display (LCD) is a flat-panel display or other electronically modulated optical device that uses the light-modulating properties of liquid crystals combined with polarizers. Liquid crystals do not emit light directly, instead using a backlight or reflector to produce images in color or monochrome.

Liquid crystal display technology works by blocking light. Specifically, an LCD is made of two pieces of polarized glass (also called substrate) that contain a liquid crystal material between them. A backlight creates light that passes through the first substrate. At the same time, electrical currents cause the liquid crystal molecules to align to allow varying levels of light to pass through to the second substrate and create the colors and images that you see.

Buzzer:

A buzzer or beeper is an audio signalling device,[1] which may be mechanical, electromechanical, or piezoelectric (piezo for short). Typical uses of buzzers and beepers include alarm devices, timers, and confirmation of user input such as a mouse click or keystroke.

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Driving while drunk is hazardous and drivers with high Blood Alcohol Content (BAC) are at expanded danger of auto crashes, roadway wounds and vehicular passings. Anticipation measures assessed incorporate permit suspension or disavowal, appropriating or seizing vehicle plates, implementing open holder bans, expanding fine punishments, imprison, ordering instruction for youth and bringing down legitimate BAC's. Despite the fact that these much obstacles made by experts to drunken drive, it is as yet proceeding with like serial scenes. In that capacity there is no viable instrument to reduce this. Here, this process have intended to plan a Drunk driving detection, which is integrated with the directing wheel. This framework is meant for making vehicle driving more secure than previously and shield the mishaps from happening due to the liquor utilization of the driver. The individual when he is at vehicle, this is necessary to infer the driver's condition continuously and here this work proposed the detection of alcohol utilizing alcohol sensor associated with Arduino. Alcohol sensor is installed on the steering of the car, with the end goal that when the level of liquor crosses a reasonable farthest point, where the start of vehicle will kill and the motor will stop. The Arduino always uses the alcohol sensor information to check drunk driving and works a bolt on the vehicle motor to stop the engine. Key Words—Alcohol Detection, Car Ignition Locking, Alcohol Sensor, Arduino Uno, Lcd Display.

Drink & drive is a leading cause of road accidents. Detecting drunk driving requires stopping vehicles and manually scanning drivers by using breath analyzers. Well here we propose a system that allows to detect drunk driving in the vehicle itself. Our system uses alcohol sensor with raspberry pi along with a GSM modem for sms notification and LCD display and also a motor to demonstrate as vehicle motor. Now our system constantly checks for driver alcohol content. The system first allows the user to configure admin numbers into the system. And if the system detects driver is drunk above permissible limit, the sensor inputs trigger the processor about the issue by providing respective voltage. Now the system sends sms notifications to both the registered users/authorities to inform about the issue. Also the system stops the motor to demonstrate as engine locking of the vehicle. Thus the system detects and prevents drunk driving incidents automatically.

1.2 OBJECTIVES OF THE STUDY:

Drink and drive issue have become solemnly that needs immediate attention. This is due to drivers‘ ignorance towards road rules and regulations and their selfish attitude that caused loss of innocent lives. Although previously there is a drunk detecting mechanism using breathalyzer but it isn‘t suitable for current fast-paced lifestyle. Therefore, to overcome these issues, this system is proposed. This system is fixed on vehicle‘s steering to measure alcohol concentration reading using MQ-3 sensor from the driver‘s exhaled breath. If the driver found to be drunk beyond the threshold level of 400 ppm, then ignition lock is activated and the car engine does not start till alcohol concentration falls to a safe level. Or, if the driver consumes an alcoholic drink while driving, upon exceeding permissible limit, the car slows down till it stops. Then, the location of the vehicle is tracked and sent as Google Map integrated link via text message to authorized unit. Simultaneously, the car buzzer goes off while the car slows down so that surrounding road users are aware of the driver‘s condition and drives at a distance. The proposed detection system is highly potential to be implemented for reducing the drunk and drive accidents.

The target of this project is to give a idea and inventive method for avoiding drunken driving of a Motorcar by locking the car. Likewise to permit a man who is not alcoholic to drive a same Motorcar. To broaden this thought with more innovative headways and make it accessible in a financially effective way. We need to plan a sort of framework which can recognize the alcohol content in the cars to prevent the conduct of alcoholic driving. The framework comprises of these two sections: International Journal of Pure and Applied Mathematics Special Issue 3000 1. Sensor Part- - used to identify the centralization of alcohol all around and send the concentration as voltage signals to the accompanying part. 2. Display Part—used to get the prepared signal and demonstrate the information to users in LCD. The sensor will be fixed close to the driver's seat. The driver should breath to the system before the individual begins the car. On the off chance that the alcohol level identified is underneath the permissible standard, the car can be started regularly. In the event that the alcohol level is over the suitable standard, the framework will send caution to the driver through LCD display. The framework ought to be protected, delicate, exact, advantageous and cheap. This sort of framework can be fixed on each car to guarantee the driver's driving security. Drunk driving detection using car ignition locking project have primary targets which need to outline the framework with the ability that gives notification to drunken driver before driving the vehicles. The project is to set up intelligent innovations for vehicles to produce alert as the notice and message will be shown in LCD display as drunken driver. Another objective is to utilize alcohol sensor as the primary sensor to sense the presence of alcohol gas noticeable all around. Essentially, the alcohol gas was identified from drunken driver after the driver entered the vehicle.

1.3 SCOPE OF THE STUDY:

- This project is one of the important Sensor based project.
- It is designed for the safety of the people.
- Alcohol Detection with Vehicle Controlling project helps to control the vehicle in case the driver has consumed the alcohol. An alcohol breath analyzer (MQ3 sensor) should be fitted/ installed inside the vehicle.
- The main goal of the project is to avoid the road accidents by the people who drive the vehicles after intake of alcohol.
- Its also helps in detecting the people who were drunk and do not allowing them to drive the vehicle.
- Its helpful to the traffic police in monitoring drunken drive cases.

The target of this project is to give a idea and inventive method for avoiding drunken driving of a car by locking the ignition.

Here, is the framework comprises of these two sections:

1. Sensor Part- - used to identify the centralization of alcohol all around and send the concentration as voltage signals to the accompanying part.

2. Display Part—used to get the prepared

signal and demonstrate the information to users in LCD.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- LCD
- Power Supply
- MQ3 Sensor
- Buzzer
- Ignition System
- DC Motor

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

To cope with helmet negligence and alcohol detection simultaneous the writer proposed a system which is very complicated and use of P89V57RD2 microcontroller makes it highly expensive also this system can only be equipped with 2 wheelers whereas ,Aurdino uno microcontroller is economical as well ascan be equipped with any class of vehicle making it more authentic and successful.

To prevent the mishap of drunken driving writer have used PIC16F877A microcontroller which is an outdated system and expensive one also which restrains its use to only certain class of society whereas we are using Arduino and Uno microcontroller which is advanced as well as economical.

Worrying about the drunken driving the writer suggests the system to overcome the issue but using mQ2 alcohol sensor has come flames .MQ2 alcohol sensor is not authentic and raises the chance of false alarm while we have used MQ3 which is highly authentic.

This study developed a prototype alcohol detection and engine locking system by using an Arduino Uno microcontroller interfaced with an alcohol sensor along with an LCD screen and a DC motor to demonstrate the concept. The system uses MQ-3 alcohol sensor to continuously monitor the blood alcohol content (BAC) to detect the existence of liquor in the exhalation of a driver. By placing the sensor on the steering wheel, our system has the capacity to continuously check alcohol level from the driver‘s breath. The ignition will fail to start if the sensors detects content of alcohol in the driver‘s breath. In case the driver got drunk while driving, the sensor will still detect alcohol in his breath and stop the engine so that the car would not accelerate any further and the driver can park by the roadside

.

2.2 REVIEW ON RELATED LITERATURE:

Currently reported by the World Health Organization (WHO), Malaysia lies at number 59 among 183 countries worldwide for road traffic accidents, stands with a percentage of 24.51

death rates by both male and female due to road accidents; stands medium high level. Apparently, death rates on Malaysian roads is third highest globally, more than China and India reads the headline of an article

[1]. This data is consistent with the data as provided by Malaysian Institute Road Safety Research (MIROS), whereby, among eight common causes of a vehicle accident in Malaysia, drunk and driving cases is the second in the list and second highest in the world with highest amount of lives lost. According to MIROS report in year 2012 [2], 23.3% contribute to drunk and driving whereby 13 times more likely to cause an accident. Based on these statistics motivates the needs to reduce and prevent such road accidents. The old-fashioned method used by officers to detect alcohol in the driver is by using Breathalyzer. Even though it has proved its function, however this method is not efficient. Nevertheless, it is impossible to do road block all the time and check driver of each car using Breathalyzer [3].

Breathalyzer is a device to check alcohol presence in the driver‘s breath by making them blow into it. This method is not as practical as it can cause congestion and traffic during peak days. In addition, there are chances of the driver to bribe officers just to avoid being summoned. If they escape this road block, and continue to drive in a drunken state, they are risking every other road users. This project has overcome previous paper limitations as a part and parcel of the system. As proposed in [4, 5], the system uses MQ-2 sensors to detect the presence of alcohol in the driver‘s breath. MQ-2 is designed to test for combustible gases such as LPG [6]. It can be tested for alcohol too, but MQ-3 sensor [7] is specially made to test for alcohol vapor in which it has a more accurate reading and higher sensitivity than MQ-2. Then, another method that was used to detect presence of alcohol is from driver‘s sweat using the IR sensor [8] whereby neither using the air-conditioner nor opening the window will crash the system functionality totally. And besides, every human‘s perspiration rate differs when consuming alcohol. A lack of accuracy will lead to poor or no result of the presence of alcohol in driver‘s sweat.

Other than that, one of the paper has used mobile phone [9] which has an accelerometer and an orientation sensor whereby the mobile phone computes accelerations based on sensor readings and compares it with typical drunk driving patterns extracted from real driving tests through acceleration of vehicles related to lane position maintenance problems such as weaving, drifting, swerving, turning abruptly or with a wide radius and speed control problems like accelerating or decelerating suddenly, braking erratically and stopping abruptly. The loophole in this system is that if kids‘ play with this phone or it gets damaged due to fall as it is portable, then the system fails. In spite of that, paper [10] made a system that has only alert system to prevent car theft by having password access, but it can be further enhanced by having an alcohol detection as well. Although the paper achieved its objective, but with alcohol detection the functionality of the system will be enhanced as well as reduce drunk and drive cases on the road.

Furthermore, in [11], the system has everything except for buzzer and led. It might seem that this paper lacks of something minor, but it does make some effect on the system. As such, while on the road, if the driver is consuming alcohol and it is within the range, any moment, it can go over the threshold level. Led light is the indicator for the driver‘s soberness in a car which can be seen by others road vehicle, and buzzer is necessary to alert any road user that the driver is not conscious enough to drive his vehicle. So, lack of this does make a little impact which can cost a life. Whilst in [12], there is no tracking system or any alert system except alcohol detection, which is not enough to take any further action. Although, the car does not start up upon detecting alcohol in the driver‘s breath, this system was not tested for the condition whereby a driver gets drunk while driving. And another important point would be the system was tested with butane from lighter than ethanol.

In [13], the paper only detects alcohol presence and locks the car upon hitting threshold level but no alert system to inform authorities. Not forgetting in paper [14], the system only detects alcohol presence and rings an alarm, but lacks GSM and GPS which is more important to alert the next of kin. Another paper had used GPS only, excluding GSM [15] which will only detect the location of the vehicle, but will not alert next of kin or police office for further action. Yet, a paper was vice versa whereby it has GSM instead of GPS [16] whereby the police cannot trace the car location and either help the driver or take legal action. Apart from that in [17-19], the system only has buzzer as an alarm system which is insufficient as it lacks of tracking system and presence of alarm inside the car can cause panic attacks and worsen the situation.

Next, in [20-22] the proposed system does not have a GPS tracker or a GSM module that can track the location of the vehicle and notify authorized people via SMS. This limitation can only detect alcohol presence in the driver‘s breath and stops the engine from running, but he will not be prosecuted for his irresponsible act of driving dangerously. Thus, the solution for this is by creating this system with engine lock using GSM, which is embedded into every four wheel vehicle. This system automatically detects the driver‘s intoxication level using an alcohol sensor (MQ-3 sensor). By using ignition, the engines lock if the driver is found to have exceeded the threshold limit of alcohol upon starting the car or slow down a moving car in case the driver consumes alcohol while driving.

This system analyses alcohol consumption by a vehicle driver and alerts authorized person if the driver is drunk by sending the vehicle‘s location using GPS module. Hence, this system can reduce drunken driving accidents and alert other vehicle users besides alerting officers so legal actions can be taken.

2.3 CONCLUSION ON REVIEWS:

Here we propose a framework where the individual is identified for liquor level in his body to stay away from accidents. Drivers will be detected before they begin their vehicle. Driver will be detected by a sensor once he seated on the driver seat by his breath. Alcohol Sensor is put in the steering to screen the breath level if the liquor content in breath is 0.08% then car motor won't start. In this framework if the driver isn't drunk he can drive else he cannot drive until the point that the liquor content decreases. Arduino uno is arranged and associated with the sensor additionally LCD display and one dc motor is associated. Once the association is given power supply to it so the engine will start running .Now liquor is sprayed in it where the liquor content is over 0.08% so the LCD display will demonstrate that alcohol is detected, dc engine will stop running and ignition also stopped. This procedure is executed same in all vehicle where the car motor will be associated with the sensor. Once the alcohol sensor is detected,its output will be sent to the engine by refering the range motor will stop its execution.While implementing this proposed framework, it can decrease the mischances by 75% and reduce the loss of property and lives. These are some more goals of this framework. 1. When driver starting car/vehicle then alcohol sensor begin detecting at condition vehicle speed equivalent to zero. 2. If alcoholic driver recognized then promptly ignition system will turn off and notification will be shown on LCD with alarm/buzzer. 3. A flag is set when first condition is passed without discovery of liquor. 4. If alcohol is recognized for this situation at that point signal is send to fuel blocker by Arduino for locking the start system.so driver feel's that vehicle is going to stop and after that he will place the car at proper location.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

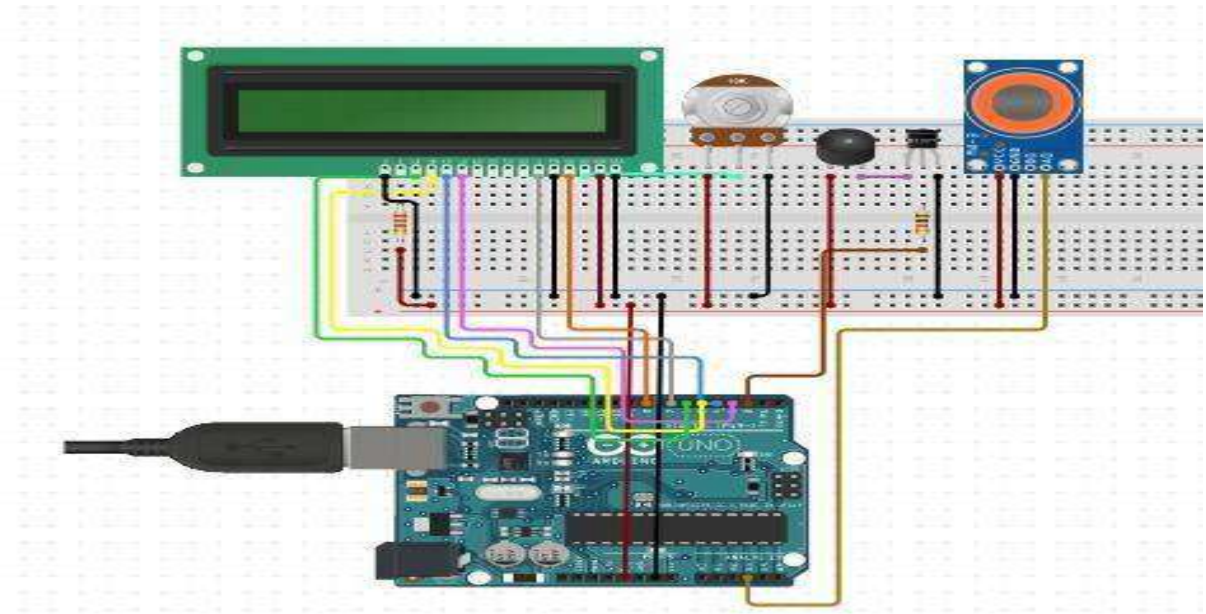

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

Accidents or Mishaps are happening calm regularly now days for some reasons. Among those reasons the calmest reason is because of the liquor dependent purchasers. A large number of the general population used to go to work places like production lines, ventures, medical clinics, workplaces and military by expending liquor. These reason hazardous mishaps in numerous spots over out of indiscretion.

A definitive purpose behind this proposed work is to lessen mishaps because of liquor utilization by identifying it.. This guarantees appropriate hard working attitudes are pursued. In this way, our proposed framework takes into account liquor checking in addition to announcing framework that screens this and reports it to concerned individual remotely over web. Our framework is made out of an IOT based circuit framework that utilizes Arduino board. The framework has MQ3 liquor sensor and to look at the liquor utilization of driver and to control vehicle start automatically. This data refresh to the cloud server alongside area and liquor content. This guarantees no marvel of mishaps because of liquor affect.

1. ARDUINO UNO

Arduino Uno Rev. 3 Microcontroller Board depends on the Atmel ATmega328 8-bit Microcontroller (MCU). Arduino Uno highlights 14 digital input/output pins,six analog inputs, and a 16MHz quartz crystal. Uno also includes a USB association, a power jack, serial port, and a reset button.

2. ALCOHOL SENSOR

This alcohol sensor is appropriate for recognizing alcohol concentration on your breath, much the same as your normal breathe analyzer. It has a high affectability and quick response time. Sensor gives a simple resistive output in view of alcohol concentration. The detection circuit is basic, all it needs is one resistor. The Alcohol sensor is shown in figure 3. A basic interface could be a 0-3.3V ADC.

3. LCD DISPLAY

LCD (Liquid Crystal Display) screen is an electronic display module and locate an extensive variety of uses. A 16x2 LCD display is extremely essential module and is regularly utilized as a part of different gadgets and circuits. These modules are favored more than seven segments and other multi section LEDs. The reasons being: LCDs are economic; easily programmable; have no confinement of showing uncommon and even custom characters. A 16x2 LCD implies it can show 16 characters for each line and there are 2 such lines. In this LCD each character is shown in figure 4 is a 5x7 pixel matrix.

4. BUZZER

A buzzer or beeper is a sound flagging device, which might be mechanical, electromechanical, or piezoelectric. Common uses of buzzers and beepers include caution devices, timers, and affirmation of client input. The buzzer gives an alarm when the alcohol is detected in the vehicle.

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

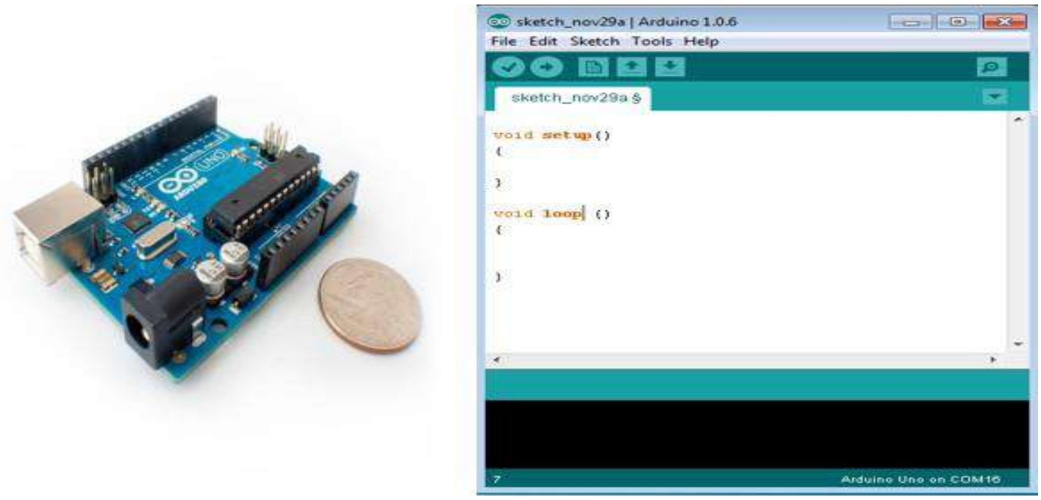

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

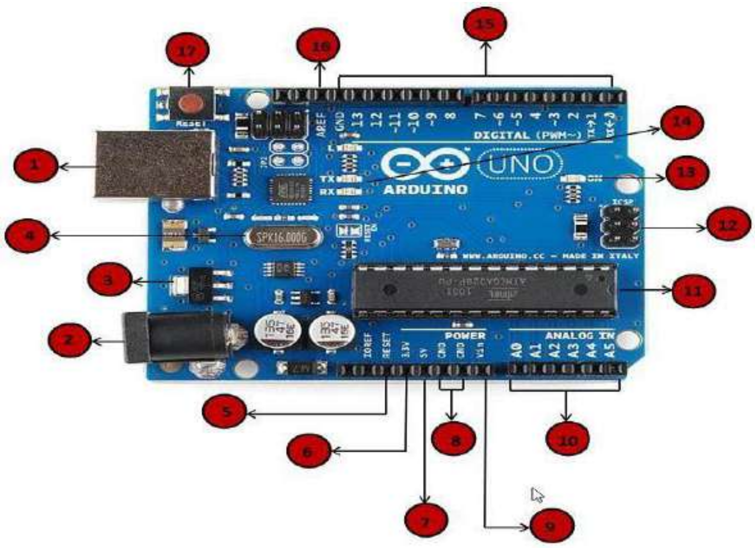

Fig.3.2.1.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can

	reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that

	your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled ―~‖ can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.3: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.4: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

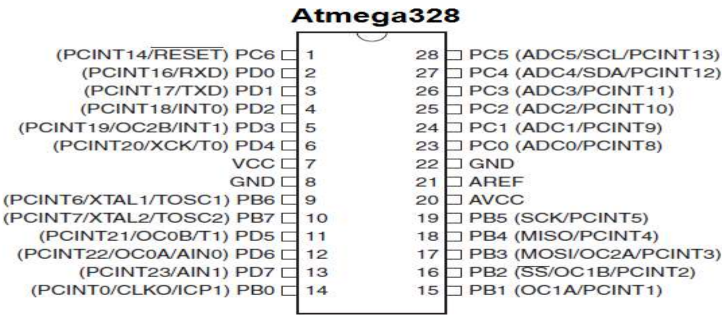

Fig.3.2.1.5 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

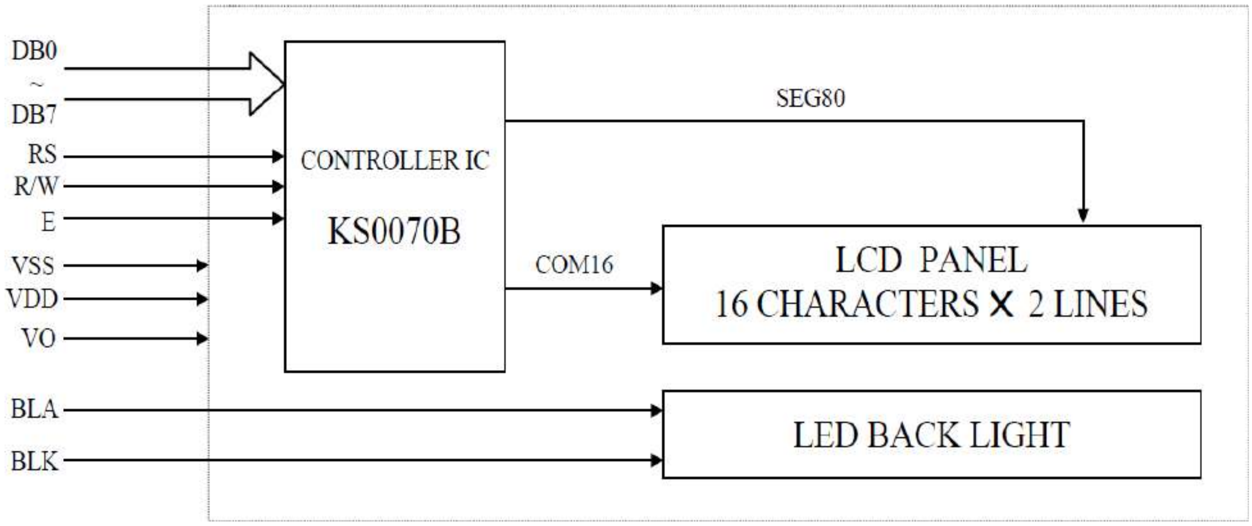

fig.3.2.2.1 LCD block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

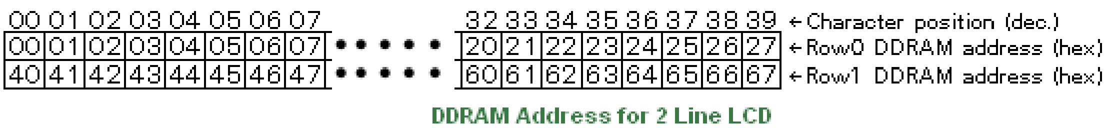

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 BUZZER

3.2.3.1 MAGNETIC TRANSDUCER

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

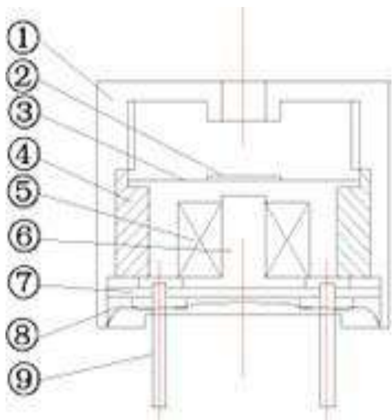

Figure 3.2.3.1 Magnetic transducer

3.2.3.2 MAGNETIC BUZZER(SOUNDER)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

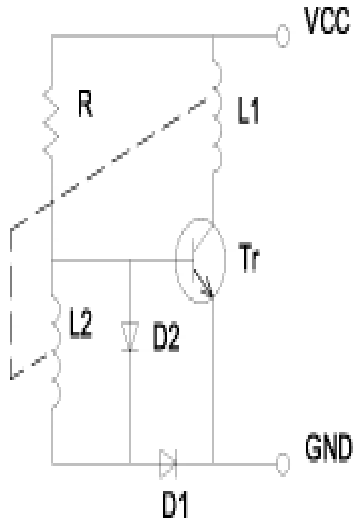

Figure 3.2.3.2 Magnetic buzzer

3.2.3.3 SPECIFICATIONS:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Direct Current Resistance: The direct current resistance is measured by ammeter directly.
Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating Temp. : Keep working well between -30℃ and +70℃.
How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

3.2.3.4HOW TO CHOOSE A BUZZER:

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self drive type to choose. Because of the internal set drive circuit, the self drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.5 INTRODUCTION OF PIEZO BUZZER:

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

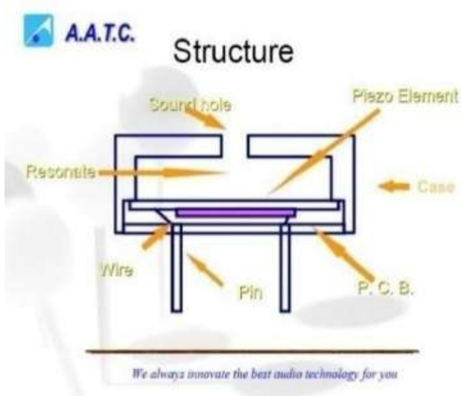

Figure 3.2.3.5 piezo buzzer

3.2.3.6 SPECIFICATIONS:

Rated Voltage: A piezo buzzer is driven by square waves(Vp-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

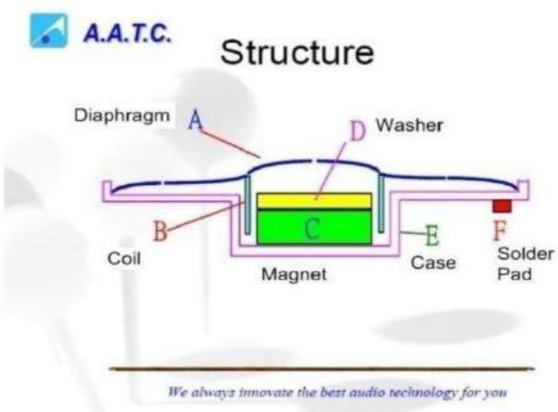

Figure 3.2.3.6 Structure of piezo buzzer

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

Sound Output: The sound output is measured by decibel meter.

Applying rated voltage and square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

.

- ## 3.2.4 MOTOR

3.2.4.1 INTRODUCTION:

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
  - AC motor, an electric motor that is driven by alternating current
    - Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
    - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction
  - DC motor, an electric motor that runs on direct current electricity
    - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
    - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
  - Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge

- Servo motor, an electric motor that operates a servo, commonly used in robotics
- Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

3.2.4.1.1 DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjuntion with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparible AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

Easy to control torque

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

Simple, cheap drive design

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance tradeoffs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

Disadvantages

- Expensive to produce
- Can't reliably control at lowest speeds
- Physically larger
- High maintenance
- Dust

3.2.4.2 WORKING OF DC MOTOR:

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.

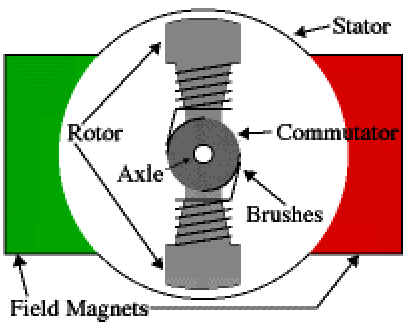

Figure 3.2.4.1 Working of dc motor

3.2.4.3 PRINCIPLE

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously.

When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the

external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator. You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).

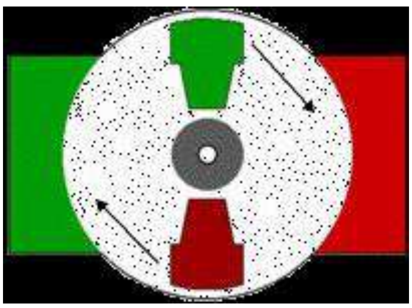

Figure 3.2.4.3 Principle

3.2.4.4 Construction and Working

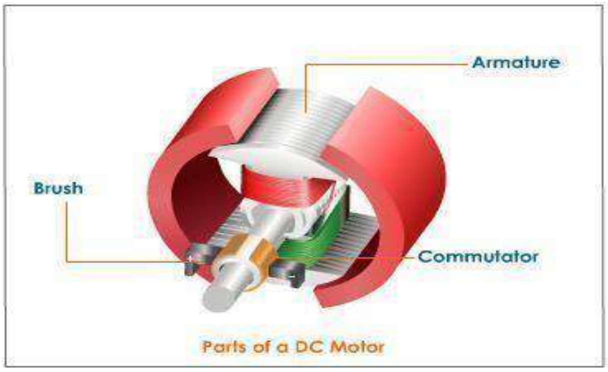

Figure 3.2.4.4 construction and working of dc motor

3.2.4.5 Parts of a DC Motor

3.2.4.6 Armature

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

3.2.4.7 Commutator

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.

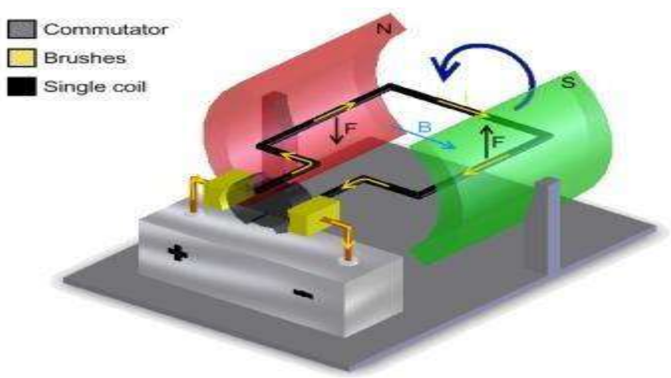

Figure 3.2.4.7 commutator

3.2.4.8 Brushes

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

3.2.4.9 Working of a DC Motor

When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.

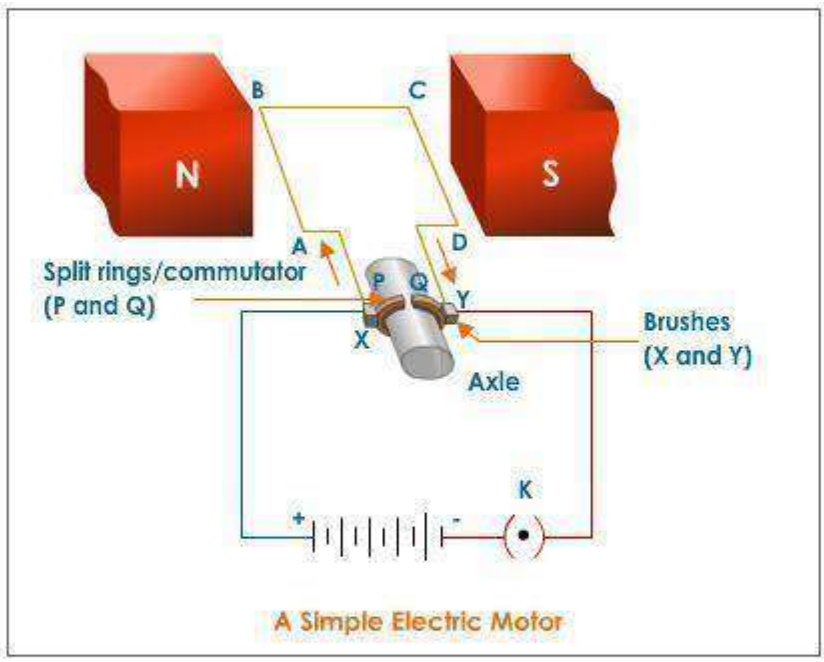

Figure 3.2.4.9 working of a dc motor

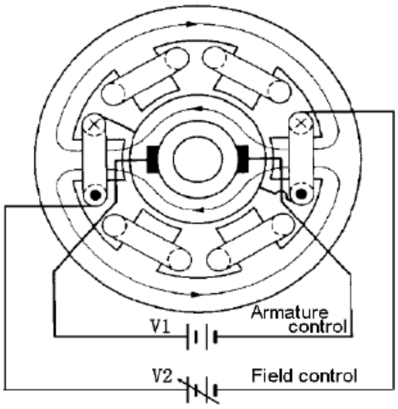
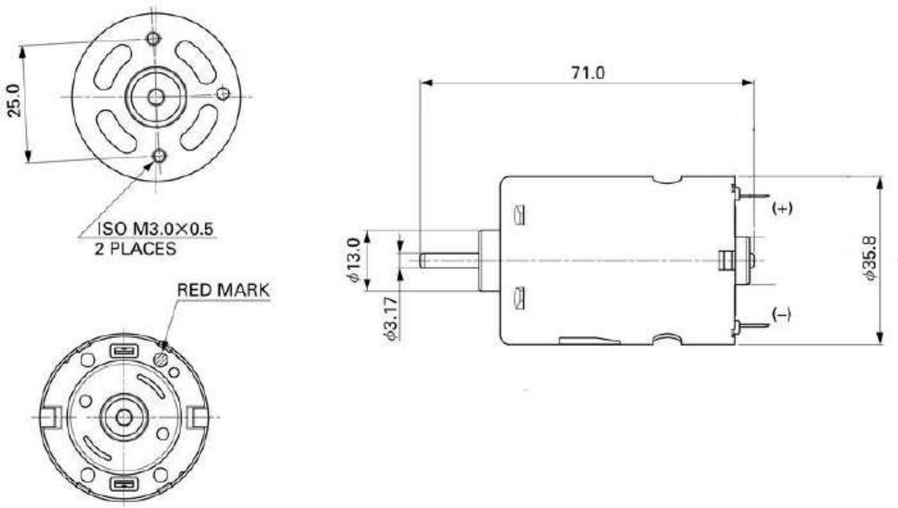
When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

However the coil keeps turning because of its own momentum.

Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.





3.2.5 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.5.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientificinstruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.5.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

● Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

● Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

● Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

● Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

● Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

● Open source and extensible software - The Arduino software is published as open sourcetools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

● Open source and extensible hardware - The plans of the Arduino boards are published under

a Creative Commons license, so experienced circuit designers c an make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

● Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✔ Download the Arduino Software (IDE)
- ✔ Proceed with board specific instructions.

3.2.5.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.5.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.5.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.3.2.5.4.2Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

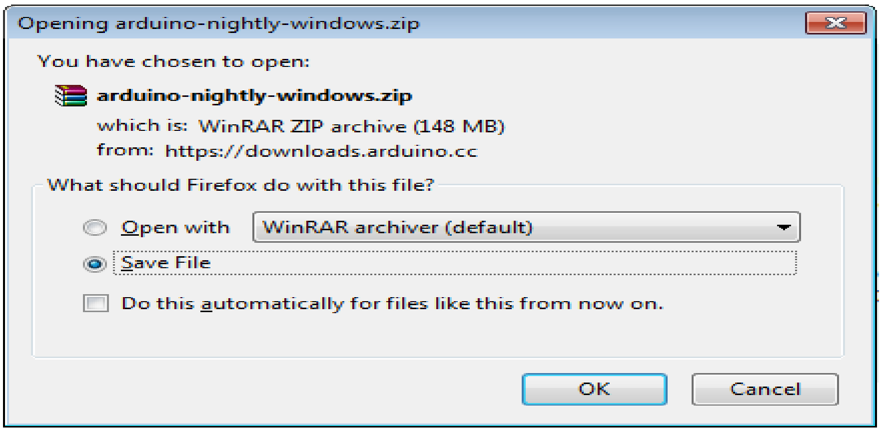


Fig.3.2.5.4.3Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

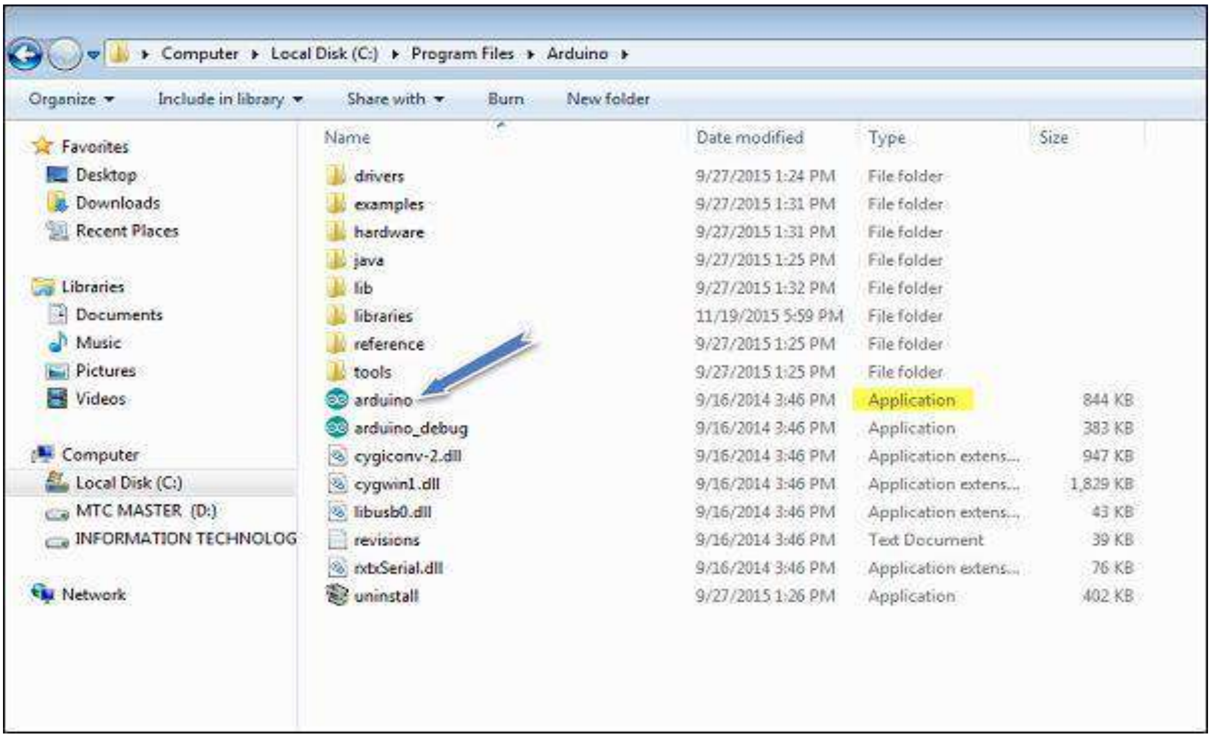

Fig.3.2.5.4.4Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

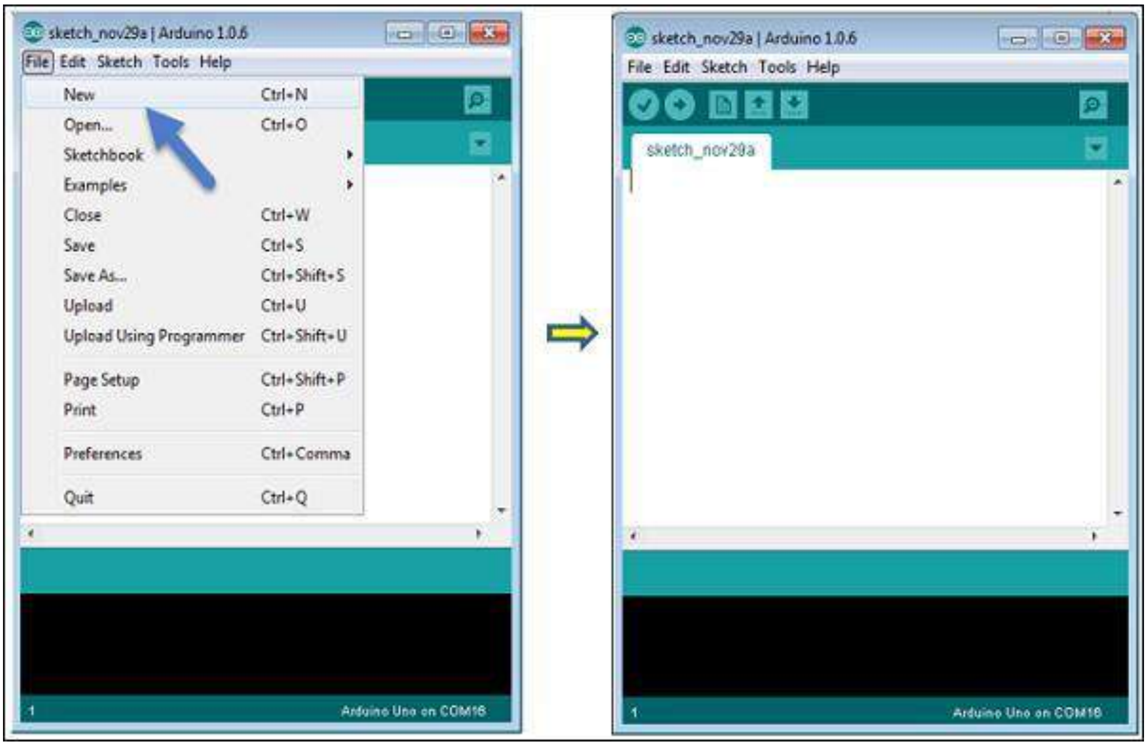

Fig.3.2.5.4.5Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

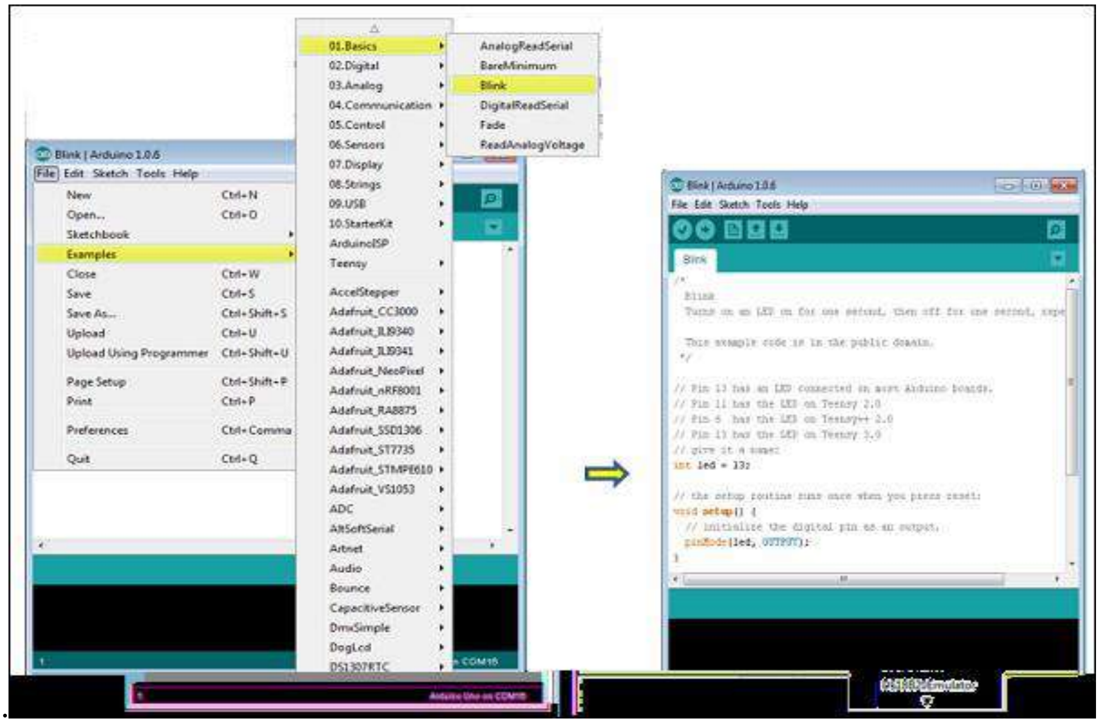

Fig.3.2.5.4.6Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

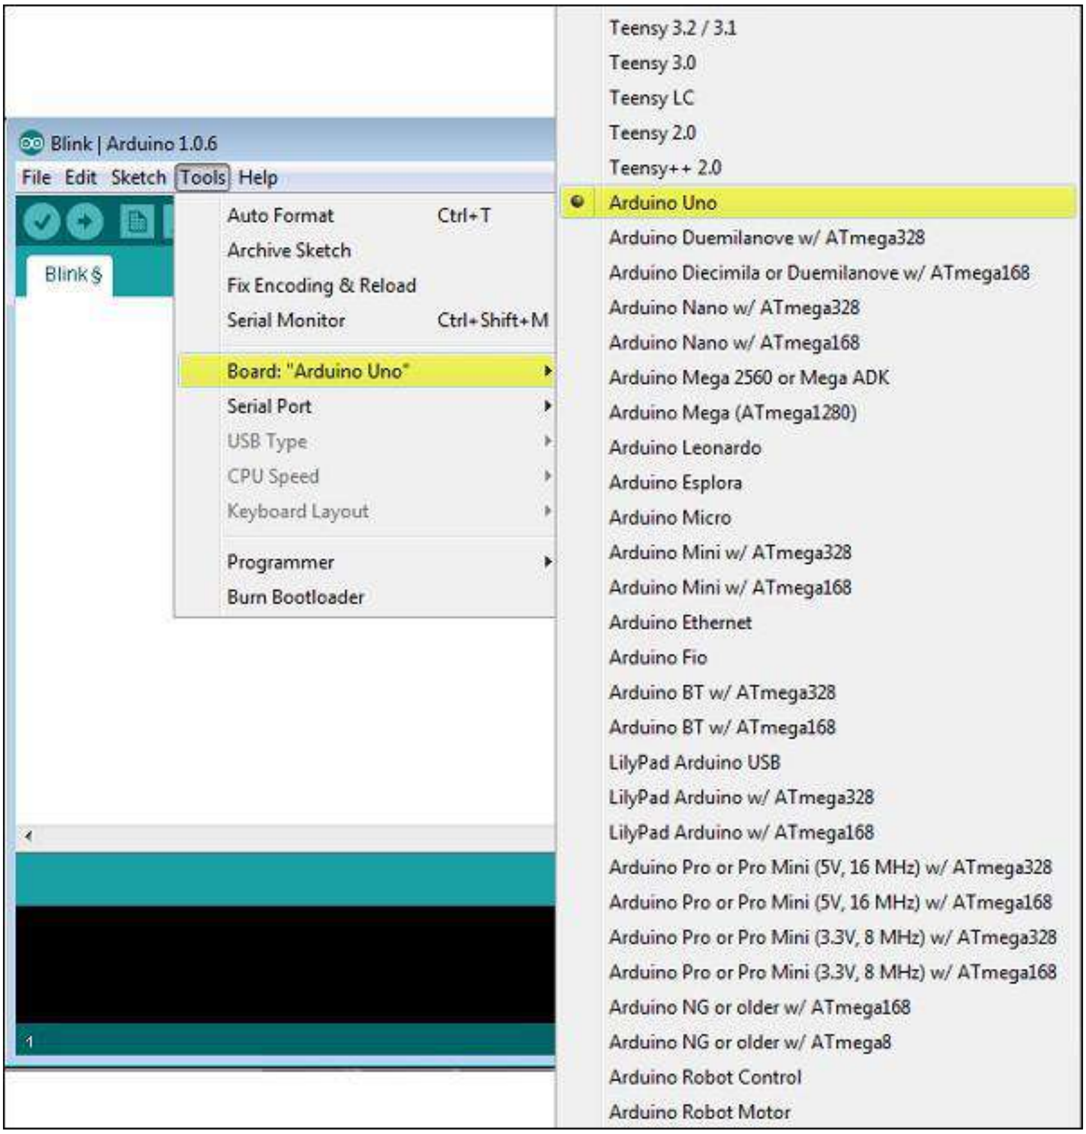

Fig.3.2.5.4.7Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

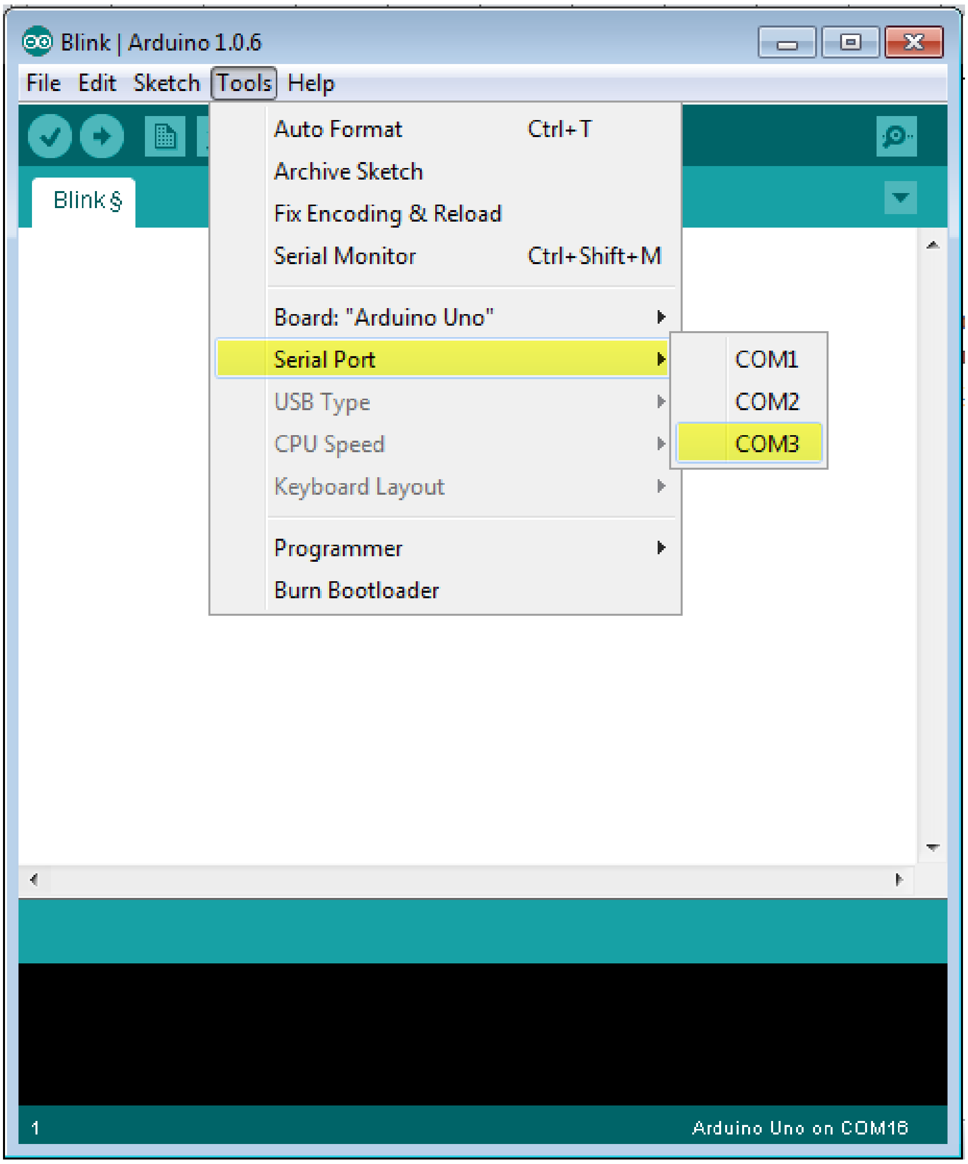

Fig.3.2.5.4.8Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

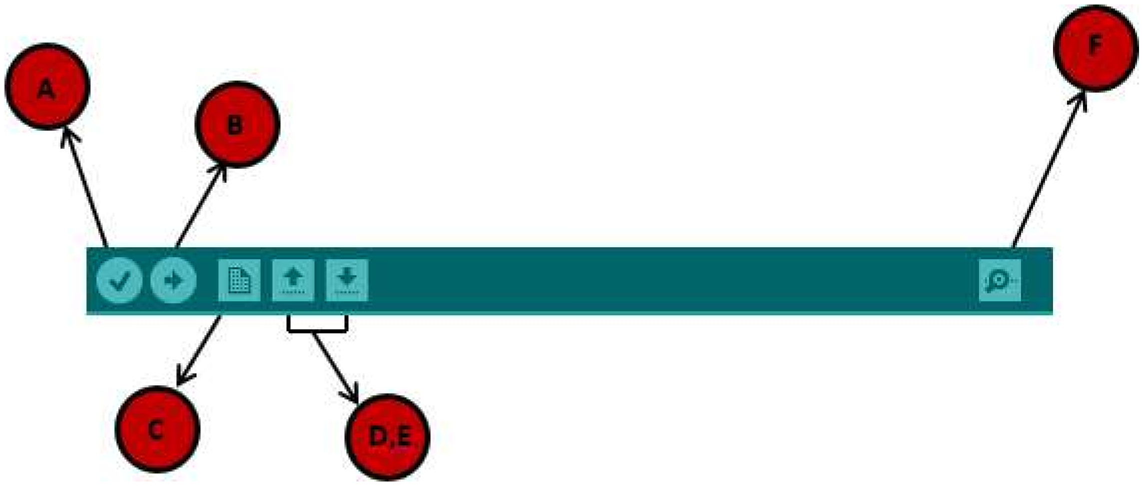

Fig.3.2.5.4.9 Upload the program to your board

A – Used to check if there is any compilation error.

B – Used to upload a program to the Arduino board.

C – Shortcut used to create a new sketch.

D – Used to directly open one of the example sketch.

E – Used to save your sketch.

F – Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note – *If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.*

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to

24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

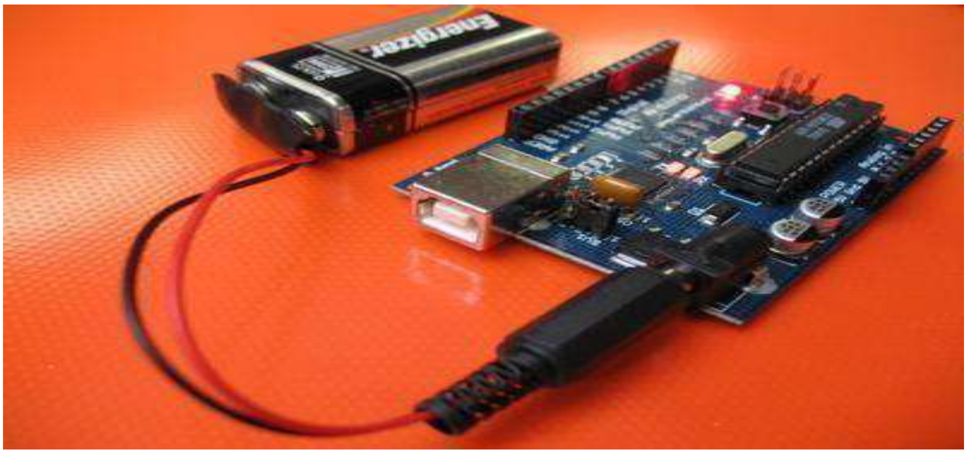

Fig.3.2.5.4.10Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called –sketches‖, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig.3.2.5.4.11Example Program

3.2.6 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electricaland Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline –From concept to completion‖.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole

packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

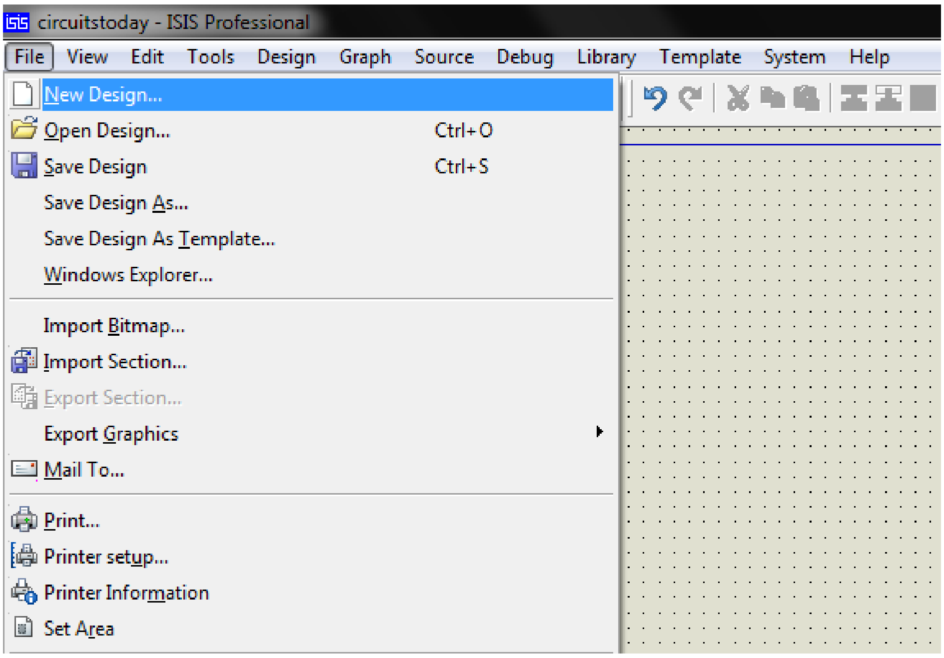

Fig.3.2.6.1Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

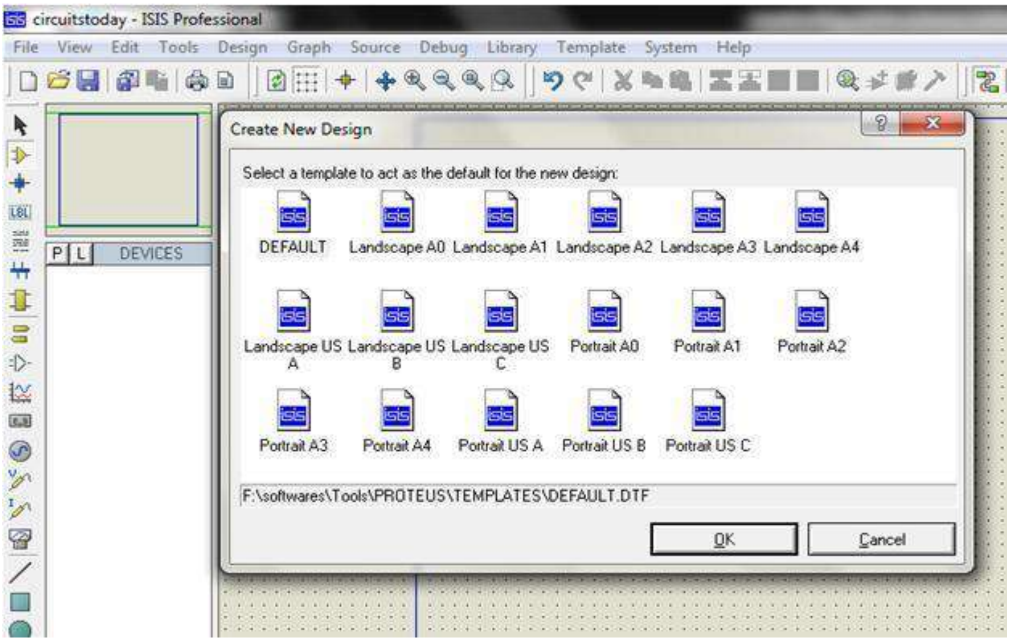

Fig.3.2.6.2Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

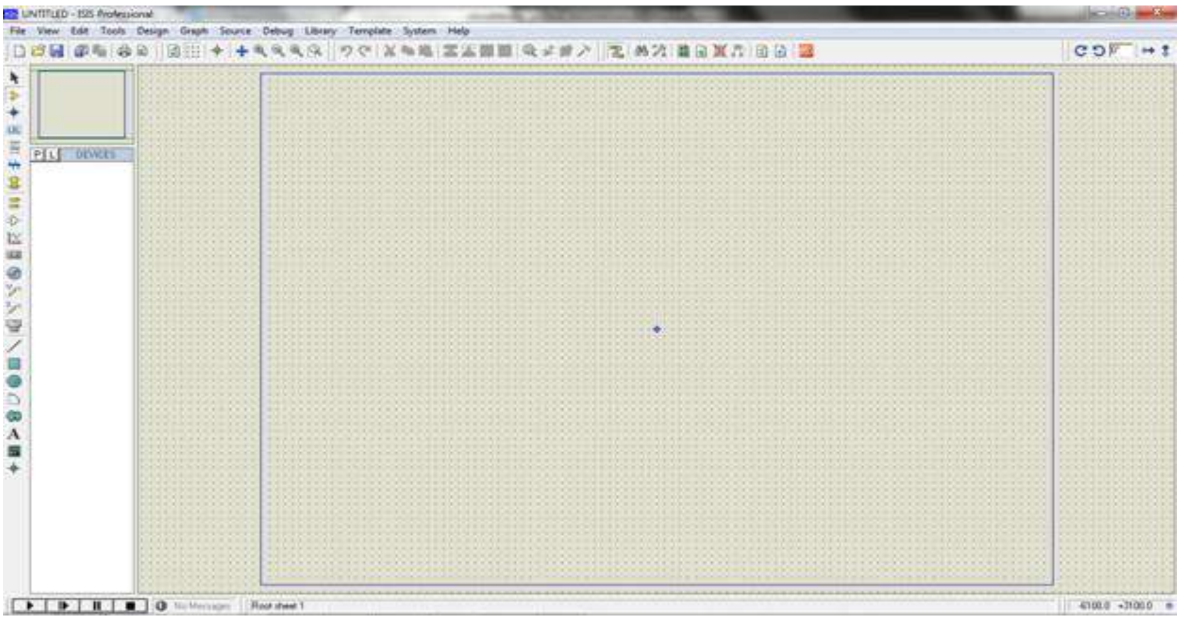

Fig.3.2.6.3Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

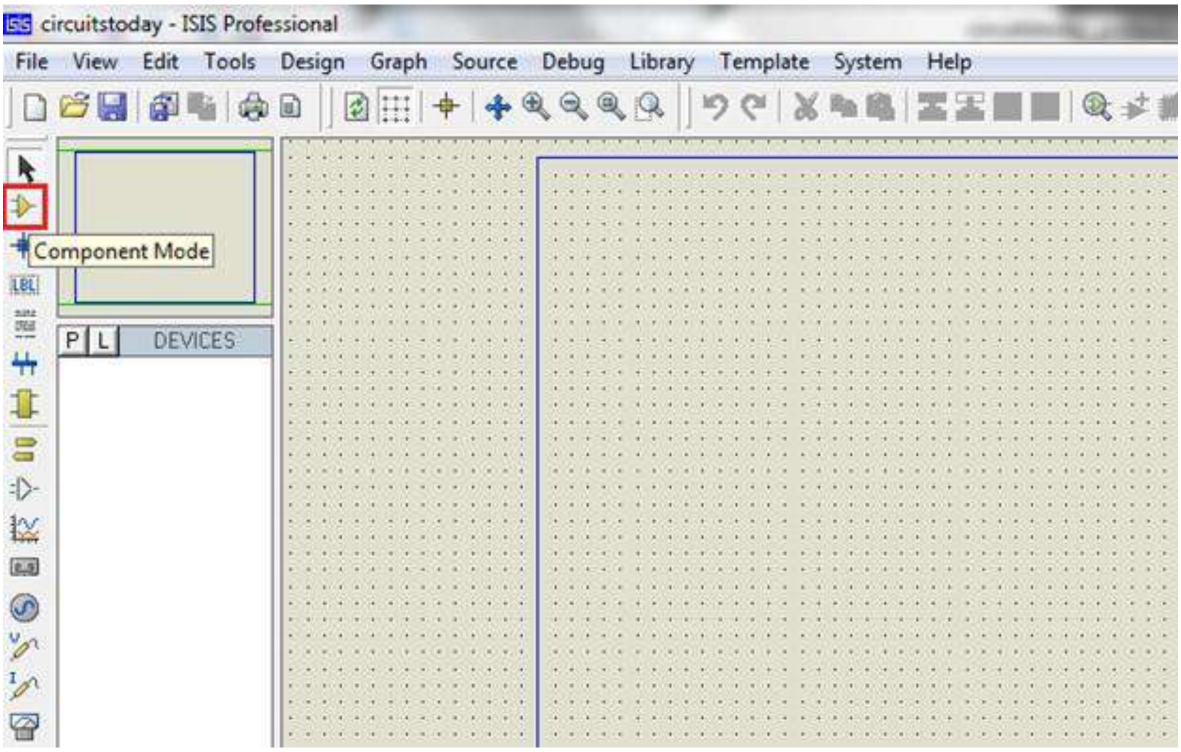

Fig.3.2.6.4Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

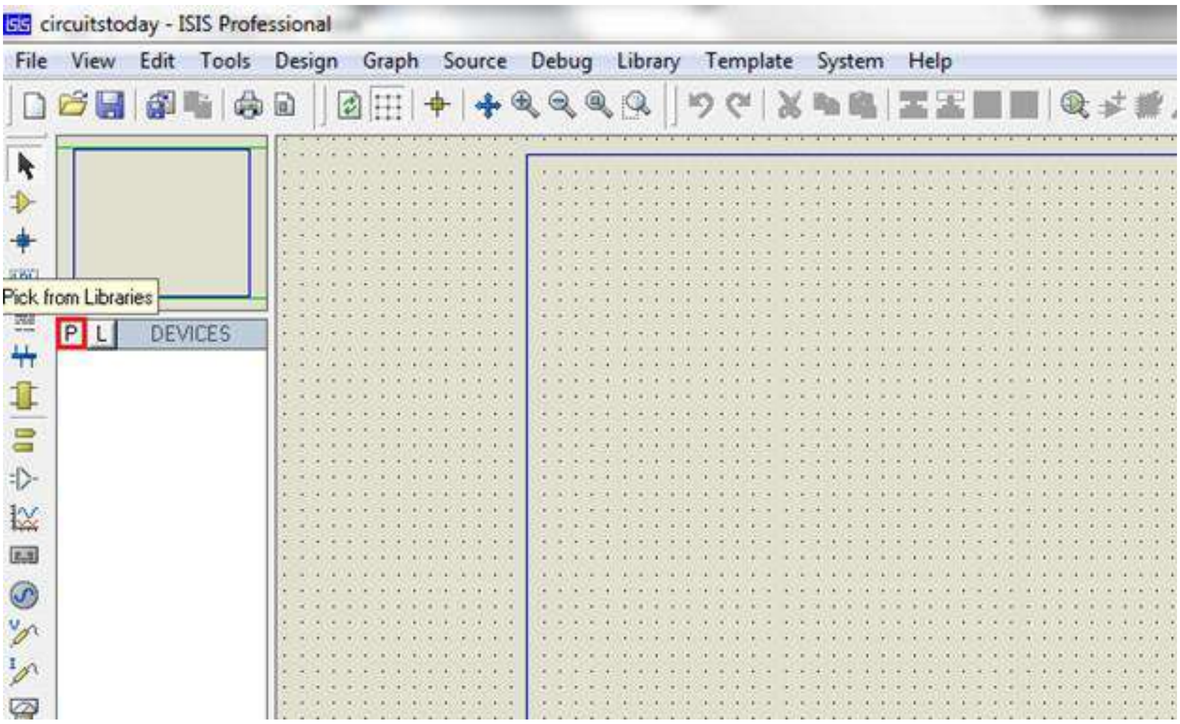

Fig.3.2.6.5Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

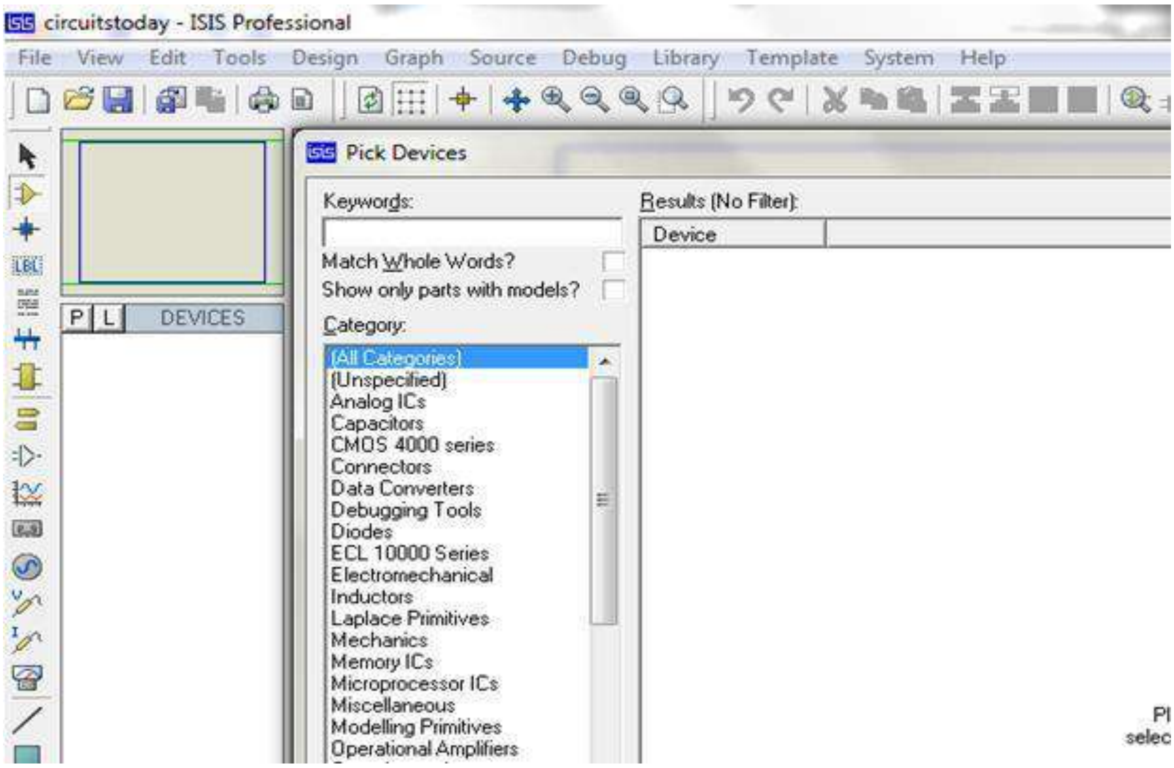

Fig.3.2.6.6Keywords Textbox

Example shows selection of push button. Select the components accordingly.

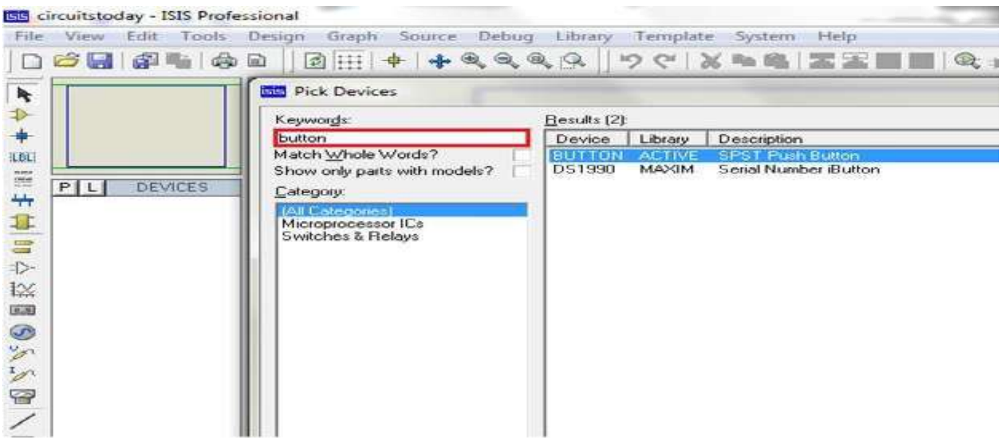

Fig.3.2.6.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

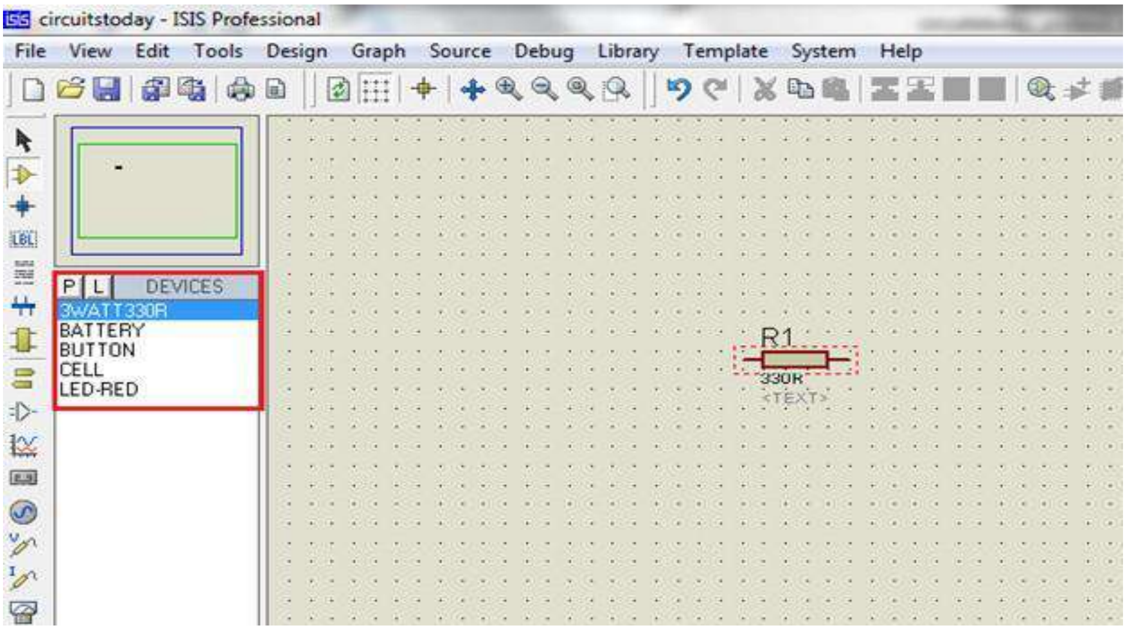

Fig.3.2.6.8Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

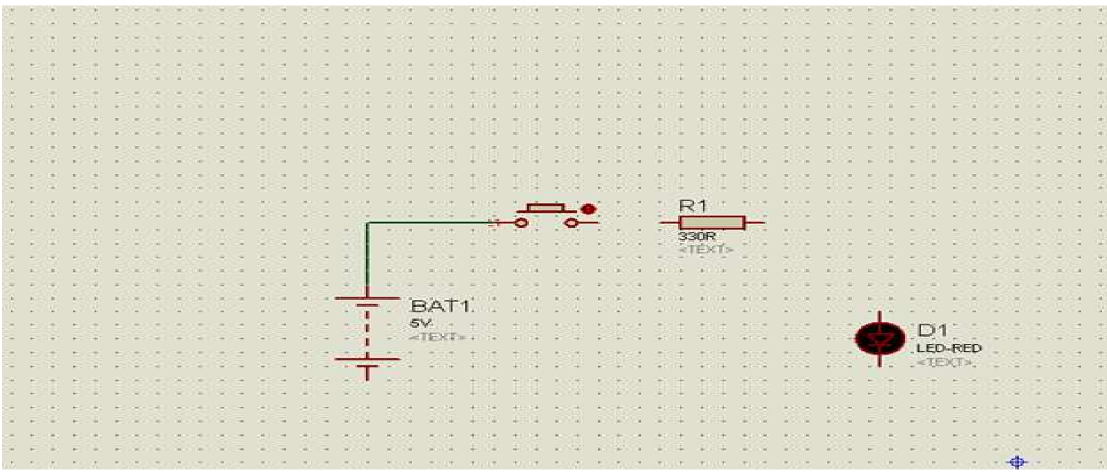

Fig.3.2.6.9Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

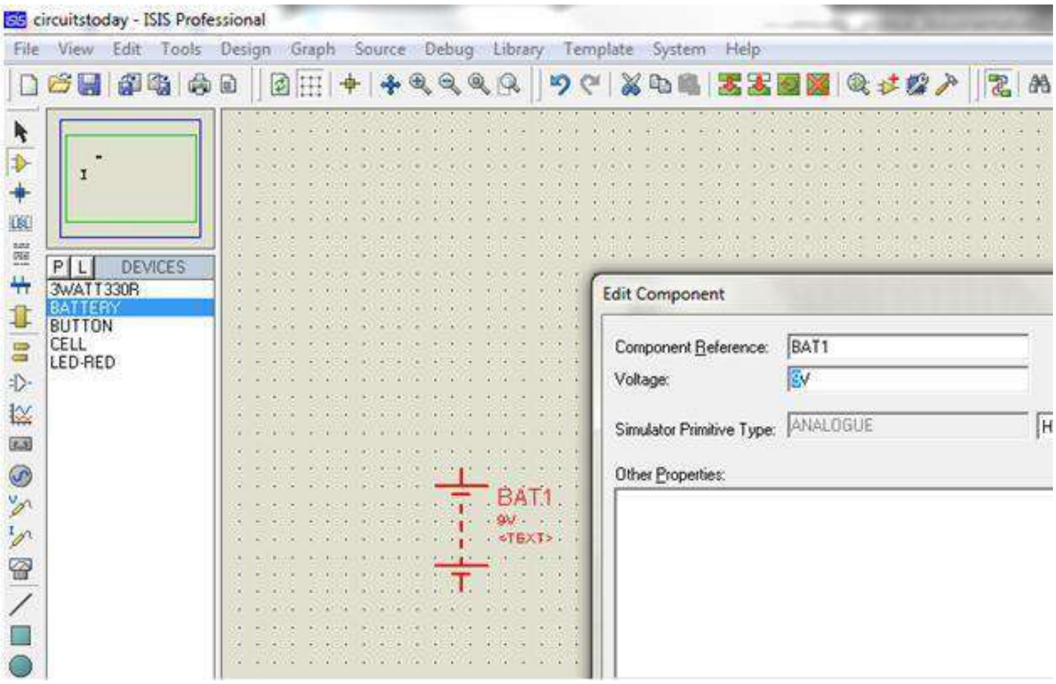

Fig.3.2.6.10Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

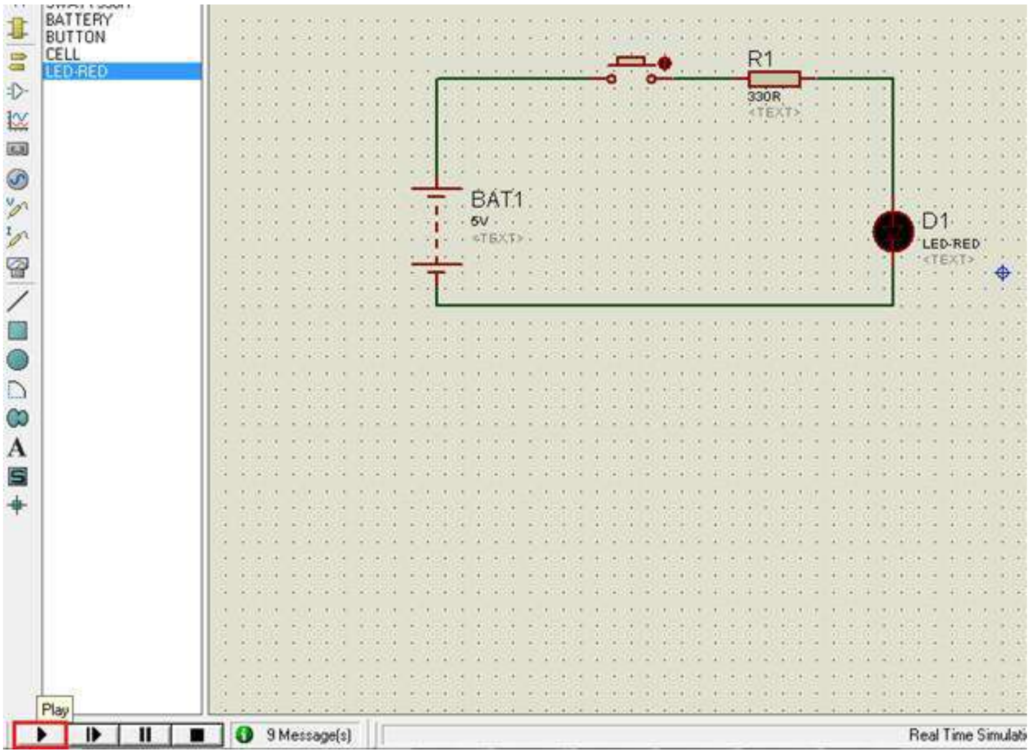

Fig.3.2.6.11Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

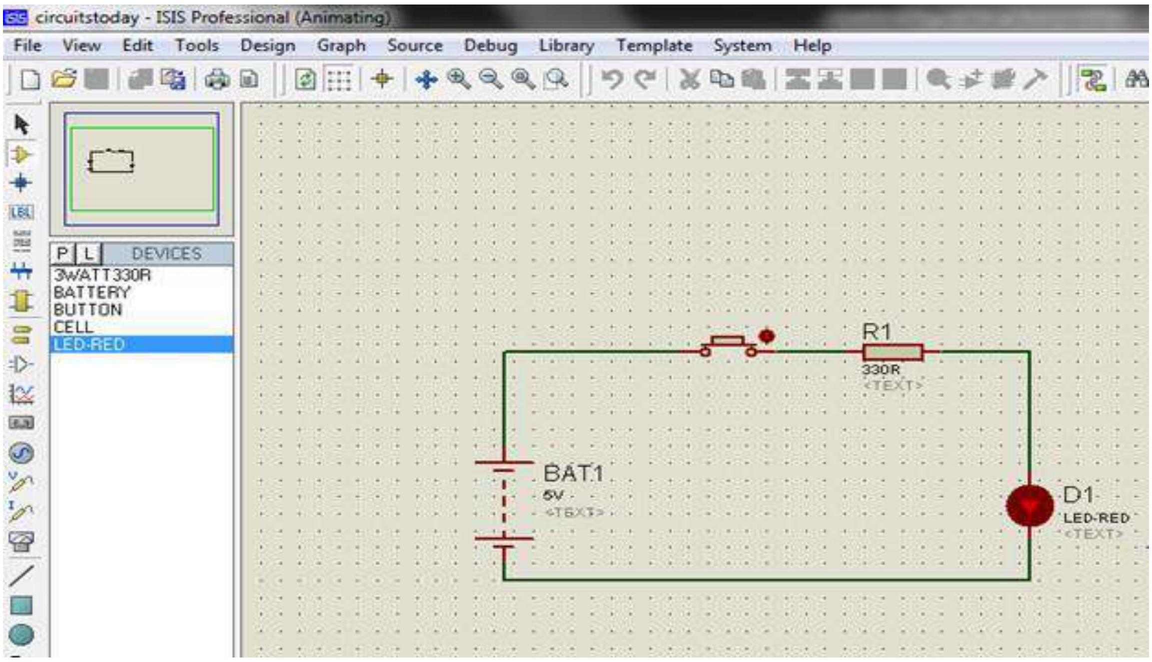

Fig. 3.2.6.12Simulation Animating

Simulation can be stepped, paused or stopped at any time.

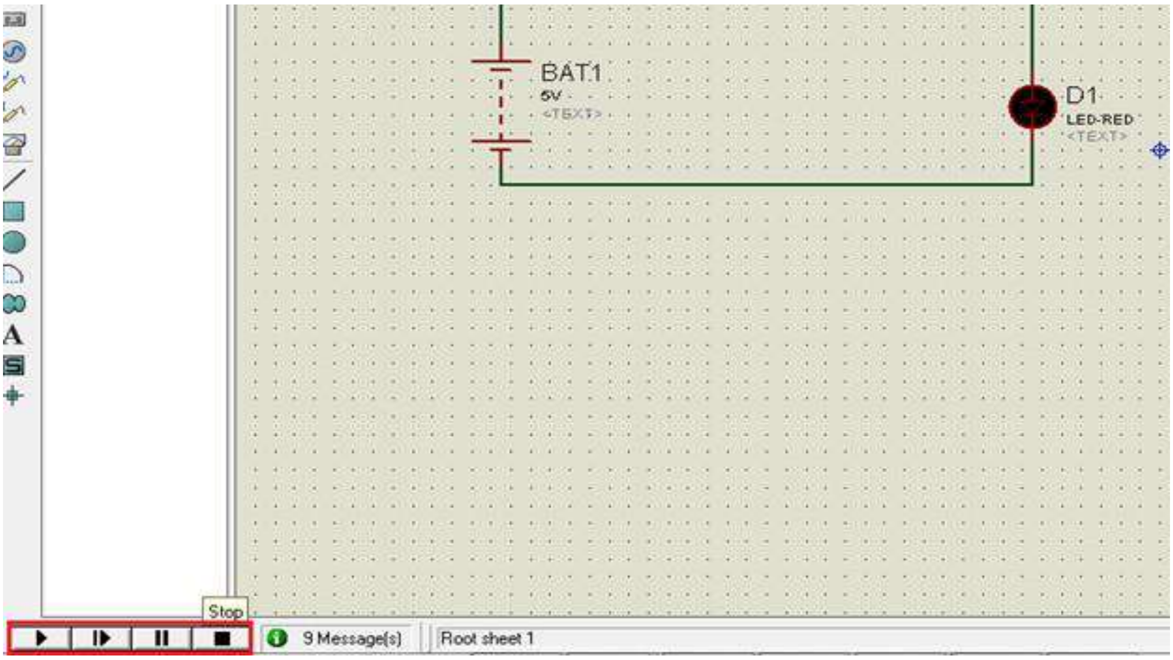

Fig.3.2.6.13Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.3.1 MQ3 SENSOR

3.3.1.1 INTRODUCTION

MQ3 is one of the most commonly used sensors in the MQ sensor series. It is a Metal Oxide Semiconductor (MOS) type of sensor. Metal oxide sensors are also known as Chemiresistors, because sensing is based on the change of resistance of the sensing material when exposed to alcohol. So by placing it in a simple voltage divider network, alcohol concentrations can be detected.

MQ3 alcohol sensor works on 5V DC and draws around 800mW. It can detect Alcohol concentrations anywhere from 25 to 500 ppm.

3.3.1.2 PIN CONFIGURATION

Pin name	**description**
VCC	This pin powers the module, typically the operating voltage is +5V
GND	Used to connect the module to system ground
DIGITAL OUT	You can also use this sensor to get digital output from this pin, by setting a threshold value using the potentiometer
ANALOG OUT	This pin outputs 0-5V analog voltage based on the intensity of the gas

3.3.1.3 SPECIFICATIONS OF MQ3 GAS SENSOR :

- Power requirements: 5 VDC @ ~165 mA (heater on) / ~60 mA (heater off)
- Current Consumption: 150mA
- DO output: TTL digital 0 and 1 (0.1 and 5V)
- AO output: 0.1- 0.3 V (relative to pollution), the maximum concentration of a voltage of about 4V
- Detecting Concentration: 0.05-10mg/L Alcohol
- Interface: 1 TTL compatible input (HSW), 1 TTL compatible output (ALR)
- Heater consumption: less than 750mW
- Operating temperature: 14 to 122 °F (-10 to 50°C)
- Load resistance: 200kΩ
- Sensitivity S: Rs(in air)/Rs(0.4mg/L Alcohol)≥5
- Sensing Resistance Rs: 2KΩ-20KΩ(in 0.4mg/l alcohol)
- Dimensions: 32 x 22 x 16 mm

.

Fig.3.3.1.3: MQ3 sensor

3.3.2 IGNITION SYSTEM

3.3.2.1 INTRODUCTION

The key ignition of an automobile serves two purposes. It ensures that only the person who carries the keys can start the car and drive it away.It not only starts the engine but activates all the other electronic and mechanical systems in the vehicle. It is connected to one of analog pic of arduino.

3.3.2.2 OBJECTIVE

We know that in case of Internal Combustion (IC) engines, combustion of air and fuel takes place inside the engine cylinder and the products of combustion expand to produce reciprocating motion of the piston. This reciprocating motion of the piston is in turn converted into rotary motion of the crank shaft through connecting rod and crank. This rotary motion of the crank shaft is in turn used to drive the generators for generating power. We also know that there are 4-cycles of operations viz.: suction; compression; power generation and exhaust. These operations are performed either during the 2-strokes of piston or during 4-strokes of the piston and accordingly they are called as 2-stroke cycle engines and 4-stroke cycle engines.

In case of petrol engines during suction operation, charge of air and petrol fuel will be taken in. During compression this charge is compressed by the upward moving piston. And just before the end of compression, the charge of air and petrol fuel will be ignited by means of the spark produced by means of for spark plug. And the ignition system does the function of producing the spark in case of spark ignition engines.

3.4 POWER SUPPLY

3.4.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as –Regulated D.C Power Supply‖.

3.4.1.1 BLOCK DIAGRAM OF POWER SUPPLY:

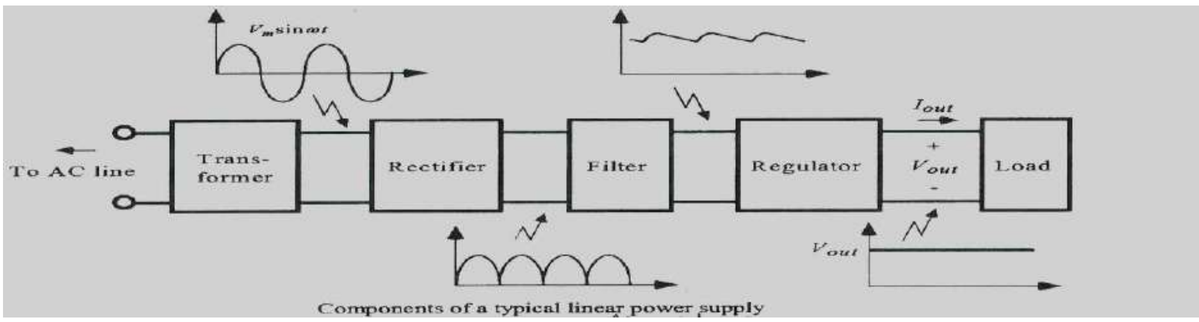

Fig.3.4.1.1.1: Block Diagram of Power Supply

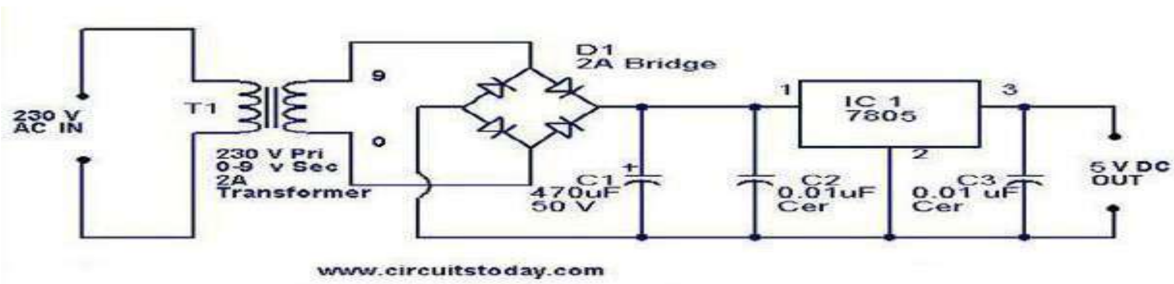

Fig.3.4.1.1.2(A): Schematic Diagram of Power Supply

3.4.2 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.4.3 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

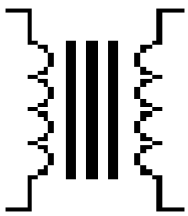

Fig.3.4.3.1: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

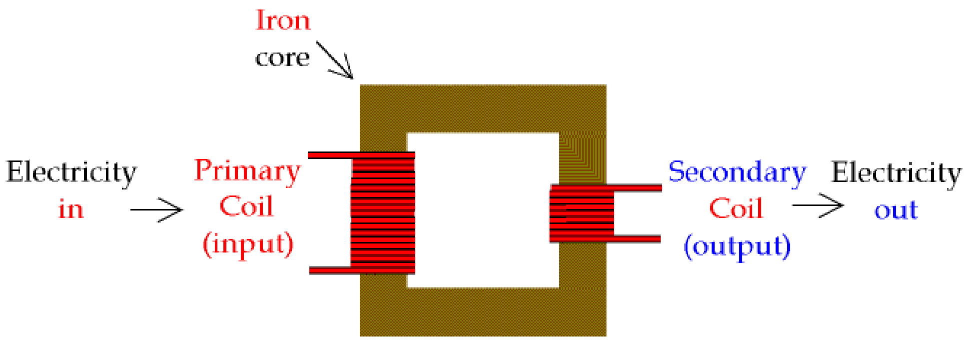

Fig.3.4.3.2: Transformer

3.4.3.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

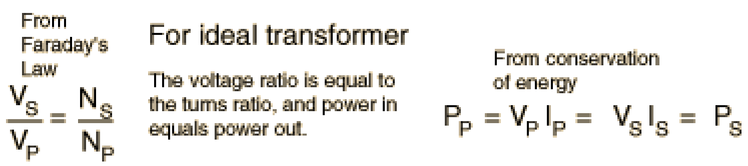

Figure 3.4.3.1.1 Basic principle of transformer

Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

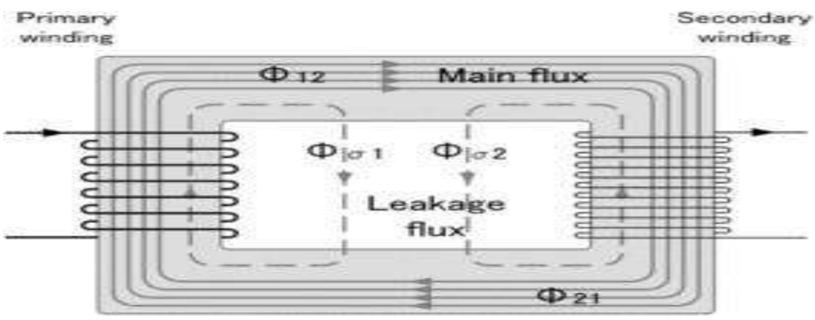

Fig.3.4.3.1.2: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.4.3.2 Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn‘s ratio of the two sets of windings determines the amount of voltage transformation.

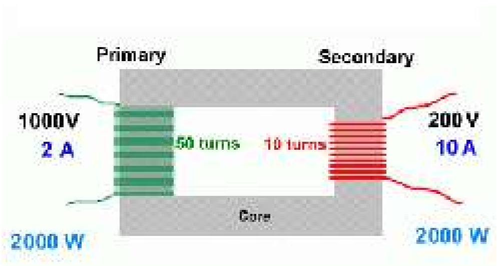

Fig.3.4.3.2.1: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

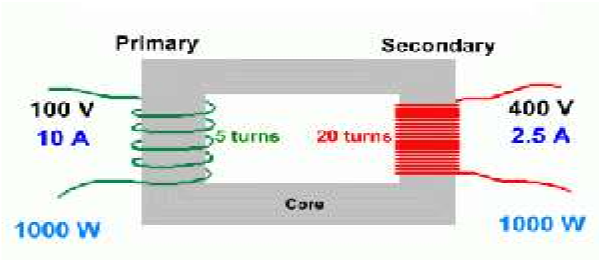

Fig. 3.4.3.2.2: Step-Up Transformer

3.4.4 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

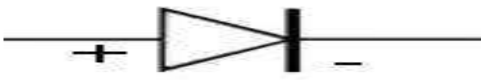

Fig.3.4.4.1: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.4.5 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

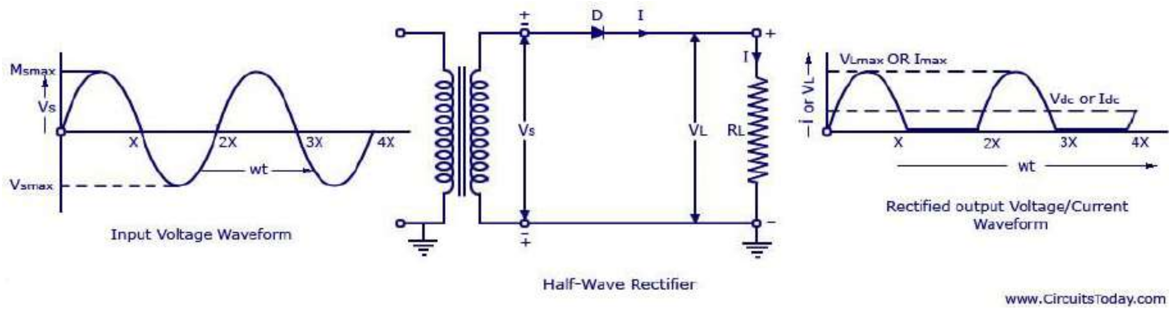

Fig.3.4.5.1: Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

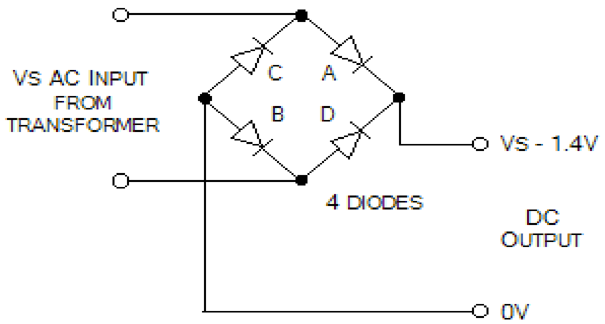

Fig.3.4.5.2: Full-Wave Rectifier

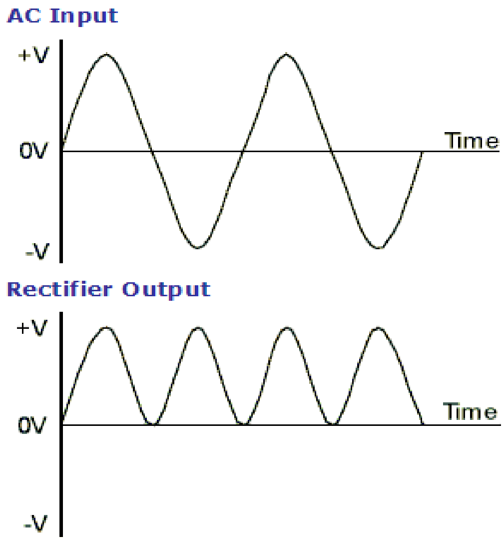

Fig.3.4.5.3(c): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

3.4.6 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

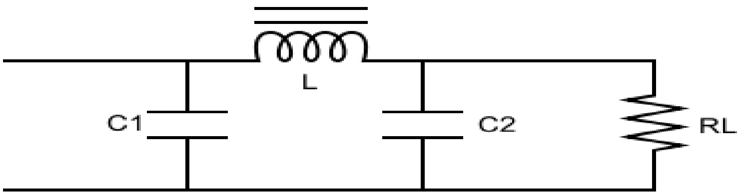

Fig.3.4.6.1: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

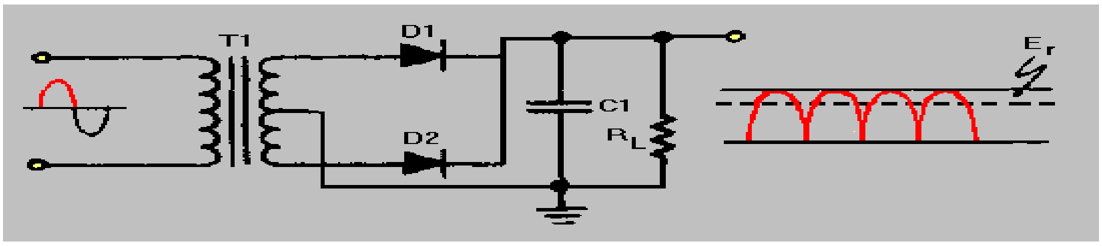

Fig. 3.4.6.2: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.4.7 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and _xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:‘78‘ indicate the negative series and ‗xx‘indicates the voltage rating. Suppose 7905 produces the maximum -5V.‘05‘indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

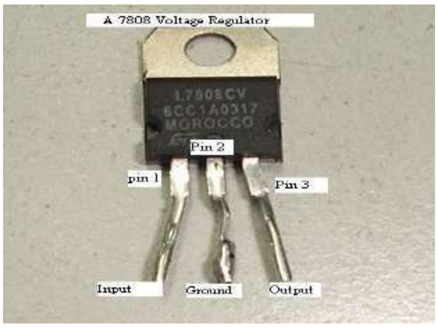

Fig.3.4.7: Regulator

4.5 RESULTS

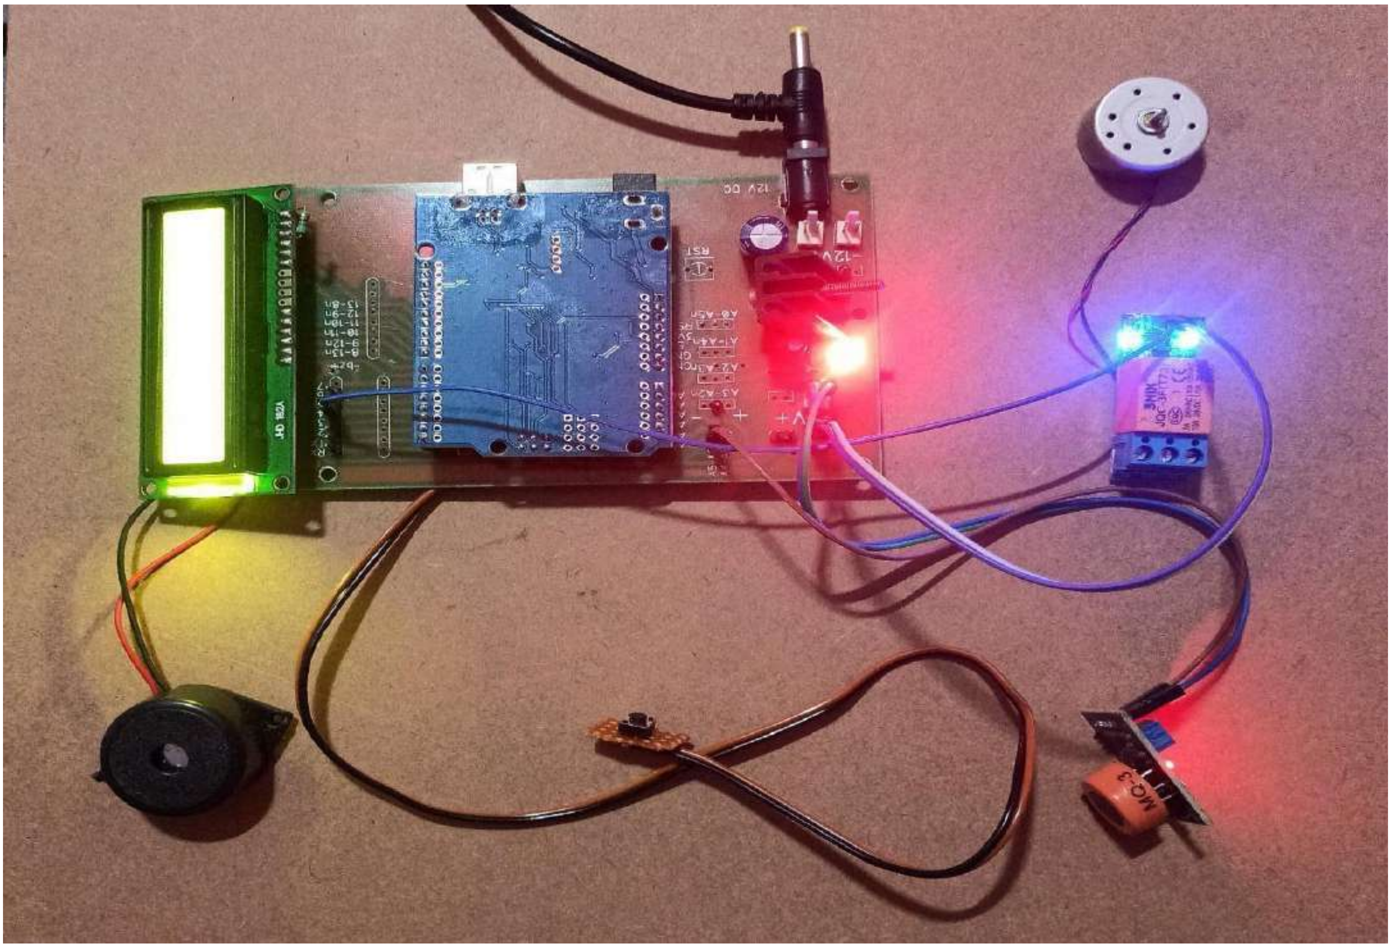

Fig.4.5 Final Output

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Here we propose a framework where the individual is identified for liquor level in his body to stay away from accidents. Drivers will be detected before they begin their vehicle. Driver will be detected by a sensor once he seated on the driver seat by his breath. Alcohol Sensor is put in the steering to screen the breath level if the liquor content in breath is 0.08% then car motor won't start. In this framework if the driver isn't drunk he can drive else he cannot drive until the point that the liquor content decreases. Arduino uno is arranged and associated with the sensor additionally LCD display and one dc motor is associated. Once the association is given power supply to it so the engine will start running .Now liquor is sprayed in it where the liquor content is over 0.08% so the LCD display will demonstrate that alcohol is detected, dc engine will stop International Journal of Pure and Applied Mathematics Special Issue 3002 running and ignition also stopped. This procedure is executed same in all vehicle where the car motor will be associated with the sensor. Once the alcohol sensor is detected,its output will be sent to the engine by refering the range motor will stop its execution.While implementing this proposed framework, it can decrease the mischances by 75% and reduce the loss of property and lives.

These are some more goals of this framework.

1. When driver starting car/vehicle then alcohol sensor begin detecting at condition vehicle speed equivalent to zero.

2. If alcoholic driver recognized then promptly ignition system will turn off and notification will be shown on LCD with alarm/buzzer.

3. A flag is set when first condition is passed without discovery of liquor.

4. If alcohol is recognized for this situation at that point signal is send to fuel blocker by Arduino for locking the start system.so driver feel's that vehicle is going to stop and after that he will place the car at proper location.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

This device is useful in avoiding the accidents on roads to some extent. The detection of alcohol and making to know the levels of alcohol that is taken by the person will be useful stat to the driver so he can be cautious while taking the alcohol further during driving a vehicle. The location of the vehicle can be traced if a GPRS module is used along with the GSM module. This device can help in reducing the road accidents and also helps saving the lives of the people. This can play a major role in reducing the drunken driving cases. This can save the lives of innocent people who will get hit by the drunken drivers with their vehicles. Installing this device in every vehicle will reduce drunken driving case to large extent.

So, we can conclude that this type of devices and more advanced devices other than these can be very useful. These types of devices are cost efficient and can be maintained easily. These types of devices plays prominent role in avoiding accidents due to drunken driving. This will be one of the better ways in reducing the drunken driving cases. This is one of road safety measure that every person who drives a vehicle should practice for their safety and other peoples too. Life is important; we have to not waste it. –SAVING A INNOCENT PERSON IS SAVING HIS FAMILY‖

6.2 FUTURE ENHANCEMENT

In future this type of device can be developed with more accuracy and efficiently. This type of devices can be installed in the vehicles during the manufacturing of the vehicles itself. This can assure the safety for the customer and can versatile feature in the automobile industry for sure. We can connect the cameras to such devices and these cameras can be used to detect the drivers who are drunk and cameras can be used as theft alarms for the vehicles. We can protect the vehicles from getting stolen and even can avoid drunken driving accidents. We can connect the GPRS module to trace the location the vehicle and can be helpful in intimating the person about location of the vehicle which is drove by the drunk driver. We can find the vehicle if stolen by tracing the location of the vehicle when necessary precautions are taken and proper hidden GPRS modules are installed in the vehicle. We can modify this type of device by connect different modules like fire sensing alarms, sounds systems can be connected etc., can be added to device. Low power consumption devices will be efficient and working of device in any condition can be taken care.

So, this type of devices can be used as multiple purpose devices. Hence, there will be large scope in developing such kind of device and cost efficiency is must.

APPENDICES

Driving while drunk is hazardous and drivers with high Blood Alcohol Content (BAC) are at expanded danger of auto crashes, roadway wounds and vehicular passings. Anticipation measures assessed incorporate permit suspension or disavowal, appropriating or seizing vehicle plates, implementing open holder bans, expanding fine punishments, imprison, ordering instruction for youth and bringing down legitimate BAC's. Despite the fact that these much obstacles made by experts to drunken drive, it is as yet proceeding with like serial scenes. In that capacity there is no viable instrument to reduce this.

Here, this process have intended to plan a Drunk driving detection, which is integrated with the directing wheel. This framework is meant for making vehicle driving more secure than previously and shield the mishaps from happening due to the liquor utilization of the driver. The individual when he is at vehicle, this is necessary to infer the driver's condition continuously and here this work proposed the detection of alcohol utilizing alcohol sensor associated with Arduino. Alcohol sensor is installed on the steering of the car, with the end goal that when the level of liquor crosses a reasonable farthest point, where the start of vehicle will kill and the motor will stop. The Arduino always uses the alcohol sensor information to check drunk driving and works bolt on the vehicle motor to stop the engine.

A

MAJOR PROJECT REPORT ON

AN EXPERIMENTAL COMPARISION OF DIFFERENT OBJECT TRACKING ALGORTHMS

Submitted by

1) Mr. P. Rahul (17K81A04N9) **2) Mr. K. Jagadeeshwar (17K81A04L7)**

3) Mr. A. Anil Kumar (17K81A04J2)

In partial fulfillment for the award of the degree of

BACHELOR OF TECHNOLOGY

IN

ELECTRONICS AND COMMUNICATION ENGINEERING

Under The Esteemed Guidance of

Mr. M. Thirupathi

Associate Professor

DEPARTMENT OF ELECTRONICS AND COMMUNICATION ENIGINEERING

ST. MARTIN'S ENGINEERING COLLEGE

(An Autonomous Institute)

Dhulapally, Secunderabad – 500 10

June 2021

BONAFIDE CERTIFICATE

This is to certify that the project entitled "AN EXPERIMENTAL COMPARISION OF DIFFERENT OBJECT TRACING ALGORITHS", is being submitted by 1.**Ms.P.Rahul (17K81A04N9), 2.Mr.K. Jagadeeshwar (17K81A04L7), 3.Mr. Anil Kumar (17K81A04J2)** in partial fulfillment of the requirement for the award of the degree of **BACHELOR OFTECHNOLOGY IN ELECTRONICS AND COMMUNICATION ENGINEERING** is recorded of bonafide work carried out by them. The result embodied in this report have been verified and found satisfactory.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "AN EXPERIMENTAL COMPARISON OF DIFFERENT OBJECT TRACKING ALGORITHMS" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

K. Jagadeeshwar (17K81A04L7)

A. Anil Kumar (17K81A04J2)

P. Rahul (17K81A04N9)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.SANTOSH KUMAR PATRA, our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B.HARI KRISHNA, Head &Professor,** Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr. A.ANAND, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our project guide **Mr. M.Thirupathi, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and cooperation that is difficult to express in words.

K. Jagadeeshwar (17K81A04L7)

A. Anil Kumar (17K81A04J2)

P. Rahul (17K81A04N9)

ABSTRACT

- This paper reviews and evaluates several state of the art object tracking algorithms. It compares the various techniques on different parameters. These algorithms are used to recognize, detect and track objects under the influence of different problems like occluded object, background clutter, illumination variations, and deformed objects or in shadowed regions.

- The target object is simultaneously tracked and learned which will help make the algorithm robust against failures. It works by working across every pixel of a given new frame but only surrounds a certain area of the previous location. Then the score is recorded of this classification algorithm for each comparison

- We will be discussing all the overall results of the different algorithms employing tables and plots. The overall performance can be a combined output of the graphs measuring precision and success. The future scope of this research includes a comprehensive examination of the application of these algorithms, along with the calculation of their efficiencies and the use of different techniques.

CHAPTER-1
INTRODUCTION

OBJECT tracking in video streams and object detection and classification in still images, as well as videos, is an active and prominent research area in the field of computer vision. It has a plethora of applications in the real world which include surveillance, traffic control and analysis, face detection, medical image processing and many more

[1]. While many advances and breakthroughs in this field over recent years have leaded to the development of a huge set of unique algorithms it still remains to be a very challenging problem. Due to the enormous set of environmental factors and other variables, it is next to impossible to develop a universal tracking algorithm. Also, the selection of the most suited algorithm doesn't depend only on the concept of the algorithm but also on its implementation. Therefore, we compare some of the readily available algorithms on several challenging video sequences with different evaluation criteria using the Open CV library

[2]. The algorithms compared are easily found in the OpenCV library of python. It is a widely used library, with over 3000 algorithms embedded in it with all the needful structures and tools for object tracking algorithms. On one hand, detection failures are inevitable, which include the miss detection where a target is misclassified as the background, the false detection where a background region is incorrectly recognized as a target, and the occlusion where an object is partially or fully invisible because of the limited camera view. Therefore, there exists misalignment between trajectories and detections during the data association where not every trajectory or detection can find its correspondence.

This paper will help in observing the real-world implementations of the many algorithms found in this broadly used library. This evaluation and comparison discussed in this paper will not only be useful in selecting an appropriate method for specific applications but also be beneficial for researching and developing new tracking algorithms. The remaining paper proceeds as follows: Section II gives a brief explanation of the different algorithms used. Followed by Section III which presents the various evaluation metrics against which the algorithms where compared. Section IV displays the results and the success and precision plots. Section V has the conclusion of the paper.

On the other hand, in real-world scenarios, targets may appear and disappear anytime and anywhere in the scene. We need to automatically tackle the initializations and terminations of trajectories to accommodate dynamic target changes. All these complex scenarios make the data association challenging. To deal with such complex scenarios, various algorithms have been proposed in the past decade. Detection failures are addressed by the continuous confidence output along with Particle Filter and the explicit occlusion reasoning.

Alternatively, they can be addressed in a global temporal window using the network flow , high-order energy minimization, and hierarchical data association. Furthermore, it is often assumed that new targets may enter or move out of the scene from some certain areas, e.g., the border of the camera view, in order to deal with trajectory initializations and terminations.

However, these data association models are either difficult to estimate (e.g., explicit occlusion reasoning) from a single camera view or subject to high computational burdens, restricting their adaptations to time-critical scenarios (e.g., surveillance). Additional reliance on the scene prior knowledge may also limit their adaptability to wider application areas. In this paper, we propose an online multi-target tracking method with unified handling of aforementioned complex scenarios.

1.2 Object Representation

In a tracking scenario, an object can be defined as anything that is of interest for further analysis. For instance, boats on the sea, fish inside an aquarium, vehicles on a road, planes in the air, people walking on a road, or bubbles in the water are a set of objects that may be important to track in a specific domain. Objects can be represented by their shapes and appearances. In this section, we will first describe the object shape representations commonly employed for tracking and then address the joint shape and appearance representations.

Points - The object is represented by a point, that is, the centroid (Figure 1(a)) or by a set of points (Figure 1(b)). In general, the point representation is suitable for tracking objects that occupy small regions in an image.

1.3 PRIMITIVE GEOMETRIC SHAPES

Object shape is represented by a rectangle, ellipse (Figure 1(c), (d), etc. Object motion for such representations is usually modeled by translation, affine, or projective (homography) transformation (see Section 5.2 for details). Though primitive geometric shapes are more suitable for representing simple rigid objects, they are also used for tracking non rigid objects.

1.3.1 Object silhouette and contour

Contour representation defines the boundary of an object (Figure 1(g), (h). The region inside the contour is called the silhouette of the object (see Figure 1(i)). Silhouette and contour representations are suitable for tracking complex non rigid shapes.

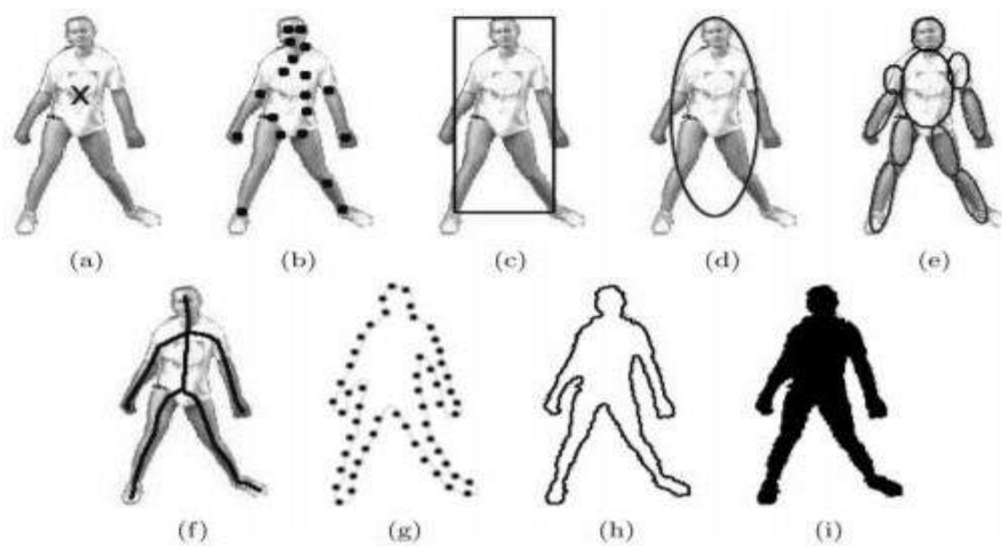

Fig. 1.1. Object representations. (a) Centroid, (b) multiple points, (c) rectangular patch, (d) elliptical patch, (e) part-based multiple patches, (f) object skeleton, (g) complete object contour, (h) control points on object contour, (i) object silhouette.

1.3.2 Articulated shape models

Articulated objects are composed of body parts that are held together with joints. For example, the human body is an articulated object with torso, legs, hands, head, and feet connected by joints. The relationship between the parts is governed by kinematic motion models, for example, joint angle, etc. In order to represent an articulated object, one can model the constituent parts using cylinders or ellipses as shown in Figure 1(e).

1.3.2 Skeletal models

Object skeleton can be extracted by applying medial axis transform to the object silhouette. This model is commonly used as a shape representation for recognizing objects. Skeleton representation can be used to model both articulated and rigid objects (see Figure 1(f)).

There are a number of ways to represent the appearance features of objects. Note that shape representations can also be combined with the appearance representations for tracking. Some common appearance representations in the context of object tracking are:

1.3.3 Probability densities of object appearance

The probability density estimates of the object appearance can either be parametric, such as Gaussian and a mixture of Gaussians or nonparametric, such as Parzen windows and histograms. The probability densities of object appearance features (color, texture) can be computed from the image regions specified by the shape models (interior region of an ellipse or a contour).

1.3.4 Templates

Templates are formed using simple geometric shapes or silhouettes. An advantage of a template is that it carries both spatial and appearance information. Templates, however, only encode the object appearance generated from a single view. Thus, they are only suitable for tracking objects whose poses do not vary considerably during the course of tracking.

1.3.5 Active appearance models

Active appearance models are generated by simultaneously modeling the object shape and appearance. In general, the object shape is defined by a set of landmarks. Similar to the contour-based representation, the landmarks can reside on the object boundary or, alternatively, they can reside inside the object region. For each landmark, an appearance vector is stored which is in the form of color, texture, or gradient magnitude. Active appearance models require a training phase where both the shape and its associated appearance is learned from a set of samples using, for instance, the principal component analysis.

1.3.5 Multiview appearance models

These models encode different views of an object. One approach to represent the different object views is to generate a subspace from the given views. Subspace approaches, for example, Principal Component Analysis (PCA) and Independent Component Analysis (ICA), have been used for both shape and appearance representation.

Another approach to learn the different views of an object is by training a set of classifiers, for example, the support vector machines or Bayesian networks. One limitation of multiview appearance models is that the appearances in all views are required ahead of time.

In general, there is a strong relationship between the object representations and the tracking algorithms. Object representations are usually chosen according to the application domain. For tracking objects, which appear very small in an image, point representation is usually appropriate. For instance, use the point representation to track the seeds in a moving dish sequence. Similarly, Shafique and Shah [2003] use the point representation to track distant birds. For the objects whose shapes can be approximated by rectangles or ellipses, primitive geometric shape representations are more appropriate use an elliptical shape representation and employ a color histogram computed from the elliptical region for modeling the appearance. In 1998, Black and Jepson used eigenvectors to represent the appearance. The eigenvectors were generated from rectangular object templates. For tracking objects with complex shapes, for example, humans, a contour or a silhouette based representation is appropriate use silhouettes for object tracking in a surveillance application.

1.4 FEATURE SELECTION FOR TRACKING

Selecting the right features plays a critical role in tracking. In general, the most desirable property of a visual feature is its uniqueness so that the objects can be easily distinguished in the feature space. Feature selection is closely related to the object representation. For example, color is used as a feature for histogram-based appearance representations, while for contour-based representation, object edges are usually used as features. In general, many tracking algorithms use a combination of these features. The details of common visual features are as follows.

—Color. The apparent color of an object is influenced primarily by two physical factors,

1) The spectral power distribution of the illuminant and

2) The surface reflectance properties of the object. In image processing, the RGB (red, green, blue) color space is usually used to represent color. However, the RGB space is not a perceptually uniform color space, that is, the differences between the colors in the RGB space do not correspond to the color differences perceived by humans. Additionally, the RGB dimensions

are highly correlated. In contrast, L∗u∗v∗ and L∗a∗b∗ are perceptually uniform color spaces, while HSV (Hue, Saturation and Value) is an approximately uniform color space. However, these color spaces are sensitive to noise. In summary, there is no last word on which color space is more efficient, therefore a variety of color spaces have been used in tracking.

—Edges. Object boundaries usually generate strong changes in image intensities. Edge detection is used to identify these changes. An important property of edges is that they are less sensitive to illumination changes compared to color features. Algorithms that track the boundary of the objects usually use edges as the representative feature. Because of its simplicity and accuracy, the most popular edge detection approach is the Canny Edge detector. An evaluation of the edge detection algorithms is provided by Bowyer et al.

—Optical Flow. Optical flow is a dense field of displacement vectors which defines the translation of each pixel in a region. It is computed using the brightness constraint, which assumes brightness constancy of corresponding pixels in consecutive frames. Optical flow is commonly used as a feature in motion-based segmentation and tracking applications. Popular techniques for computing dense optical flow include methods by Horn and Schunck, Lucas and Kanade, Black and Anandan, and Szeliski and Couglan. For the performance evaluation of the optical flow methods, we refer the interested reader to the survey by Barron et al.

—Texture. Texture is a measure of the intensity variation of a surface which quantifies properties such as smoothness and regularity. Compared to color, texture requires a processing step to generate the descriptors. There are various texture descriptors: Gray-Level Cooccurrence Matrices (GLCM's) (a 2D histogram which shows the cooccurrences of intensities in a specified direction and distance), Law's texture measures (twenty-five 2D filters generated from five 1D filters corresponding to level, edge, spot, wave, and ripple), wavelets (orthogonal bank of filters), and steerable pyramids. Similar to edge features, the texture features are less sensitive to illumination changes compared to color.

CHAPTER-2

MATLAB

2.1 What is MATLAB?

MATLAB (matrix laboratory) is a multi-paradigm numerical computing environment and fourth- generation programming language. A proprietary programming language developed by MathWorks, MATLAB allows matrix manipulations, plotting of functions and data, implementation of algorithms, creation of user interfaces, and interfacing with programs written in other languages, including C, C++, Java, Fortran and Python. Although MATLAB is intended primarily for numerical computing, an optional toolbox uses the MuPAD symbolic engine, allowing access to symbolic computing capabilities. An additional package, Simulink, adds graphical multi-domain simulation and model-based design for dynamic and embedded systems.

The name MATLAB stands for matrix laboratory. It was invented in the late 1970s by Cleve Moler, then chairman of the computer science department at the University of New Mexico. MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development and analysis. MATLAB was first adopted by control design engineers, little's specialty, but quickly spread to many other domains. It is now also used in education, in particular the teaching of linear algebra and numerical analysis, and is popular amongst scientists involved with image processing.

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation.

Typical uses include:

- Math and computation
- Algorithm development
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including Graphical User Interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar noninteractive language such as C or Fortran.

2.2 Introduction of MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building.

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrixlaboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most users of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M-files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

2.3 The MATLAB System

The MATLAB system consists of five main parts:

a. Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and Command Window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

b. The MATLAB Mathematical Function:

This is a vast collection of computational algorithms ranging from elementary functions like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigen values, Bessel functions, and fast Fourier transforms.

c. The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create complete large and complex application programs.

d. Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

e. The MATLAB Application Program Interface (API):

This is a library that allows you to write C and Fortran programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files

2.4 MATLAB Working Environment

Matlab Desktop is the main Mat lab application window. The desktop contains five sub windows, the command window, the workspace browser, the current directory window, the command history window, and one or more figure windows, which are shown only when the user displays a graphic.

The command window is where the user types MATLAB commands and expressions at the prompt (>>) and where the output of those commands is displayed. MATLAB defines the workspace as the set of variables that the user creates in a work session. The workspace browser shows these variables and some information about them. Double clicking on a variable in the workspace browser launches the Array Editor, which can be used to obtain information and income instances edit certain properties of the variable.

The current Directory tab above the workspace tab shows the contents of the current directory, whose path is shown in the current directory window. For example, in the windows operating system the path might be as follows: C:\MATLAB\Work, indicating that directory “work” is a subdirectory of the main directory “MATLAB”; WHICH IS INSTALLED IN DRIVE C. clicking on the arrow in the current directory window shows a list of recently used paths. Clicking on the button to the right of the window allows the user to change the current directory.

MATLAB uses a search path to find M-files and other MATLAB related files, which are organize in directories in the computer file system. Any file run in MATLAB must reside in the current directory or in a directory that is on search path. By default, the files supplied with MATLAB and math works toolboxes are included in the search path. The easiest way to see which directories are on the search path. The easiest way to see which directories are soon the search path, or to add or modify a search path, is to select set path from the File menu the desktop, and then use the set path dialog box. It is good practice to add any commonly used directories to the search path to avoid repeatedly having the change the current directory.

The Command History Window contains a record of the commands a user has entered in the command window, including both current and previous MATLAB sessions. Previously entered MATLAB commands can be selected and re-executed from the command history window by right clicking on a command or sequence of commands. This action launches a menu from which to select various options in addition to executing the commands. This is useful to select various options in addition to executing the commands. This is a useful feature when experimenting with various commands in a work session.

2.5 Using the MATLAB Editor to create M-Files:

The MATLAB editor is both a text editor specialized for creating M-files and a graphical MATLAB debugger. The editor can appear in a window by itself, or it can be a sub window in the desktop. M-files are denoted by the extension .m, as in pixelup.m. The MATLAB editor window has numerous pull-down menus for tasks such as saving, viewing, and debugging files. Because it performs some simple checks and also uses color to differentiate between various elements of code, this text editor is recommended as the tool of choice for writing and editing M-functions. To open the editor , type edit at the prompt opens the M-file filename.m in an editor window, ready for editing. As noted earlier, the file must be in the current directory, or in a directory in the search path.

2.5.1 Getting Help

The principal way to get help online is to use the MATLAB help browser, opened as a separate window either by clicking on the question mark symbol (?) on the desktop toolbar, or by typing help browser at the prompt in the command window. The help Browser is a web browser integrated into the MATLAB desktop that displays a Hypertext Markup Language(HTML) documents. The Help Browser consists of two panes, the help navigator pane, used to find information, and the display pane, used to view the information. Self-explanatory tabs other than navigator pane are used to perform a search.

2.6 History of MATLAB

Cleve Moler, the chairman of the computer science department at the University of New Mexico, started developing MATLAB in the late 1970s.He designed it to give his students access to LINPACK and EISPACK without them having to learn Fortran. It soon spread to other universities and found a strong audience within the applied mathematics community.

Jack Little, an engineer, was exposed to it during a visit Moler made to Stanford University in 1983. Recognizing its commercial potential, he joined with Moler and Steve Bangert. They rewrote MATLAB in C and founded MathWorks in 1984 to continue its development. These rewritten libraries were known as JACKPAC. In 2000, MATLAB was rewritten to use a newer set of libraries for matrix manipulation, LAPACK

MATLAB was first adopted by researchers and practitioners in control engineering, Little's specialty, but quickly spread to many other domains. It is now also used in education, in particular the teaching of linear algebra, numerical analysis, and is popular amongst scientists involved in image processing. With 2004 marking the 20th anniversary of The MathWorks, it’s a good time to look back at the origins of MATLAB.MATLAB is now a full-featured technical computing environment, but it started as a simple “Matrix Laboratory.”

Three men, J. H. Wilkinson, George Forsythe, and John Todd, played important roles in the origins of MATLAB. Our account begins more than 50 years ago.

Wilkinson was a British mathematician who spent his entire career at the National Physical Laboratory (NPL) in Teddington, outside London.Working on a simplified version of a sophisticated design by Alan Turing, Wilkinson and colleagues at NPL built the Pilot Automatic Computing Engine (ACE), one of Britain's first stored-program digital computers. The Pilot ACE ran its first program in May 1950. Wilkinson did matrix computations on the machine and went on to become the world's leading authority on numerical linear algebra.

2.7 Strengths of MATLAB ?

- MATLAB is relatively easy to learn
- MATLAB code is optimized to be relatively quick when performing matrix operations
- MATLAB may behave like a calculator or as a programming language
- MATLAB is interpreted, errors are easier to fix

Although primarily procedural (for example: *C*), MATLAB does have some object-oriented elements(for example: *C++*)

2.8 Key Features

High-level language for numerical computation, visualization, and application development

- Interactive environment for iterative exploration, design, and problem solving
- Mathematical functions for linear algebra, statistics, Fourier analysis, filtering, optimization, numerical integration, and solving ordinary differential equations
- Built-in graphics for visualizing data and tools for creating custom plots
- Development tools for improving code quality and maintainability and maximizing performance
- Tools for building applications with custom graphical interfaces

- Functions for integrating MATLAB based algorithms with external applications and languages such as C, Java, .NET, and Microsoft Excel

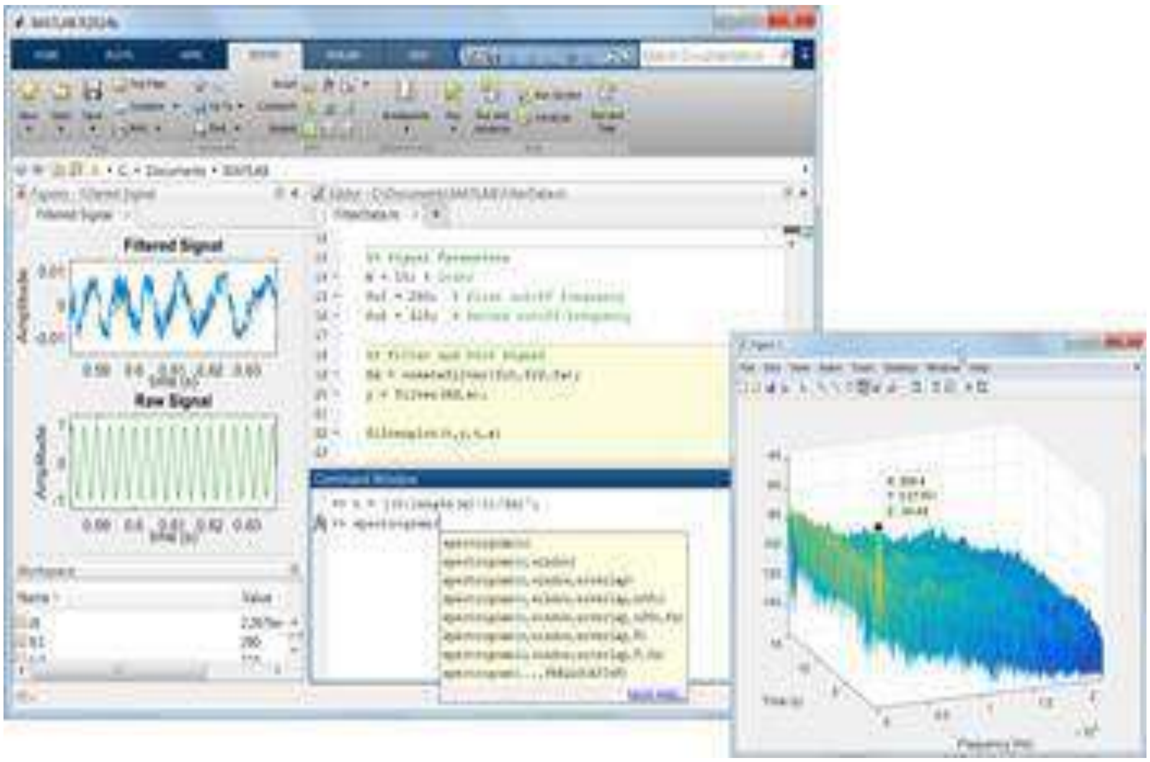

Figure: 2.1

Analyzing and visualizing data using the MATLAB desktop. The MATLAB environment also lets you write programs and develop algorithms and applications.

2.9 Numeric Computation

MATLAB provides a range of numerical computation methods for analyzing data, developing algorithms, and creating models. The MATLAB language includes mathematical functions that support common engineering andscience operations. Core math functions use processor-optimized libraries to provide fast execution of vector and matrix calculations.

Available methods include:

- Interpolation and regression

- Differentiation and integration
- Linear systems of equations
- Fourier analysis
- Eigenvalues and singular values
- Ordinary differential equations (ODEs)
- Sparse matrices

MATLAB add-on products provide functions in specialized areas such as statistics, optimization, signal analysis, and machine learning.

CHAPTER-3

INTRODUCTION TO IMAGE PROCESSING

3.1 What is an image?

An image is an array, or a matrix, of square pixels (picture elements) arranged in columns and rows.

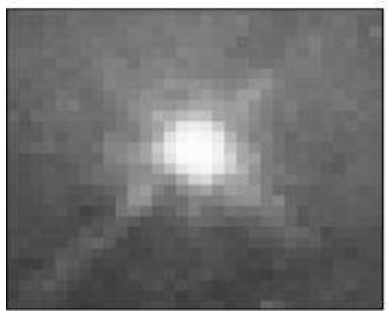

Figure 3.1: An image — an array or a matrix of pixels arranged in columns and rows.

In a (8-bit) greyscale image each picture element has an assigned intensity that ranges from 0 to 255. A grey scale image is what people normally call a black and white image, but the name emphasizes that such an image will also include many shades of grey.

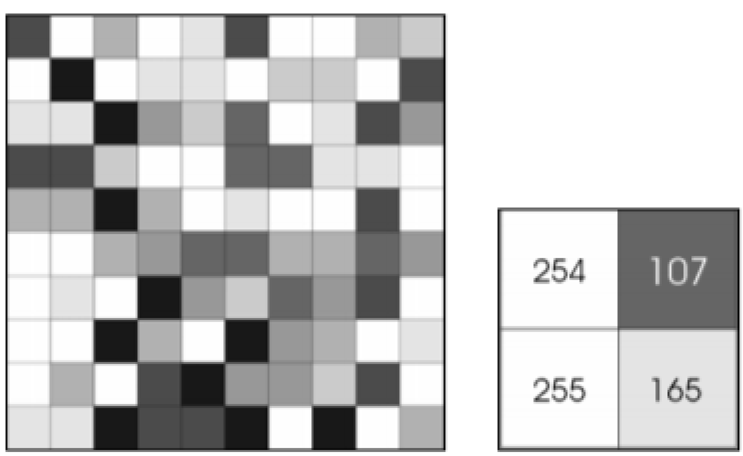

Figure 3.2: Each pixel has a value from 0 (black) to 255 (white). The possible range of the pixel values depend on the colour depth of the image, here 8 bit = 256 tones or greyscales.

A normal greyscale image has 8 bitcolour depth = 256 greyscales. A “true colour” image has 24 bitcolour depth = 8 x 8 x 8 bits = 256 x 256 x 256 colours = ~16 million colours.

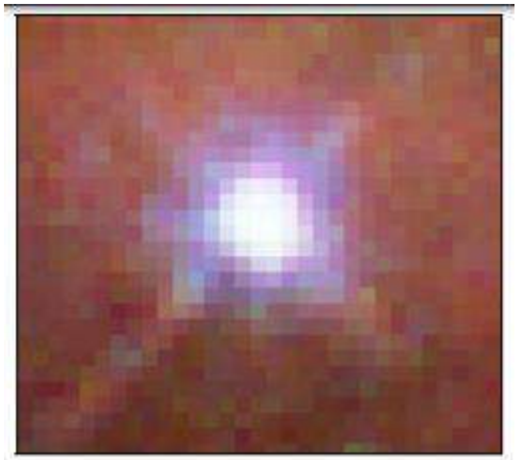

Figure 3.3: A true-colour image assembled from three greyscale images coloured red, green and blue. Such an image may contain up to 16 million different colours.

Some greyscale images have more greyscales, for instance 16 bit = 65536 greyscales. In principle three greyscale images can be combined to form an image with 281,474,976,710,656 greyscales.

There are two general groups of ‘images’: vector graphics (or line art) and bitmaps (pixel-based or ‘images’). Some of the most common file formats are:

GIF — an 8-bit (256 colour), non-destructively compressed bitmap format. Mostly used for web. Has several sub-standards one of which is the animated GIF.

JPEG — a very efficient (i.e. much information per byte) destructively compressed 24 bit (16 million colours) bitmap format. Widely used, especially for web and Internet (bandwidth-limited).

TIFF — the standard 24 bit publication bitmap format. Compresses nondestructively with, for instance, Lempel-Ziv-Welch (LZW) compression.

PS — Postscript, a standard vector format. Has numerous sub-standards and can be difficult to transport across platforms and operating systems.

PSD – a dedicated Photoshop format that keeps all the information in an image including all the layers.

Colours

For science communication, the two main colour spaces are RGB and CMYK.

RGB

The RGB colour model relates very closely to the way we perceive colour with the r, g and b receptors in our retinas. RGB uses additive colour mixing and is the basic colour model used in television or any other medium that projects colour with light. It is the basic colour model used in computers and for web graphics, but it cannot be used for print production. The secondary colours of RGB – cyan, magenta, and yellow – are formed by mixing two of the primary colours (red, green or blue) and excluding the third colour. Red and green combine to make yellow, green and blue to make cyan, and blue and red form magenta. The combination of red, green, and blue in full intensity makes white.

In Photoshop using the "screen" mode for the different layers in an image will make the intensities mix together according to the additive colour mixing model. This is analogous to stacking slide images on top of each other and shining light through them.

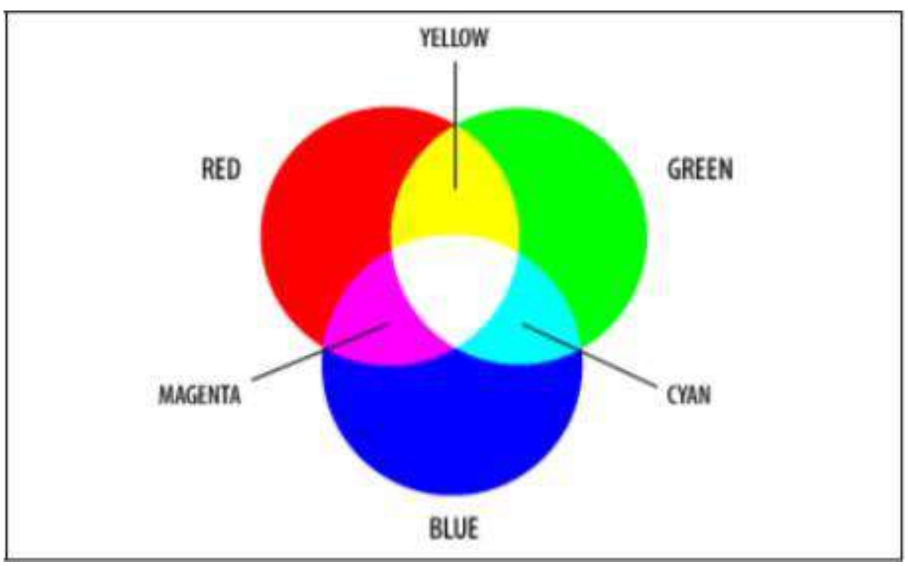

Figure 3.4: The additive model of RGB. Red, green, and blue are the primary stimuli for human colour perception and are the primary additive colours. Courtesy of adobe.com.

CMYK

The 4-colour CMYK model used in printing lays down overlapping layers of varying percentages of transparent cyan (C), magenta (M) and yellow (Y) inks. In addition a layer of black (K) ink can be added. The CMYK model uses the subtractive colour model.

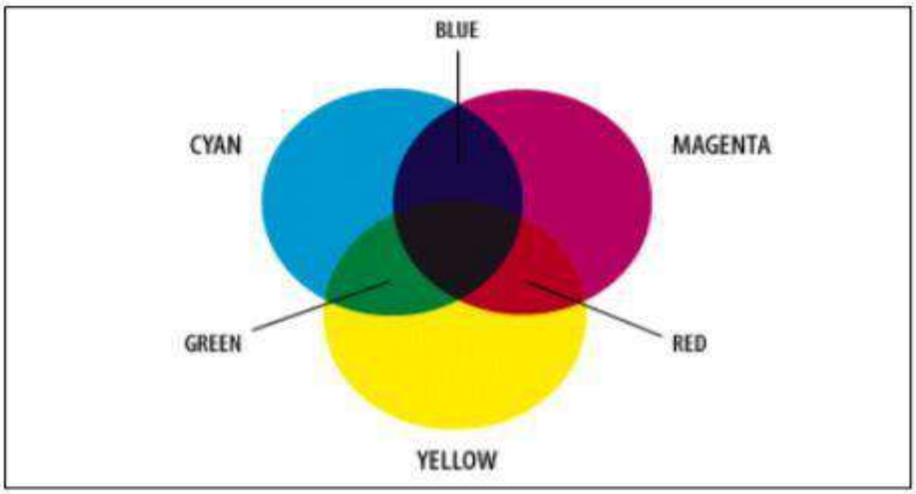

Figure 3.5: The colours created by the subtractive model of CMYK don't look exactly like the colours created in the additive model of RGB Most importantly, CMYK cannot reproduce the brightness of RGB colours. In addition, the CMYK gamut is much smaller than the RGB gamut. Courtesy of adobe.com.

3.2 Gamut

The range, or gamut, of human colour perception is quite large. The two colour spaces discussed here span only a fraction of the colours we can see. Furthermore the two spaces do not have the same gamut, meaning that converting from one colour space to the other may cause problems for colours in the outer regions of the gamuts.

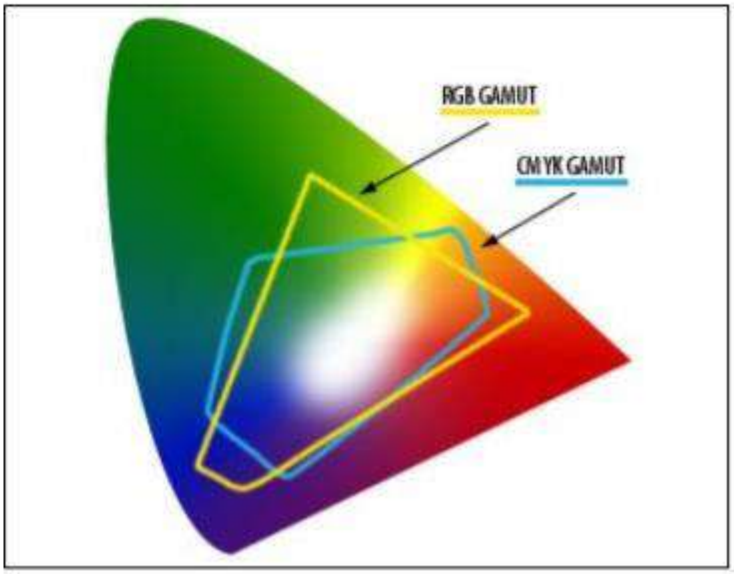

Figure 3.6: This illustration clearly shows the different gamuts of the RGB and CMYK colour spaces. The background is the CIE Chromaticity Diagram (representing the whole gamut of human colour perception). Courtesy adobe.com.

3.3 Astronomical images

Images of astronomical objects are usually taken with electronic detectors such as a CCD (Charge Coupled Device). Similar detectors are found in normal digital cameras. Telescope images are nearly always greyscale, but nevertheless contain some colour information. An astronomical image may be taken through a colour filter. Different detectors and telescopes also usually have different sensitivities to different colours (wavelengths).

3.4 Filters

A telescope such as the NASA/ESA Hubble Space Telescope typically has a fixed number of well-defined filters. A filter list for Hubble’s WFPC2 (Wide Field and Planetary Camera 2) camera is seen below.

Name	Type	Wheel	Slot	Notes	In WF/PC-1?	$\bar{\lambda}$(Å)	$\Delta\bar{\lambda}$(Å)	Peak T (%)	Peak λ (Å)

Filter list for Hubble's WFPC2 camera (Wide Field and Planetary Camera 2). Filter names are to the left (names include approximate wavelength in nm) in column 1. Column 5 contains the physical property of the radiation the filter lets through. Column 7 is the central wavelength. The N's and W's are short for Narrow and Wide.

Filters can either be broad-band (Wide) or narrow-band (Narrow). A broad-band filter lets a wide range of colours through, for instance the entire green or red area of the spectrum. A narrow-band filter typically only lets a small wavelength span through, thus effectively restricting the transmitted radiation to that coming from a given atomic transition, allowing astronomers to investigate individual atomic processes in the object.

A filename such as 502nmos.fits indicates that the filter used has a peak at 502 nm. In the table below, you can see that this filter is a narrow bandwidth filter, i.e. it only lets radiation with wavelengths within a few nm of 502 nm through. Below is an example of an image composed from narrow-band exposures. This results in very sharply defined wisps of nebulosity since each exposure separates light from only some very specific physical processes and locations in the nebula.

Figure 3.7: Example of an image constructed from narrow-band exposures. Since the narrowband exposures probe individual atomic transitions the result is an image that has very ‘sharp’ features.

Galaxies are often studied through broad-band filters as they allow more light to get through. Also the processes in a galaxy are more ‘mixed’ or complicated, result from the outputs of billions of stars and so narrow-band filters give less ‘specific’ information about the processes there.

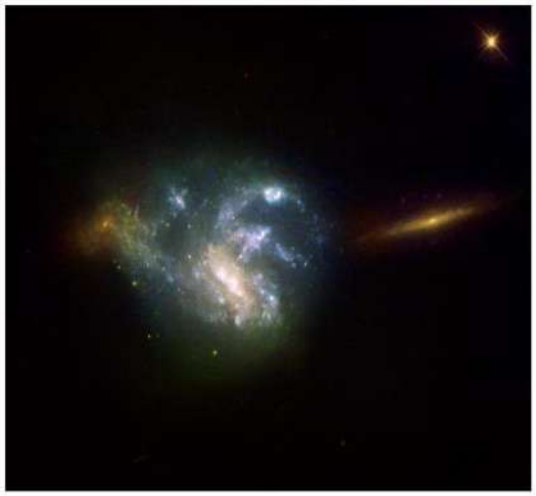

Figure 3.8: A broad-band image of the “Hyperactive galaxy NGC 7673”.

A visual example of the different filters available onboard Hubble is seen in the following figure.

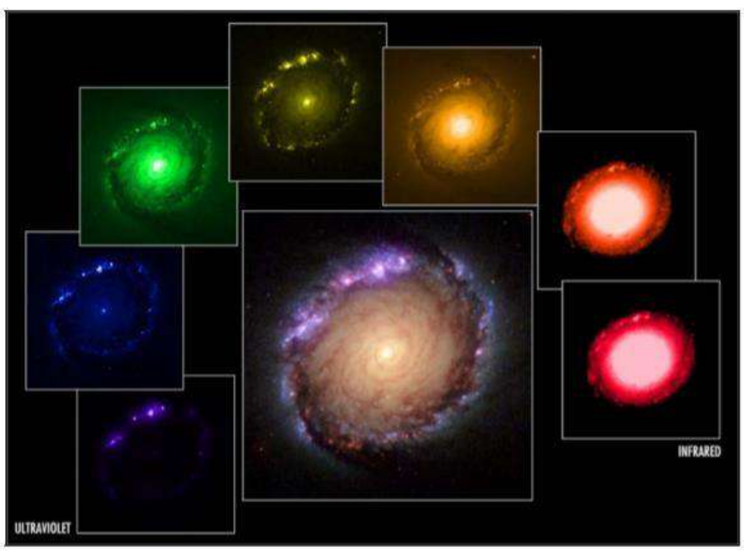

Figure 3.9: An example of an image constructed from 7 broad-band filters all the way from ultraviolet (left) to infrared (right).

A figure illustrating the process of stacking together different colour exposures is seen below.

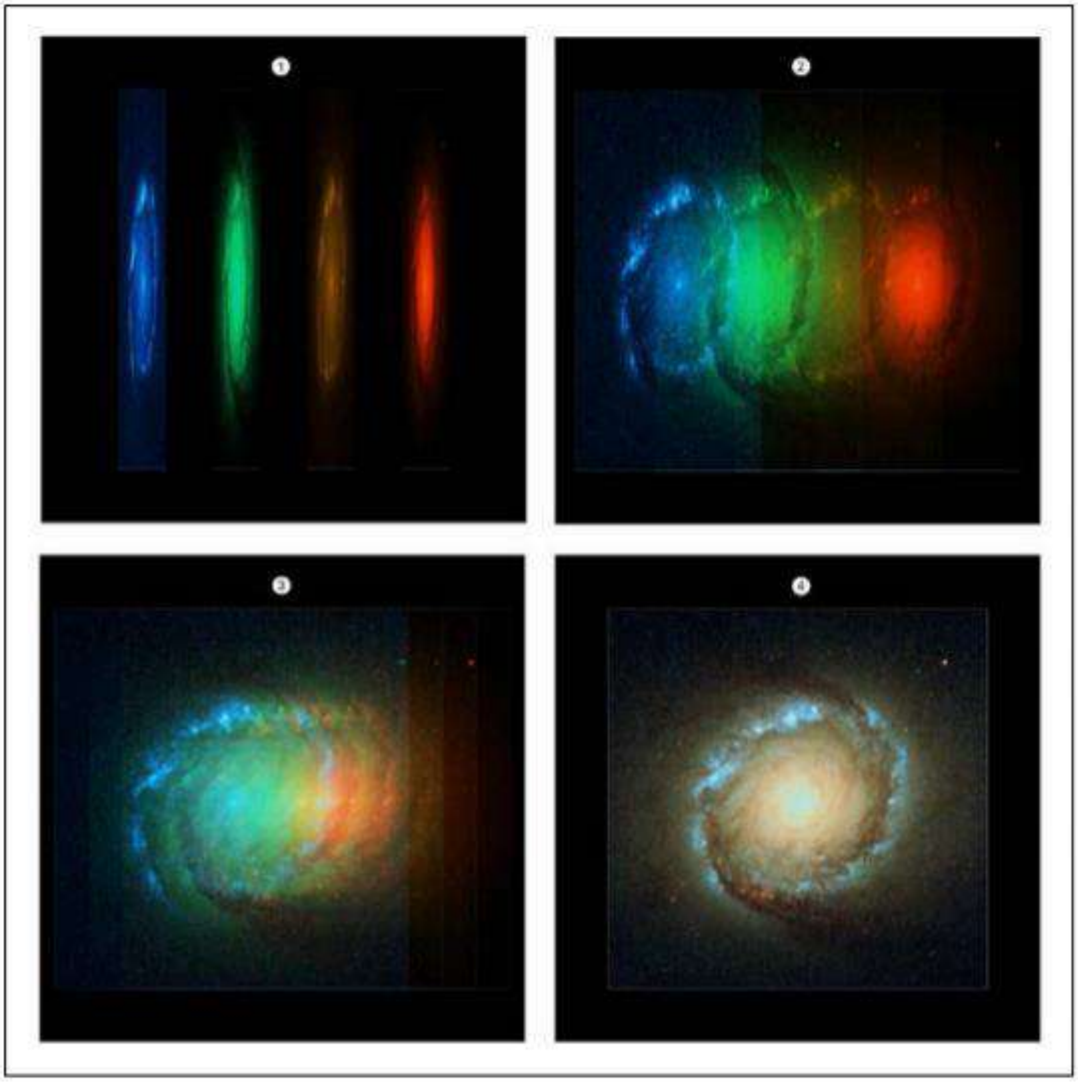

Figure 3.10: An example of how a colour image is constructed from four broad-band filters (seen from the side in 1.): blue, green yellow and red. When the images are overlaid (2. and 3.) the resulting image (4.) is a colour composite.

3.5 Assigning colours to different filter exposures

The astronomical images we see on the web and in the media are usually ‘refined’ or ‘processed’ as compared to the raw data that the astronomers work on with their computers. In ‘pretty pictures’ all artefacts coming from the telescope or the detectors are for instance removed as they do not say anything about the objects themselves. It is very rare that images are taken with the sole intention of producing a ‘pretty’ colour picture. Most ‘pretty pictures’ are constructed from data that was acquired to study some physical process, and the astronomer herself probably never bothered to assemble the greyscale images to a colour image.

3.5 Natural colour images

It is possible to create colour images that are close to “true-colour” if three wide band exposures exist, and if the filters are close to the r, g and b receptors in our eyes. Images that approximate what a fictitious space traveller would see if he or she actually travelled to the object are called “natural colour” images. To make a natural colour image the order of the colours assigned to the different exposures should be in “chromatic order”, i.e. the lowest wavelength should be given a blue hue, the middle wavelength a green hue and the highest wavelength should be red.

3.6 Representative colour images

If one or more of the images in a data set is taken through a filter that allows radiation that lies outside the human vision span to pass – i.e. it records radiation invisible to us - it is of course not possible to make a natural colour image. But it is still possible to make a colour image that shows important information about the object. This type of image is called a representative colour image. Normally one would assign colours to these exposures in chromatic order with blue assigned to the shortest wavelength, and red to the longest. In this way it is possible to make colour images from electromagnetic radiation far from the human vision area, for example x-rays. Most often it is either infrared or ultraviolet radiation that is used.

3.7 Enhanced colour images

Sometimes there are reasons to not use a chromatic order for an image. Often these reasons are purely aesthetic, as is seen in the example below. This type of colour image is called an enhanced colour image.

Figure 3.11: An example of an enhanced colour image (not in chromatic order): Sometimes it is necessary to break the 'rules' for image processing. Here the Hydrogen-alpha filter is coloured blue instead of the red colour it is in nature. This is an example of a so-called false-colour image, where the blue was chosen for aesthetic reasons.

3.8 You are the judge

When processing raw science images one of the biggest problems is that, to a large degree, you are 'creating' the image and this means a colossal freedom within a huge parameter space. There are literally thousands of sliders, numbers, dials, curves etc. to twist and turn. Speaking of right and wrong, there really are no wrong or right images. There are some fundamental scientific principles that should normally be observed, but the rest is a matter of aesthetics — taste. Chromatic ordering of the exposures is one of the important scientific principles.

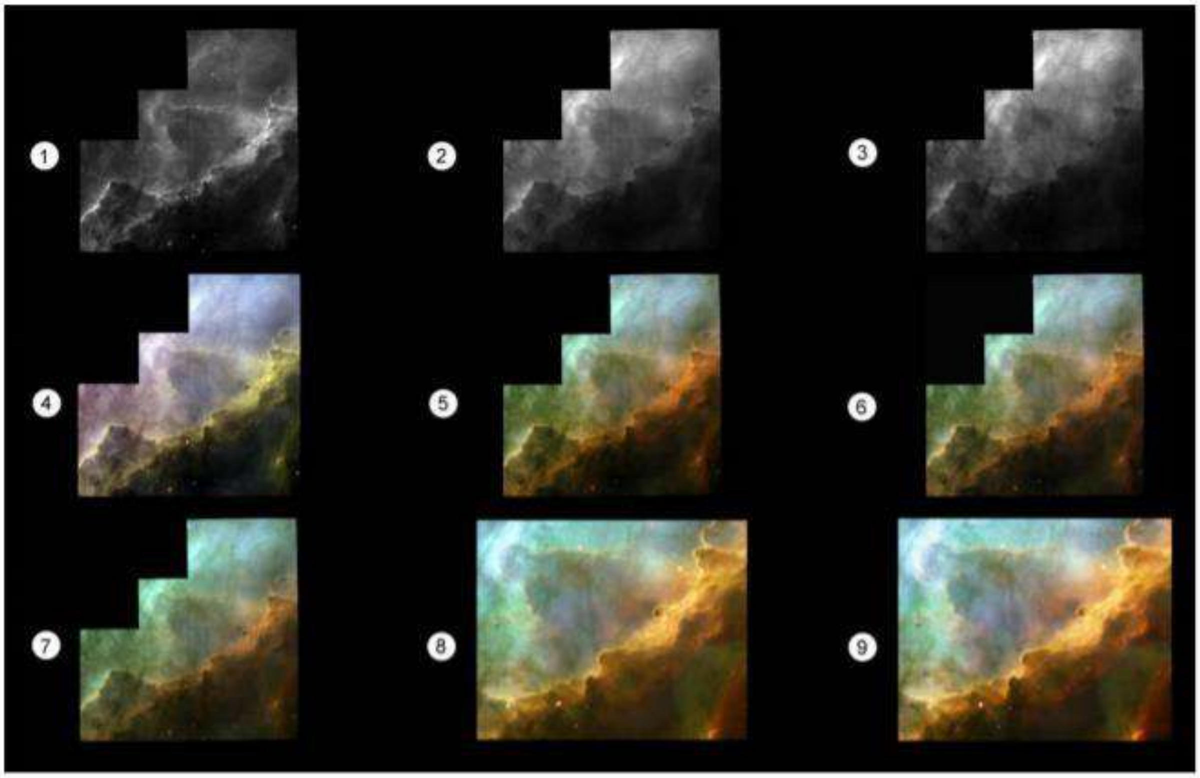

Figure 3.12: Sequences in the production of a Hubble Space Telescope image of Messier 17. First the individual exposure (taken through three different filters): 1. 673n (Sulphur) shown in red in the final image), 2. 656n (hydrogen, green), 3. 502n (oxygen, blue), 4. First colour composite attempt, 5. Improving, 6. Improving, 7. Improving, 8. Adjusting the composition and then 9. Final colour and contrast adjustments for the final image.

3.9 Stretch function

One particularly important aspect of image processing is the choice of the best stretch function. You choose which "stretch function" or representation to use in the Fits Liberator window. A logarithmic representation of the pixel values tends to suppress the bright parts of the image, i.e. the stars, and to enhance the fainter part, e.g. nebulosity. This can be desirable if the 'faint stuff' needs 'a boost', but a logarithmic stretch function can also reduce the contrast in an image, producing a lower dynamic range as is seen in the example below.

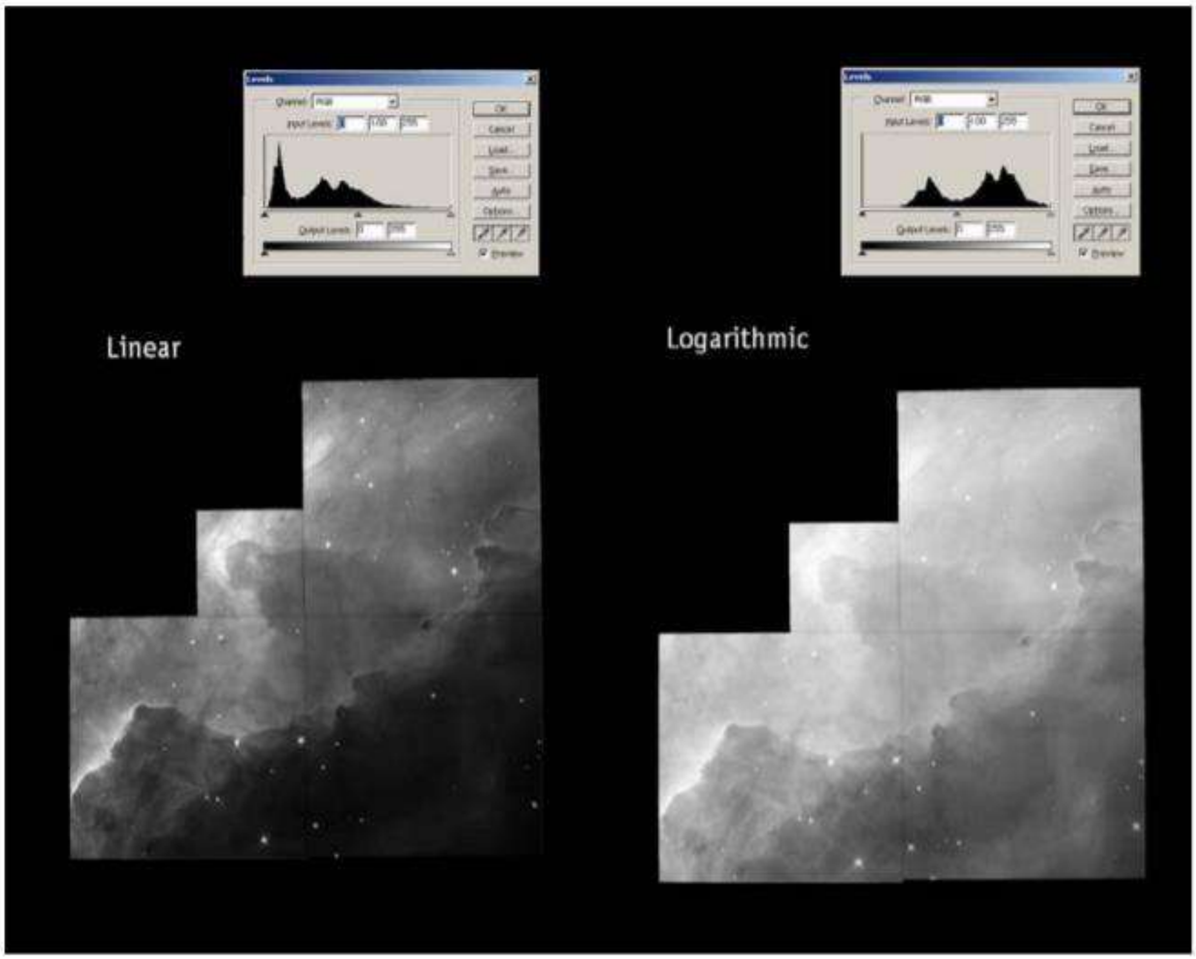

Figure 3.13: The difference between two stretch functions. To the left is a linear representation of the pixels and to the right a logarithmic. It is seen that the log lowers the contrast too much and therefore is not the aesthetically desirable function to choose here.

Various techniques have been developed in Image Processing during the last four to five decades. Most of the techniques are developed for enhancing images obtained from unmanned spacecrafts, space probes and military reconnaissance flights. Image Processing systems are becoming popular due to easy availability of powerful personnel computers, large size memory devices, graphics softwares etc.

Image Processing is used in various applications such as:

- Remote Sensing
- Medical Imaging

- Non-destructive Evaluation
- Forensic Studies
- Textiles
- Material Science.
- Military
- Film industry
- Document processing
- Graphic arts
- Printing Industry

The common steps in image processing are image scanning, storing, enhancing and interpretation. The schematic diagram of image scanner-digitizer diagram is shown in figure.

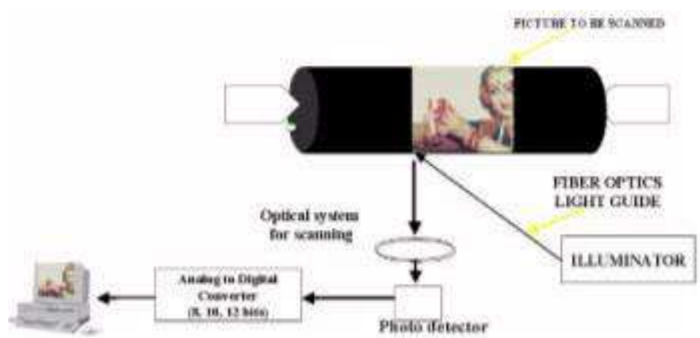

Figure 3.14

Methods of Image Processing

There are two methods available in Image Processing.

3.10 Analog Image Processing

Analog Image Processing refers to the alteration of image through electrical means. The most common example is the television image. The television signal is a voltage level which varies in amplitude to represent brightness through the image. By electrically varying the signal, the displayed image appearance is altered. The brightness and contrast controls on a TV set serve to adjust the amplitude and reference of the video signal, resulting in the brightening, darkening and alteration of the brightness range of the displayed image.

3.11 Digital Image Processing

In this case, digital computers are used to process the image. The image will be converted to digital form using a scanner – digitizer (as shown in Figure 1) and then process it. It is defined as the subjecting numerical representations of objects to a series of operations in order to obtain a desired result. It starts with one image and produces a modified version of the same. It is therefore a process that takes an image into another. The term digital image processing generally refers to processing of a two-dimensional picture by a digital computer. In a broader context, it implies digital processing of any two-dimensional data. A digital image is an array of real numbers represented by a finite number of bits. The principle advantage of Digital Image Processing methods is its versatility, repeatability and the preservation of original data precision.

The various Image Processing techniques are:

- Image representation
- Image preprocessing
- Image enhancement
- Image restoration
- Image analysis
- Image reconstruction
- Image data compression

3.12 Image Representation

An image defined in the "real world" is considered to be a function of two real variables, for example, f(x,y) with f as the amplitude (e.g. brightness) of the image at the real coordinate position (x,y). The effect of digitization is shown in Figure.

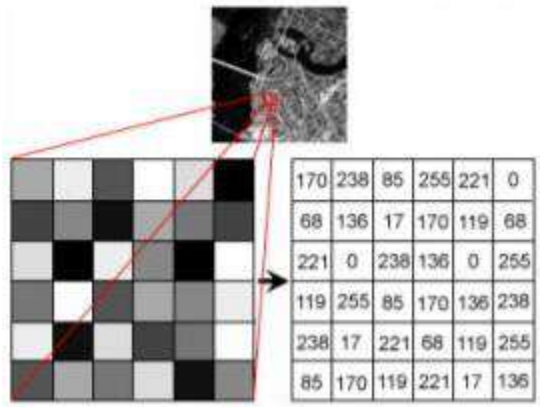

Figure: 3.15

The 2D continuous image f(x,y) is divided into N rows and M columns. The intersection of a row and a column is called as pixel. The value assigned to the integer coordinates [m,n] with {m=0,1, 2,...,M-1} and {n=0,1,2,...,N-1} is f[m,n]. In fact, in most cases f(x,y)--which we might consider to be the physical signal that impinges on the face of a sensor. Typically an image file such as BMP, JPEG, TIFF etc., has some header and picture information. A header usually includes details like format identifier (typically first information), resolution, number of bits/pixel, compression type, etc.

3.13 Image Preprocessing

3.13.1 Scaling

The theme of the technique of magnification is to have a closer view by magnifying or zooming the interested part in the imagery. By reduction, we can bring the unmanageable size of data to a manageable limit. For resampling an image Nearest Neighborhood, Linear, or cubic convolution techniques are used.

3.13.2 Magnification

This is usually done to improve the scale of display for visual interpretation or sometimes to match the scale of one image to another. To magnify an image by a factor of 2, each pixel of the original image is replaced by a block of 2x2 pixels, all with the same brightness value as the original pixel.

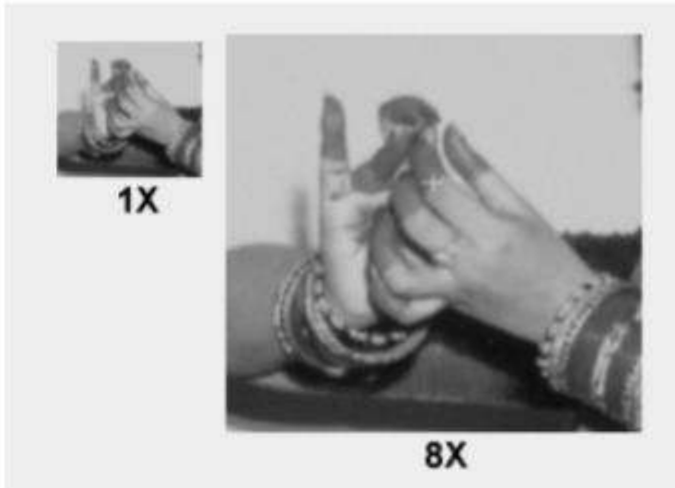

Figure 3.16 Figure Image Magnification

3.13.3 Reduction

To reduce a digital image to the original data, every mth row and mth column of the original imagery is selected and displayed. Another way of accomplishing the same is by taking the average in 'm x m' block and displaying this average after proper rounding of the resultant value.

Figure 3.17 Image Reduction Rotation

Rotation is used in image mosaic, image registration etc. One of the techniques of rotation is 3-pass shear rotation, where rotation matrix can be decomposed into three separable matrices.

3-pass shear rotation

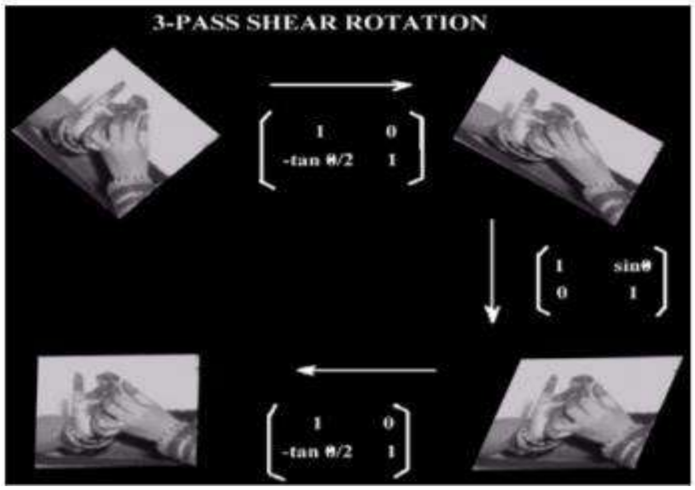

Figure 3.18 Pass Shear Rotation

3.14 Advantages

1. No scaling – no associated resampling degradations.

2. Shear can be implemented very efficiently.

3.15 Mosaic

Mosaic is a process of combining two or more images to form a single large image without radiometric imbalance. Mosaic is required to get the synoptic view of the entire area, otherwise capture as small images.

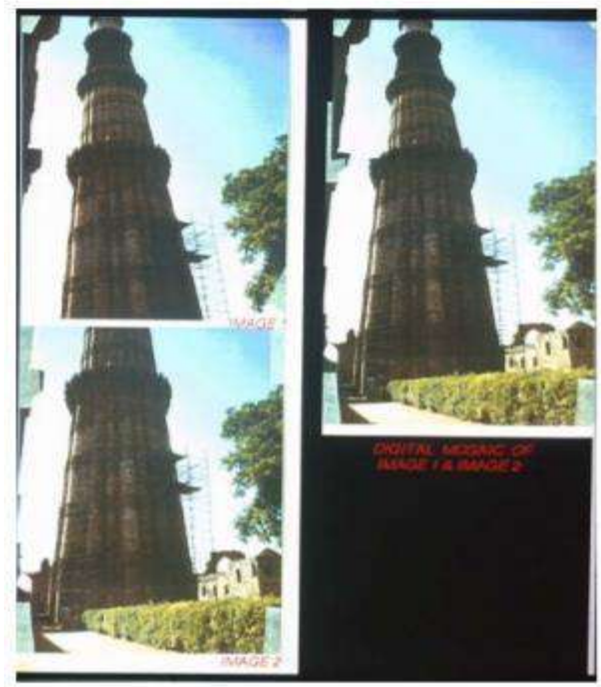

Figure 3.19 Image Mosaicking

3.16 Image Enhancement Techniques

Some times images obtained from satellites and conventional and digital cameras lack in contrast and brightness because of the limitations of imaging sub systems and illumination conditions while capturing image. Images may have different types of noise. In image enhancement, the goal is to accentuate certain image features for subsequent analysis or for image display. Examples include contrast and edge enhancement, pseudo-coloring, noise filtering, sharpening, and magnifying. Image enhancement is useful in feature extraction, image analysis and an image display. The enhancement process itself does not increase the inherent information content in the data. It simply emphasizes certain specified image characteristics. Enhancement algorithms are generally interactive and application dependent.

Some of the enhancement techniques are:

- Contrast Stretching
- Noise Filtering
- Histogram modification

3.17 Contrast Stretching:

Some images (eg. over water bodies, deserts, dense forests, snow, clouds and under hazy conditions over heterogeneous regions) are homogeneous i.e., they do not have much change in their levels. In terms of histogram representation, they are characterized as the occurrence of very narrow peaks. The homogeneity can also be due to the incorrect illumination of the scene.

Ultimately the images hence obtained are not easily interpretable due to poor human perceptibility. This is because there exists only a narrow range of gray-levels in the image having provision for wider range of gray-levels. The contrast stretching methods are designed exclusively for frequently encountered situations. Different stretching techniques have been developed to stretch the narrow range to the whole of the available dynamic range.

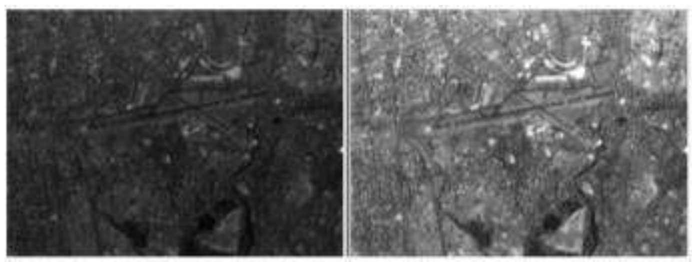

Figure contrast stretching

Noise filtering is used to filter the unnecessary Noise Filtering N information from an image. It is also used to remove various types of noises from the images. Mostly this feature is interactive. Various filters like low pass, high pass, mean, median etc., are available.

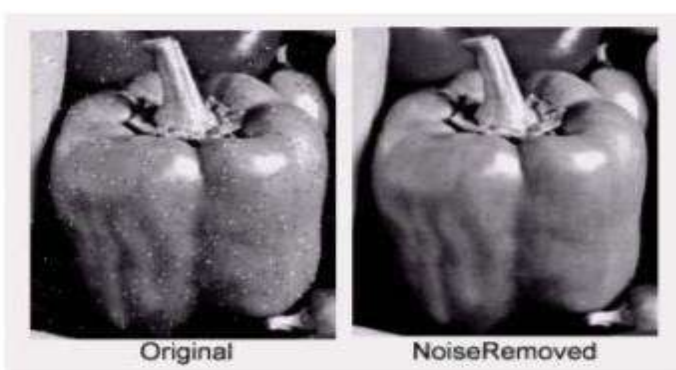

Figure 3.20 Noise Removal

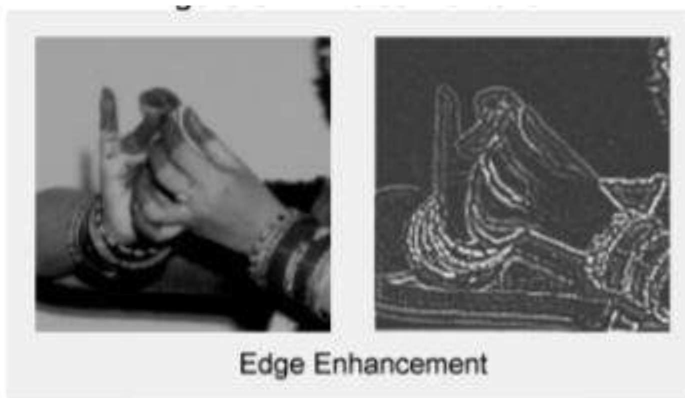

Figure 3.21: Edge Enhancemen

3.18 Histogram Modification

Histogram has a lot of importance in image enhancement. It reflects the characteristics of image. By modifying the histogram, image characteristics can be modified. One such example is Histogram Equalization. Histogram equalization is a nonlinear stretch that redistributes pixel values so that there is approximately the same number of pixels with each value within a range. The result approximates a flat histogram. Therefore, contrast is increased at the peaks and lessened at the tails.

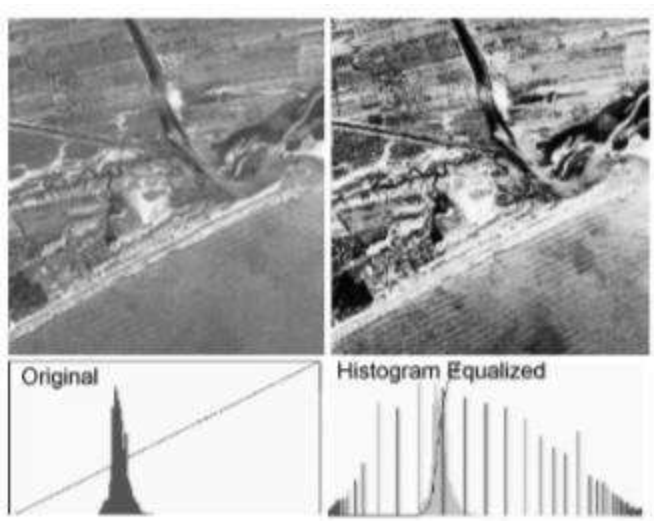

Figure 3.22 : Histogram equalized output

3.19 Image Analysis

Image analysis is concerned with making quantitative measurements from an image to produce a description. In the simplest form, this task could be reading a label on a grocery item, sorting different parts on an assembly line, or measuring the size and orientation of blood cells in a medical image. More advanced image analysis systems measure quantitative information and use it to make a sophisticated decision, such as controlling the arm of a robot to move an object after identifying it or navigating an aircraft with the aid of images acquired along its trajectory. Image analysis techniques require extraction of certain features that aid in the identification of the object. Segmentation techniques are used to isolate the desired object from the scene so that measurements can be made on it subsequently. Quantitative measurements of object features allow classification and description of the image.

3.20 Image Segmentation

Image segmentation is the process that subdivides an image into its constituent parts or objects. The level to which this subdivision is carried out depends on the problem being solved, i.e., the segmentation should stop when the objects of interest in an application have been isolated e.g., in autonomous air-toground target acquisition, suppose our interest lies in identifying vehicles on a road, the first step is to segment the road from the image and then to segment the contents of the road down to potential vehicles. Image thresholding techniques are used for image segmentation.

3.20.1 Classification

Classification is the labeling of a pixel or a group of pixels based on its grey value. Classification is one of the most often used methods of information extraction. In Classification, usually multiple features are used for a set of pixels i.e., many images of a particular object are needed. In Remote Sensing area, this procedure assumes that the imagery of a specific geographic area is collected in multiple regions of the electromagnetic spectrum and that the images are in good registration. Most of the information extraction techniques rely on analysis of the spectral reflectance properties of such imagery and employ special algorithms designed to perform various types of 'spectral analysis'. The process of multispectral classification can be performed using either of the two methods: Supervised or Unsupervised. In Supervised classification, the identity and location of some of the land cover types such as urban, wetland, forest etc., are known as priori through a combination of field works and toposheets. The analyst attempts to locate specific sites in the remotely sensed data that represents homogeneous examples of these land cover types. These areas are commonly referred as TRAINING SITES because the spectral characteristics of these known areas are used to 'train' the classification algorithm for eventual land cover mapping of reminder of the image. Multivariate statistical parameters are calculated for each training site. Every pixel both within and outside these training sites is then evaluated and assigned to a class of which it has the highest likelihood of being a member.

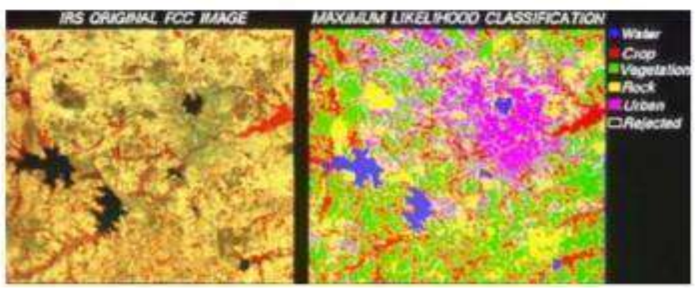

Figure 3.23: Image Classification

In an Unsupervised classification, the identities of land cover types has to be specified as classes within a scene are not generally known as priori because ground truth is lacking or surface features within the scene are not well defined. The computer is required to group pixel data into different spectral classes according to some statistically determined criteria. The comparison in medical area is the labeling of cells based on their shape, size, color and texture, which act as features. This method is also useful for MRI images.

3.21 Image Restoration

Image restoration refers to removal or minimization of degradations in an image. This includes de-blurring of images degraded by the limitations of a sensor or its environment, noise filtering, and correction of geometric distortion or non-linearity due to sensors. Image is restored to its original quality by inverting the physical degradation phenomenon such as defocus, linear motion, atmospheric degradation and additive noise.

Figure 3.24 Weiner – Image Restoration

3.22 Image Reconstruction from Projections

Image reconstruction from projections is a special class of image restoration problems where a two- (or higher) dimensional object is reconstructed from several one-dimensional projections. Each projection is obtained by projecting a parallel X-ray (or other penetrating radiation) beam through the object. Planar projections are thus obtained by viewing the object from many different angles. Reconstruction algorithms derive an image of a thin axial slice of the object, giving an inside view otherwise unobtainable without performing extensive surgery. Such techniques are important in medical imaging (CT scanners), astronomy, radar imaging, geological exploration, and nondestructive testing of assemblies.

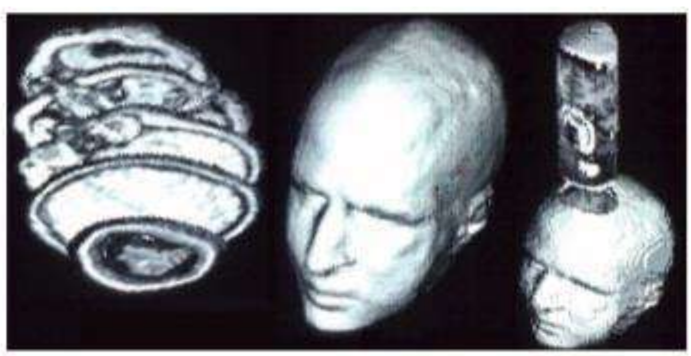

Figure 3.26 MRI Slices

3.23 Image Compression

Compression is a very essential tool for archiving image data, image data transfer on the network etc. They are various techniques available for lossy and lossless compressions. One of most popular compression techniques, JPEG (Joint Photographic Experts Group) uses Discrete Cosine Transformation (DCT) based compression technique. Currently wavelet based compression techniques are used for higher compression ratios with minimal loss of data.

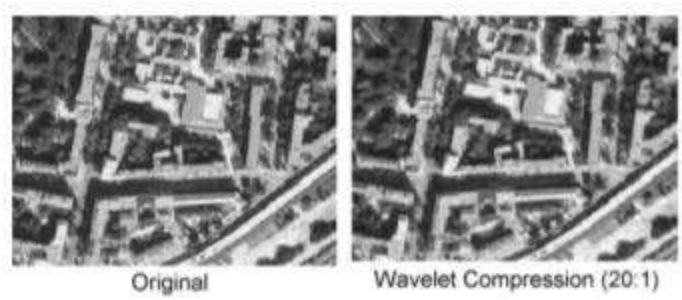

Figure 3.27. Wavelet Image Compression

CHAPTER-4

DIGITAL IMAGE PROCESSING

4.1 Digital image processing

Background

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

4.2 What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

4.3 What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

4.3.1 Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

4.3.2 Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green andB (xylem) for blue. An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is calledsampling. Digitizing the amplitude values is called quantization.

4.4 Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)= (0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

4.5 Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0) f(0,1) ……….. f(0,N-1)

f (1,0) f(1,1) ………… f(1,N-1)

f (xylem) = f (M-1,0) f(M-1,1) .... f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

f (1,1) f(1,2) .... f(1,N)

f (2,1) f(2,2) …….. f (2,N) . . .

f = . . .

f (M,1) f(M,2) .... f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Format name	Description	recognized extension
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

4.6 Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name	Description
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255] (1byte per Element).
Uint16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).
Uint 32	unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element).
Int8	signed 8_bit integers in the range [-128,127] 1 byte per element)
Int 16	signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
Int 32	Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

4.7 Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

4.8 Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

4.9 Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

4.10 Indexed Images

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

4.11 RGB Image

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors.

CHAPTER-5

PROPOSED METHOD

Describing the different algorithms implemented in this paper in brief to highlight the working mechanism along with a few important merits and demerits and Table I described the list of problems.

5.1 Tracking-Learning-Detection (TLD)

TLD is a framework used for tracking an arbitrary object in a video for a long time . Since the three different subtasks of tracking, detection and learning are undertaken by different parts of the same process, it is described as a framework and not as a tracking method. The target object is simultaneously tracked and learned which will help make the algorithm robust against failures . The tracker estimates the target's motion and predicts its position in the next frame according to the frame of reference. The Detector scans the image to restrict all appearances that have been observed before to a location. The Learning component estimates the detector's errors and produces numerous training examples to make sure that such errors are avoided in the future. The framework aims to achieve improved tracking by preventing learning from disinformation. It achieves this by shutting down the learning task in case of occlusions or when the object is no longer in the frame. The detection component can detect the object again if it appears in the video afterward.

5.2 Boosting

Boosting is one of the older algorithms which is usually used for comparison to show an improvement in the latest ones. It's based on an online version of AdaBoost, which also powers the machine learning supporting Haarcascades.This algorithm has to be trained rigorously with numerous positive examples (initial or starting bounding box provided by the user or the previous detection algorithms) and with an equal number of negative examples (patches around the actual object in the image). It works by working across every pixel of a given new frame but only surrounds a certain area of the previous location. Then the score is recorded of this classification algorithm for each comparison. The highest scoring part is labeled as the new location. As more new frames are added to this classifier it keeps getting updated.

5.3 Multiple Instance Learning

(MIL) With large datasets being used to solve complex issues today, research and interest in multiple instance learning has grown rapidly. Another advantage is that it allows the use of data with weak labeling. As a result, it has been used for various applications such as drug activity prediction, text categorization and content based image retrieval and classification. It is a supervised learning algorithm used for cases in which the training data is not labeled completely. In supervised learning, all training instances are labeled individually. But, only a bag of instances is labeled in MIL. In the case of binary classification, if at least one training instance in a bag is positive, the bag is positively labeled. Only if every training instance in a bag is negative, the bag is negatively labeled. The objective of the algorithm is to classify instances or bags by using labeled bags as training data.

5.4 Kernelized Correlation Filter

(KCF) The KCF algorithm used the shift invariance property of Fourier transform. This use not only simplifies the calculation of the correlation parameter but also makes it exceedingly fast. KCF is also able to bypass the issue of a huge amount of training data available from each frame of input due to its lightweight implementation. The large overlapping regions between various positive samples in Multiple Instance Learning are the property exploited by this tracker. KCF algorithm adopts and implements FFT and IFT which are fast and inverse Fourier Transform. By doing so the computation efficiency is increased of the algorithm. The accuracy and speed of this algorithm can be easily be compared on accounts of performance to various different and latest algorithms in OpenCV library. Although it’s reporting of tracking failure is an improvement over the previous versions it is unable to recover from full occlusions.

5.5 Median Flow

While using the median flow algorithm, an object is represented by a bounding box and then the object’s movement is estimated between successive frames using sparse optical flow. The algorithm assumes that the object is a combination of independent points which move in a synchronous manner and thus constitute the motion of the entire object. The algorithm is initialized by setting up the bounding box around the target object. A grid is then generated within the box. The points on the grid are then tracked between two consecutive frames. Next, the quality of the point predictions is estimated and each point is assigned an error. The best half of the predictions are used to estimate the displacement of the entire bounding box

CHAPTER 6

EVALUATION METRICS

In this work, the success and precision rate of the algorithms are used for quantitative analysis and comparison. Additionally, the robustness of the algorithms has been evaluated using the TRE parameter. TRE stands for Temporal Robustness Evaluation. TRE is a parameter to measure the tracker's robustness to initialization by varying the initialization by starting at different frames. Some tracker's performance may depend on the initialization, changing if the initialization is done at another start frame. The success parameter is used to define the intersections over union of the ground truth and the predicted bounding boxes while the precision metric defines the percentage of frame locations within a certain threshold distance from those of the ground truth

6.1 Precision

This precision value is measured and tracked using a very common and well known metric called the Center Location error. Its definition is the average Euclidean distance between the manually labeled ground truths and the center locations of the tracked target [14]. Hence for precision evaluation, we utilized the scale of rectangle obtained from the tracker considering the ground truth.

$$P = \frac{|r_t|}{|r_a|} \qquad (1)$$

The overall performance for that sequence is measured using the average center location error over all the frames of one sequence. However, the output location could be arbitrary and the average center location error might not properly estimate the tracking performance if the tracker loses the target.

6.2 Success

Bounding box overlap is another evaluation metric. For evaluation of the success parameter we used the following formula for each frame is the video sequence:

$$S = \frac{r_t \cap r_a}{r_t \cup r_a} \qquad (2)$$

Here art is the bounding rectangle obtained from the tracker and ra is the bounding rectangle to represent the ground truth. The value thus obtained from the above formula is known as the overlap score which can be use to define success of the algorithm [2, 15-17]. The overlap score is essentially a ratio of the area of interception and area of union. Tracking algorithms which have a number of frames with an S value of greater than a given threshold are said to be successful. Although instead of basing it all on one threshold value we have also found out the values of Area Under Curve (AUC) for each algorithm for a better evaluation.

CHAPTER-8
CONCLUSION

When all the algorithms were tested under the same environment, it can be concluded that BOOSTING Tracker is quite slow and doesn't work very well. It should be noted that it has only been included for legacy reasons. The MIL Tracker is found to be wanting against other algorithms especially in reporting failure. It was interesting to observe the TLD tracker as it was incredibly prone to false-positives, which was not initially expected, thus not making a good choice when using the OpenCV object trackers. Median-Flow Tracker was the fastest tracker to be tested in our environment which did a considerably good job when it came to reporting failures. However, if the object changes their appearance quickly enough, or there is a too large jump in object motion, the object changes their appearance quickly enough, or there is a too large jump in object motion, the tracker fails to perform. The tracker should not be used for fast-moving objects. The Kernelized Correlation Filters (KCF) tracker was one of the quicker trackers, faster than BOOSTING, MIL, and TLD tracker. It was noted that similar to MIL Tracker it was prone to occlusion but was much more reliable in its performance, making it one of the most favorable trackers that can be used. The future scope of this research includes a comprehensive examination of the application of these algorithms, along with the calculation of their efficiencies and the use of different techniques.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "BABY CRADLE AND HEALTH MONITORING SYSTEM USING IOT" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

1) Ms. P. Venkata Sai Kumar (17K81A04N7)

2) Mr. K. Nagaraju (18K85A0438)

3) Mr. J. Ram Reddy (18K85A0440)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtednessto **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communications for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We sincerely thank our project internal guide, Mr. S. Ravi Kumar, Associate Professor, Department of ECE and our class project coordinator Ms. P. pushpa Assistant Professor, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE**for their advice, supervision, and the vital contribution as and when required during this project work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Juggling the responsibilities of a job and new born baby may seem challenging for working parents. Infant health safety and security is always a matter of concern for kith and kin by leaving their baby in care centers. At present, female participation in the work force in the industrialized nations has greatly increased, thereby affecting infant care in many families. Both parents are required to work due to the high cost of living. However, they still need to look after their babies, thereby increasing workload and stress, especially of the mother. Working parents cannot always care of their babies. They either send their babies to their parents or hire a baby caregiver while they are working. Some parents worry about the safety of their babies in the care of others. Thus, they go home to check on their babies during their free time. In this paper author has designed an advance cradle system which monitor baby health conditions such as temperature, baby cry and wetness. Parents not only monitor but also can control cradle via mobile. The experimental result shows that the designed system works successfully for the infant healthcare and thus can be implemented practically.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

At present, female participation in the work force in the industrialized nations has greatly increased, thereby affecting infant care in many families. Both parents are required to work due to the high cost of living. During early stages infant needs proper rest and sleep for growth and development. Hence, it is a responsibility of parents by guardian to provide necessary care and attention to the infant. But with the modern lifestyle, parents are busy and have a lot of work with little time to provide for the little ones. When a baby is born in a family there has to be someone to look after the baby. Some parents have to do a double task of keeping a check on the baby as well as do the household work.

However, they still need to look after their babies, thereby increasing workload and stress, especially of the mother. Working parents cannot always care for their babies. They either send their babies to their parents or hire a baby caregiver while they are working. It is always difficult to relay on some strangers to look after their baby. Some parents worry about the safety of their babies in the care of others. Thus, they go home to check on their babies during their free time, such as lunch or tea break. So to help such parents we have decided to come up with a smart cradle which will help a mother or a father have a track of their child and do their work simultaneously.

A baby monitoring system that can monitor the babies' condition real time is proposed to solve these problems. A baby monitoring system consisting of different sensors and Wi-Fi modules. This proposed system will give the parents relaxing time and it can send data and immediately notify the parents about urgent situations, thereby shortening the time needed to handle such scenarios. Generally, babies cry because they are hungry, tired, unwell, or need their diaper changed. If a system could understand the uneasiness of the baby or why the baby might be crying it means that for both working and non-working parents could save their time and provide the necessary care and attention to the infant. This baby cradle health monitoring system is used in various hospitals and maternity homes for infants to sleep in and take care of them.

1.2 OBJECTIVES OF THE STUDY:

Under fast-paced life conditions, everyone is busy in their professional life including parents. They leave the house early in the morning and come back before dinner time. Even the mothers are working. Thus, they do not have sufficient time to take care of their babies. Not all parents could afford a nanny to help them with their children. Then, after working for long hours, the mothers still have to manage the house and take care of their babies simultaneously. Parents might not have the time to take care of their baby.

Studies about the monitoring of a baby have been carried out and found that baby health conditions better while being monitored by the parents. Most available automated cradles are designed to check the infant health conditions non-stop. However, the existing systems not accurate and they doesn’t give absolute values. Thus, allowing the automated cradle to take care of the baby is also a problem. Several types of baby cradles are available in stores, but they are expensive, and not everyone can afford them. In addition, the existing automatic cradles in the literature have many limitations in terms of functionality, cost, and communication technology support.

To the best of our knowledge, no previous studies have developed a smart cradle with IOT support from scratch, similar to that in the present study. To overcome this problem, a new automatic IOT-based baby monitoring system is designed, allowing the parents to access an account to monitor the baby’s condition anywhere and anytime.

This proposed system will give the parents relaxing time and allow them to take less stress about wellbeing if the baby when they are away as they can get update about the status of infant inside the cradle. It can send data and immediately notify the parents about urgent situations, thereby shortening the time needed to handle such scenarios. Generally, babies cry because they are hungry, tired, unwell, or need their diaper changed. If a system could understand the uneasiness of the baby or why the baby might be crying it means that for both working and non-working parents could save their time and provide the necessary care and attention to the infant. This baby cradle health monitoring system is used in various hospitals and maternity homes for infants to sleep in and take care of them.

1.3 SCOPE OF THE STUDY:

IOT (**internet of things**) based baby cradle and health monitoring system is such a type of system that is used to monitor and check the health conditions of the baby present in the cradle with the help of internet resources and Wi-Fi module. At present scenario, the number of working women had been increased. They can't take care of their baby due to long working hours. So, they need to send their babies to their grandparent's home or some baby care centers. On the other hand it is difficult to afford the baby care taker due to financial instabilities and also requires man power as well. Even if the parents sends their baby to grandparents houses still, they worry about their baby and they can't see the real time conditions of their baby. If they want to check the conditions of the baby they have to come home from working place which is quite complicate and waste of time.

To overcome and to facilitate all the above situations, so many baby care health monitoring systems are available in the market but, they can't give accurate and absolute values about baby health conditions. Here we proposed a system that is called baby cradle and health monitoring system using IOT which is efficient, reliable, and friendly to use. By using this system the parents can monitor and check all the health conditions of the baby from their work place or else any place which is far away from the baby. This IOT based baby cradle and health monitoring system is very much useful to working parents as well as nurses in maternity units of hospital.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino Uno
- LCD
- Power Supply
- Wi-Fi Module
- Wet Sensor
- Heart Beat Sensor
- Lm35
- Sound Sensor

1.4.2 SOFTWARE REQUIREMENT:

- Proteus Software
- Arduino Software

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop andbefore assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the toll booth system with better efficiency, with less time delay and the results were also satisfactory and we successfully got the output in mobile telnet app and LCD screen. We would like to improve the project in future for further developments.

CHAPTER-2
LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

To address these challenges, we designed and fabricated a baby monitoring system for a smart cradle using Node MCU as the microcontroller while the system was developed using Arduino IDE. This system consists of a cradle that can swing whenever the sound sensor detects crying. A mini fan is attached on top of the cradle to provide ventilation. The mini fan and the swinging of the cradle can be switched on either by the sensors or through remote control from the MQTT server. An external Wi-Fi camera has been installed on the cradle to enable real-time vision monitoring. The parents can see the baby's condition and talk to the baby using the ready-made mobile application of the Wi-Fi camera. An Internet of Things-based baby monitoring system for smart cradle is proposed in this paper. The novelty of this work lies in the proposed IOT-BBMS automation system by adopting the following methodology and contributions:

(i) A smart baby cradle prototype is designed and fabricated with auto-swinging support, web camera and musical toy to test the proposed system.

(ii) A new Algorithm is proposed and implemented in Node MCU controller to perform the required monitoring and control tasks.

(iii) Utilizing the Node MCU as the microcontroller and adafruit MQTT as IOT server to retrieve data from sensors and send commands to actuators.

(iv) The system could gather accurate real time data and response by actuating the proper relay to switching fan, toys and swinging motor.

2.2 REVIEW ON RELATED LITERATURE:

Few studies have investigated the possibilities of automated baby cradle using different perspectives. A baby monitoring system has been proposed in [1], in which an enhanced noise cancelling system that monitors the baby and reduces sound pollution has been suggested. The main function of the system is to reduce the noise that might disturb the baby by playing relaxing songs.

This system can also adjust the room's light intensity with the aid of a light sensor. However, our system has more advanced features, such as supporting real-time monitoring over the IOT network and vision monitoring using web camera.

The authors Goyal and Kumar [2] introduced an E-baby cradle that can swing automatically when it detects crying and stops swinging when the crying stops. The speed for the swinging cradle can be controlled based on the user's need. First, the alarm goes off when the mattress is wet, indicating that the mattress should be changed. Second, when the baby does not stop crying for a certain time, the alarm alerts the parents to attend to their baby. However, it is only applicable when parents are near the cradle, because it only uses a buzzer alarm, the sound of which might frighten the baby. Parents cannot monitor their baby when they are away from home, for example when at work or when traveling to other places. A similar automatic baby monitoring system was proposed in [3].

The authors developed a low-budget system that swings the cradle when the crying sound is detected, and the cradle stops when the baby stops crying. The built-in alarm goes off under either one of the following conditions: the mattress is wet or the baby does not stop crying after a certain period.

2.3 CONCLUSION ON REVIEW:

The overall methodology adopted in this research had been discussed earlier. Issues in the existing systems were identified by conducting a comprehensive literature review on studies related to baby monitoring systems. Then, we introduced a smart cradle that combines the concept of IOT with baby monitoring system. Subsequently, the selection of material for the smart cradle was carried out. All the hardware and materials used in building this system, which were suitable for a baby, were selected. The priority is to ensure the safety of the baby. The modelling phase is followed by the system design, determining the GUI of applications, and prototype phase.

The system design is separated into two phases, namely, the cradle design and control system design. A cradle prototype for the baby monitoring system was designed. In the control system design, the types of electronic components were determined and purchased for implementation in the system. Then, coding was performed according to how the system was proposed. After the modelling phase, the designed baby monitoring system was then enhanced and optimized through several tests to achieve the expected outcome. Subsequently, the system was installed on the cradle prototype for the testing phase before finalizing the smart cradle.

When the testing failed due to some coding errors or other problems, the testing phase was repeated until the cradle achieved the expected outcome that satisfied the research object.

CHAPTER-3

EMBEDDED SYSTEMS

3.1 INTRODUCTION TO EMBEDDED SYSTEMS:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer. The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware. The simplest devices consist of a single microprocessor (often called a "chip”), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine. As the embedded system is the combination of both software and hardware.

3.2 APPLICATION OF EMBEDDED SYSTEMS:

- Manufacturing and process control
- Construction industry
- Transport

- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

3.3 MICRO PROCESSOR (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- **Application Specific Integrated Circuits (ASIC)**

3.4.1 THREE BASIC ELEMRNTS OF MICROPROCESSOR:

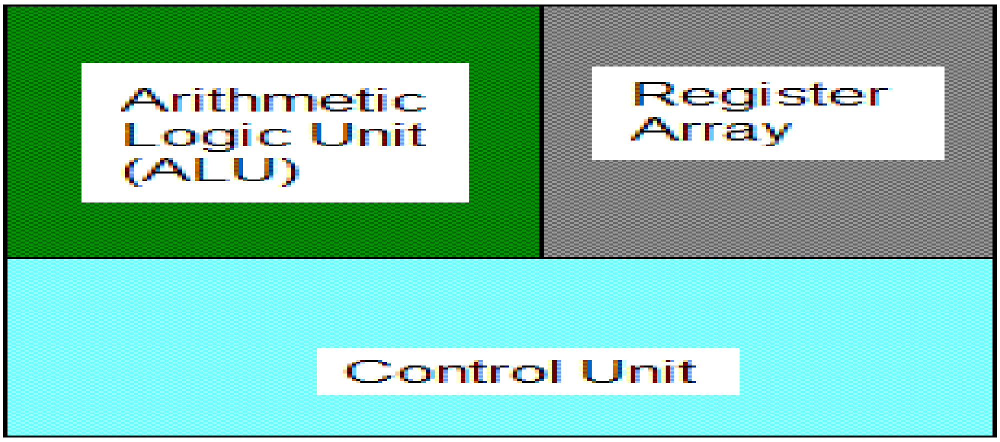

Fig.3.3.1: Three Basic Elements Of Microprocessor

3.4 HARVARD ARCHITECTURE:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

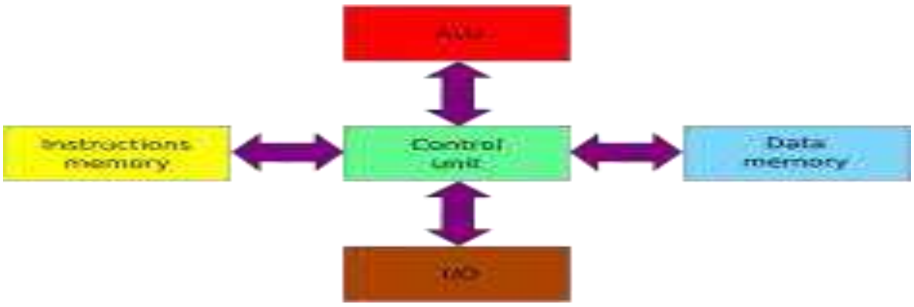

Fig.3.4.1: Harvard Architecture

3.4.1 USES OF THE HARVARD ARCHITECTURE:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces. Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip

Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture

3.4.2 VON- NEUMANN ARCHITECTURE:

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

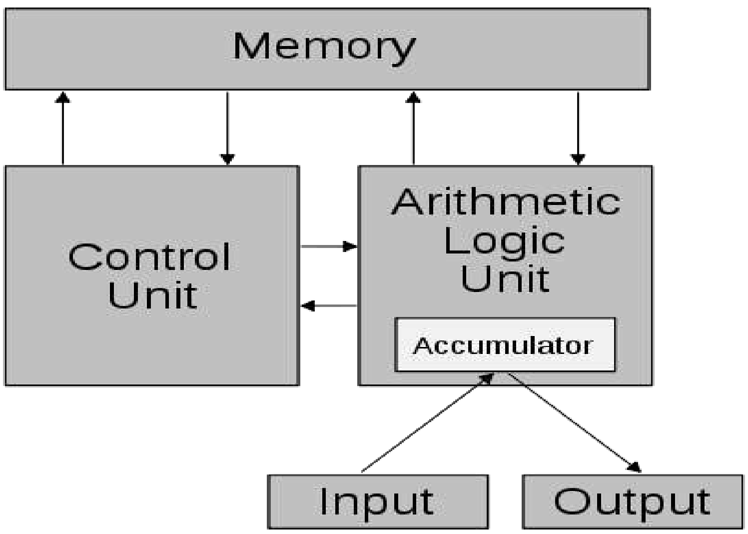

Fig.3.4.2: Schematic of the Von-Neumann Architecture.

CHAPTER-4

PROJECT DESIGN

4.1 OVERVIEW OF DESIGN:

The cradle is designed to connect to the all sensors to it. It swings when the switch is turned on by the user or when the sound sensor detected the baby's cry. The control circuit components are installed into the attached electrical box after the circuit testing phase. Figure 4.1 shows the circuit diagram of the virtual connection of electrical components using Fritzing software. The components are installed on the breadboard to ensure that the system works successfully before transferring the components onto the solder circuit panel. The shaft of the DC motor is connected to the cradle to allow swinging whenever the baby cry is detected or initiated by the user. The LED in Figure 6 replaces the lullaby toy given that the circuit design software does not have a library of lullaby toys. The control system of the smart baby cradle is equipped with 5 V USB power source, sound sensor module, temperature and humidity sensor, relays, ESP 8266 Wi-Fi module, and geared motor. Figure 4.1 shows the stimulation of temperature and wet sensors in the Proteus software. After the electronics stimulation in Proteus Simulation software, all the electrical and electronic components were assembled and connected to the micro-controller and programmed using Arduino software (IDE).

However, the Proteus software was not fully utilized, because some of the component libraries were not found in the software, as well as on the Internet. Therefore, the sensors and components had to be tested the Proteus software. In the practical implementation of the designed system, the original 9 V DC battery source was changed to AC to DC 12 V output converter, because the 9 V DC battery was unable to supply the current efficiently to the entire circuit. Hence, an AC to DC power supply was used. A 5 V 3 A USB module was used to convert the 12 V output to 5 V output for the activation of the mini fan. It was also used to supply electricity to the NodeMCU microcontroller. The USB module has a built-in step-down converter that can reduce an input of 6–24 V to the output of 5 V, with a maximum output current of 3 A at full load. The connection of the NodeMCU is coded to connect to a certain Wi-Fi network with the given password written in the coding, because the Internet of UMP has certain restrictions, which would cause the connection of the system to fail. The process is then retested using the programmer mobile phone’s data hotspot.

The connection was successful, and no time delay was encountered during the performance of the sending and fetching of data to and from the MQTT server. The DHT22 temperature and humidity sensor was mounted on the side of the electrical box by drilling a hole to enable the sensor to fit in the hole, as shown in Figure 8 (a), to measure the ambient temperature. Thus, the DHT22 sensor can be exposed to the surrounding temperature and then measured for uploading to the MQTT server. A sound sensor is placed at the top of the baby’s cradle to enable sound detection. Figure 8(b) shows the MD10-POT 10 Amp DC motor driver used to vary the speed of the 12 V DC motor that swings the cradle. The motor driver supports the motor voltage that ranges from 7 V to 30 V and can withstand the maximum current up to 10 A continuous and 30 A peak (10 seconds). The speed, round per minute (RPM), of the connected DC motor can be varied by tuning the potentiometer and the rotating direction with a two-direction switch. The black knob under the DHT22 in Figure 8 (a) is the potentiometer of the DC motor driver that allows the user to manually adjust the speed of the baby cradle.

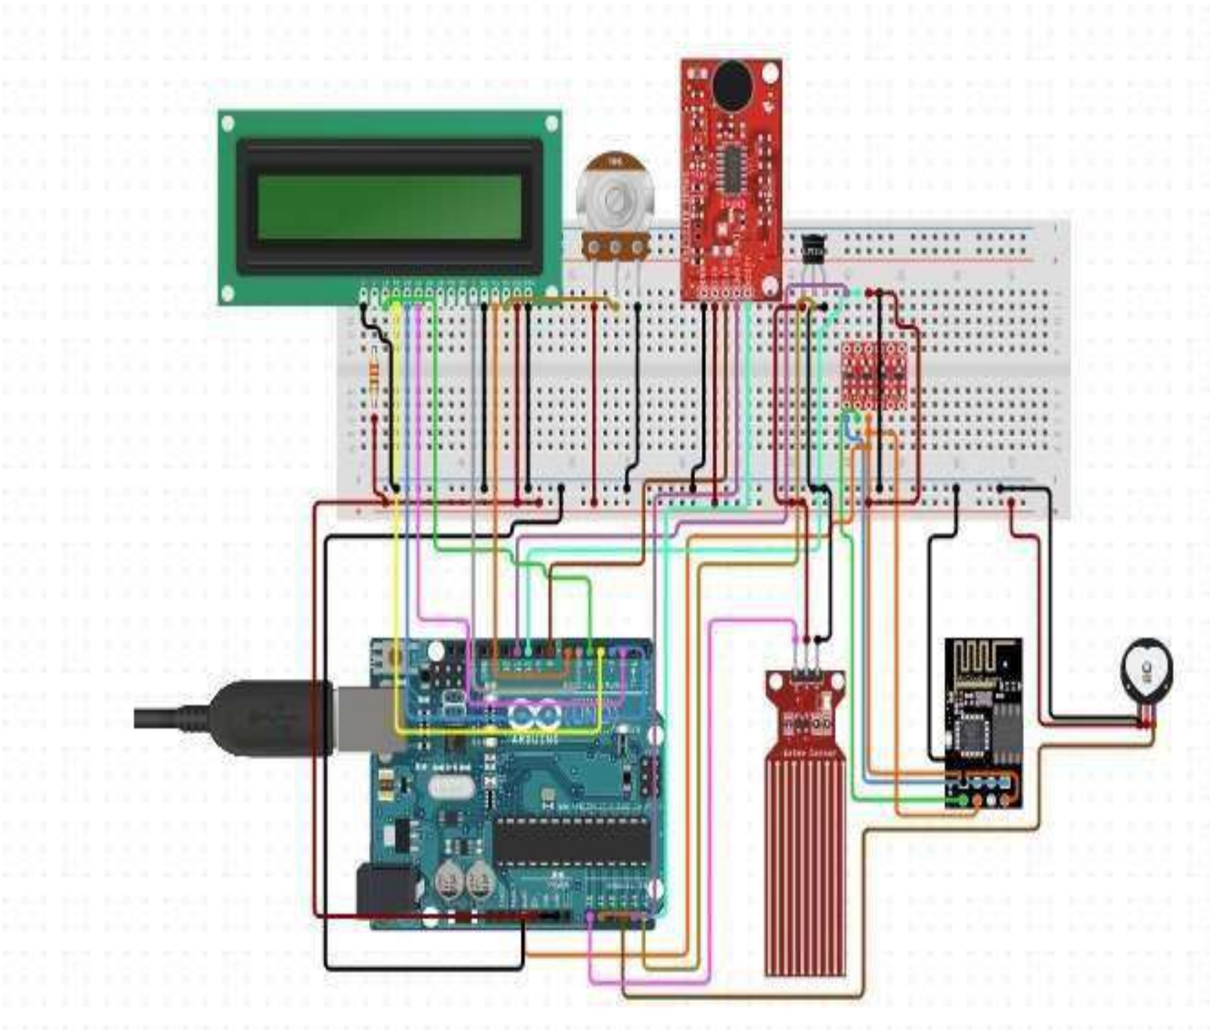

Fig.4.1 Overview Of The Design

4.2 EQUIPMENT ANALYSIS:

4.2.1 ARDUINO UNO:

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle. Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions. You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software). Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable. Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program. Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

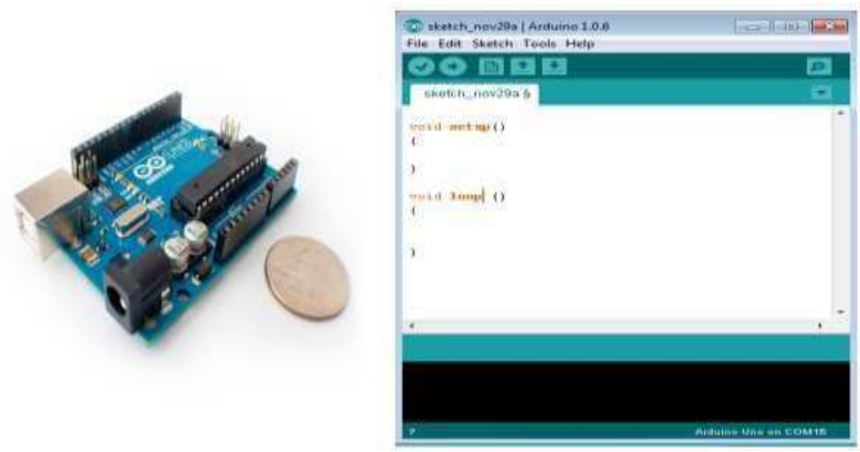

Fig 4.2.1 Arduino Uno

4.2.2 BOARD TYPES:

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE. The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2

Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2

4.2.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

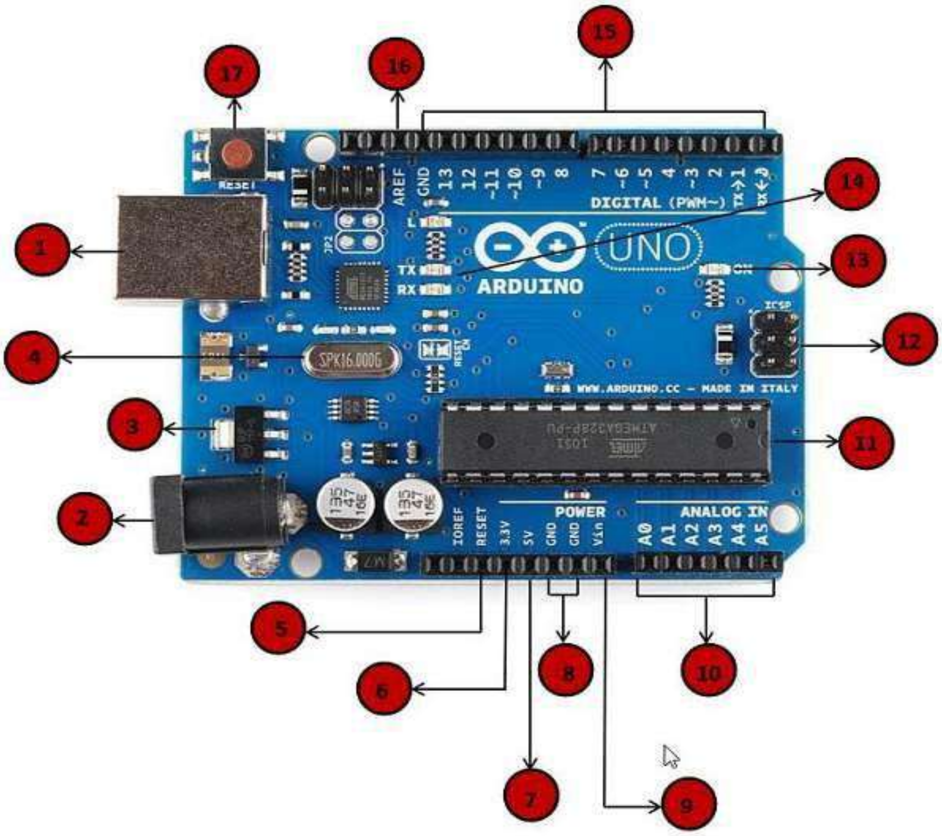

Fig 4.2.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. The Arduino calculates time by using the crystal oscillator. The number printed on top of the Arduino crystal is

	16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works with 3.3 volt and 5 volt. • GND (8) (Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator**

	This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labelled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

4.2.4 ARDUINO FAMILY:

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino. Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.4.2.3 Arduino Family

4.2.5 ADVANTAGES OF ARDUINO:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

4.2.6 APLLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model.

4.3 POWER SUPPLY UNIT:

4.3.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as "Regulated D.C Power Supply".

4.3.2 BLOCK DIAGRAM OF POWER SUPPLY:

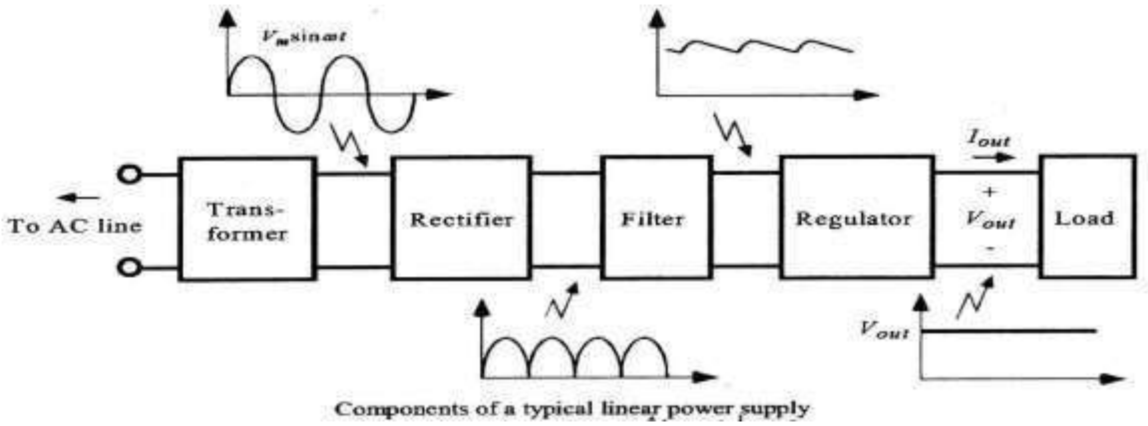

Fig.4.3.1 Block Diagram of Power Supply

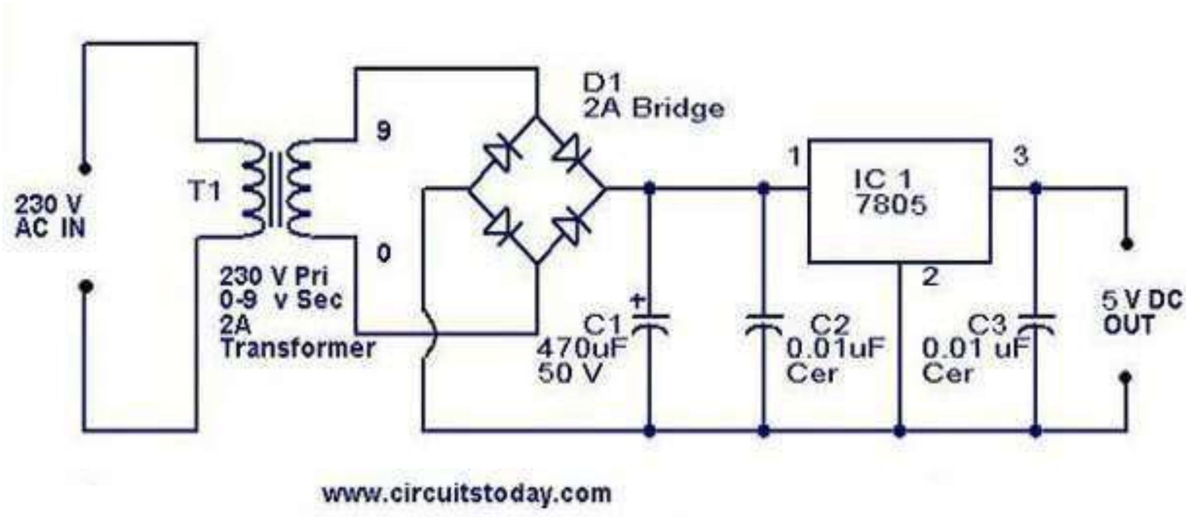

Fig.4.3.2 Schematic Diagram of Power Supply

4.3.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a different form of energy – such as solar, mechanical, or chemical - into electrical energy. A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.3.4 TRANSFORMER:

A transformer is a device that transfers electrical energy transfers from one circuit to another through inductively coupled conductors to the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction (or) Transformer. A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa. Transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core. Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core.

Transformers can increase voltage (step-up) as well as reduce voltage (step-down). Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

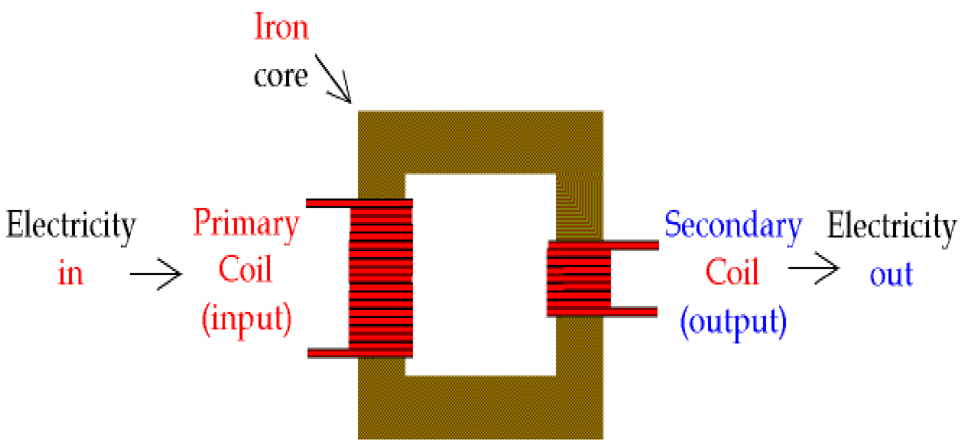

Fig.4.3.3 Transformer

4.3.5 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

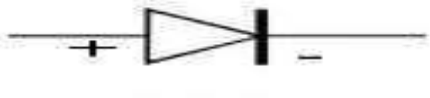

Fig.4.3.4 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

4.3.6 RECTIFIER:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier: The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure

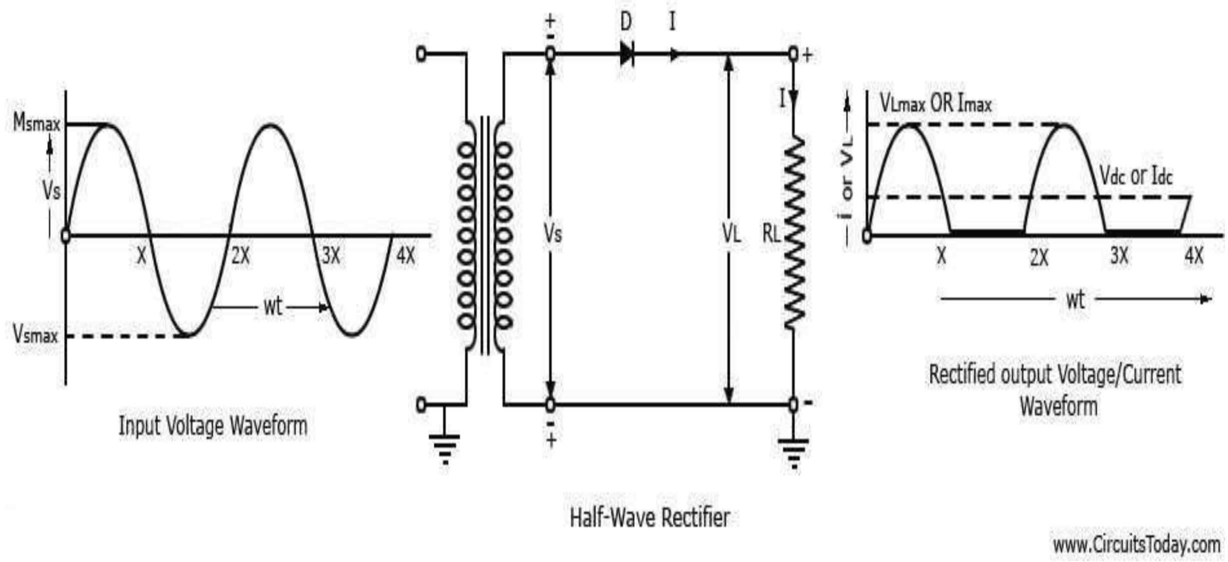

Fig.4.3.5 Half Wave Rectifier

As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs. While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

.

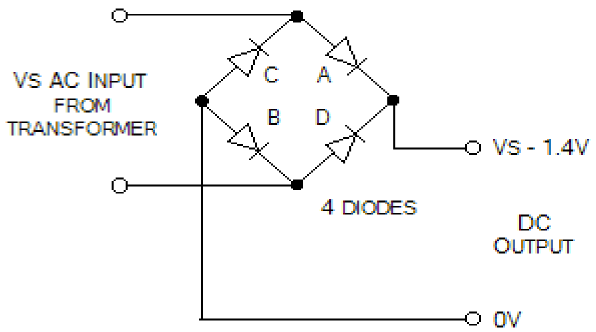

Fig.4.3.6 Full-Wave Rectifier

4.3.7 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

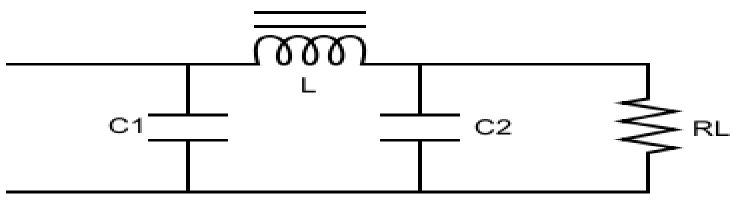

Fig.4.3.7 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

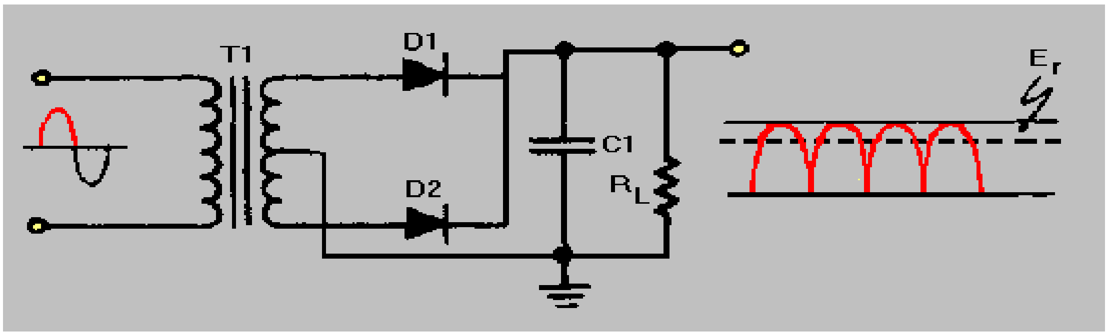

Fig.4.3.8 Centered Tapped Full-Wave Rectifier with a Capacitor Filter

4.3.8 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx' indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

4.4 16*2 ALPHANUMERIC LCD:

4.4.1 LCD SCREEN DISPLAY:

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the LCD has different memories to display data, those are discussed below.

4.4.2 BLOCK DIAGRAM OF LCD:

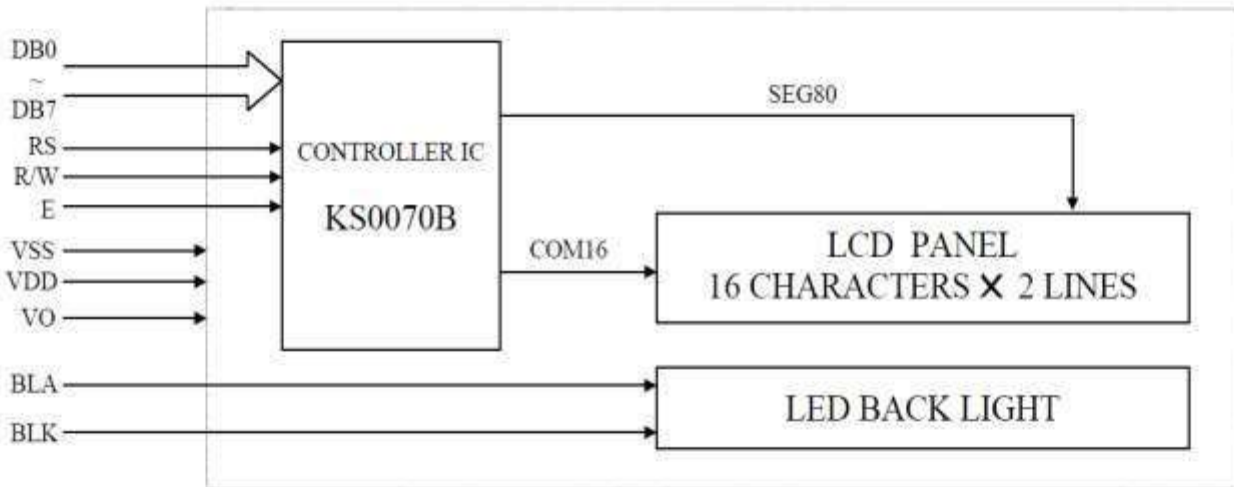

Fig.4.4.1 LCD Block Diagram

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Fig.4.4.2 DDRAM Addresses For 2 Line LCD

4.4.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ASCII value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

4.4.4 BUSY FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing. To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

4.4.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

4.4.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing.
- 61 x 15.8 mm viewing area and 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line.
- Can display 224 different symbols
- Low power consumption (1 mA typical)

4.4.7 SCHEMATIC DIAGRAM:

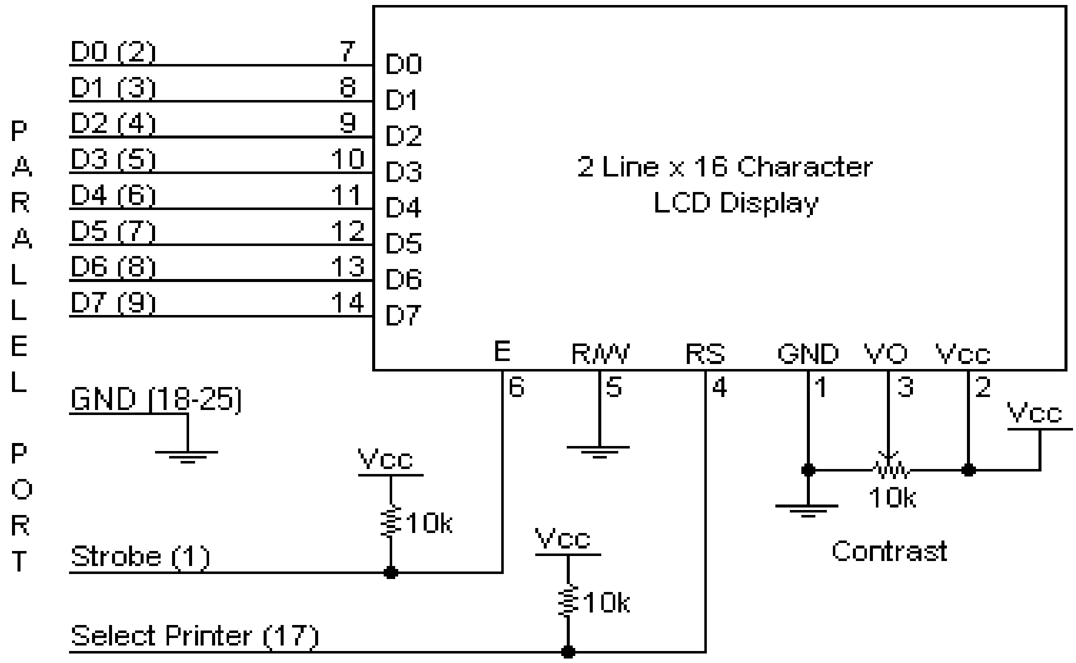

Fig.4.4.3 Schematic Diagram Of LCD

4.4.8 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors. We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program. The 10k Potentiometer controls the contrast of the LCD panel.

You can use a bench power supply set to 5v or use a on board +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

4.5 LM35 SENSOR:

Lm35 is a Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. . The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range.

The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies.

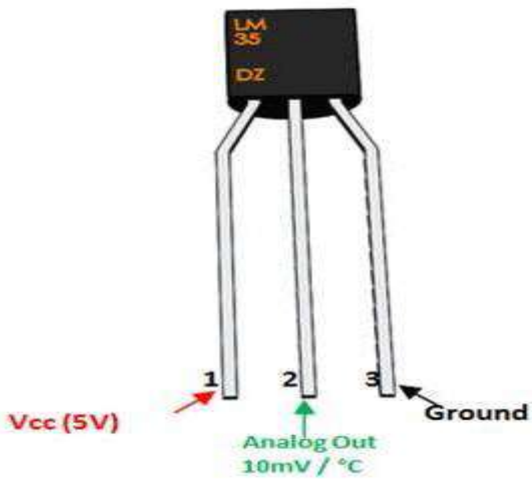

Fig.4.5 Temperature Sensor

4.5.1 THE CHARACTERISTICS OF LM35 SENSOR IS:

For each degree of centigrade temperature it outputs 10milli volts. ADC accepts the output from LM35 and converts that data into digital form which is sent to microcontroller for further processing. The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids.

The thermodynamic equilibrium between the hot body and the testing body is established by material contact. In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom.

4.5.2 PIN CONFIGURATION:

Pin Number	Pin Name	Description
1	Vcc	Input voltage is +5V for typical applications
2	Analog Out	There will be increase in 10mV for raise of every 1°C. Can range from -1V(-55°C) to 6V(150°C)
3	Ground	Connected to ground of circuit

Table 4.5 Pin Configuration Of Temperature Sensor

4.5.3 FEATURES AND SPECIFICATIONS:

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60 µA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

4.5.4 APPLICATIONS:

- Measuring temperature of a particular environment
- Providing thermal shut down for a circuit/component
- Monitoring Battery Temperature and Measuring Temperatures for HVAC applications.

4.6 HEART BEAT SENSOR:

4.6.1 ABOUT HEART BEAT SENSOR?

Heartbeat Sensor is an electronic device that is used to measure the heart rate i.e. speed of the heartbeat. Monitoring body temperature, heart rate and blood pressure are the basic things that we do in order to keep us healthy. The working of the Pulse/Heart beat sensor is very simple. The sensor has two sides, on one side the LED is placed along with an ambient light sensor and on the other side we have some circuitry. This circuitry is responsible for the amplification and noise cancellation work. The LED on the front side of the sensor is placed over a vein in our human body. This can either be your Finger tip or you ear tips, but it should be placed directly on top of a vein. Now the LED emits light which will fall on the vein directly. The veins will have blood flow inside them only when the heart is pumping, so if we monitor the flow of blood we can monitor the heart beats as well. If the flow of blood is detected then the ambient light sensor will pick up more light since they will be reflect ted by the blood, this minor change in received light is analyzed over time to determine our heart beats.

Fig.4.6 Heart Beat Sensor Diagram

4.6.2 PIN CONFIGURATION:

Pin Number	Pin Name	Wire Colour	Description
1	Ground	Black	Connected to the ground of the system
2	Vcc	Red	Connect to +5V or +3.3V supply voltage
3	Signal	Purple	Pulsating output signal.

Table 4.6 Pin Configuration

4.6.3 WORKING OF HEART BEAT SENSOR:

4.6.4 FEATURES AND SPECIFICATIONS:

- Biometric Pulse Rate or Heart Rate detecting sensor
- Plug and Play type sensor
- Operating Voltage: +5V or +3.3V
- Current Consumption: 4mA
- Inbuilt Amplification and Noise cancellation circuit
- .Diameter: 0.625”
- Thickness: 0.125” Thick

4.6.4 APPLICATIONS:

- Sleep Tracking
- Anxiety monitoring
- Remote patient monitoring/alarm system
- Health bands
- Advanced gaming consoles

4.7 SOUND SENSOR:

Sound detection sensor module detects the intensity of sound where sound is detected via a microphone and fed into an LM393 op-amp. It comprises an onboard potentiometer to adjust the set point for sound level.

Fig.4.7 Sound Sensor Diagram

4.7.1 ABOUT SOUND SENSOR MODULE:

Sound Detection Sensor Module consists of four pins i.e. VCC, GND, DO, AO. Digital out pin is connected to the output pin of LM393 comparator IC while the Analog pin is connected to Microphone. The internal Circuit diagram of the Sound Detection Sensor Module is given below. Using Sound Detection Sensor Module with a microcontroller is very easy. Connect the Analog/Digital Output pin of the module to the Analog/Digital pin of Microcontroller. Connect VCC and GND pins to 5V and GND pins of Microcontroller. When the sound level exceeds the setpoint, an LED on the module is illuminated and the output is set low.

This Sound Detection Sensor Module consists of a Microphone, resistors, capacitor, potentiometer, comparator LM393 IC, Power, and status LED in an integrated circuit. LM393 IC LM393 Comparator IC is used as a voltage comparator in this Sound Detection Sensor Module. Pin 2 of LM393 is connected to Preset (10KΩ Pot) while pin 3 is connected to Microphone. The comparator IC will compare the threshold voltage set using the preset (pin2) and the Microphone pin (pin3).

Microphone: The microphone in the Sound sensor module detects the sound. This sound is fed into the LM393 IC.

Preset (Trimmer pot): Using the onboard preset, you can adjust the threshold (sensitivity) of the digital output.

4.7.2 PIN CONFIGURATION:

Pin Name	Description
VCC	The Vcc pin powers the module, typically with +5V
GND	Power Supply Ground
DO	Digital Output Pin. Directly connected to digital pin of Microcontroller
AO	Analog Output Pin. Directly connected to an analog pin of Microcontroller

Table 4.7 Pin Configuration

4.7.3 SPECIFICATIONS:

- Operating voltage: 3.3V to 5V DC
- LM393 comparator with threshold preset
- PCB Size: 3.4 * 1.6cm
- Induction distance: 0.5 Meter
- Operating current; 4~5mA
- Microphone sensitivity (1kHz): 52 to 48 dB

4.7.4 APPLICATIONS:

- Hearing aids
- Telephones
- Tape recorders and karaoke
- Live and recorded audio engineering
- Radio and television broadcasting
- Speech recognition technology

4.8 WET SENSOR:

4.8.1 ABOUT WET SENSOR

The moisture sensor is used to measure the wet condition of the baby's bed. It is fixed in the bed of the baby and measure the values. The probe can be powered with an DC supply or batteries in the range of 3.5 to 20 volts. The output is a voltage in the range of 0 to 3V, so any multimeter can be used to measure the moisture level.

Fig.4.8 Wet Sensor Diagram

4.8.2 PIN CONFIGURATION:

S.No:	Name	Function
1	VCC	Connects supply voltage- 5V
2	GND	Connected to ground
3	D0	Digital pin to get digital output
4	A0	Analog pin to get analog output

Table 4.8 Pin Configuration

4.8.3 SPECIFICATIONS:

- Measuring ranges: permittivity 1 - 80, bulk conductivity 0 - 200 mS.m-1, temperature -5 to 50°C, volumetric soil moisture 0 -1 m3.m-3.
- Accuracy: permittivity ±.2.5, bulk conductivity ± 10 mS.m-1, temperature ± 0.7, volumetric soil moisture ± 0.03 m3.m-3.
- Response time: ~5 seconds.
- Calibration: suitable for a variety of standard soil types.
- Environmental sealed to IP67, connector to IP65.
- Operating temperature: 0 to 50 °C.

4.8.4 APLPLICATIONS:

- Salinity monitoring
- Plant nutrient status and fertigation
- Pollution and land reclamation
- Soil moisture mapping Specifications

4.9 DEFINE MODULES:

4.9.1 ESP8266 WIFI MODULE:

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

4.9.2 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I^2C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I^2S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

4.9.3 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring
- Natural Language-based voice assistants.

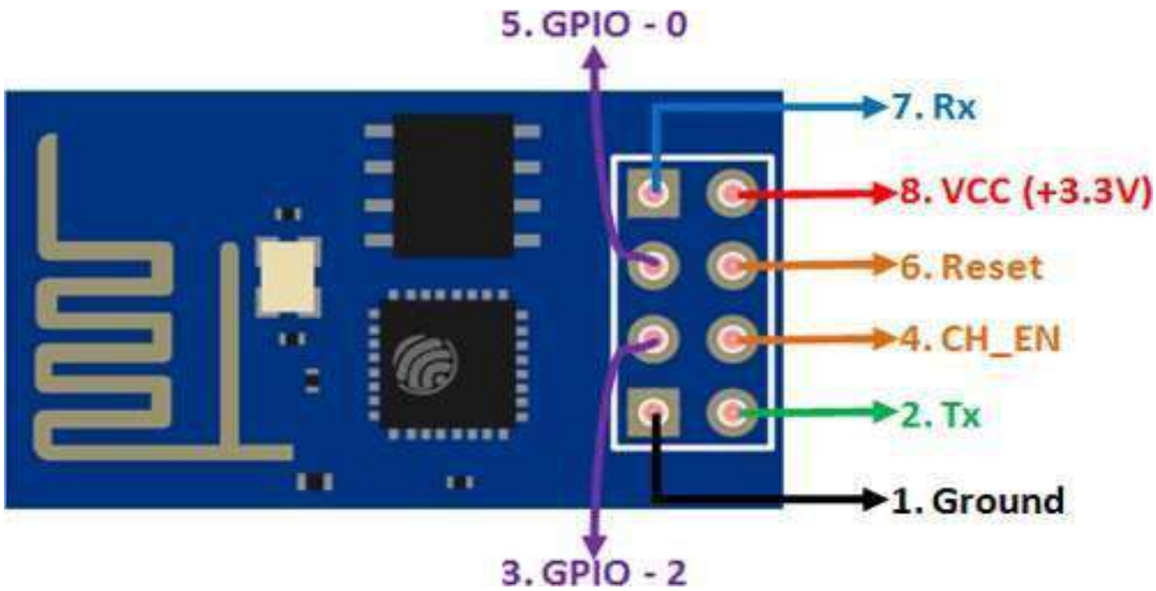

Fig.4.9.1 ESP8266 Wi-Fi Module Pin Out

4.9.4 STRUCTURE AND CONFIGURATION:

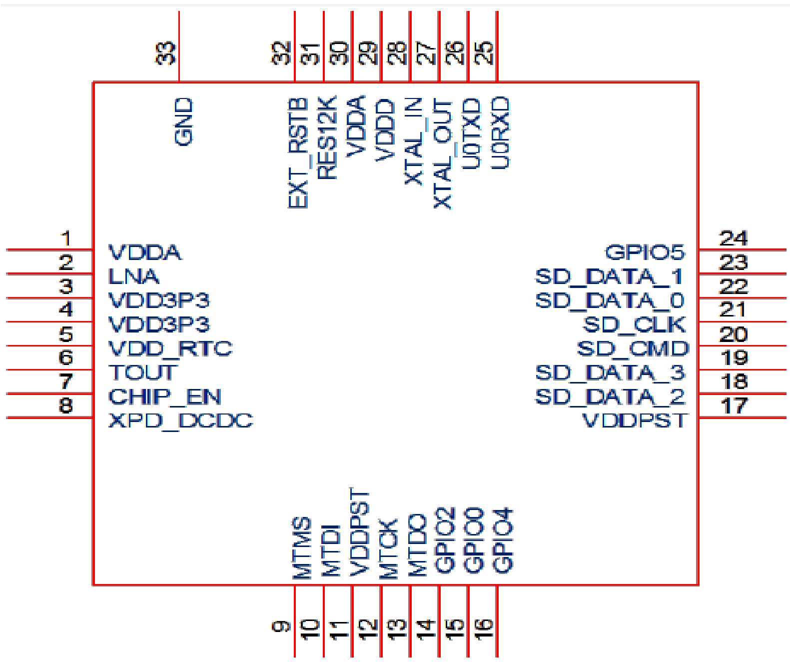

Fig.4.9.2 Structure and configuration

4.10 MODULE FUNCTIONALITIES:

4.10.1 ESP8266 WIFI MODULE

The ESP8266 Wi-Fi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much Wi-Fi ability as a Wi-Fi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost-effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area.

CHAPTER-5
SOFTWARE DESCRIPTION

5.1 SOFTWARE REQUIREMENTS:

- Arduino software
- Programming language
- Proteus simulation

5.1.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments.

A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming.

As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IOT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

5.1.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics.

Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers.
- The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version. Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

- Getting Started with Arduino and Genuino products:-
  Install the Arduino Software (IDE) on Windows PCs-
  This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software(IDE)

✓ Proceed with board specific instructions.

5.1.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.
When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

5.1.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.5.1.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.5.1.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

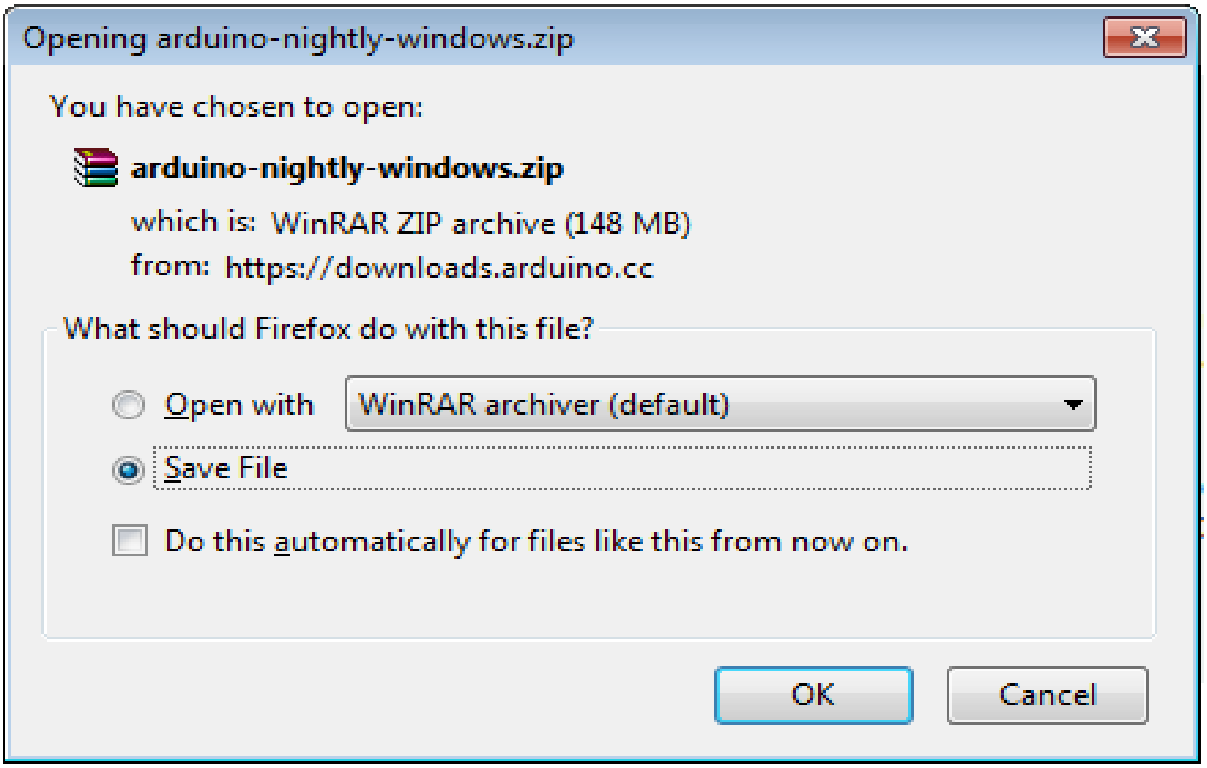

Fig.5.1.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

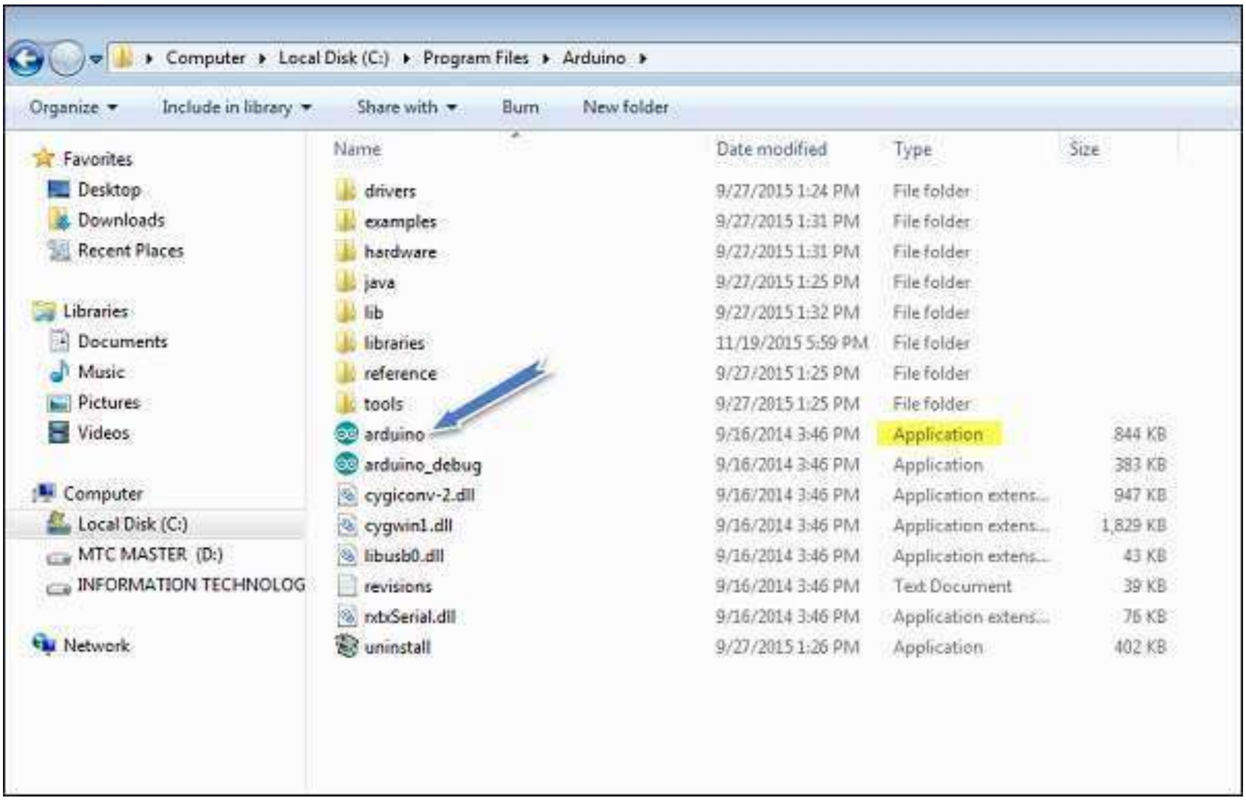

Fig.5.1.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

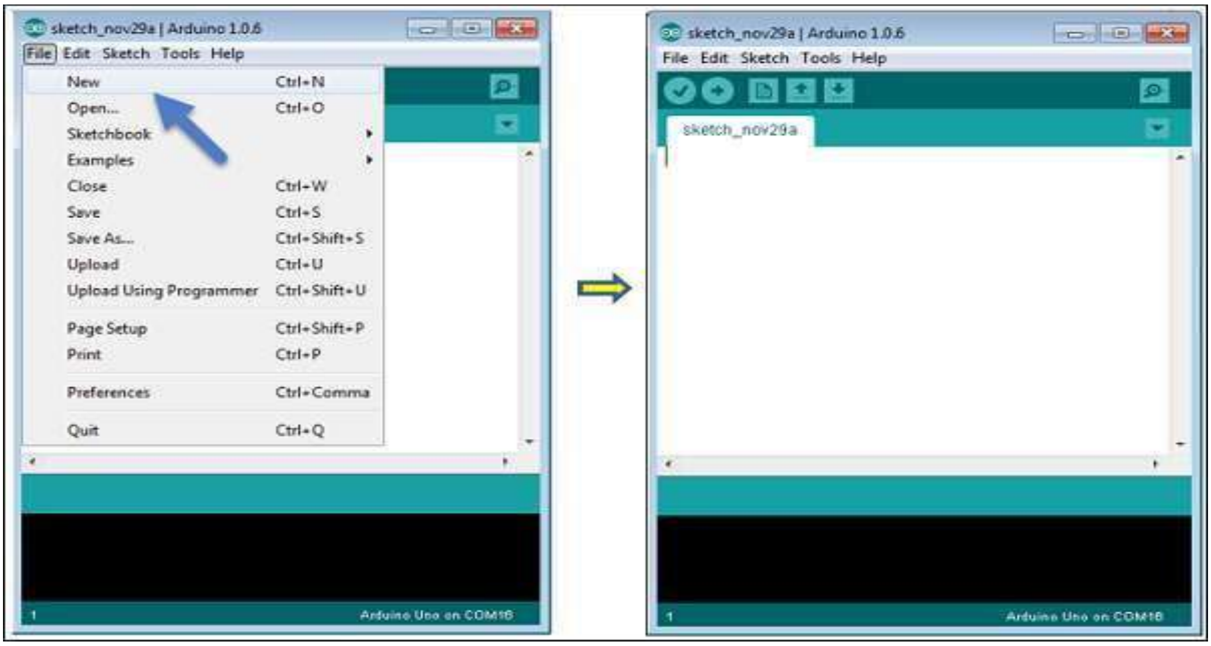

Fig.5.1.5 Open Your First Project

To open an existing project example, select File → Example → Basics → Blink.

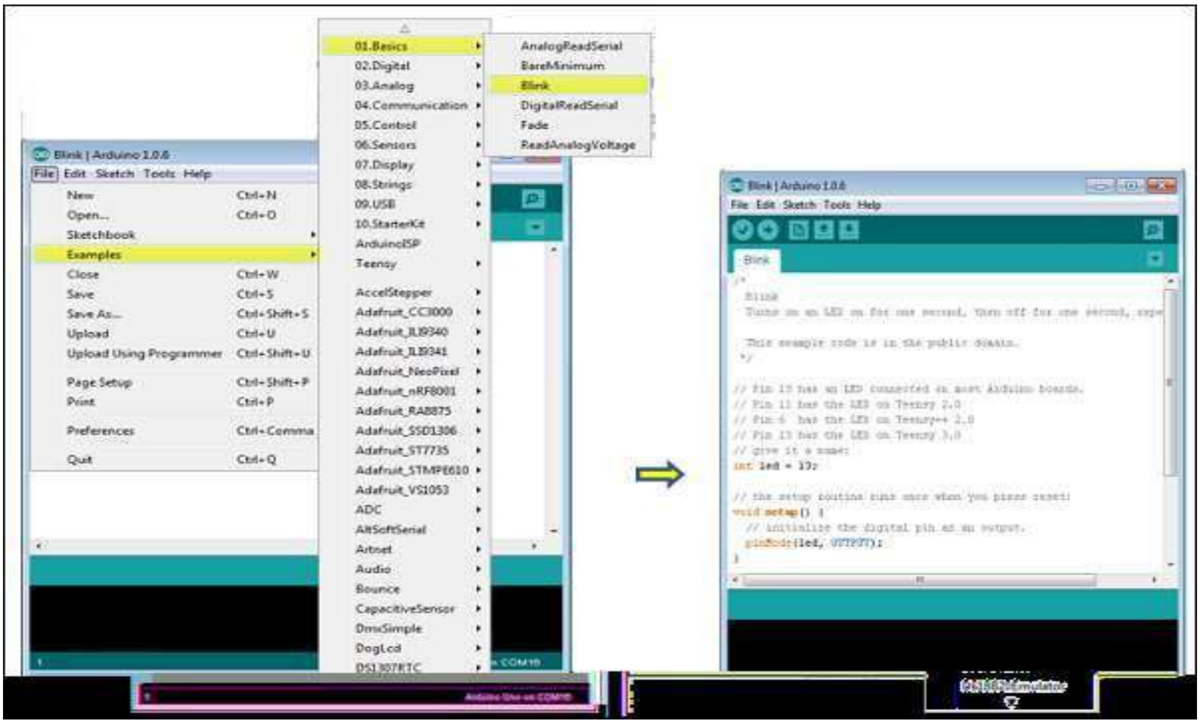

Fig.5.1.6 Open Your First Program

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

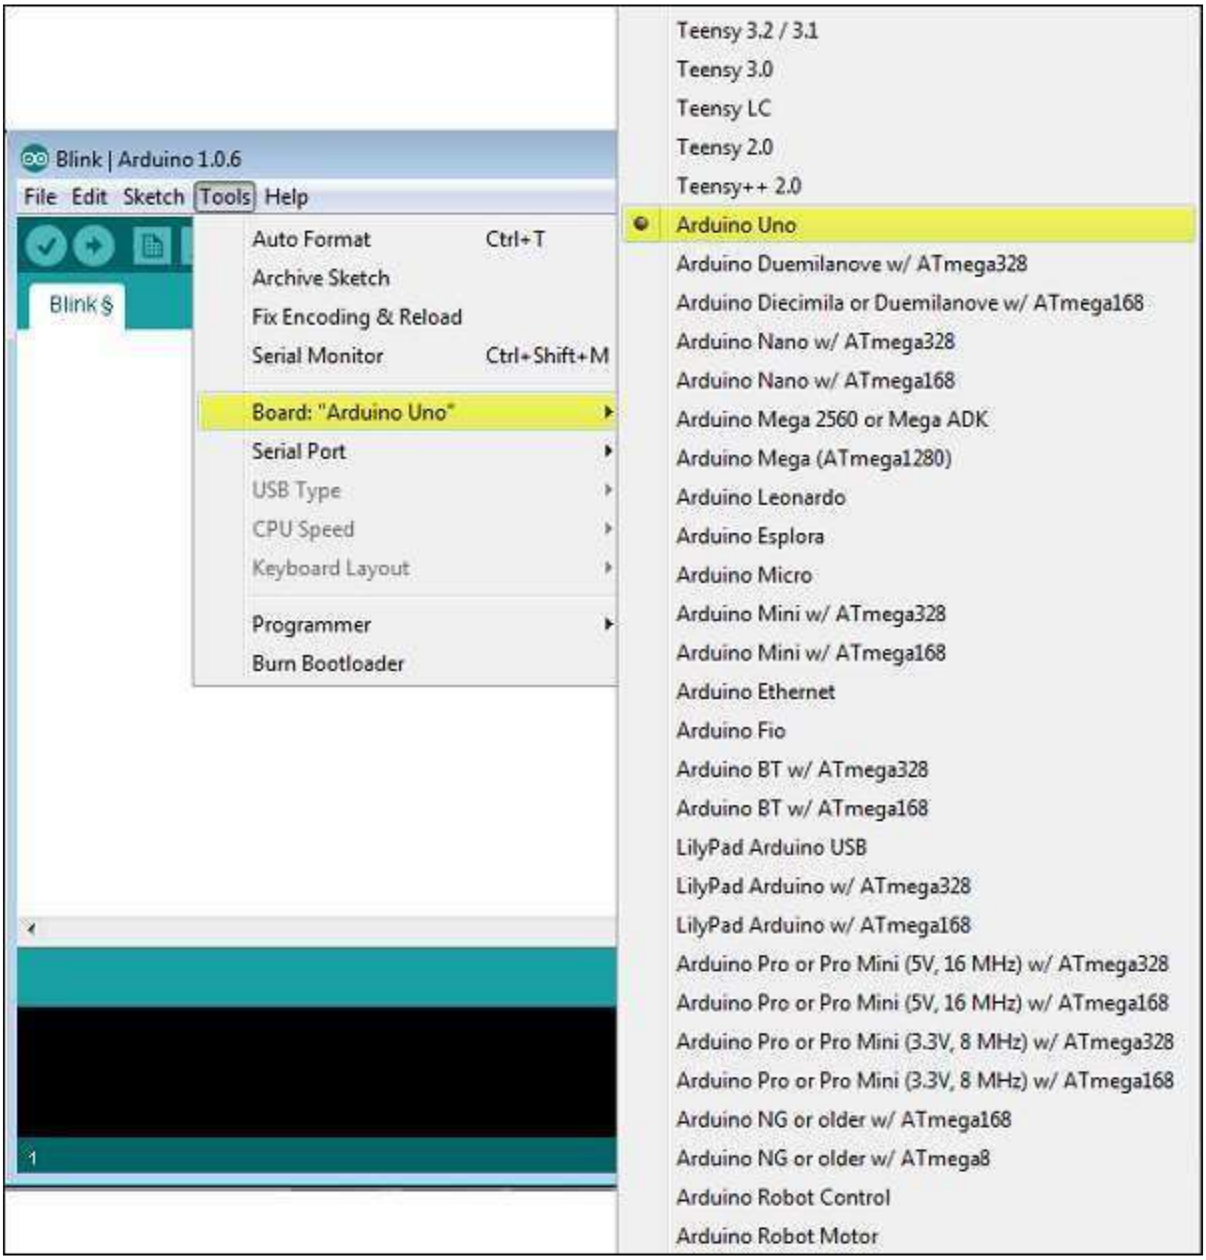

Fig.5.1.7 Select Your Arduino Board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

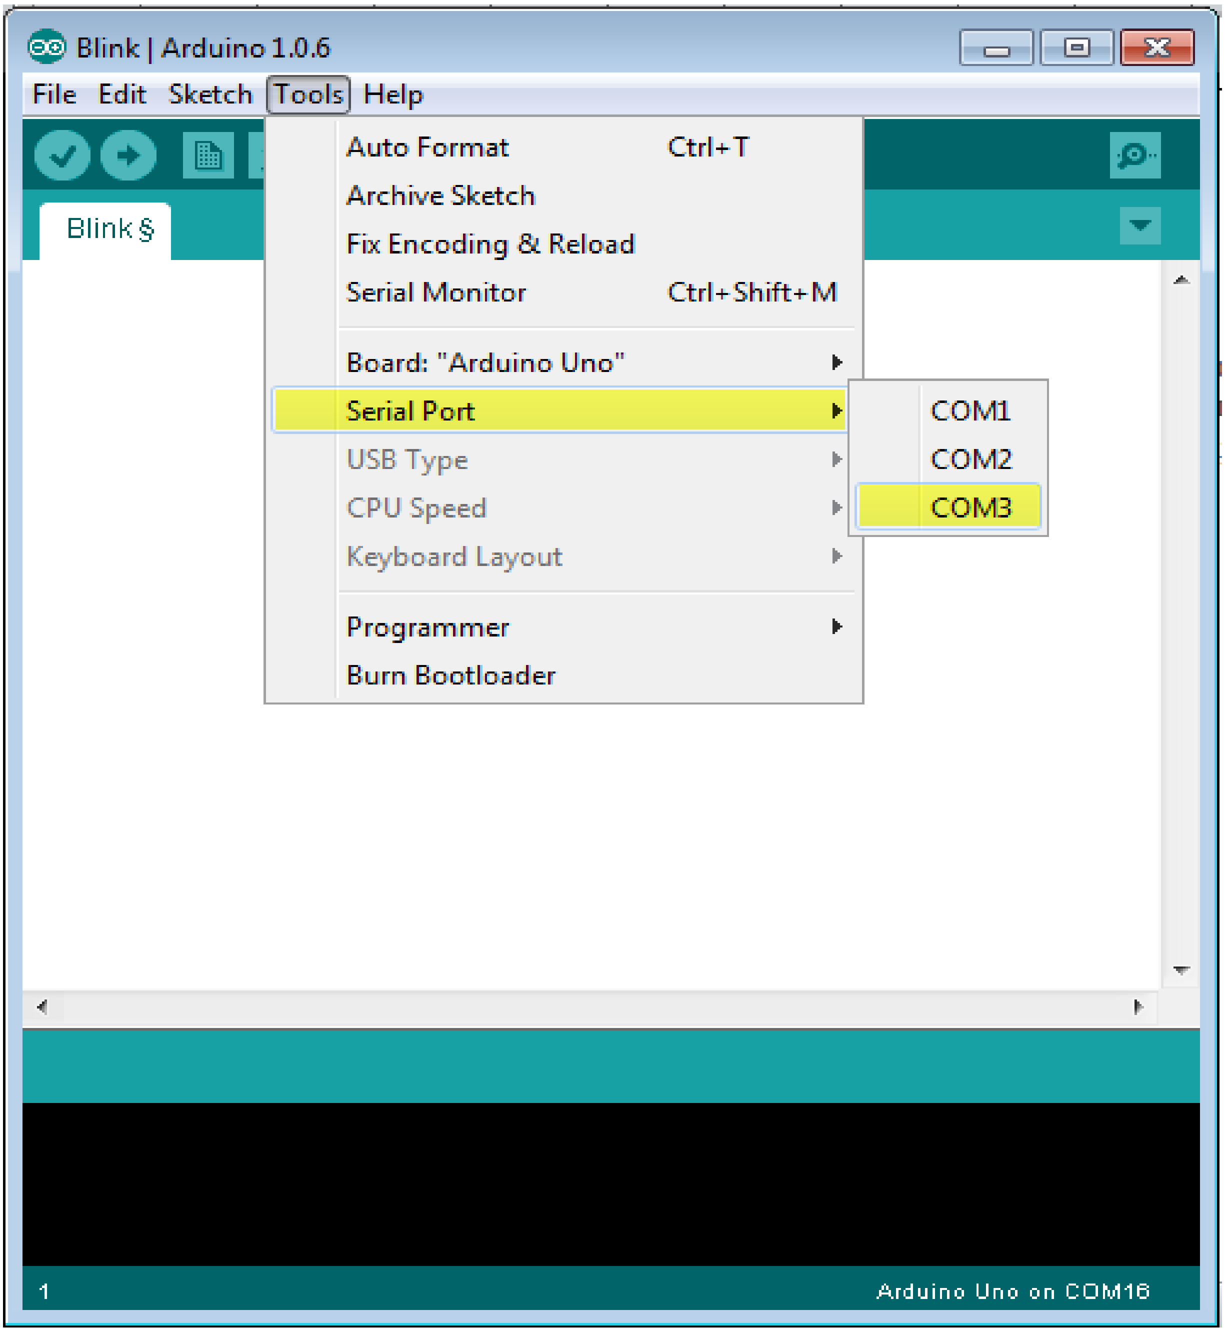

Fig.5.1.8 Select Your Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

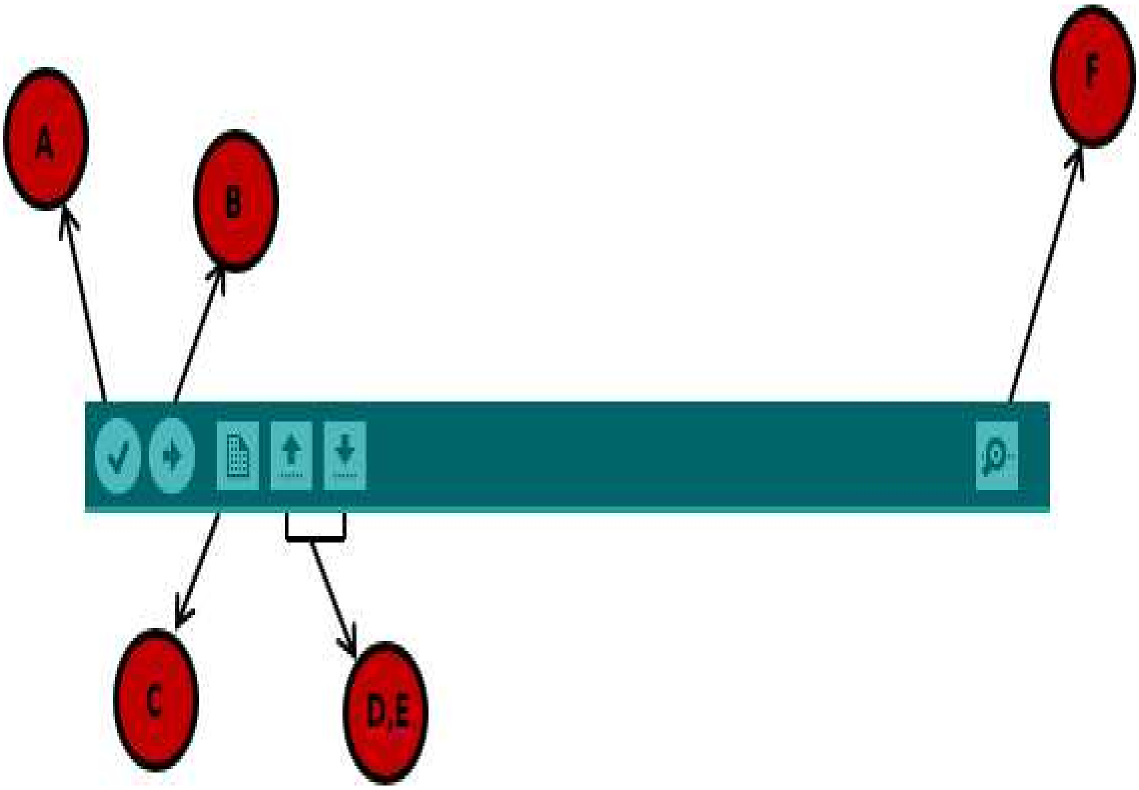

Fig.5.1.9 Upload the Program to Your Board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

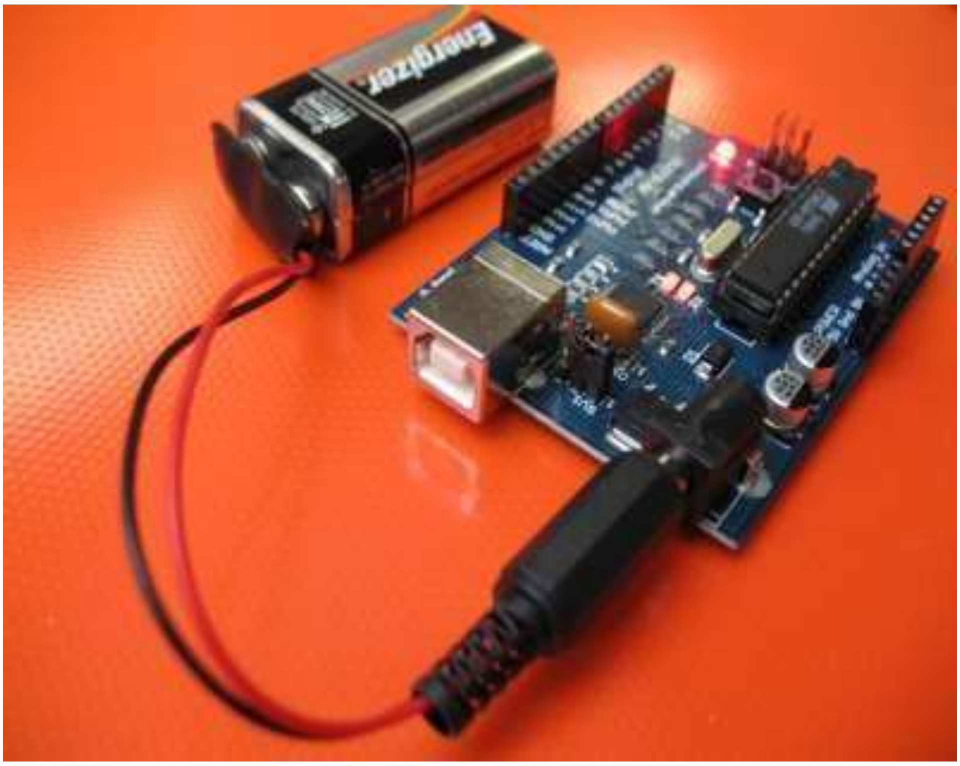

Fig.5.1.10 Connecting A battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run. Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig.5.1.11 Example Program

5.1.5 MC PROGRAMMING LANGUAGE: EMBEDDED C:

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

5.2 PROTEUS SOFTWARE:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto manual routing options to the PCB Designer.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

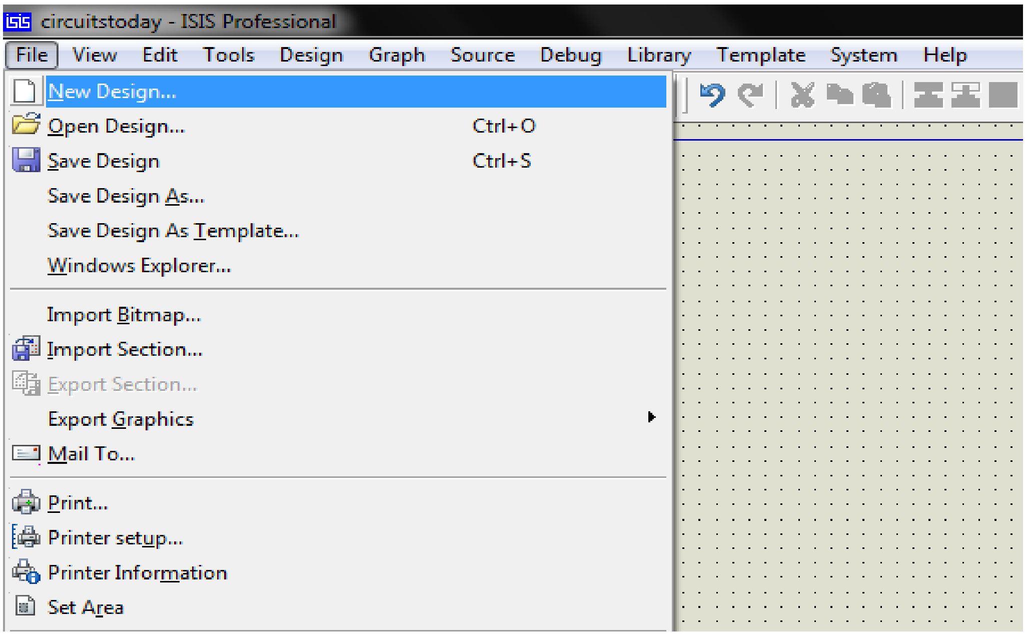

Fig.5.2.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

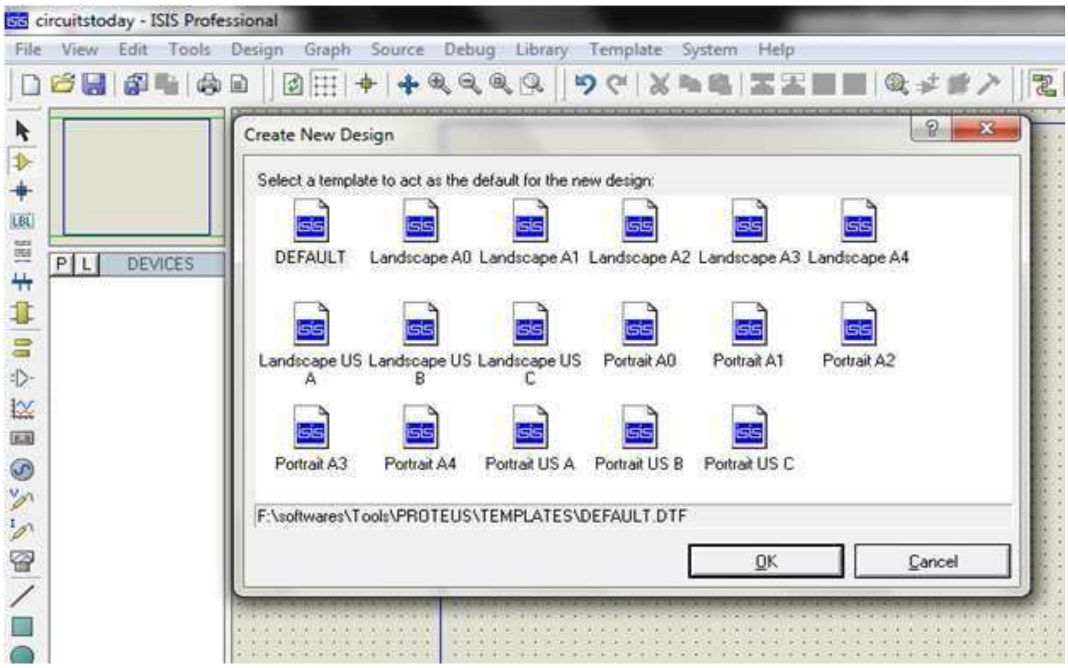

Fig.5.2.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

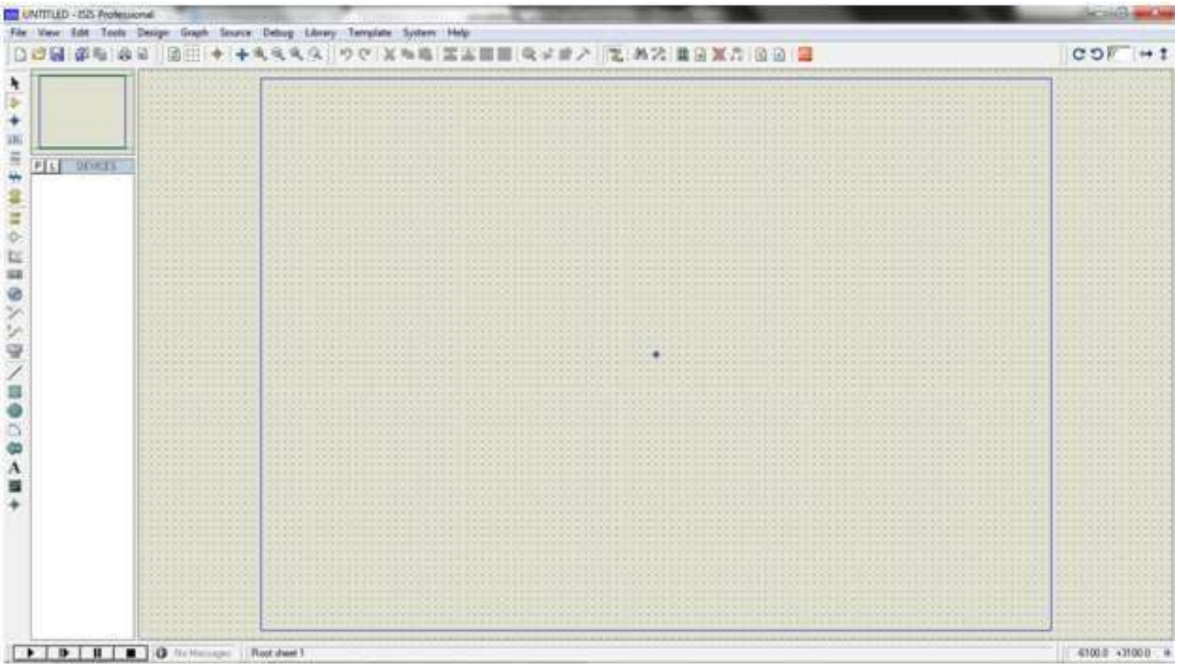

Fig.5.2.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

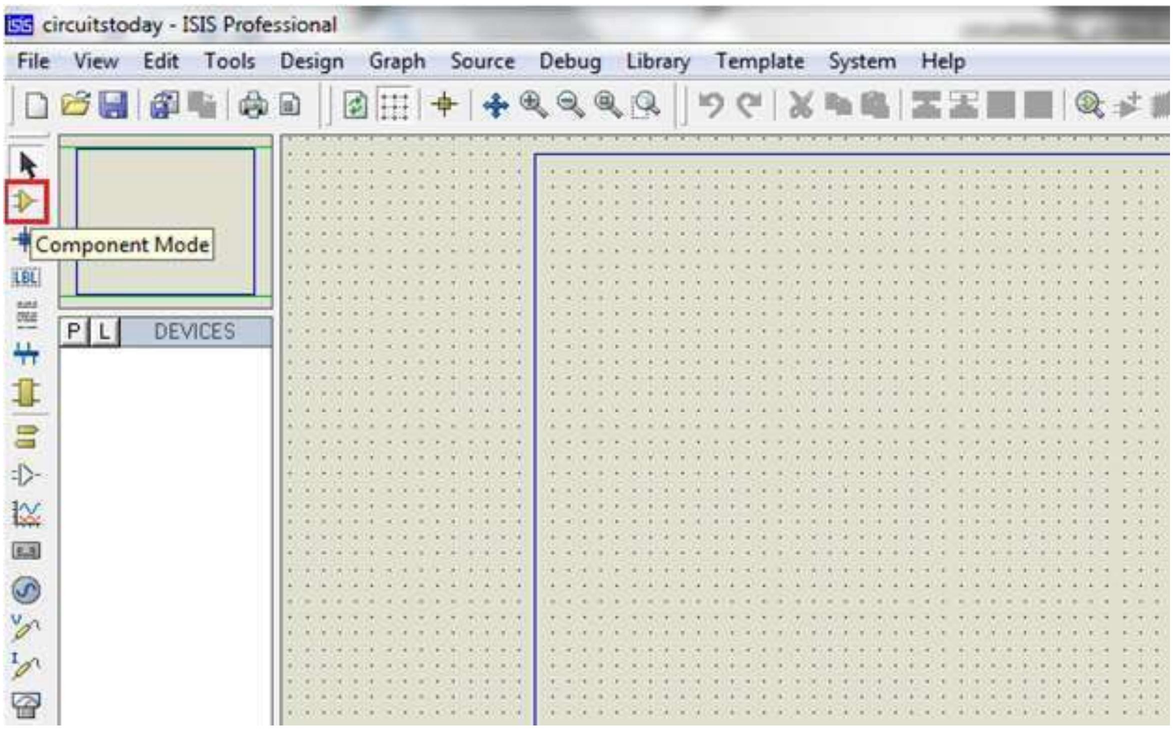

Fig.5.2.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

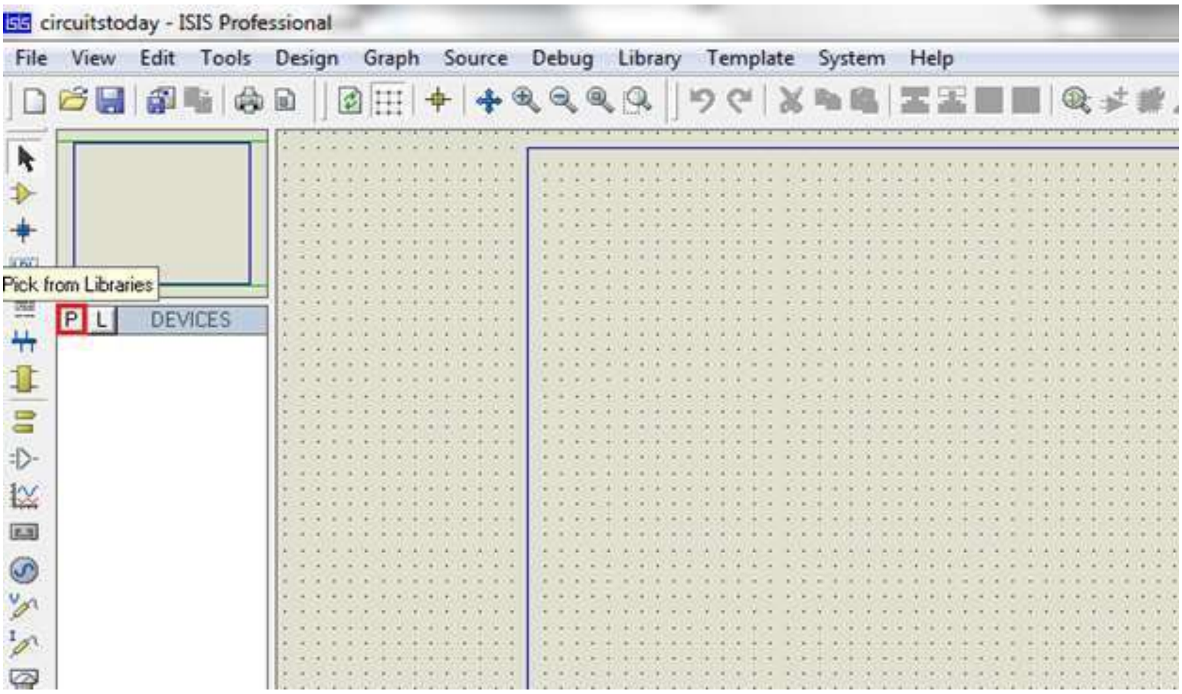

Fig.5.2.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

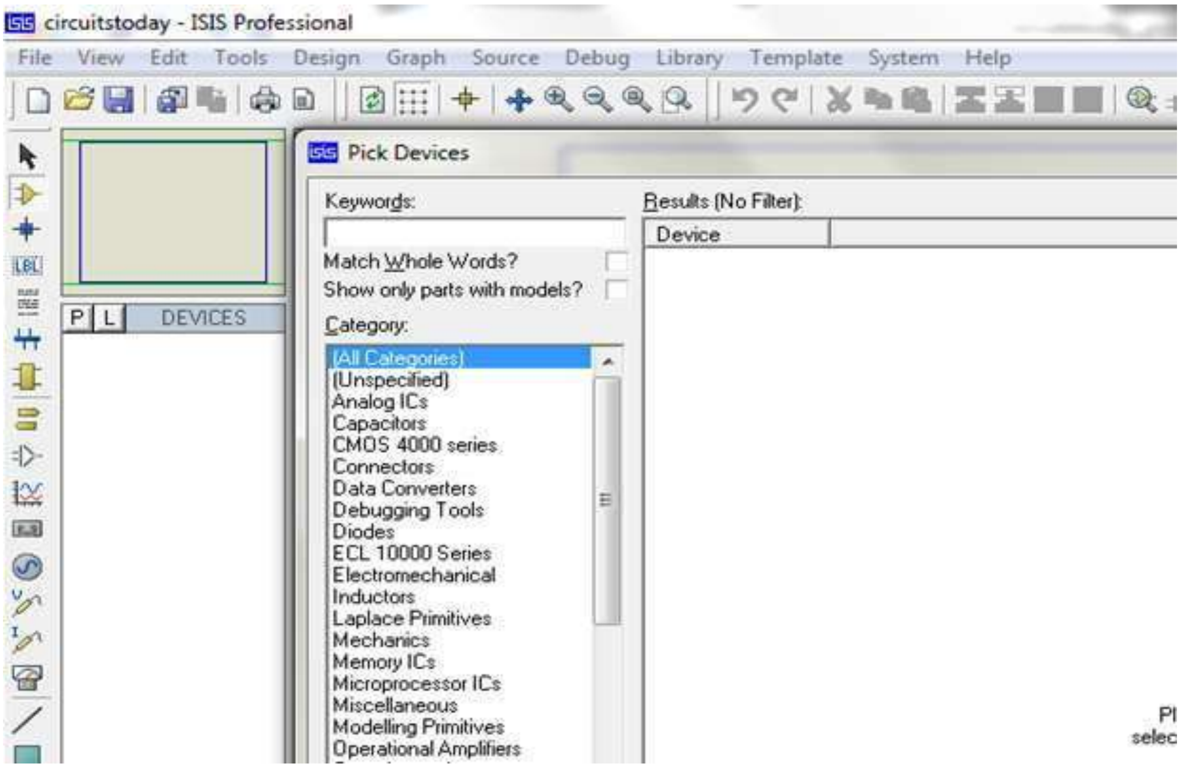

Fig.5.2.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

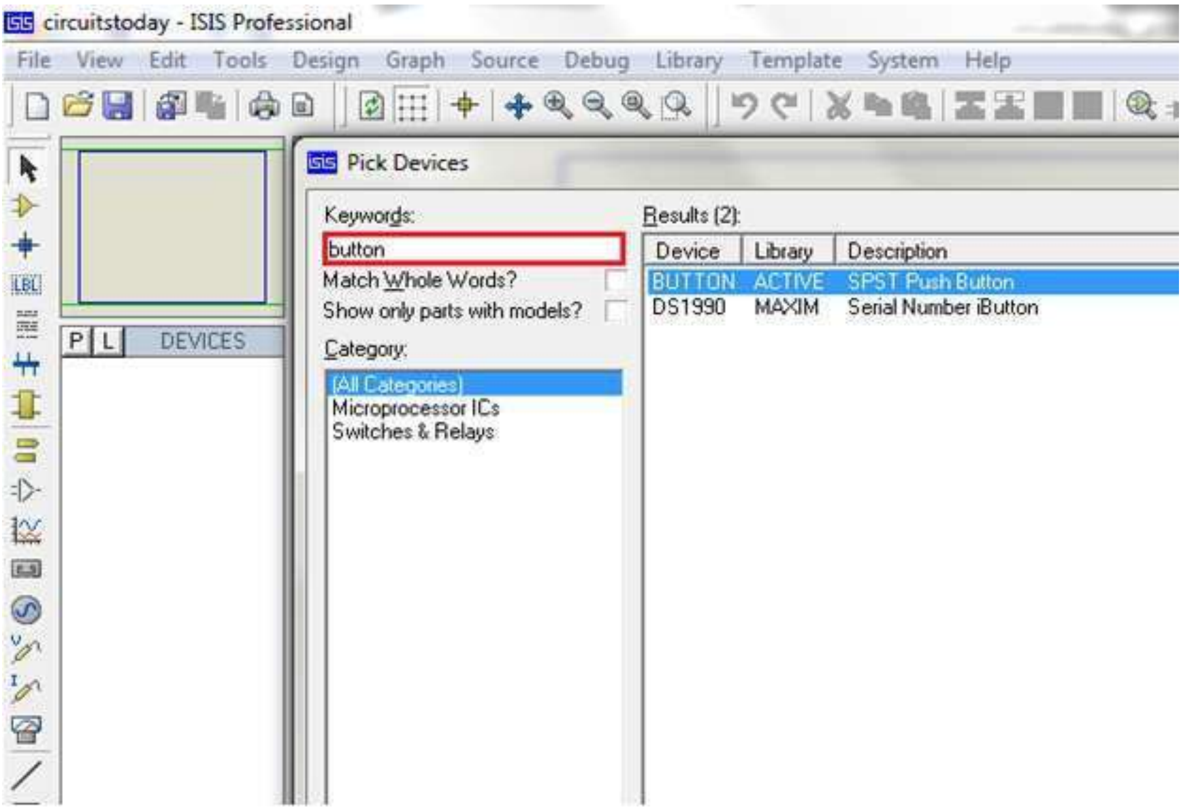

Fig.5.2.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

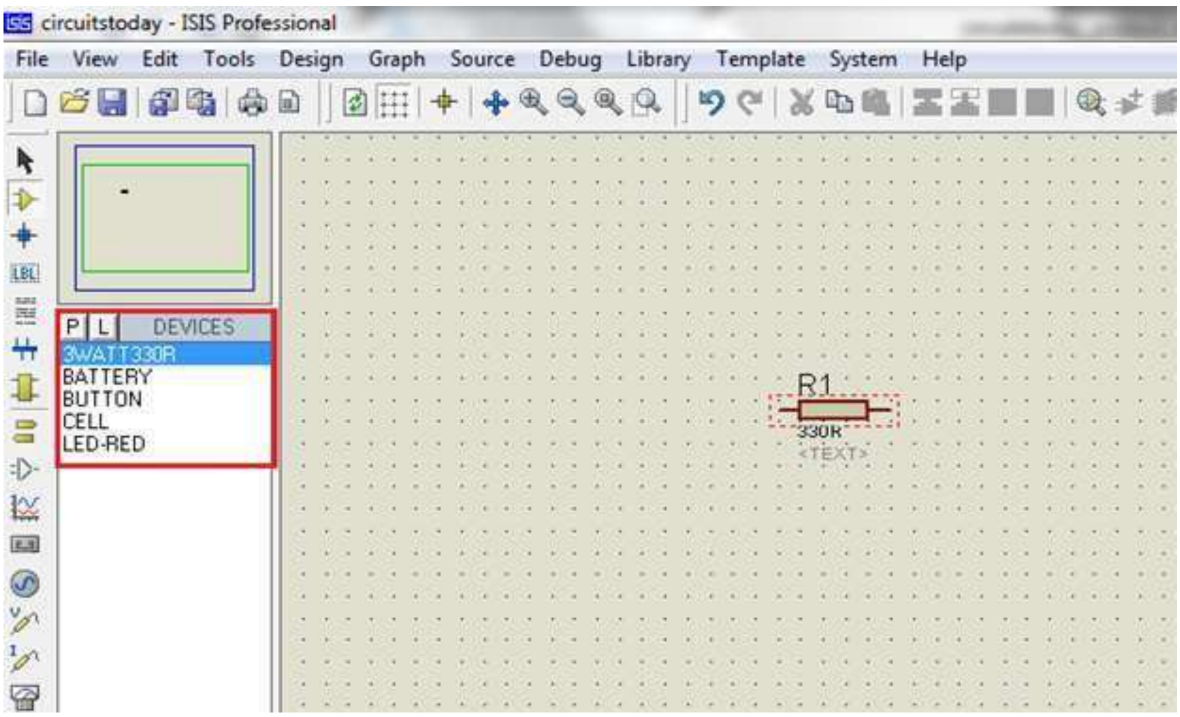

Fig.5.2.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

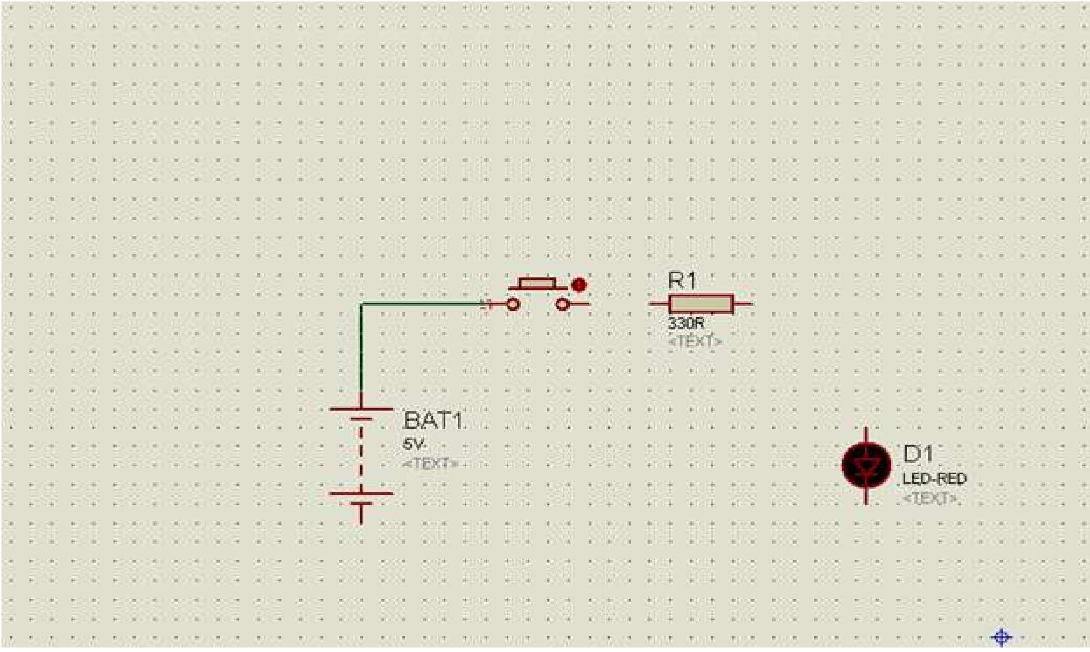

Fig.5.2.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

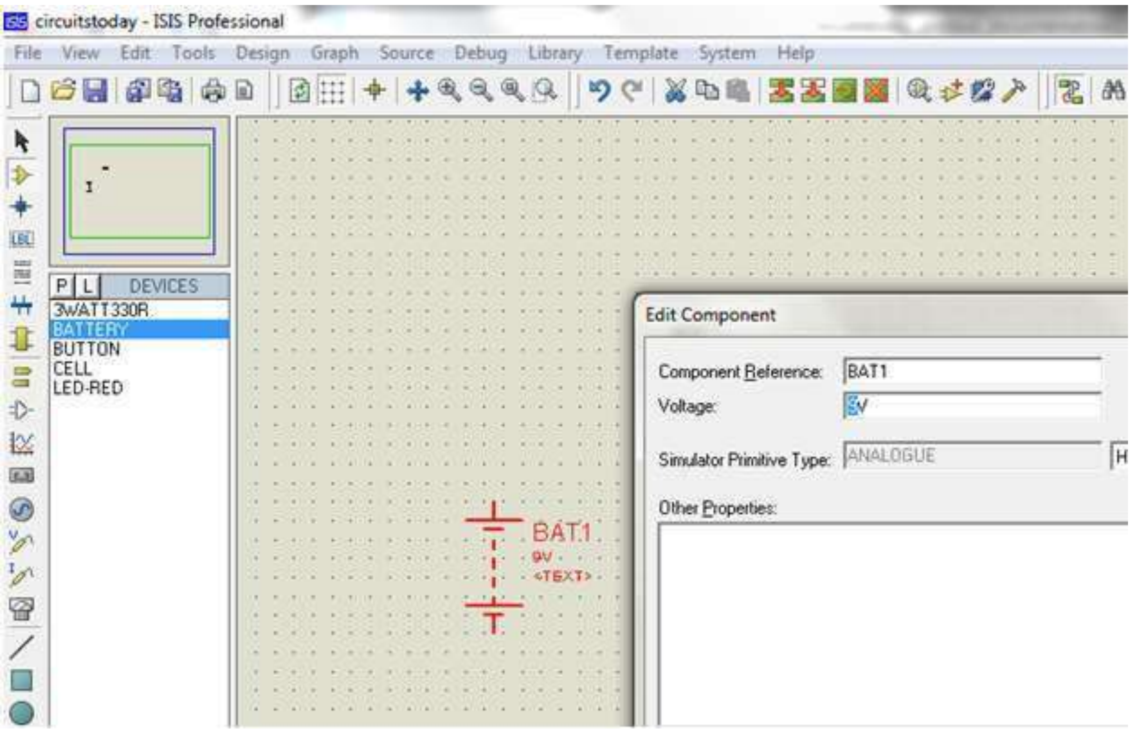

Fig.5.2.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

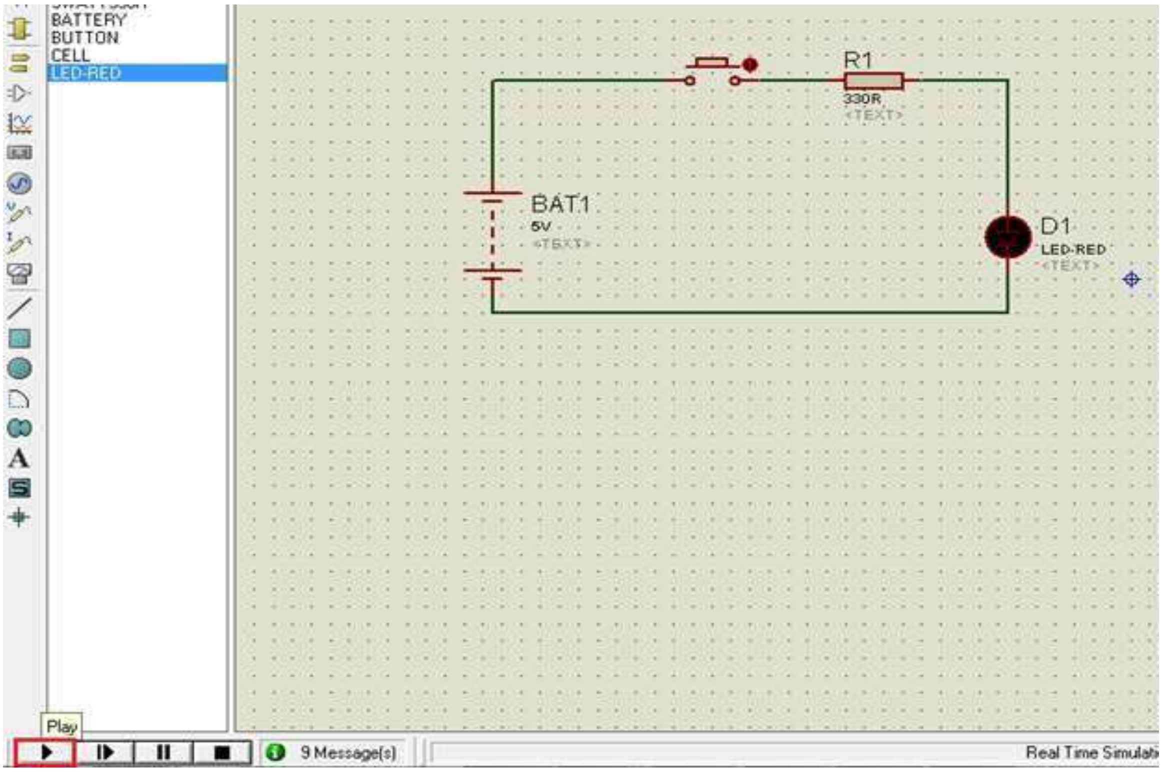

Fig.5.2.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

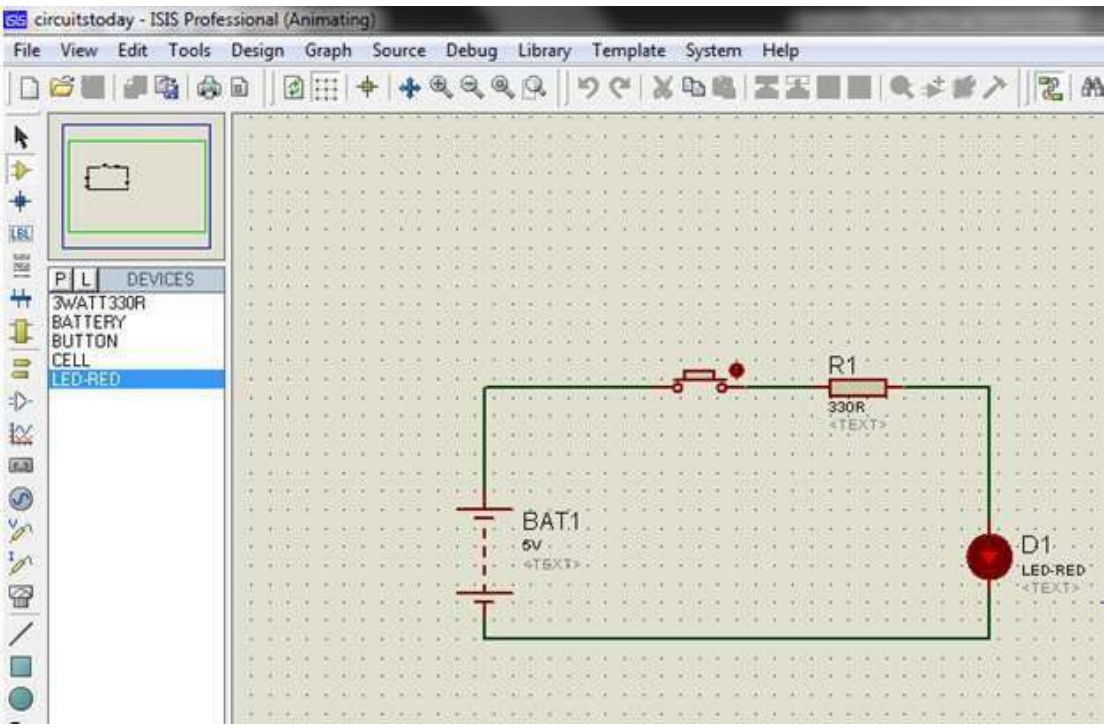

Fig.5.2.13 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

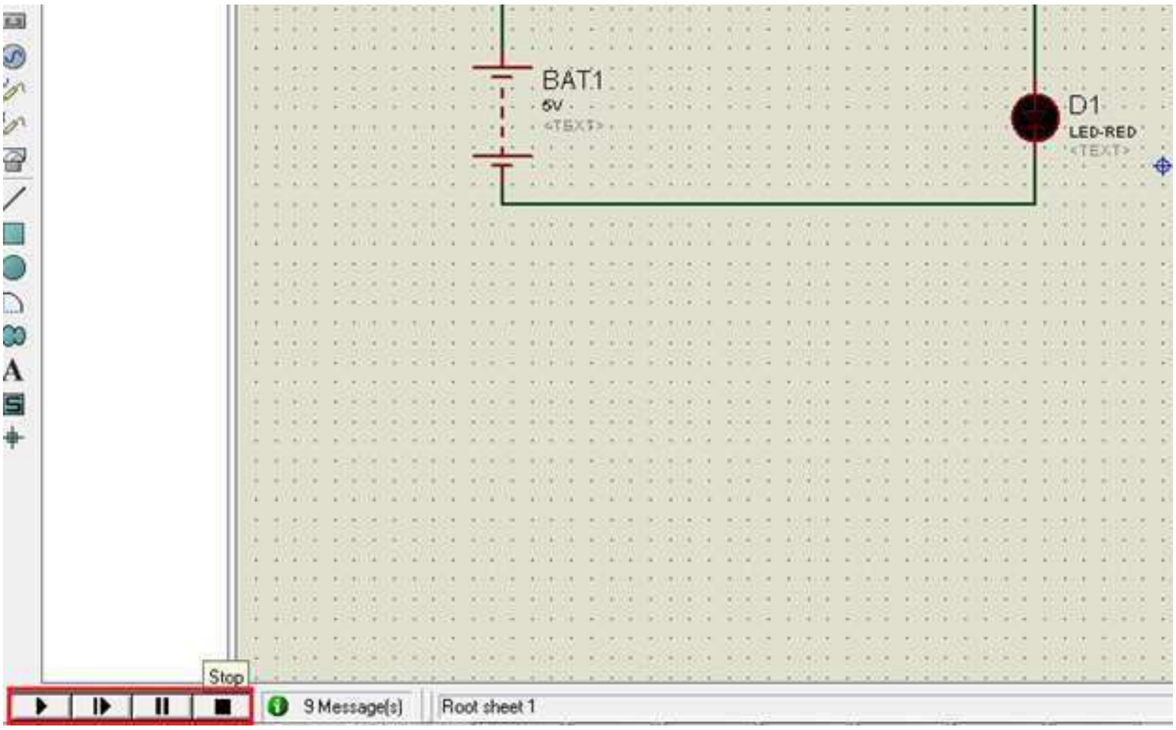

Fig.5.2.14 Simulation Step-Pause-Stop Buttons/

CHAPTER-6

PROJECT TESTING AND CODE IMPLEMENTATION

6.1 SOFTWARE TESTING:

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

6.2 TESTING LEVELS:

There are various testing levels based on the specificity of test.

- **Unit testing:** Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.
- **Integration Testing:** Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.
- **System Testing:** System testing tests a completely integrated system to verify that the system meets its requirements.
- **Acceptance testing:** Acceptance testing tests the readiness of application, satisfying all requirements.
- **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

6.3 SYSTEM TEST CASES:

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

6.4 CODE IMPLEMENTATION:

6.4.1 PROJECT CODE:

```
#include <LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);
#include <SoftwareSerial.h>
SoftwareSerial mySerial(2,3);

unsigned int hbpin = 4;
int hcount = 0, hbval = 0;
 int temp = A4,sound = A3,water = A5;
char res[130];

void serialFlush(){
  while(Serial.available() > 0) {
  char t = Serial.read();
  }
}

void myserialFlush(){

CHAPTER-7

PROJECT IMPLEMENTATION

7.1 BLOCK DIAGRAM OF PROJECT:

The system consists of an Arduino UNO microcontroller that is inbuilt with a Wi-Fi module. The UNO is a microcontroller based on ESP8266.It has 17 GPIO PINS(0-16) out of which 6 pins (GPIO 6-11) are connected to the flash memory chip .It has both input/output digital pins ,a single analog inputs, inbuilt Wi-Fi module and a USB connection . It contains everything needed to support the microcontroller; simply connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started. The micro-controller is attached with a temperature and humidity sensor (DHT11), a sound sensor, APR module, BJT and a servo motor. The sound sensor is used in order to detect the sound of the baby that is mainly when the baby cries it detects the sound and notifies the MCU. The MCU in turn notifies the Servo motor that makes the cradle swing. When a baby cries in the cradle, the microphone detects it and converts the sound signal into an electrical signal.

The electrical signal is then fed into an amplifier. The microcontroller then notifies the blynk server which in turn notifies the parent that the baby is crying. At the same time the microcontroller also notifies the parent through Wi-Fi module. If the baby relaxes and stops crying the parent is again notified that the baby is fine and stopped crying. The cradle stops swinging after a certain time. The temperature and humidity sensor consists of a material called thermistor and an IC on the back side of the sensor. For measuring humidity they use the humidity sensing component which has two electrodes with moisture holding substrate between them. So as long as the humidity change, the conductivity of the substrate changes or the resistance between these electrodes changes. On the other hand, for measuring temperature this sensors use a thermistor. A thermistor is actually a variable resistor that changes its resistance with the change of the temperature.

These sensors are made by sintering of semi conductive materials such as ceramics or polymers in order to provide larger changes in the resistance with just small changes in temperature. The resistance decreases with increase in the temperature. These changes in resistance is measured and processed by the IC which makes it ready to be read by a microcontroller. The microcontroller then notifies the blynk server which in turn notifies the parent about the temperature and wetness change. The microcontroller also notifies the BJT that in turn rotates the fan when the parent allows it to do so. The fan would also rotate incase the room temperature is high automatically.

The blynk app notifies every situation to the parent. Customization in blynk app can be easily done. The feeding time of the baby is accordingly preset and notified.

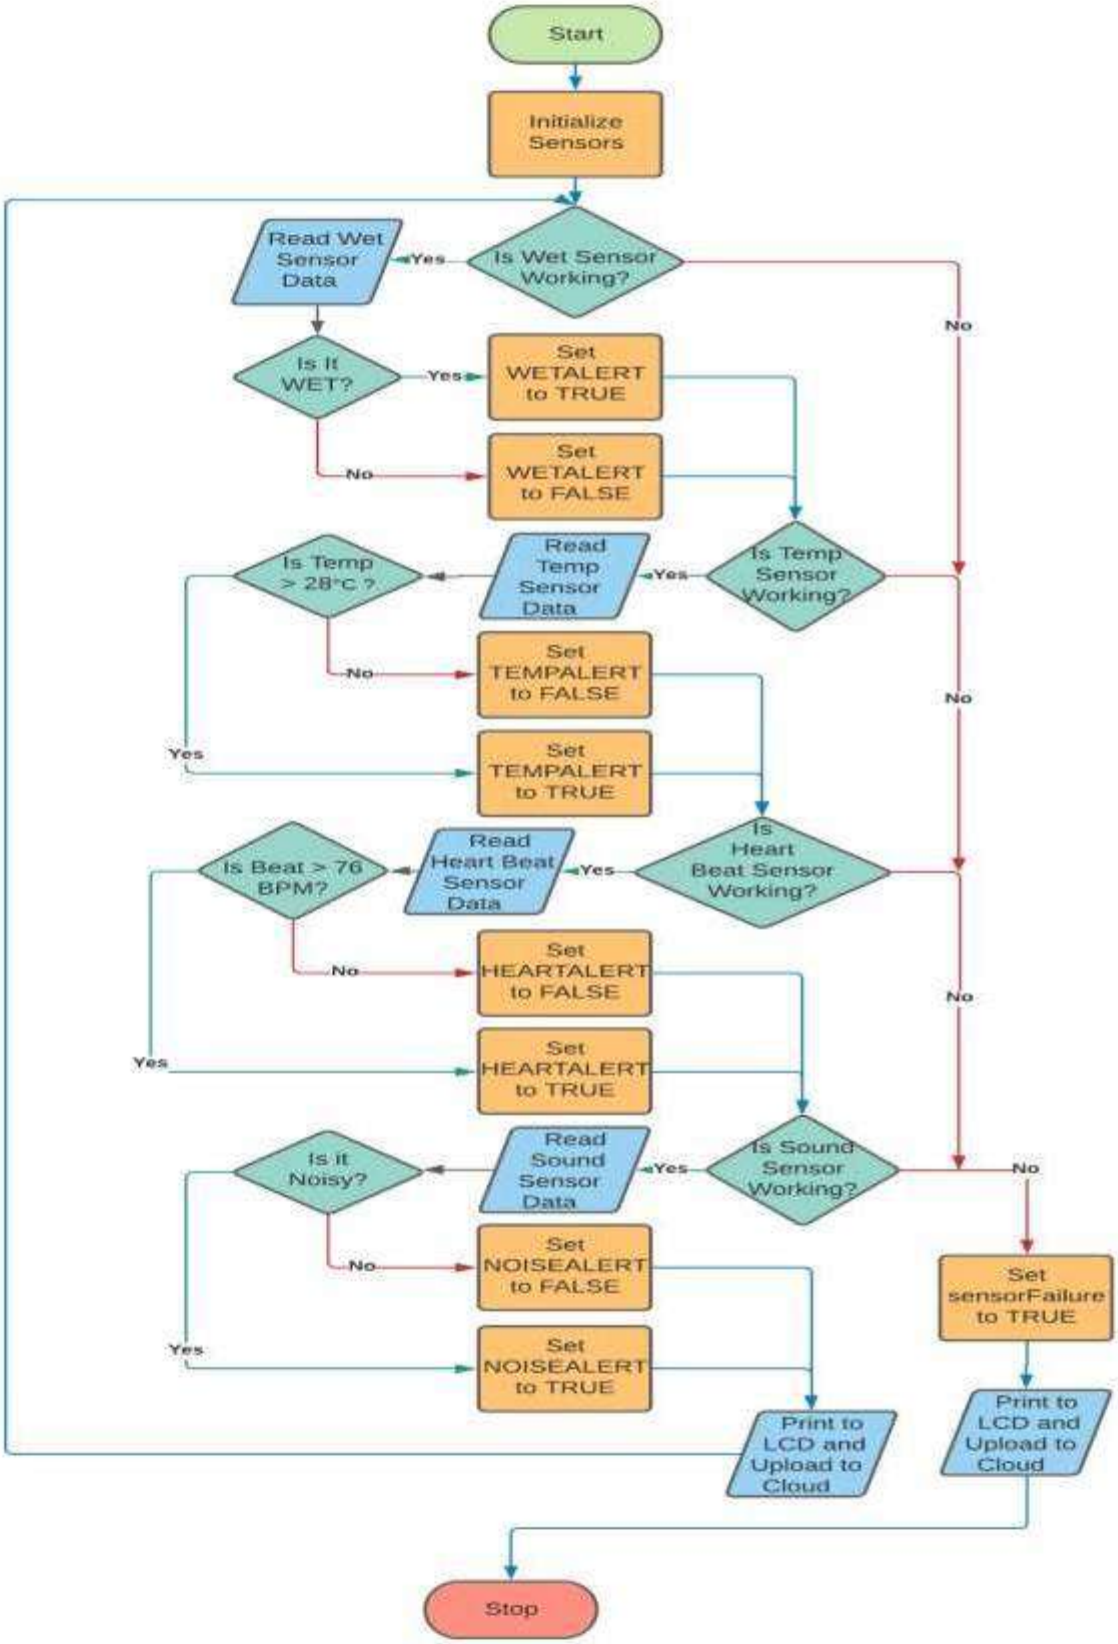

Fig.7.2 Flow Chart

7.3 RESULTS:

In this section, the results, discussion, and validation of IoT-BBMS are presented in detail. Figure 7.3.1 shows the final prototype of the developed smart cradle. Several manufacturing steps were carried out prior to the implementation of the control system for the smart cradle. The data measured by the utilized sensors, namely, sound sensor, heart beat sensor temperature, and wet sensor are updated to the Internet and can be accessed via the Adafruit MQTT server and MQTT Dash mobile applications. A mobile MQTT application, which is compatible with the Android operating system mobile phone, can be downloaded from the Play Store. The application's name is ''MQTT Dash,'' which can be synchronized with the Adafruit MQTT server. After some optimization and testing, we select this application for developing our dashboard due to its simplicity and user friendliness in terms of the view and usage.

During the synchronization process, the targeted MQTT server address is required, followed by the host port, the username, and the specified authentication token provided by the server. Figure 10 shows the requirements of the synchronization process for the mobile apps to share the same data received from the sensors. The password represents the authentication token (AIO key) generated by the MQTT server. As shown in Figures 7.3.2, the sensors data is uploading to server and MQTT Dash apps are synchronized and displayed the same readings uploaded by the NodeMCU microcontroller of the baby monitoring system. The smart cradle can swing automatically whenever sound is detected by the sound sensor. A notification, shown in Figure 7.3.2 is sent to the user through IFTTT mobile application to notify the user that crying is detected on the baby monitoring system. The user can also remotely control the cradle to swing manually by toggling the switch in the MQTT server or mobile apps. The mini fan is designed to turn on automatically whenever the room's temperature, measured by the temperature sensor, is higher than 28 ◦C. The user can also remotely switch the mini fan ON and OFF through the MQTT server and mobile application. A musical toy, which can be controlled by the user, is installed to entertain the baby. For visual monitoring of the baby's situation.

CHAPTER-8

CONCLUSION AND FUTURE ENHANCEMENT

8.1 ADVANTAGES:

- Cost efficient
- User friendly
- Ensure safety
- Minimum manual work
- Baby sooth comfortably
- Baby stays healthy

8.2 APPLICATIONS:

- Provide a smart solution for child care industry.
- Help working women balance their work and domestic chores.
- Can be used in day care centers for the aid of human beings.
- Can be utilized in nurses in maternity units of hospital.

8.3 CONCLUSION:

The integration of various sensors with Arduino will provide a better way for the monitoring of the baby. Recent advances in sensor technologies and wireless communication technologies enable the creation of a new generation of healthcare monitoring systems with wearable electronics and photonics. Parents in the present world are busy in their professional life, so they do not get sufficient time to take care of their babies. It may be expensive for the household to afford a nanny. The constant recording of multiple biological parameters of a baby and analysis of overall health helps a mother to understand the overall health condition of the baby, and can take actions for improvement, if necessary. Cradle temperature and wetness is also measured. This is an efficient system for monitoring the baby's health condition from any distance.

8.4 FUTURE ENHANCEMENT:

To enhance the security of the baby apart from the basic requirement more modules can be added like PIR sensor to detect the motion, camera to see the surroundings or the person who has been around the baby. The mobile app we used for the prototype model is the built in app for Bluetooth module. Depending upon the requirement, android or iOS app can be made which increases the scope of project in app development framework.

PUBLICATION

Submitted Paper in the Conference ICSMEC-21 with paper ID (ICSMEC21-0034) and got Acceptance for the Paper.

APPENDICES

This project shows, that the functionalities of the baby monitoring system can be completely managed using the 'Internet of Things' concept based on the IOT technology. In reference to survey of baby care by working parents, we examine and report on the conditions of total time spent to take care of the baby and by a particular working parents and further evaluate total time wastage as well as human errors involvement, while doing so. Finally, to provide an optimal solution, we consent with the idea of making baby cradle and health monitoring system completely automated, with assistance of IOT technology.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, our beloved Principal, St. Martin's Engineering College for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept. project coordinator Dr. A. Anand Kumar** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Ms. T. Sowmya, Assistant Professor**, Department of ECE and our class project coordinator **Ms. P. Pushpa**, **Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Malayadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

2. M. Dona Thomas
3. M. Harish Reddy

ABSTRACT

With heavy automation taking place these days, the number of industries as well as number of accidents in those industries have increased substantially. Human errors and manual safety systems lead to increase in industrial accidents. So here we propose a GSM based industrial protection system that detects gas, temperature as well as light to keep track of accidents. The system needs to detect if the temperature of a machine or environment goes above a certain level, if it goes above a level, it is an indication of a malfunction. So here we use temperature sensor to detect a possible accident. Next indication is the malfunction or overloading of machines leading to smoke. We use gas detectors to detect hazardous gas and similarly a light sensor to detect light due to spark or any flash caused due to malfunctions. All these indicators/sensors constantly provide their input to the microcontroller connected to them. The microcontroller constantly processes this data. On encountering a warning signal from any of these sensors the microcontroller now communicates this data to a GSM modem interfaced to it and sends out an SMS message to intended user as a warning.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

GLOSSORY OF TERMS

GSM- (Global System for Mobile Communications)

A digital mobile phone standard used extensively in Europe, the Middle East, Africa, Asia and in parts of America and Canada. First introduced in 1991, the GSM standard has been deployed at three different frequency bands: 900 MHz, 1800 MHz and 1900 MHz GSM 1900 is primarily deployed in North America. Named after its frequency band around 900 MHz, GSM-900 has provided the basis for several other networks using GSM technology. GSM uses narrowband TDMA which allows eight simultaneous calls on the same radio frequency. Along with CDMA and TDMA it represents the second generation of wireless networks.

2G: Second-generation mobile network or service. Generic name for second generation networks, for example GSM

Bandwidth: The range of frequencies available to be occupied by signals. In analogue systems, it is measured in terms of Hertz (Hz) and in digital systems in bit/s per second (bit/s). The higher the bandwidth, the greater the amount of information that can be transmitted in a given time. High bandwidth channels are referred to as broadband which typically means 1.5/2.0 Mbit/s or higher. Bit (binary digit): A bit is the primary unit of electronic, digital data. Written in base-2, binary language as a “1” or a “0”. Bit/s: Bits per second. Measurement of the transmission speed of units of data (bits) over a network. Also, kbit/s: kilobits (1’000) per second; Mbit/s: megabits (1’000’000) per second, and Gbit/s:

Gigabits (1’000’000’000) per second.

Sensor: A device, such as a photoelectric cell, that receives and responds to a signal or stimulus.

Server: (1) A host computer on a network that sends stored information in response to requests or queries.

(2) The term server is also used to refer to the soft-ware that makes the process of serving information possible.

SIM: Subscriber identity module (card). A small printed circuit board inserted into a GSM-based mobile phone. It includes subscriber details, security information and a memory for a personal directory of numbers. This information can be retained by subscribers when changing handsets.

SMS (Short Message Service): A service available on digital networks, typically enabling messages with up to 160 characters to be sent or received via the message Centre of a network operator to a subscriber's mobile phone.

Spectrum: The radio frequency spectrum of hertzian waves used as a transmission medium for cellular radio, radiopaging, satellite communication, over-the-air broadcasting and other services.

TD-SCDMA: Time Division Synchronous Code Division Multiple Access. A third-generation mobile standard under the IMT-2000 project. It uses spread spectrum CDMA technology in the TDD technique.

Wireless: Generic term for mobile communication services which do not use fixed-line networks for direct access to the subscriber.

Mobile: As used in this report, the term refers to mobile cellular systems.

Analogue: Transmission of voice and images using electrical signals. Analogue mobile cellular systems include AMPS, NMT and TACS.

Digital: Representation of voice or other information using digits 0 and 1. The digits are transmitted as a series of pulses. Digital networks allow for higher capacity, greater functionality and improved quality

Coverage: Refers to the range of a mobile cellular network, measured in terms of geographic coverage (the percentage of the territorial area covered by mobile cellular) or population coverage (the percentage of the population within range of a mobile cellular network).

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Protection is the main concern for every industry. Every industry wants to work in safe and secured that are beneficial for the Employees and specially for their production process say for raw materials in the industry. Every industry wants their workers to keep safe and secured from various incidents like accidents caused due to Fire detector or accidents due to fire in their go down or their machinery department.

Industry security is the most significant one for every industry owner. To get the absolute peace of mind whether you are at industry or out of industry you must ensure that your industry is installed with the perfect industry security monitoring system. This GSM Bases industrial security system can be used to provide security system for home, industrial, office, School, Collages using GSM technique. Security systems are certain electronic devices which are used to detect intrusions in industry.

The basic components of an industry automation security system are motion detectors, fire detectors and motion detector. It is cheaper and maintained easily than any other security device. All the sensors are activated on the Security system. Whenever systems experience abnormal condition in the industry like any fire/smoke occurs in the industry and any intrusion into the industry the Security system alerts the security personnel as well as the owner of the industry by sending SMS alerts to the users of the industry. The system operates with the help of sensors installed in this system.

1.2 OBJECTIVES OF THE STUDY:

The main objectives of this project Industrial Protection Systems using GSM are:

i. To understand and gain knowledge about the function of Arduino, wireless sensors system and the basic concept of GSM Technology.

ii. To design an Industrial Protection Systems using GSM that requires low cost, low power consumption and user friendly.

iii. Industrial safety is needed to check all the possible chances of accidents for preventing loss of life and permanent disability of any industrial employee, any damage to machine and material.

iv. To eliminate accidents causing work stoppage and production loss.

v. To reduce workman's compensation, insurance rate, and all the cost of accidents.

vi. To achieve better morale among industrial employees.

vii. To prevent accidents in the industry by reducing any hazards.

Specific Objectives

i. To interface LM35 temperature sensor, GSM SIM800l Modem, 16X2 LCD, and process control devices (through relays) with the Arduino UNO.

ii. To send the measured temperature to distant user wirelessly with the help of GSM module (SIM 800) Via SMS.

iii. To send commands through user's mobile phone to control the process control devices based on sensed sensor readings.

iv. To test and implement the GSM Based Industrial Process Monitoring and Control System.

1.3 SCOPE OF THE STUDY:

The scope for this project focuses primarily on the protection system in the industries. In this study, GSM technology is used to establish a protection system for industries and by applying the wireless sensory system to detect and collects the parameter information like smoke, gas, temperature, and fire. The other purpose is that the designated system could be able to transmit and receive the information through SMS (Short Message Service) or Call using GSM (Global System for Mobile communication) technology in case of crisis or emergency event occurred. The Arduino Uno act as the micro-controller for the protection system. The idea is to see how well this project can benefit the industries in term of secureness and protection. The scope includes connecting the different industrial process control systems to relays for controlling the industrial environment complex tasks like nuclear plants and reactors in the industry. A GSM server is implemented with Arduino, sensors and relays. The GSM Modem can provide the necessary data related to the industry to a maintenance officer located anywhere at any time. According to data received officer will take some action by sending some AT commands to Arduino through mobile unit to GSM modem. Arduino decodes the commands and controls the industrial process devices through relays.

Significance of the project

i. Industrial and Factory process monitoring and control delivers increased productivity and improves product quality.
ii. It also presents real-time data that helps in making informed decisions.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino UNO
- LCD
- Power Supply
- Buzzer
- GSM Module(800l)
- Temperature Sensor (LM35)
- Light Sensor (LDR Sensor)
- Gas Sensor (MQ2)
- 12V DC Motor

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

We collected all the required components and to interface it ,checked the working condition of all the sensors.
Also, verified the threshold values of Sensors, which are helpful in calculating the exact values.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

Majority of the companies in INDIA have not implemented Automatic protection systems in industry. Except few large industries majority of the companies cannot afford to invest huge amount of money in the existing costly setups to meet the requirements of Industrial Automation.

Existing methods widely use the following technologies to communicate the information from one end to the other end of the company.

Using Bluetooth — But it is limited to short range.

Using Zigbee/ IEEE802.15.4 — Range is up to only few Kms maximum.

Using Wi-Fi — Requires costly equipment setup and high-power consumption.

All the methods discussed above are quite expensive and complex to implement and not very reliable. The availability of information at various nodes simultaneously is not achieved.

Bluetooth Technology

Bluetooth Technology is a radio frequency (RF)-based, short-range connectivity technology that promises to change the face of computing and wireless communication. It is designed to be an inexpensive, wireless networking system for all classes of portable devices. The projected cost of the Radio chip was around $5.

A complete Bluetooth system will require these elements:

- An RF portion for receiving and transmitting data includes short-range radio transceiver, an external antenna, and a clock reference (required for synchronization)
- A module with a baseband microprocessor
- Memory
- An interface to the host device (such as a mobile phone)

Its normal range of operation is 10m (at 1mW transmit power) and can be increased up to 100m by increasing the transmit power to 100mW. The system operates in unlicensed 2.4 GHz frequency-band; hence it can be used worldwide without any licensing issues. It provides an aggregate bit rate of approximately 1Mbps.

Zigbee Technology

The Zigbee radio specification designed for low cost and power consumption than Bluetooth. The specification is based on IEEE 802.15.4 standard. The radio operates in the same ISM band as Bluetooth and is capable of connecting 255 devices per network. The specification supports data rates of up to 250Kbps at a range of up to 30m. These data rates are slower than Bluetooth, but in exchange the radio consumes significantly with low power with a large transmission range. The goal of Zigbee is to provide radio operation for months or years without recharging, thereby targeting applications such as sensor networks and inventory tags. The beauty of Zigbee is that devices from different manufacturers will be able to work together, as long as all are compliant to the standard. It has been suggested that the name evokes the haphazard paths that bees follow as they harvest pollen, similar to the way packets would move through a mesh network.

Zigbee is standardized at two levels – the radio chips must follow certain design rules, and the protocol layers that actually make the network function are defined and controlled by the Zigbee Alliance. Advantages are: Reliable and self-healing, supports large number of nodes, Easy to deploy, very long battery life, Secure and Low cost.

Wi-Fi Technology

Wi-Fi is the name given by the Wi-Fi Alliance to the IEEE 802.11 suite of standards. 802.11 defined the initial standard for wireless local area networks (WLANs).

But because of its costly equipment setup and high-power consumption this technology is not preferred.

2.2 REVIEW ON RELATED LITERATURE:

GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. GSM is an international digital cellular telecommunication. The GSM standard was released by ETSI (European Standard Telecommunication Standard) back in 1989. In less than ten years since the first GSM network was commercially launched, it became, the world's leading and fastest growing mobile standard, spanning over 190 countries.

GSM characteristics

Mobile Frequency Range RX: 925-960; TX: 880-915

Multiple Access Method TDMA/FDMA

Duplex Method FDD

Number of Channels 124 (8 users per channel)

Channel Spacing 200kHz

Modulation GMSK (0.3 Gaussian Filter)

Channel Bit Rate 270.833Kb

Global System for Mobile (GSM) is a second-3

generation cellular standard developed to

deliver high quality and secure mobile voice and data services (such as SMS/ Text Messaging) with full roaming capabilities across the world using digital modulation.

Rozita Teymourzadeh, Salah Addin Ahmed, Kok Wai Chan, and Mok Vee Hoong suggested Smart GSM Based Home Automation System. This research work investigates the potential of 'Full Home Control', which is the aim of the house Automation Systems in near future. The implementation of the house automation technology using Global System for Mobile Communication (GSM) modem to manage home appliances like security system via SMS, light conditional system. The proposed research work is targeting functionality of the GSM protocol, which allows the user to manage the target system faraway from residential using frequency bandwidths. The concept of AT commands Nd serial communication has been applied towards development of the smart GSM-based home automation system. Home owners are going to be ready to receive feedback status of any home appliances in check whether switched on or off remotely from their mobile phones. PIC16F887 microcontroller with the mixing of GSM provides the smart automated house system with the specified baud of 9600 bps. The proposed prototype of GSM based home automation system was implemented and tested with maximum of 4 loads and shows the accuracy of ≥98%.

2.3 CONCLUSION ON REVIEWS:

In this chapter it will review and discuss about the "Industrial Protection System using GSM". The idea of this project originates from the problem faced by any user to inspect the condition/surrounding area in industries. Sensor detection of a remote place could be difficult or sometimes impossible for example in places where humans are prohibited to enter. The problem can be solved by using wireless sensor network to ensure the safeties of the area can be in check continuously by the user at any time and from anywhere. This chapter will explain about all the components that will be used and some related researches regarding this project. This chapter begins with a general outline of GSM technology, wireless sensor network, microcontroller (Arduino), and others related components. The second part of this chapter is dedicated to a related research that has correlation with this project "Industrial Protection System Using GSM". The third part of this chapter is the overview of the GSM standard, wireless sensor network, microcontroller (Arduino), and others hardware or software that are used in this project.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

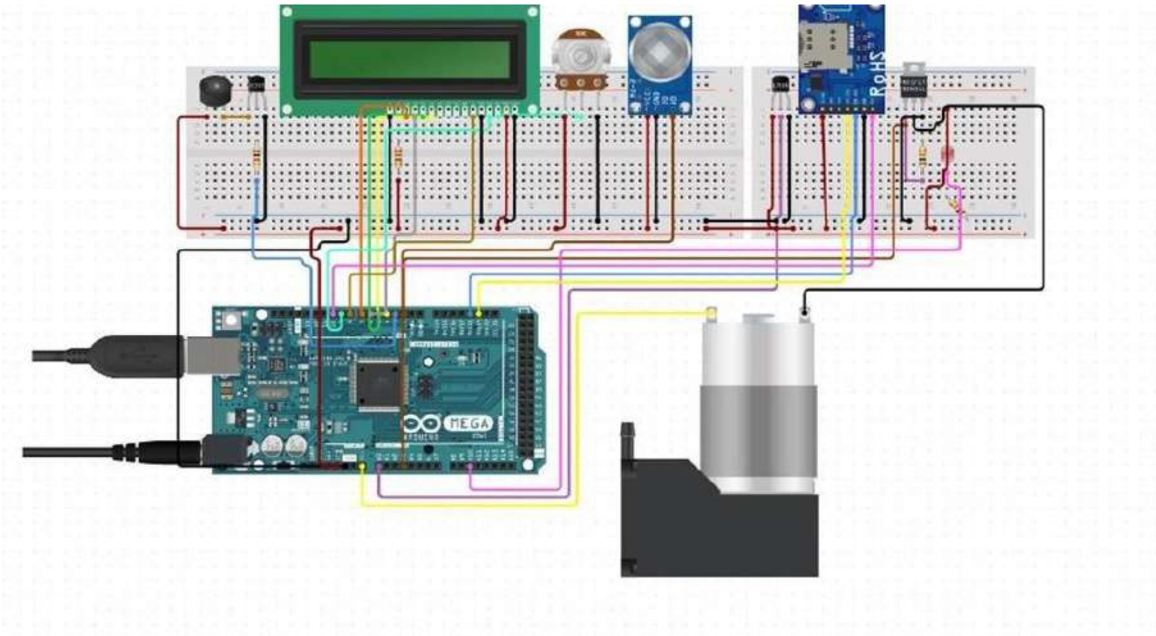

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

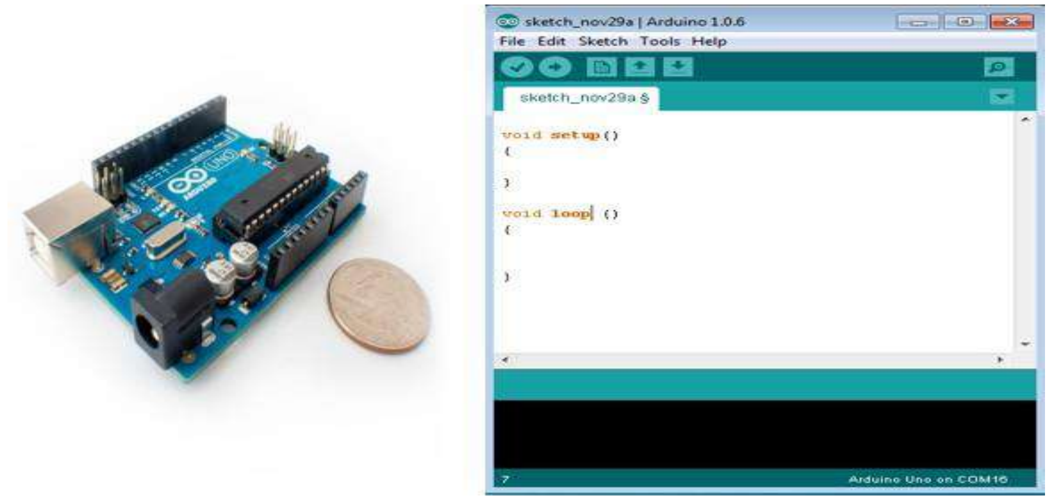

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

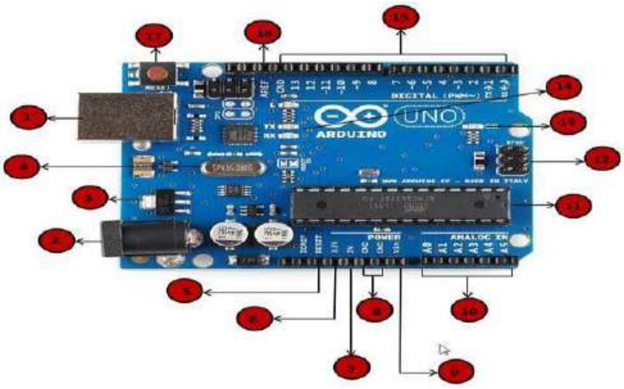

Fig.3.2.1.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.

4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of

	MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.3: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

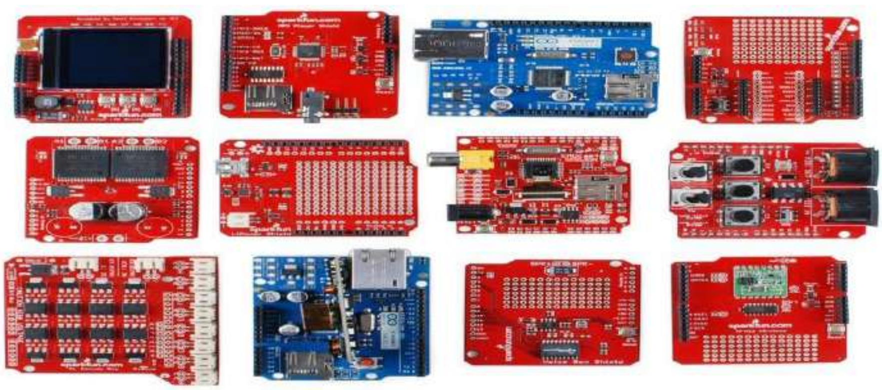

Fig.3.2.1.4: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

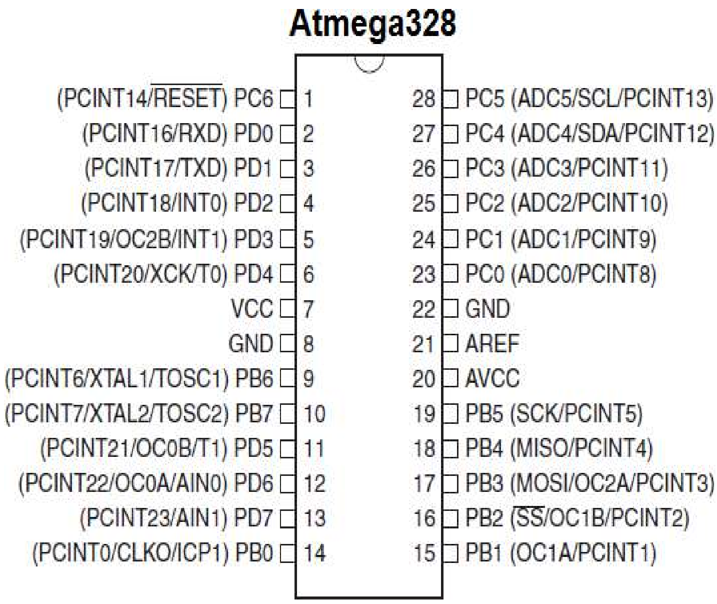

Fig.3.2.1.5 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

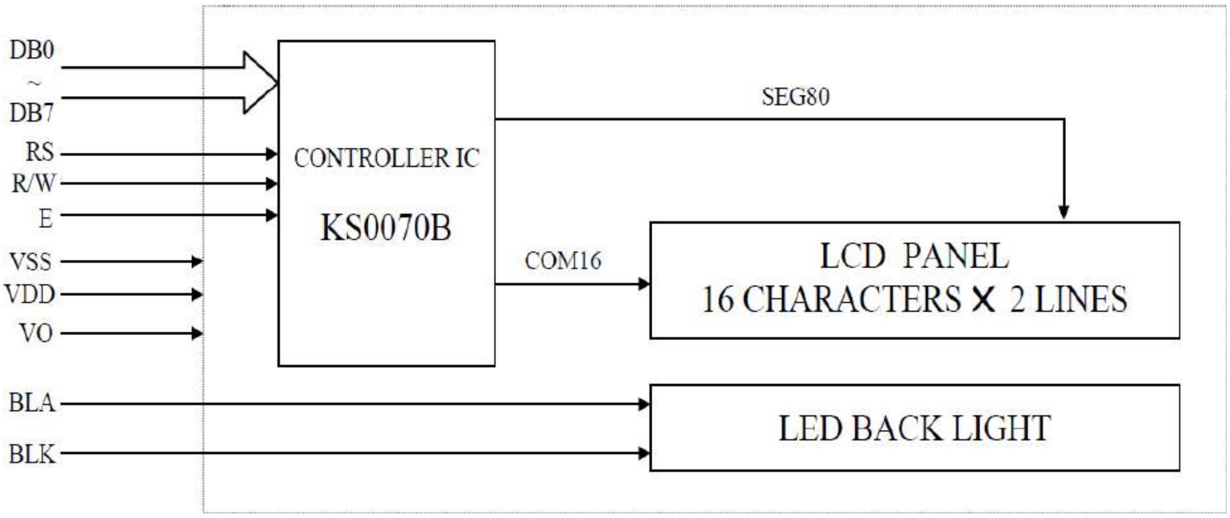

Fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So, whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

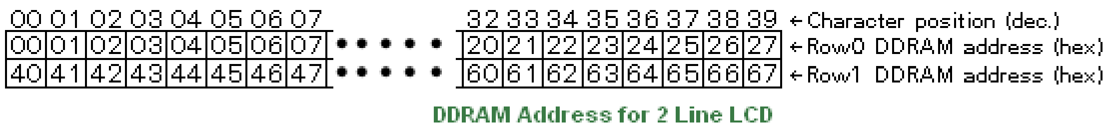

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is a status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e., BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g., LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16-character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 BUZZER

3.2.3.1 MAGNETIC TRANSDUCER

Magnetic transducers contain a magnetic circuit consisting of an iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

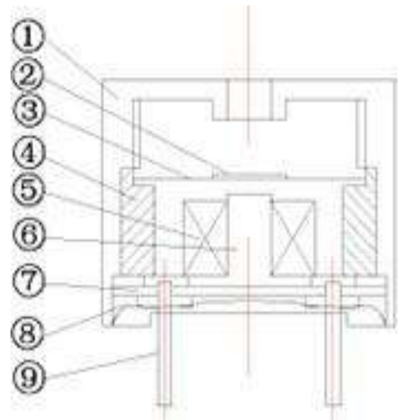

Fig.3.2.3.1 Magnetic Transducer

3.2.3.2 MAGNETIC BUZZER(SOUNDER)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

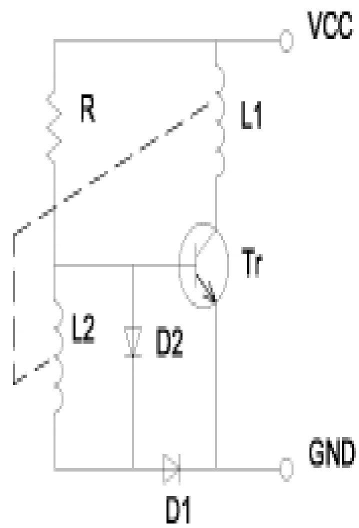

Fig.3.2.3.2 Magnetic Buzzer

3.2.3.3 SPECIFICATIONS:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Direct Current Resistance: The direct current resistance is measured by ammeter directly.
Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating Temp: Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

3.2.3.4 HOW TO CHOOSE A BUZZER:

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usuallyseen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.5 INTRODUCTION OF PIEZO BUZZER:

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

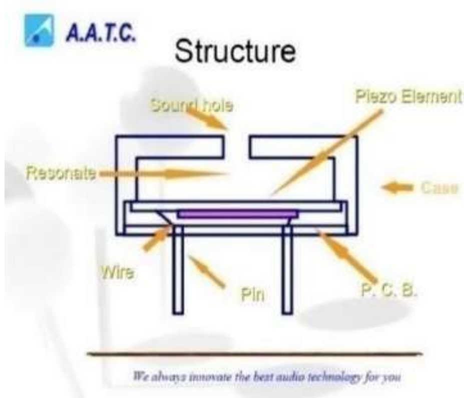

Fig.3.2.3.5 piezo buzzer

3.2.3.6 SPECIFICATIONS:

Rated Voltage: A piezo buzzer is driven by square waves (Vp-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

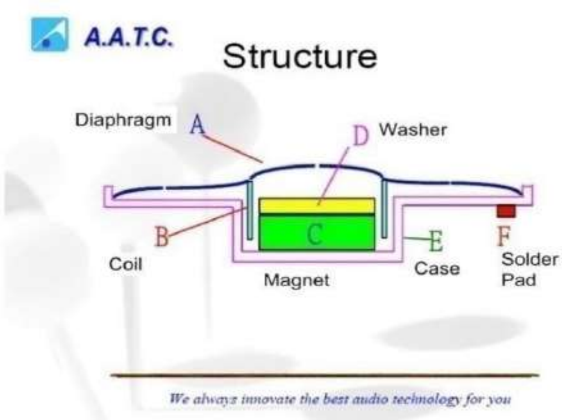

Fig. 3.2.3.6 structure of piezo buzzer

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

Sound Output: The sound output is measured by decibel meter.

Applying rated voltage and square waves, and the distance of 10 cm. **Rated Frequency:** A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency. **Operating Temp.:** Keep working well between -30℃ and +70℃.

3.2.4 TEMPERATURE SENSOR(LM35):

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range.

The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60µA from its supply, it has very low self-heating, less than 0.1°C in still air.

3.2.4.1 Features:

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60µA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical

- Low impedance output, 0.1 W for 1 mA load

Fig 3.2.4.1: Temperature Sensor

The characteristic of this LM35 sensor is:

For each degree of centigrade temperature, it outputs 10milli volts. ADC accepts the output from LM35 and converts that data into digital form which is sent to microcontroller for further processing.

3.2.4.2 TEMPERATURE SENSING CIRCUIT:

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact. In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

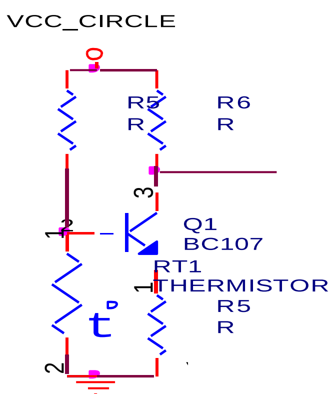

Fig.3.2.4.2: Temperature Sensing Circuit

3.2.5 GAS SENSOR:

- ➢ Gas sensors main aim is to sense hazardous gases that evolve its surroundings
- ➢ Gas sensor detects the concentrations of combustible gas in the air and outputs its reading as an analog voltage. The sensor can measure concentrations of flammable gas of 300 to 10,000 ppm. The sensor can operate at temperatures from -20 to 50°C and consumes less than 150 mA at 5 V.
- ➢ High sensitivity to LPG, Propane and Hydrogen.

3.2.6 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.6.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are
completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and
wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for

beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under

a Creative Commons license, so experienced circuit designers can make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-
This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.
When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega

2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

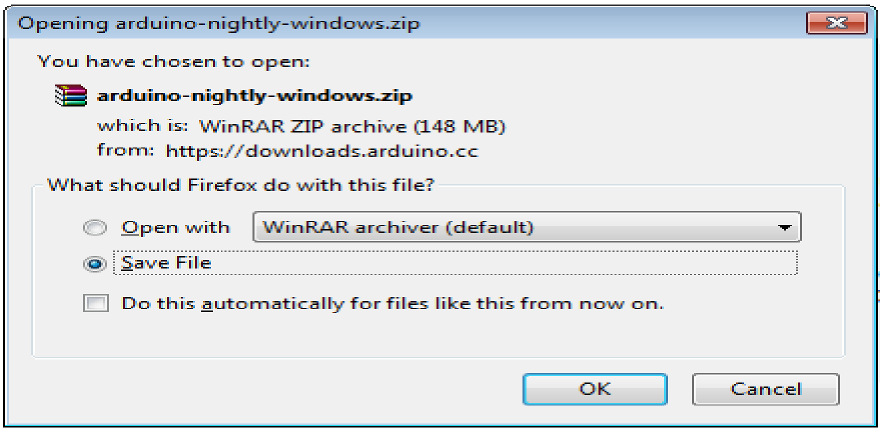

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

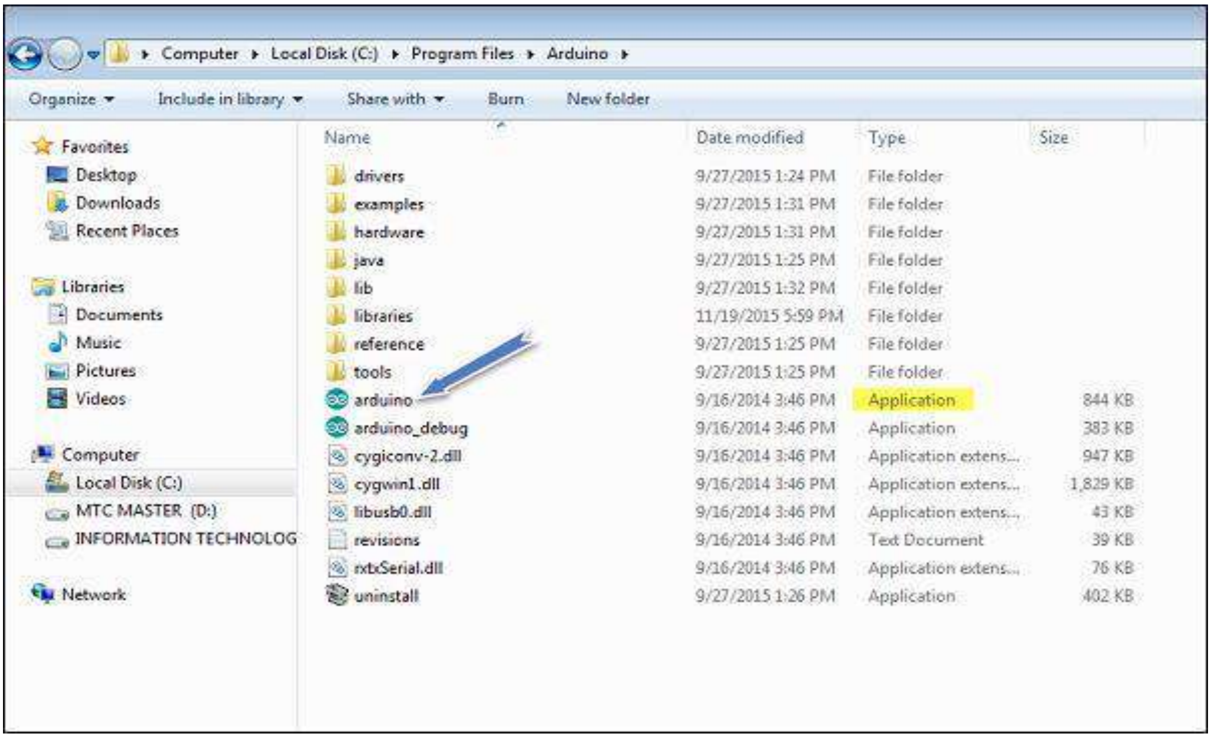

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

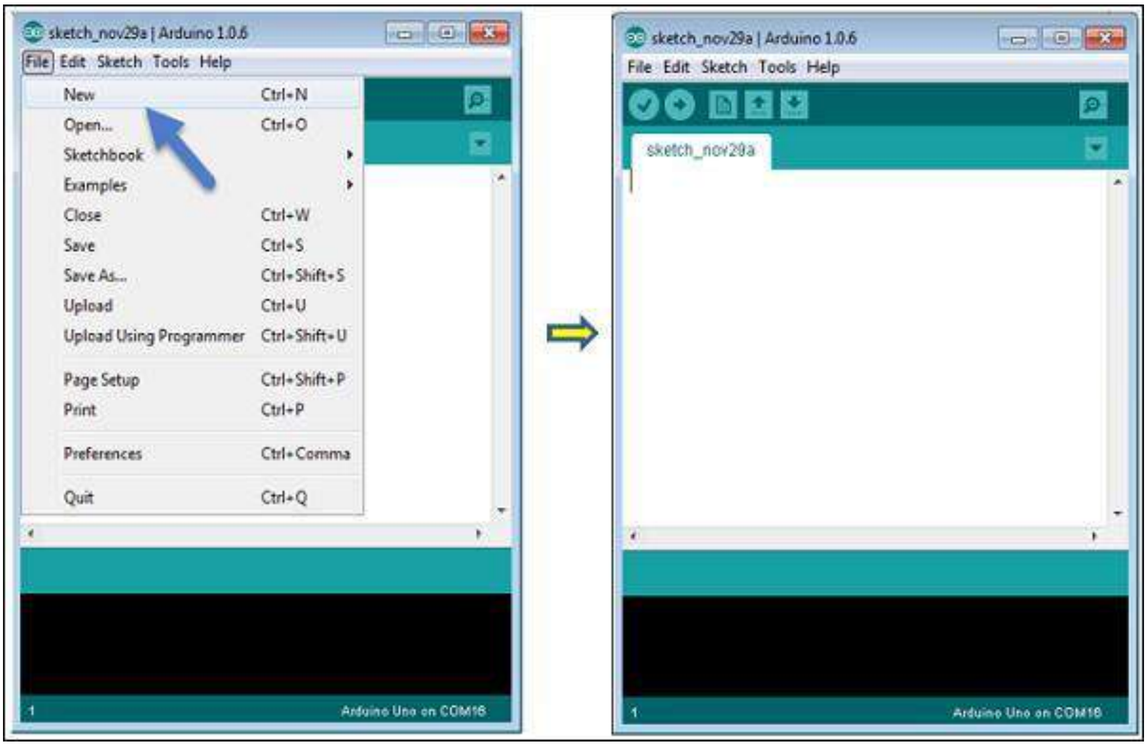

Fig. 3.2.6.4.5 Open your first project.

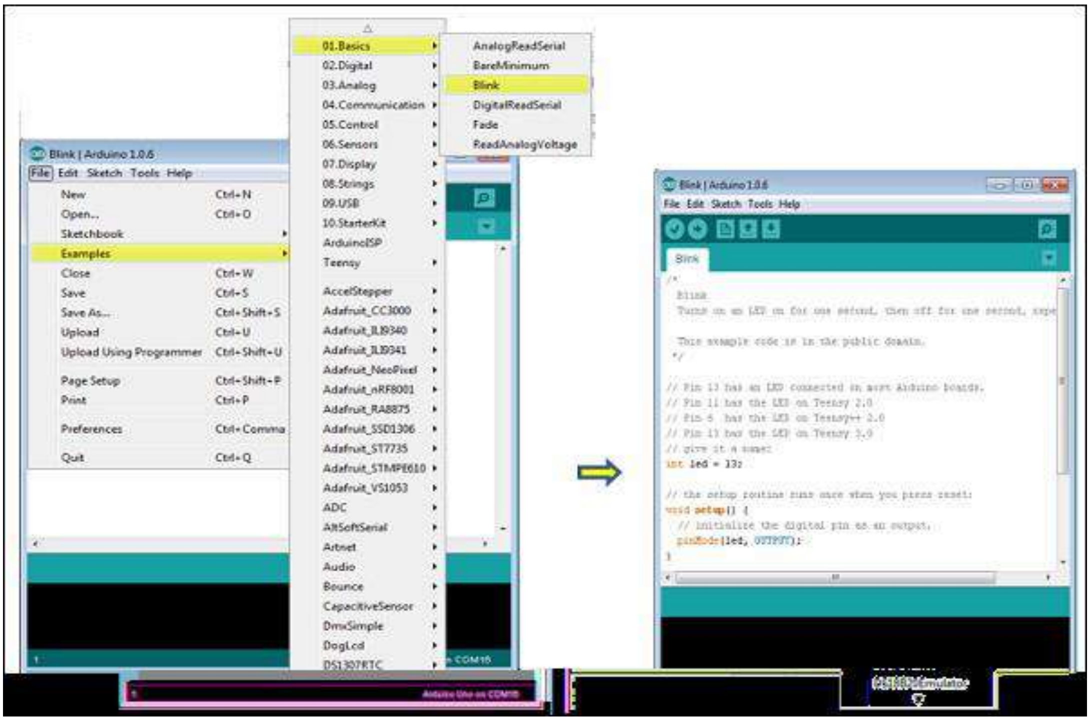
To open an existing project example, select File → Example → Basics → Blink.



.

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

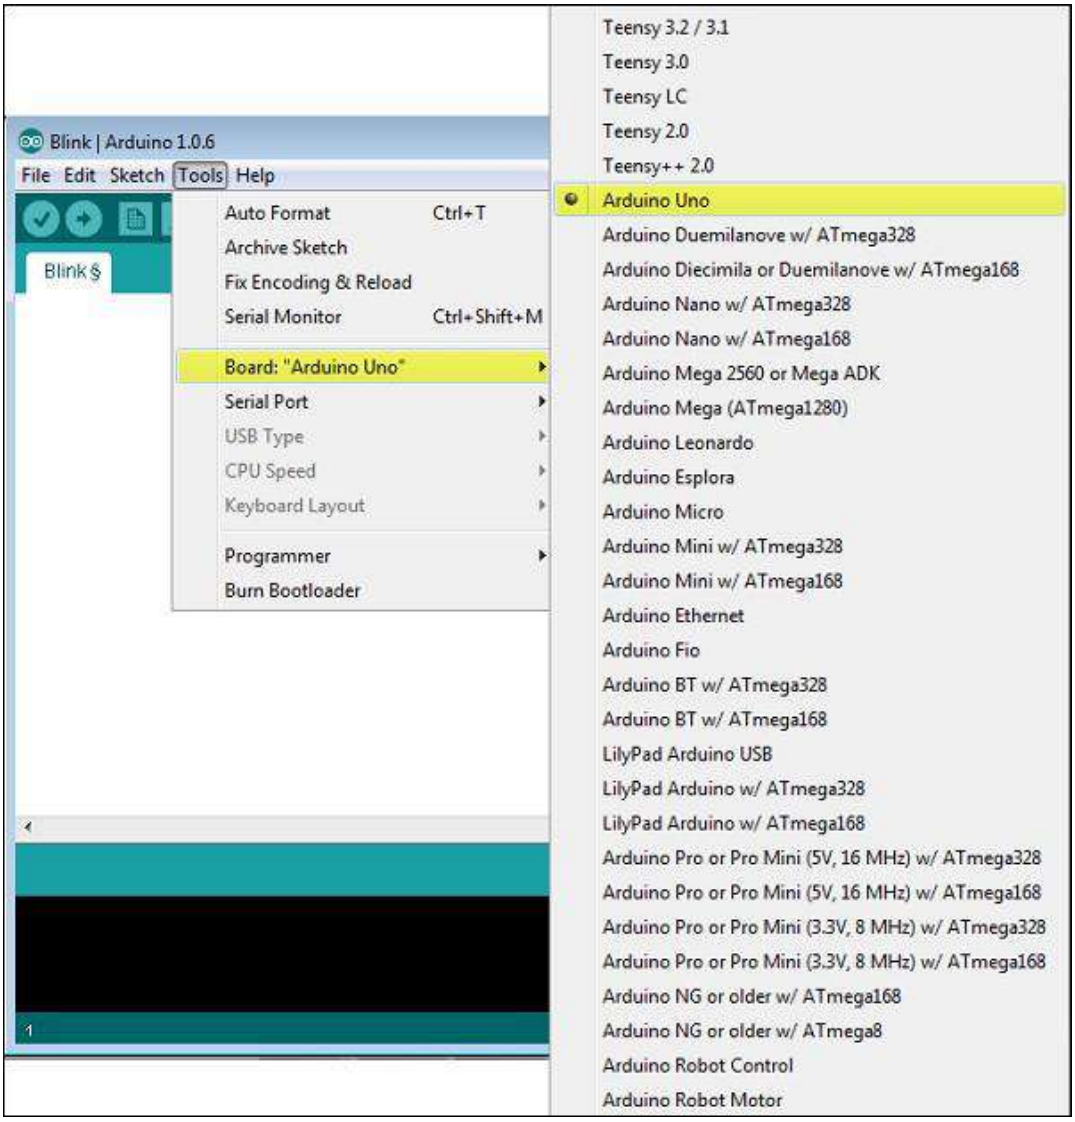


Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

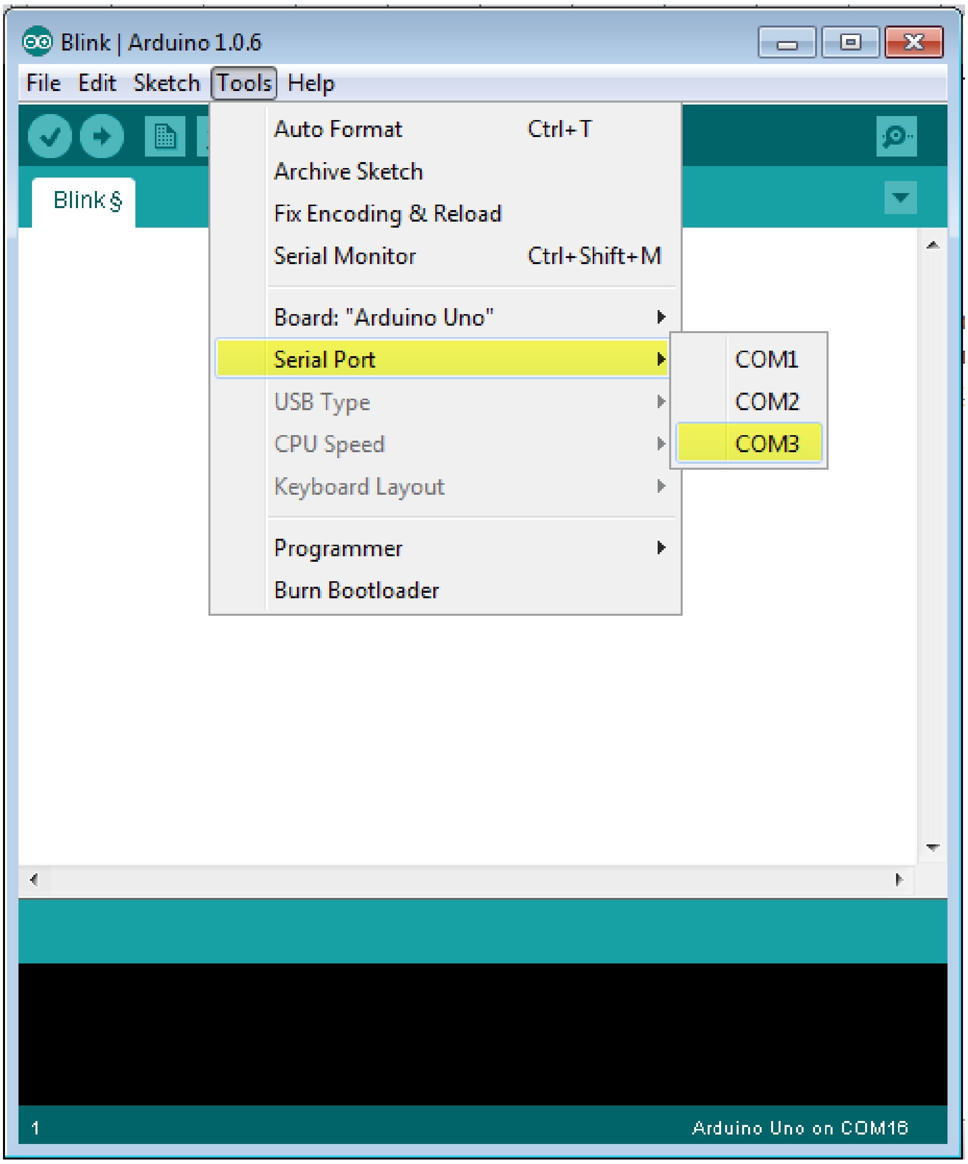

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

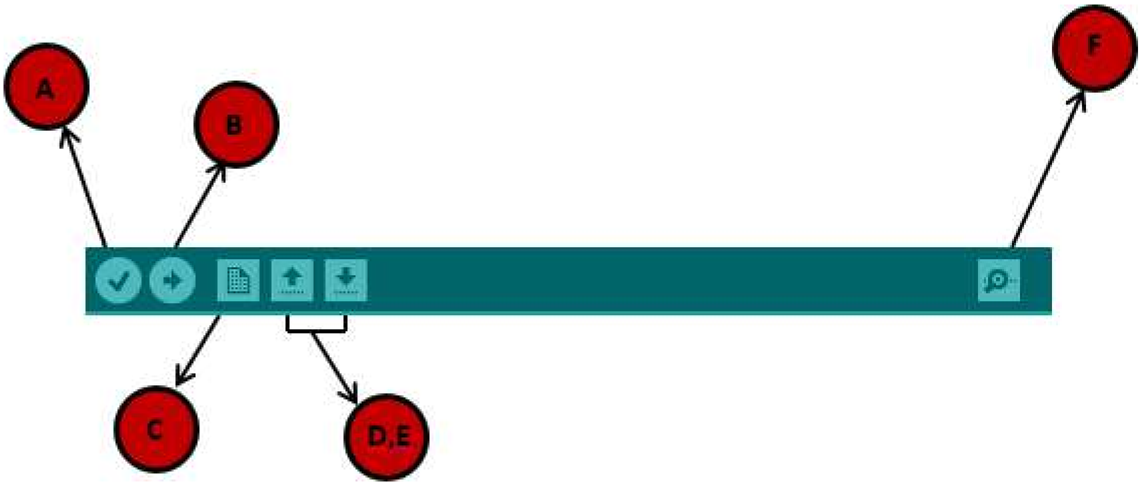

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

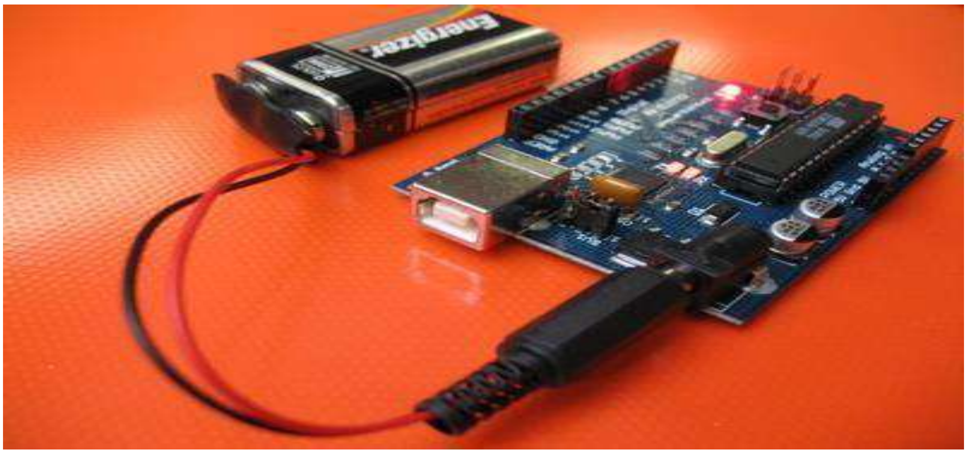

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab Centre Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole

packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select new design in File menu

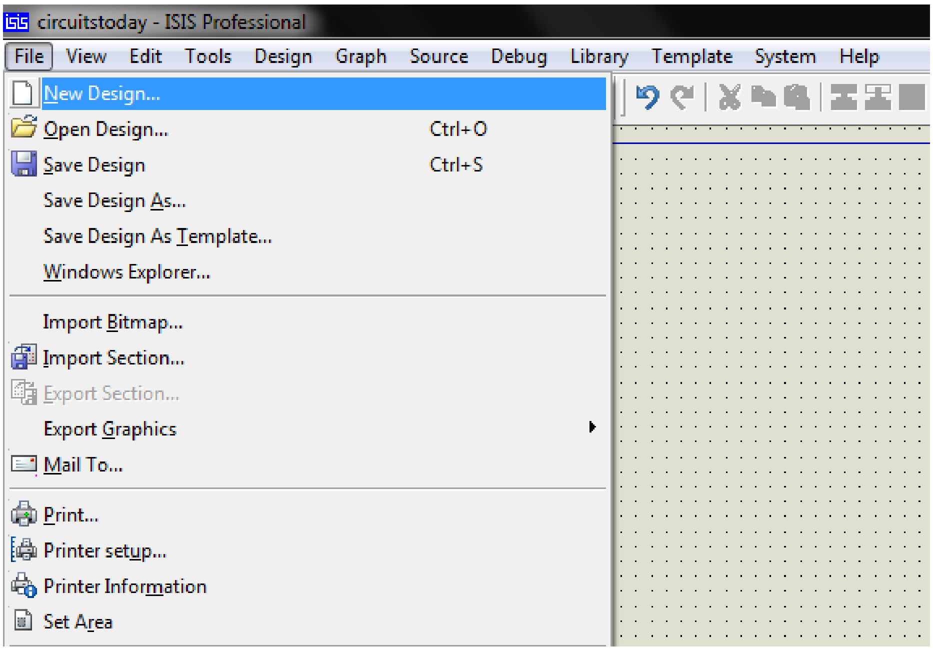

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

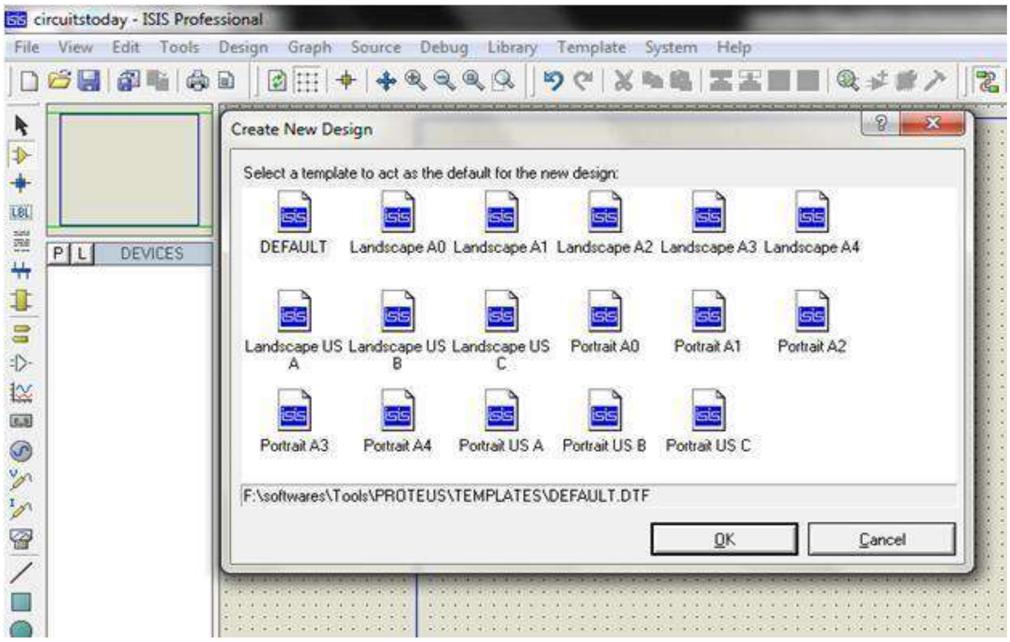

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

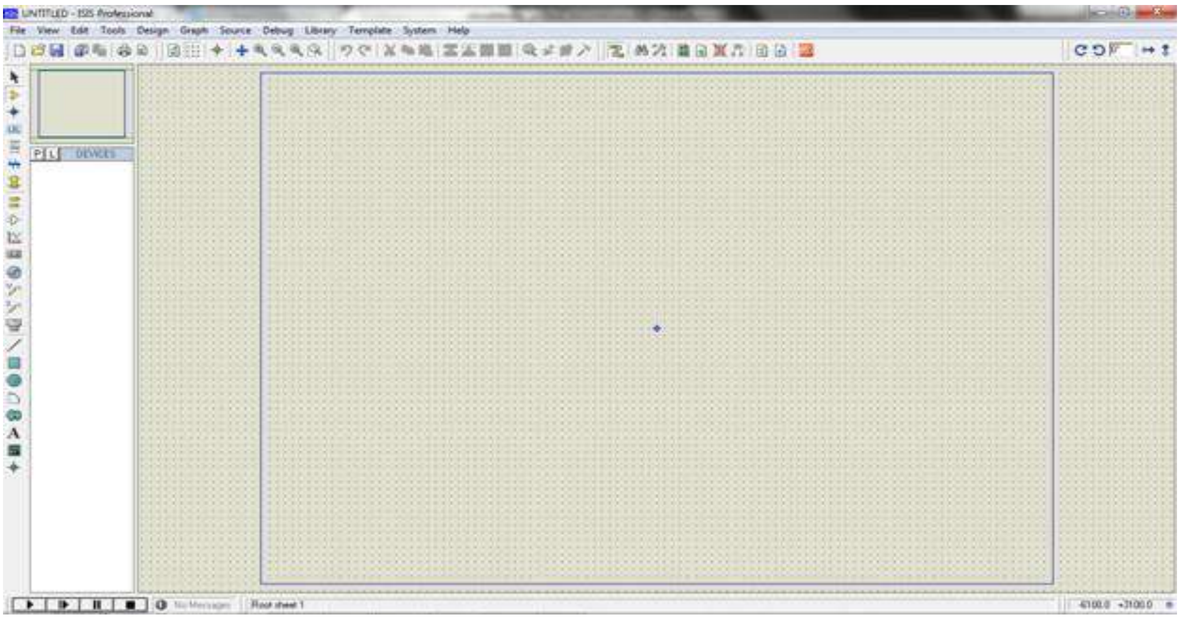

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

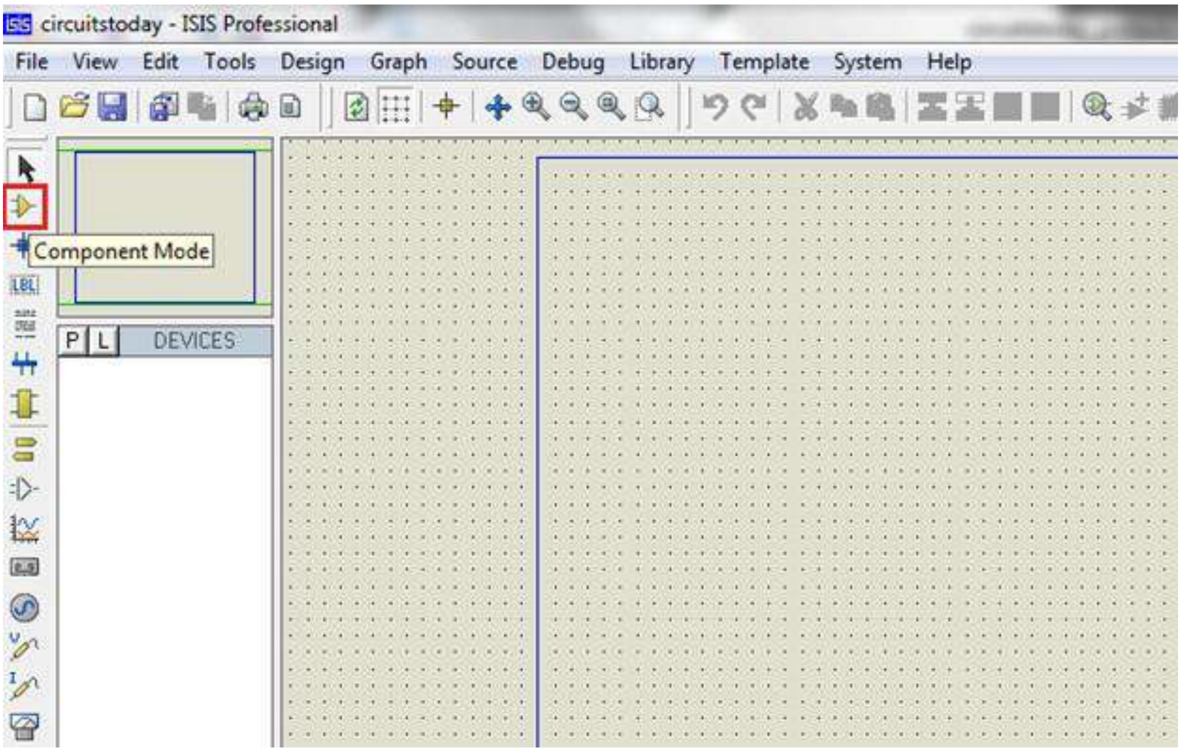

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

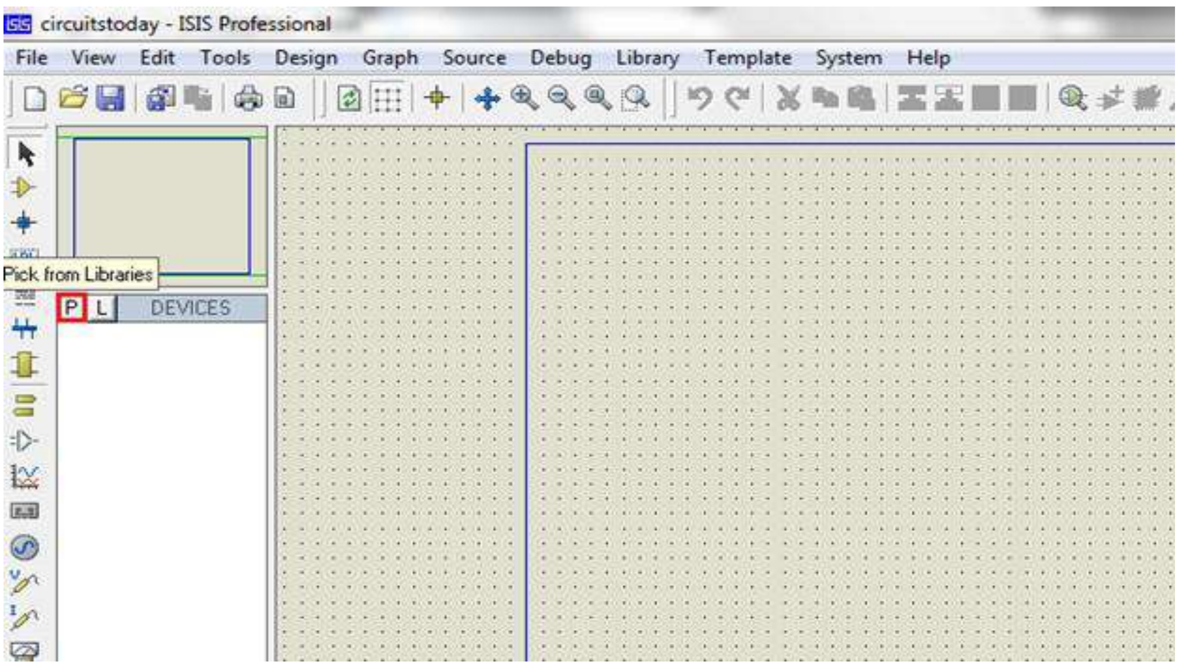

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

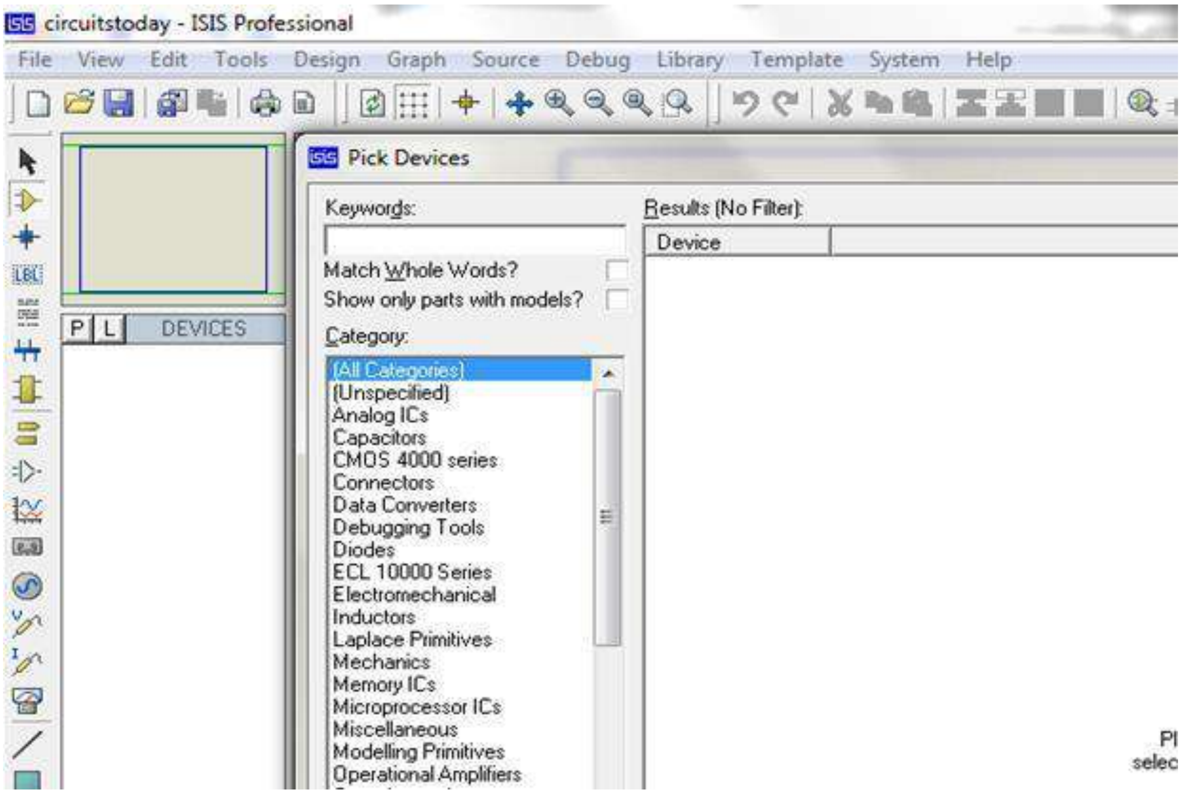

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

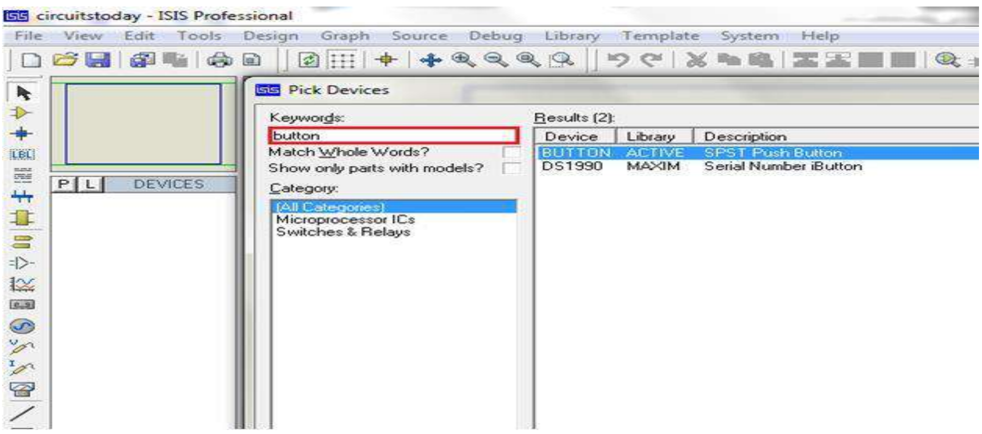

Fig. 3.2.7.7 :Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

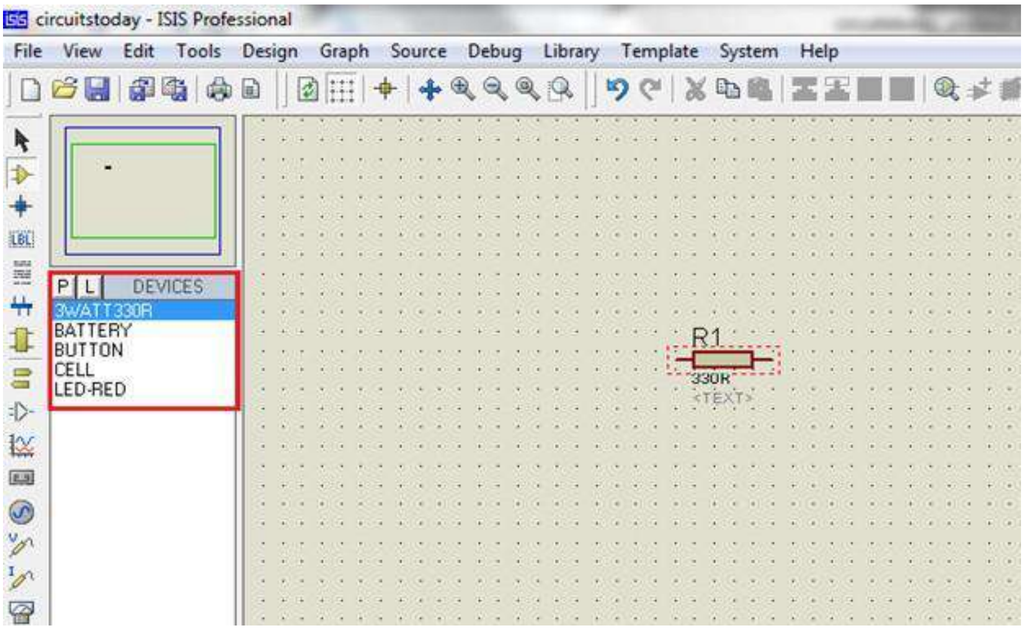

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

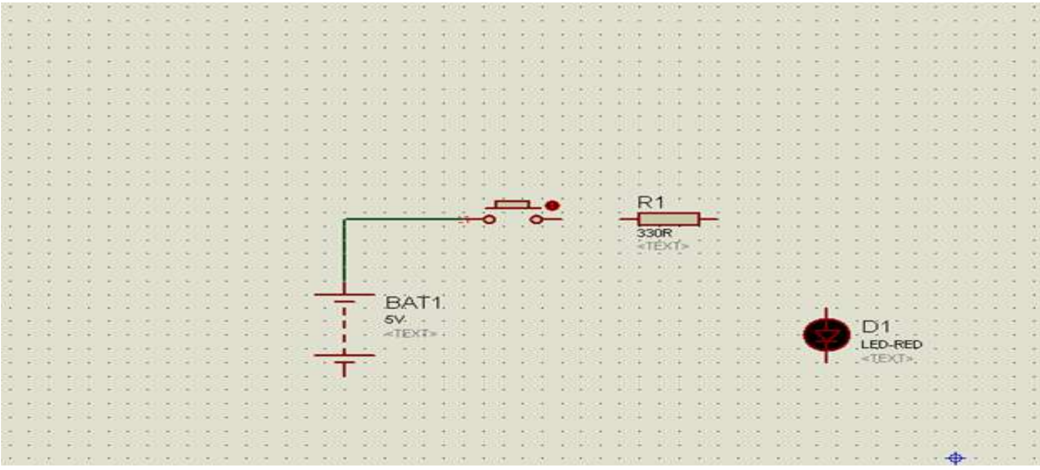

Fig. 3.2.7.9 :Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

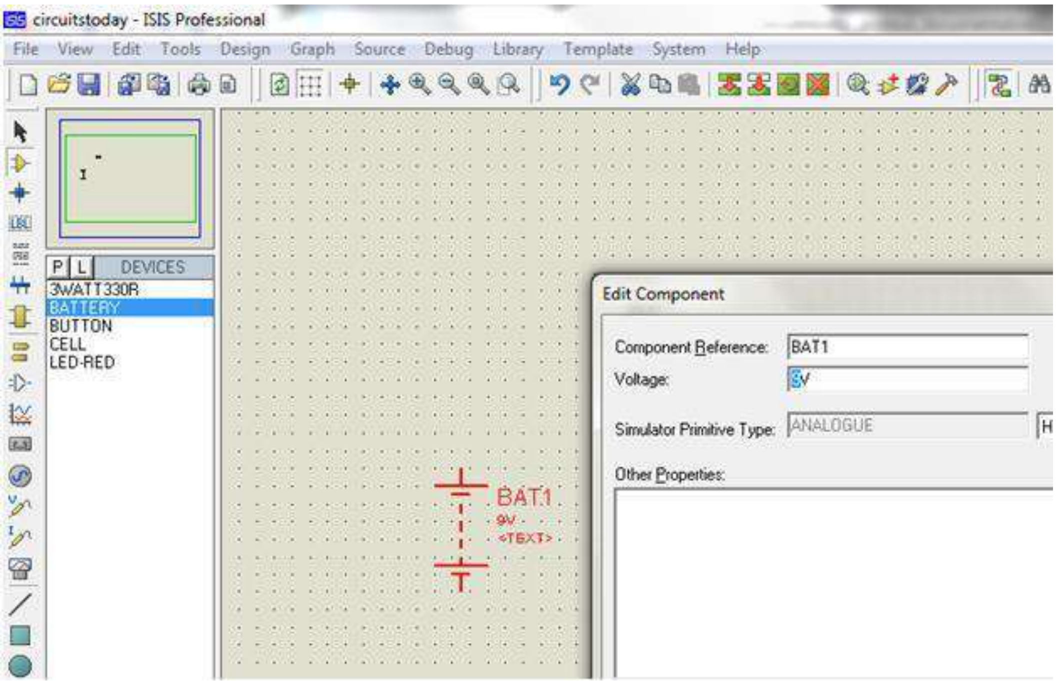

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

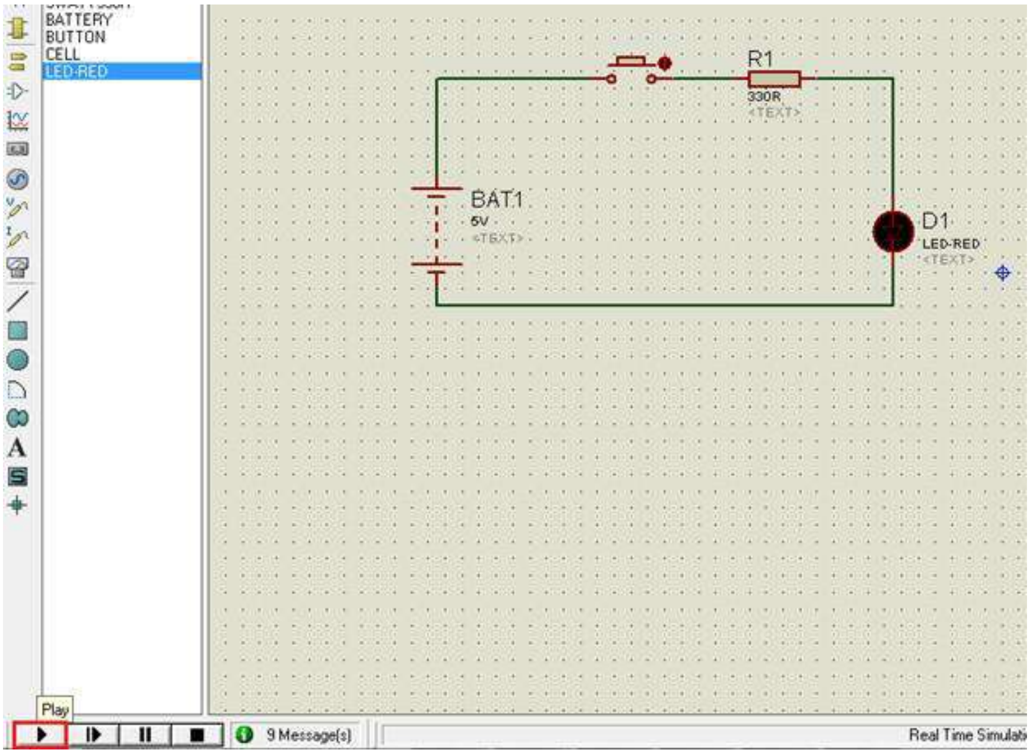

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

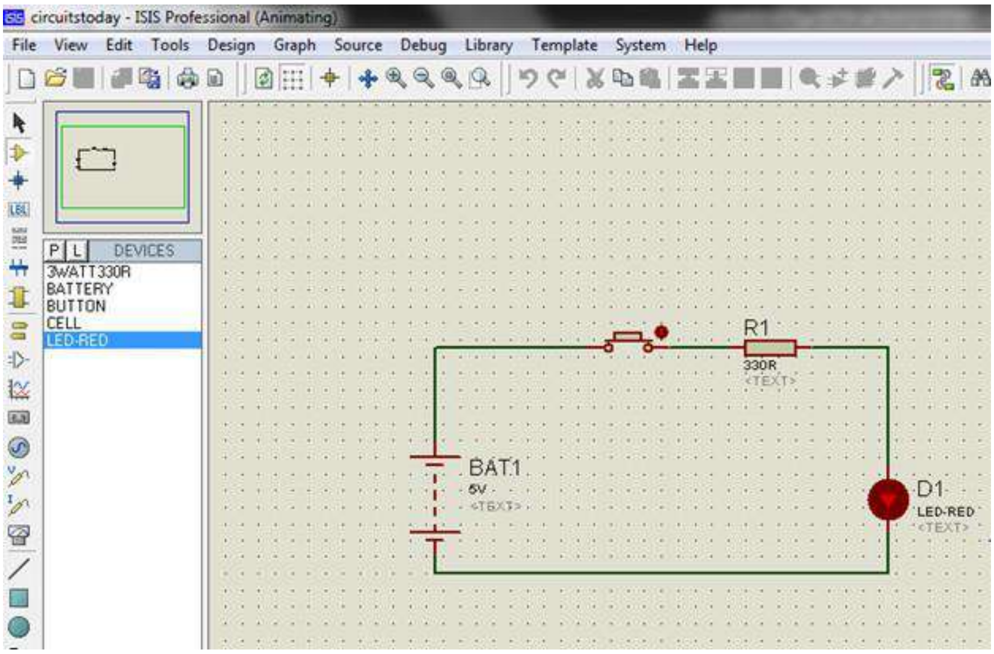

Fig. 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

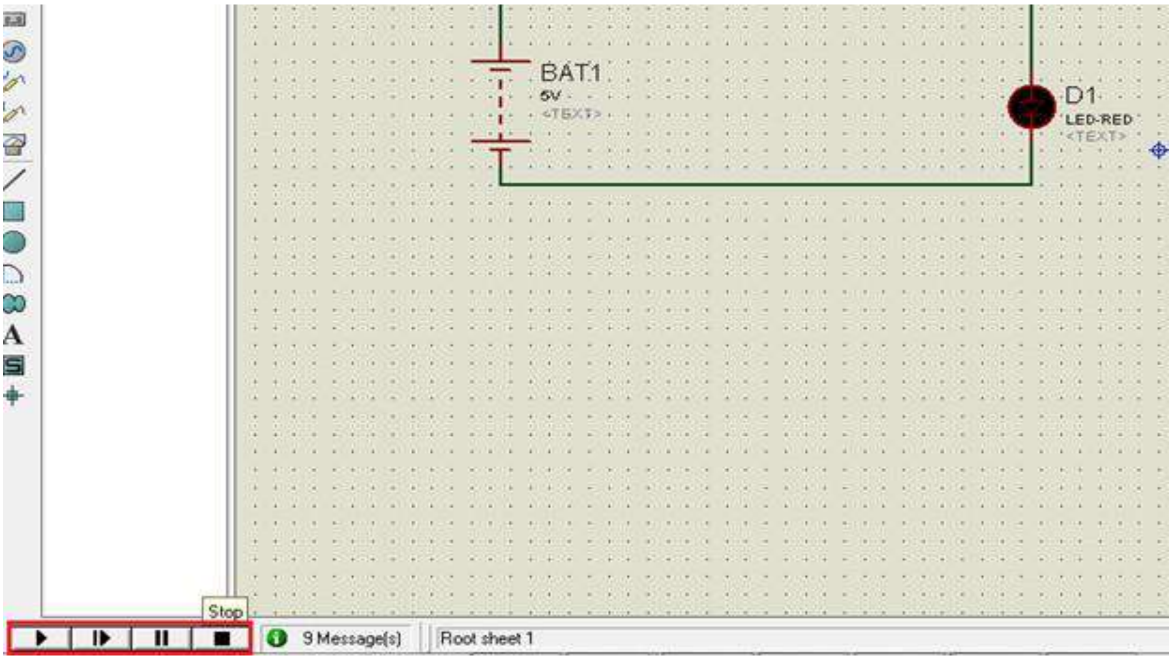

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works MATLAB documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.3 DEFINE THE MODULES:

3.3.1 GSM MODULE

GSM is a mobile communication modem; it is stands for global system for mobile communication (GSM). The Theory of GSM was developed at Bell Laboratories in 1970.Mobile communication system is used widely throughout the world. GSM is an open and digital cellular technology used for transmitting data and mobile voice operates at the 850MHz, 900MHz frequency bands. For communication purposes GSM system was developed as a digital system using time division multiple access technique. A GSM digitizes and reduces the data, then sends the data through a channel with two different streams of client data, each in its own stream of data the digital system can carry 64 kbps to 120 Mbps of data rates.

There are various cell sizes in a GSM system such as macro, micro and Pico cells. Each cell varies as per the implementation domain. There are various cell sizes in a GSM network namely macro, micro, Pico and umbrella cells. The coverage area of each cell varies according to the implementation of the environment.

SIM 800L:

SIM800L is a miniature cellular module which allows for GPRS transmission, sending and receiving SMS and making and receiving voice calls. Low cost and small footprint and quad band frequency support make this module perfect solution for any project that require long range connectivity. After connecting power module boots up, searches for cellular network and login automatically. On board LED displays connection state (no network coverage - fast blinking, logged in - slow blinking).

This module has two antennas included. First is made of wire (which solders directly to NET pin on PCB) - very useful in narrow places. Second - PCB antenna - with double sided tape and attached pigtail cable with IPX connector. This one has better performance and allows to put your module inside a metal case - as long the antenna is outside.

3.3.1.1 Specifications:

- Supply voltage: 3.8V - 4.2V
- Recommended supply voltage: 4V
- Power consumption:
  - Sleep mode < 2.0mA
  - Idle mode < 7.0mA
  - GSM transmission (avg): 350 mA
  - GSM transmission (peek): 2000mA
- Module size: 25 x 23 mm
- Interface: UART (max. 2.8V) and AT commands
- SIM card socket: micro-SIM (bottom side)
- Supported frequencies: Quad Band (850 / 950 / 1800 /1900 MHz)
- Antenna connector: IPX
- Status signalling: LED
- Working temperature range: -40 do + 85 ° C

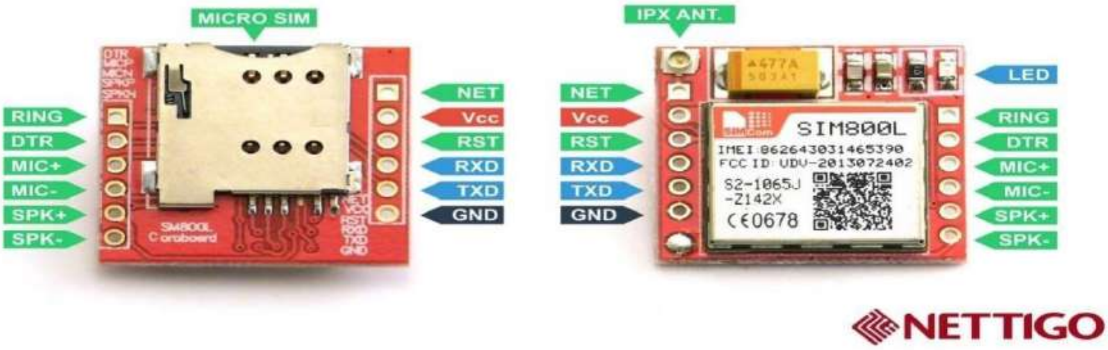

Fig.3.3.1: GSM Module

Pinout (bottom side - left):

- RING (not marked on PBC, first from top, square) - LOW state while receiving call
- DTR - sleep mode. Default in HIGH state (module in sleep mode, serial communication disabled). After setting it in LOW the module will wake up.
- MICP, MICN - microphone (P + / N -)
- SPKP, SPKN - speaker (P + / N -)

Pinout (bottom side - right):

- NET - antenna
- VCC - supply voltage
- RESET - reset
- RXD - serial communication
- TXD - serial communication
- GND – ground

3.3.1.2 GSM Commands:

Command	Description
AT+CMGD	DELETE SMS MESSAGE
AT+CMGF	SELECT SMS MESSAGE FORMAT
AT+CMGL	LIST SMS MESSAGES FROM PREFERRED STORE
AT+CMGR	READ SMS MESSAGE
AT+CMGS	SEND SMS MESSAGE
AT+CMGW	WRITE SMS MESSAGE TO MEMORY
AT+CMSS	SEND SMS MESSAGE FROM STORAGE
AT+CMGC	SEND SMS COMMAND
AT+CNMI	NEW SMS MESSAGE INDICATIONS
AT+CPMS	PREFERRED SMS MESSAGE STORAGE
AT+CRES	RESTORE SMS SETTINGS
AT+CSAS	SAVE SMS SETTINGS
AT+CSCA	SMS SERVICE CENTER ADDRESS
AT+CSCB	SELECT CELL BROADCAST SMS MESSAGES
AT+CSDH	SHOW SMS TEXT MODE PARAMETERS
AT+CSMP	SET SMS TEXT MODE PARAMETERS
AT+CSMS	SELECT MESSAGE SERVICE

Table 3.3.1: GSM Commands

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

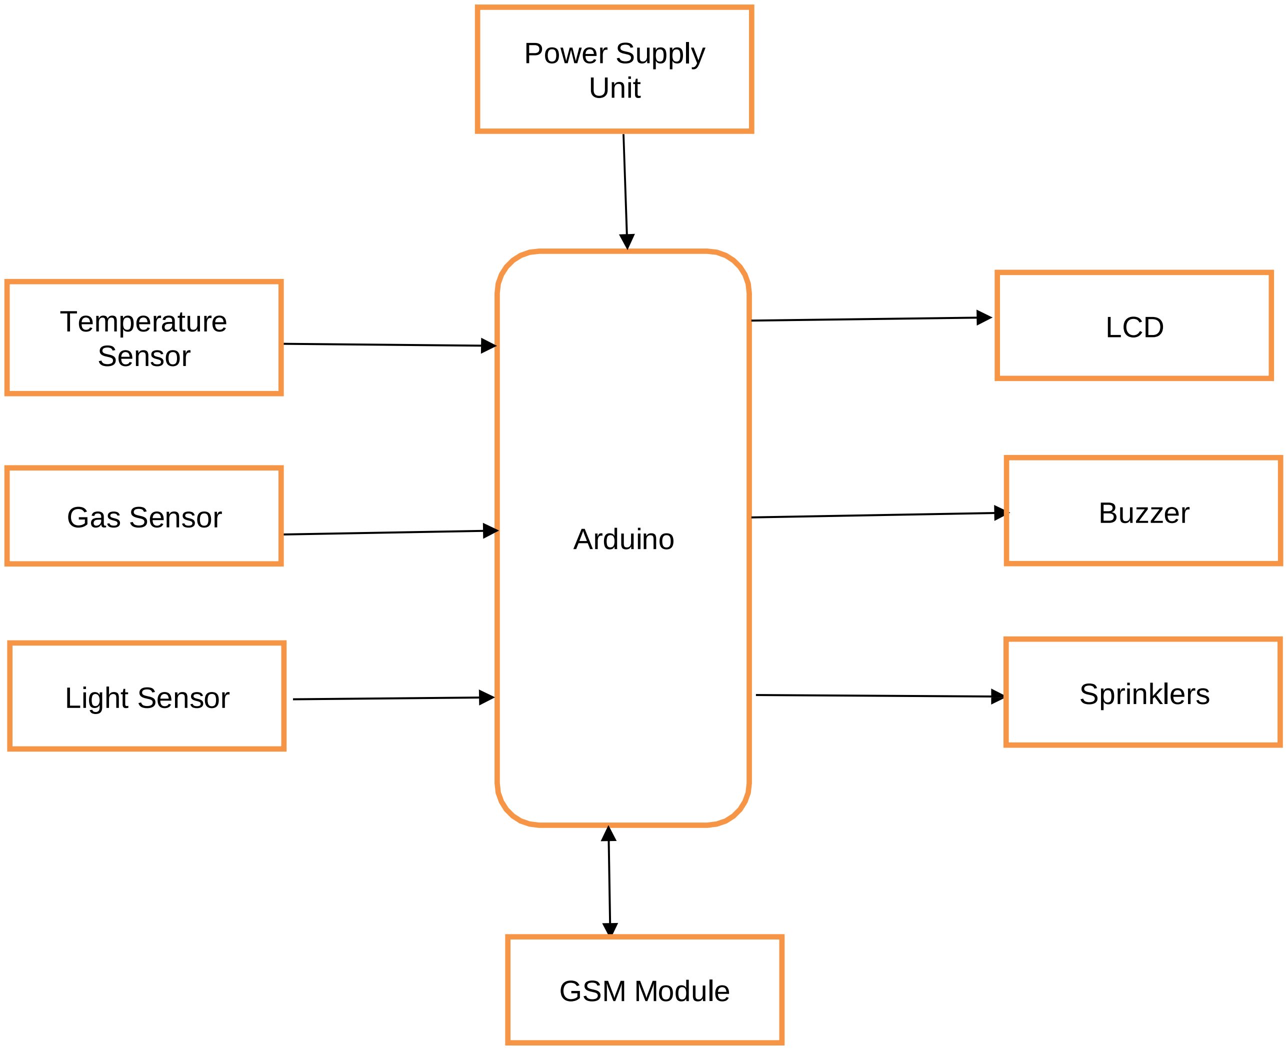

Fig.4.1: Block diagram of the project

4.2 FLOW CHART

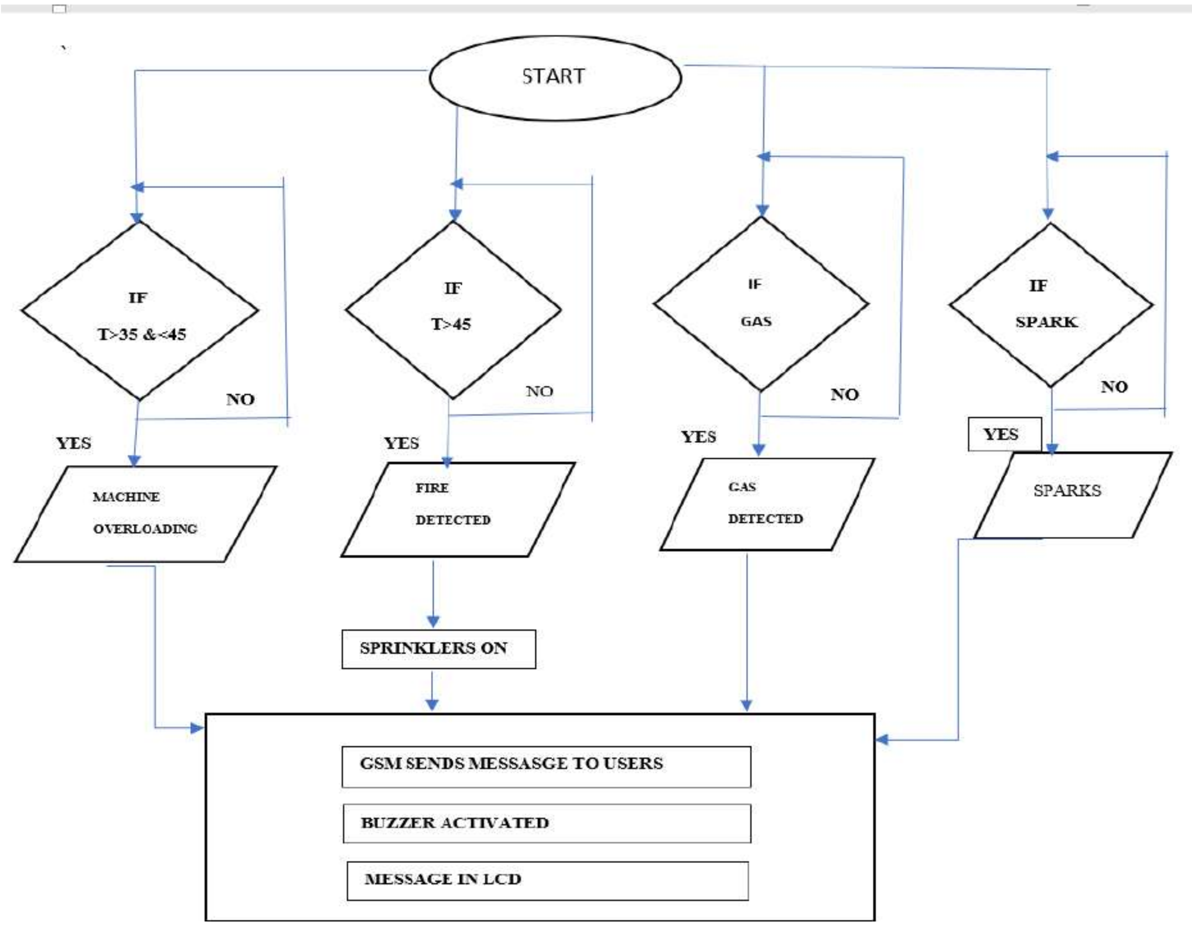

Fig.4.2 Flow Chart

4.3 IMPLEMENTATION STAGES

The following figures shows the output of proposed system in different test cases

Fig.4.3.1: Test case-1

The Fig.4.3.1 represents values of sensors. Since we have taken the outputs as active low here L:1 means the light sensor has not detected any sparks or light and it is in off state, similarly the G:1 means the gas sensor has not detected any gas and it is in off state. T:15 means the temperature detected by temperature sensor is 15.

Fig.4.3.2: Test case-2

The Fig.4.3.2 shows data displaying on LCD screen when machine is overloaded.

Fig.4.3.3: Test case-3

The Fig.4.3.3 shows data displaying on LCD screen when Sparks are detected. This tells us that once the sparks have been detected the light sensor detects the intensity of light and if it has crossed the threshold limit, this information will be passed to GSM and the message saying ‘SPARKS DETECTED’ will be sent to the authority and it will be displayed on the lcd to alert people in the respective area.

Fig.4.3.4: Test case-4

The Fig.4.3.4 shows data displaying on LCD screen when hazardous gas is detected. Once gas has been leaked in the particular area, if it has crossed the threshold limit it will be detected by the gas sensor and this information will be initiated by the GSM and a message

'GAS DETECTED' will be sent to authority and a message saying 'GSM INIT' and 'GAS DETECTED' will be displayed on lcd to alert people.

Fig.4.3.5: Test Case-5

The Fig.4.3.5 shows the conformation of the message sent. This figure shows us that the message has been sent regarding the accident taken place in the respective area under the surveillance of industry protection system.

4.4 PROJECT CODE:

```
#include <LiquidCrystal.h> //LCD
#include <SoftwareSerial.h> //COMMINCATION GSM MODULE

LiquidCrystal lcd(13,12,11,10,9,8);  //RS 13,EN 12, D4 11 ,D5 10,D6 9,D7 8

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

- Security system in industry using ZigBee technology uses a ZigBee transmitter at the site location and another ZigBee receiver is placed at the control panel. Information received at the receiver will be sent to the PC. The security people will take appropriate action according to the problem failure like fire generated, gas leakage etc.
- But a drawback of this system is that the information can be passed only to few meters.
- The proposed system uses GSM module which enables us to know the security status of industry, by sending commands via SMS and this information can be sent to multiple members simultaneously.
- This system also uses sprinklers to put out fire in case of a fire accident.
- The project industrial protection system works on SMS sent by the user with the help of a GSM modem. The device works by comparing the readings of the gas sensor, temperature and light sensor with a threshold limit initially set by the programmer.
- As soon as the reading of the sensors reaches the threshold limit SMS would be generated to inform the concerned authorities regarding the failure or the signal of the industrial safety under threat.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

The main agenda of our project was to provide a safe environment for the workers several industrial accidents like fire and vibration and the incidents of unauthorized access can be resolved using our system A simple system to improve the standards is developed. It is a real time monitor able system developed with simple hardware which simplifies the possibility of error free security system. This system can be easily implemented with maximum reliability and high security with low cost,

- One can implement a few more sensors and connect it to the satellite as a global feature of this system.
- Adding more sensor to monitor other environmental parameters such as Co2, Pressure and Oxygen Sensor.
- In aircraft, navigation and military there is a great scope of this real -time system.
- It can also be implemented in hospitals or medical institutes for the research & study in "Effect of Weather on health and Diseases", hence to provide better precaution alerts.
- Voice announcement system can be added to indicate device conditions. We can add voice announcement system along with the buzzer so if there are hazardous parameters detected then respective voice message will be announced.

APPENDICES

A practical goal of industrial safety is to lighten the environmental impact on the manufacturing unit and each person and the role of the industrial safety professionals is to find leverage or opportunities for considerable improvement using practical effort.

The main aim of this proposed project is to design and implement a flexible, cost-effective and powerful GSM Based Industrial protection system. A GSM based Industrial Protection system is needed for the occupant's convenience and safety. This system helps you to detect burglary, leaking of harmful gas, smoke caused due to fire and after detecting suspicious activity, it sends an alarm message to the owner number as well as security personnel. The concerned person will take some action as soon as possible, by sending some commands to the Microcontroller unit through registered mobile and controls the industrial devices through Relays.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Kumar, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come. We sincerely thank our **Class Project Coordinator, Ms. P. Pushpa,** Department of ECE and our project **Internal guide, Ms. R. Alekya, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr.R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Multimedia security is one of the key challenges in today's world, as dependency on multimedia information is increasing day by day. Easily available image editing software have enabled every common user of a smart phone and computer, to hack into the information of the images and video and alter it to some extent. To authenticate the genuineness of images, detection of image tempering is need of the time. Various techniques have been proposed to use image features for detection of image forgery. The techniques of forgery detection work in two domains of image forgery; copy-move forgery detection (CMFD) and image splicing detection (ISD). This paper presents a comprehensive comparative analysis for the use of local texture descriptors i.e. local binary pattern (LBP) and local ternary pattern (LTP) for forgery detection in an image. The project also presents a technique to integrate fast Fourier transform (FFT) with local texture descriptors for image forgery detection using existing block-based methodology. Performance of the technique(s) and descriptor(s) is tested for benchmarked dataset CASIA v1.0. Results are evaluated by using standard detection metrics detection accuracy and recall.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

GLOSSARY OF COMMONLY USED TERMS

IMAGE: An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

MATLAB: Matlab is a programming and numeric computing platform used millions of engineers and scientists to analyze the data.

DWT (Discrete wavelet transform): The **discrete wavelet transform** (**DWT**) is a computerized technique to compute fast wavelet transform of a signal. The **discrete wavelet transform** (**DWT**) is an optimum solution for computational time overhead.

BLOCK PROCESSING: Some image processing operations involve processing an image in sections called blocks, rather than processing an entire image at once. The input image is divided into blocks, each block calls the specified function and results are consolidated to form an output image.

FEATURE EXTRACTING: Feature extraction is a part of the dimensionality reduction process, in which, an initial set of the raw data is divided and reduced to more manageable groups. These features are easy to process, but still able to describe the actual data set with the accuracy and originality.

SVM (SUPPORT VECTOR MACHINE): Support vector machines (**SVMs**) are particular linear **classifiers** which are based on the margin maximization principle. They perform structural risk minimization, which improves the complexity of the **classifier** with the aim of achieving excellent generalization performance.

IMAGE SPLICNG FORGERY: Image splicing is an image editing method to copy a part of an image and paste it onto another image, and it is commonly followed by postprocessing such as local/global blurring, compression, and resizing.

COPY MOVE FORGERY: Copy-move forgery is a specific type of image tampering where a part of the image is copied and pasted somewhere else in the image with the intent to cover an important image feature.

CHAPTER 1

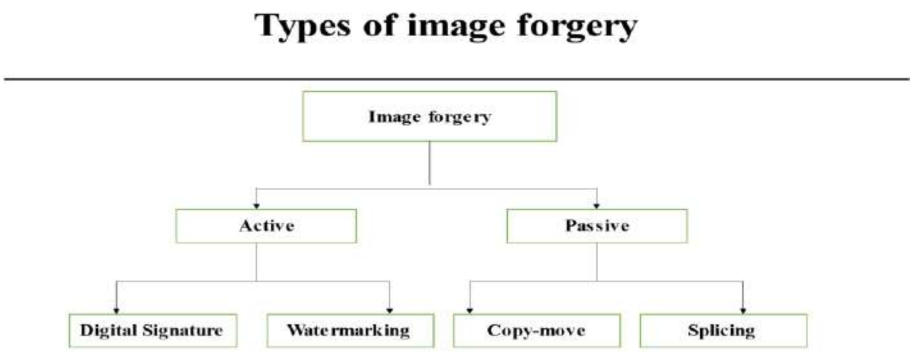
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

Multimedia security is one of the key challenges in today's world, as dependency on multimedia information is increasing day by day. Easily available image editing software have enabled every common user of a smart phone and computer, to hack into the information of the images and video and alter it to some extent. To authenticate the genuineness of images, detection of image tempering is need of the time. Various techniques have been proposed to use image features for detection of image forgery. The techniques of forgery detection work in two domains of image forgery,copy-move forgery detection (CMFD) and image splicing detection (ISD). This project presents a comprehensive comparative analysis for the use of local texture descriptors i.e. local binary pattern (LBP) and local ternary pattern (LTP) for forgery detection in an image. The project also presents a technique to integrate fast fourier transform (FFT) with local texture descriptors for image forgery detection using existing block-based methodology. So, the main objective of the project is to detect the forged/tempered part of the image.

1.2 OBJECTIVES OF THE STUDY

Digital images are used in many fields as the basic source of information and for proofs. The process of creating a fake image has become a simple process by using existing technology and powerful editing software. Image splicing is a technique to combine number of multiple images into a single image. Copy move image is a technique to copy and paste the certain parts of image at different parts of image.



multi-image forgery in the images may be detected through analysis of local texture and LBP. It has been used by various researchers for detecting image forgery. Image splicing detection has been achieved in the Forgery Detection using LBP and LTP In first approach chrominance component is divided in overlapping blocks of size 3x3 and then two type of features are extracted from these blocks i.e. LBP and LTP.

1) Local Binary Pattern (LBP): LBP was initially proposed in for extracting local features of an image. LBP possesses a two valued code matrix .

$$LBP_{x,y} = \sum_{x=0}^{X-1} s(g_x - g_t)2^x$$
$$s(x) = \begin{cases} 1, if\, x \geq 0; \\ 0, otherwise \end{cases} \quad (1)$$

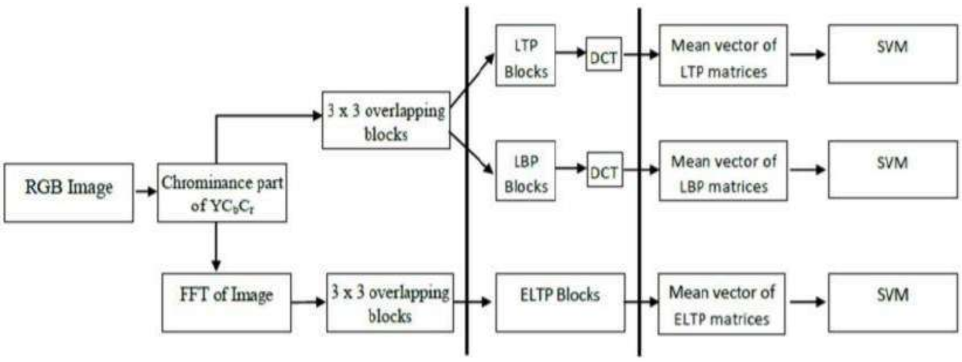


Fig. 1.1 Image splicing detection methodology

where ‘gx’ and ‘gt’ are the gray value of current neighborhood pixel and central pixel respectively. ‘X’ is the number of pixels in the block. A binary matrix is returned by the above equation which is then converted to decimal for convenience as shown in Figure 4.

2) Local Ternary Pattern (LTP): LBP is prone to random and quantization noise in near-uniform regions because its value depends center pixel value. Local ternary pattern (LTP) was proposed as an enhancement to LBP and generates 3- valued code by following equation 2. present work by following the methodology shown in Figure 1. RGB image is firstly converted into YCBCR format. Chrominance part of the converted image is used for further evaluation, as chrominance part include suitable information for forgery detection. Two different approaches have been suggested in the methodology for forgery detection.

$$s'(g_x, i_t, th) = \begin{cases} 1, & g_x \geq g_t + th \\ 0, & g_x - g_t < th \\ -1, & g_x \leq g_x - th \end{cases} \qquad (2)$$

where ‘th’ is the constant threshold value. DCT is applied on these feature matrices to generate feature coefficients (LBP/LTP). Mean for every DCT block is calculated for dimensionality reduction and generating the final feature vector. This vector is then fed to SVM classifier for classifying the image as authentic or forged.

A. Forgery Detection using FFT and ELTP (FFT-ELTP)

In the second approach, chrominance component is transformed using fast Fourier transform and then segmented into overlapping bocks. Instead of using LBP or LTP for feature extraction, the present paper evaluates extension of LTP as enhanced local ternary pattern (ELTP) [27] code for these blocks to generate a feature vector:

1) Fast Fourier Transform: Fast fourier transform (FFT) is an efficient way to compute discrete fourier transform (DFT). An image matrix is transformed to discrete fourier coefficients by formulation in equation 3.

$$Y_{p+1,q+1} = \sum_{j=0}^{m-1} \sum_{k=0}^{n-1} w_m^{jp} w_n^{kq} X_{j+1,k+1} \qquad (3)$$

where ‘wm’ and ‘wn’ are complex root of unity, defined as and respectively and ‘i' is the imaginary unit.

2) **Enhanced Local Ternary Pattern:** Yuan et. al have extended the LTP to attain better features for the image by introducing ELTP. The constant value in the LTP makes it less robust for gray level transformations. ELTP uses a dynamic threshold value based on the mean absolute deviation(mad) of the respective block. ELTP achieves significantly better results in texture classification in comparison to LBP and its variants. The generated feature vector in this approach will contain ELTP code for every FFT block of the image. This is fed to SVM classifier for classification of the image as authentic or forged.

1.3 SCOPE OF THE STUDY

The scope of this project focuses on proposing a forgery detection technique using both FFT and local features method, with both descriptor and feature matching methods, and its performance on accurately detecting tampered images. Apart from the proposed CMFD techniques an existing CMFD technique namely SIFT, which is used for feature extraction method.

The performance of the proposed FFT and local features method is evaluated using images which have underwent different geometrical attacks, namely translation, different degrees of rotation, symmetrical and asymmetrical scaling. The proposed technique is also tested on images with multiple copy-move regions. The proposed work is implemented using Matlab and tested using various datasets of images.

1.4 ORGANIZATION OF CHAPTERS

For proper presentation of the work, the project will be divided into five (5) chapters. Chapter one will cover the introduction which talks about the overview and scope of the study, objectives of the study. Chapter two will deal with review of related Literature on the topic and this is broken down into appropriate sub-topics. Chapter three will deal with the methodology the researcher employed which comprises of the research design for the study and the introduction to matlab software. Chapter four deals with the implementation stages, results of the project. Chapter five deals with the conclusion and future enhancement of the project.

1.4.1 INTRODUCTION

The project proposes a method of detection technology to detect the digital image forgery by using both FFT and Local Features. This proposed method has higher accuracy of detection of tampered part of image than the existing methods.

1.4.2 LITERATURE SURVEY

The survey is done on existing technology used for detection of image forgery and also the methods used for detection of image forgery.

1.4.3 PROJECT DESIGN

The project was designed by using existing block-based technology and DCT and DWT as main algorithm.

1.4.4 PROJECT IMPLEMENTATION

The project is implemented step by step process for obtaining final output

1.4.5 CONCLUSION AND FUTURE ENHANCEMENT

The proposed technique increase accuracy of detection of tampered part of image when compared to existing technique

CHAPTER 2

LITERATURE REVIEW

2.1 LITERATURE REVIEW ON RESEARCH AREA

In today's world, visual media is the primary source of communication. Visual media is paragon at explaining the situation at its best. Malicious modification of digital images with the intent to deceive for the sake of altering the public perception is termed as Digital Image Forgery. Forgery has a sole purpose of changing public perception. Forging an image takes just one thing into consideration that people usually believe what they see. Decisions can be easily manipulated by altering the images with user-friendly and easily available image editing tools like Sumopaint, Paintshop Pro, Photoshop CC and HitFilm Express. These easily available tools make forgery no longer restricted to specialists. Manipulation is done so precisely that it hardly leaves any visible traces. An observer cannot sense manipulation with naked eye and needs some scientific methods to detect forgery in the image. Image is commonly manipulated with two basic operations of copy-paste or image splicing. Image splicing is very basic and harmful type of forgery. Image Splicing creates a composite image by blending cropped regions to same or different image. Some post processing operations like blurring are performed after pasting the region to completely merge the pasted portion with the background. Figure 1 highlights the process of image splicing and Figure 2 elaborated an example of the same. Image forgery detection can be active or passive. An active approach makes use of prior information, embedded into the image to verify its authenticity. Such information is embedded using digital watermark or digital signatures. Passive approaches are prioritized over the active approach as they do not need any prior information but the image itself. These approaches have no knowledge about the origin of the image. As tampering is not visually detectable, passive approach analyses the underlying statistical characteristic of the image which are supposed to be definitely disturbed by the manipulation process. Image forensics predominantly uses passive approach to verify image authenticity. This paper discusses techniques to detect image splicing forgery.

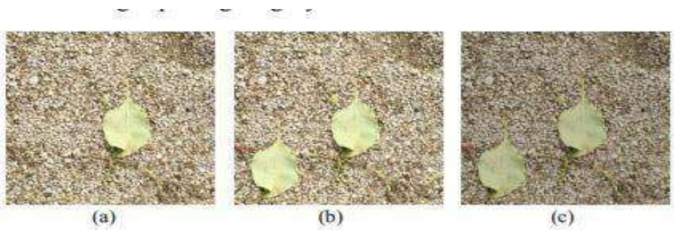

Fig. 2.0. (a) Original Image (b) Forged Image (c) Image Retouching

Fig. 2.1 Image Splicing by using two different images

Taking into account the fact that pasting of a cropped portion onto a different image, replaces the existing micro edge patterns of the host image with its own patterns, which make the pasted portion different from the rest of the image and such disturbance is peculiar along its boundary, visual descriptor LBP and its variants are used to encode the micro edge patterns and DCT is used to encode the frequency content with respect to each blocks LBP value. This approach utilizes the chrominance component of the RGB image which is believed to capture the disturbance created by forgery better than any other colour channel. A technique of forgery detection is presented that uses fast fourier transform of the chrominance component for extracting local features of the image. SVM Classifier is used for classifying the images as forged or authentic.

2.2 REVIEW ON RELATED LITERATURE

A detection technique based on the combination of LBP, discrete wavelet transforms (DWT) and principal component analysis (PCA) was proposed with support vector machine (SVM). The combination of LBP and DWT asserted for the improvement in accuracy rate in CASIAv1.0 is 97.21% and in case of Columbia dataset is 95.13%. Another method which was also based on LBP and DCT. This method was suggested to detect copy move and image splicing forgery. It used DCT to convert the LBP image into its frequency domain, in-order to discover any chances of tampering more precisely. After that, for each block statistical measures of computed DCT coefficients are calculated. Such methods train the SVM classifier to differentiate between the authentic and forged images. This method yielded the best precision on CASIAv1.0 as 97%, CASIAv2.0 as 97.50% and CISDE dataset as 97.77%. had proposed a technique to detect image splicing forgery. This technique was imitation of the magnitude component of 2D arrays which were acquired by applying multi-size block discrete cosine transform (MBDCT) on testing images, using LBP. The dimensionality of feature set was deducted by using the kernel principal component analysis (K-PCA), to ensure it to be more efficient mathematically. Using this reduced feature set, SVM was able to classify the authentic images and tampered images. This method attained a precision of 90.46%. A tampering detection technique is proposed in using multi- scale LBP and DCT. This technique divides the image into non-overlapping blocks of various sizes 32*32, 64*64, 16*16. After dividing in the blocks, they were passed to DCT to extract the coefficients. In-order to build a feature set of the image, standard deviation was calculated with respect to computed coefficients. In the proposed method, the classifier was trained by using the SVM along with radial basis function (RBF) kernel. It attained the precision rate on CASIAv1.0 96% and on CASIAv2.0 97.3%. Other research paper put forward another method to determine the image authenticity. It this method, Markov features were extracted discretely in all the three domains. It was the first method which combined three domains, they were – spatial domain, DCT and DWT domain. Efficient classifier used in the proposed method, reduced the computational complexity as well as yield an efficient TPR, TNR and precision rate without making use of PCA. It attained a precision rate of 99.80% on Columbia Image Splicing Detection Evaluation Dataset (CISDE).

Another method to detect image splicing forgery, by using Markov features in QDCT domain was developed. It took RGB image without converting into grey scale to avoid any color distortion and it also resulted in improved precision. Markov feature were extracted from quaternion discrete cosine transform (QDCT) frequency domain of the blocked color image. SVM classifier was trained by these extracted features. This method enhanced the precision level to 92.38%. proposed a method to discover whether an image was authentic or tampered, based on spatial and DCT based Markov features. First, Markov features were extracted from spatial and DCT domains and then they were combined. In order to reduce the dimensionality, the most relevant features were extracted from combined feature set, by using a PCA.

SVM along with RBF kernel method was used, to optimize the classification process. This method was determined to be more than 98% precise, when assessed on Columbia Image Splicing Detection Evaluation Dataset (CISDE). One more method to detect image splicing forgery proposed in [10] deploy quantization- based Markov feature extraction. The performance was enhanced by reducing the loss of information, so quantization is used in this method. Two Markov feature selection method made use of the summation and maximization of the color feature. The proposed method had been tested on CASIAv1.0, CASIAv2.0 and Columbia color datasets and the results were precise to be 98.95%, 97.25% and 95.24% respectively used a noise level evaluation method which was intensity dependent, to determine image splicing forgery in the digital image. Here, the base used for splicing forgery detection was a variable noise level which vary depending on image taken from different sources. This method was outstanding, as it was the only method with varying noise level of blocks taken from different image sources and captured by the same camera. For localization of image splicing, [28] had proposed another method to highlight forged region in the image. This method utilized previous noise level estimation algorithm and PCA based algorithms, in order to determine block wise noise level of a testing image. K-means clustering was used to differentiate between the spliced region and the original region. When difference between spliced region and original region was small noise, then this method attained high performance. Contrary, when the spliced region and the original region had same noise level, then this method failed to localize the tampering.

2.3 PROPOSED METHOD

The project has presented two approaches for detecting image splicing. Both the approaches use overlapping blocks to extract image features. First approach extracts LBP or LTP features based on gray values of the image chrominance whereas second approach extract the ELTP features from fast fourier transform of the chrominance channel. Results of these techniques have been presented in comparative manner. It can be observed that LBP and ELTP perform as better features to classify the image as forged or authentic. ELTP in particular comes out to be a significantly better feature in comparison to existing image splicing detection techniques. The FFT-ELTP technique perform fairly by achieving an accuracy of 88.62% on compressed images of CASIAv1.0 dataset. However, all of the presented approaches involve complex transformations like DCT and FFT which increases the complexity of the methodology.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

The image that has to be tested for genuiness is given as the input image. The input image can be either RGB or grey image. The given input image undergoes preprocessing part which involves conversion of RGB image into chrominance part of image and then block processing is applied to divide the image into 3*3 or 4* 4 overlapping blocks. Then feature extraction of image is done by applying DWT and DCT algorithm and then the output is given to the image classifier SVM(support vector machine).The mentioned process is shown in the below figure.

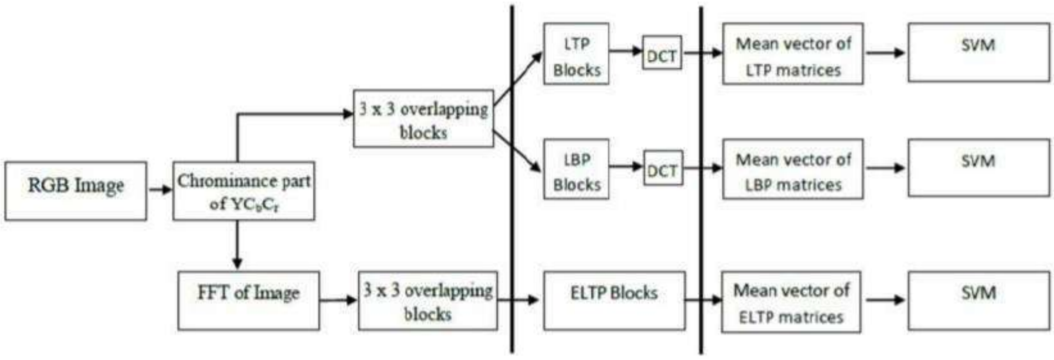

Fig 3.1 Overview of the Design

3.2 INTRODUCTION TO IMAGE PROCESSING

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces. The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by combination of methods, especially in a pseudo-photograph.

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

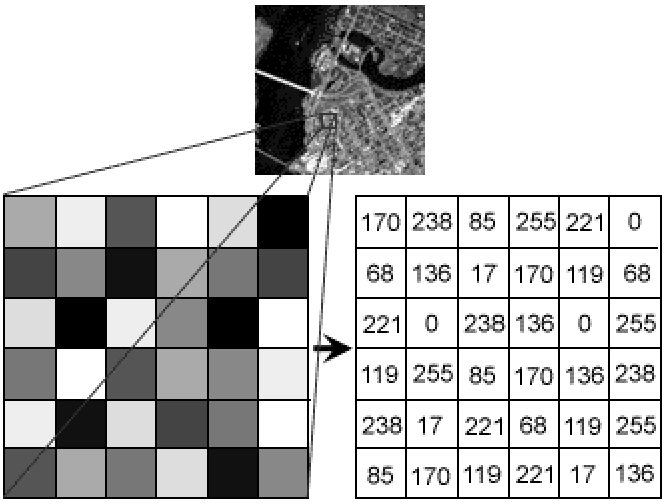

Fig 3.1 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

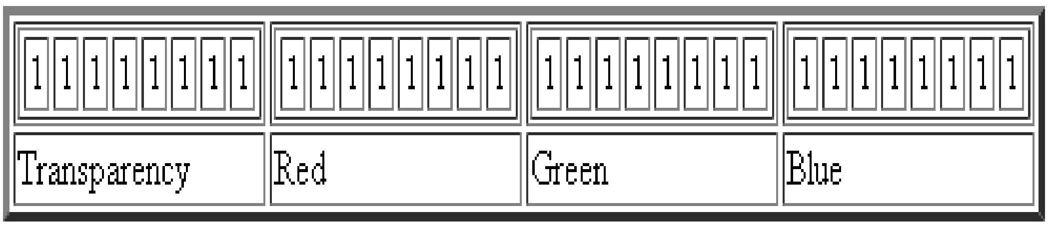

Fig 3.2 Transparency image

3.3 IMAGE FILE SIZES

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

3.4 IMAGE FILE FORMATS

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

3.4.1 RASTER FORMATS

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

3.4.2 VECTOR FORMATS

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

3.5 TYPES OF IMAGES

Binary Images

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1. Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors.

3.6 IMAGE PROCESSING

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

3.6 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING

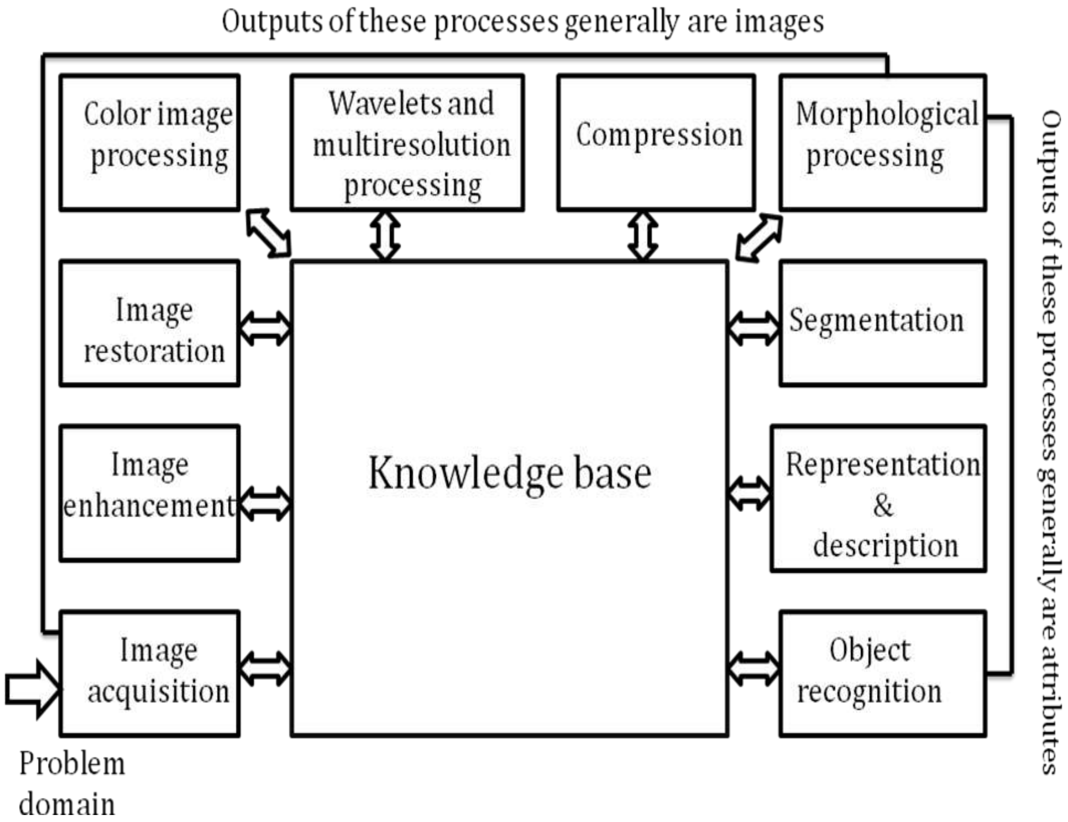

Fig 3.3 Image fundamental

3.6.1 IMAGE ACQUISITION

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application

3.6.2 IMAGE ENHANCEMENT

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

3.6.3 IMAGE RESTORATION

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a "good" enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

3.6.4 COLOR IMAGE PROCESSING

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

3.6.5 WAVELETS AND MULTIRESOLUTION PROCESSING

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform-based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

3.6.6 COMPRESSION

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image cmpression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

3.6.7 MORPHOLOGICAL PROCESSING

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

3.6.8 SEGMENTATION

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

3.6.9 REPRESENTATION AND DESCRIPTION

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

3.6.10 OBJECT RECOGNITION

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

3.6.11 KNOWLEDGEBASE

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented pre-processing techniques using MATLAB.

3.7 INTRODUCTION TO SOFTWARE: MATLAB (2013rb version)

3.7.1. INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.7.2 THE MATLAB SYSTEM

The MATLAB system consists of five main parts

- **DEVELOPMENT ENVIRONMENT**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **THE MATLAB MATHEMATICAL FUNCTION LIBRARY**

  This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **THE MATLAB LANGUAGE**

  This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **GRAPHICS**

  MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **THE MATLAB APPLICATION PROGRAM INTERFACE (API)**

  This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3.7.3 GRAPHICAL USER INTERFACE (GUI)

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in

M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

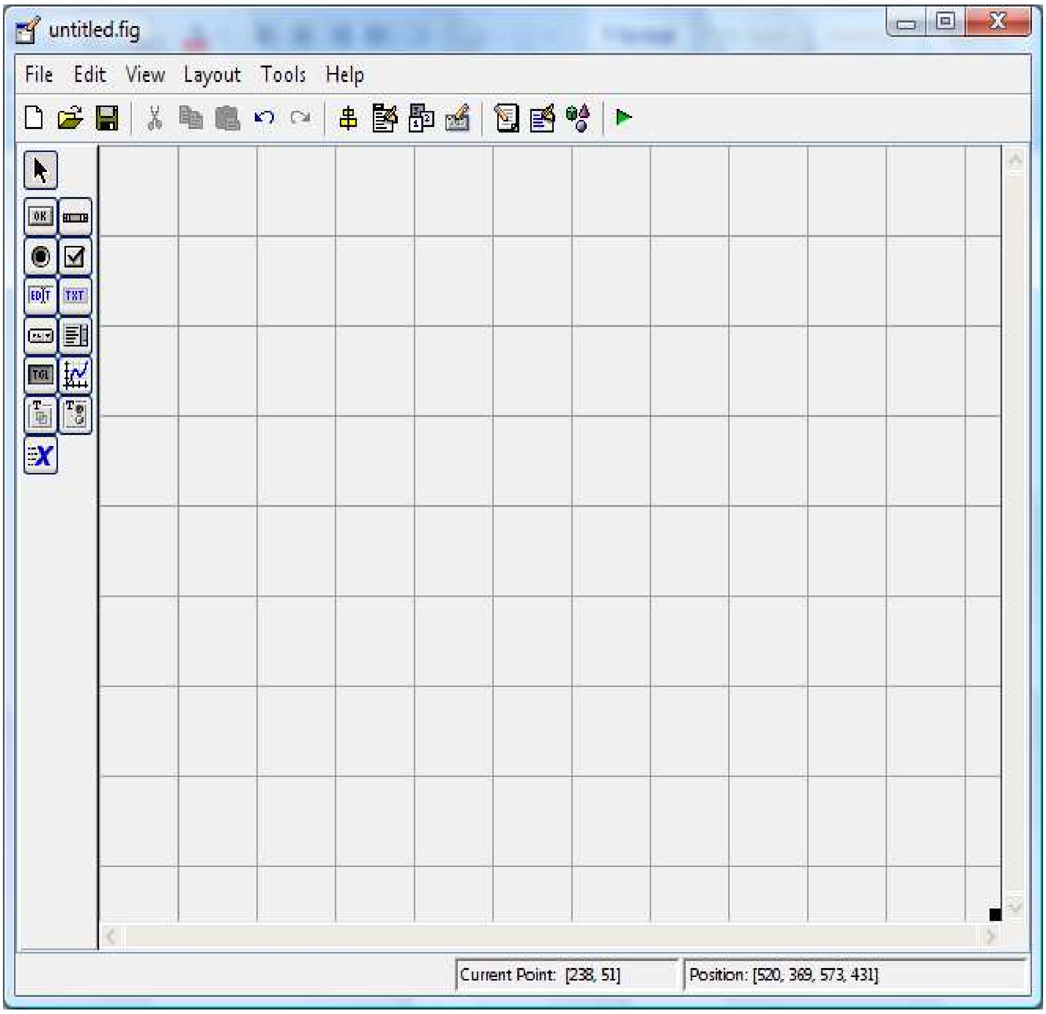

Fig 3.4 GUI window

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.8 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

- **Introduction** - describes the components of the MATLAB system.
- **Development Environment** - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.
- **Manipulating Matrices** - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.
- **Graphics** - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.
- **Programming with MATLAB** - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.9 DEVELOPMENT ENVIRONMENT

3.9.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

STARTING AND QUITTING MATLAB

3.9.2 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3.9.3 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.9.4 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.9.5 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

COMMAND WINDOW

Use the Command Window to enter variables and run functions and M-files.

COMMAND HISTORY

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

RUNNING EXTERNAL PROGRAMS

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

LAUNCH PAD

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

HELP BROWSER

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

HELP NAVIGATOR

Use to Help Navigator to find information. It includes:

PRODUCT FILTER - Set the filter to show documentation only for the products you specify.

CONTENTS TAB - View the titles and tables of contents of documentation for your products.

INDEX TAB - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

SEARCH TAB - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

FAVORITES TAB - View a list of documents you previously designated as favorites.

DISPLAY PANE

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

BROWSE TO OTHER PAGES - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

BOOKMARK PAGES - Click the Add to Favorites button in the toolbar.

PRINT PAGES - Click the print button in the toolbar.

FIND A TERM IN THE PAGE - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

CURRENT DIRECTORY BROWSER

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

SEARCH PATH

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

WORKSPACE BROWSER

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

ARRAY EDITOR

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

EDITOR/DEBUGGER

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

3.10 MANIPULATING MATRICES

3.10.1 ENTERING MATRICES

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.

- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

    16     3     2    13

     5    10    11     8

     9     6     7    12

     4    15    14     1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

3.10.2 EXPRESSIONS

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables

- Numbers
- Operators
- Functions

VARIABLES

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

NUMBERS

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.10.3 OPERATORS

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 3.1 Expression of Arithmetic Operations in MATLAB

3.10.4 FUNCTIONS

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2- \varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 3.2 Expressions of Functions in MATLAB

3.11 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include.

3.11.1 CREATING GUIs WITH GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.11.2 GUI DEVELOPMENT ENVIRONMENT

The process of implementing a GUI involves two basic tasks.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

THE IMPLEMENTATION OF A GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of itschildren (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and thecallbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

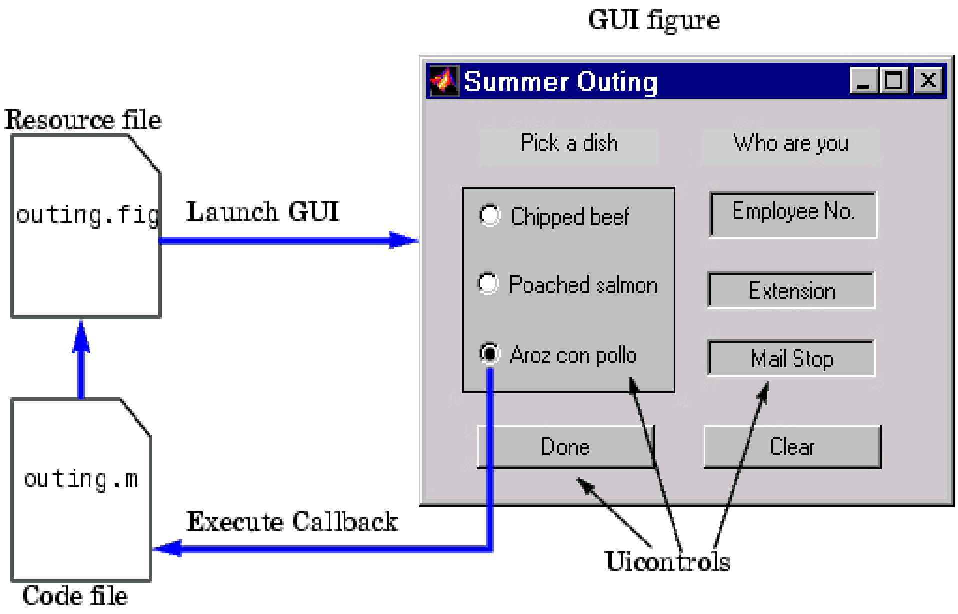

Fig 3.5 Graphical User Blocks

3.11.3 FEATURES OF THE GUIDE-GENERATED APPLICATION M-FILE

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

3.11.4 BEGINNING THE IMPLEMENTATION PROCESS

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

COMMAND-LINE ACCESSIBILITY

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.11.5 USER INTERFACE CONTROL

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

PUSH BUTTONS

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

PROPERTIES TO SET

String - set this property to the character string you want displayed on the push button.

TAG - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

PROGRAMMING THE CALLBACK

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

TOGGLE BUTTONS

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

PROGRAMMING THE CALLBACK

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

FROM THE GUIDE APPLICATION M-FILE

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed
```

end

ADDING AN IMAGE TO A PUSH BUTTON OR TOGGLE BUTTON

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

RADIO BUTTONS

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

IMPLEMENTING MUTUALLY EXCLUSIVE BEHAVIOR

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

OBTAINING THE RADIO BUTTON HANDLES

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

   .

   .

   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

CHECKBOXES

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

EDIT TEXT

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

OBTAINING NUMERIC DATA FROM AN EDIT TEST COMPONENT

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

TRIGGERING CALLBACK EXECUTION

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

STATIC TEXT

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

FRAMES

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uncontrol's can appear within frames (axes cannot).

PLACING COMPONENTS ON TOP OF FRAMES

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

LIST BOXES

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

SINGLE OR MULTIPLE SELECTION

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

SELECTION TYPE

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

TRIGGERING CALLBACK EXECUTION

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

POPUP MENUS

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

PROGRAMMING THE POPUP MENU

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');
```

selected_string = string_list{val}; % convert from cell array to string

% etc.

ENABLING OR DISABLING CONTROLS

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

AXES

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

AXES CALLBACKS

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.11.6 PLOTTING TO AXES IN GUIS

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIS WITH MULTIPLE AXES

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

FIGURE

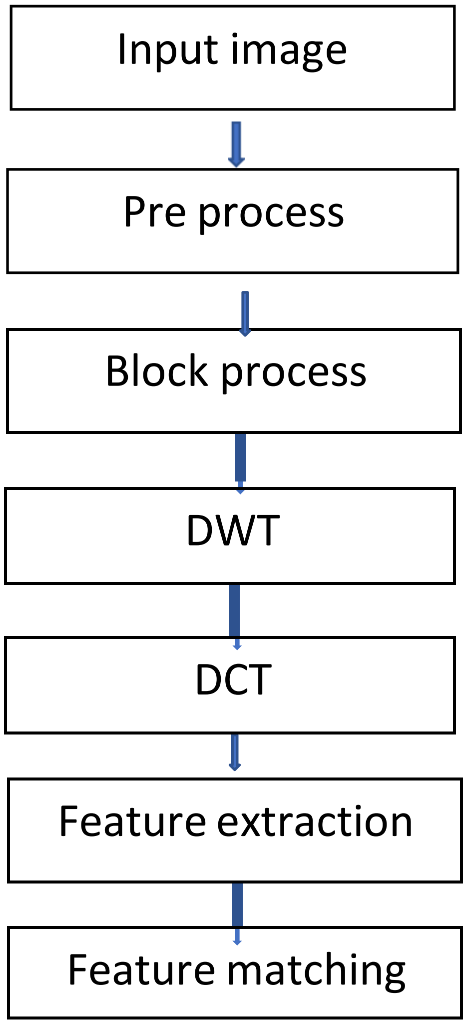
Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control

CHAPTER 4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT

The basic procedure that every image should go through during image forgery detection is shown the following block diagram. The first step includes preprocessing which is used for image enhancement and followed by block process to divide the image into 3*3 or 4*4 overlapping blocks and then DWT and DCT algorithm is applied followed by feature extraction and feature matching is done and post processing is done then output image is given to image classifier to detect the tampered part and the displayed as final output. This basic process is shown in following block diagram



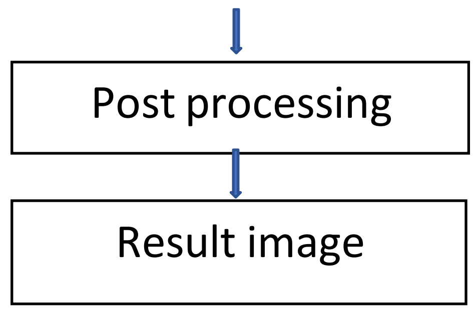


Fig.4.1: Block diagram of the project

4.5 RESULTS

By Performing feature matching and sorting copy and move part is detected.

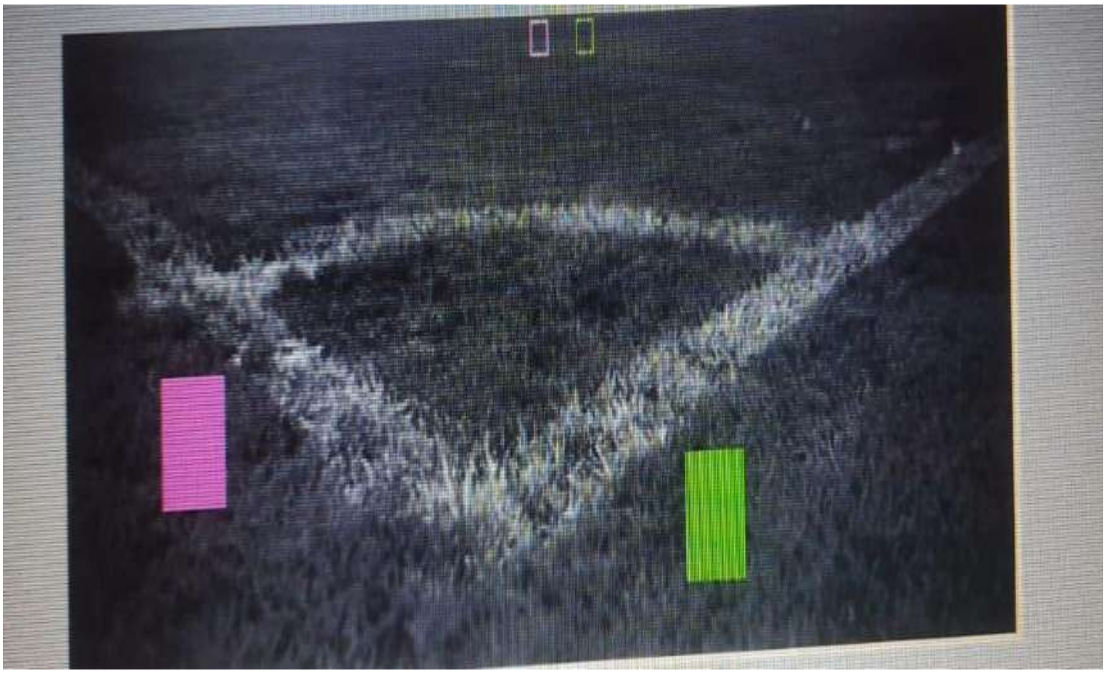

Fig 4.10: Final Output

CHAPTER-5

CONCLUSION AND FUTURE ENHANCEMENT

CONCLUSION

The proposed approach can be used to detect the digital image forgery by using FFT and Local features successfully. It can be observed that LBP and ELTP perform as better features to classify the image as forged or authentic. The presented approaches involve complex transformations like DCT and FFT which increases the complexity of the methodology. The accuracy of detecting the copied parts of the image is increased when compared to existing techniques. The time taken for detection of forgery is reduced. The proposed system had successfully overcome the difficulties in the existing techniques.The proposed forgery detection had used block-based division techniques and feature extraction and SVM for image classifiers for accuracy of detection.

FUTURE ENHANCEMENT

The proposed method consists of FFT and DCT as main algorithm which increases complexity of the system. In future development complexity can be reduced. In future based on key point division the forgery detection technique can be developed. Further accuracy and reduction of time can be achieved in future practices.

PUBLICATION

Submitted Paper in the Conference ICSMEC- 21 with Paper ID (ICSMEC21-0045) and got Acceptance for the Paper. The paper was submitted under the name of Detection of Digital Image Forgery using FFT and Local features. The authors and coauthors of the project D. Saibhargavi, D. Pavani, B. Harish. This project has been completed under the guidance of Ms. R. Alekya Assistant professor ECE dept.

APPENDIX

The project proposes a technology to detect the genuiness of the image, this project is used to detect whether the image is genuine or forged. This project had got motivated from the existing methods published in IEEE papers under the name of Image-Splicing Forgery Detection Based on Improved LBP and K-Nearest Neighbors Algorithm," no. September 2015.This method uses both FFT and LOCAL FEATURES to detect the tampered part of the image and final result is displayed by performing certain processing techniques. This proposed techniques gives greater accuracy compared to existing methods .

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, Department of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our Class Project Coordinator **Ms. P. Pushpa, Assistant Professor**, Department of Electronics and Communication Engineering and our project guide **Mrs.A.Soumya, Assistant Professor**, Department of Electronics and Communication Engineering for guidance and encouragement in carrying out this project work.

ABSTRACT

Underground cables are prone to a wide variety of faults due to underground conditions, wear and tear, rodents etc. Also detecting fault source is difficult and entire line is to be dug in order to check entire line and fix faults. So here we propose an cable fault detection over IOT that detects the exact fault position over IoT that makes repairing work very easy. The repairmen know exactly which part has fault and only that area is to be dug to detect the fault source. This saves a lot of time, money and efforts and also allows to service underground cables faster. We use IOT technology that allows the authorities to monitor and check faults over internet. The system detects fault with the help of potential divider network laid across the cable. Whenever a fault gets created at a point shorting two lines together, a specific voltage gets generated as per the resistors network combination. This voltage is sensed by the microcontroller and is updated to the user. The information conveyed to the user is the distance to which that voltage corresponds to. The microcontroller retrieves the fault line data and displays over LCD display, also it transfers this data over internet to display online. We use IoT Gecko to develop the online system that links with the system to display the cable faults online.

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Power supply networks are growing continuously and their reliability getting more important than ever. The complexity of the whole network comprises numerous components that can fail and interrupt the power supply for end user. For most of the worldwide operated low voltage and medium voltage distribution lines, underground cables have been used for many decades. Underground high voltage cables are used more and more because they are not influenced by weather conditions, heavy rain, storm, snow and pollution. Even though the Cable manufacturing technology is improving steadily; there are still influences which may cause cable to fail during test and operation. A cable in good condition and installed correctly can last a lifetime of about 30 years. However cables can be easily damaged by incorrect installation or poorly executed jointing, while subsequent third party damage by civil works such as trenching or curb edging.

1.1.1 Types of Faults in Cables

1.1.1.1 Open Circuit Fault

When there is a break in the conductor of the cable, it is called open circuit fault of the cable. The open circuit fault can be checked by megger. For this purpose, the three conductors of the 3-core cable at the far end are shorted and earthed. Then resistance between each conductor and earth is measured by a megger. The megger will indicate zero resistance in the circuit of the conductor that is not broken. However, if the conductor is broken, the megger will indicate infinite resistance in its circuit.

1.1.1.2. Short Circuit Fault

When two conductors of a multi-core cable come in electrical contact with each other due to insulation failure, it is called short-circuit fault. The two terminals of the megger are connected to any two conductors. If the megger gives zero reading, it indicates short-circuit fault between these two conductors. The same step can be repeated for other conductors taking two at a time.

1.1.1.3. Earth Fault

When the conductor of the cable comes in contact with earth, it is called earth fault or ground fault. To identify this fault, one terminal of the megger is connected to the conductor and the other terminal connected to earth. If megger indicates zero reading, it means the conductor is earthed. The same procedure is repeated for other conductors of the cable. This project is used to detect the location of fault in digital way. Locating the faulty point in an underground cable helps to facilitate quicker repair, improve the system reliability and reduced outage period.

1.2 OBJECTIVES OF THE STUDY:

The evaluation of IoT in the electrical Power Industry transformed the way things performed in usual manner. IoT increased the use of wireless technology to connect power industry assets and infrastructure in order to lower the power consumption and cost. The applications of IoT are not limited to particular fields, but span a wide range of applications such as energy systems, homes, industries, cities, logistics, heath, agriculture and so on. Since 1881, the overall power grid system has been built up over more than 13 decades, meeting the ever increasing demand for energy. Power grids are now been considered to be one of the vital components of infrastructure on which the modern society depends. It is essential to provide uninterrupted power without outages or losses. It is quiet hard to digest the fact that power generated is not equal to the power consumed at the end point due to various losses. It is even harder to imagine the after effects without power for a minute. Power outages occur as result of short circuits. This is a costly event as it influences the industrial production, commercial activities and consumer lifestyle. Government & independent power providers are continuously exploring solutions to ensure good power quality, maximize grid uptime, reduce power consumption, increase the efficiency of grid operations and eradicate outages, power loss & theft. Most importantly, the solution should provide a real-time visibility to customers on every penny paid for their energy. There is an increasing need of a centralized management solution for more reliable, scalable, and manageable operations while also being cost effective, secure, and interoperable. In addition, the solution should enable power providers and utilities to perform effective demand forecasting and energy planning to address the growing need for uninterrupted quality power [5]. The goal of IoT is not just only connecting things such as machines, devices and appliances, but also allowing the things to communicate, exchanging control data and other necessary information while executing applications. It consists of IoT devices that have unique identities and are capable of performing remote sensing, monitoring and actuating tasks. These devices are capable of interacting withone another directly or indirectly. Data collection is performed locally or remotely via centralized servers or cloud based applications. These devices may be data collection devices to which various sensors are attached such as temperature, humidity, light, etc., or they may be data actuating devices to which actuators are connected, such as relays. IoT system is composed of three layers: the perception layer, the network layer, and the application layer as shown in Figure 1. The perception layer includes a group of Internet-enabled devices that can percept, detect objects, collect systems information, and exchange information with other devices through the Internet communication networks. Sensors, Global Positioning Systems (GPS), cameras, and Radio Frequency Identification Devices (RFID) are examples of devices that exist at perception layer. The network layer is responsible of forwarding data from perception layer to the application layer under the constraints of devices' capabilities, network limitation and the applications' constraints. IoT systems use a combination of Internet and short-range networks based on the communicated parties. Short-range communication technologies such as Bluetooth and ZigBee are used to carry the information from perception devices to a nearby gateway. Other technologies such as Wi-Fi, 2G, 3G, 4G, and Power line Communication (PLC) carry the information for long distances based on the application. The upper layer is the application layer, where incoming information is processed to induce insights for better power's distribution design and management strategies.

1.3 SCOPE OF THE STUDY:

- The work can be extended for open circuit fault, short circuit Line to Line Fault (LL) and double Line to Ground Fault (LLG).
- The open circuit fault can be detected using a capacitor in ac circuit which measures the change in impedance and calculate the distance of fault.
- The proposed system in this paper detect only the location of Short Circuit fault in underground cable line, and also detect the location of open circuit fault, to detect the

open circuit fault capacitor is used in circuit which measure the change in resistance & calculate the distance of fault.

- For future research, the system would proceed with similar neural networks structure for different types fault section and fault location estimation.
- We can further develop a better user interface by which detection of open circuit fault is possible in near future.
- To find the fault in ac circuits, fluctuation in impedance is measured with the help of capacitor. In this way we can find the fault distance.
- We use an Ethernet shield to establish connection to the web page. If we use a Wi-Fi module instead of an Ethernet shied then we can make it wireless.
- With the help of an SD card, we can develop a better user interface. In the future it can be used to find the error in open circuit faults
- In this project we detect the exact location of short circuit fault in the underground cable from feeder end in km by using Arduino.
- In future, this project can be implemented to calculate the impedance by using a capacitor in an AC circuit and thus measure the open circuit fault.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- LCD
- Power Supply
- WI-FI Module ESP8266
- Switches
- Relay
- Load

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the underground cable fault with better efficiency, with less time delay and the results were also satisfactory and we successfully got the output in mobile telnet app and LCD screen. We would like to improve the project in future for further developments.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

The idea of Underground transmission cable was first introduced by W. M. Callender before the American Institute of Electrical Engineers, at Philadeithia, September, 1884.he told in his paper that — For underground work, the first thing to be decided upon is the conduit A practical algorithm with wavelet Multi Resolution Analysis (MRA) coefficients are designed by Tag Eldin (2010) for fault detection and classification. The line currents at the two ends are evaluated through an online WT algorithm with MRA for fault identification. The magnitudes of spikes in wavelet coefficients are used in the fault detection and classification process. To segregate the ground faults from phase-to-phase faults, the smooth coefficient examination of neutral current is employed. The designed technique by Reddy et al. (2009) with a mixture of impedance calculation and CWT method identifies the disturbance with fault occurrence. There are many schemes with the relay for identification of the proper faulty phase in order to protect the power system from transmission line faults. The scheme employs the NN, WT or both, to address the issues. WT with exact tools are used by Mohammad Ali et al. (2014) for transient signal in transmission lines. An ANN has a large variation between the measured signal and associated signal. Transmission lines are used to distribute the electric power at the destination. The fault localization issues are addressed by Mohammad Abdul Baseer (2013) by traveling wave voltage and current signals on a transmission line network. Fourier Transform (FT) is used to get the frequency components in fault signal. The wavelet MRA is essential in signal analysis and compatible with traveling wave signals. A fault detection method has been designed by Durga Prasad & Srinivasu (2015) for protection of transmission lines by root mean square values of 3-phase power. Input signal for detection algorithm is changed during faults and non-fault cases. The designed method is authenticated for faults of many types at various moments and various locations. The transmission line is an important part, susceptible to fault of electrical power system, because of its large physical dimension. A model has been designed by Andre de Souza Gomes (2013) to functionally characterize the phases of a transmission line. The detection and classification plans are designed by a set of fault simulation and real record. Dhivya Dharani.A, Sowmya.T the paper titles as―Development of a Prototype Underground Cable Fault Detector ―Cable faults are damage to cables which affects the resistance in the cable. If allowed to persist, this can lead to a voltage breakdown. To locate a fault in the cable, the cable must first be tested for faults. This prototype is assembled with a set of resistors representing cable length in Kilo meters and fault creation is made by a set of switches at every known Kilo meters (km's) to cross check the accuracy of the same. The fault occurring at what distance and which phase is displayed on a 16X2 LCD interfaced with the microcontroller. Nikhil Kumar Sain, Rajesh Kajla paper titled as ―Underground Cable Fault Distance Conveyed. This paper proposes fault location model for underground power cable using microcontroller. The aim of this project is to determine the distance of underground cable fault from base station in kilometres. This project uses the simple concept of ohm's law. When any fault like short circuit occurs, voltage drop will varydepending on the length of fault in cable, since the current varies. R.K.Raghul Mansingh, R.Rajesh, S.Ramasubramani, G.Ramkumar titled as ―Underground Cable Fault Detection using Raspberry Pi and Arduino‖-The aim of this project is to determine the underground cable fault. This project uses the simple concept of CT Theory. When any fault like short circuit occurs, voltage drop will vary depending on the length of fault in cable, since the current varies CT is used to calculate the varying. The signal conditioner manipulates the change in voltage and a microcontroller is used to make the necessary calculations so that the fault distance is displayed by IOT devices.

2.2 REVIEW ON RELATED LITERATURE:

Sectionalizing:

Sectionalizing procedure reduces cable reliability, because it depends on physically cutting and splicing the cable. Dividing the cable into successively smaller sections and measuring both ways with an ohmmeter or high-voltage insulation resistance (IR) tester enable to narrow down search for a fault. This laborious procedure normally involves repeated cable excavation.

Thumping:

When high voltage is supplied to faulty cable, the resulted high current arc makes a noise loud enough to hear above ground. While this method eliminates the sectionalizing method's cutting and splicing, it has its own drawback. Thumping requires a current on the order of tens of thousands of amps at voltages as high as 25 kV to make an underground noise loud enough to hear above ground. The heating from this high current often causes some degradation of the cable insulation. The limit of damage can be reduced by passing minimum required power to conduct the test.

Time-Domain Reflectometry:

The Time domain reflectometer (TDR) is an electronic instrument that uses time domain reflectometry to characterize and locate faults in metallic cables. The TDR sends a lowenergy signal through the cable, causing no insulation degradation. A theoretically perfect cable returns that signal in a known time and in a known profile. Impedance variations in a "real-world" cable alter both the time and profile, which the TDR screen or printout graphically represents. One weakness of TDR is that it does not pinpoint faults.

Arc Reflection Method:

This method is often referred to as a high voltage radar technique that overcomes the 200 Ω limitation of low-voltage radar. In addition to the TDR, an arc reflection filter and surge generator is required. The surge generator is used to create an arc across the shunt fault which creates a momentary short circuit that the TDR can display as a downward-going reflection. The filter protects the TDR from the high voltage pulse generated by the surge generator and routes the low-voltage pulses down the cable. Arc reflection is the most accurate and easiest pre location method. The fault is displayed in relation to other cable landmarks such as splices, taps and transformers and no interpretation is required. Arc reflection makes it possible for the TDR to display "before" and "after" traces or cable signatures. The "before" trace is the low-voltage radar signature that shows all cable landmarks but does not show the downward reflection of a high resistance shunt fault. The "after" trace is the high-voltage signature that includes the fault location even though its resistance may be higher than 200 Ω. This trace is digitized, stored and displayed on the screen and the cursors are positioned in order to read the distance to the high resistance fault.

2.3 CONCLUSION ON REVIEWS:

Today, the methods to find fault became increasingly complex and these methods include usage of Fourier analysis, Wavelet Transformation etc. But still, the time is taken to report the fault and to rectify it is reduced slightly. Thus came the use of Microprocessor followed in by IoT. The fault is identified and is stored in the cloud. The stored data is updated in the database for an app and HTML page. Thus the repairmen are given as much information about the fault is provided.

Programs uploaded in Arduino UNO kit to detect faults from the underground cables. When a fault occurs in the underground cables, we can find out faults through Arduino controller kit. LCD display which displays the faults in Kilometer. In this project we created faults manually. Cable has many types. Every cable has different resistance which depends upon the material used. The value of the resistance is depends upon the length of the cable. In here resistance is the leading role of the project. If any deviation occurs in the resistance, the value of the voltage will be changed that particular point is called FAULT. We are finding out those faults.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

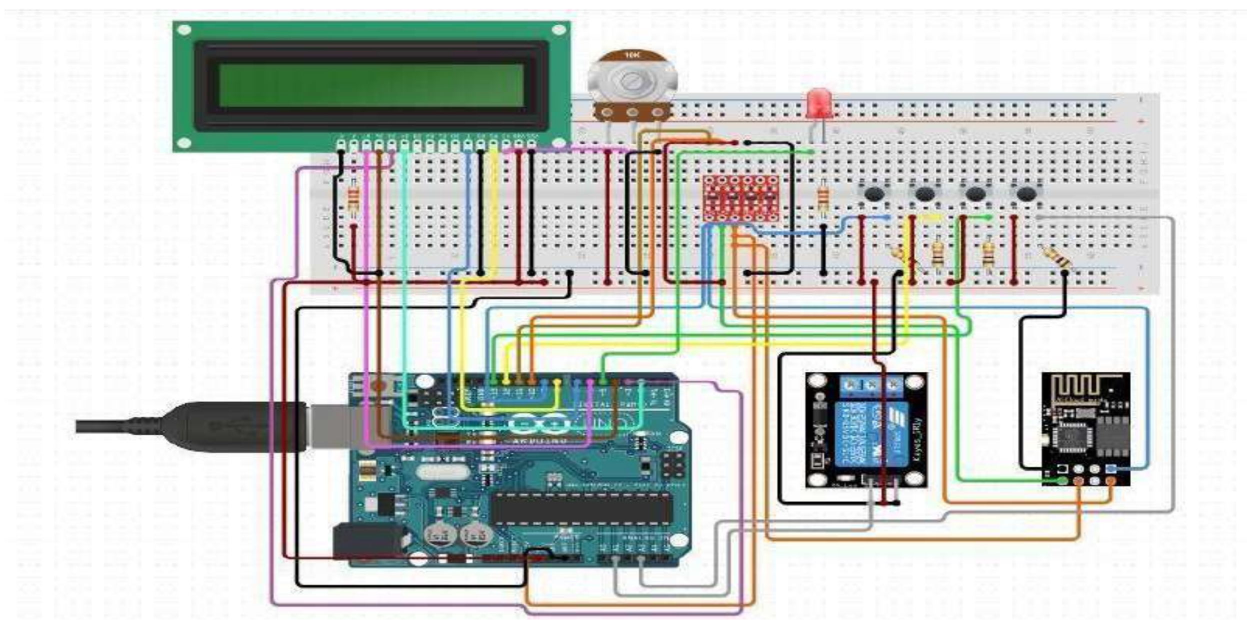

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

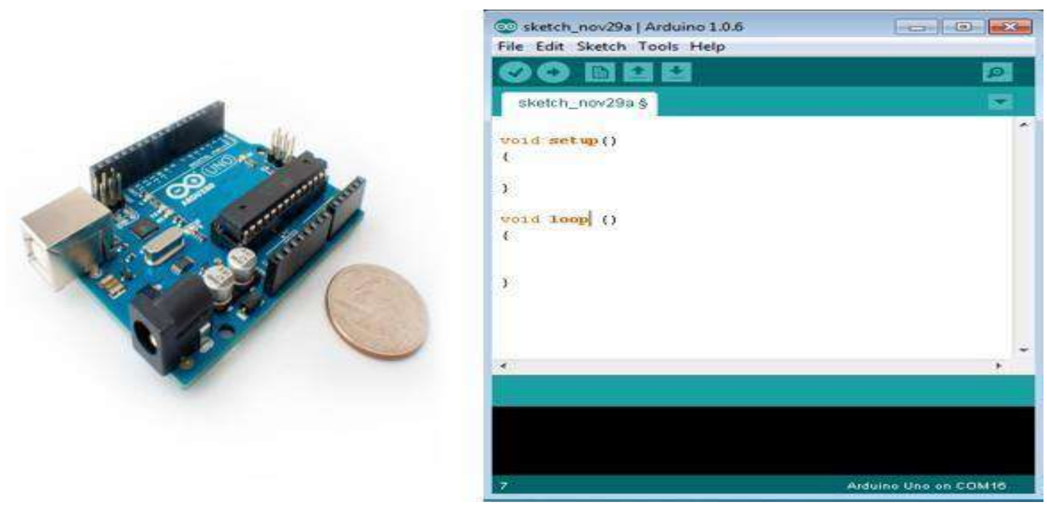

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

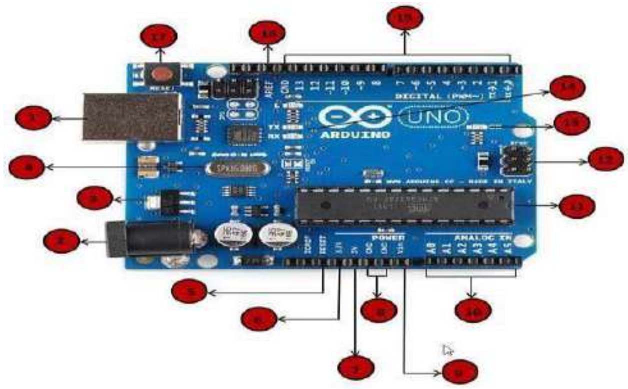

Fig.3.2.1.3 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt

	• 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs**

	On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 3.2.1.3.1 Board description of Arduino UNO

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.4: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.5: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

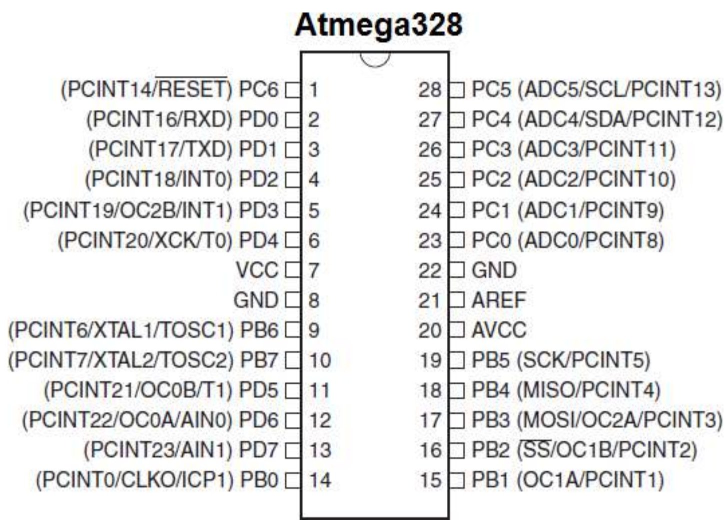

Fig.3.2.1.6 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

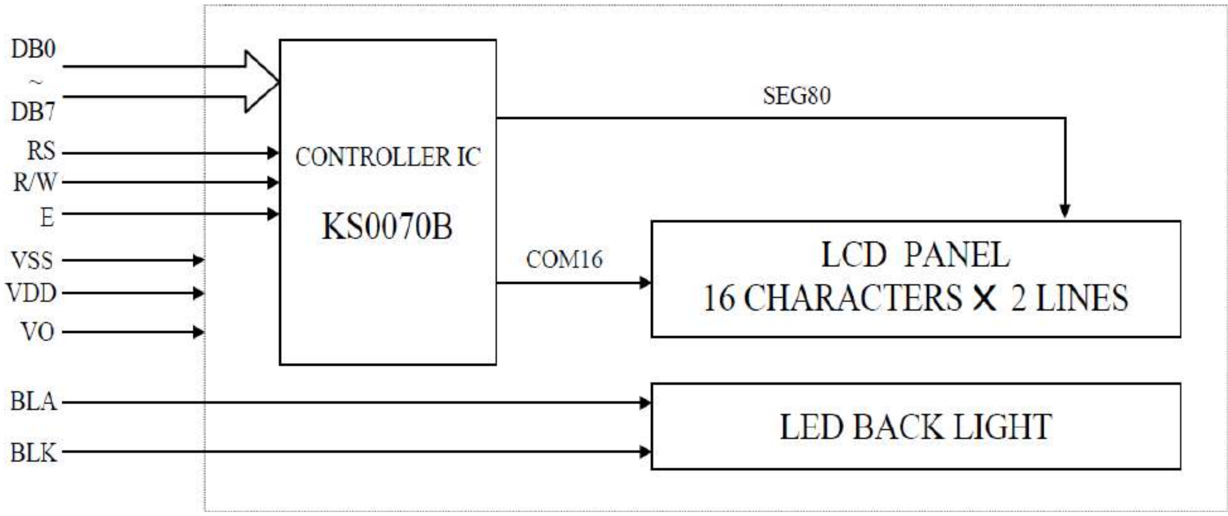

fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.
Figure below will show you the DDRAM addresses of 2 Line LCD.

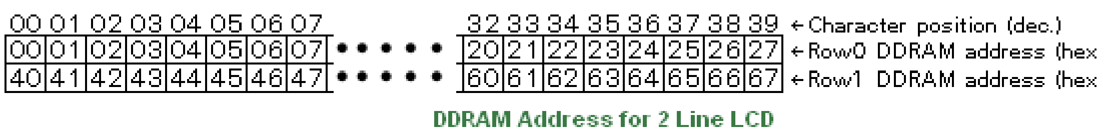

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible

- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 POWER SUPPLY UNIT

3.2.3.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable l voltage supply for electronic circuits and other devices. A power supply can by broken down into a ser of blocks, each of which performs a particular function. A d.c power supply which maintains the out voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Po Supply”.

3.2.3.2 BLOCK DIAGRAM OF POWER SUPPLY:

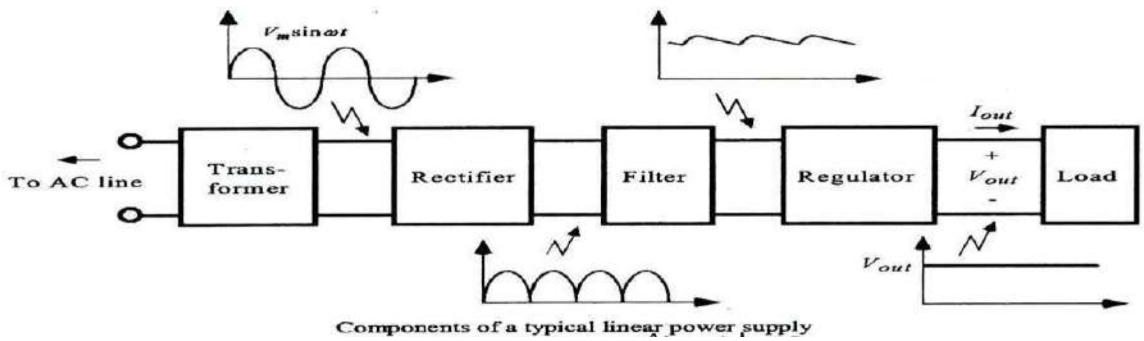

Figure 3.2.3.2.1: Block Diagram of Power Supply

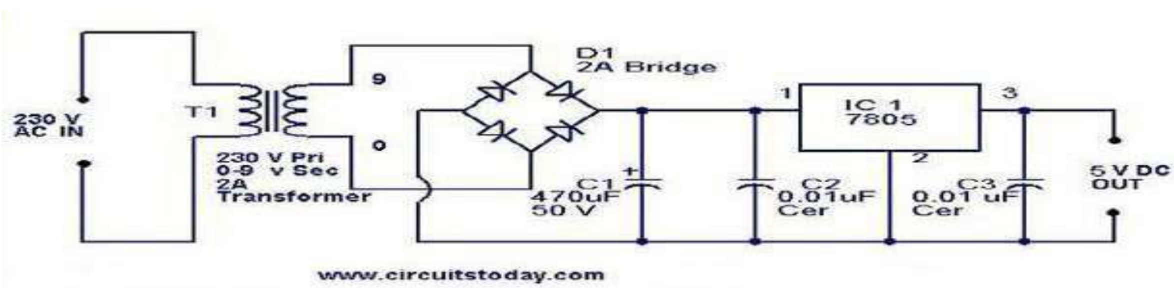

Figure 3.2.3.2.2: Schematic Diagram of Power Supply

3.2.3.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert aa different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.2.3.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

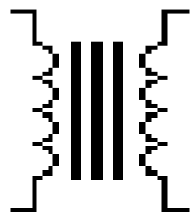

Figure 3.2.3.4.1 : Transformer Symbol

Transformer is a device that converts the one form energy to another form of energy like a transducer.

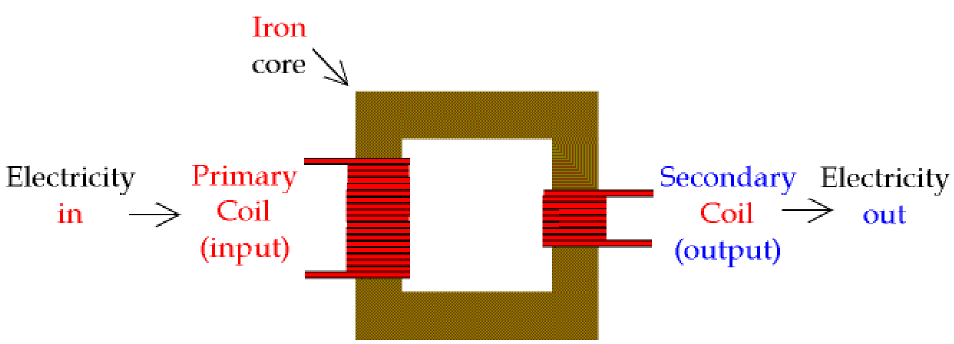

Figure 3.2.3.4.2 : Transformer

3.2.3.5 BASIC PRINCIPLE OF TRANSFORMER:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

3.2.3.6 WORKING OF TRANSFORMER:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

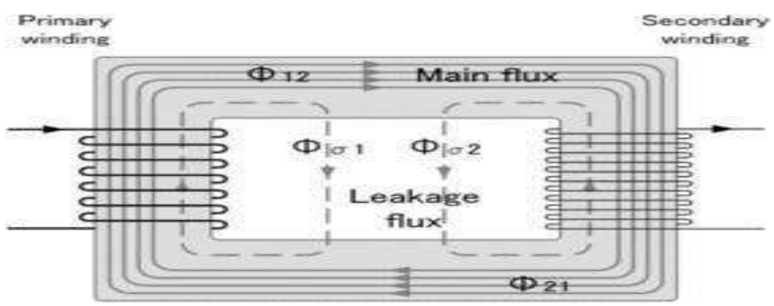

Figure 3.2.3.6 : Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.2.3.7 . Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

3.2.3.7.1 Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

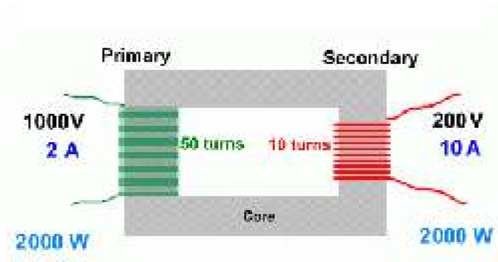

Figure 3.2.3.7.1 : Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

3.2.3.7.2 Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

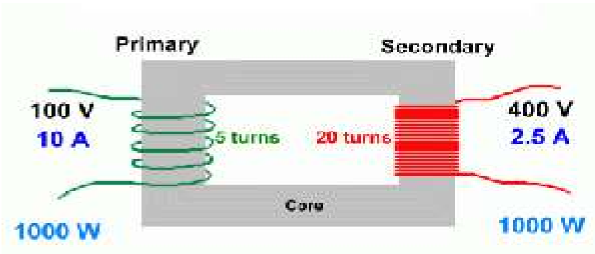

Figure 3.2.3.7.2 : Step-Up Transformer

3.2.3.8 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

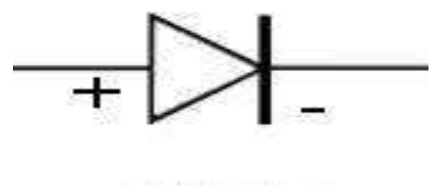

Figure 3.2.3.8 : Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.2.3.9 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

3.2.3.10 The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

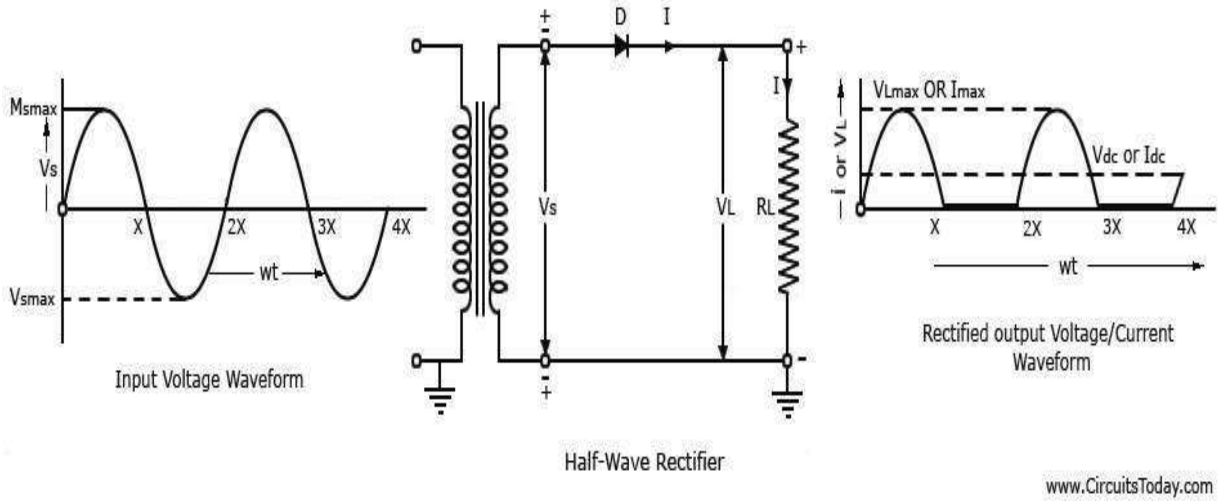

Figure 3.2.3.10 : Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

3.2.3.11 The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

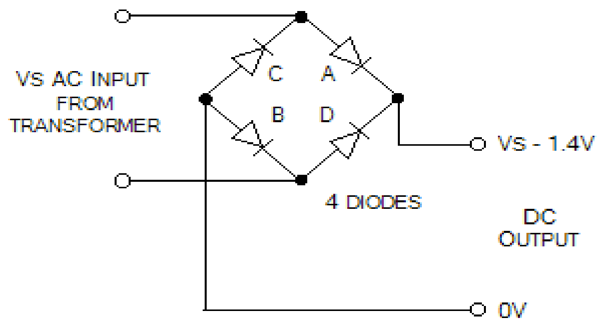

Figure 3.2.3.11.1: Full-Wave Rectifier

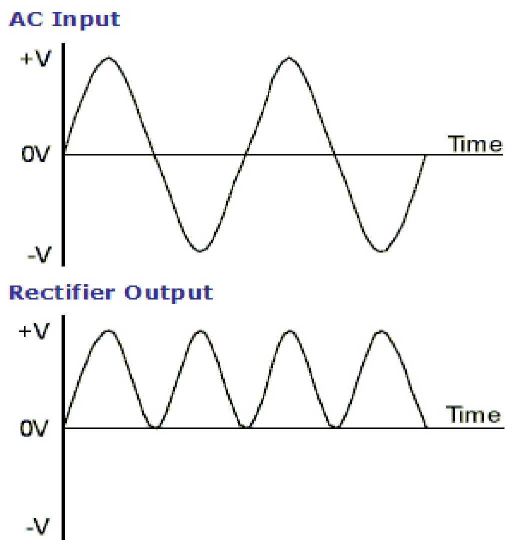

Figure 3.2.3.11.2: Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

3.2.3.12 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letterpi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

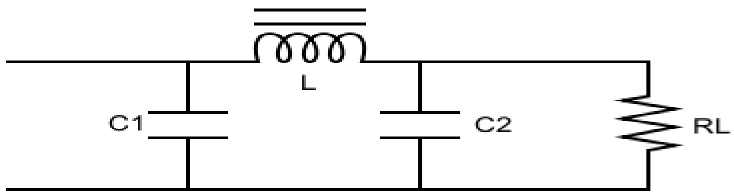

Figure 3.2.3.12.1 : Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

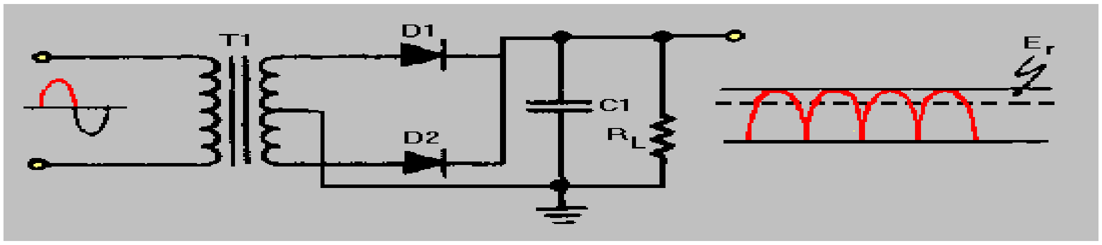

Figure 3.2.3.12 : Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.2.3.13 . VOLTAGE REGULATOR:

A voltage regulator is an electricalregulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

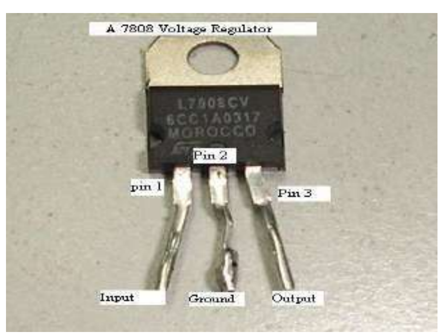

Fig.3.2.3.13 Voltage Regulator

3.2.4 Relay

3.2.4.1 Introduction

A relay is used to isolate one electrical circuit from another. It allows a low current control circuit to make or break an electrically isolated high current circuit path. The basic relay consists of a coil and a set of contacts. The most common relay coil is a length of magnet wire wrapped around a metal core. When voltage is applied to the coil, current passes through the wire and creates a magnetic field. This magnetic field pulls the contacts together and holds them there until the current flow in the coil has stopped. The diagram below shows the parts of a simple relay.

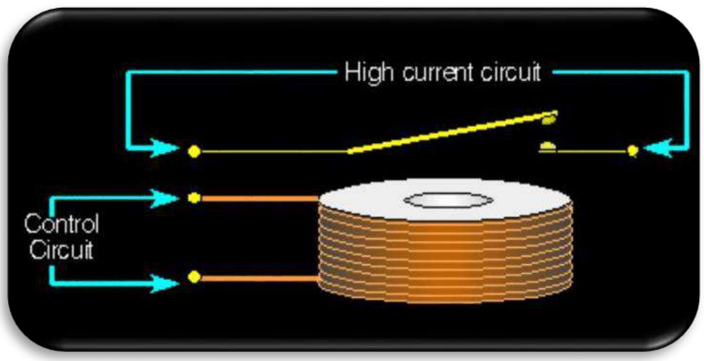

Figure 3.2.4.1 : Relay

3.2.4.2 Operation:

When a current flows through the coil, the resulting magnetic field attracts an armature that is mechanically linked to a moving contact. The movement either makes or breaks a connection with a fixed contact. When the current is switched off, the armature is usually returned by a spring to its resting position shown in figure 6.6(b). Latching relays exist that require operation of a second coil to reset the contact position.

By analogy with the functions of the original electromagnetic device, a solid-state relay operates a thyristor or other solid-state switching device with a transformer or light-emitting diode to trigger it.

3.2.4.3 Pole and throw

3.2.4.3.1 SPST

SPST relay stands for Single Pole Single Throw relay. Current will only flow through the contacts when the relay coil is energized.

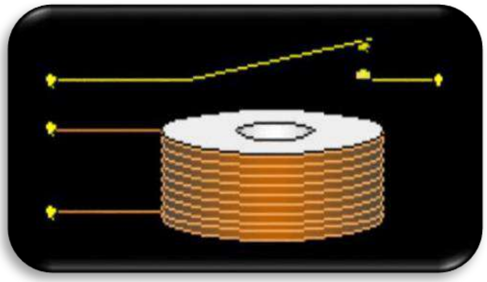

Figure 3.2.4.3.1 : SPST Relay

3.2.4.3.2 SPDT Relay

SPDT Relay stands for Single Pole Double Throw relay. Current will flow between the movable contact and one fixed contact when the coil is De-energized and between the movable contact and the alternate fixed contact when the relay coil is energized. The most commonly used relay in car audio, the Bosch relay, is a SPDT relay.

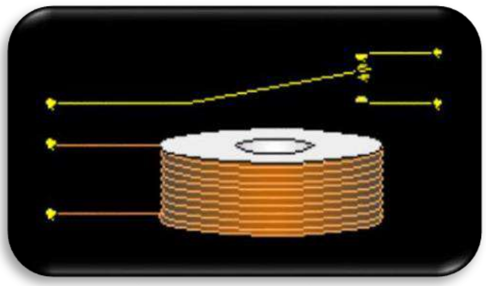

Figure 3.2.4.3.2 : SPDT Relay

3.2.4.3.3 DPST Relay

DPST relay stands for Double Pole Single Throw relay. When the relay coil is energized, two separate and electrically isolated sets of contacts are pulled down to make contact with their stationary counterparts. There is no complete circuit path when the relay is De-energized.

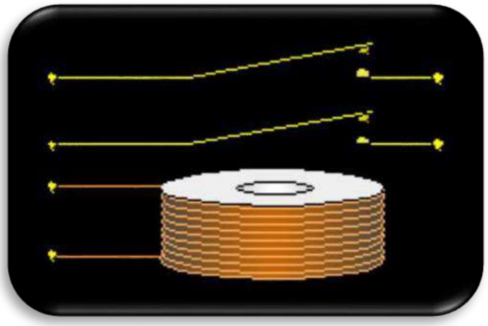

Figure 3.2.4.3.3 : DPST Relay

3.2.4.3.4 DPDT Relay

DPDT relay stands for Double Pole Double Throw relay. It operates like the SPDT relay but has twice as many contacts. There are two completely isolated sets of contacts.

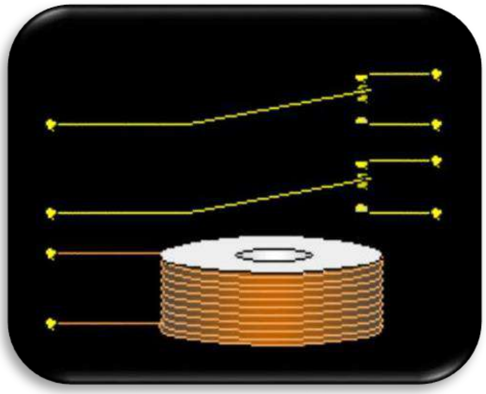

Figure 3.2.4.3.4.1 : DPDT Relay

This is a 4 Pole Double Throw relay. It operates like the SPDT relay but it has 4 sets of isolated contacts.

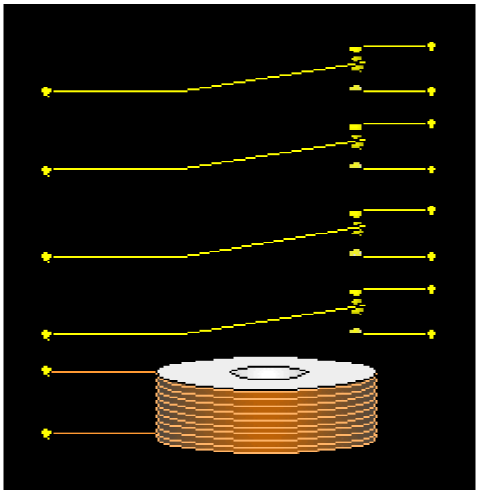

Figure 3.2.4.3.4.2 :Pole Double Throw relay

3.2.4.4 Types of relay:

1. Latching Relay
2. Reed Relay
3. Mercury Wetted Relay
4. Machine Tool Relay
5. Solid State Relay (SSR)

3.2.4.4.1 Latching relay

Latching relay, dust cover removed, showing pawl and ratchet mechanism. The ratchet operates a cam, which raises and lowers the moving contact arm, seen edge-on just below it. The moving and fixed contacts are visible at the left side of the image.

A **latching relay** has two relaxed states (bi-stable). These are also called "impulse", "keep", or "stay" relays. When the current is switched off, the relay remains in its last state. This is achieved with a solenoid operating a ratchet and cam mechanism, or by having two opposing coils with an over-center spring or permanent magnet to hold the armature and contacts in position while the coil is relaxed, or with a remanent core. In the ratchet and cam example, the first pulse to the coil turns the relay on and the second pulse turns it off. In the two coil example, a pulse to one coil turns the relay on and a pulse to the opposite coil turns the relay off. This type of relay has the advantage that it consumes power only for an instant, while it is being switched, and it retains its last setting across a power outage. A remanent core latching relay requires a current pulse of opposite polarity to make it change state.

Figure 3.2.4.4.1 : Latching relay

3.2.4.4.2 Reed Relay:

A **mercury-wetted reed relay** is a form of reed relay in which the contacts are wetted with mercury. Such relays are used to switch low-voltage signals (one volt or less) because of their low contact resistance, or for high-speed counting and timing applications where the mercury eliminates contact bounce. Mercury wetted relays are position-sensitive and must be mounted vertically to work properly. Because of the toxicity and expense of liquid mercury, these relays are rarely specified for new equipment. See also mercury switch.

3.2.4.4.3 Machine tool relay:

A **machine tool relay** is a type standardized for industrial control of machine tools, transfer machines, and other sequential control. They are characterized by a large number of contacts (sometimes extendable in the field) which are easily converted from normally-open to normally-closed status, easily replaceable coils, and a form factor that allows compactly installing many relays in a control panel. Although such relays once were the backbone of automation in such industries as automobile assembly, the programmable logic controller (PLC) mostly displaced the machine tool relay from sequential control applications.

3.2.4.4.4 Solid-state relay

A solid state relay (SSR) is a solid state electronic component that provides a similar function to an electromechanical relay but does not have any moving components, increasing long-term reliability. With early SSR's, the tradeoff came from the fact that every transistor has a small voltage drop across it. This voltage drop limited the amount of current a given SSR could handle. As transistors improved, higher current SSR's, able to handle 100 to 1,200 Amperes, have become commercially available. Compared to electromagnetic relays, they may be falsely triggered by transients.

Figure 3.2.4.4.4 : Solid relay, which has no moving parts

3.2.4.5 Specification

- Number and type of contacts – normally open, normally closed, (double-throw)
- Contact sequence – "Make before Break" or "Break before Make". For example, the old style telephone exchanges required Make-before-break so that the connection didn't get dropped while dialing the number.
- Rating of contacts – small relays switch a few amperes, large contactors are rated for up to 3000 amperes, alternating or direct current
- Voltage rating of contacts – typical control relays rated 300 VAC or 600 VAC, automotive types to 50 VDC, special high-voltage relays to about 15 000 V
- Coil voltage – machine-tool relays usually 24 VAC, 120 or 250 VAC, relays for switchgear may have 125 V or 250 VDC coils, "sensitive" relays operate on a few milli-amperes

3.2.4.5 Applications:

3.2.4.5.1 Relays are used:

- To control a high-voltage circuit with a low-voltage signal, as in some types of modems,
- To control a high-current circuit with a low-current signal, as in the starter solenoid of an automobile,

- To detect and isolate faults on transmission and distribution lines by opening and closing circuit breakers (protection relays),
- To isolate the controlling circuit from the controlled circuit when the two are at different potentials, for example when controlling a mains-powered device from a low-voltage switch. The latter is often applied to control office lighting as the low voltage wires are easily installed in partitions, which may be often moved as needs change. They may also be controlled by room occupancy detectors in an effort to conserve energy,
- To perform logic functions. For example, the boolean AND function is realized by connecting relay contacts in series, the OR function by connecting contacts in parallel. Due to the failure modes of a relay compared with a semiconductor, they are widely used in safety critical logic, such as the control panels of radioactive waste handling machinery.
- As oscillators, also called vibrators. The coil is wired in series with the normally closed contacts. When a current is passed through the relay coil, the relay operates and opens the contacts that carry the supply current. This stops the current and causes the contacts to close again. The cycle repeats continuously, causing the relay to open and close rapidly. Vibrators are used to generate pulsed current.
- To generate sound. A vibrator, described above, creates a buzzing sound because of the rapid oscillation of the armature. This is the basis of the electric bell, which consists of a vibrator with a hammer attached to the armature so it can repeatedly strike a bell.

3.2.5 SOFTWARE EXPLANATION:

Arduino software

Proteus simulation

3.2.5.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.5.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands ofdifferent projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics

principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key toolto learn new things. Anyone - children, hobbyists, artists, programmers

- can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX- 24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and

wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software (IDE)
- ✓ Proceed with board specific instructions.

3.2.5.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.5.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.5.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.5.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

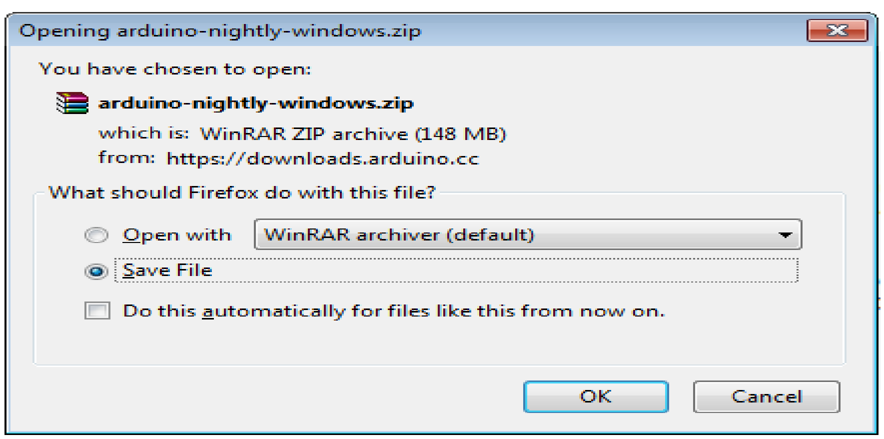

Fig. 3.2.5.4.3 Download Arduino IDE Software

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

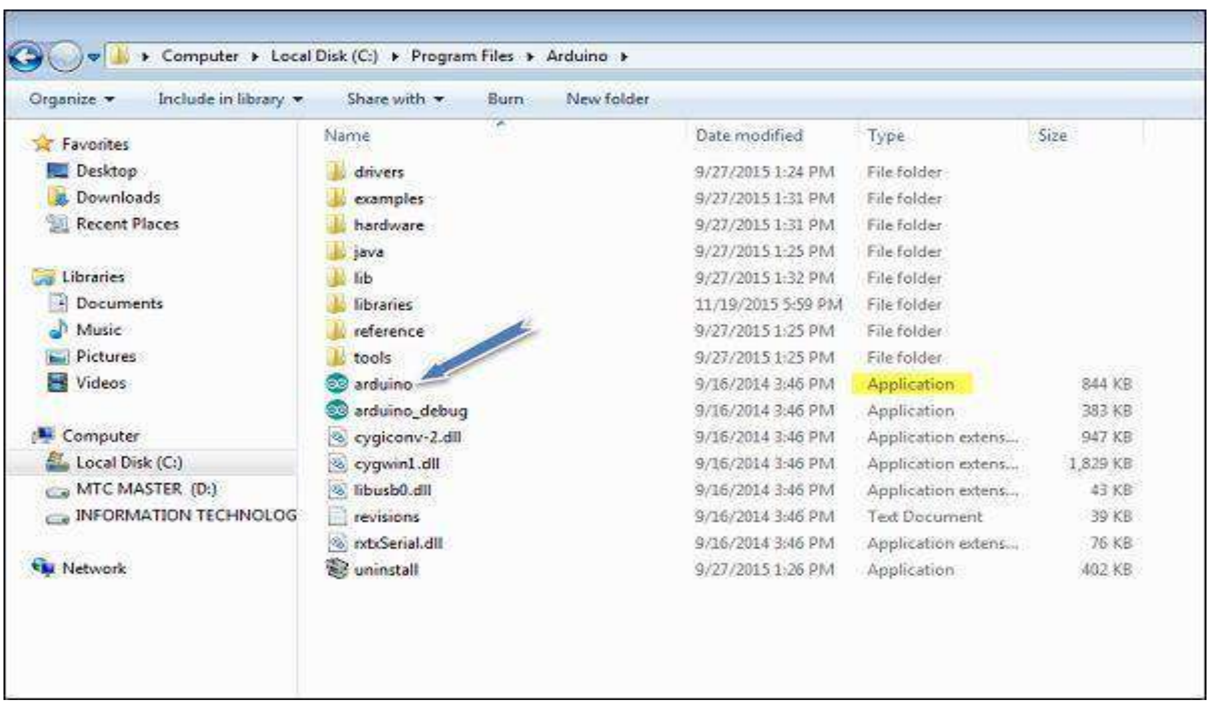

Fig. 3.2.5.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

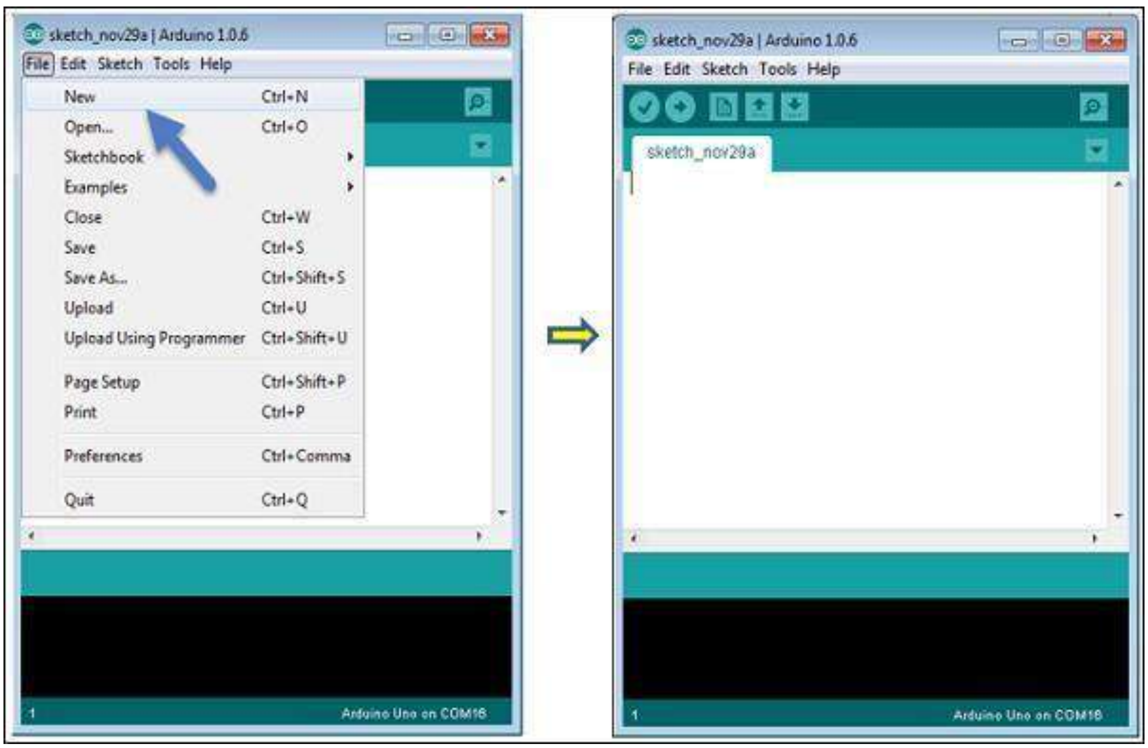

Fig. 3.2.5.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

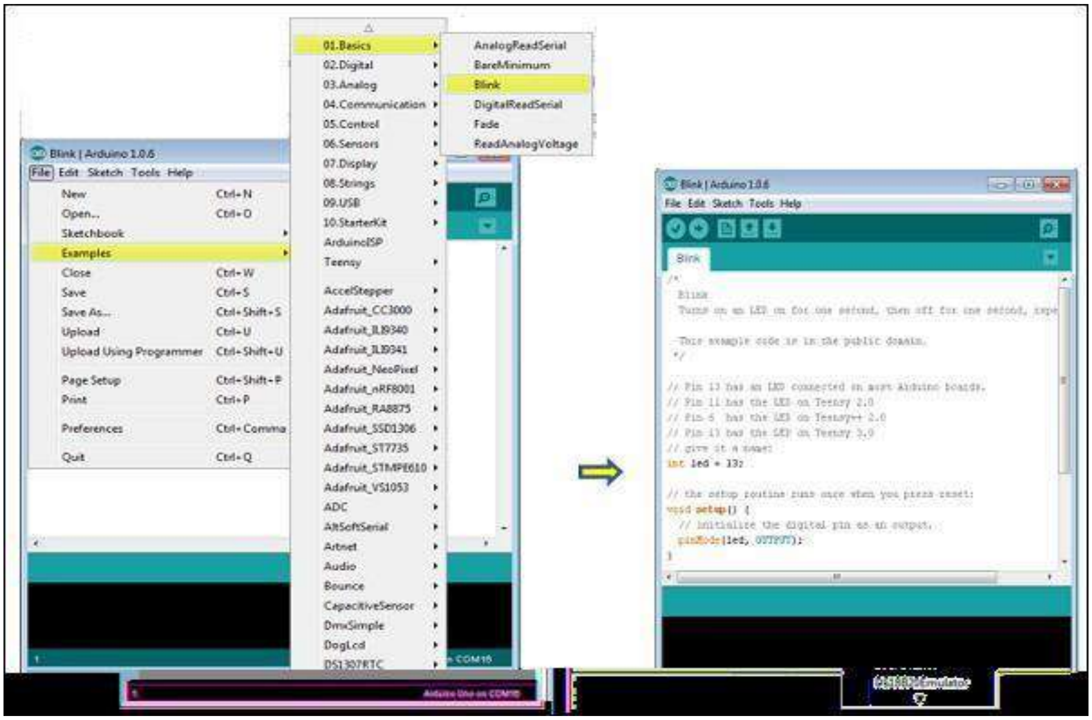

Fig. 3.2.5.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

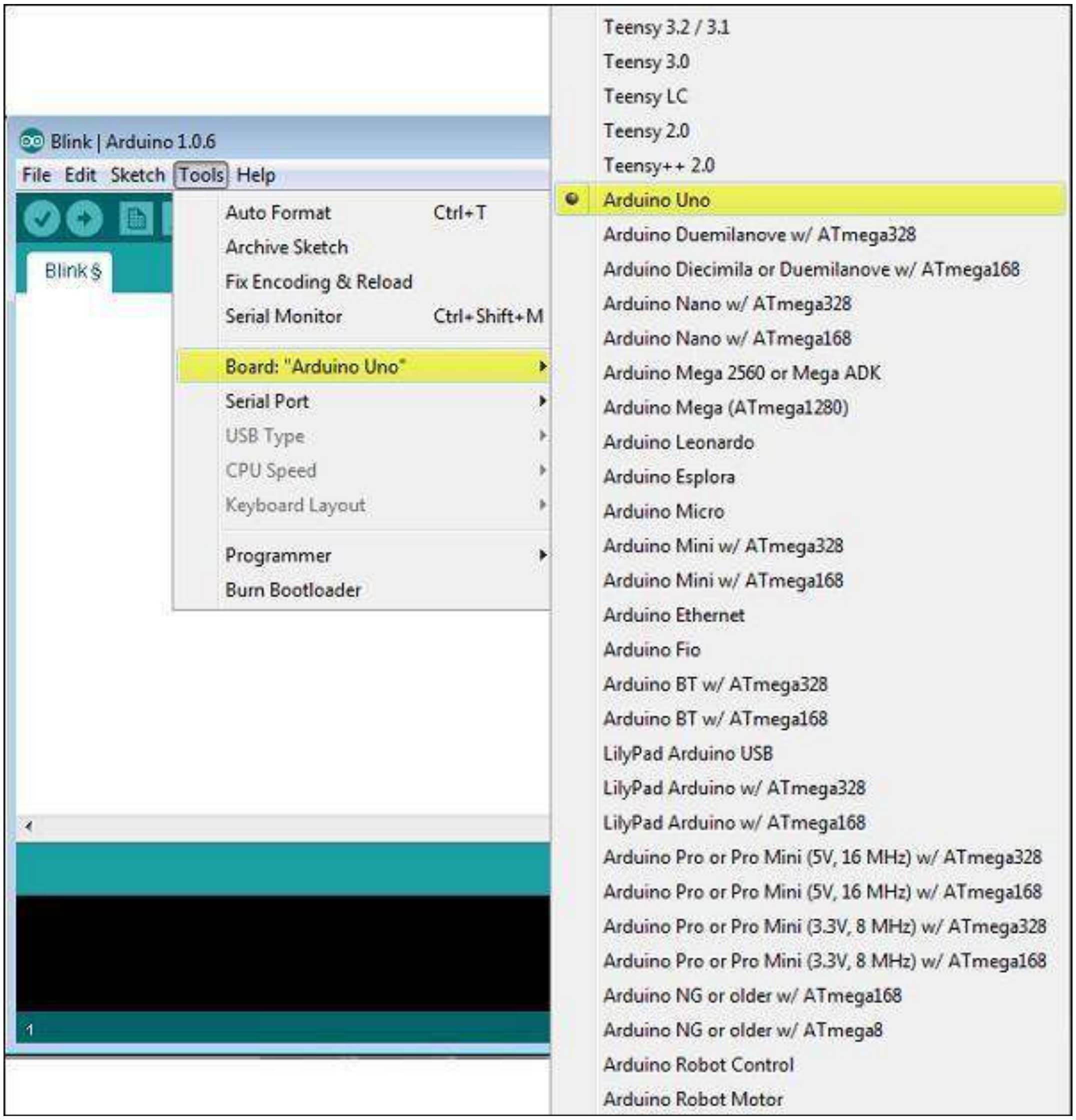

Fig. 3.2.5.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

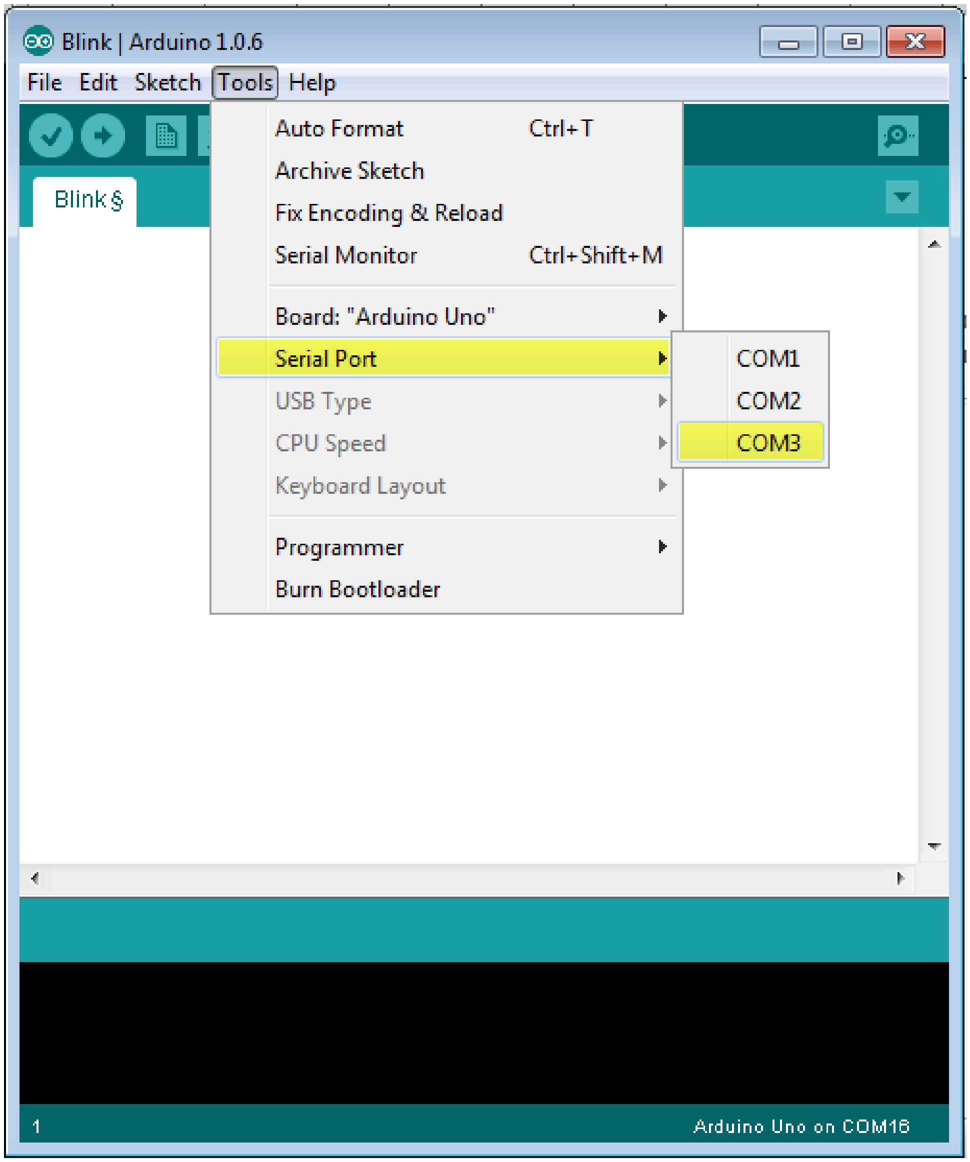

Fig. 3.2.5.4.8 Select your serial port.

Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

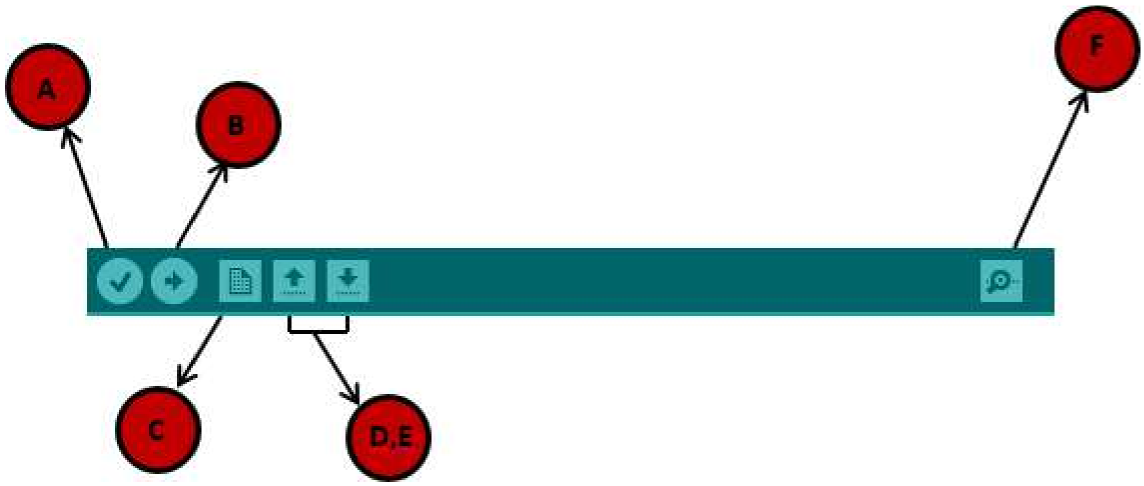

Fig. 3.2.5.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USBconnection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

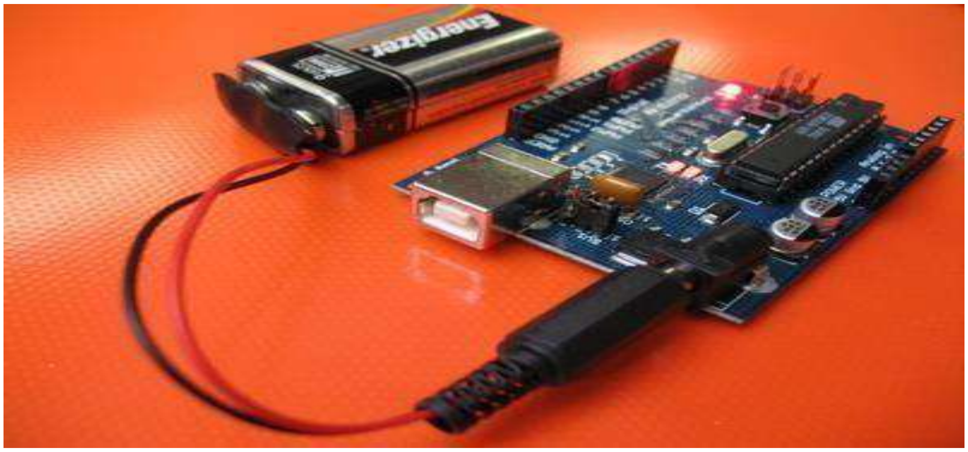

Fig. 3.2.5.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

Fig. 3.2.5.4.11 Example Program

3.2.6 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

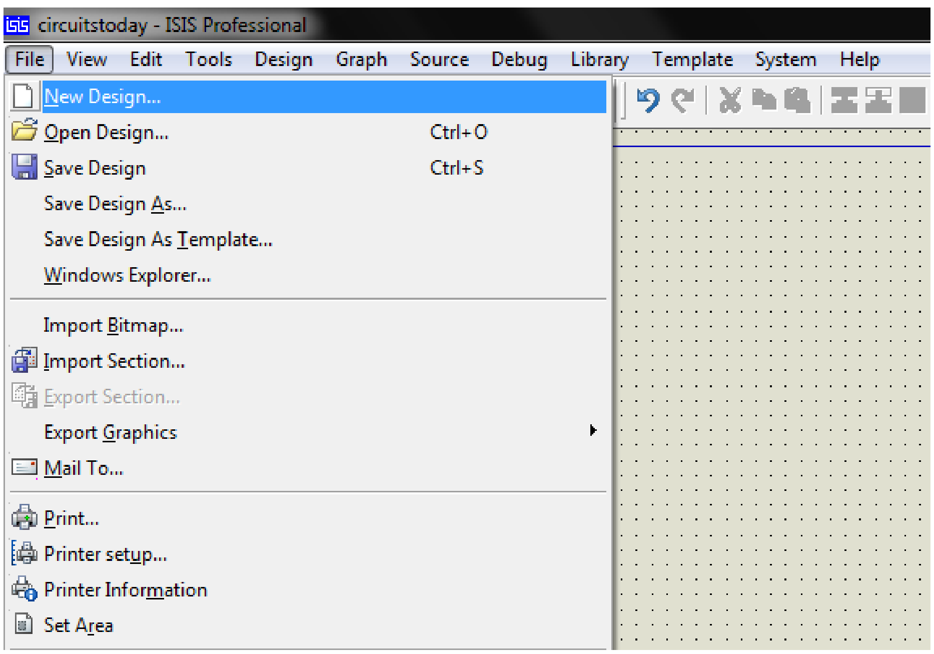

Fig. 3.2.6.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

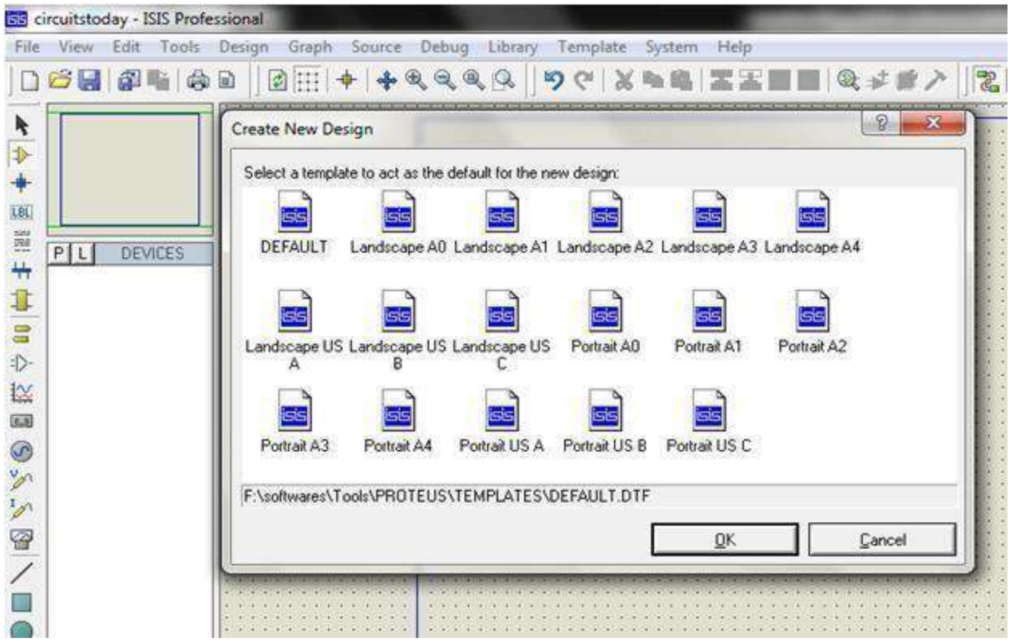

Fig. 3.2.6.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to createa new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

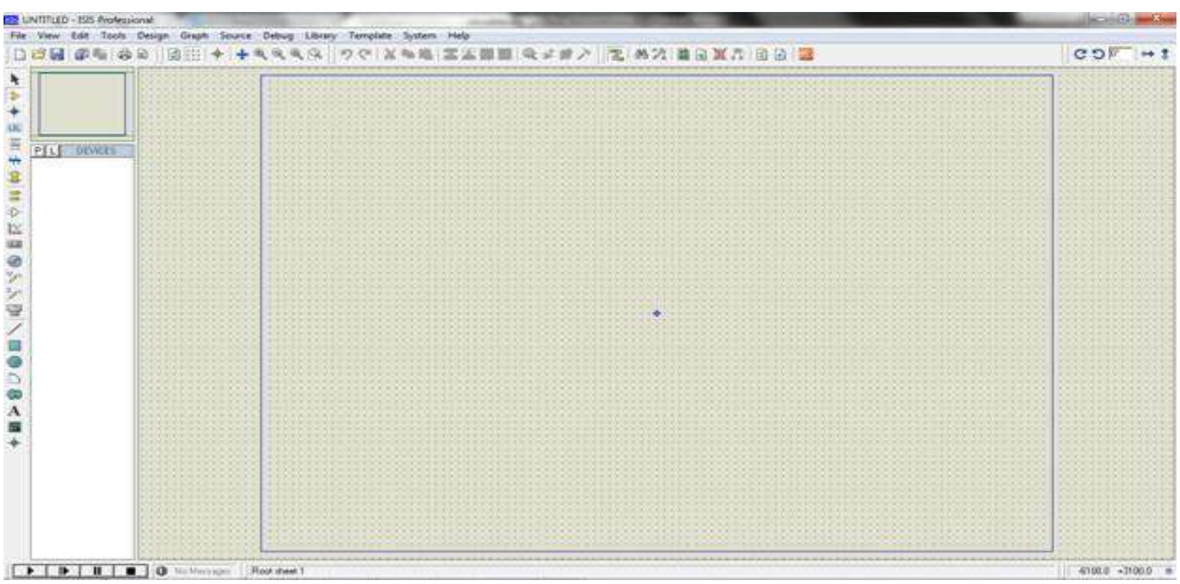

Fig. 3.2.6.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

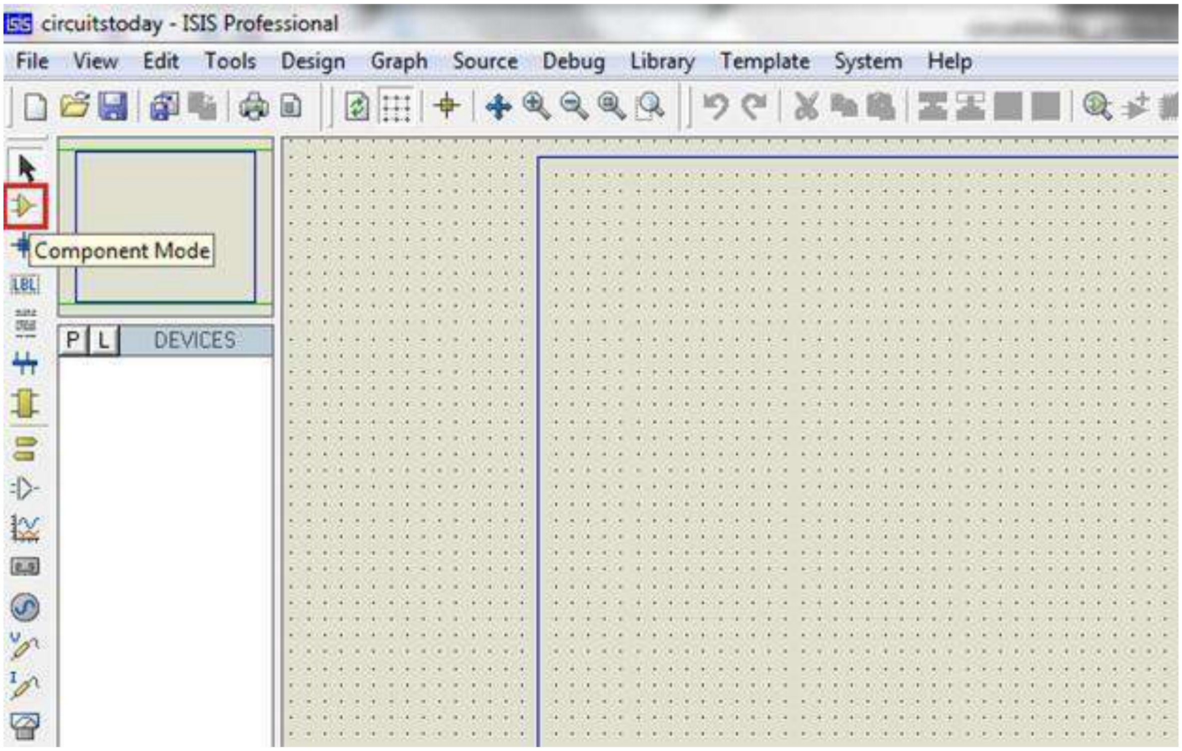

Fig. 3.2.6.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

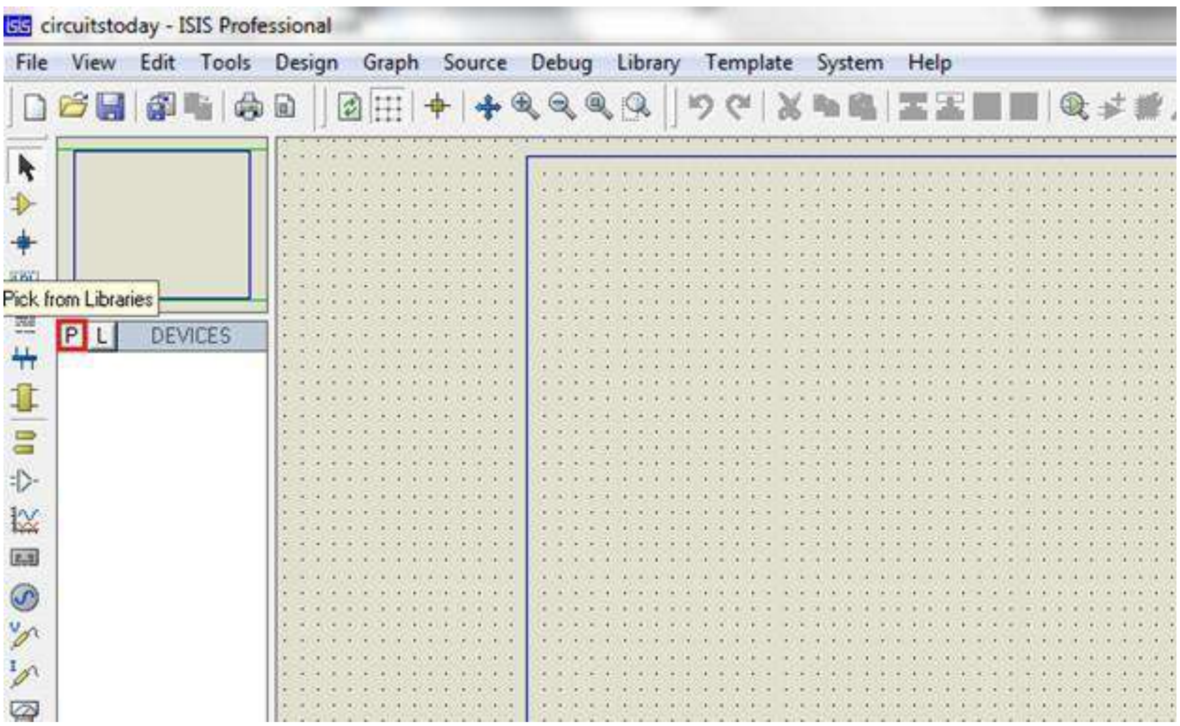

Fig. 3.2.6.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

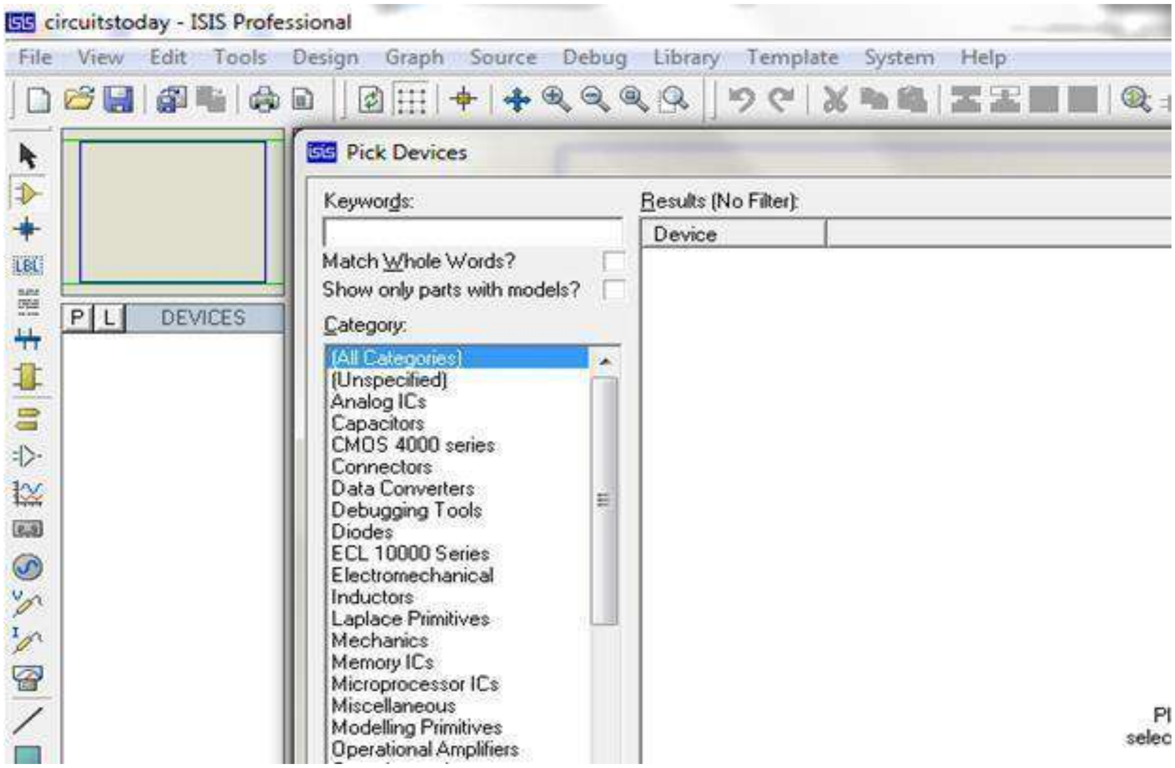

Fig. 3.2.6.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

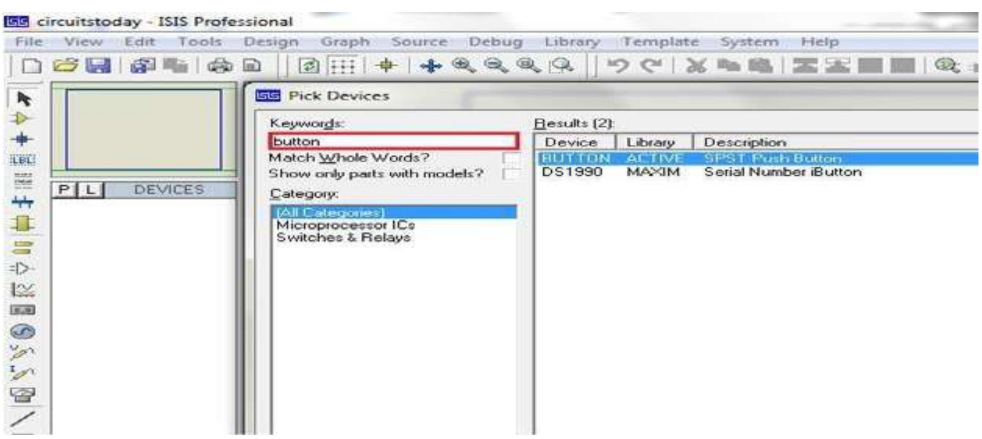

Fig. 3.2.6.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

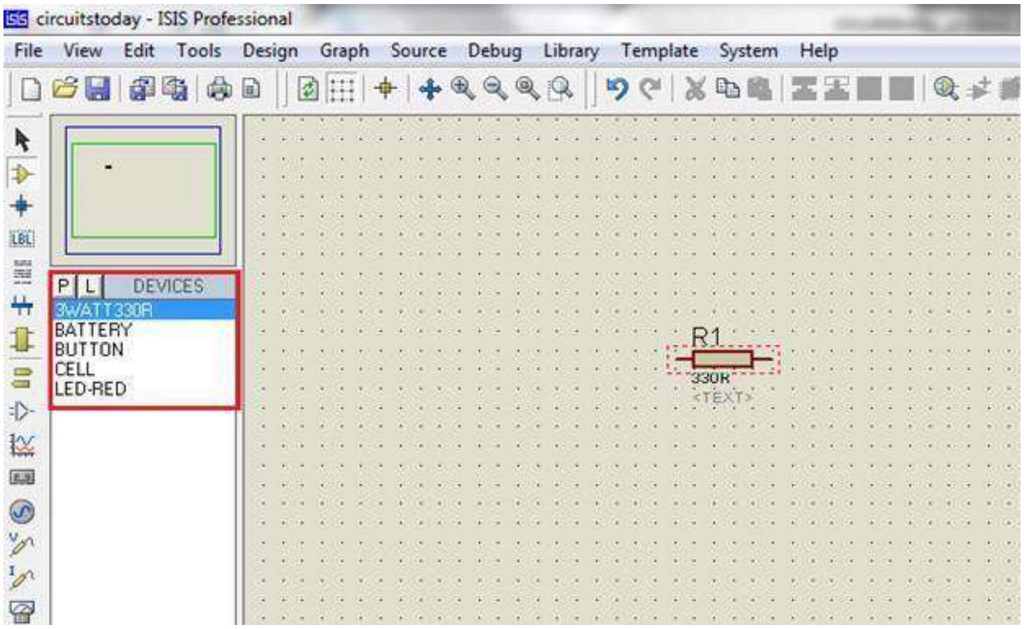

Fig. 3.2.6.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

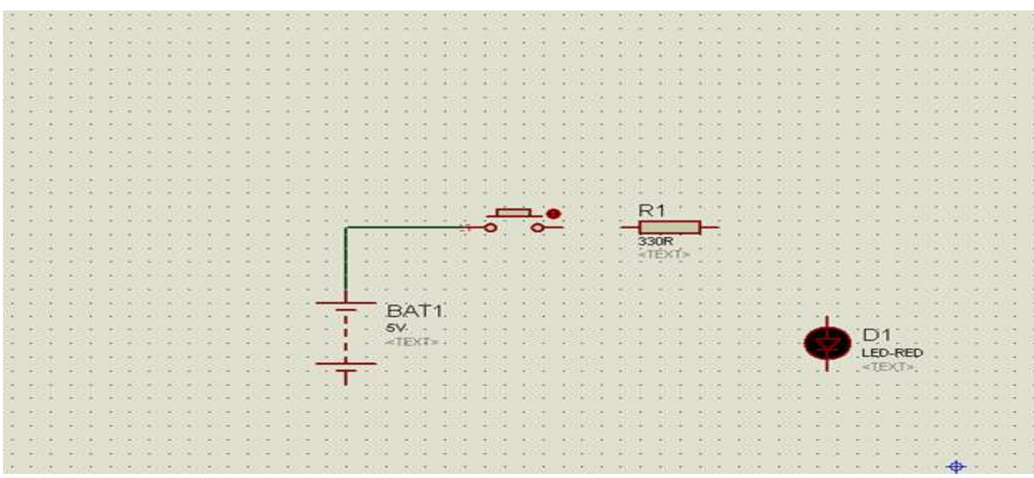

Fig. 3.2.6.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

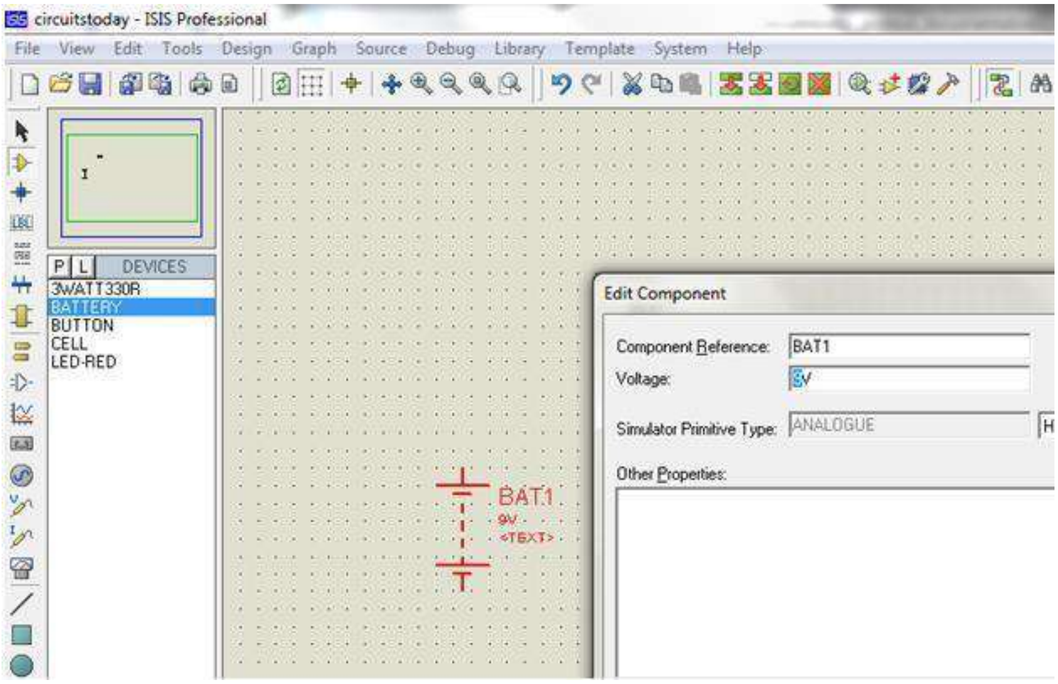

Fig. 3.2.6.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

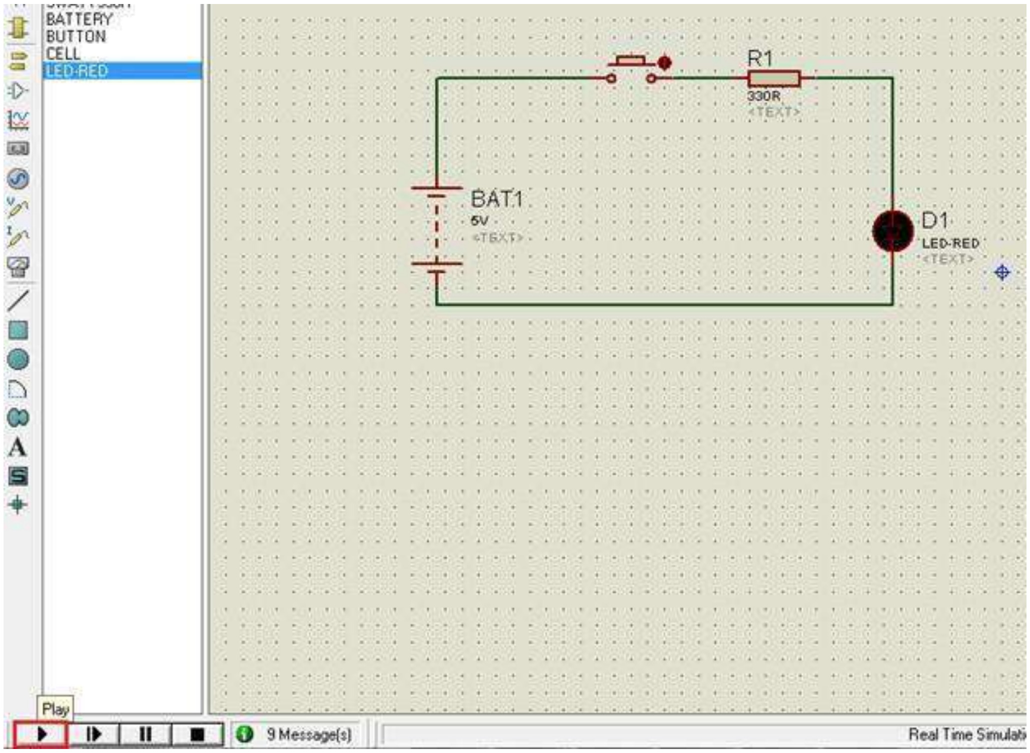

Fig. 3.2.6.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

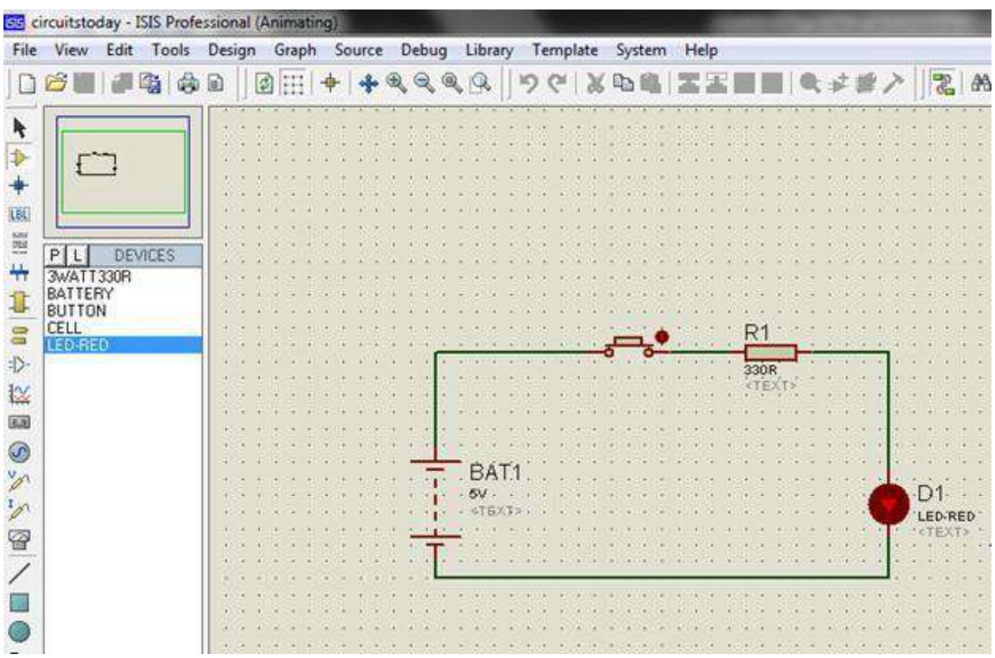

Fig . 3.2.6.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

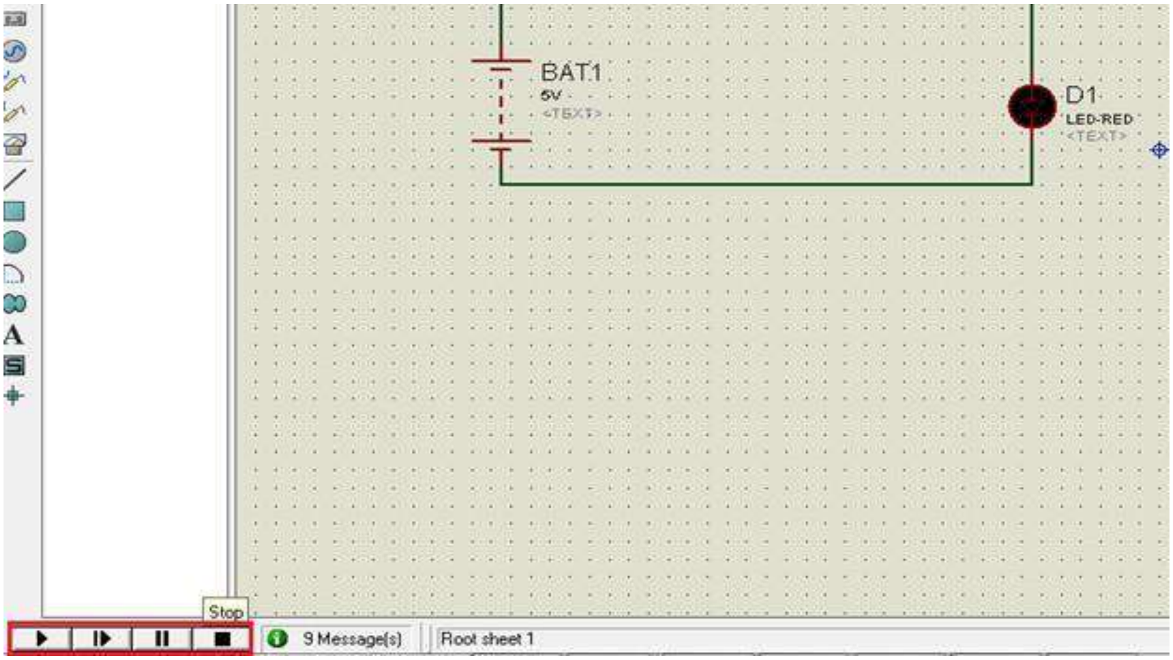

Fig. 3.2.6.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.2.7 TELNET MOBILE APP:

Telnet is a client-server protocol, based on a reliable connection-oriented transport. Typically, this protocol is used to establish a connection to Transmission Control Protocol (TCP) port number 23, where a Telnet server application (telnetd) is listening. Telnet, however, predates TCP/IP and was originally run over Network Control Program (NCP) protocols.

Even though Telnet was an ad hoc protocol with no official definition until March 5, 1973,[3] the name actually referred to *Teletype Over Network Protocol* as the RFC 206 (NIC 7176) on Telnet makes the connection clear:[4]

The TELNET protocol is based upon the notion of a virtual teletype, employing a 7-bit ASCII character set. The primary function of a User TELNET, then, is to provide the means by which its users can 'hit' all the keys on that virtual teletype.[5]

Essentially, it used an 8-bit channel to exchange 7-bit ASCII data. Any byte with the high bit set was a special Telnet character. On March 5, 1973, a Telnet protocol standard was defined at UCLA[6] with the publication of two NIC documents: Telnet Protocol Specification, NIC 15372, and Telnet Option Specifications, NIC 15373.

Many extensions were made for Telnet because of its negotiable options protocol architecture. Some of these extensions have been adopted as Internet standards, IETF documents STD 27 through STD 32. Some extensions have been widely implemented and others are proposed standards on the IETF standards track (see below) Telnet is best understood in the context of a user with a simple terminal using the local Telnet program (known as the client program) to run a logon session on a remote computer where the user's communications needs are handled by a Telnet server program.

When Telnet was initially developed in 1969, most users of networked computers were in the computer departments of academic institutions, or at large private and government research facilities. In this environment, security was not nearly as much a concern as it became after the bandwidth explosion of the 1990s. The rise in the number of people with access to the Internet, and by extension the number of people attempting to hack other people's servers, made encrypted alternatives necessary.

3.3 DEFINE THE MODULES:

3.3.1 ESP8266 WIFI MODULE

3.3.1.1 INTRODUCTION

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

3.3.1.2 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I^2C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I^2S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

3.3.1.3 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security

- Home air quality and water quality monitoring
- Natural Language-based voice assistants.

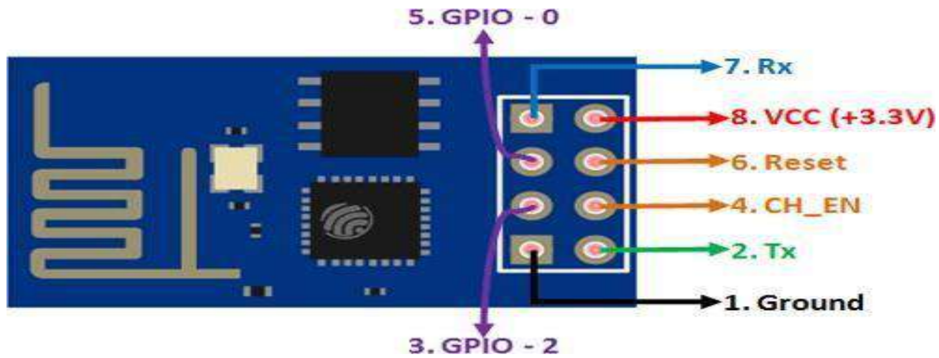

Fig.3.3.1.3 ESP8266 wifi module pin out

3.3.1.4 STRUCTURE AND CONFIGURATION:

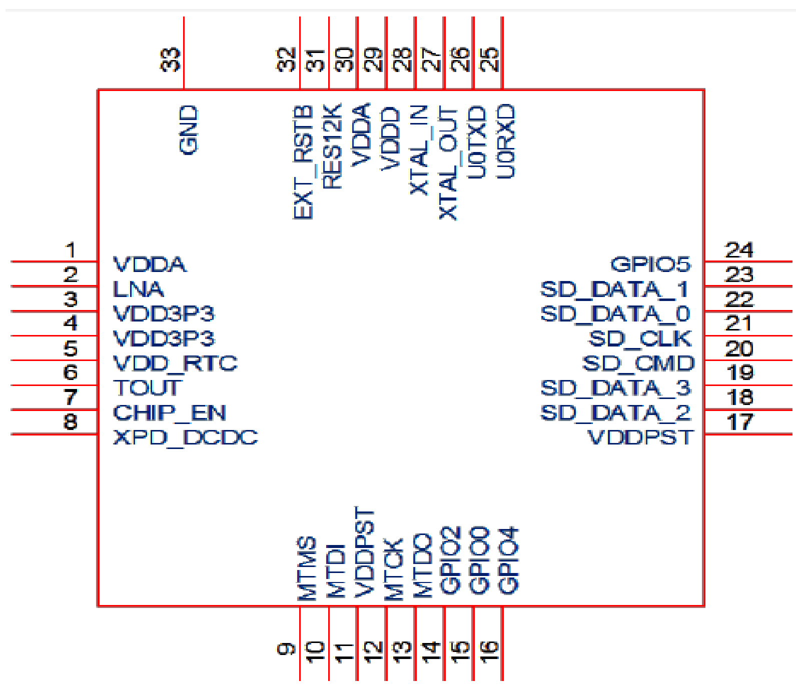

Fig.3.3.1.4 Structure and configuration

3.4 MODULE FUNCTIONALITIES:

3.4.1 ESP8266 WIFI MODULE

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution!

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

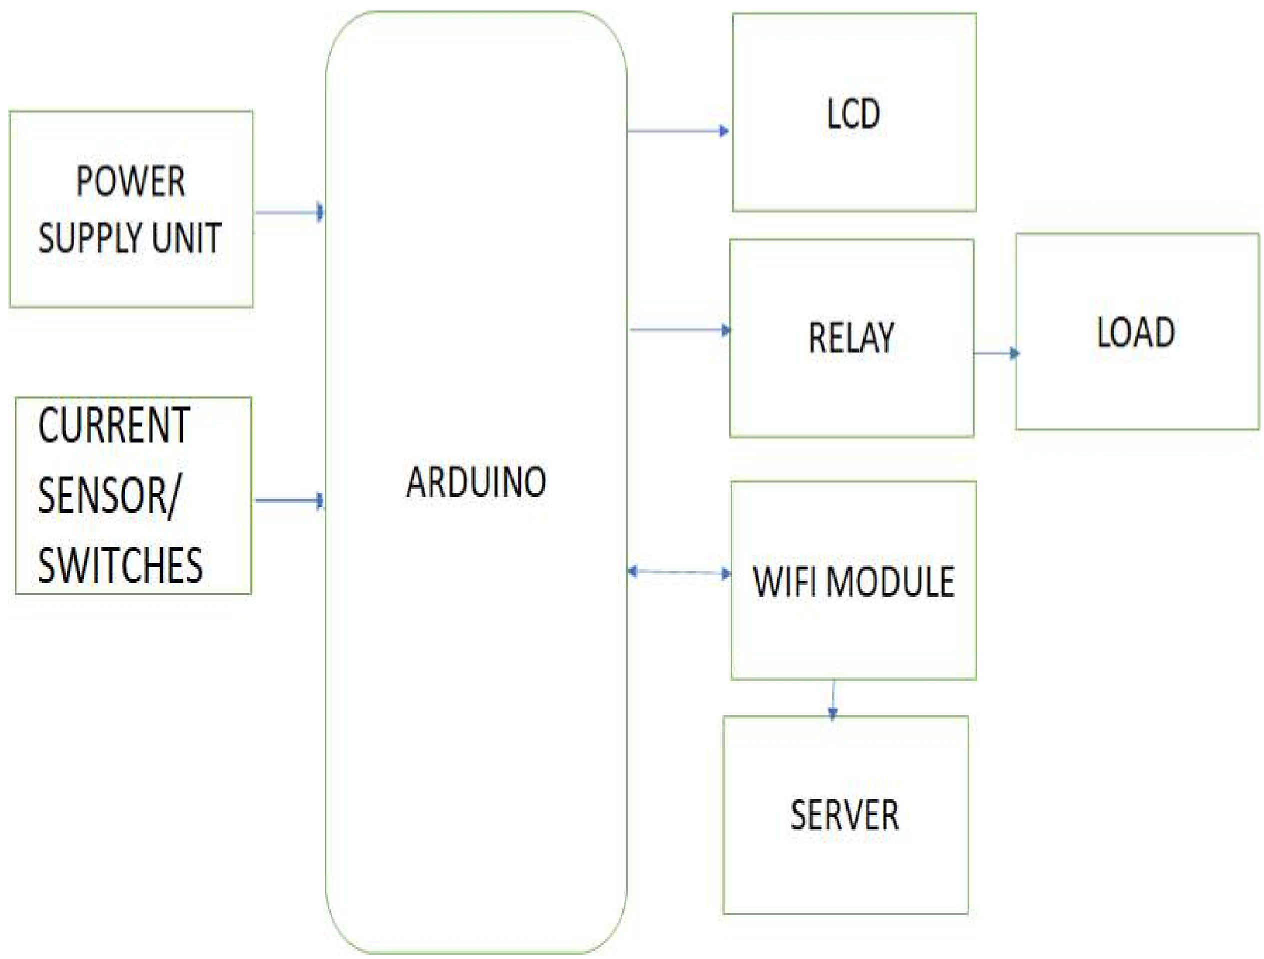

Fig.4.1: Block diagram of the project

4.2 FLOW CHART

  delay(100);
  digitalWrite(load,HIGH);
  delay(1000);
}

}//loop
```

4.5 RESULTS

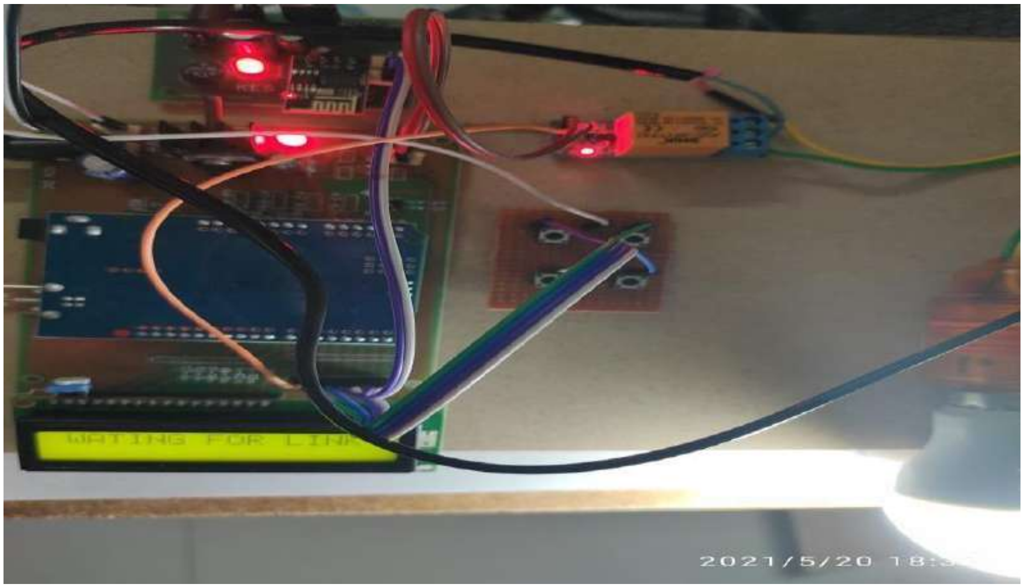

Figure 4.5.1: Output image of Load (bulb) glowing indicating there is no fault

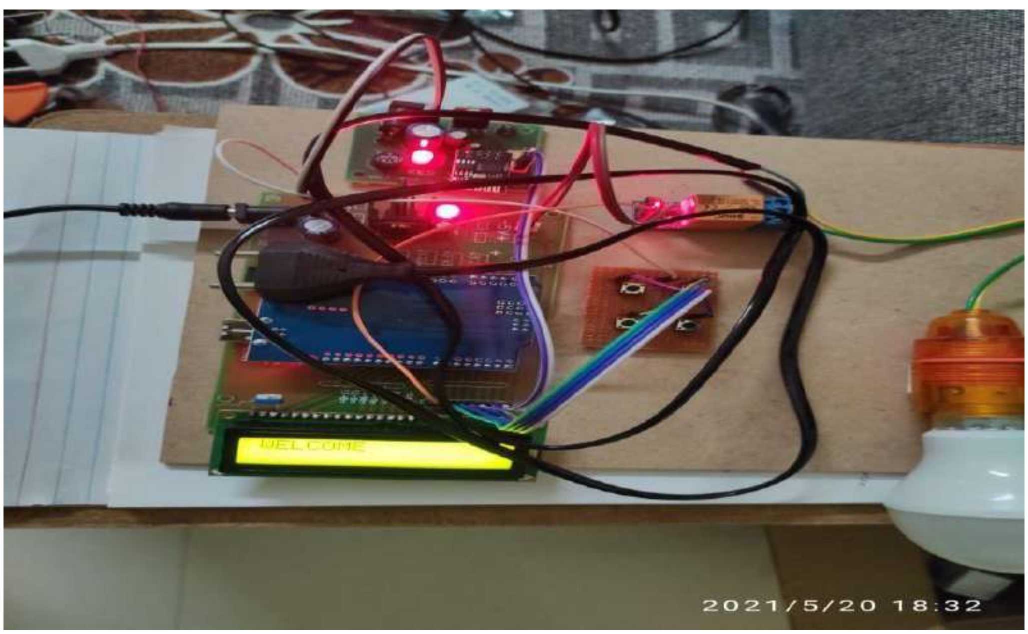

Figure 4.5.2: Output image of Load (bulb) off indicating there is a fault

CHAPTER-5

PROJECT TESTING

In general, fault location techniques for underground cable network can be categorized in two groups:

Tracer method

The tracer method is an exhaustive way to locate a faulted segment by ―walking‖ through the cable circuits. A faulted segment can be determined from audible or electromagnetic signals and requires dispatching crew member stop the outage area. There have been various techniques largely used in the industries, including the tracing approach

through acoustic, electromagnetic or current.

Terminal method

The terminal method is a technique used to determine a fault location of a distribution cable network from one or both ends without tracing exhaustively. A bridge technique is one of the most popular terminal methods that links with a resistor to determine a fault location .It is a technique used to detect fault location of cable from one or both ends without tracing.

Security: IoT is a combination of physical objects ("things"), sensors, embedded software and keeps a goal of effective connectivity and faithful data exchange. The current graphs imply that IoT market growing at remarkable rate. However, some of these devices suffer from limited memory, power consumption and processing power. These issues may cause IoT to become penetrable and hence security is at utmost priority to IoT domain.

As stated in a 2015 report by Hewlett-Packard on IoT research [3]:

1. Per 100, 70 devices still use un-encrypted network services
2. Per 100, 90 devices collected at least one piece of personally identifiable information (via device, cloud or mobile app)
3. Per 100, 70 devices (with cloud and mobile app components) enabled an attacker to identify valid user accounts through enumeration.
4. 80% of devices (with cloud and mobile app components) failed to require passwords of

sufficient complexity

5.Behind every 10 device every 6 devices user interfaces (UI) were vulnerable

Following are the vulnerabilities of the IoT as per The Open Web Application Security Project (OWASP)

1) Insufficient protection compositions.
2) Dubiously secured Software/Firmware
3) Doubtful Network Services
4) Doubtful Web Interface
5) Worst Physical Security
6) Doubtful Cloud Interface
7) Doubtful Mobile Interface
8) Privacy Concerns
9) Doubtful Authentication/Authorization
10) Inadequate Transport Encryption Ongoing approaches to secure IoT have attempted to put a grip on communication protocol-based mechanisms, such as encryption for data-at-rest or in-transit.

But this itself is doubtful if the respective endpoints themselves are capable of being modified either by local access or remote connections. Gartner claims that by year 2020 more than 25% of identified attacks in a particular company will be on IoT devices or systems, even though IoT will only contribute to less than 10% of IT security budgets.

While testing our project, we found the following risks

- Unexpected testing Result
- Failure of component
- Impact the quality, timeline, and cost
- Implementation may become difficult or impossible
- Include design, implementation, interface, verification and maintenance problem

While testing our project we found following constraints

- Additional Resources (Cost increase)
- Fast Completion (Risk Increase and Quality Decrease.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

The short circuit fault at a particular distance in the underground cable is located to rectify the fault efficiently using simple concepts of Ohms law. The work automatically displays the phase, distance and time of occurrence of fault with the help of ESP8266 Wi - Fi module in a webpage. The benefits of accurate location of fault are fast repair to revive back the power system, it improves the system performance, it reduce the operating expense and the time to locate the faults in the field.

6.2 FUTURE ENHANCEMENT

The work can be extended for open circuit fault, short circuit Line to Line Fault (LL) and double Line to Ground Fault (LLG). The open circuit fault can be detected using a capacitor in ac circuit which measures the change in impedance and calculate the distance of fault.

PUBLICATION

Submitted Paper in the Conference ICSMEC - 21 with Paper ID (ICSMEC21-0056) and got Acceptance for the Paper.

APPENDICES

The main aim of this project is to find the accurate and specific location of the fault occur in the underground cable with the help of IoT device and by using Arduino UNO microcontroller kit. The result is shown on a web page and also the message is being sent on the mobile phone with the help of ESP8266. The urban region uses an underground electrical cable wirerather than using the overhead lines. But it is hard to spot the fault location in underground cable accurately that leads to difficulty in repairing. This system finds the specific location of the fault in the cable. The underground cables are prone to get faults due to wear and tear, underground conditions, rodents etc. The whole cable is to be dugout for the invigilation and fault fixing as we not know the fault location accurately. Our purpose is to find the location of fault exactly that isto be fixed for the ease in the process of repairing. The potential divider network system is used to detect the fault that laid across the cable. When lines are short together then a fault is created at that point, a particular voltage is generated as per the network combination of the resistors. The microcontroller sensed the voltage change and send a signal to the user. The information about the location at which that voltage coincide is sent to the user.

DECLARATION

We, the students of **Bachelor of Technology** in Department of Electronics and Communication Engineering, session: <2017 - 2021>, St. Martin’s Engineering College, Dhulapally, Kompally, Secundrabad, hereby declare that the project work entitled “VEHICLE MOVEMENT STREET LIGHT WITH LIGHT SENSING ATMEGA” is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied is this project report has not been submitted in any university for award of any degree.

MAJJI ANUSHA (17K81A04M3)

SHETLEM TULASI (17K81A04P4)

THATI SANTOSH KUMAR (17K81A04P7)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. Project coordinator project coordinator **Dr. A. Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our Project Internal Guide, **Mrs. K. Anitha, Assistant Professor,** Department of ECE and our class Project Coordinator **Ms**. **P. Pushpa, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our Project Coordinators **Dr. Maalyadri, Professor in IT** and **Dr. R. Santosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1.MAJJI ANUSHA (17K81A04M3)

2.SHETLEM TULASI (17K81A04P4)

3.THATI SANTOSH KUMAR (17K81A04P7)

ABSTRACT

The main purpose Vehicle Movement Based Street Lights with External Light Sensing Using ATMEGA project is that it saves energy by putting on the lights of the system only when the system detects movement of vehicle. The system switches on the street light ahead of the vehicle and switches off the trailing lights simultaneously.

The movement of vehicle gets detected by sensors. The system automatically puts on the lights that are ahead of the vehicle detected and as soon as the vehicle moves ahead, the trailing lights are switched off.

This system is more efficient for saving a lot of energy than existing system where the street lights are kept on always unlike this system where the street lights are put on only when movement of vehicle is detected. During day time these lights are dim as this system has the capability to sense external lights.

Thus, this system senses the external light and then accordingly switches ON or OFF the street lights. It uses PWM to control the intensity through microcontroller. The IR sensors sense the vehicle movements and send it to a ATMEGA microcontroller that initiates commands for switching the lights ON/OFF.

GLOSSARY

Manual System:

A manual system is like a bookkeeping system in which records maintenance is done by hand, without using a computer system or any automatic system. In this type of system transactions are written in journals, from which the information is manually retrieved into a set of financial statements. These systems suffer from higher rate of inaccuracy, and they are much slower than computerized systems. ”

Automated system:

Automated system is a combination of both software and hardware which is designed and programmed to work automatically without the need of any human operator to provide inputs and instructions for each operation. “

Automated systems allow you to monitor your processes in real time and identify problems as they arrive, enabling quick adjustments along the way. While manual systems can be difficult to coordinate, similar to the old cliche that "the right hand doesn't know what the left hand is doing," automated systems work in tandem on their own.

Pulse width modulation:

PWM is a way to control analog devices with a digital output. Another way to put it is that you can output a modulating signal from a digital device such as an MCU to drive an analog device. It’s one of the primary means by which MCUs drive analog devices like variable-speed motors, dimmable lights, actuators, and speakers. PWM is not true analog output, however. PWM “fakes” an analog-like result by applying power in pulses, or short bursts of regulated voltage.

Arduino:

The **ArduinoUno** is an open source board with the Microchip ATmega328P microcontroller and developed by Arduino.cc. The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits.[1] The board has 14 digital I/O pins (six capable of PWM output), 6 analog I/O pins, and is programmable with the Arduino IDE (Integrated Development Environment), via a type B USB cable. It can be powered by the USB cable or by an external 9-volt battery, though it accepts voltages between 7 and 20 volts.

Arduino IDE:

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of third-party cores, other vendor development boards.

Proteus:

The **Proteus Design Suite** is a proprietary software tool suite used primarily for automation. The software is used mainly by electronic design engineers and technicians to create schematics and electronic prints for manufacturing printed circuit boards.

IR sensor:

An infrared (IR) sensor is an electronic device that measures and detects infrared radiation in its surrounding environment. While measuring the temperature of each color of light (separated by a prism), he noticed that the temperature just beyond the red light was highest. IR is invisible to the human eye, as its wavelength is longer than that of visible light (though it is still on the same electromagnetic spectrum)

LDR sensor:

A Light Dependent Resistor (LDR) is also called a photoresistor or a cadmium sulfide (CdS) cell. It is also called a photoconductor. It is basically a photocell that works on the principle of photoconductivity. The passive component is basically a resistor whose resistance value decreases when the intensity of light decreases. This **optoelectronic device** is mostly used in light varying sensor circuit, and light and dark activated switching circuits.

Relay:

A Light Dependent Resistor (LDR) is also called a photoresistor or a cadmium sulfide (CdS) cell. It is also called a photoconductor. It is basically a photocell that works on the principle of photoconductivity. The passive component is basically a resistor whose resistance value decreases when the intensity of light decreases. This **optoelectronic device** is mostly used in light varying sensor circuit, and light and dark activated switching circuits.

LED Bulbs:

An **LED lamp** or **LED light bulb** is an electric light that produces light using light-emitting diodes (LEDs). LED lamps are significantly more energy-efficient than equivalent incandescent lamps and can be significantly more efficient than most fluorescent lamps. The most efficient commercially available LED lamps have efficiencies of 200 lumens per watt (Lm/W). Commercial LED lamps have a lifespan many times longer than incandescent lamps.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Automation plays an increasingly very important role in the world economy and in daily life. Automatic systems are being preferred over any kind of manual system. We can also call it an "SMART STREET LIGHT SENSING". Intelligent light sensing refers to public street lighting that adapts to movement by pedestrians, cyclists and cars. Intelligent street lighting, also referred to as adaptive street lighting, dims when no activity is detected, but brightens when movement is detected. This type of lighting is different from traditional, stationery and illumination, or dimmable street lighting that dims at pre-determined times.

Street lights are doing more than ever in today's smart cities. With digital networks and embedded sensors, they collect and transmit information that help cities monitor and respond to any circumstance, from traffic and air quality to crowds and noise. They can detect traffic congestion and track available parking spaces. Those very same networks can remotely control LED lights to turn on and off, flash, dim and more, offering cities a chance to maximize low-energy lighting benefits while also improving pedestrian and bicyclist safety. With street lights creating a network canopy, those networks of data can be used by more than just lighting departments, empowering even schools and businesses via a lighting infrastructure that brightens the future of the digital city.

Smart lighting helps cities save energy, lower costs, reduce maintenance—all while better serving citizens and reducing energy use and CO2 emissions. Automation and networked control can further increase your energy savings and reduce maintenance spending. Networked street lighting built on a scalable platform can reduce crime up to 10% and make roadways safer through improved visibility. Leveraging intelligent control systems can rapidly increase lighting efficiencies and traffic management.

The research work shows automatic control of streetlights as a result of which power is saved to some extent. In the scope of industrialization, automation is a step beyond mechanization. Whereas mechanization provided human operators with machinery to assist the users with muscular requirements of work, automation greatly decreases the need for human sensory and mental requirements as well. Basically, street lighting is one of the important parts. Therefore, the street lamps are relatively simple but with the development of urbanization, the number of streets increases rapidly with high traffic density. There are several factors need to be considered in order to design a good street lighting system such as night-time safety for community members and road users, provide public lighting at cost effective, the reduction of crime and minimizing it is effect on the environment.

1.2 OBJECTIVE OF THE STUDY:

The idea of designing a new system for the streetlight that do not consume huge amount of electricity and illuminate large areas with the highest intensity of light is concerning each engineer working in this fields. Providing street lighting is one of the most important and expensive responsibilities of a city. Manual control is prone to errors and leads to energy wastages and manually dimming during mid night is impracticable. Also, dynamically tracking the light level is manually impracticable. The current trend is the introduction of automation and remote management solutions to control street lighting.

At the beginning, street lamps were controlled by manual control where a control switch is set in each of the street lamps which is called the first generation of the original street light. After that, another method that has been used was optical control method done using high pressure sodium lamp in their system. Nowadays, it is seen that the method is widely used in the country. The method operates by set up an optical control circuit, change the resistance by using of light sensitive device to control street lamps light up automatically at dusk and turn off automatically after dawn in the morning. Due to the technological development nowadays, road lighting can be categorized according to the installation area and performance, for an example, lighting for traffic routes, lighting for subsidiary roads and lighting for urban center and public amenity areas. The WSN helps in improving the network sensing for street lighting. Meanwhile, street light system can be classified according to the type of lamps used such as incandescent light, mercury vapor light, metal halide light, high pressure sodium light, low pressure sodium light, fluorescent light, compact fluorescent light, induction light and LED light. Different type of light technology used in lighting design with their luminous efficiency, lamp service life and their considerations. The LED is considered a promising solution to modern street lighting system due to its behavior and advantages. Apart from that, the advantages of LED are likely to replace the traditional street lamps such as the incandescent lamp, fluorescent lamp and high-pressure Sodium Lamp in future but LED technology is an extremely difficult process that requires a combination of advanced production lines, top quality materials and high- precision manufacturing process. Therefore, the research work highlights the energy efficient system of the street lights system using LED lamps with IR sensor interface for controlling and managing.

With the wide accessibility of adaptable lighting innovation like light transmitting diode lights and all over accessible remote web association, quick responding, dependable working, and power moderating street lighting frameworks get to be reality. The reason for this work is to portray the Smart Street Lighting framework, a first way to deal with perform the interest for adaptable smart lighting frameworks. The goal of this undertaking is to plan an automated lighting framework which focuses on the saving of power; to construct a vitally energy efficient smart lighting framework with integrated sensors and controllers.

1.3 SCOPE OF THE PROJECT:

- Automation systems are being preferred over the manual mode because it reduces the use of energy to saves energy. These automation systems play an essential role in making our daily life more comfortable and facilitate users from ceiling fans to washing machines and in other applications.
- Among all exciting applications, street lights play a vital role in our environment and also plays a critical role in providing light for safety during night-time travel. In this scenario, when the street lights are in working functionality over the whole night that consumes a lot of energy and reduces the lifetime of the electrical equipment such as electric bulb etc.
- Especially in cities streetlights, it is a severe power consuming factor and also the most significant energy expenses for a city. In this regard, an intelligent lighting control system can decrease street lighting costs up to 70% [3] and increase the durability of the equipment.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino UNO
- Infrared (IR) sensor

- Liquid Cristal Display
- Light Depended Resistor (LDR) sensor
- Relay
- Potentiometer
- Resistor(100K)
- LED Bulbs

1.4.2 SOFTWARE REQUIREMENT:

- Arduino IDE
- PROTEUS software

1.5 PROCUMENT OF EQUIPMENT:

♦ We brought all the required hardware components in a electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software.

♦ Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way.

♦ We observed that the LED bulb glows when the vehicle movement is detected and it stays in ON condition until sometime. It stays in OFF when there is light surroundings.

CHAPTER -2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

The idea of designing a new system for the streetlight that do not consume huge amount of electricity and illuminate large areas with the highest intensity of light is concerning each engineer working in this field. Providing street lighting is one of the most important and expensive responsibilities of a city. Lighting can account for 10-38% of the total energy bill in typical cities worldwide [1]. Street lighting is a particularly critical concern for public authorities in developing countries because of its strategic importance for economic and social stability. Inefficient lighting wastes significant financial resources every year, and poor lighting creates unsafe conditions. Energy efficient technologies and design mechanism can reduce cost of the street lighting drastically.

Manual control is prone to errors and leads to energy wastages and manually dimming during mid night is impracticable. Also, dynamically tracking the light level is manually impracticable. The current trend is the introduction of automation and remote management solutions to control street lighting [2].

There are various numbers of control strategy and methods in controlling the street light system such as design and implementation of CPLD based solar power saving system for street lights and automatic traffic controller [1], design and fabrication of automatic street light control system [3].

2.2 REVIEW ON RELATED LITERATURE:

In this system two kinds of sensors will be used which are light sensor and photoelectric sensor. The light sensor will detect darkness to activate the ON/OFF switch, so the streetlights will be ready to turn on and the photoelectric sensor will detect movement to activate the streetlights. LDR, which varies according to the amount of light falling on its surface, this gives an induction for whether it is a day-night time, the photoelectric sensors are placed on the side of the road, which can be controlled by microcontroller. The photoelectric will be activated only on the night time. If any object crosses the photoelectric beam, a particular light will be automatically ON. By using this as a basic principle, the intelligent system can be designed for the perfect usage of streetlights in any place.

S. Suganya et al [2] have proposed about Street Light Glow on detecting vehicle movement using sensor is a system that utilizes the latest technology for sources of light as LED lamps. It is also used to control the switching of street light automatically according to the light intensity to develop flow based dynamic control statistics using infrared detection technology and maintain wireless communication among lamppost and control terminal using ZigBee Wireless protocol. It also combines various technologies: a timer, a statistics of traffic flow magnitude, photodiodes, LED, power transistors.

K. Santha et al [3] have surveyed on Street Lighting System Based on Vehicle Movements. The system operates in the automatic mode which regulates the streetlight according to brightness and dimness algorithm and light intensity. The control can be made according to the seasonal variation. It includes a time cut-out function and an automatic control pattern for conserving more electricity. The whole project was implemented using a PIC microcontroller.

Srikanth et al [4] proposed a ZigBee based Remote Control Automatic Street Light System. The system is designed with the help of ZigBee modules that helps in detecting the faulty lights and control the light. It also discusses about an intelligent system that takes automatic decisions for ON/OFF/DIMMING considering the vehicle movement or pedestrian and also the surrounding environment. PIR motion sensor is used to detect movement of both living and non-living things.

M. Abhishek et al [5] have implemented design of traffic flow-based street light control system with effective utilization of solar energy in the year 2015. They used the renewable source of energy i.e., the solar power for street lighting. They have also used 8052 series microcontroller and is developed by replacing the normal bulbs with the LEDs due to which the power consumption is reduced by 3 times. Sensors are placed on either side of the road which senses the vehicle movement and sends the commands to the microcontroller to switch ON and OFF the lights. Here all the street lights remain switched off and it glows only when it senses the vehicle movement. Hence, because of the microcontroller, even when its night the lights are switched off.

Bhuvaneshwari et al [6] have analyzed the street light with auto tracking system by which one can increase the conversion efficiency of the solar power generation. Here, the sun tracking sensor is the sensing device which senses the position of the sun time to time and gives the output to the amplifier based on light density of the sun. Sun tracking sensor is LDR, amplifier unit is used to amplify the LDR signals which converts low level signals to high level signals and the output is given to comparator.

The LM324 IC is used as an amplifier. Comparator compares the signals and gives the command to AT89C51 microcontroller. Steve Chadwick [7] reports on the two-installation case studied in Scotland and Wales and explains the details and benefits of the technology. The system was called as MINOS that had a track record of over 100,000 units installed and working successfully.

Somchai Hiranvarodom [8] describes a comparative analysis of photovoltaic (PV) street lighting system in three different lamps. Namely, a low-pressure sodium lamp, a high-pressure sodium lamp and a fluorescent lamp have been used for installation in each mast to determine the suitable system to install in a typical rural area of Thailand. All three systems have been mounted with the same module type and wattage in different places within the Raja Mangala Institute of Technology, Thanya Buri district, Pathumthani province of Thailand. An operation of solar street lighting system can be divided into 2 period of time, namely, at 18.00-22.00 hours and 05.00-06.00 hours. The design of a control circuit was experimentally done in this work. The aim of this work is to determine the appropriate system to install in a typical rural area or a typical rural village of Thailand.

Radhi Priyasree [9] explains a system to reduce the power consumption of street lights by avoiding inefficient lighting which wastes significant financial resources each year. This is done by dimming the lights during less traffic hours. For this purpose, PIR sensor is used which detects any movement. This work also aims at reducing the fatal crashes and road accidents caused due to alcohol consumption. This is done using skin sensors placed in vehicle doors and also using breadth sensors inside the vehicle. By implementing this death rates due to drunk driving can be reduced to a great extent. The prototype has been implemented and works as expected and will prove to be very useful and will fulfill all the present constraints if implemented on a large scale. It also aims at detecting consumption of alcohol by the driver and if it exceeds certain level, it impairs the driver from entering into the Vehicle. This prevents occurrence of accidents or any fatal crashes. This initiative will help the government to save this energy and meet the domestic and industrial needs. From this literature survey, the methods each one has implemented and used is simple and easy to understand. These papers and journals have given many ideas to further implement a much efficient system and make things automated. The presentations are simple and clean with all the necessary information needed for a basic learner or reader.

CHAPTER-3

PROPOSED SYSTEM

3.1 OVERVIEW OF THE DESIGN:

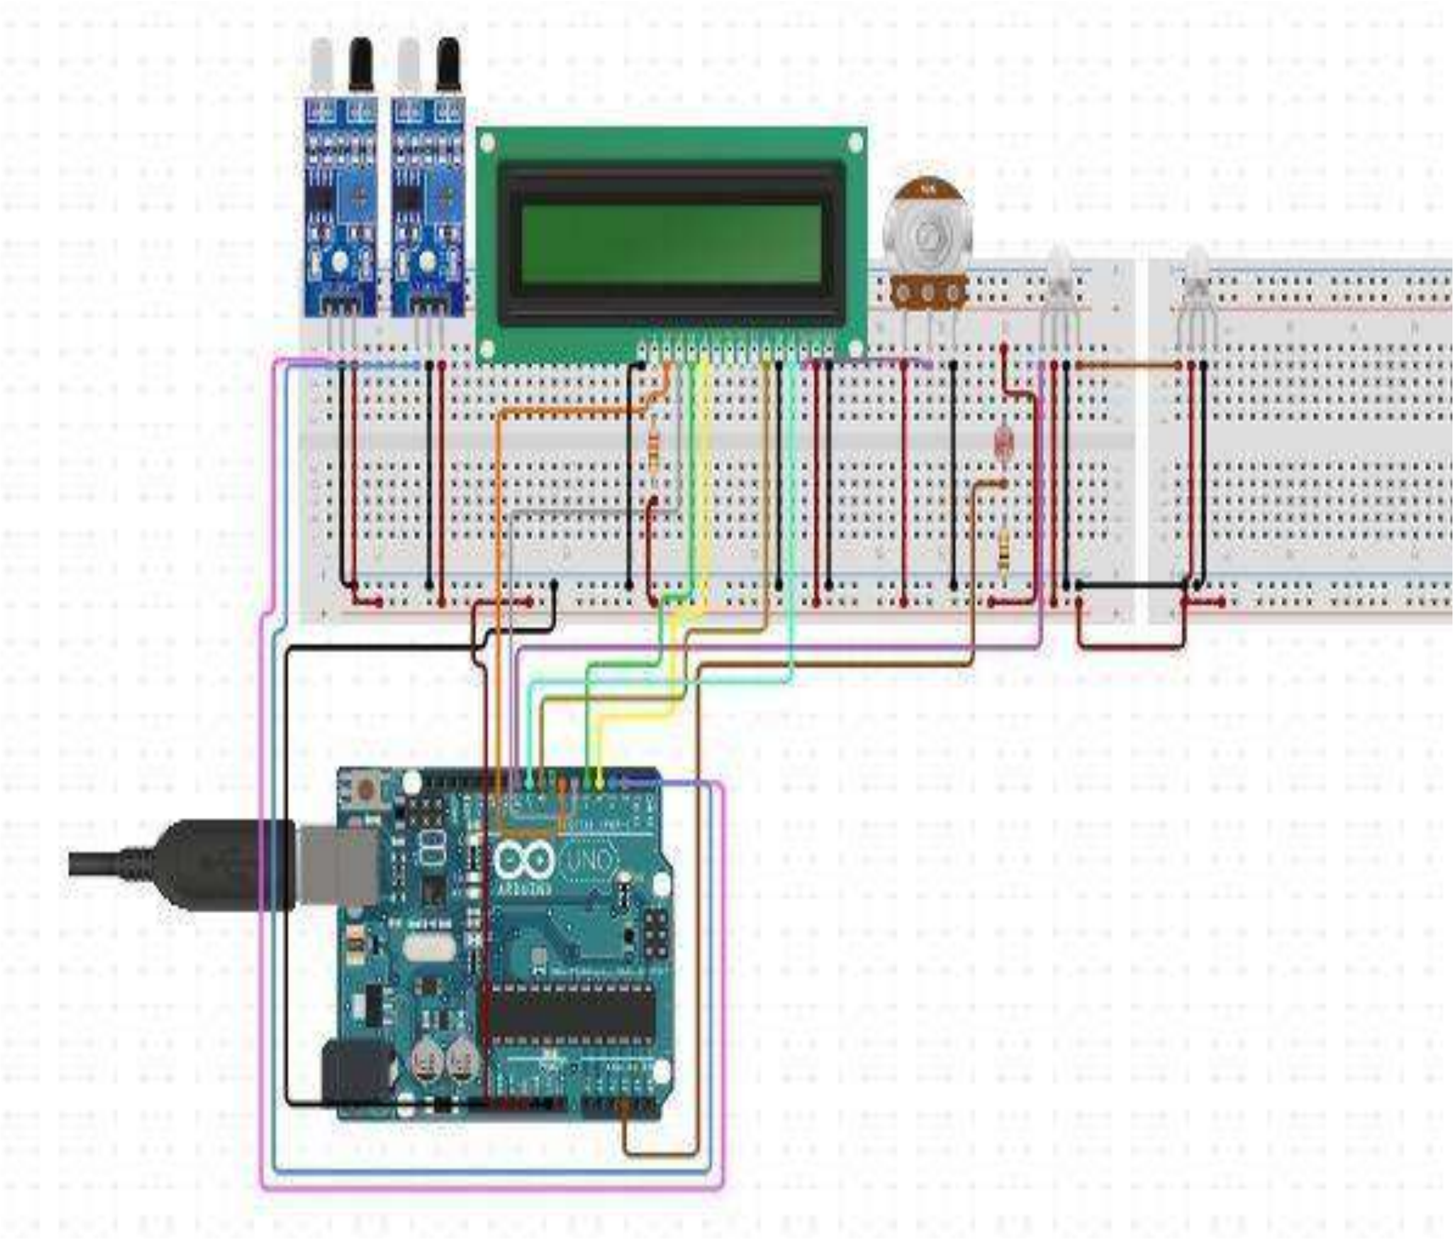

Fig: 3.1 – Schematic of System

3.2 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB
Frequency(Clock Speed)	16Mhz

Table 3 Specifications

3.3 ARDUINO:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.

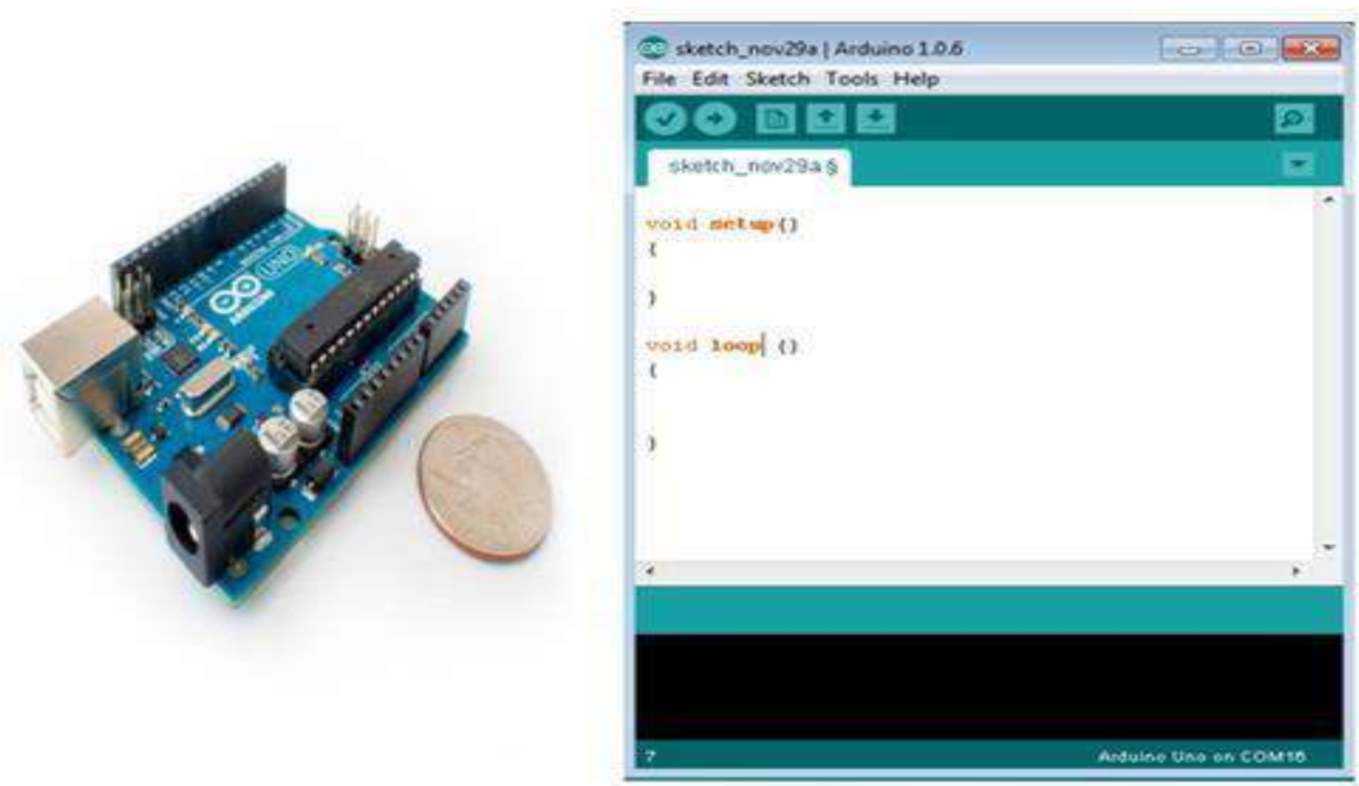

Fig 3.2 Arduino UNO

3.3.1 BOARD TYPES:

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

Table 3.3 Arduino boards based on AT91SAM3X8E microcontroller

3.3.2 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

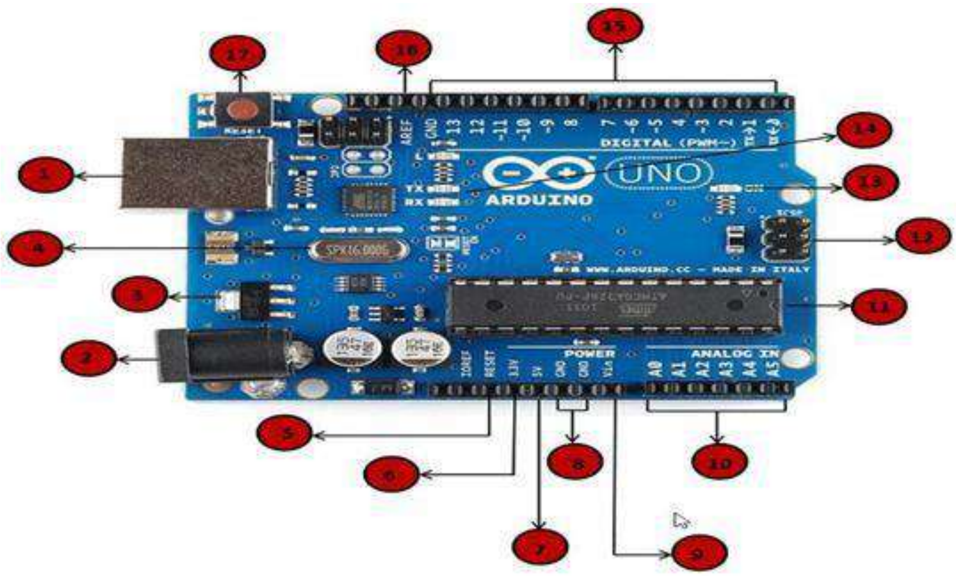

Fig: 3.3.1 – Arduino Pin Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.

5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.

10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.

12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.

14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 3.4 Pin Description

3.4 ARDUINO FAMILY:

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino

Fig: 3.4.1 Arduino Family

3.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

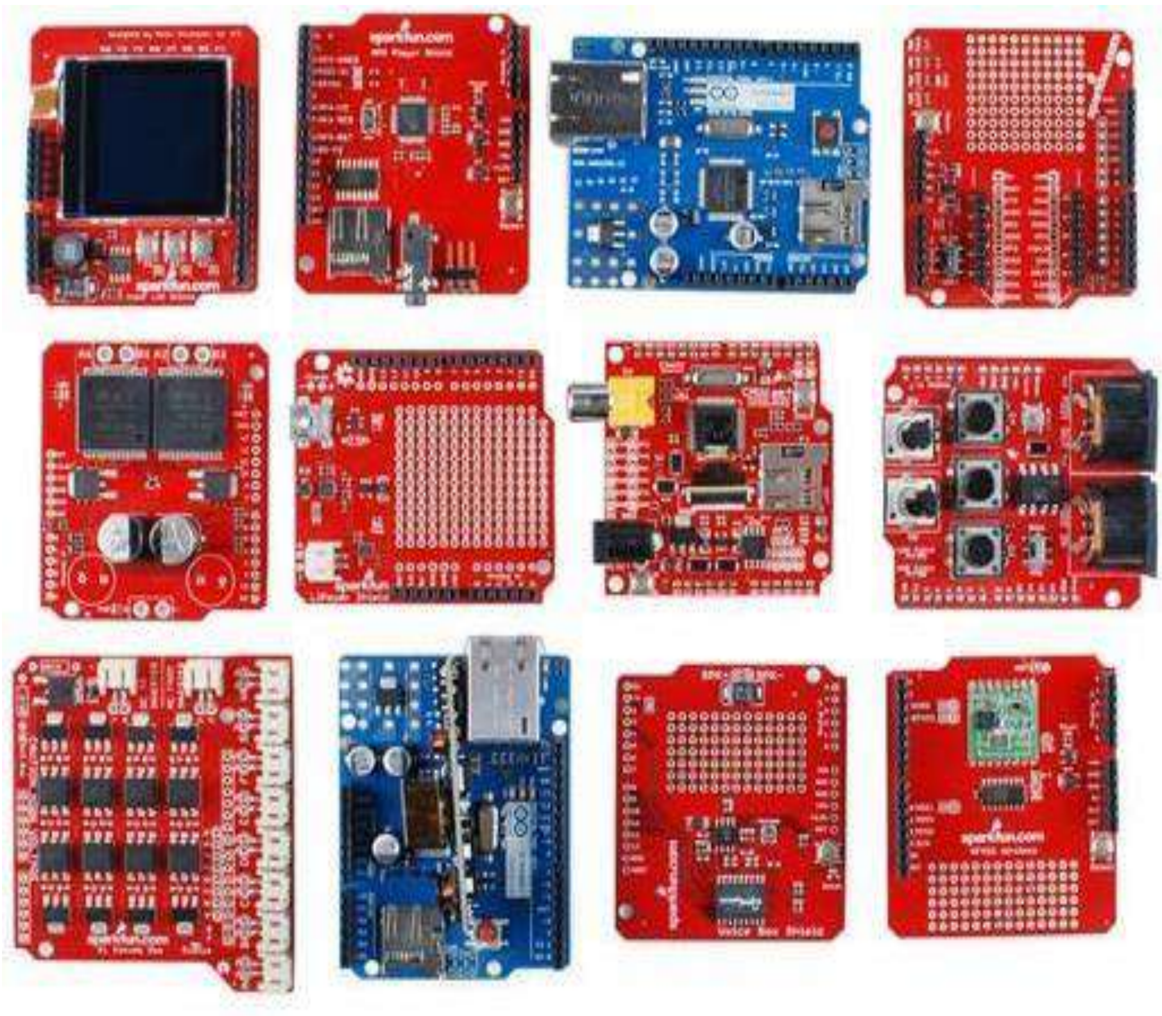

Fig.3.5.1: Arduino Shields

3.6 PIN DESCRIPTION OF ATMEGA328:

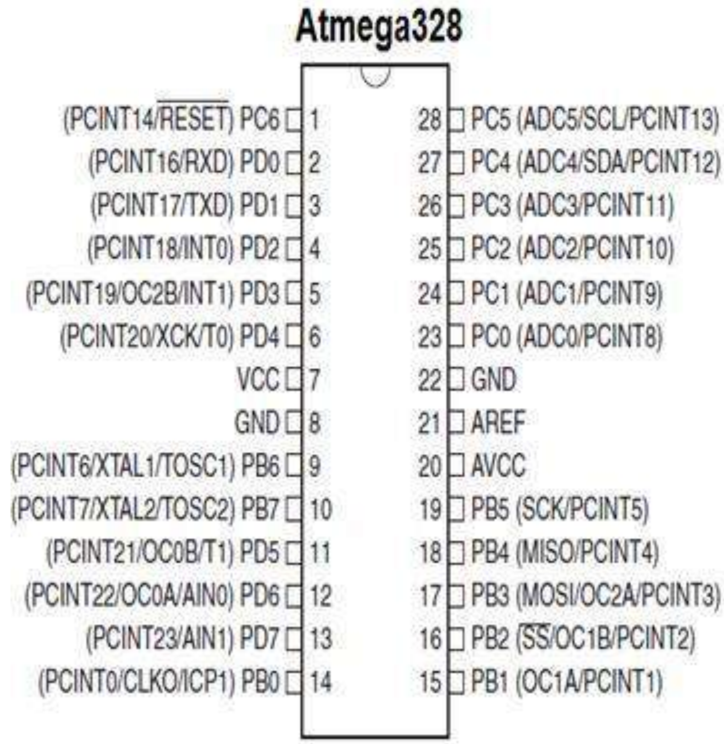

Fig: 3.6.1 Pin description of ATMEGA328

3.61 ADVANTAGES OF ARDUINO:

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

3.6.2 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low-powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model.

3.7 RELAY

Relays are switches that open and close circuits electro mechanically or electronically. **Relays** control one electrical circuit by opening and closing contacts in another circuit. As **relay diagrams** show, when a **relay** contact is normally open (NO)

Fig: 3.7.1 RELAY

3.7.1 ELECTROMECHANICAL RELAYS:

Basic parts and functions of electromechanical relays include:

1. **Frame:** Heavy-duty frame that contains and supports the parts of the relay.
2. **Coil:** Wire is wound around a metal core. The coil of wire causes an electromagnetic field.
3. **Armature:** A relays moving part. The armature opens and closes the contacts. An attached spring returns the armature to its original position.
4. **Contacts:** The conducting part of the switch that makes (closes) or breaks (opens) a circuit.

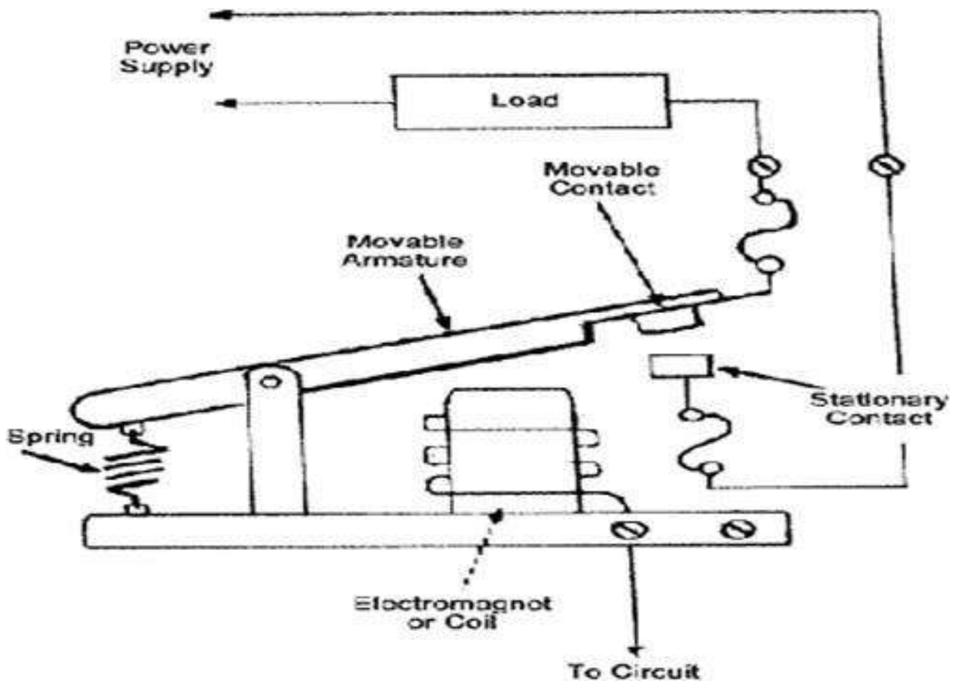

Fig:3.7.2 Internal Circuit of Relay.

Relays involve two circuits: the energizing circuit and the contact circuit. The coil is on the energizing side; and the relays contacts are on the contact side. When a relays coil is energized, current flow through the coil creates a magnetic field. Whether in a DC unit where the polarity is fixed, or in an AC unit where the polarity changes 120 times per second, the basic function remains the same: the magnetic coil attracts a ferrous plate, which is part of the armature. One end of the armature is attached to the metal frame, which is formed so that the armature can pivot, while the other end opens and closes the contacts. Contacts come in a number of different configurations, depending on the number of Breaks, poles and Throws that make up the relay. For instance, relays might be described as Single-Pole, Single-Throw (SPST), or Double-Pole, Single-Throw (DPST). These terms will give an instant indication of the design and function of different types of relays.

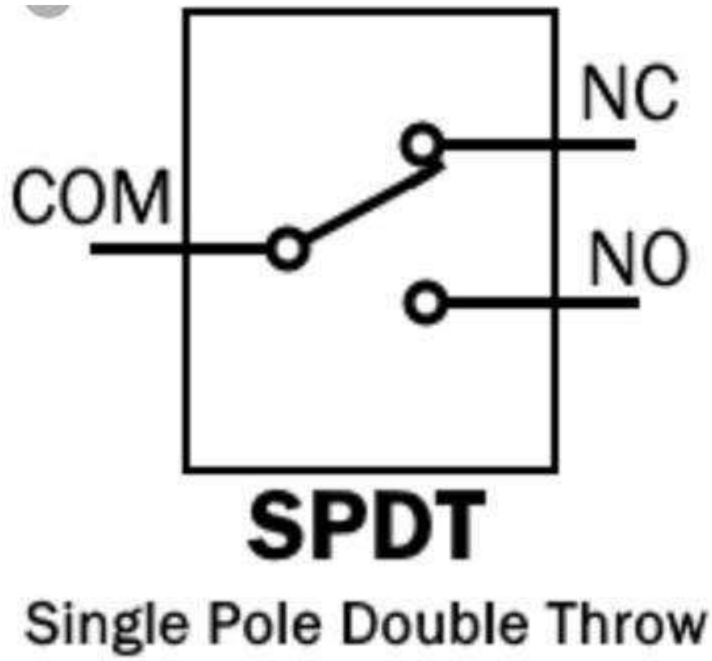

Fig:3.7.3 SPDT

- **Break** -This is the number of separate places or contacts that a switch uses to open or close a single electrical circuit. All contacts are either single break or double break. A single break (SB) contact breaks an electrical circuit in one place, while a double break (DB) contact breaks it in two places. Single break contacts are normally used when switching lower power devices such as indicating lights. Double break contacts are used when switching high-power devices such as solenoids.
- **Pole** -This is the number of completely isolated circuits that relays can pass through a switch. A single-pole contact (SP) can carry current through only one circuit at a time. A double-pole contact (DP) can carry current through two isolated circuits simultaneously. The maximum number of poles is 12, depending upon a relays design.
- **Throw** -This is the number of closed contact positions per pole that are available on a switch. A switch with a single throw contact can control only one circuit, while a double-throw contact can control two.

3.8 POWER SUPPLY UNIT

3.8.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as "Regulated D.C Power Supply".

3.8.2 BLOCK DIAGRAM OF POWER SUPPLY:

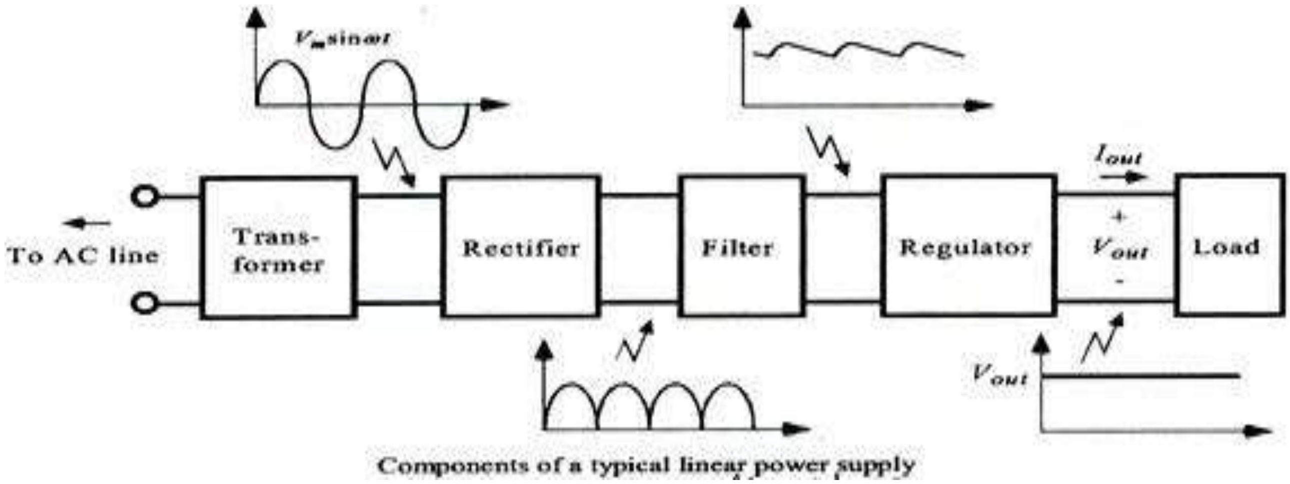

Fig: 3.8.1 Block Diagram of Power Supply

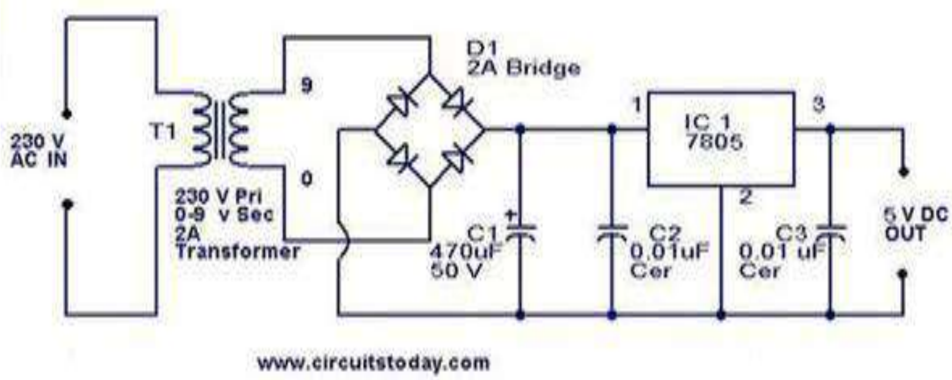

Fig: 3.8.2 Schematic Diagram of Power Supply

3.8.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.8.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the secondary winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

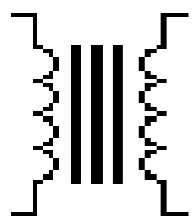

Fig: 3.8.3 Transformer Symbol

3.8.5 BASIC PRINCIPLE OF TRANSFORMER:

A transformer makes use of Faraday's_law and the ferromagnetic properties of an iron_core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

3.8.6 WORKING OF TRANSFORMER:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

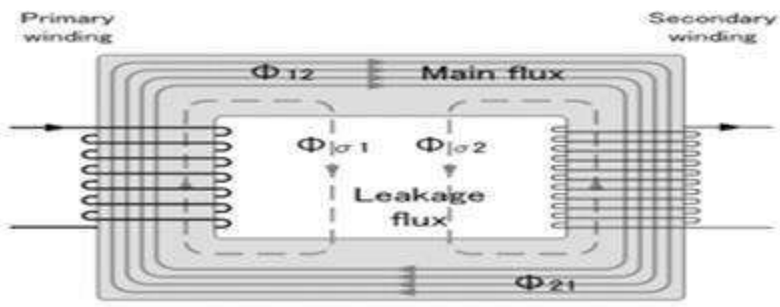

Fig:3.8.4 Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

- They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
- Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.8.7 CLASSIFICATION OF TRANSFORMER:

- Step-Up Transformer

- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

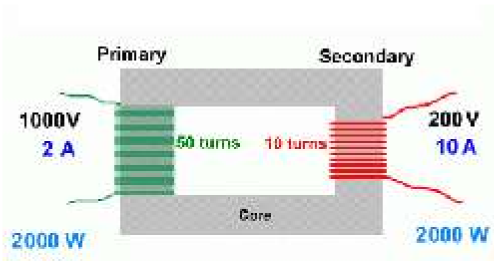

Fig:3.8.5 Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input. Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

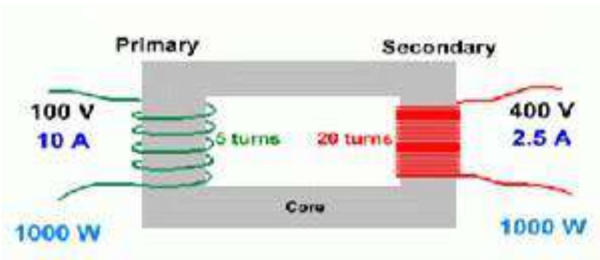

Fig: 3.8.6 Step-Up Transformer

3.8.8 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

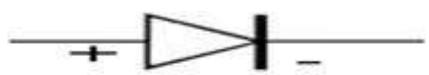

Fig: 3.8.7 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.8.9 RECTIFIERS:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

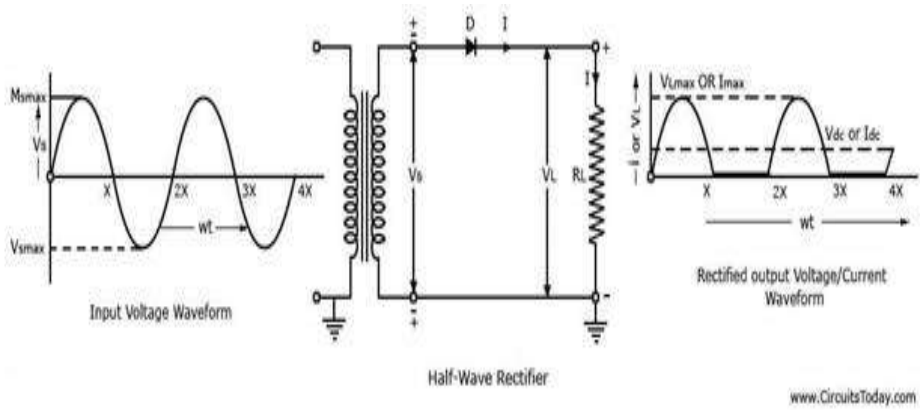

Fig: 3.8.8 Half Wave Rectifier

Figure shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

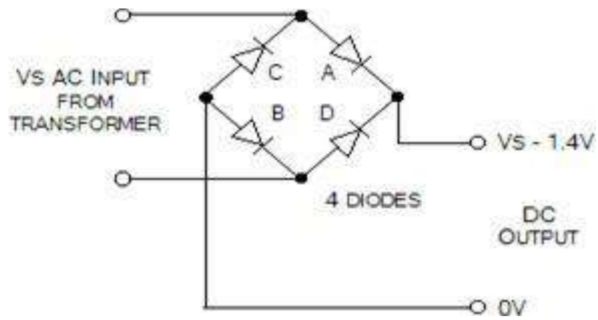

Fig:3.8.9 Full-Wave Rectifier

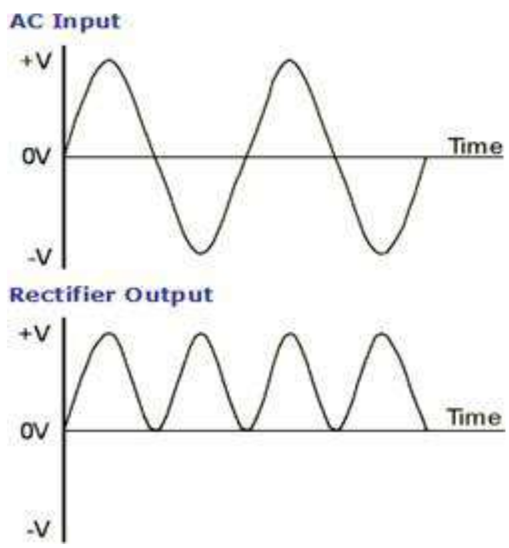

Fig:3.8.10 Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC.

3.8.10 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

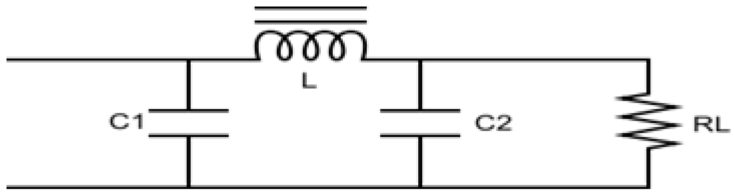

Fig:3.8.11 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

- The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
- The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
- The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

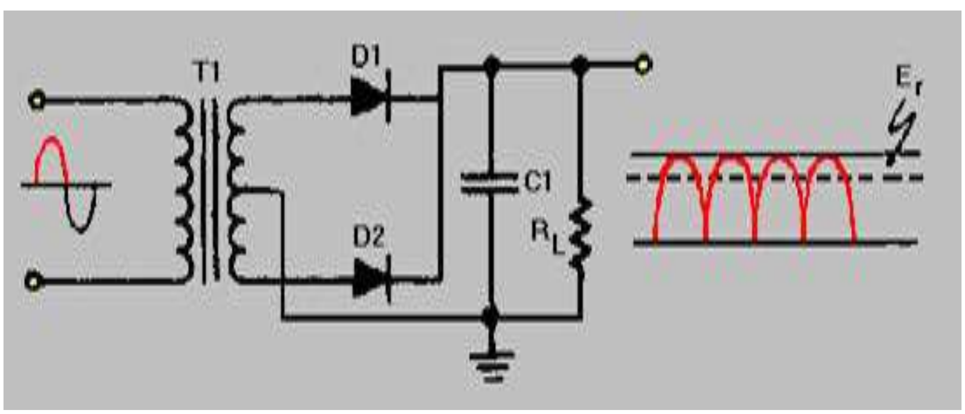

Fig:3.8.12 Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.8.11 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx' indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx 'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

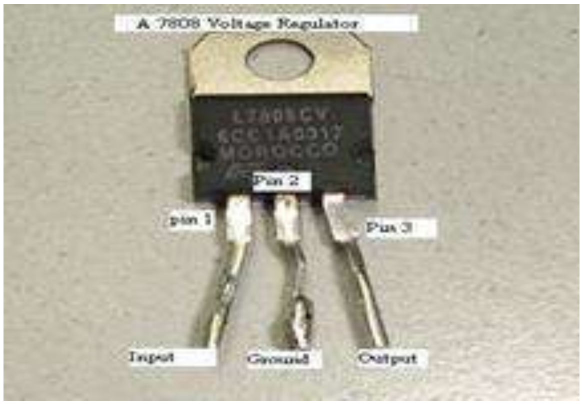

Fig:3.8.13 Regulator

3.9 HARDWARE COMPNENTS:

3.9.1 LDR SENSOR:

A **photoresistor** or **light dependent resistor** or **cadmium sulfide (CdS) cell** is a resistor whose resistance decreases with increasing incident light intensity. It can also be referred to as a **photoconductor**.

A photo resistor is made of a high resistance semiconductor. If light falling on the device is of high enough frequency, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, there by lowering resistance.

A photoelectric device can be either intrinsic or extrinsic. An intrinsic semiconductor has its own charge carriers and is not an efficient semiconductor, e.g. silicon. In intrinsic devices the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electron across the entire bandgap. Extrinsic devices have impurities, also called dopants, added whose ground state energy is closer to the conduction band; since the electrons do not have as far to jump, lower energy photons (i.e., longer wavelengths and lower frequencies) are sufficient to trigger the device. If a sample of silicon has some of its atoms replaced by phosphorus atoms (impurities), there will be extra electrons available for conduction. This is an example of an extrinsic semiconductor.

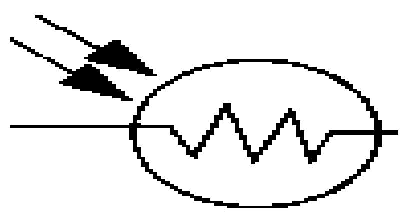

Fig: 3.9.1 The symbol for a photoresistor

Applications:

Photoresistors come in many different types. Inexpensive cadmium sulfide cells can be found in many consumer items such as camera light meters, street lights, clock radios, alarms, and outdoor clocks.

They are also used in some dynamic compressors together with a small incandescent lamp or light emitting diode to control gain reduction.

Lead sulfide (PbS) and indium antimonide (InSb) LDRs (light dependent resistor) are used for the mid infrared spectral region. Ge:Cu photoconductors are among the best far-infrared detectors available, and are used for infrared astronomy and infrared spectroscopy.

Transducers are used for changing energy types.

Fig: 3.9.2 A light dependent resistor

3.9.2 IR TRANSMITTER & RECEIVER:

- IR stands infrared red spectrum, by using this region we can detect number of obstacles passing through a region.
- IR consists of two sections one is transmitter section and other is receiver section.

- **Transmitter section:** it consists of a LED which continuously transmits a modulated signal of range(40 to 250khz).
- **Receiver section:** Receiver section consists of a photo diode it will continuously track and receive the IR rays from LED
- **Functionality:** The IR transmitter will continuously transmit IR rays and receiver (photo diode) will continuously receive the rays whenever some obstacle passes through the IR pair the transmission will be braked by which we come to know that an intruder have been detected. In this way this communication will help us in safeguarding and many other applications.

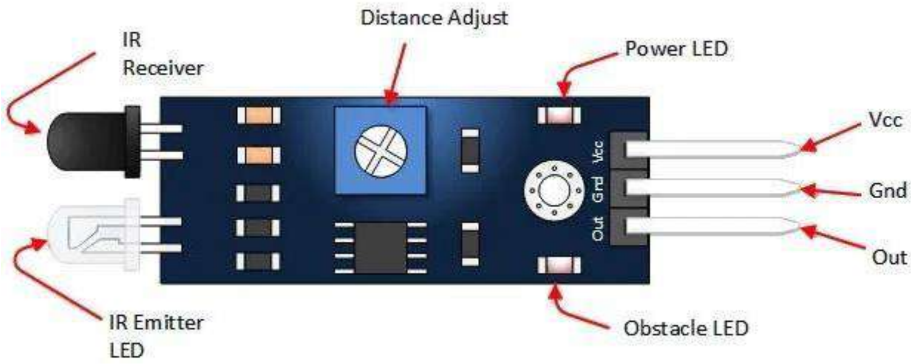

Fig: 3.9.3 IR Sensor

3.9.3 LED

Introduction:

A light-emitting diode (LED) is a semiconductor light source. LEDs are used as indicator lamps in many devices, and are increasingly used for lighting. Introduced as a practical electronic component in 1962, early LEDs emitted low-intensity red light, but modern versions are available across the visible, ultraviolet and infrared wavelengths, with very high brightness.

The LED is based on the semiconductor diode. When a diode is forward biased, electrons are able to recombine with holes within the device, releasing energy in the form of photons. This effect is called electroluminescence and the color of the light (corresponding to the energy of the photon) is determined by the energy gap of the semiconductor. An LED is usually small in area (less than 1 mm^2), and integrated optical components are used to shape its radiation pattern and assist in reflection. LEDs present many advantages over incandescent light sources including lower energy consumption, longer lifetime, improved robustness, smaller size, faster switching, and greater durability and reliability. However, they are relatively expensive and require more precise current and heat management than traditional light sources. Current LED products for general lighting are more expensive to buy than fluorescent lamp sources of comparable output.

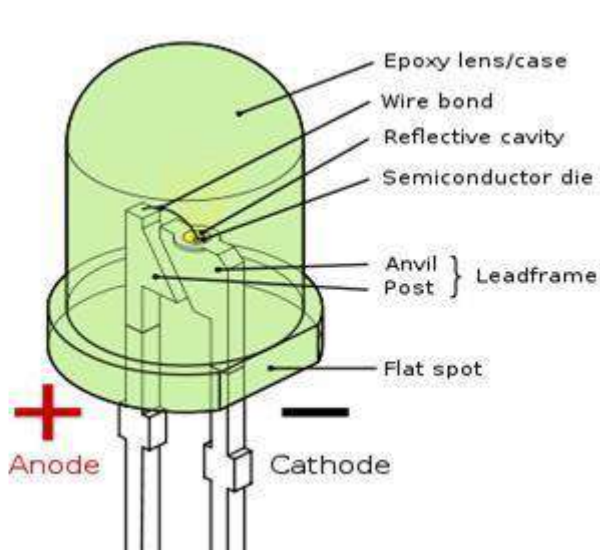

Fig: 3.9.4 LED

Working:

Charge-carriers—electrons and holes—flow into the junction from electrodes with different voltages. When an electron meets a hole, it falls into a lower energy level, and releases energy in the form of a photon. The wavelength of the light emitted, and therefore its color, depends on the band gap energy of the materials forming the p-n junction. In silicon or germanium diodes, the electrons and holes recombine by a non-radiative transition which produces no optical emission, because these are indirect band gap materials. The materials used for the LED have a direct band gap with energies corresponding to near-infrared, visible or near-

3.10 SOFTWARE REQUIREMENTS:

3.10.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open-source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

- ✓ Download the Arduino Software(IDE)
- ✓ Proceed with board specific instructions.

3.10.2 How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig: 3.10.1 USB Cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig: 3.10.2 A to Mini B Cable

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

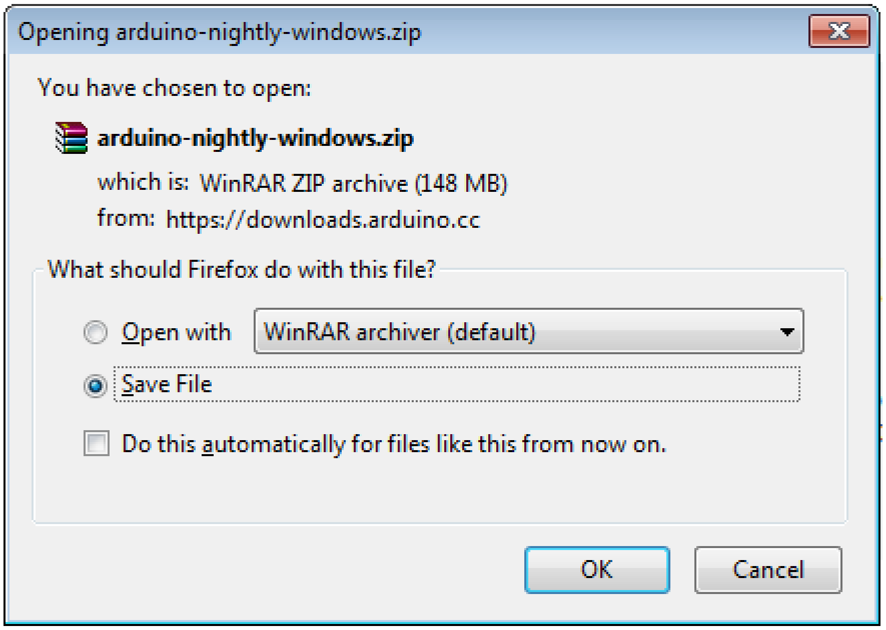

Fig: 3.10.3 Download Arduino IDE Software

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

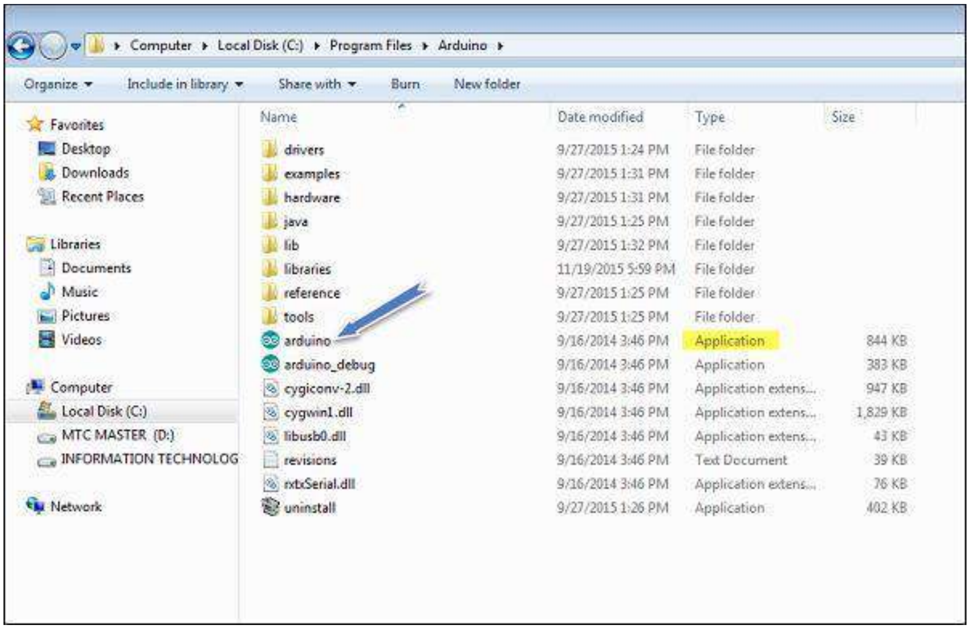

Fig: 3.10.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

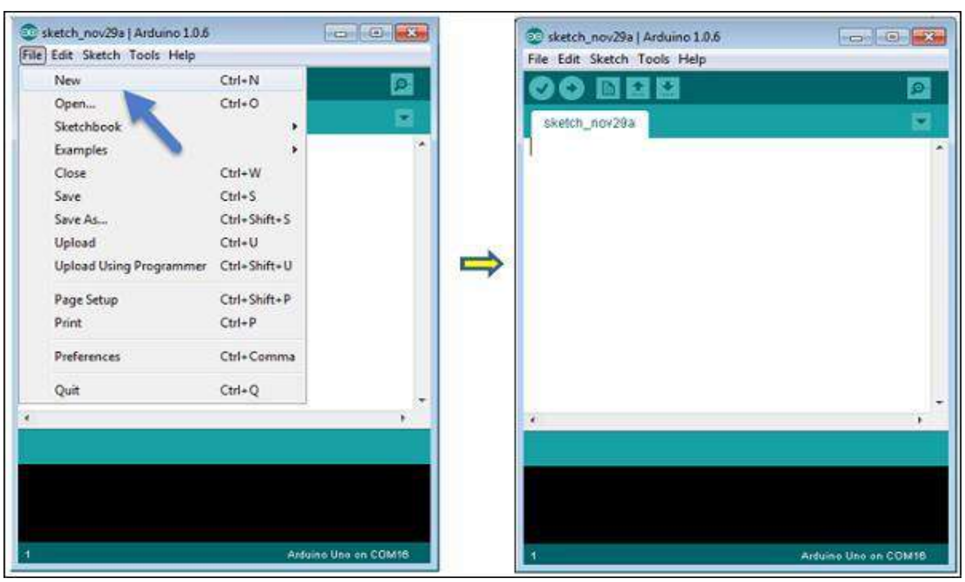

Fig: 3.10.5 Open Your First Project

To open an existing project example, select File → Example → Basics → Blink.

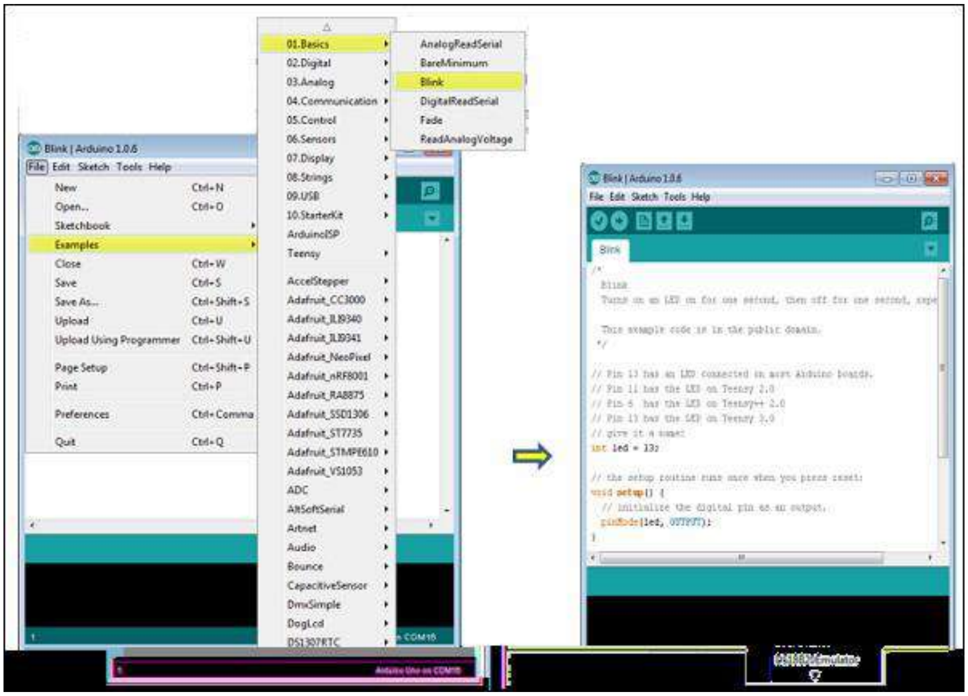

Fig: 3.10.6 Open Your First Program

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

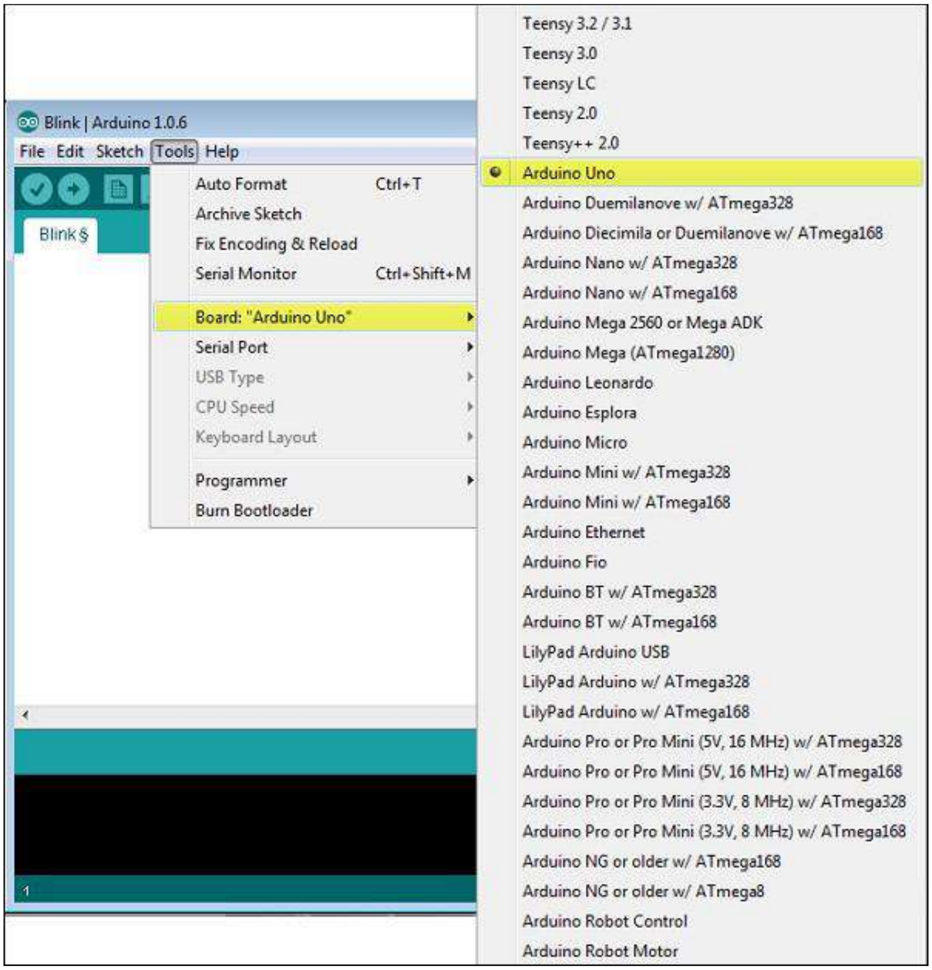

Fig: 3.10.7 Select Your Arduino Board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

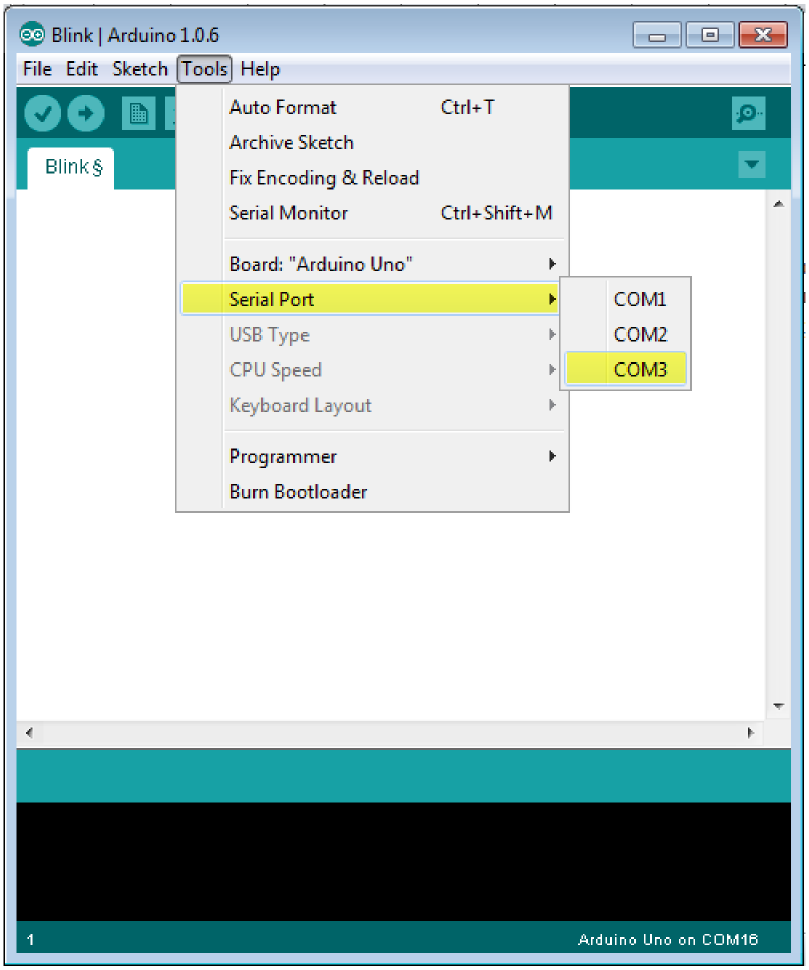

Fig: 3.10.8 Select Your Serial Port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

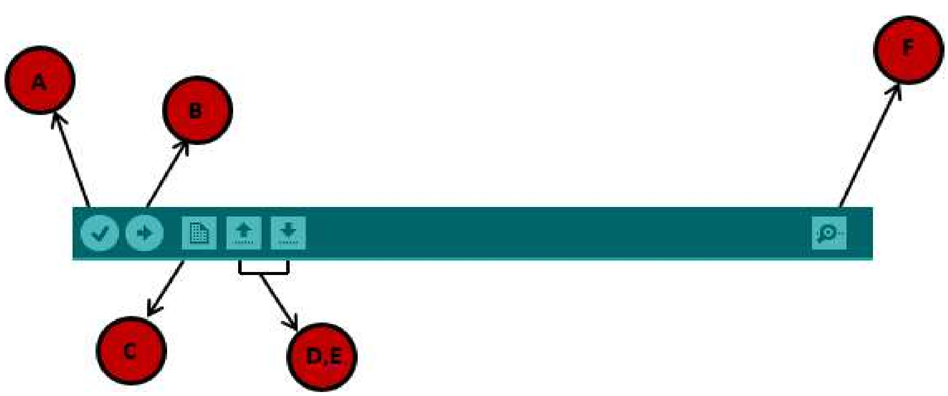

Fig: 3.10.9 Upload the Program To Your Board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

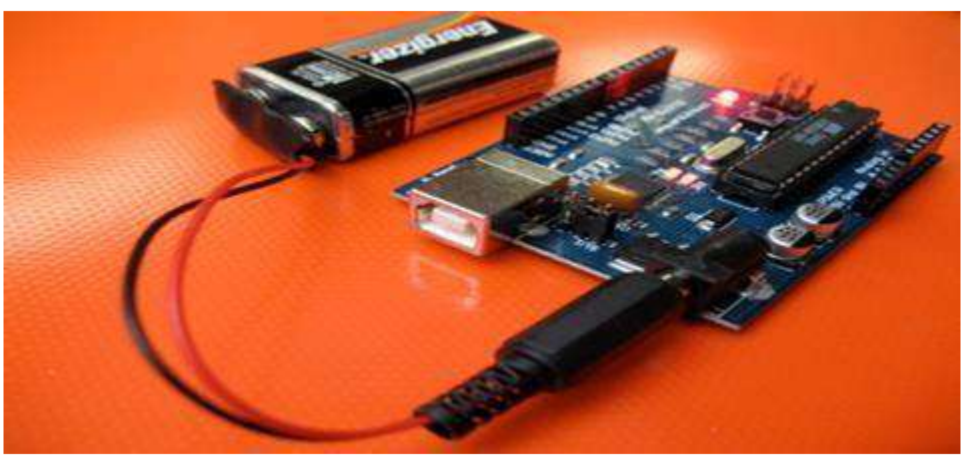

Fig:3.10.10 Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC

.

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

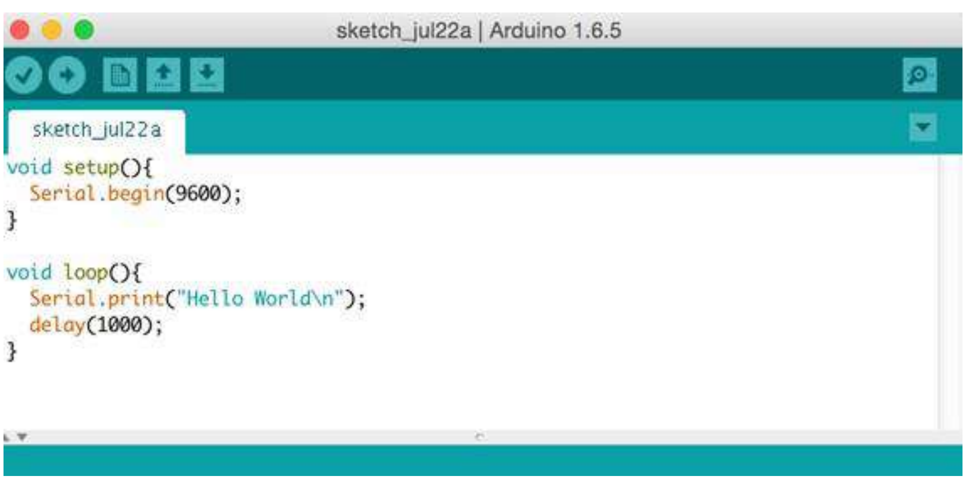

Fig: 3.10.11 Example Program

3.11 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

3.12 PROTEUS:

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

3.12.1 Starting New Design

Step 1: Open ISIS software and select New design in File menu

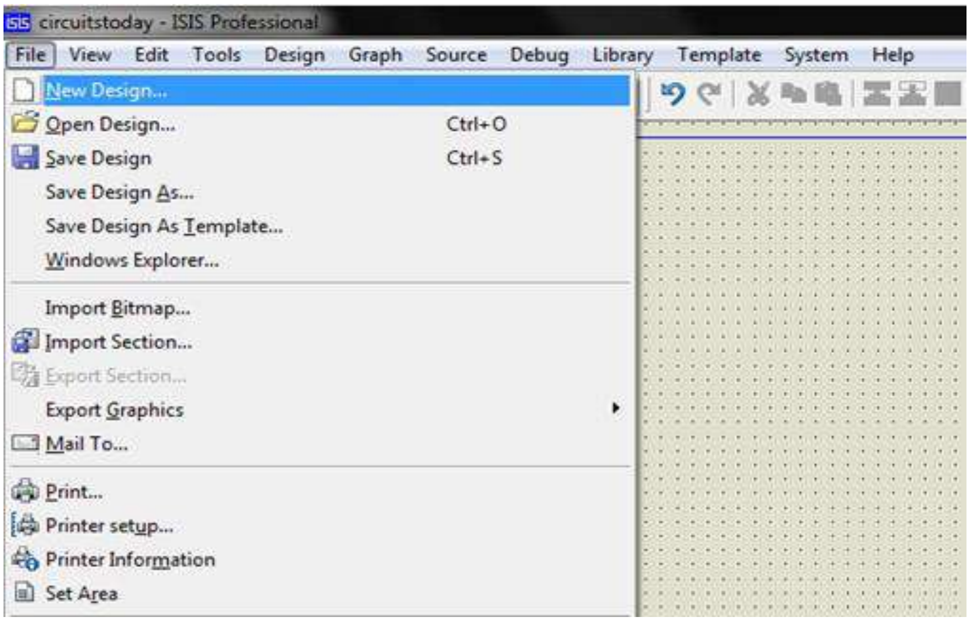

Fig: 3.12.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

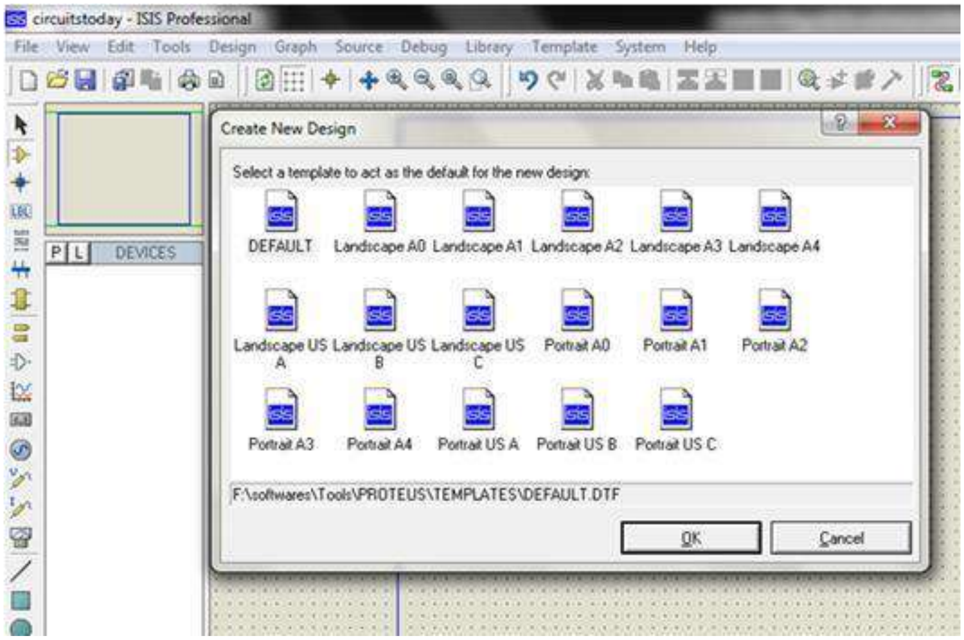

Fig:3.12.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

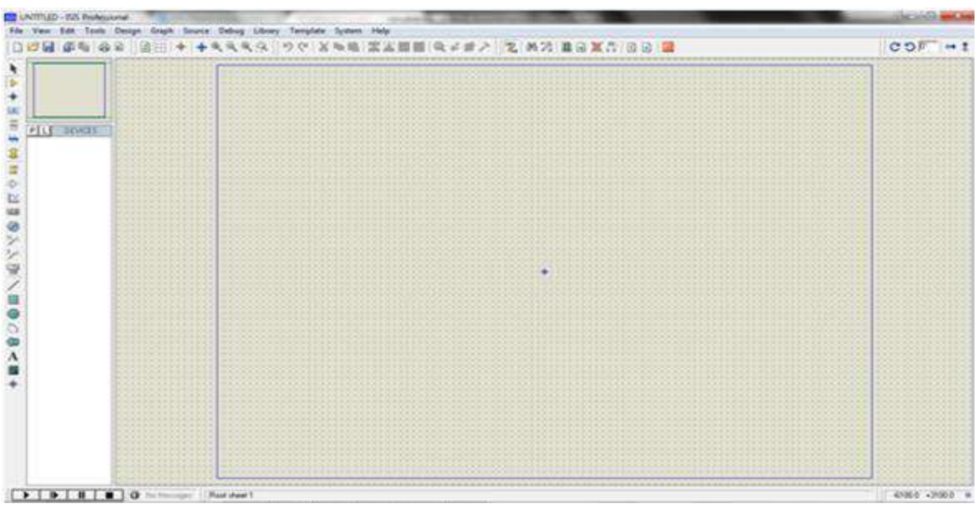

Fig:3.12.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

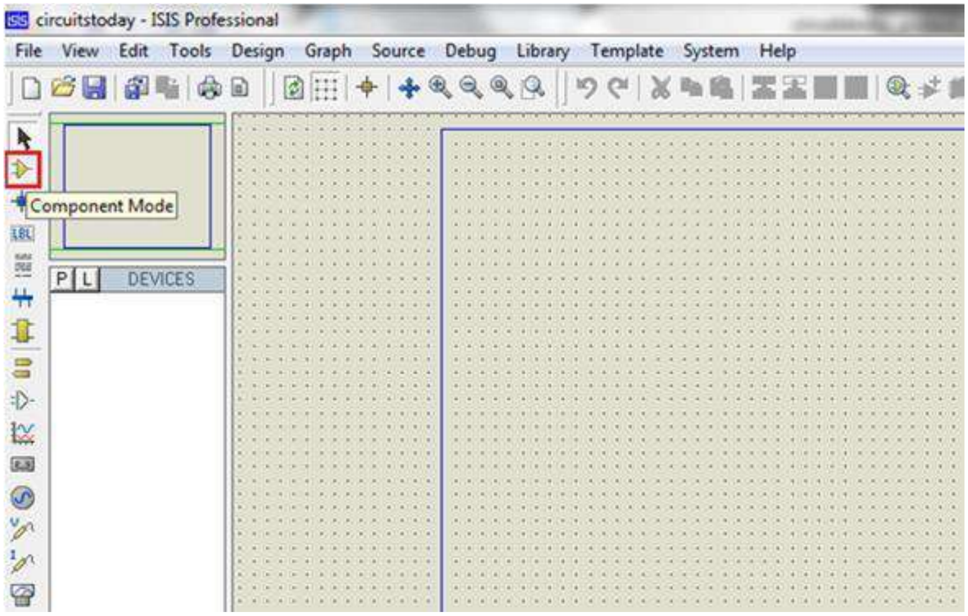

Fig: 3.12.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

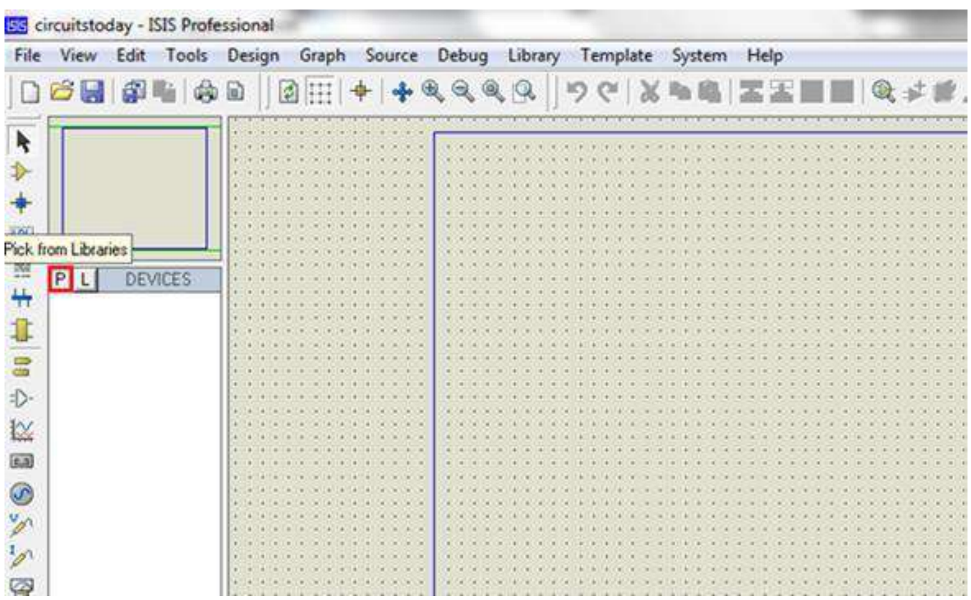

Fig: 3.12.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

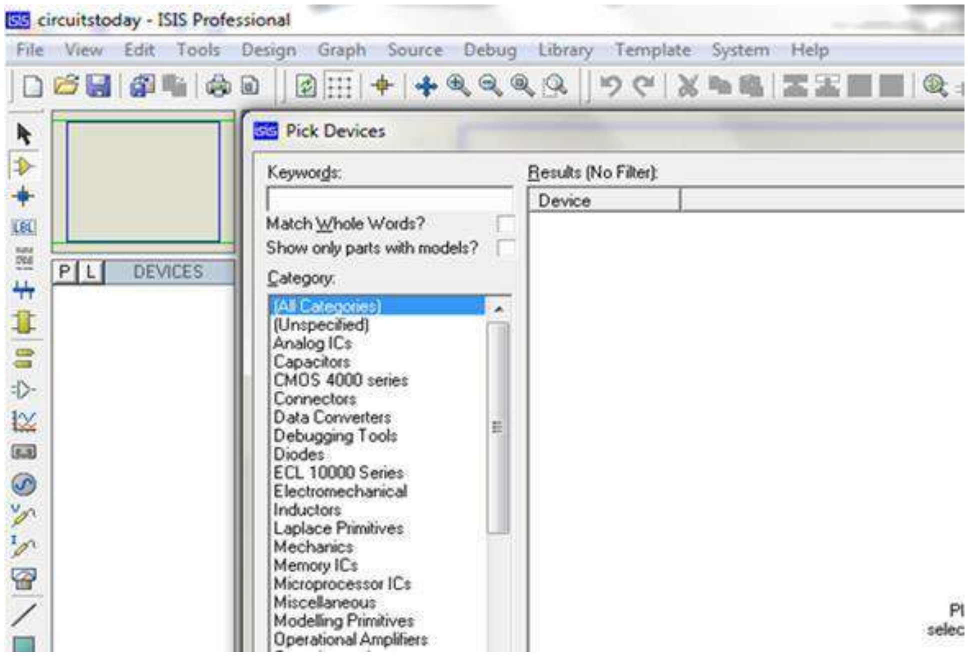

Fig: 3.12.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

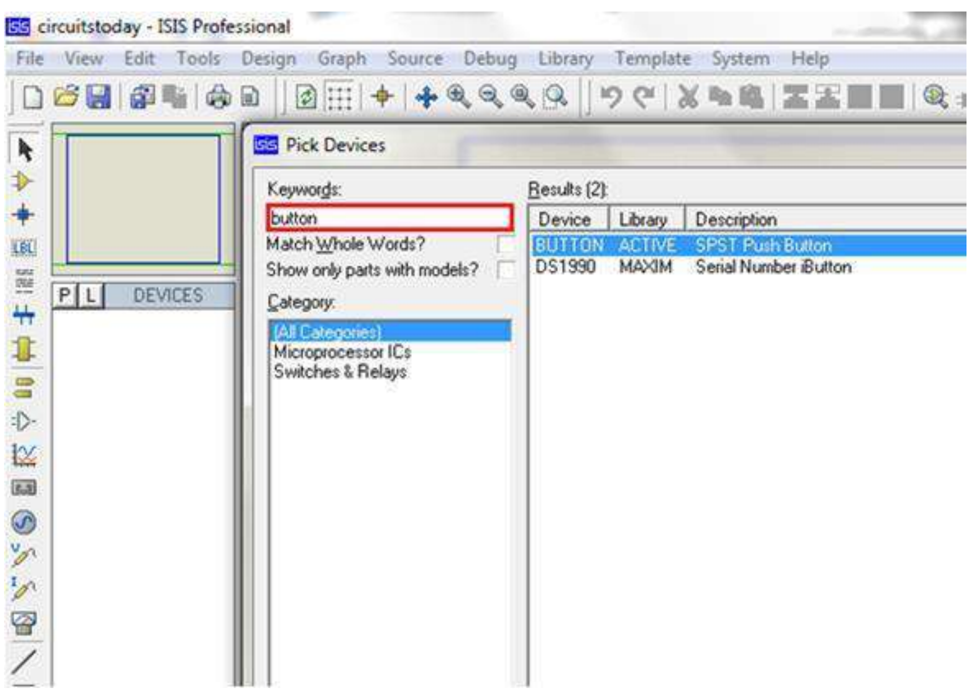

Fig: 3.12.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

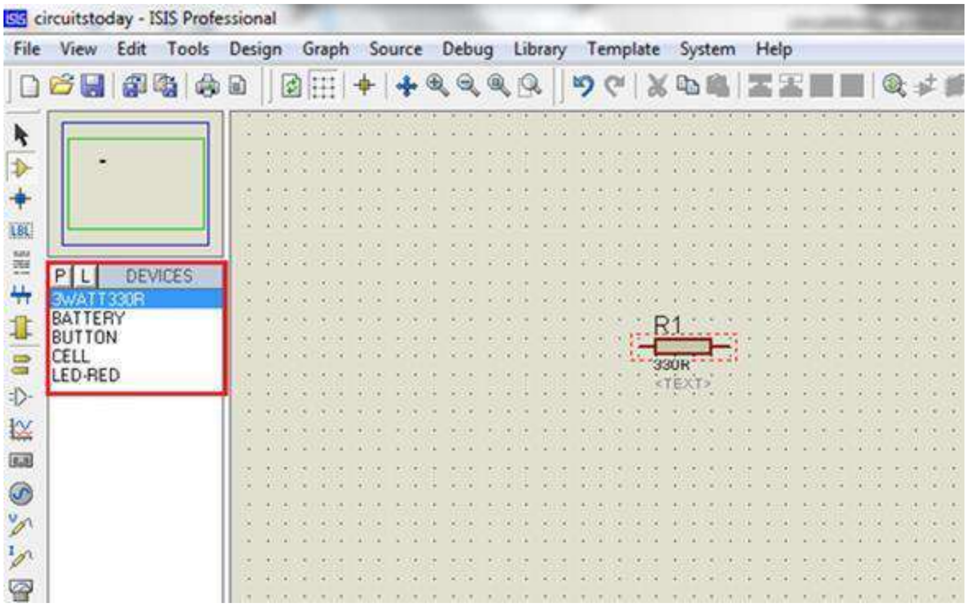

Fig: 3.12.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

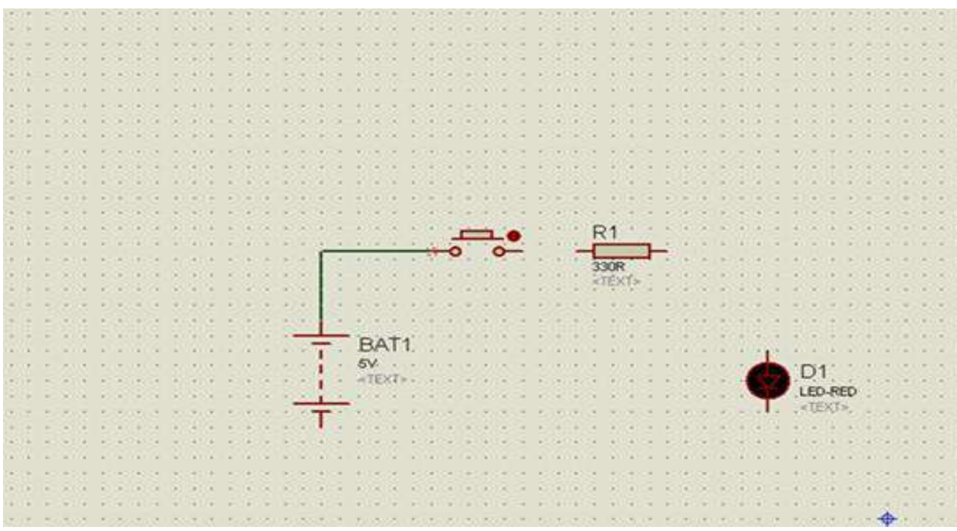

Fig:3.12.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

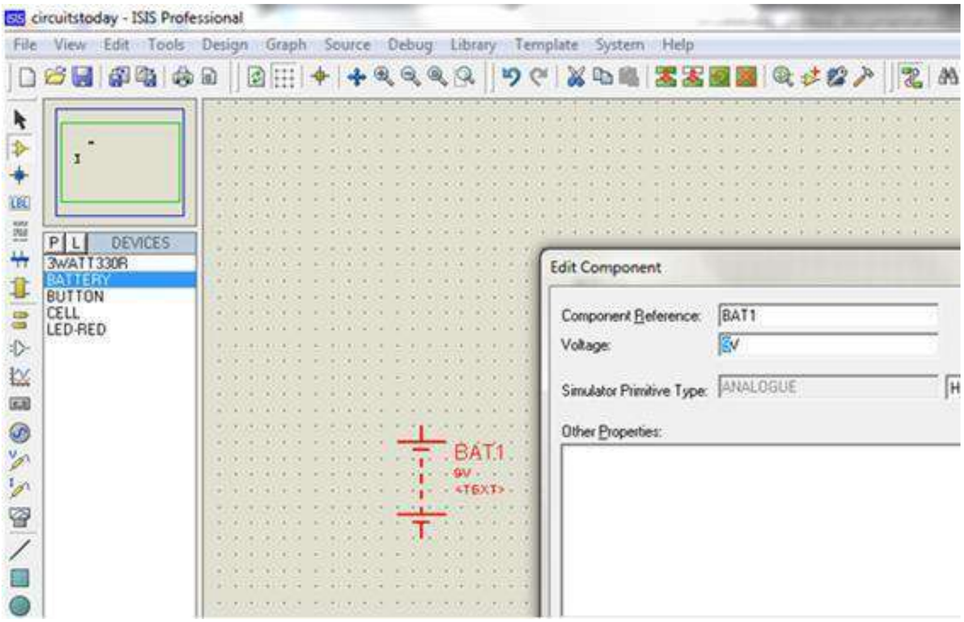

Fig: 3.12.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation

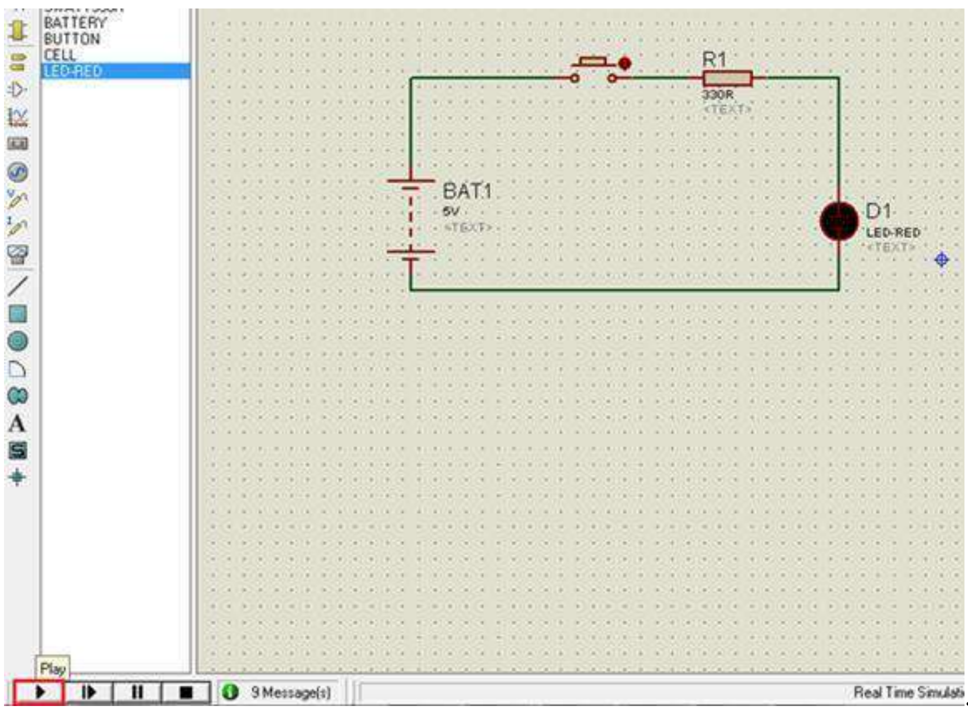

Fig: 3.12.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

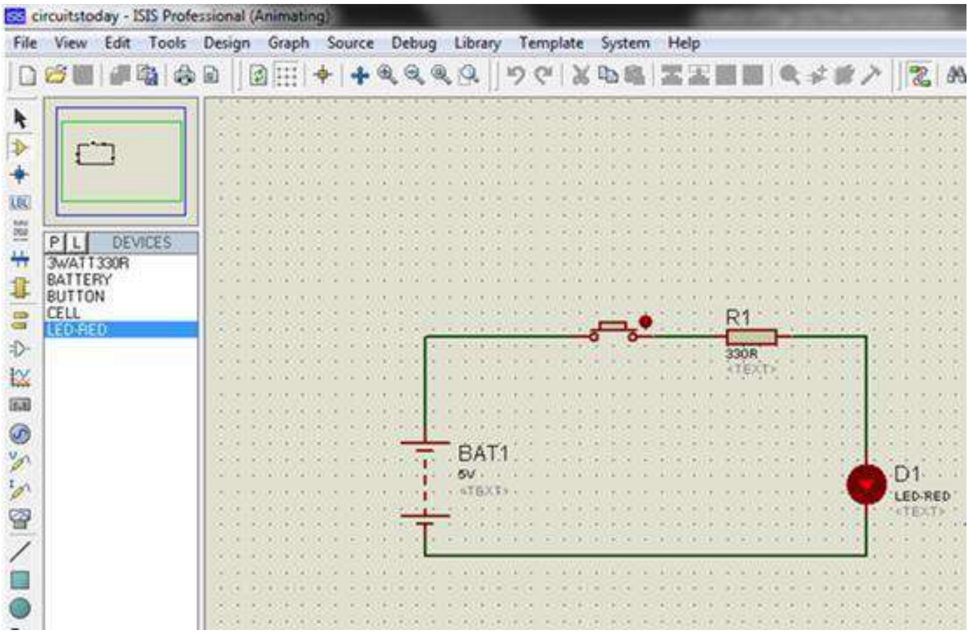

Fig:3.12.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

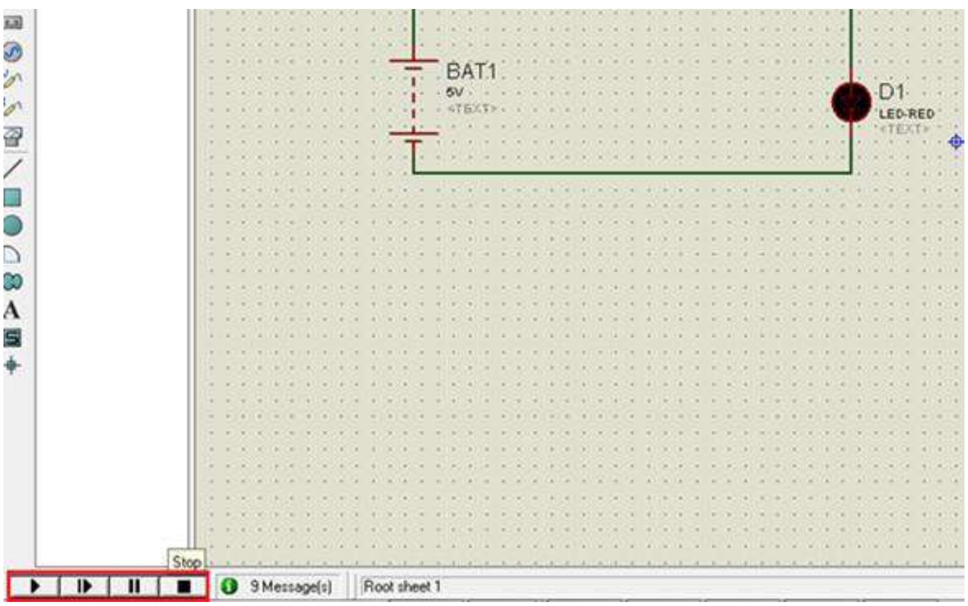

Fig: 3.12.13 Simulation Step-Pause-Stop Buttons

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM:

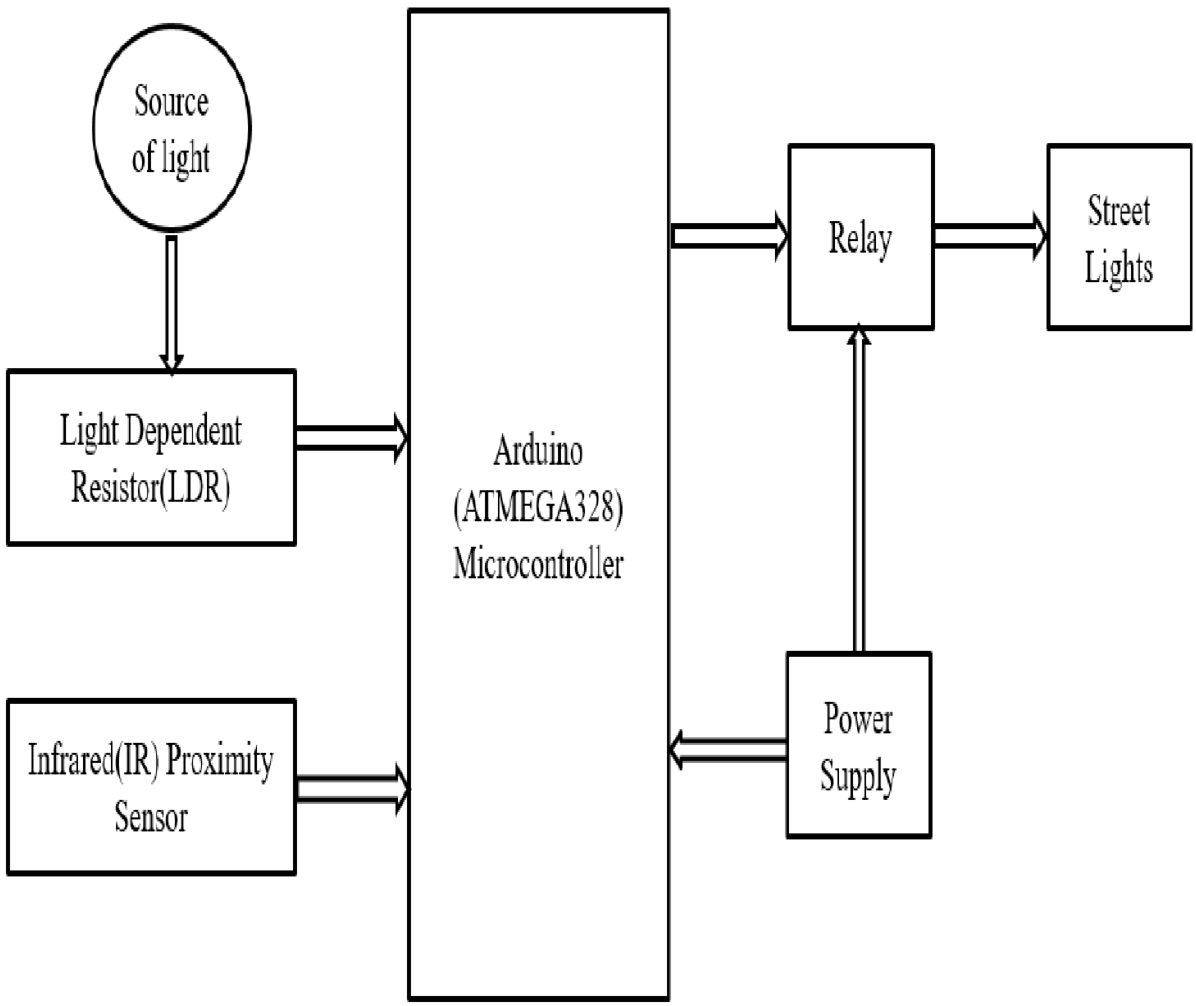

Fig: 4.1 Block Diagram Of The System

4.2 FLOW CHART:

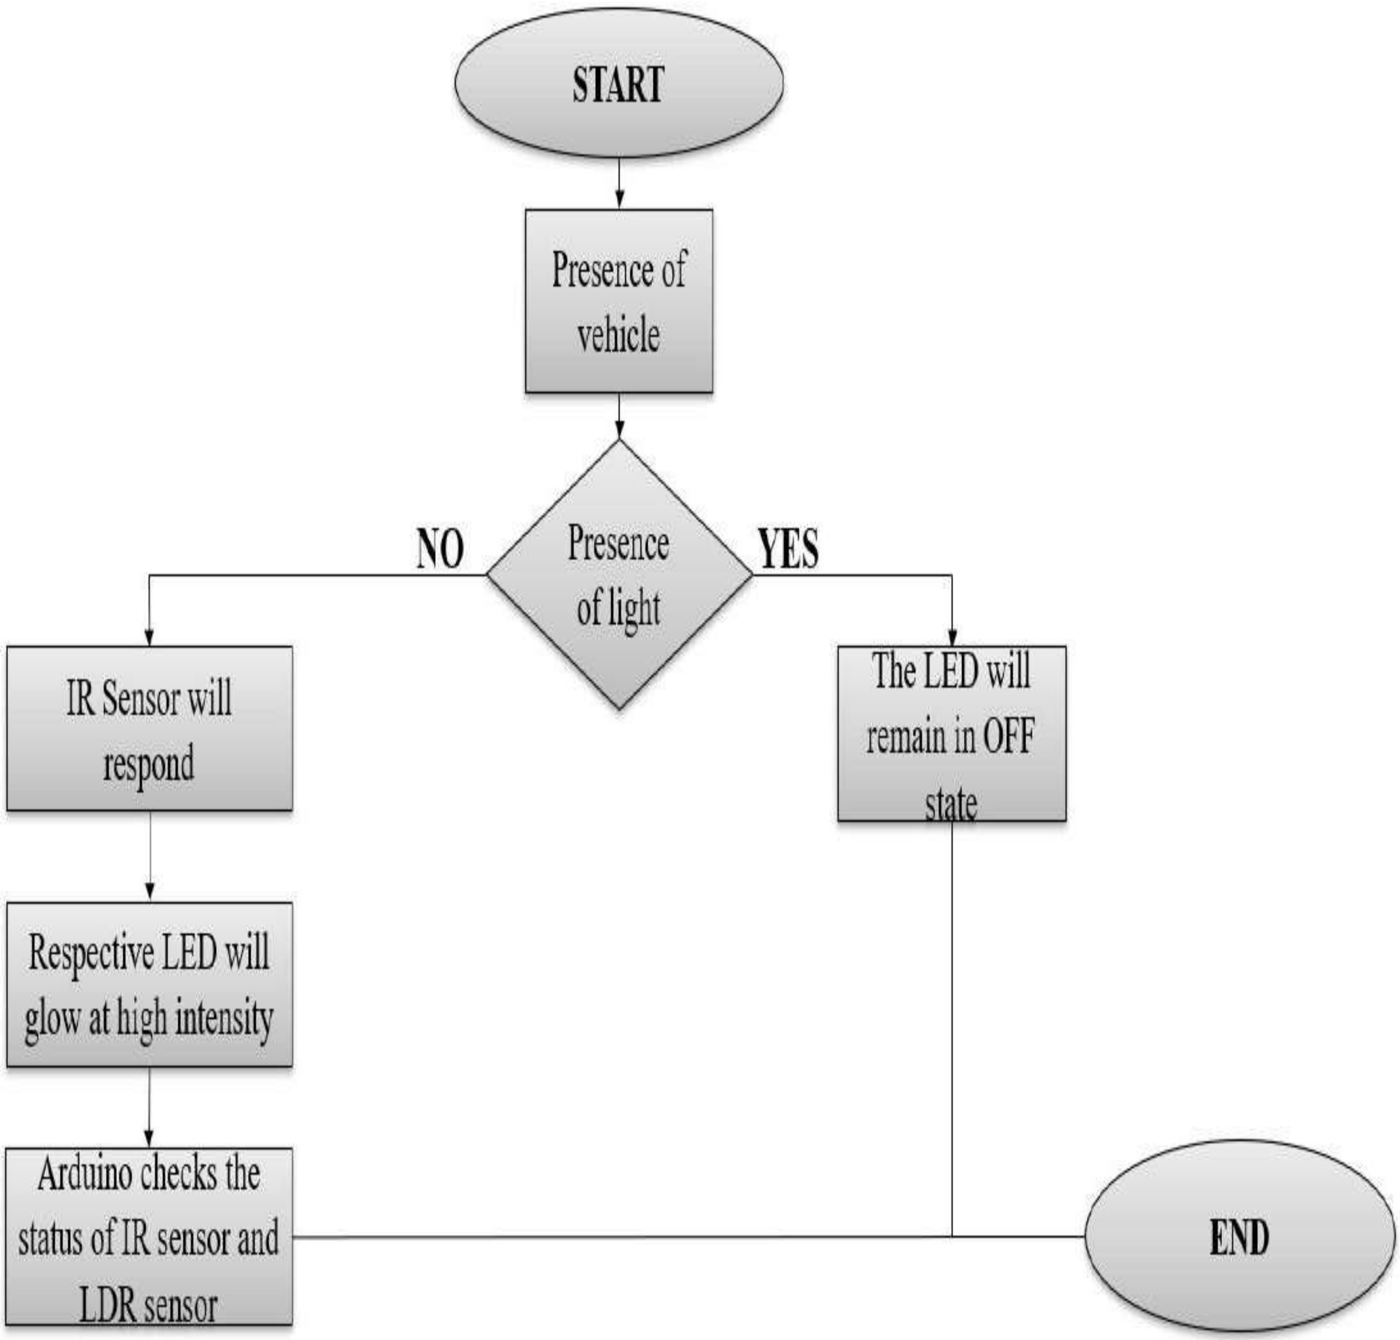

Fig: 4.2 Flow Chart

4.3 IMPLEMENTATION STAGES:

Stage 1:

When we switch on the power supply, the circuit will be activated and LCD displays.

Fig: 4.3.1 Starting Of The Operation

Stage 2:

When light is in surroundings, even when vehicle movement is detected or not, lights will be in OFF state.

Stage 3:

When it is dark, when vehicle movement is there ,the LED bulb corresponding to the movement glows for some time and then switches off.

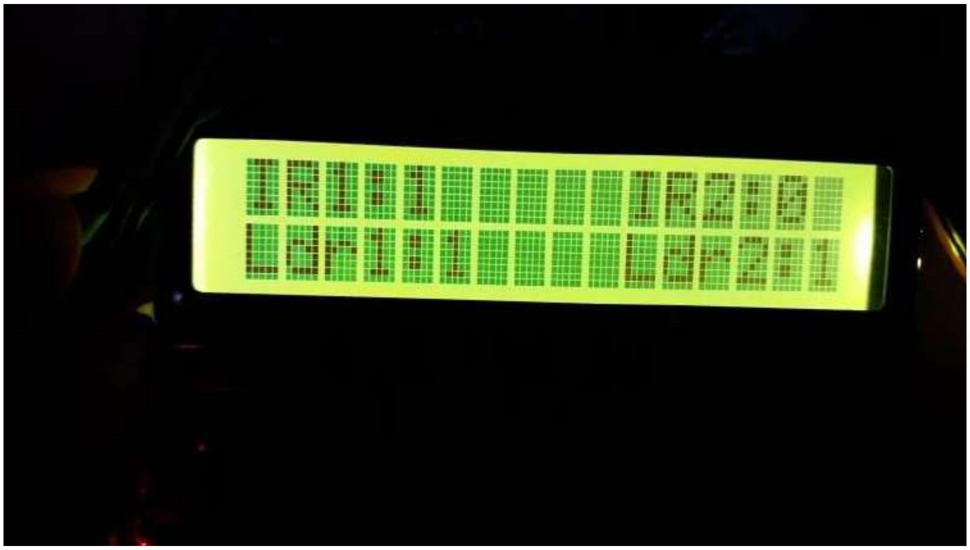

Fig: 4.3.2 Vehicle Movement Is Detected

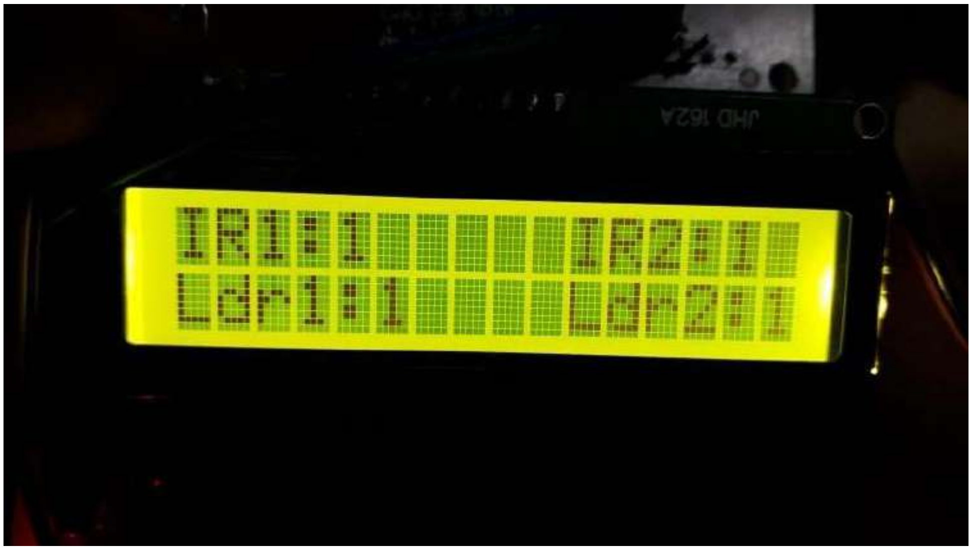

Fig: 4.3.3 Vehicle Movement Is Detected

Working:

Case i:

- Arduino is supplied with power.
- Arduino checks with IR sensor for presence of vehicle.
- If IR sensor doesn't detect any vehicle as an obstacle, then it sends information to Arduino.
- LDR sensor sends information to Arduino about lightening conditions.
- If there is light, then the LED remain in OFF state.

Case ii:

- Arduino checks with IR sensor for presence of vehicle.
- If IR sensor detects any vehicle as an obstacle, then it sends information to Arduino.
- LDR sensor sends information to Arduino about lightening conditions.
- If there is light, then the LED remain in OFF state.

Case iii:

- Arduino checks with IR sensor for presence of vehicle.
- If IR sensor doesn't any vehicle as an obstacle, then it sends information to Arduino.
- LDR sensor sends information to Arduino about lightening conditions.
- If it is dark, then the LED remain in OFF state

Case iv:

- Arduino checks with IR sensor for presence of vehicle.
- If IR sensor detects any vehicle as an obstacle, then it sends information to Arduino.
- LDR sensor sends information to Arduino about lightening conditions.
- If it is dark, then the LED remain in ON state.
- The respective led glows with high intensity until vehicle passes.
- Arduino checks the status of IR and LDR sensors.

4.4 PROJECT CODE:

```
#include <LiquidCrystal.h>
LiquidCrystal lcd (13,12,11,10,9,8);  //RS 13,EN 12, D4 11 ,D5 10,D6 9,D7 8

int ir1 = A0;
int ir2 = A1;
int ldr1 = A2;
int ldr2 = A3;
int light1=6;
int light2=7;

void setup(void)
{
  Serial.begin(9600);
  lcd.begin(16,2);
  lcd.clear();lcd.setCursor(0, 0);lcd.print("WELCOME");
  delay(1000);
 pinMode(light1,OUTPUT);
   pinMode(light2,OUTPUT);
   pinMode(ir1,INPUT);
```

```
  pinMode(ir2,INPUT);
  pinMode(ldr1,INPUT);
  pinMode(ldr2,INPUT);
  digitalWrite(light1,LOW);
  digitalWrite(light2,LOW);
}
void loop(void)
{
// int accident_sensor_data = digitalRead(accident_sensor);
 //Serial.println(accident_sensor_data);
 // delay(1000);
   int id1 = digitalRead(ir1);
   int id2 = digitalRead(ir2);
   int ld1 = digitalRead(ldr1);
   int ld2 = digitalRead(ldr2);
   delay(1000);
   lcd.clear();
   lcd.setCursor(0, 0);lcd.print("I1:");lcd.print(id1);lcd.print("     ");
   lcd.setCursor(8, 0);lcd.print("I2:");lcd.print(id2);lcd.print("     ");
   lcd.setCursor(0, 1);lcd.print("L1:");lcd.print(ld1);lcd.print("     ");
   lcd.setCursor(8, 1);lcd.print("L2:");lcd.print(ld2);lcd.print("     ");
   delay(1000);

   if(id1 == LOW || ld1 == LOW)
    {
      lcd.clear();lcd.setCursor(0, 1);lcd.print("LIGHT 1 ON");
      digitalWrite(light1,HIGH);
      delay(5000);
    }
```

```
    else
    {
      digitalWrite(light1,LOW);
    }
        if(id2 == LOW || ld2 == LOW)
    {
      lcd.clear();lcd.setCursor(0, 1);lcd.print("LIGHT 2 ON");
      digitalWrite(light2,HIGH);
      delay(5000);
    }
     else
    {
      digitalWrite(light2,LOW);
    }
}
```

4.5 FINAL OUTPUT:

- Since it is dark, LDR sensor decreases the resistance and allows conduction.
- When IR sensor detects and object, it sends information to Arduino.
- Arduino receives and analyzes the information and turns LED Bulb into ON state

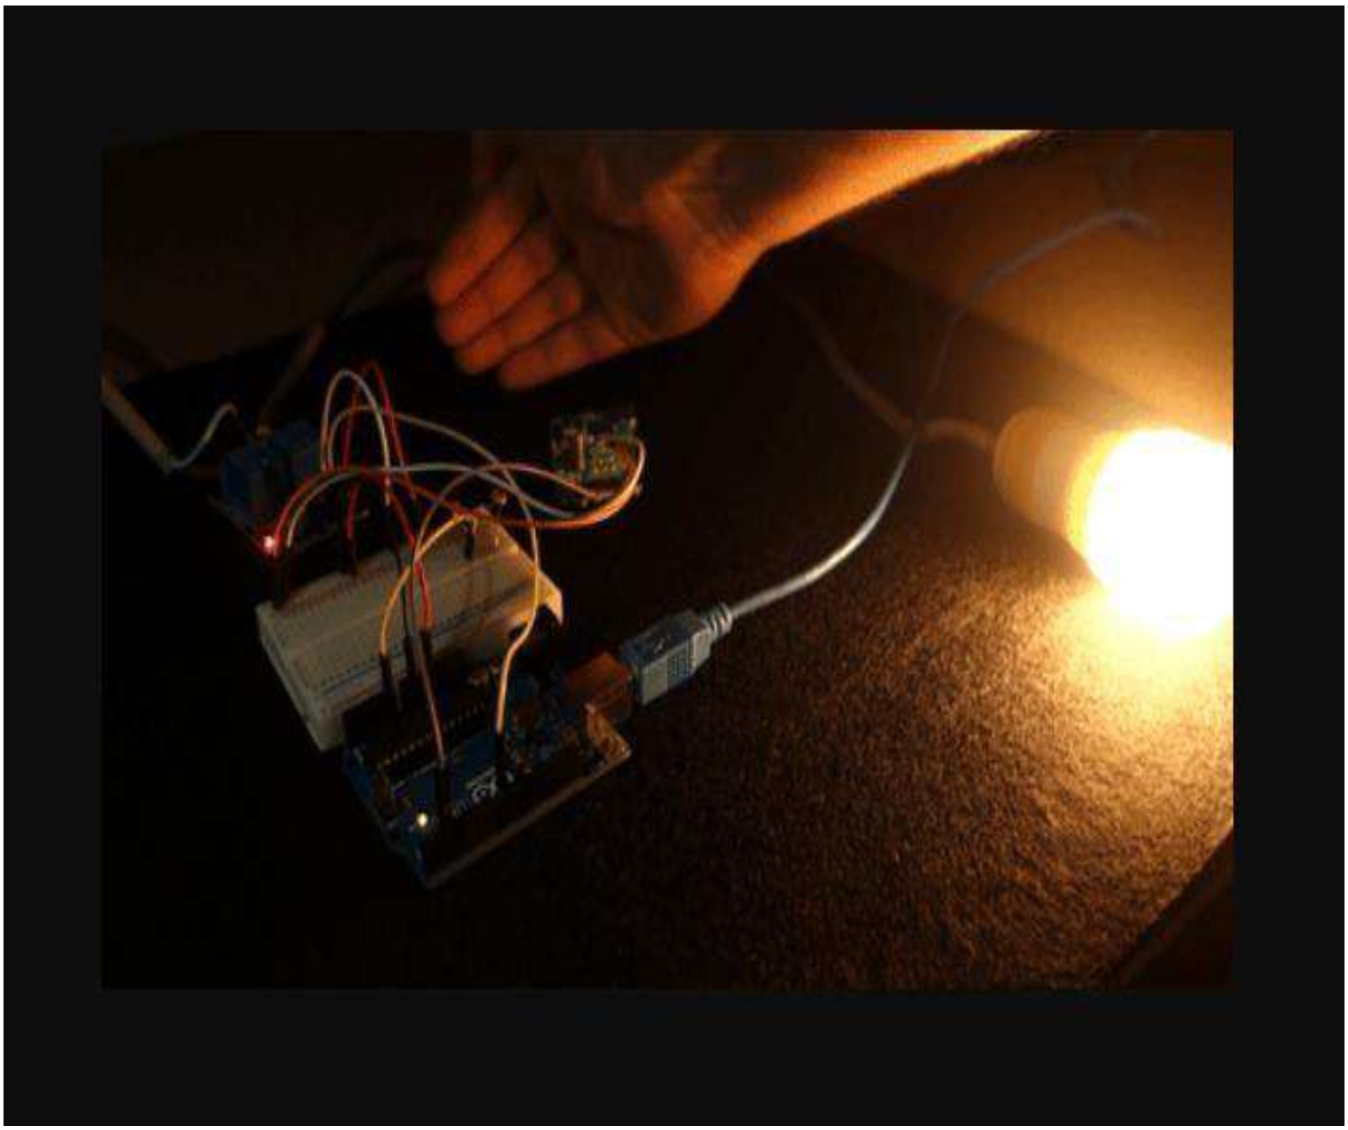

Fig: 4.5 Final Output

.

CHAPTER – 5
PROJECT TESTING

5.1 SOFTWARE TESTING:

Software Testing is a process of executing the application with an intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working. The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

5.2 TESTING LEVELS:

There are various testing levels based on the specificity of test.

• **Unit testing:** Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.

• **Integration Testing**: Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.

• **System Testing:** System testing tests a completely integrated system to verify that the system meets its requirements.

• **Acceptance testing:** Acceptance testing tests the readiness of application, satisfying all requirements.

• **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc.

5.3 SYSTEM TEST CASES:

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

- LED lighting in the street light provides a greater amount of power consumption in comparison to high pressure sodium lamp due to its various advantages. The system was designed for automatically turn OFF during the day time and automatically turn ON during the bad weather and night time.
- Manual operation for the street light specifically lighting street light at a particular time of the day and switching them off at another specific time consumes to be wastage of a lot of electric energy.
- The proposed system offers a street lightning system based on vehicle movement, i.e. the street lights will be switched on when they detect movement of any vehicle coming towards them. For this system, IR light as a sensor is used with Arduino microcontroller.
- IR sensors will be implanted at a certain distance away from the point where the streets lights are implanted and whenever any vehicle passes by the l sensors, the streets lights will be switched ON and the duration of their ON timings will be controlled by Arduino microcontroller.
- When there are no vehicles passing by, the street lights will be in a dim state and the intensity of the street lights can also be controlled and programmed via Arduino microcontroller.

CHAPTER-6

CONCLUSION AND FUTURE SCOPE

6.1 CONCLUSION:

- By using Smart Street light, one can save surplus amount of energy which is done by LED's and adding additional feature for security purposes.
- It prevents unnecessary wastage of electricity, caused due to manual switching of streetlights when it's not required.
- The system is now used only for one way traffic in highways, and can be extended to make the current system in two-way traffic.

6.2 FUTURE SCOPE:

- The number of channels can be increased to interface a greater number of light sensors which is possible by using advanced versions of microcontrollers.
- We can record number of vehicles and vehicle registration number by using internet of things. It detects the speed of vehicles passing by.
- It displays the status of the street and it helps to control. This way it helps decrease the calamities.
- The system can be driven by solar panel for more efficiency and less power consumption.
- Further the project can be enhanced by using appropriate sensors for detecting the failed street light and then sending an SMS to the control department via GSM modem for appropriate action.

Using this smart project, we can also estimate the speed of the vehicle, recognizing the number plate, recognizing the accidents took place on roads etc. This Smart Street light project not only helps in rural areas but also beneficial in urban areas too. As we are moving towards more advancement, we require more power so use of renewable resources is useful and advantageous. With this project, we can even add smart parking of vehicle and it is even useful for driverless cars. This project has a bright future not only to save power but also reduced the calamities and even reduced the crime rate.

PUBLICATION

Submitted Paper in the Conference ICSMEC – 21 with Paper ID (ICSMEC21-0012) and got Acceptance of paper.

APPENDICES

This project report gives the detail study of the “Smart Street Light System”. The construction, working principle, implementation of the project is given throughout this report. Circuit meets expectations appropriately to turn road light ON/OFF depending on the movement of the vehicle. LD sensor senses the day or night time. The IR sensor senses the motion of the vehicle.

The results of our project work support our hypothesis that the Smart Street Light circuit would solve the power consumption problem. The final conclusion drawn from our project is that the circuit is very efficient and it can be used in street of India.

DECLARATION

We, the students of **'Bachelor of Technology in Department of Electronics & Communication Engineering'**, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **'TOWARDS FASTER THAN NYQUIST TRANSMISSION FOR BEYOND 5G WIRELESS COMMUNICATION'** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

B. Sai Santosh(17K81A04J3)
MD Muttaheer Ahmed(17K81A04M9)
S.T. Narsimha Charyulu(17K81A04P0)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his in valuable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his price less and meticulous supervision teach and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Department project coordinator Dr. A. Anand Kumar** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project guide, **Dr. A. Chaitanya Krishna, Professor,** Department of ECE and our class project coordinator **Ms. P. Pushpa, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out the project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr. Malayadri**, **Professor in IT** and **DR. R. Santosh Kumar, Associate professor in CSE** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1. B. Sai Santosh
2. MD Muttaheer Ahmed
3. S.T. Narsimha Charyulu

ABSTRACT

Faster-Than-Nyquist (FTN) is a technique that can improve the spectral efficiency of communication systems by making better use of available spectrum resources at the cost of inter-symbol interference (ISI) and inter-carrier interference (ICI). In this paper, we propose a hybrid signalling scheme for a practical application of FTN for MIMO transmission. We propose a new slot structure optimized for the hybrid signalling supporting both FTN signalling and orthogonal frequency division multiplexing (OFDM) signalling. Specifically, in the proposed slot structure, data transmission is based on the FTN signalling and the pilot transmission is based on the OFDM signalling. Numerical results confirm that the proposed signalling scheme has clear benefit over the systems employing only OFDM or FTN signalling.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

LIST OF ACRONYMS AND DEFINITIONS:

FTN	:	Faster than Nyquist Transmission
MIMO	:	Multi Input Multi Output
OFDM	:	Orthogonal Frequency Division Multiplexing
MSE	:	Mean Square Error
PAPR	:	Peak Average power Ratio
GUI	:	Graphical User Interface

GLOSSARY OF TERMS:

FTN : Faster than Nyquist Signalling scheme transmits signals faster than the Nyquist rate in order to improve efficiency

PAPR : Peak to Peak average ratio reduction scheme for OFDM system

OFDM : Multiplexing is a technique for transmitting large amounts of digital data over radio wave.

Chapter 1

INTRODUCTION

With the advent of 5G wireless communications, we are witnessing unprecedented services such as tactile internet, virtual augmented reality, autonomous driving, factory automations, and high-resolution video streaming, to name just a few [1], [2]. To support wide variety of services and enhanced user experience, we need to push the spectral efficiency of wireless systems to the limit. One viable approach to enhance the spectral efficiency is to transmit the symbol faster than the Nyquist rate. In doing so, symbol rate higher than two times of bandwidth can be achieved at the expense of the orthogonality violation among symbols. Such a transmission scheme, commonly called the faster-than-Nyquist (FTN) signaling [3], has received much attention in recent years as a means to improve the spectral efficiency of wireless systems. It has been shown that 25% faster symbol transmission is achieved by employing deliberately designed pulse shaping filters and binary symbols without virtual loss of performance [3]. It has also been shown in [4] that 42% faster symbol transmission can be achieved by the FTN signaling with square-root raised cosine pulse shaping filter.

Recently, multi-carrier systems employing the FTN signaling have been proposed [5]. Key feature of this scheme over the single carrier counterpart is to improve the bandwidth utilization by reducing the distance between adjacent subcarriers. Although multi-carrier FTN technology has received some research interests, commercial use of this scheme is rare due to the complication caused by the interference-carrier interference (ICI) control. In fact, due to the ICI caused by the overlap of pilot subcarriers, channel estimation quality would be deteriorated, resulting in the severe degradation of the symbol detection and decoding performance. In [6], effect of ICI on the channel estimation has been analyzed when the pilot signals are allocated using the FTN signaling. In [7], an approach to turn off part of subcarriers to ensure the orthogonality of pilot subcarriers has been suggested.

An aim of this paper is to propose an FTN signaling scheme suitable for multiple-input multiple-output (MIMO) transmission. Our work is motivated by the fact that the FTN-based pilot transmission degrades the channel estimation quality severely, in particular for MIMO systems. In order to support more symbols than the conventional OFDM systems can allow while ensuring the accuracy of the channel estimation quality, we propose a hybrid signaling scheme supporting both FTN signaling and OFDM signaling in the transmission time interval (TTI). Key feature of the proposed scheme is to support the data transmission using the FTN signaling and control and pilot signals using the conventional OFDM signaling. Since the pilot signals are transmitted by the OFDM signaling, orthogonality of pilot subcarriers is guaranteed, which ensures that the accurate channel estimation can be achieved even in the MIMO transmission. By controlling the ICI terms of data symbols using the nonlinear receiver techniques (e.g., BCJR [8]), we can achieve the substantial improvement in the spectral efficiency of the data transmission. In our simulations, we show that the proposed hybrid signaling achieves more than 20% gain in the spectral efficiency over the conventional OFDM systems.

1.1 MIMO-OFDM

MIMO-OFDM is the foundation for most advanced wireless local area network (Wireless LAN) and mobile broadband network standards because it achieves the greatest spectral efficiency and, therefore, delivers the highest capacity and data throughput. Greg Raleigh invented MIMO in 1996 when he showed that different data streams could be transmitted at the same time on the same frequency by taking advantage of the fact that signals transmitted through space bounce off objects (such as the ground) and take multiple paths to the receiver. That is, by using multiple antennas and precoding the data, different data streams could be sent over different paths. Raleigh suggested and later proved that the processing required by MIMO at higher speeds would be most manageable using OFDM modulation, because OFDM converts a high-speed data channel into a number of parallel, lower-speed channels.

Operations:

In modern usage, the term “MIMO” indicates more than just the presence of multiple transmit antennas (multiple input) and multiple receive antennas (multiple output). While multiple transmit antennas can be used for beamforming, and multiple receive antennas can be used for diversity, the word "MIMO" refers to the simultaneous transmission of multiple signals (spatial multiplexing) to multiply spectral efficiency (capacity).

Traditionally, radio engineers treated natural multipath propagation as an impairment to be mitigated. MIMO is the first radio technology that treats multipath propagation as a phenomenon to be exploited. MIMO multiplies the capacity of a radio link by transmitting multiple signals over multiple, co-located antennas. This is accomplished without the need for additional power or bandwidth. Space-time codes are employed to ensure that the signals transmitted over the different antennas are orthogonal to each other, making it easier for the receiver to distinguish one from another. Even when there is line of sight access between two stations, dual antenna polarization may be used to ensure that there is more than one robust path.

OFDM enables reliable broadband communications by distributing user data across a number of closely spaced, narrowband subchannels. This arrangement makes it possible to eliminate the biggest obstacle to reliable broadband communications, inter symbol interference (ISI). ISI occurs when the overlap between consecutive symbols is large compared to the symbols’ duration. Normally, high data rates require shorter duration symbols, increasing the risk of ISI. By dividing a high-rate data stream into numerous low-rate data streams, OFDM enables longer duration symbols. A cyclic prefix (CP) may be inserted to create a (time) guard interval that prevents ISI entirely. If the guard interval is longer than the delay spread—the difference in delays experienced by symbols transmitted over the channel—then there will be no overlap between adjacent symbols and consequently no inter symbol interference. Though the CP slightly reduces spectral capacity by consuming a small percentage of the available bandwidth, the elimination of ISI makes it an exceedingly worthwhile tradeoff.

A key advantage of OFDM is that fast Fourier transforms (FFTs) may be used to simplify implementation. Fourier transforms convert signals back and forth between the time domain and frequency domain. Consequently, Fourier transforms can exploit the fact that any complex waveform may be decomposed into a series of simple sinusoids. In signal processing applications, discrete Fourier transforms (DFTs) are used to operate on real-time signal samples. DFTs may be applied to composite OFDM signals, avoiding the need for the banks of oscillators and demodulators associated with individual subcarriers. Fast Fourier transforms are numerical algorithms used by computers to perform DFT calculations.

FFTs also enable OFDM to make efficient use of bandwidth. The subchannels must be spaced apart in frequency just enough to ensure that their time-domain waveforms are orthogonal to each other. In practice, this means that the subchannels are allowed to partially overlap in frequency.

MIMO-OFDM is a particularly powerful combination because MIMO does not attempt to mitigate multipath propagation and OFDM avoids the need for signal equalization. MIMO-OFDM can achieve very high spectral efficiency even when the transmitter does not possess channel state information (CSI). When the transmitter does possess CSI (which can be obtained through the use of training sequences), it is possible to approach the theoretical channel capacity. CSI may be used, for example, to allocate different size signal constellations to the individual subcarriers, making optimal use of the communications channel at any given moment of time.

More recent MIMO-OFDM developments include multi-user MIMO (MU-MIMO), higher order MIMO implementations (greater number of spatial streams), and research concerning “massive MIMO” and “Cooperative MIMO” for inclusion in coming 5G standards.

MU-MIMO is part of the IEEE 802.11ac standard, the first Wi-Fi standard to offer speeds in the gigabit per second range. MU-MIMO enables an access point (AP) to transmit to up to four client devices simultaneously. This eliminates contention delays, but requires frequent channel measurements to properly direct the signals. Each user may employ up to four of the available eight spatial streams. For example, an AP with eight antennas can talk to two client devices with four antennas, providing four spatial streams to each. Alternatively, the same AP can talk to four client devices with two antennas each, providing two spatial streams to each.

Multi-user MIMO beam forming even benefits single spatial stream devices. Prior to MU-MIMO beamforming, an access point communicating with multiple client devices could only transmit to one at a time. With MU-MIMO beamforming, the access point can transmit to up to four single stream devices at the same time on the same channel.

The 802.11ac standard also supports speeds up to 6.93 Gbit/s using eight spatial streams in single-user mode. The maximum data rate assumes use of the optional 160 MHz channel in the 5 GHz band and 256 QAM (quadrature amplitude modulation). Chipsets supporting six spatial streams have been introduced and chipsets supporting eight spatial streams are under development.

Massive MIMO consists of a large number of base station antennas operating in a MU-MIMO environment While LTE networks already support handsets using two spatial streams, and handset antenna designs capable of supporting four spatial streams have been tested, massive MIMO can deliver significant capacity gains even to single spatial stream handsets. Again, MU-MIMO beamforming is used to enable the base station to transmit independent data streams to multiple handsets on the same channel at the same time. However, one question still to be answered by research is: When is it best to add antennas to the base station and when is it best to add small cells?

Another focus of research for 5G wireless is Cooperative MIMO (CO-MIMO). In CO-MIMO, clusters of base stations work together to boost performance. This can be done using macro diversity for improved reception of signals from handsets or multi-cell multiplexing to achieve higher downlink data rates. However, CO-MIMO requires high-speed communication between the cooperating base stations.

1.2 Introduction and Background:

The OFDM strategy is based off a binary coding system called QPSK, which is a 2-bit per symbol format. The purpose of this system is to help detect errors and increase security by encrypting the data. We will use the following digital encoding system as an example of OFDM strategy:

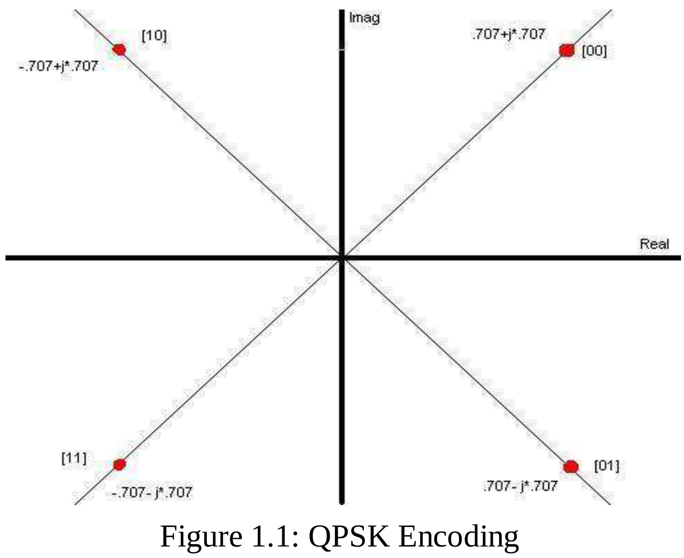

Figure 1.1: QPSK Encoding

The general full design of the OFDM system starts at an analog to digital converter (ADC) that converts analog data to digital if the system is for example a cellular telephone. If the source of data is a digital component, such as a computer, this step is skipped. Next, the digital data sorted, every two bits into its equivalent QPSK format as shown above in Figure 1. The data is sorted so it is encoded depending on which quadrant of the complex plane it lies in. For example, a bit pairing of [10] would correspond to -0.707+ j*0.707, [01] would correspond to 0.707-j*0.707 and so on.

This data is then grouped into 16 distinct, separate channels; the purpose of this will later be shown when noise figures are examined. Next the Inverse Fast Fourier Transform is computed, and the data is shifted out serially to an antenna, cable or other transmitting device.
The full system can be looked at in Figure 2:

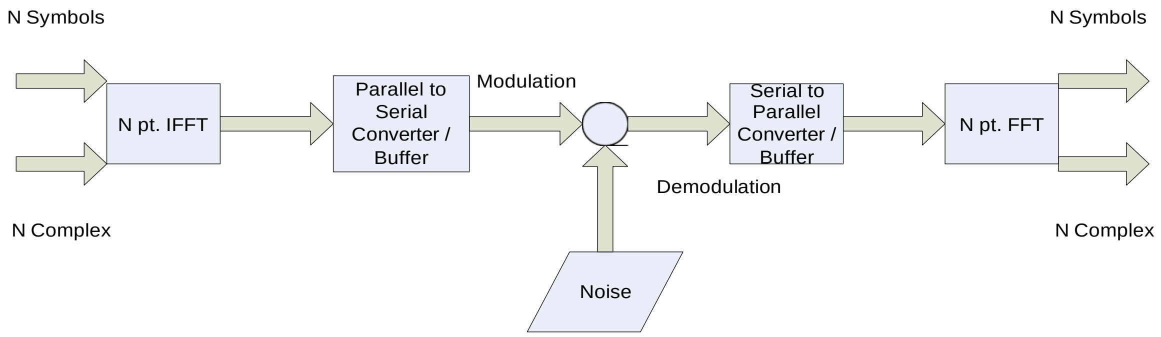

Figure 1.2: Full OFDM System

During the data's transmission, often noise is mixed in with the signal. So, at the receiver, the original data plus noise is entered into a Fast Fourier Transform after a serial to parallel conversion has taken place. The data resulting from the FFT would be complex in nature, and an effort will be made to reconstruct the original binary sequence of numbers for each channel.

Multiple Input Multiple Output (MIMO)-OFDM is widely recognized as a key technology for future wireless communications due to its high spectral efficiency and superior robustness to multipath fading channels. For MIMO-OFDM systems, accurate channel estimation is essential to guarantee the system performance. Generally, there are two categories of channel estimation scheme for MIMO-OFDM systems. The first one is nonparametric scheme, which adopts orthogonal frequency-domain pilots or orthogonal time-domain training sequences to convert the channel estimation in MIMO systems to that in single antenna systems. However, such scheme suffers from high pilot overhead when the number of transmit antennas increases. The second category is parametric channel estimation scheme, which exploits the sparsity of wireless channels to reduce the pilot overhead. The parametric scheme is more favorable for future wireless systems as it can achieve higher spectral efficiency. However, path delays of sparse channels are assumed to be located at the integer times of the sampling period, which is usually unrealistic in practice.

In this letter, a more practical sparse MIMO-OFDM channel estimation scheme based on spatial and temporal correlations of sparse wireless MIMO channels is proposed to deal with arbitrary path delays. The main contributions of this letter are summarized as follows. First, the proposed scheme can achieve super-resolution estimates of arbitrary path delays, which is more suitable for wireless channels in practice. Second, due to the small scale of the transmit and receive antenna arrays compared to the long signal transmission distance in typical MIMO antenna geometry, channel impulse responses (CIRs) of different transmit-receive antenna pairs share common path delays, which can be translated as a common sparse pattern of CIRs due to the spatial correlation of MIMO channels.

Meanwhile, such common sparse pattern is nearly unchanged along several adjacent OFDM symbols due to the temporal correlation of wireless channels. Compared with previous work which just simply extends the sparse channel estimation scheme in single antenna systems to that in MIMO by exploiting the spatial correlation of MIMO channels [5] or only considers the temporal correlation for single antenna systems, the proposed scheme exploits both spatial and temporal correlations to improve the channel estimation accuracy. Third, we reduce the pilot overhead by using the finite rate of innovation (FRI) theory, which can recover the analog sparse signal with very low sampling rate, as a result, the average pilot overhead per antenna only depends on the channel sparsity level instead of the channel length.

1.3 Sparse Channel Model:

Multipath signal propagation, the most salient feature of wireless channels, is a curse and a blessing from the viewpoint of capacity and reliability of such channels. On the one hand, multipath leads to signal fading – fluctuations in received signal strength – that severely impacts the reliability of such channels. On the other hand, knowledge of multipath structure can be exploited for diversity – multiple independent modes of communication – to increase the rate and/or reliability of communication. The impact of fading versus diversity on performance is governed by the amount of channel state information (CSI) known to the system. For example, if perfect CSI is available at the receiver (coherent communication), then the reliability of the fading channel converges to that of the AWGN as the level of diversity increases. Furthermore, the gap in the performance of coherent or non-coherent communication is generally quite significant. Technological advances in wideband multi-antenna RF frontends are enabling learning CSI at a finer resolution afforded by the increase in the spatial temporal signal space dimensions.

Accurate modeling of channel characteristics in time, frequency, and space, as a function of physical multipath characteristics, is thus critical for analyzing the impact of such emerging sophisticated RF front ends. In particular, while most existing models for wireless channels assume a rich multipath environment, there is growing experimental evidence that physical channel exhibit a sparse structure even with small number of antennas and especially at wide bandwidths we use a virtual representation of physical multipath channels that we have developed in the past several years to present a framework for modeling spare multipath channels and to study certain the implications of sparsity on channel learning and optimal communication. The virtual representation samples the multipath geometry in angle delay-Doppler at a resolution commensurate with the signal space dimensions and characterizes the statistically independent degrees of freedom (DOF) available for communication.

Sparse channels correspond to a sparse set of dominant non-vanishing virtual coefficients. A key implication of sparse multipath is that the DOF scale sub-linearly with the signal space dimensions in contrast to the linear scaling inherent in most existing models that implicitly assume a rich multipath. Sparsity of multipath in angle-delay Doppler leads to channel coherence in time, frequency and space that has significant implications for optimal communication in the low-SNR/wideband regime. In particular, we show that sparse multipath channels are perfectly learnable in the limit of large bandwidth and thus naturally bridge the gap between coherent and non-coherent extremes. From a spatial viewpoint, we argue that adapting the array configurations (antenna spacings) can dramatically increase MIMO capacity in sparse multipath in the low-SNR regime.

The following characteristics of MIMO are considered:

1) **ChannelSparsity**: LTE resolves the individual propagation paths from transmitters to receivers which results in a channel impulse response showing only a few peaks and many zeros which can be stated as a sparse signal. In an outdoor environment CIR is normally sparse due to many significant scatterers.

2) **SpatialCorrelation**: As compared to the long signal transmission distance, the scale of the transmit/receive antenna array is impeccably small, therefore channels of various transmit-receive antenna pairs share very similar scatterers. Meanwhile, for many communication systems, the path delay difference from the same scatterer is very much less than the system sampling period. Hence, CIRs of different transmit receive antenna pairs have a common sparse pattern, even though the corresponding path gains may be quite different.

3) **TemporalCorrelation**: Path delays of CIRs for several adjacent OFDM symbols are almost unchanged which can be equivalently stated as a common sparse pattern of CIRs because of the temporal correlation of MIMO channels. In wireless channels, the path gains vary continuously compared to the path delays. Hence, the channel sparse pattern is almost unchanged for several adjacent OFDM symbols as well as the path gains are also correlated.

SUPER RESOLUTION SPARSE MIMO-OFDM CHANNEL ESTIMATION

A pilot pattern is briefly introduced based on which a super resolution sparse MIMO-OFDM channel estimation is applied. Also, the required number of pilots is discussed under the framework of FRI theory. A. Pilot Pattern The pilot pattern used is shown in fig.3, P pilots are spaced equidistant to each other such that there is a pilot interval G between each other. In the meantime, each pilot is assigned with a pilot index I such that 0<I

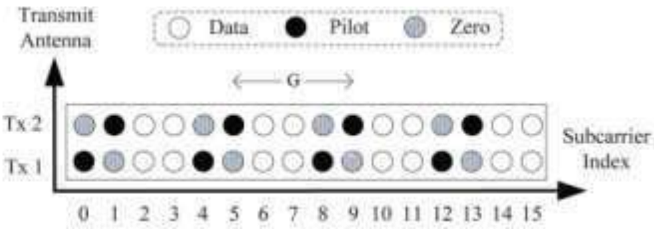

Figure 1.3: Pilot Pattern

B. SpatialandTemporalCorrelation: As the wireless channel is sparse by nature and the small scale of various transmit/receive antennas is negligible with respect to the large signal transmission distance, CIRs of multiple pairs of transmit-receive antennas have the common path delays, which is correspondingly interpreted as a common sparse pattern of CIRs owing to the spatial correlation of the MIMO channels. Hence, by utilizing such spatially common sparse pattern distributed among Mt transmit antennas and Mr. receiver antennas pertaining to the ith transmit antenna, the channel frequency response is given by H=VA+N ....(1) Where V is a Vander monde matrix of size P*P, A is path gain of size P*Mr. and N is additive white Gaussian noise. Comparing (1) with the traditional direction-of-arrival (DOA) problem it’s been observed that these two are mathematically equivalent. Explicitly, the classical DOA problem is to commonly estimate the DOAs of the M sources from a group of time-domain quantities, which are acquired from the P sensors outputs at Mt Mr discrete points in time.

On the contrary, the path delays of M multipaths in (1) are estimated from a group of frequency-domain quantities, which are obtained from P pilots of Mt Mr discrete pairs of antenna. The Total Least Square-Estimating Signal Parameters via Rotational Invariance Techniques (TLS-ESPRIT) algorithm is used to estimate path delays with arbitrary values by applying it to (1). Additionally, the temporal correlation of wireless channels is also exploited to enhance the precision of the channel estimation. Initially, path delays of CIRs for various adjacent OFDM symbols are almost unaltered which is similarly, made reference to as a common sparse pattern of CIRs because of the temporal correlation of MIMO channels. Furthermore, path gains throughout adjacent OFDM symbols are also correlated pertaining to the temporal continuity of the CIR. Also various adjacent OFDM symbols are also correlated. Hence, noise is decreased which in turn improves the accuracy of channel estimation.

C. PilotOverhead: Based on the FRI theory it is stipulated that CIRs of Mt Mr transmit-receive antenna pairs are like the Mt Mr. semi period sparse subspaces, and the P pilots are like the Tp multichannel filters. Hence, with respect to the FRI theory, the least required number of pilots for a transmit antenna is Tp=2Q(i.e., Q is the sparsity level) in a noiseless environment. On the contrary, for the non-parametric channel estimation techniques the necessary number of pilots highly depend upon channel length L, whereas the super resolution sparse parametric scheme only requires 2Q pilots where Q<<l

1.4 Code Division Multiple Access (CDMA)

Overview of CDMA:

Code division multiple access (CDMA) is a modulation and multiple-access scheme based on spread-spectrum communication. In this scheme, multiple users share the same frequency band at the same time, by spreading the spectrum of their transmitted signals, so that each user's signal is pseudo-orthogonal to the signals of the other users.

CDMA Signals:

In a CDMA system, each signal consists of a different pseudorandom binary sequence (called the spreading code) that modulates a carrier, spreading the spectrum of the waveform. A large number of CDMA signals share the same frequency spectrum. If CDMA is viewed in either the frequency or time domain, the multiple access signals overlap with each other. However, the use of statistically orthogonal spreading codes separates the various signals in the code space.

CDMA Receivers:

A CDMA receiver separates the signals by means of a correlator that uses the particular binary sequence to dispreads the signal and collects the energy of the desired signal. Other users signals, whose spreading codes do not match this sequence, are not dispreads in bandwidth and, as a result, contribute only to the noise. These signals represent a self-interference generated by the system. The output of the correlator is sent to a narrow-bandwidth filter. The filter allows all the desired signal's energy to pass through but reduces the interfering signal's energy by the ratio of the bandwidth before the correlator to the bandwidth after the correlator. This reduction greatly improves the signal-to-interference ratio of the desired signal. This ratio is also known as the processing gain. The signal-to-noise ratio is determined by the ratio of the desired signal power to the sum of all of the other signal powers. It is enhanced by the processing gain or the ratio of spread bandwidth to baseband data rate.

CDMA Channel Assignments

A CDMA digital cellular waveform design uses a pseudorandom noise (PN) sequence to spread the spectrum. The sample rate of the spreading sequence (called the chip rate) is chosen so that the bandwidth of the filtered signal is several times the bandwidth of the original signal.

A typical system might use multiple PN sequences. In addition, it might use repeated spreading codes of known lengths to ensure orthogonality between signals intended for different users. The channel assignment is essentially determined by the set of codes that are used for that link. Thus, the signal transmitted at any time in a logical channel is determined by: The frequency of operation for the base station The current symbol The specific orthogonal spreading code assigned for the logical channel The PN spreading code.

CDMA Signal Processing:

In the demodulation of CDMA signals, the different paths may be independently received, which greatly reduces the severity of the multipath fading. However, multipath fading is not eliminated because occasionally there may be multiple paths that cannot be independently processed by the demodulator.

Different users in CDMA employ signals that have very small cross-correlation. Thus, correlators can extract individual signals from a mixture of signals even though they are transmitted simultaneously in the same frequency band. CDMA systems employ wideband signals with good cross-correlation properties, which means the output of a filter matched to one user's signal is small when it receives a different user's signal as input. In direct-sequence spread-spectrum systems, a high-rate antipodal pseudorandom spreading sequence modulates the transmitted signal so that the bandwidth of the resulting signal is roughly equal to the rate of the spreading sequence. The cross-correlation of the signals is then largely determined by the cross-correlation properties of the spreading signals. Although CDMA signals overlap in both time and frequency domains, they can be separated, based on their spreading waveforms.

Spreading rates can be chosen to exceed the coherence bandwidth so that the channel becomes frequency selective. For instance, different spectral components are affected unequally by the channel, and only parts of the signal are affected by fades. Expressing the same observation in time domain terms, multipath components are resolvable at a resolution equal to the chip period and can be combined coherently, for example, by means of a rake receiver. Coherent combination of multipath components requires an estimate of the channel impulse response. Such an estimate can be calculated from a training sequence or by means of a pilot signal.

FUNDAMENTALS OF THE IS-95A CDMA SYSTEM:

This section describes the important features of the IS-95A CDMA system specifications. The CDMA Reference Block set is designed to help you develop models to simulate different components of the IS-95A CDMA system.

Channel Schematics:

The following figure illustrates an IS-95A forward channel. The transmitter section includes channel coding, modulation and spreading, and filtering. The receiver section includes filtering, dispreading and demodulation, and channel decoding

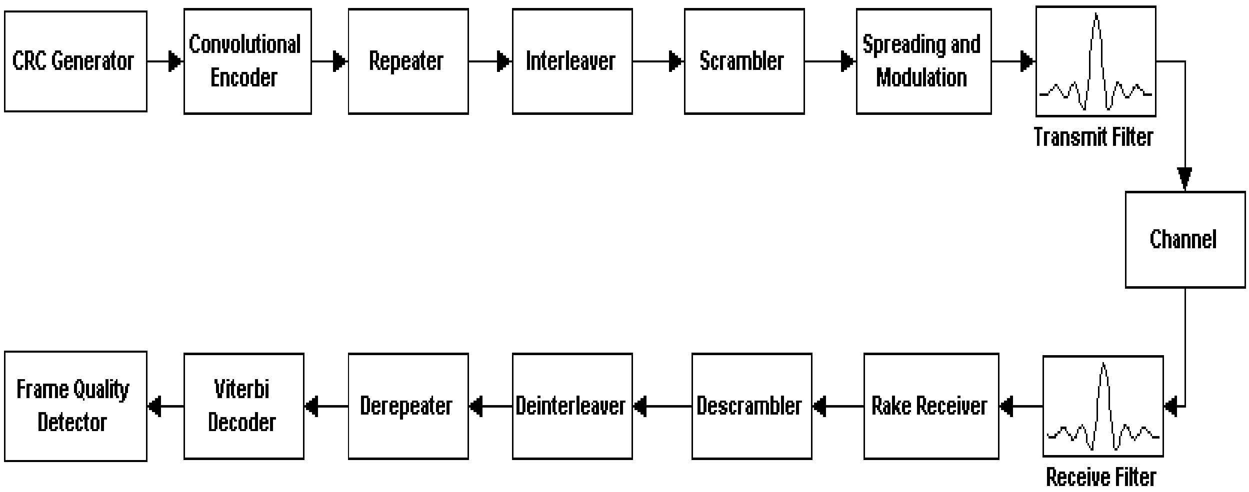

Fig.1.4. IS-95A Forward Channel Diagram

The following figure illustrates an IS-95A reverse channel. It includes many of the same operations that are in the forward channel, but the functionalities of the blocks correspond to the reverse channel specifications.

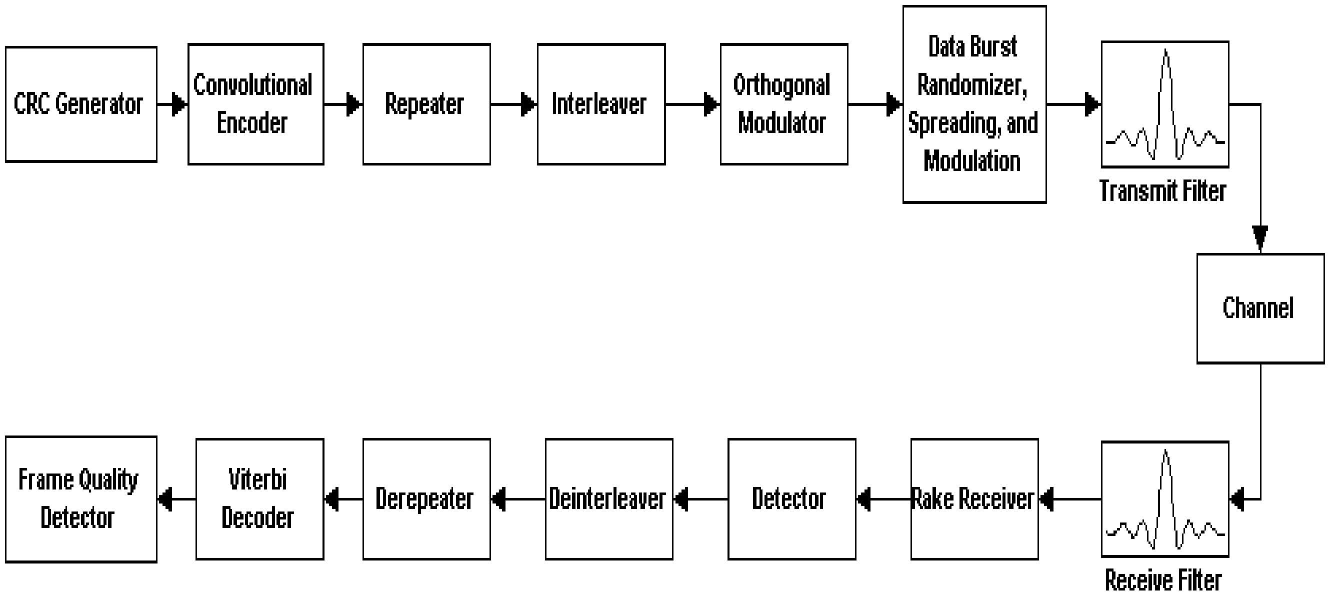

Fig.1.5. Reverse Channel diagram

Channel Assignment in IS-95A

The CDMA system requires spreading of the spectrum using a PN sequence. In IS-95A, the rate of this PN sequence (called the chip rate) is 1.2288 Mchips/s. This causes the resulting bandwidth of the spread signals to be about 1.25MHz, which is about one-tenth of the total bandwidth allocated to one cellular service carrier.

The IS-95A system uses two PN codes: The short PN code is a pair of periodic binary PN sequences with a period of 215. These sequences are used for spreading and dispreading signals into in-phase and quadrature components.

The same short PN code is used by multiple base stations using the same frequency band by using different timing offsets in the code cycle. The long PN code is a sequence with a period of 242-1, and this is used for spreading on the reverse link, as well as for data scrambling and power control burst randomization.

In addition to the PN codes, there is a set of length-64 mutually orthogonal codes called the Walsh code, which is used for ensuring orthogonality between the signals for different users receiving from the same base station. The Walsh code is also used for modulation for the reverse channel of IS-95A. Thus, the logical channel on the forward link is determined by the short PN code offset, the Walsh code assigned, and the assigned frequency of operation. On the reverse link, the logical channel is determined by the short PN code offset, the long code offset, and the assigned frequency of operation.

The IS-95A forward link uses several logical channels: The Pilot channel modulates a constant symbol and is used for channel estimation, which allows for coherent demodulation of the other channels that carry information bits. The Sync channel is used for providing synchronization and configuration information to the mobile stations. The Paging channels are used for control information and sending paging messages to the mobile station. The Traffic channel carries the speech or data.

Similarly, the reverse link has the Traffic and Access logical channels: The Access channel is meant for control information, and is used for originating requests, responding to paging and other messages, or providing other data to the base station. The Traffic channel carries the speech or data. The Traffic channel supports variable data rate operation. According to the J-STD-008 requirement, there are two sets of Traffic channel data rates. Rate Set I has a maximum data rate of 9.6 kbps, whereas Rate Set II has a maximum data rate of 14.4 kbps. Both rate sets support full, half, quarter, and eighth rates with respect to the maximum data rate.

Forward Channel Coding:

The IS-95A system uses the forward channels Sync, Paging, and Traffic to carry information from the base station to the mobile units. The channel coding operations in the forward CDMA operations use 20 ms frames for all channels, except for the Sync channel, which is coded using 26.666 ms frames. For error protection, a 1/2-rate convolutional code is used for all information channels. The receiver can use the Viterbi algorithm for optimal decoding of the encoded data. because the system uses variable data rates, the number of bits generated by the vocoder in one frame changes depending on the voice activity. To ensure that the symbol rate at the modulation stage is kept constant, the symbols are repeated for the lower data rate frames. For protection against bursts of errors, the frame data is interleaved prior to modulation. These error protection measures improve the overall bit error rate (BER) on the link.

Base Station Modulation and Spreading:

The IS-95A forward CDMA channel consists of the Pilot channel for coherent demodulation and the information channels. These channels are spread orthogonally by using a set of codes of length 64 called the Walsh codes. The combined signal is spread in quadrature by a pair of PN sequences with a fixed spreading rate.

The base station transmitter performs the encoding, the repetition, the interleaving, and the scrambling prior to spreading. The generated modulation symbols also need to carry power control commands to correct the mobile station transmit power. For this purpose, some of the symbols are replaced with command bits known as power control bits. The locations of these bits are randomized using a scheme based on a decimated long PN code. The details of these are in the IS-95A standard. The spread signal is filtered at baseband before transmission.

Base Station Transmitter Interface:

The base station transmitter interface combines the various channels in the CDMA forward channel. The forward channel contains the Pilot channel, the Sync channel, the Paging channels, and multiple Traffic channels. Each Traffic channel has a unique Walsh code assigned to it. These Walsh codes are orthogonal to each other, and the different symbol streams are spread by their respective Walsh code (in bipolar form) and added together in a manner such that the weight given to each corresponds to the intended power in that channel. The Traffic channel has a variable data rate. In the case of lower data rate frames, the symbols are repeated, and the Traffic channel power is reduced by the same repetition factor. This reduction ensures that the power transmitted for each information data bit (before coding and repetition) is the same.

Coherent Rake Receiver:

The coherent rake receiver demodulates the desired channel in the input signal by dispreading it with the corresponding Walsh code and the short PN code. The mobile user receives the signal transmitted from the serving CDMA base station through several paths with different propagation delays. The received signal, in addition to being corrupted by noise, is also distorted by the channel fading. For a basic receiver design, the delay-spread results in a loss of performance.

The rake receiver, on the other hand, uses the direct-sequence spreading of the coded signal to separate the components of the received signal corresponding to different propagation-delay paths. You can almost say that the rake receiver derives diversity gain from a potentially poor channel. After rake receiver dispreading, a demodulation routine detects the transmitted data from each delayed-path component and combines the results.

Reverse Channel Coding:

On the reverse CDMA channel in IS-95A, all the transmission uses 20 ms frames. The channels used in the reverse link are: The Traffic Channel and Access Channel. The Traffic channel carries data and speech. The data rate on the Traffic channel is variable; hence each frame may have a different rate. The Access channel carries control messages and requests to the base station.

The mobile station convolutionally encodes the data transmitted on the reverse channel. The station uses a 1/3-rate code when the Traffic channel uses Rate Set I, and a 1/2-rate code when the Traffic channel uses Rate Set II. The Access channel uses the 1/3-rate code. As in the case of the forward channel, the Viterbi algorithm provides optimal decoding at the receiver. Also, prior to modulation, symbols are repeated in the case of lower data rates, and the frame data is interleaved for protection against burst errors.

Mobile Station Walsh Modulation and Spreading:

The reverse CDMA channel is composed of the Access and Traffic channels. These channels share the same assigned CDMA frequency using direct-sequence CDMA techniques. Each of these channels is assigned a distinct user long PN code sequence, which is used for spreading the spectrum of the signal.

All transmission on the reverse CDMA channel in IS-95A uses 20-ms frames. The data frames are convolutionally encoded and interleaved for error protection. The modulation used is a 64-ary orthogonal modulation. Direct sequence spreading and filtering are used to obtain the modulation signal for transmission. Because the reverse traffic channel has a variable rate, randomized gating is used in the case of lower data rate frames to control the transmit power. Because the power control is done by gating, the power level of the transmitted symbols is kept constant, unlike the forward channel. The details of these transmitter tasks are in the IS-95A standard.

Non-coherent Rake Receiver:

There is no pilot available for the reverse link transmission, as there is for the forward link. A pilot is valuable for obtaining good carrier channel estimation, making it possible to perform coherent detection and combining of multipath components. The absence of carrier phase and amplitude estimation necessitates either non-coherent or differential coherent detection. Timing of all paths must also be acquired and tracked. This discussion assumes that timing is available, but phase and amplitude estimates are not.

The Walsh modulator collects log264 = 6 data bits and transmits one of 64 orthogonal Walsh functions. The demodulator tracks L independent paths. Assume that each path has a separate demodulator, but that their outputs are non-coherently combined. The optimum non-coherent demodulator of Walsh modulation is a bank of 64 orthogonal non-coherent correlators. Each of the 64 non-coherent correlators squares each of the two quadrature components and adds the results. For a single path, this demodulator makes its decision by selecting the largest of the 64 output magnitudes. In the case of L paths, the demodulator adds the individual non-coherent correlator outputs for each of the L independent paths before deciding.

In practice, it is possible to decide for each bit separately, rather than making decisions for all six bits at once. This may be done by finding the difference between the highest correlation values that correspond to the two possible values (0 and 1) of the bit of interest. Such an approach may be applied bit by bit and used to arrive at soft decisions (decisions whose difference value serves as a metric for decision reliability). Soft decisions can be used in the Viterbi decoder for the convolution code to improve performance.

1.5 Orthogonal Frequency Division Multiplexing (OFDM)

Orthogonal frequency-division multiplexing (OFDM), essentially identical to coded OFDM (COFDM) and discrete multi-tone modulation (DMT), is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. Many closely spaced orthogonal sub-carriers are used to carry data. The data is divided into several parallel data streams or channels, one for each sub-carrier. Each sub-carrier is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate, maintaining total data rates like conventional single-carrier modulation schemes in the same bandwidth.

OFDM has developed into a popular scheme for wideband digital communication, whether wireless or over copper wires, used in applications such as digital television and audio broadcasting, wireless networking and broadband internet access.

The primary advantage of OFDM over single-carrier schemes is its ability to cope with severe channel conditions (for example, attenuation of high frequencies in a long copper wire, narrowband interference and frequency-selective fading due to multipath) without complex equalization filters.

Channel equalization is simplified because OFDM may be viewed as using many slowly-modulated narrowband signals rather than one rapidly-modulated wideband signal. The low symbol rate makes the use of a guard interval between symbols affordable, making it possible to eliminate inter symbol interference (ISI) and utilize echoes and time-spreading (that shows up as ghosting on analogue TV) to achieve a diversity gain, i.e. a signal-to-noise ratio improvement. This mechanism also facilitates the design of single frequency networks (SFNs), where several adjacent transmitters send the same signal simultaneously at the same frequency, as the signals from multiple distant transmitters may be combined constructively, rather than interfering as would typically occur in a traditional single-carrier system.

Example of applications:

The following list is a summary of existing OFDM based standards and products. For further details, see the Usage section at the end of the article.

Wire

- ADSL and VDSL broadband access via POTS copper wiring.
- DVB-C2, an enhanced version of the DVB-Digital cable TV standard.
- Power line communication (PLC).
- ITU-TG.hn, a standard which provides high-speed local area networking over existing home wiring (power lines, phone lines and coaxial cables).
- Trail Blazer telephone line modems.
- Multimedia over Coax Alliance (MOCA) home networking.

Wireless

- The wireless LAN (WLAN) radio interfaces IEEE 802.11a, g, n and HIPERLAN/2.
- The digital radio systems DAB/EUREKA 147, DAB+, Digital Radio Mondale, HD Radio, T-DMB and ISDB-TSB.
- The terrestrial digital TV systems DVB-T and ISDB-T.
- The terrestrial mobile TV systems DVB-H, T-DMB, ISDB-T and Media FLO forward link.
- The wireless personal area network (PAN) ultra-wideband (UWB) IEEE 802.15.3a implementation suggested by Wi Media Alliance.

The OFDM based multiple access technology OFDMA is also used in several 4G and pre-4G cellular networks and mobile broadband standards:

- The mobility mode of the wireless MAN/broadband wireless access (BWA) standard IEEE 802.16e (or Mobile-Wi MAX).
- The mobile broadband wireless access (MBWA) standard IEEE 802.20.
- The downlink of the 3GPPLong Term Evolution (LTE) fourth generation mobile broadband standard. The radio interface was formerly named High Speed OFDM Packet Access (HSOPA), now named Evolved UMTS Terrestrial Radio Access (E-UTRA).

Key features:

The advantages and disadvantages listed below are further discussed in the Characteristics and principles of operation section below.

Summary of advantages:

- Can easily adapt to severe channel conditions without complex time-domain equalization.
- Robust against narrow-band co-channel interference.
- Robust against inter symbol interference (ISI) and fading caused by multipath propagation.

- High spectral efficiency as compared to conventional modulation schemes, spread spectrum, etc.
- Efficient implementation using Fast Fourier Transform (FFT).
- Low sensitivity to time synchronization errors.
- Tuned sub-channel receiver filters are not required (unlike conventional FDM).
- Facilitates single frequency networks (SFNs); i.e., transmitter macro diversity.

Summary of disadvantages:

- Sensitive to Doppler shift.
- Sensitive to frequency synchronization problems.
- High peak-to-average-power ratio (PAPR), requiring linear transmitter circuitry, which suffers from poor power efficiency.
- Loss of efficiency caused by cyclic prefix/guard interval.

Characteristics and principles of operation

ORTHOGONALITY

In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that crosstalk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

The orthogonality requires that the sub-carrier spacing is $\Delta f = \frac{k}{T_U}$ Hertz, where T_U seconds is the useful symbol duration (the receiver side window size), and k is a positive integer, typically equal to 1. Therefore, with N sub-carriers, the total passband bandwidth will be $B \approx N \cdot \Delta f$ (Hz).

The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e., near half the Nyquist rate for the double-side band physical passband signal).

Almost the whole available frequency band can be utilized. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users. A simple example: A useful symbol duration T_U = 1 ms would require a sub-carrier spacing of $\Delta f = \frac{1}{1\,\mathrm{ms}} = 1\,\mathrm{kHz}$ (or an integer multiple of that) for orthogonality. N = 1,000 sub-carriers would result in a total pass band bandwidth of $N\Delta f$ = 1 MHz For this symbol time, the required bandwidth in theory according to Nyquist is $N/2T_U$ = 0.5 MHz (i.e., half of the achieved bandwidth required by our scheme). If a guard interval is applied (see below), Nyquist bandwidth requirement would be even lower. The FFT would result in N = 1,000 samples per symbol. If no guard interval was applied, this would result in a base band complex valued signal with a sample rate of 1 MHz, which would require a baseband bandwidth of 0.5 MHz according to Nyquist. However, the passband RF signal is produced by multiplying the baseband signal with a carrier waveform (i.e., double-sideband quadrature amplitude-modulation) resulting in a passband bandwidth of 1 MHz A single-side band (SSB) or vestigial sideband (VSB) modulation scheme would achieve almost half that bandwidth for the same symbol rate (i.e., twice as high spectral efficiency for the same symbol alphabet length). It is however more sensitive to multipath interference.

OFDM requires very accurate frequency synchronization between the receiver and the transmitter; with frequency deviation the sub-carriers will no longer be orthogonal, causing inter-carrier interference (ICI) (i.e., cross-talk between the sub-carriers). Frequency offsets are typically caused by mismatched transmitter and receiver oscillators, or by Doppler shift due to movement. While Doppler shift alone may be compensated for by the receiver, the situation is worsened when combined with multipath, as reflections will appear at various frequency offsets, which is much harder to correct. This effect typically worsens as speed increases,[1] and is an important factor limiting the use of OFDM in high-speed vehicles. Several techniques for ICI suppression are suggested, but they may increase the receiver complexity.

Implementation using the FFT algorithm:

The orthogonality allows for efficient modulator and demodulator implementation using the FFT algorithm on the receiver side, and inverse FFT on the sender side. Although the principles and some of the benefits have been known since the 1960s, OFDM is popular for wideband communications today by way of low-cost digital signal processing components that can efficiently calculate the FFT.

Guard intervals for elimination of inter symbol interference:

One key principle of OFDM is that since low symbol rate modulation schemes (i.e., where the symbols are relatively long compared to the channel time characteristics) suffer less from inter symbol interference caused by multipath propagation; it is advantageous to transmit a number of low-rate streams in parallel instead of a single high-rate stream. Since the duration of each symbol is long, it is feasible to insert a guard interval between the OFDM symbols, thus eliminating the inter symbol interference.

The guard interval also eliminates the need for a pulse-shaping filter, and it reduces the sensitivity to time synchronization problems.

A simple example: If one sends a million symbols per second using conventional single-carrier modulation over a wireless channel, then the duration of each symbol would be one microsecond or less. This imposes severe constraints on synchronization and necessitates the removal of multipath interference. If the same million symbols per second are spread among one thousand sub-channels, the duration of each symbol can be longer by a factor of a thousand (i.e., one millisecond) for orthogonality with approximately the same bandwidth. Assume that a guard interval of 1/8 of the symbol length is inserted between each symbol. Intersymbol interference can be avoided if the multipath time-spreading (the time between the reception of the first and the last echo) is shorter than the guard interval (i.e., 125 microseconds). This corresponds to a maximum difference of 37.5 kilometers between the lengths of the paths.

The cyclic prefix, which is transmitted during the guard interval, consists of the end of the OFDM symbol copied into the guard interval, and the guard interval is transmitted followed by the OFDM symbol. The reason that the guard interval consists of a copy of the end of the OFDM symbol is so that the receiver will integrate over an integer number of sinusoid cycles for each of the multipaths when it performs OFDM demodulation with the FFT.

Simplified equalization:

The effects of frequency-selective channel conditions, for example fading caused by multipath propagation, can be considered as constant (flat) over an OFDM sub-channel if the sub-channel is sufficiently narrow-banded (i.e., if the number of sub-channels is sufficiently large). This makes frequency domain equalization possible at the receiver, which is far simpler than the time-domain equalization used in conventional single-carrier modulation. In OFDM, the equalizer only has to multiply each detected sub-carrier (each Fourier coefficient) in each OFDM symbol by a constant complex number, or a rarely changed value.

Our example: The OFDM equalization in the above numerical example would require one complex valued multiplication per subcarrier and symbol (i.e., $N = 1000$complex multiplications per OFDM symbol, i.e., one million multiplications per second, at the receiver).

The FFT algorithm requires $N \log_2 N = 10{,}000$complex-valued multiplications per OFDM symbol (i.e., 10 million multiplications per second), at both the receiver and transmitter side. This should be compared with the corresponding one million symbols/second single-carrier modulation case mentioned in theexample, where the equalization of 125 microseconds time-spreading using a FIR filter would require, in a naive implementation, 125 multiplications per symbol (i.e., 125 million multiplications per second). FFT techniques can be used to reduce the number of multiplications for an FIR filter-based time-domain equalizer to a number comparable with OFDM, at the cost of delay between reception and decoding which also becomes comparable with OFDM.

If differential modulation such as DPSK or DQPSK is applied to each sub-carrier, equalization can be completely omitted, since these non-coherent schemes are insensitive to slowly changing amplitude and phase distortion.

In a sense, improvements in FIR equalization using FFTs or partial FFTs leads mathematically closer to OFDM, but the OFDM technique is easier to understand and implement, and the sub-channels can be independently adapted in other ways than varying equalization coefficients, such as switching between different QAM constellation patterns and error-correction schemes to match individual sub-channel noise and interference characteristics.

Some of the sub-carriers in some of the OFDM symbols may carry pilot signals for measurement of the channel conditions (i.e., the equalizer gain and phase shift for each sub-carrier). Pilot signals and training symbols (preambles) may also be used for time synchronization (to avoid inter symbol interference, ISI) and frequency synchronization (to avoid inter-carrier interference, ICI, caused by Doppler shift).

OFDM was initially used for wired and stationary wireless communications. However, with an increasing number of applications operating in highly mobile environments, the effect of dispersive fading caused by a combination of multi-path propagation and Doppler shift is more significant. Over the last decade, research has been done on how to equalize OFDM transmission over doubly selective channels.

Channel coding and interleaving:

OFDM is invariably used in conjunction with channel coding (forward error correction), and almost always uses frequency and/or time interleaving.

Frequency (subcarrier) interleaving increases resistance to frequency-selective channel conditions such as fading. For example, when a part of the channel bandwidth fades, frequency interleaving ensures that the bit errors that would result from those subcarriers in the faded part of the bandwidth are spread out in the bit-stream rather than being concentrated. Similarly, time interleaving ensures that bits that are originally close together in the bit-stream are transmitted far apart in time, thus mitigating against severe fading as would happen when travelling at high speed.

However, time interleaving is of little benefit in slowly fading channels, such as for stationary reception, and frequency interleaving offers little to no benefit for narrowband channels that suffer from flat fading (where the whole channel bandwidth fades at the same time).

The reason why interleaving is used on OFDM is to attempt to spread the errors out in the bit-stream that is presented to the error correction decoder, because when such decoders are presented with a high concentration of errors the decoder is unable to correct all the bit errors, and a burst of uncorrected errors occurs. A similar design of audio data encoding makes compact disc (CD) playback robust.

A classical type of error correction coding used with OFDM-based systems is convolutional coding, often concatenated with Reed-Solomon coding. Usually, additional interleaving (on top of the time and frequency interleaving mentioned above) in between the two layers of coding is implemented.

The choice for Reed-Solomon coding as the outer error correction code is based on the observation that the Viterbi decoder used for inner convolutional decoding produces short errors bursts when there is a high concentration of errors, and Reed-Solomon codes are inherently well-suited to correcting bursts of errors.

Newer systems, however, usually now adopt near-optimal types of error correction codes that use the turbo decoding principle, where the decoder iterates towards the desired solution. Examples of such error correction coding types include turbo codes and LDPC codes, which perform close to the Shannon limit for the Additive White Gaussian Noise (AWGN) channel. Some systems that have implemented these codes have concatenated them with either Reed-Solomon (for example on the Media FLO system) or BCH codes (on the DVB-S2 system) to improve upon an error floor inherent to these codes at high signal-to-noise ratios.

Adaptive transmission:

The resilience to severe channel conditions can be further enhanced if information about the channel is sent over a return-channel. Based on this feedback information, adaptive modulation, channel coding and power allocation may be applied across all sub-carriers, or individually to each sub-carrier. In the latter case, if a particular range of frequencies suffers from interference or attenuation, the carriers within that range can be disabled or made to run slower by applying more robust modulation or error coding to those sub-carriers.

The term discrete multitone modulation (DMT) denotes OFDM based communication systems that adapt the transmission to the channel conditions individually for each sub-carrier, by means of so-called bit-loading. Examples are ADSL and VDSL.

The upstream and downstream speeds can be varied by allocating either more or fewer carriers for each purpose. Some forms of rate-adaptive DSL use this feature in real time, so that the bitrate is adapted to the co-channel interference and bandwidth is allocated to whichever subscriber needs it most.

OFDM extended with multiple access:

OFDM in its primary form is considered as a digital modulation technique, and not a multi-user channel access method, since it is utilized for transferring one bit stream over one communication channel using one sequence of OFDM symbols. However, OFDM can be combined with multiple accesses using time, frequency, or coding separation of the users.

In Orthogonal Frequency Division Multiple Access (OFDMA), frequency-division multiple access is achieved by assigning different OFDM sub-channels to different users. OFDMA supports differentiated quality of service by assigning different number of sub-carriers to different users in a similar fashion as in CDMA, and thus complex packet scheduling or Media Access Control schemes can be avoided. OFDMA is used in:

- the mobility mode of the IEEE 802.16Wireless MAN standard, commonly referred to as WiMAX,
- the IEEE 802.20 mobile Wireless MAN standard, commonly referred to as MBWA,

- The 3GPP Long Term Evolution (LTE) fourth generation mobile broadband standard downlink. The radio interface was formerly named High Speed OFDM Packet Access (HSOPA), now named Evolved UMTS Terrestrial Radio Access (E-UTRA).
- The now defunct Qualcomm/3GPP2Ultra Mobile Broadband (UMB) project, intended as a successor of CDMA2000, but replaced by LTE.

OFDMA is also a candidate access method for the IEEE 802.22Wireless Regional Area Networks (WRAN). The project aims at designing the first cognitive radio based standard operating in the VHF-low UHF spectrum (TV spectrum).

In Multi-carrier code division multiple access (MC-CDMA), also known as OFDM-CDMA, OFDM is combined with CDMA spread spectrum communication for coding separation of the users. Co-channel interference can be mitigated, meaning that manual fixed channel allocation (FCA) frequency planning is simplified, or complex dynamic channel allocation (DCA) schemes are avoided.

Space diversity:

In OFDM based wide area broadcasting, receivers can benefit from receiving signals from several spatially dispersed transmitters simultaneously, since transmitters will only destructively interfere with each other on a limited number of sub-carriers, whereas in general they will actually reinforce coverage over a wide area. This is very beneficial in many countries, as it permits the operation of national SFNs, where many transmitters send the same signal simultaneously over the same channel frequency. SFNs utilize the available spectrum more effectively than conventional multi-frequency broadcast networks (MFN), where program content is replicated on different carrier frequencies. SFNs also result in a diversity gain in receivers situated midway between the transmitters.
