BONAFIDE CERTIFICATE

This is to certify that the project entitled "Recursive Block Based Key Point Matching Copy Move Image Forgery Detection" is being submitted by **1. Ms. A. Sriya [17K81A0401], 2. Ms. A. Varshika [17K81A0402],**
3. Ms. V. Bindu Priya [17K81A0456] in partial fulfillment of the requirement for the award of the degree of **BACHELOR OFTECHNOLOGY IN ELECTRONICS AND COMMUNICATION ENGINEERING** is recorded of bonafide work carried out by them. The result embodied in this report have been verified and found satisfactory.

DECLARATION

We, the students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2017-2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project work entitled '**Recursive Block Based Key point Matching for Copy Move Image Forgery Detection**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

A. Sriya	A. Varshika	V. Bindu Priya
17K81A0401	17K81A0402	17K81A0456

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his valuable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to, **Dr. B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept.project coordinator and our internal coordinator Dr. A. Anand Kumar, Professor,** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for along time to come.

We sincerely thank our class coordinator **Ms. A. Soumya**, **Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**,**Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

A. Sriya (17K81A0401) A. Varshika (17K81A0402) V. Bindu Priya(17K81A0456)

ABSTRACT

Images are used as legal proof in areas like forensic investigations. The authenticity of an image intended for investigation may adversely affect the result of such investigations, if the image is a manipulated one. In such fields, the detection of image forgery is very critical and sensitive. Among the prevailing methods, Block based methods divide the images into overlapping regular blocks and find the match between every block of the whole image. This method is found to be more accurate though computationally expensive. Whereas Keypoint based methods compute the key points of an image and find the match between those keypoints. If the image is forged by copy paste (splicing), there will be the highest number of keypoint matches between the corresponding regions. This method is found to be computationally efficient but the accuracy is less. The proposed method utilizes the advantages of both keypoint based and block-based forgery detection methods. We identify meaningful irregular blocks and the similarity of such blocks are measured using the number of matched SIFT keypoints. To identify whether the image is forged or not, an adaptive threshold is employed on the number of keypoint matches and judiciously decide whether to go for block based matching strategy or not for each block. We show that the proposed method achieves better detection rate without compromising the merit on the computational complexity of keypoint based forgery detection

CHAPTER 1 : INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

- The authenticity of an image is crucial in many fields today. The most common ways to tamper a digital image is copy-paste forgery which is used to conceal objects or produce a non-existing scene.
- An image can be copied and pasted in two ways : Active approach and Passive approach.
- In Passive approach there are two more types of copying or forging images i.e., Independent and Dependent forgery. Independent forgery is defined as the methods that are used to detect the forgeries independent of forgery type but based on the artifact traces left during the process of re-sampling and due to lighting inconsistencies.
- This project deals with Dependent Forgery, to be more specific Copy paste (splicing) forgery.

1.2 OBJECTIVE OF THE PROJECT

The main objective of the project is to check whether the query image has been copy pasted into the test image i.e., whether a particular picture has been forged into another image.

1.3 SCOPE OF THE PROJECT

The main scope of the project is to identify the key points/features in the images which will help in determining whether the forgery is done or not.

1.4 INTRODUCTION OF PROJECT

In this day and age, digital image tampering has been made easy with widely available image editing softwares, such as Adobe Photoshop. The advancement of image editing softwares has reached a level such that image tampering can be done without degrading its quality or leaving obvious traces. This is alarming as images are now being presented as supporting evidence and historical records in various fields, such as in forensic investigation, law enforcement, journalistic photography and medical images. Moreover, in many instances, tampered images have appeared in the news or social media, such as the manipulated images of Iranian missile test released on July 9, 2008 by Sepah News, the official media arm of Iran's Revolutionary Guard. The tampered image, shown in Fig. 1 is aimed at exaggerating the country's military capabilities. The forgery is detected a day later when the same source released another image taken from the same angle at almost the same time, but with different content. The scientific community is also not spared from image tampering. stated that 20% of accepted manuscripts of the Journal of Cell Biology contains inappropriate figure manipulation. Hence, image tampering and detection have garnered substantial attention as manipulated images can be used to misrepresent their meaning with This paper is organized as follows: Section II presents the recent works on Copy-Move Forgery Detection, focusing on block based and keypoint based CMFD techniques. Section III presents the research methodology of the proposed CMFD technique, focusing on speeded up robust features (SURF) and Oriented FAST and rotated BRIEF (ORB) as the feature extraction methods and 2 Nearest Neighbour (2NN) and Hierarchical Agglomerative Clustering (HAC) as the feature matching method. Section IV presents the result of our proposed CMFD technique with a summary of the contribution and achievements of the work. Lastly, we conclude this work and provide potential future works.

1.5 INTRODUCTION TO CMFD:

CMFD is a non-intrusive detection technique where a portion of the image's content is copied and moved to another region of the same image. In general, tampered regions in copy move forgery can be in the form of an object, texture or wording. Manipulation of textures, such as ocean and grass fields can be used to hide details of an image and are generally harder to identify. Furthermore, copy move forgery can be associated with different geometric transforms, such as translation, rotation, scaling or multiple duplication of manipulated regions in a single image. Copy-move forgery detection can be segregated into two categories, namely block-based and keypoints-based CMFD techniques. Block-based techniques can be categorized into frequency transform, moment invariant, dimension reduction and intensity. In recent years, keypoints-based CMFD has garnered more attention.

1.6 KEYPOINTS-BASED CMFD TECHNIQUES

In keypoints-based CMFD, information of distinctive features (interest point) such as edge, blob and corners of an image are extracted and stored in the form of a feature vector. The feature vector is typically constructed using pixel information within a specific window of the interest point. With keypoints techniques, the preprocessing step of block division can be eliminated. Common keypoints-based CMFD techniques used are Scale Invariant Feature Transform (SIFT) and SURF. SIFT was initially introduced in the field of object recognition. SIFT is designed to be robust against scale and rotation and the algorithm performs well even with noise and changes in illumination. SIFT is used to detect salient points at different scales from the Difference of Gaussian (DoG) in scale space representation. Amerini et al. performed SIFT for CMFD and the implementation is tested on the MICC-F220. Compared to the work of Fridrich et al. and Popescu and Farid, CMFD with SIFT obtained a minimum of 10% increase in True Positive Rate (TPR) and reduction of computational time from 70.97s to 4.94s. Even though SIFT has successfully reduced the computational complexity of CMFD with the introduction of DoG, the number of feature vectors generated is still relatively high. This would impact the matching phase especially for images with high resolution. Hence, He et al. proposed the use of PCA to reduce the dimensionality of SIFT feature vectors. Apart from computational complexity, SIFT techniques also face difficulties in detecting flat copied regions. Mohamadian and Pouyan proposed the use of SIFT and Zernike moments. Zernike moments detection method can be performed on regions where SIFT features are not found. However, the approach would increase the computational time as both methods have to be applied on the image. SURF is the state of the art technique in CMFD . SURF was initially implemented in object recognition and adopted in CMFD due to its scale and rotation-invariant properties. Bo et al. demonstrated the use of SURF technique in the field of CMFD. The author extended Bay’s technique by increasing the length of the feature vector from 64 to 128. However, the experimental results were not shared in the paper. Mishra et al. [9] implemented CMFD with SURF and obtained a TPR of 70%. The concept of Hierarchical Agglomerative Clustering

(HAC) is introduced to perform grouping on the matched keypoints. The SURF and HAC combination was tested on the MICC-F220 database and achieved a TPR of 73%. Hashmi et al. [10] introduced a preprocessing step to CMFD by transforming images into dyadic wavelet domain (DyWT) before applying the SURF technique. The combination of SURF and DyWT is more robust and it is capable of sustaining various attacks. With the implementation, an increase in TPR of 76% is obtained. However, the authors did not discuss the tradeoff between computational time and performance improvement.

Image forgery detection is attracting the attention of scientists in computer vision, digital image processing, biomedical technology, investigation, forensics, etc. With popular and complicated technologies and powerful software tools in digital images, it is difficult to confirm if the image is original or not through naked eyes. This challenges researchers to develop algorithms and propose methods to detect the forgery in image. Upon the survey on IEEE and Elsevier, the number of publications on image forgery detection from 2000 increased rapidly in 2010 and more in the following years . An image can be faked by changing any characteristics including brightness, darkness or image parameters, or hiding information. Watermarking and digital signature are solutions of information security in which a security code is inserted in the image so these methods have information of a code and the original image. A question is asked in the case if there is no code or signature inserted or information of the original image, how to confirm its authenticity. Blind/passive techniques in which the detection is done in the tested image itself without any prior information are developed to solve the problem given.

According to blind/passive techniques are grouped into two kinds: copy-move and splicing. The copy-move is defined by cutting an image region and pasting it to another place in the same image while splicing is understood by cutting an image region and pasting it to a different image. Based on this classification, searching the regions having similar features in copy-move images or completely different regions in spliced images is the principle of forgery detection. Many techniques are proposed and used in this field but actually, they can solve only problems on copy-move or splicing separately. The dataset in the previous publications often consists of copy-move images or spliced images, not both in images. This paper proposes a method which can detect the forgery in images not only for copy-move or splicing but also for both. The literature review and proposed method are presented in part II and III. Simulation results and conclusions are shown in the following parts.

The technique of manipulating the characteristics of an image is image forgery. The most commonly used techniques are copy move, image splicing and steganography. Images are taken as legal proof in areas like forensic investigations. The authenticity of an image is very critical as a forged image can change the result of an investigation. With the advancement of image editing and manipulating software, image forgery has become an easy task. The forgery has become so advanced that it makes the detection of forged regions a difficult task. As a result there have been technological methods to prove the credibility of an image. Among different types of forgery, the copy-move method has developed so much that it has become very difficult to find it out at a glance. The method of copy-move forgery is to copy a part of the image and cunningly paste it to another part of the same image. Since the copied part of the image is pasted to the same image most of the image properties will be the same that makes detection difficult. One can rotate; scale, compress, and can even add noise to the forged region. To find out such forgery three methods are mainly used: Block-based methods, Key point based methods and combination of both block based and key-point based methods.

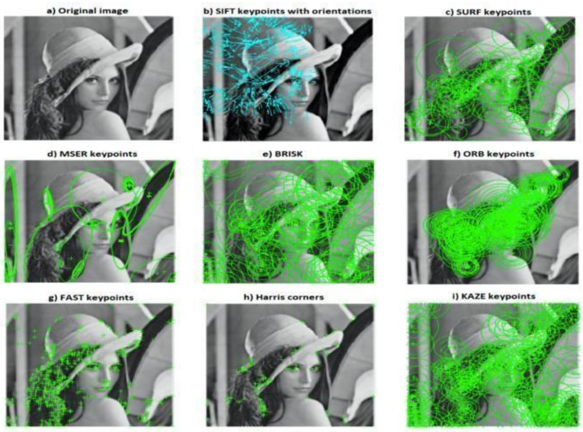

Figure 1.1Key Point Based Technique Example

1.7 BLOCK BASED CMFD TECHNIQUE

Block based method splits the image into overlapping blocks and applies a suitable technique to extract features on the basis of which the blocks are compared to determine similarity. Firstly the image is preprocessed i.e. Converted to grayscale.

Preprocessing is optional. Then the image is subdivided into overlapping blocks of pixels. For an image size of M × N and a block n size of bxb, the number of overlapped blocks is given by (M-b+1) x (N-b+1). On each of these blocks, a feature vector is extracted. After feature extraction matching is done. Feature vector depends on which feature has been used. Highly similar feature vectors are matched as pairs. Methods that are used for matching are lexicographic ordering on the feature vectors and nearest neighbor determination [9]. Any one from both can be used. The similarity of two features can be determined by different similarity criteria, e.g., the Euclidean distance. There are a number of algorithms that according to the features that are selected for the feature extraction.The block-based methods divide the images into overlapping regular blocks and find the match between every block of the whole image Some other methods are also used. Machine learning approaches are also used to detect forgery, like BusterNet. Various methods to detect forgery are compared. Block Based methods are more accurate but the segmentation of the image into overlapping blocks makes the method computationally expensive. Keypoint based methods identify the key points of an image and use it to find the copy-pasted forged region.

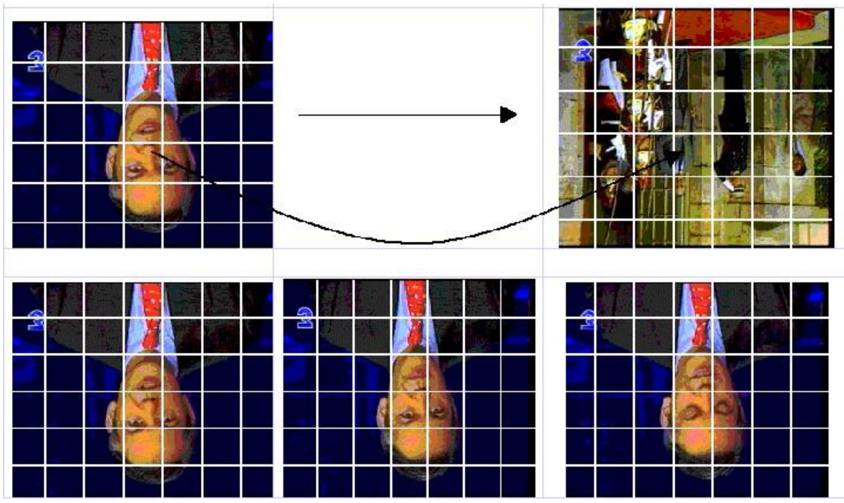

Figure 1.2 Block based technique example

The keypoint based methods differ in choosing the algorithms for detecting keypoints and the keypoint matching threshold for detecting whether the image is forged or not. Clearly the block based methods are computationally expensive as it requires an exhaustive search. A natural choice is to combine both the methods to achieve comparable accuracy of block based methods but without compromising on the computational advantage offered by keypoint matching based methods.

1.8 INTRODUCTION TO IMAGE PROCESSING

1.8.1 IMAGE

An image is a two-dimensional picture, which has a similar appearance to some subject, usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Figure 1.3 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

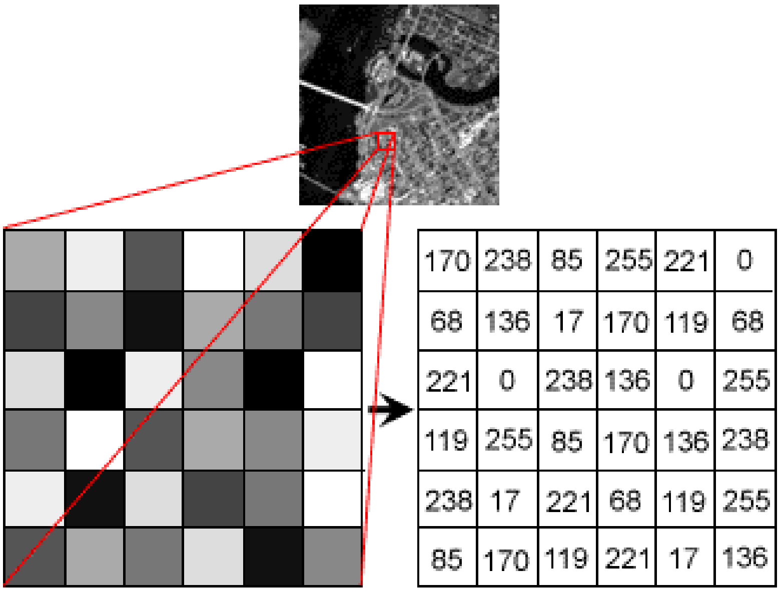

Figure 1.4 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1
Transparency	Red	Green	Blue

Figure 1.5 Transparency image

1.8.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.8.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

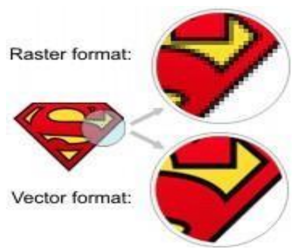

Figure 1.6 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

1.8.4 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

1.8.5 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text.

All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.8.6 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

1.8.7 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

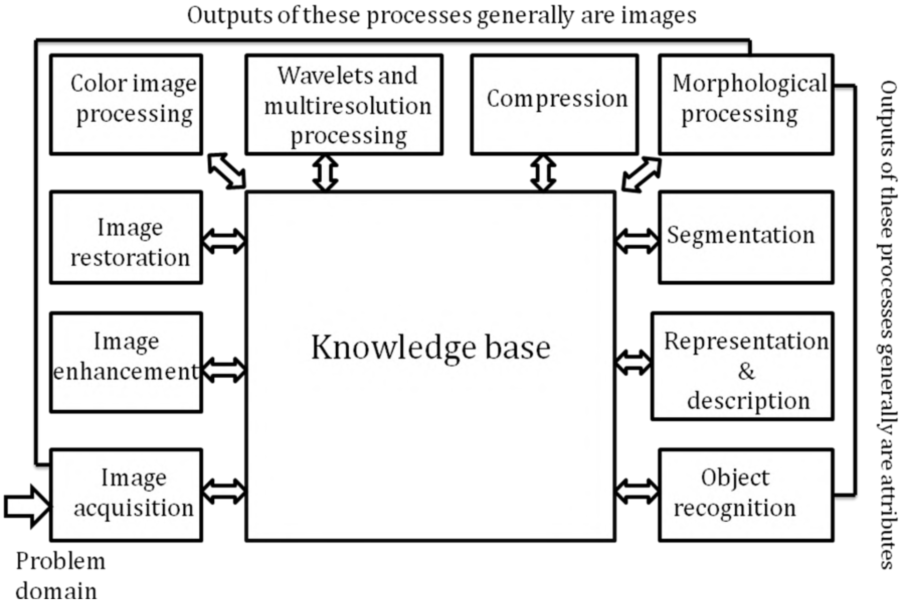

Figure 1.7 Image fundamental

1.8.8 IMAGE ACQUISITION

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Figure 1.8 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Figure 1.9 Digital camera cell

1.8.9 IMAGE ENHANCEMENT

Image enhancementis among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of an interesting image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Figure 1.10 Image enhancement

1.8.10 IMAGE RESTORATION

Image restorationis an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Figure 1.11 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

1.8.11 COLOR IMAGE PROCESSING

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Figure 1.12 Colour & grayscale image

1.8.12 WAVELETS AND MULTI RESOLUTION PROCESSING

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950’s, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

Figure 1.13 RGB histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called Multiresolutiontheory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.8.13 COMPRESSION

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

1.8.14 MORPHOLOGICAL PROCESSING

Morphological processingdeals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Figure 1.14 Blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.8.15 SEGMENTATION

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

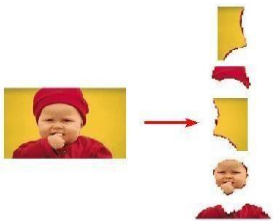

Figure 1.15 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

1.8.16 REPRESENTATION AND DESCRIPTION

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

1.8.17 OBJECT RECOGNITION

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

1.8.18 KNOWLEDGEBASE

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.8.19 COMPONENTS OF AN IMAGE PROCESSING SYSTEM

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

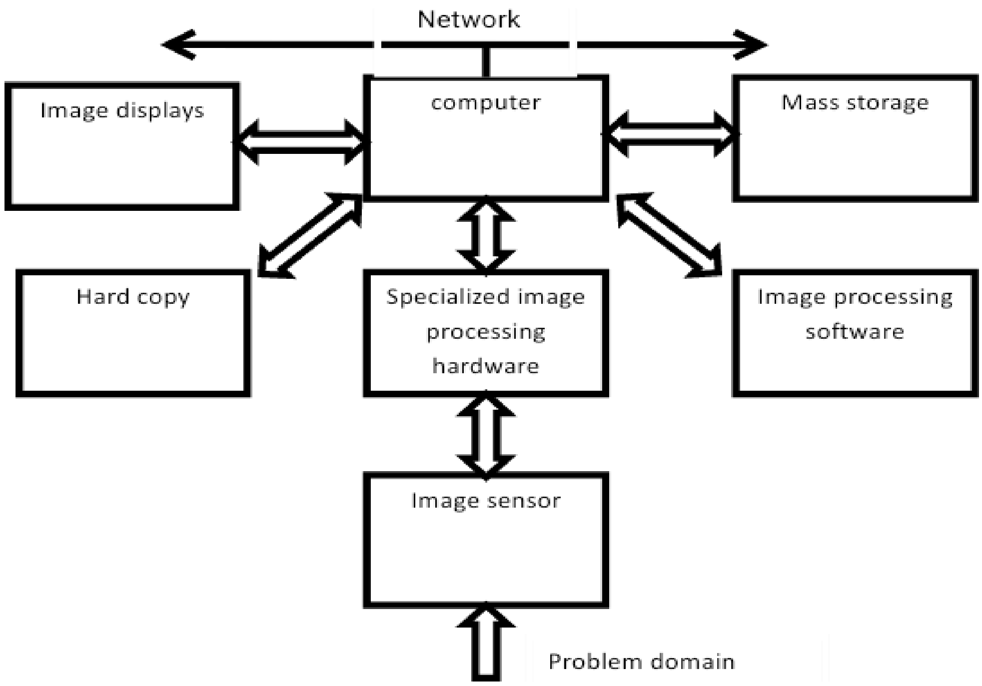

Figure 1.16 Components of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

Equation 1-1 Each component of GCM

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where

$$\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$$

Equation 1-2 Hue values set

then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl_p}, \mathrm{hl}_{N_p}) = (i, j))$$

Equation 1-3 Each component of CCM

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pairwise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001)proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

1.8.20 INTEGRATED COLOR AND INTENSITY CO – OCCURRENCE MATRIX

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

1.8.21 HSV COLOR SPACE

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

1.8.22 PROPERTIES OF HSV COLOR SPACE

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

1.8.23 NON INTERVAL QUANTIZATION

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

In this way three component vector of the HSV from one dimensional vector, which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

1.8.24 IMAGE RETRIEVAL

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002]

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

1.8.25 OVERVIEW OF TEXTURE

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions.

1.9 ORGANIZATION OF CHAPTERS

1.9.1 INTRODUCTION

This section provides information about the project such as overview, objective and scope of the project. Along with that, this chapter also includes information about the techniques that have been used or considered while working on the project.

1.9.2 LITERATURE SURVEY

This section provides the information about the existing methods on the detection of forgery with the help of which this project was modified.

1.9.3 PROJECT DESIGN

This section provides the information about the methodology that is applied in this project i.e., the design is discussed and also the software used to implement it.

1.9.4 PROJECT IMPLEMENTATION

This section provides the information about the algorithm used and discusses each and every step in the algorithm. It also contains the results of the project.

1.9.5 CONCLUSION AND FUTURE ENHANCEMENT

This section concludes the project along with the applications of it. This project can be enhanced further for better results and wide utility and the future enhancement chances are mentioned here.

CHAPTER 2 : LITERATURE REVIEW

As discussed in the introduction block-based methods divide images into overlapping regularly shaped blocks. In consecutive blocks a major portion of a block will get duplicated in the next block. Once the blocks are divided, each block is compared with every other block using block level features. Block based algorithms follow the same framework, with the difference in what feature and metric it uses for block matching. Fridrich et al. used quantized discrete cosine transform as a block feature. Popescu and Farid use a reduced dimension representation for image blocks using principal component analysis(PCA). Luo et al. use RGB color components along with direction information. Li et al. use SV vector as block feature by applying both singular value decomposition (SVD) and discrete wavelet transform(DWT). Mahdian and Saic used 24 blur invariant moments. Kang and Wei use singular values of a reduced rank approximation. Bayram et al. calculate the FourierMellin transformation of the image blocks. Wang et al. with different radii create a circle with the block center as the center and find the average intensity. Lin et al. calculate each block and sub-blocks the average gray result. Ryu et al. calculate Zernike moments of each block. BravoSolario and Nandi [calculate the information entropy of each block. The problem with this type of algorithm is that the complexity is high, that it won't be able to detect forgery, if the forged region is applied with some image transformation, and also because of the regular shape of the blocks this type of algorithm has less recall rate.

Keypoint based methods find the key points of the images. For each keypoint find the similarity with all other key points in the same image. If there is a similarity beyond the predefined similarity threshold, that particular keypoint region is suspected as forged. The two important methods to find the key points of the images are Scale Invariant Feature Transform (SIFT) and Speeded Up Robust Features(SURF) . SIFT is used to find the key points and find the similarity between the SIFT-vector. In and use SURF to find the key points. The matched keypoint region may not be the exact forgery region. There can be situations like more than one forgery happens on a single image and in such cases if there are no matched keypoints in some region then forgery can't be detected for that region. For such an algorithm the detection accuracy will be less compared to the block-based methods. Clearly, the complexity will be less as it avoids exhaustive searching and the recall rate of images with transformed copy move image patches are high.

Combined block-based and keypoint based methods are also used to detect the image forgery. These algorithms judiciously take the advantages of both block-based and feature keypoints based methods. In such an algorithm, the image is segmented into non-overlapping blocks. For each block, compute the key points. Then compute the similarity between the block by matching the key points. Based on the predefined similarity threshold the forged region is identified. The SIFT algorithm is used to find the feature keypoints and adaptive over-segmentation is used to divide the image into blocks.

2.1 CONCLUSION ON REVIEWS

The detection accuracy will get reduced when the copy-move happens in the same image block and also if the number of image keypoints is less. We propose an improved version of existing combined block-based and feature keypoint based methods for better accuracy without much increase in the complexity. The adaptive over-segmentation algorithm proposed by Pun et al. is used to divide the images into non-overlapping irregular blocks. For each block find the SIFT keypoints and calculate the number of matched keypoints. If the number of keypoint matches for two blocks are found to be greater than a precomputed threshold, a copy move is detected and the image is found to be forged. If there are no keypoint matches, the image can be treated as unaltered else we need to decide whether it's actually forged or not by considering additional measures. The strategy that we have adopted for this is to apply block-based methods only to a regular region around the matched keypoints instead of applying to the entire image to reduce the complexity.

CHAPTER 3 : PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

In CMFD, the typical workflow consists of five main stages; image acquisition, image pre-processing, feature extraction, feature matching and visualization.

3.1.1 IMAGE ACQUISITION

In our proposed work, images are taken from the CMFD datasets or own images to evaluate the proposed CMFD method. Both datasets contain tampered images which have suffered different geometrical attacks, namely translation, different degrees of rotation and symmetric or asymmetric scaling or a combination of them. Table I illustrates the various geometrical attacks available in the MICC-F2000 database. The different attacks are represented by θ, SX and SY, where θ represents the degree of rotation, SX and SY represents the scaling factor in the x and y axis respectively.

3.1.2 IMAGE PRE-PROCESSING

Image pre-processing is generally performed to reduce the amount of redundant information in an image and to improve the computational efficiency in the following CMFD stages. In our work, the pre-processing operations consist of image RGB to grayscale conversion, image resizing and tampered region identification.

3.1.3 CMFD USING Oriented FAST AND Rotated BRIEF (ORB) :

Oriented FAST and Rotated BRIEF (ORB) [11] is a binary descriptor that uses oFAST keypoints and rBRIEF features for feature extraction. A typical binary descriptor consists of three main components, namely the sampling pattern, orientation compensation and sampling pairs. The ORB approach does not have a specific sampling pattern. However, it uses oFAST moments and rBRIEF learned pairs for its orientation compensation and sampling pairs respectively. With ORB, Rublee et al. [11] introduced the concept of intensity centroid to obtain orientation information of an interest point. As a descriptor, ORB is capable of producing uncorrelated feature vectors, which implies that each element of the feature vector contains unique information. Furthermore, ORB produces descriptors with high variance; this implies that the features respond differently to different inputs, making it more discriminative. 1) Oriented FAST keypoints: The ORB algorithm uses FAST detector to identify interest points within an image. FAST is a feature from accelerated segment test and it is the method of choice for locating interest points in real time systems. In order to obtain FAST keypoints, the intensity of the central pixel is compared with its neighboring pixels located on a circle of fixed radius.

After identifying a set of interest points, the interest points are sorted using Harris corner measure to select the top N points. Even though FAST has low computation cost, it is not scale or rotation invariant. Hence, in order to achieve scale invariance, a scale pyramid of the image is employed to generate FAST features at each level.

The proposed method converts the input image into grayscale and is then segmented in too many super pixels using SLIC. SLIC will divide the images into meaningful super pixels that will improve the recall rate. For each block SIFT key points are identified and will be used as the primary check for forgery detection. The keypoints are matched using simple Euclidean distance measure. The number of matched keypoints between the blocks is recorded and will be used to find a dynamic threshold for identifying the forged regions. Based on the matched keypoints and threshold the image is divided into 3 categories: Forged Not-Forged, and Forgery Suspected. If the number of matching is greater than zero and less than the threshold then it belongs to the Forgery Suspected category. For this type of image, apply block based method to a particular region around the matched keypoints instead of applying to the whole image to reduce the computational complexity. Finally, apply some morphological operations mentioned by Pun et al. to get the approximate forged region. Each of these step is explained in detail in following subsections. A. Preprocessing In the preprocessing step the image is segmented into meaningful image blocks. Traditionally in block based forgery detection methods images are divided into overlapping blocks of the same size and uniform structure. This approach will get better accuracy if the block size is small, but that will increase the complexity of that algorithm. To reduce the complexity without much drop in accuracy an adaptive over segmentation method has been proposed. For segmenting the images into blocks, simple linear iterative clustering (SLIC) algorithm is used. This algorithm will use the K-means clustering approach to segment the image into meaningful clusters. SLIC will generate k clusters for an image. Then combine the similar superpixel and segment the images into a meaningful region. This will give a more accurate forgery region and helps to reduce the complexity. The texture of the image can be used to decide cluster size. For a smooth textured image the segment size can be large and for an image having detailed texture the segment size should be small. Thus the initial size of a cluster is calculated based on the texture of that image. The initial size for SLIC is calculated using the energy distribution of the image proposed by Pun et al. The percentage of the low-frequency energy distribution of an image is calculated and if that is greater than 50% of the frequency energy then Eq.1 is used otherwise Eq.2 is used, Where H x W represents the height and width of the image. Note that as per the equations Eq.1 and 2 a smooth image gets a bigger block size and a detailed image gets a smaller block size. Sizeinitial = $\sqrt{H * W * 0.02}$ (1) Sizeinitial = $\sqrt{H * W * 0.01}$ (2) B. Keypoint Detection Segmentation will divide the images into meaningful superpixels. Each super pixel represents a block and for each block the keypoints are identified. Christlein et al. perform a comparative study between popular keypoint detection algorithms and proved that SIFT is a very good feature detector which are invariant to geometric transformations like scale, translation and rotation and are invariant to brightness and illumination. So in the proposed method we are using the SIFT algorithm for identifying the key points. Instead of finding key points of the whole image, we will find key points for each block and that will represent the block feature. The normalized 128-dimensional SIFT descriptor describes keypoints in terms of location, scale, and orientation.

3.2 DEFINE THE MODULES

3.2.1 INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modelling, simulation, and prototyping

- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non-interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In the industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available to include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2.2 THE MATLAB SYSTEM

The MATLAB system consists of five main parts

- **Development Environment:**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigenvalues, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using the IMAGE PROCESSING toolbox.

3.2.3 GRAPHICAL USER INTERFACE (GUI)

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG file contains binary data that does not need to be parsed when the associated GUI-based M function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited and callback functions that are executed when a user interacts with GUI objects for example when a button is pushed.

To launch GUIDE from the MATLAB command window, type :

guide filename

Where filename is the name of an existing FIG-file on the current path. If the filename is omitted,

GUIDE opens a new (i.e., blank) window.

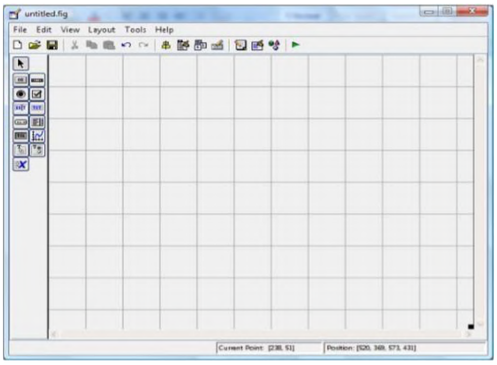

Figure 3.1 MATLAB procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, pushbuttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.3 GETTING STARTED TO MATLAB

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativitycomputing power that will change the way you work.

3.3.1 INTRODUCTION.

- describes the components of the MATLAB system.

3.3.2 DEVELOPMENT ENVIRONMENT

- introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.3.3 MANIPULATING MATRICES

- introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.3.4 GRAPHICS

- introduces MATLAB graphic capabilities, including information about plotting data,annotating graphs, and working with images. 2.4.5 Programming with MATLAB
- describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.4 DEVELOPMENT ENVIRONMENT

3.4.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.4.2 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type Matlab.

At the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup and reduce startup time in some situations.

3.4.3 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu on the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.4.4 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools(graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your LaunchPad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.4.5 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- LaunchPad
- Help Browser Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

LaunchPad

MATLAB's LaunchPad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the Help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favourites tab - View a list of documents you previously designated as favourites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term on the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT file, which has a .mat extension. There are options for saving to different formats. To read in a MAT file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop.

3.5 DIGITAL IMAGE PROCESSING

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

3.5.1 DIGITAL IMAGE PROCESSING DEFINITION

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital images by means of a digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensors, so it is not surprising that images play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

3.5.2 ABOUT IMAGE

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

3.5.3 GRAY SCALE IMAGE

A grayscale image is a function I(xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem)takes non-negative values assume the image is bounded by arectangle[0, a] ·[0, b]I: [0, a] · [0, b] → [0, info)

3.5.4 COLOR IMAGE

It can be represented by three functions, R (xylem)for red,G (xylem)for green *and* B (xylem)for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

3.5.5 COORDINATE CONVENTION

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

3.6 IMAGE AS MATRICES

The preceding discussion leads to the following representation for a digitized image function:

$$
f(xylem) = \begin{matrix} f(0,0) & f(0,1) & \ldots\ldots\ldots.. & f(0,N-1) \\ f(1,0) & f(1,1) & \ldots\ldots\ldots\ldots & f(1,N-1) \\ . & . & & . \\ . & . & & . \\ f(M-1,0) & f(M-1,1) & \ldots\ldots\ldots\ldots\ldots\ldots & f(M-1,N-1) \end{matrix}
$$

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

$$
f = \begin{matrix} f(1,1) & f(1,2) & \ldots\ldots\ldots\ldots & f(1,N) \\ f(2,1) & f(2,2) & \ldots\ldots\ldots\ldots & f(2,N) \\ . & . & & . \\ . & . & & . \\ f(M,1) & f(M,2) & \ldots\ldots\ldots. & f(M,N) \end{matrix}
$$

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

3.7 READING IMAGES

Images are read into the MATLAB environment using function imread whose syntax is “ Imread (‘filename’) “

FORMAT NAME	DESCRIPTION	RECOGNIZED EXTENSION
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photographic Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Table 3-1 Image formats

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chest x ray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. Theprompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

3.8 DATA CLASSES

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

NAME	DESCRIPTION
Double	Double _ precision, floating_ point numbers the approximate.
uint8	unsigned 8_bit integers in the range [0,255] (1byte per element).
unit16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).
unit32	unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element).
int8	signed 8_bit integers in the range [-128,127] 1 byte per element).
int16	signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
int32	Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).
single	single _precision floating _point numbers with values in the approximate range (4 bytes per element).
char	characters (2 bytes per element).
logical	values are 0 to 1 (1byte per element).

Table 3-2Dataclasses

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logic or by using relational operators.

3.9 IMAGE TYPES

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

3.9.1 INTENSITY IMAGES

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

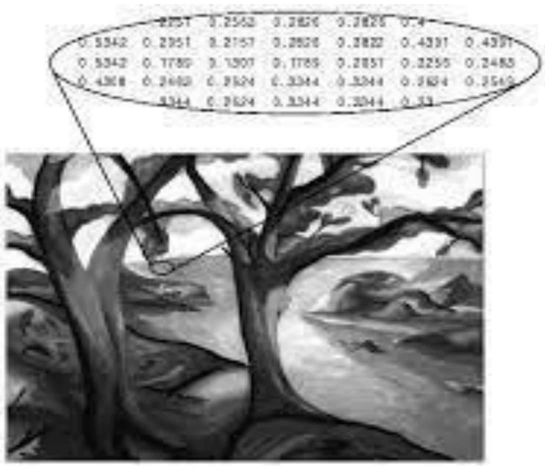

Figure 3.2 Intensity image example

3.9.2 BINARY IMAGES

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

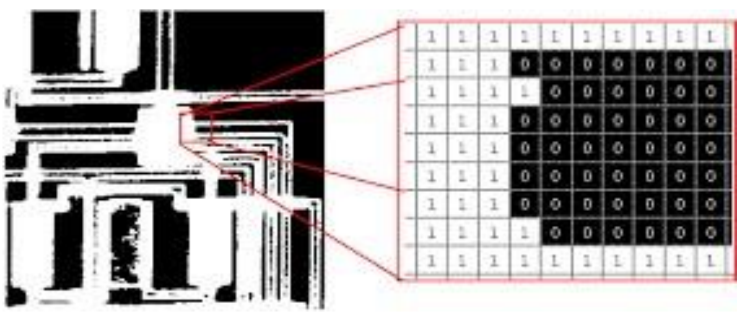

Figure 3.3 Binary image example

3.9.3 INDEXED IMAGES

An indexed image has two components: 1. A data matrix integer, x 2. A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

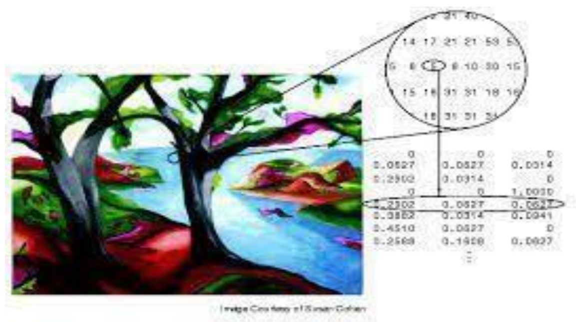

Figure 3.4 Indexed image example

3.9.4 RGB IMAGE

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as "stack" of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors.

Figure 3.5 RGB image example

3.10 IMAGE FORGERY

3.10.1 DEFINITION OF IMAGE FORGERY

Image forgery means manipulation of the digital image to conceal some meaningful or useful information of the image. There are cases when it is difficult to identify the edited region from the original image. The detection of a forged image is driven by the need of authenticity and to maintain integrity of the image.

3.10.2 CLASSIFICATION OF IMAGE FORGERY TECHNIQUES

There are two kinds of techniques for image forensics: one is active protection, and the other is passive detection. Which again consist of many different methods, as shown in below figure:

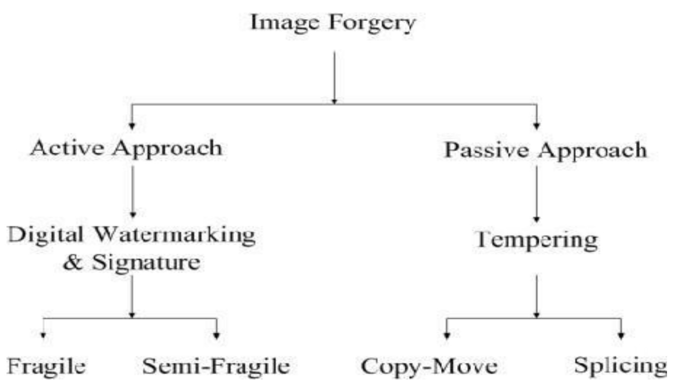

Figure 3.6 Classification of image forgery techniques

A. Active Approach

In this active approach, the digital image requires some kind of pre-processing such as watermark embedded or signatures are generated at the time of creating the image. However, in practice this would limit their application. Digital watermarking and signature are two main active protection techniques, as something is embedded into images when they are obtained. We can detect if the Image is tampered, if special information cannot be extracted from that obtained image. Watermarking is such a method of active tampering detection, as a security structure is embedded into the image, but most present imaging devices do not contain any watermarking or signature module and that are similar to the application of active protection. This structure is used for integrity evaluation in the sense that if any discrepancy is found with the structure then the image is tampered and an inverse analysis over the structure is done to locate tampered Regions of the image. In recent times, various schemes are proposed for providing security to the image, which is analogous to the concept of watermarking like, message authentication code, image hash, image checksum and image shielding as a counterpart to it.

B. Passive Approach

Passive image forensics is usually a great challenge in image processing techniques. There is not a particular method that can treat all these cases, but many methods each can detect a special forgery in its own way. The stream of passive tampering detection deals with analyzing the raw image based on various statistics and semantics of image content to localize tampering of image. Neither construct is embedded in the image and nor associated with it for security, as like active approaches and hence this method is also known as raw image analysis. The localization of tampering is solely based on image feature statistics. Hence, algorithms and methods of detection and localization of image based on passive tampering vary depending upon the type of security construct used. Nevertheless, passive tampering detection typically aims for localization of tampering on raw images.

3.10.3 TYPES OF IMAGE FORGERY

A. Image Retouching:

Image Retouching is considered as less harmful kind of digital image forgery than other types present. In case of image retouching original image does not significantly changes, but there is enhancement or reduces certain feature of original image. This technique is popular among magazine photo editors. This type of Image forgery is present in almost all magazine covers that would employ this technique to enhance certain features of an image so that it is more attractive. Actually, the fact is that such enhancement is ethically wrong.

Figure 3.7 Image forgery example

B. Image splicing or photomontage:

This technique for making forgery images is more aggressive than image retouching. Image splicing is fundamentally simple process and can be done as crops and pastes regions from the same or separate sources. This method refers to a paste-up produced by sticking together images using digital tools available such as Photoshop. In Image Splicing technique there is composition of two or more images, which are combined to create a fake image. Examples include several infamous news reporting cases involving the use of faked images. Fig below shows how to create forge Image; by copying a spliced portion from the source image into a target image, it is a composite picture of scenery which is forge image.

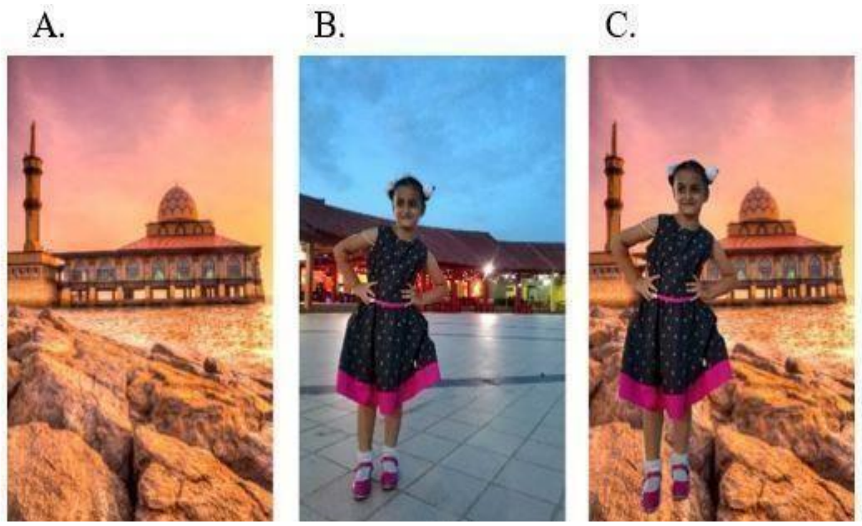

Figure 3.8 Image splicing example

C. Copy-Move Attack:

The copy move forgery is popular as one of the most commonly used kind of image tampering techniques. In this technique, one needs to cover a part of the image in order to add or remove information. In the Copy-Move image manipulation technique a part of the same image is copied and pasted into another part of that image itself. In a copy-move attack, the intention is to hide something in the original image with some other part of the same image . The example of the Copy-Move type is as shown in figure 3 below. The original image contains only three missiles and its Copy-Moved version on the right has four missiles.

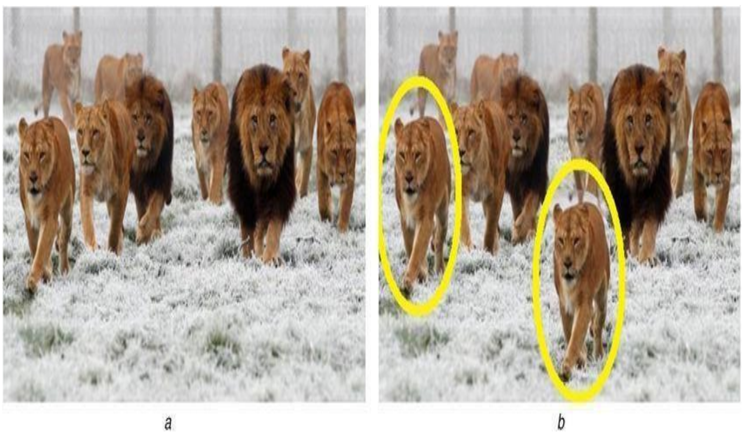

Figure 3.9 Copy move image example

CHAPTER 4 : PROJECT IMPLEMENTATION

4.1 IMPLEMENTATION STAGES

4.1.1 BLOCK DIAGRAM:

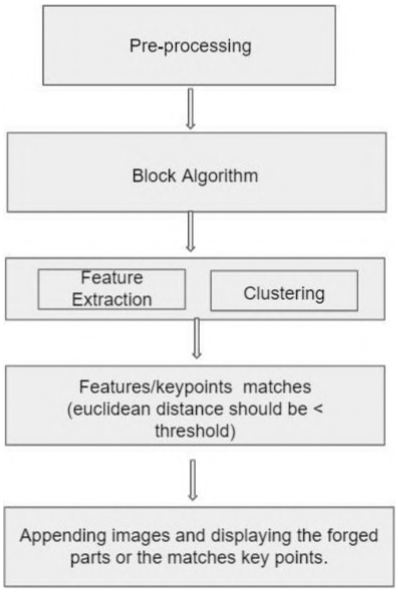

Figure 4.1 Block diagram of project

The above figure represents the block diagram of the project. Each and every block performs specific tasks or functions in order to obtain the required output.

The functions of each and every block is as discussed below:

PRE-PROCESSING-

This block is responsible for the pre-processes i.e., converting an RGB image into a Grayscale image for easier and effective results and also to make sure that all the images are of the same dimensions.

BLOCK ALGORITHM-

Application of block algorithm is nothing but dividing the image into required number of blocks (or frames) for effective search.

FEATURE EXTRACTION-

Features are extracted from the images using keypoint technique i.e., key points (or patches) are extracted in every block that was formed due to block based algorithm.

CLUSTERING-

After all the features/key points are extracted they are clustered into an array for better comparison process between the key points.

KEY POINT MATCHING-

Here all the key points are compared and depending upon the euclidean distances between the key points, matched key points are found and marked.

APPENDING IMAGES AND DISPLAY-

The input images are appended and the matched key points are connected for better understanding of the forged area.

4.1.2 PROGRAM ALGORITHM:

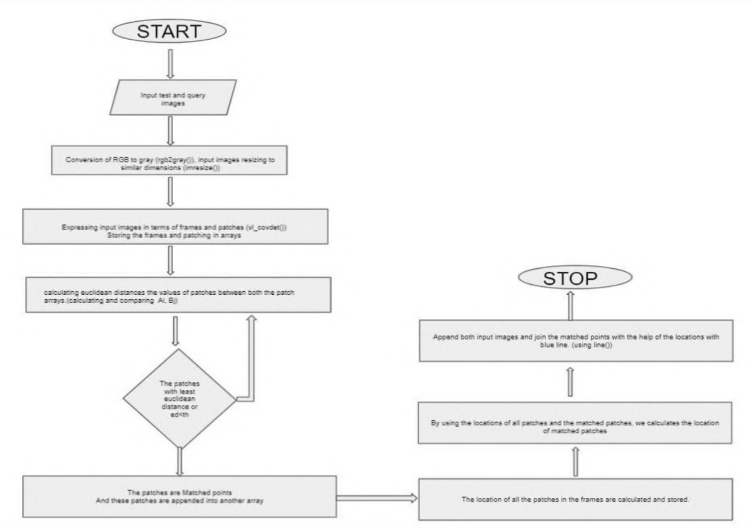

Figure 4.2 Program algorithm

The above figure is the algorithm of the project. The steps include:

STEP 1:

- Take two images as input, one is a query image and the other is a test image (where the test image is an image on which the query image has been copy pasted i.e., spliced image).

STEP 2:

- The default type of images that is available are RGB, so the images have to be converted from RGB to Grayscale for better processing using the rgb2gray() function.

- The images may be of different dimensions when initially considered so it is important to resize the images. It is done by using the imresize() function.

STEP 3:

- The images are now divided into frames and patches where frames are nothing but blocks that are considered in the images and patches are the key points which contain crucial information about the image.

- These frames and patches are then stored in the form of arrays for easier access.

- This entire process is carried out by the vl_covdet() function which is usually used to extract features in an image.

STEP 4:

- After extracting the features/key points, the matched key points have to be accessed or extracted.

- For identifying the matched points it's important to find the euclidean distances between the patches of both the images.

- The patches or key points which have the least euclidean distance between them or euclidean distance less than the given threshold between them will be considered as the matched key points.

- The distances will be calculated between each pair of patches repeatedly until all the patches or key points in the array are considered.

- All the matched points are then stored separately in an array.

STEP 5:

- The locations of all the points in the images are calculated and stored in variables again in the form of an array.

- The matched points locations are found by using that array where location of each pixel or feature is stored.

STEP 6:

- The pre-processed query image and test image are appended for better understanding of the result.

- The matched points are marked on both images as the locations of the points have been calculated in the previous step.

- The matched points are now connected using a line function with a blue straight line displaying the forged area in the image.

4.2 RESULTS

Figure 4.3 Query image

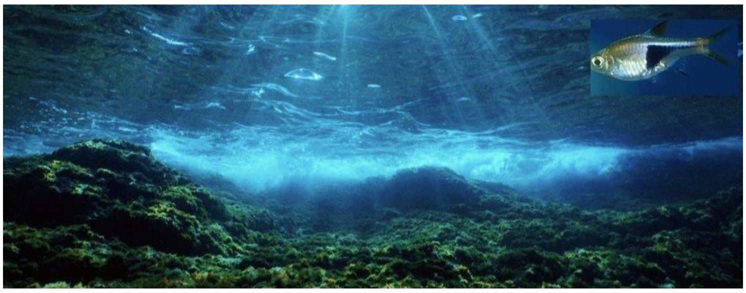

Figure 4.4 Test image or copy pasted image

In this project we considered two images: Fig 7.1 - Query image, Fig 7.2 - Test image.

The query image has been copy pasted into the test image which is considered as the forged image. Now we have to show the region of forgery.

Fig 7.3 shows the output of the project:

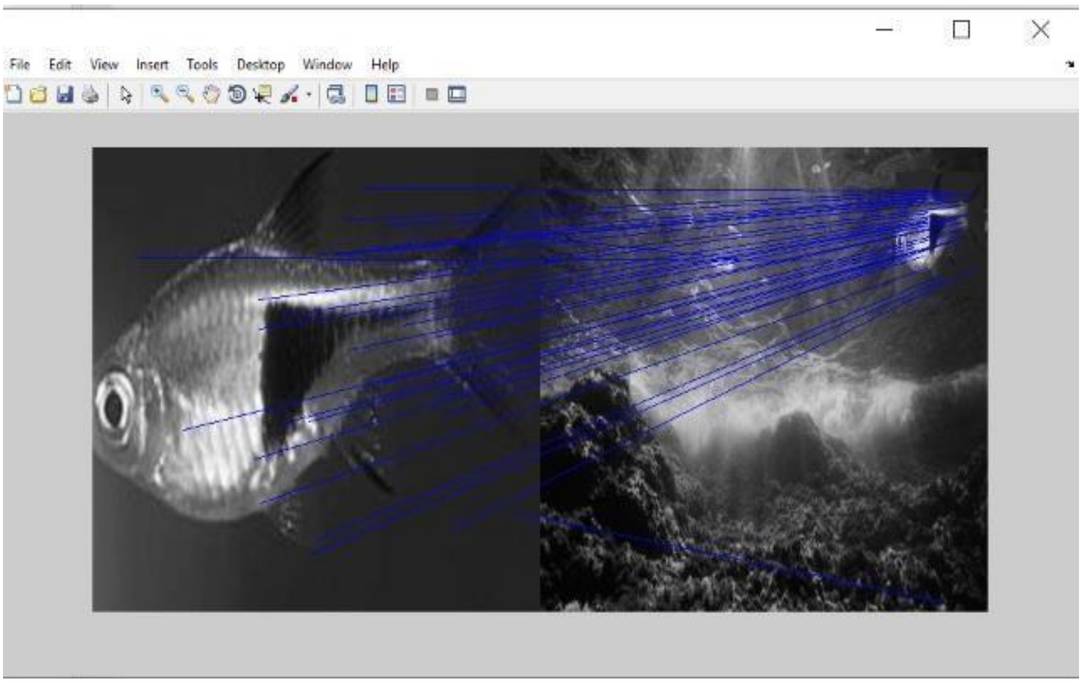

Figure 4.5 Project output

The figure shows blue lines connecting points in one image to another. These points are the matched key points where the Euclidean distance is least or less than the threshold. The output displays the forged area thus indicating that the query image has been copy pasted into the test image which shows a forged image result.

CHAPTER 5 : CONCLUSION AND FUTURE SCOPE

5.1 CONCLUSION

We have proposed a copy paste detection technique that achieves high detection accuracy of block based methods without compromising the advantage and recall rate offered by Key point detection based methods. This was achieved by primarily applying block based detection strategy in forgery detection and by judiciously applying the key point based detection at each and every block. By using the advantages of both the techniques we were able to detect the forgery up to 96.67% accuracy. We believe that our research has moved a step forward for a false proof copy move forgery detection technique that aims ultimately to assist law enforcement agencies to accept images as a piece of evidence.

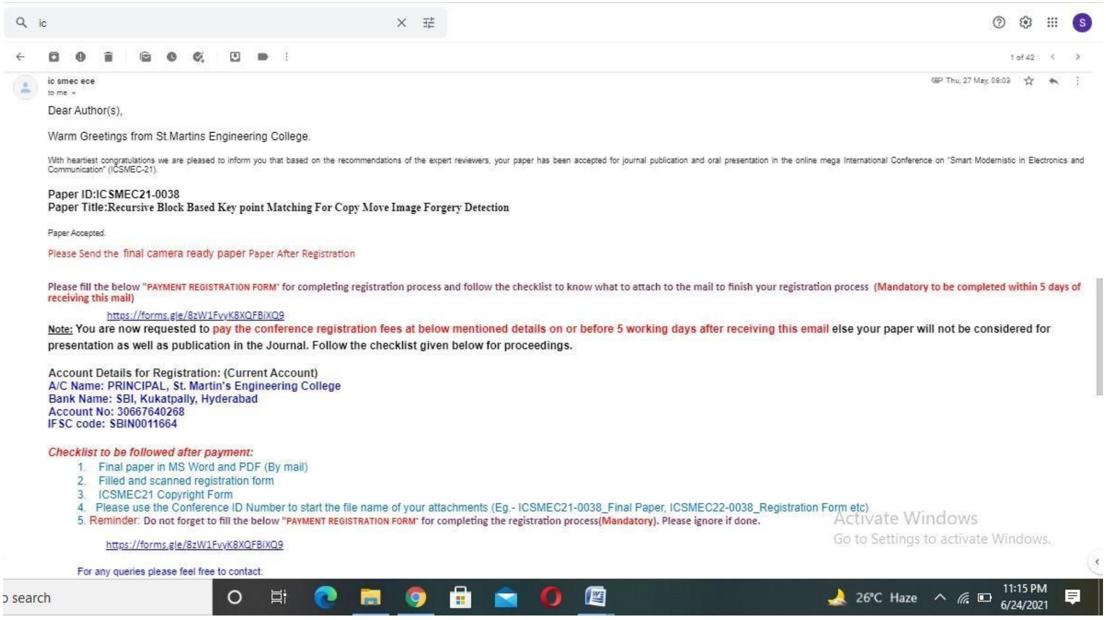
5.1.1 APPLICATIONS:

This technology can be used to verify the authenticity of an image.It can be used in situations where images are legal evidence and alsocan be used in forensic investigations.

5.2 FUTURE SCOPE:

- Future research in the field may concentrate on finding or identifying the forgery without the help of any query image and also to be able to find copy move forgery.
- It also may concentrate on recognizing profoundly compounded pictures. This method can further be developed for recognizing phony videos for investigation purposes.

PUBLICATION



ic smec ece
to me
Thu, 27 May, 08:03

Dear Author(s),

Warm Greetings from St.Martins Engineering College.

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in the online mega International Conference on "Smart Modernistic in Electronics and Communication" (ICSMEC-21).

Paper ID:ICSMEC21-0038
Paper Title:Recursive Block Based Key point Matching For Copy Move Image Forgery Detection

Paper Accepted.

Please Send the final camera ready paper Paper After Registration

Please fill the below "PAYMENT REGISTRATION FORM" for completing registration process and follow the checklist to know what to attach to the mail to finish your registration process (Mandatory to be completed within 5 days of receiving this mail)

https://forms.gle/8zW1FvyK8XQFBiXQ9

Note: You are now requested to pay the conference registration fees at below mentioned details on or before 5 working days after receiving this email else your paper will not be considered for presentation as well as publication in the Journal. Follow the checklist given below for proceedings.

Account Details for Registration: (Current Account)
A/C Name: PRINCIPAL, St. Martin's Engineering College
Bank Name: SBI, Kukatpally, Hyderabad
Account No: 30667640268
IFSC code: SBIN0011664

Checklist to be followed after payment:

1. Final paper in MS Word and PDF (By mail)
2. Filled and scanned registration form
3. ICSMEC21 Copyright Form
4. Please use the Conference ID Number to start the file name of your attachments (Eg.- ICSMEC21-0038_Final Paper, ICSMEC22-0038_Registration Form etc)
5. Reminder: Do not forget to fill the below "PAYMENT REGISTRATION FORM" for completing the registration process(Mandatory). Please ignore if done.

https://forms.gle/8zW1FvyK8XQFBiXQ9

For any queries please feel free to contact:

The project has been approved by international conference that is being conducted by out college i.e., ICSMEC-21 for publication.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communications for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We sincerely thank our project internal guide, Mr. S. Ravi Kumar, Associate Professor, Department of ECE and our class project coordinator Ms. A. Sowmya, Assistant Professor, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this project work and for their support and co- operation that is difficult to express in words.

1. B.S.S. Prabhath
2. Ch. Rohith Kiran
3. C.S. Sai Teja

// ABSTRACT

By the use of a large number of M antennas in the base station side, makes it possible to beamform different signals to different users, so the signals add up constructively at the desired user and destructively everywhere else, that is why massive MIMO-ODFM combing with beamforming is a promising technology for next-generation wireless communication network (5G).

Indeed, the performance of Massive MIMO systems is systematically dependent on users' selection method especially when the number of users is huge in the cell. In this project, we focus on the performance of such a system in terms of max rate using the zero-forcing precoding method. We use MATLAB software for the simulation process and the performance of the user selection techniques are observed. In the existing method the data rate is low and bit error rate of the system is high which is not ideal for 5G wireless communication network. In our project we overcome these limitations using MIMO-OFDM-IM system which is very ideal for 5G wireless communication network.

CHAPTER 1

INTRODUCTION

1.1 INTRODUCTION

Orthogonal frequency division multiplexing (OFDM) has become the most popular multicarrier signalling form for high-speed wireless communications and has been included in many standards such as Long Term Evolution (LTE), IEEE 802.11 wireless local area network (WLAN) and digital video broadcasting (DVB). Due to its efficient implementation and robustness to the frequency selectivity, OFDM and its combination with multiple-input multiple-output (MIMO) system sun surprisingly appear as a strong alternative for 5G networks. OFDM with index modulation (OFDM-IM) is a recently proposed novel scheme that transmits information not only by M-ary constellation symbols but also by the indices of the active subcarriers which are activated according to the incoming information bits. Subcarrier index modulation techniques for OFDM have attracted considerable attention from researchers and have been investigated in some recent studies due to the interesting trade-offs they offer in error performance and spectral efficiency compared to classical OFDM systems. The bit error probability of OFDM-IM is analytically derived. The spectral efficiency of OFDM-IM is improved by selecting the active subcarriers in a more flexible way, where index modulation is applied for both in-phase and quadrature components of the subcarriers. The authors deal with the problem of selecting the optimal number of active subcarriers in OFDM-IM. More recently, OFDM-I Mis-combined with coordinate interleaving to achieve additional diversity gains. However, the combination of OFDM-IM and MIMO transmission techniques remains an open and interesting research problem.

In this study, we propose MIMO-OFDM-IM with index modulation (MIMO-OFDM-IM) as an efficient alternative multicarrier transmission scheme for 5G networks by combining MIMO and OFDM-IM transmission techniques. In the proposed scheme, each transmit antenna transmits its OFDM-IM frame as in Vertical Bell Labs layered space-time (V-BLAST) scheme, and at the receiver side, these OFDM-IM frames are separated and demodulated using a novel and low complexity minimum mean square error (MMSE) detection and log-likelihood ratio (LLR) calculation based detector. It is shown via computer simulations that the MIMO-OFDM-IM scheme achieves significantly better bit error rate (BER) performance than classical V-BLAST type MIMO-OFDM-IM for several

MIMO configurations. The rest of the letter is organized as follows. The system model of MIMO-OFDM-IM is presented, receiver structure of the MIMO –OFDM –IM scheme is given. Simulation results are provided. we propose MIMO-OFDM-IM with index modulation (MIMO-OFDM-IM) as an efficient alternative multicarrier transmission scheme for 5G networks by combining MIMO and OFDM-IM transmission techniques. In the proposed scheme, each transmit antenna transmits its OFDM-IM frame as in Vertical Bell Labs layered space-time (V-BLAST) scheme [12], and at the receiver side, these OFDM-IM frames are separated and demodulated using a novel and low complexity minimum mean square error (MMSE) detection and log-likelihood ratio (LLR) calculation based detector.

Orthogonal frequency division multiplexing (OFDM) has become one of the most common multicarrier transmission techniques for wideband wireless communications in recent years. Because of its benefits like efficient implementation and strength to frequency selective fading channels, OFDM has been enclosed in several standards like long term evolution (LTE), IEEE 802.11x wireless local area network (LAN), digital video broadcasting (DVB) and IEEE 802.16e-WiMAX. Considering the benefits of multiple-input multiple-output (MIMO) systems over single-antenna systems like improved rate and energy efficiency, the mixture of OFDM and MIMO transmission techniques seems like a robust difference for future wireless standards like 5G and beyond. OFDM with index modulation (OFDM-IM) can be a new multicarrier transmission method that has been planned as another to classical OFDM. Stimulating from the SM conception, in OFDM-IM, index modulation techniques are applied for the indices of the offered subcarriers of an OFDM system.

In the OFDM-IM method, only a set of available subcarriers are preferred as active consistent with the data bits, whereas the remaining inactive subcarriers are set zero. In different words, the data is transmitted not only by the information symbols selected from M-ary signal constellations, however additionally by the indices of the active subcarriers. Not like classical OFDM, the number of active subcarriers may be adjusted within the OFDM-IM scheme, and this flexibility within the system style provides a stimulating trade-off between error performance and spectral efficiency. Moreover, it's been shown that OFDM-IM has the potential to realize a more robust error performance than classical OFDM for low-to-mid spectral efficiency values. Due to its adjustable range of active subcarriers, OFDM-IM may be a potential candidate not just for high-speed wireless communications systems however additionally for machine-to-machine (M2M) communications systems that need low power consumption.

In statistics and signal processing, a minimum mean square error (MMSE) estimator is an estimation method that minimizes the mean square error (MSE), which is a common measure of estimator quality, of the fitted values of a dependent variable. In the Bayesian setting, the term MMSE more specifically refers to estimation with a quadratic loss function. In such a case, the MMSE estimator is given by the posterior mean of the parameter to be estimated. Since the posterior mean is cumbersome to calculate, the form of the MMSE estimator is usually constrained to be within a certain class of functions. Linear MMSE estimators are a popular choice since they are easy to use, easy to calculate, and very versatile. It has given rise to many popular estimators such as the Wiener–Kolmogorov filter and Kalman filter.

An M-ary transmission is a type of digital modulation where instead of transmitting one bit at a time, two or more bits are transmitted simultaneously. This type of transmission results in reduced channel bandwidth. This process is known as quadrature modulation.

M-ary Encoding. The word binary represents two-bits. This is the type of digital modulation technique used for data transmission in which instead of one-bit, two or more bits are transmitted at a time. As a single signal is used for multiple bit transmission, the channel bandwidth is reduced. An M-ary transmission is a type of digital modulation where instead of transmitting one bit at a time, two or more bits are transmitted simultaneously. This type of transmission results in reduced channel bandwidth. However, sometimes, two or more quadrature carriers are used for modulation. Multi-level modulation techniques permit high data rates within fixed bandwidth constraints. A convenient set of signals for M-ary PSK is

$\varphi i(t) = A \cos(\omega ct + \theta i), 0 < t \leq Ts,$

where the M phase angles are $\theta i = 0, 2\pi M , . . ., 2(M - 1)\pi M$.

For equiprobable ones and zeros, the PSD for M-ary PSK is S

$\varphi(\omega) = A 2 TsSa2(\omega - \omega c) Ts 2.$

The symbols, in this case, are of duration Ts, so the information (or bit rate) Tb satisfies Ts = Tb log2 M. The potential bandwidth efficiency of M-ary PSK can be shown to be FB B = log2 M bps/Hz.

All signals have the same energy Es over the interval (0, Ts), and each signal is correctly demodulated at the receiver if the phase is within $\pm\pi/M$ of the correct phase θi. No information is contained in the energy of the signal. A probability of error calculation involves analysing the received phase at the receiver (in the presence of noise) and comparing it to the actual phases. An exact solution is difficult to compute but for P< 10−3 an approximate probability of making a symbol error is P 2erfcs 2Es η sin2 π M, M > 2. If a Gray code is used, then the corresponding bit error is approximately Pbe/ log2 M. Stremler provides a table of the SNR requirements of M-ary PSK for fixed error rates. The results indicate that for QPSK (M = 4) has definite advantages over coherent PSK (M = 2) the bandwidth efficiency is doubled for only about a 0.3dB increase in SNR. For higher-rate transmissions in band-limited channels, the choice M = 8 is often used. Values of M > 8 are seldom used due to excessive power requirements. M-ary PSK requires more complex equipment than BPSK signalling. Carrier recovery is also more complicated. The requirement that the carrier is recovered can be mitigated by using a comparison between the phases of two successive symbols. This leads to M-ary differential PSK and is in principle similar to DPSK (which is differential PSK for M = 2). For large SNR the probability of error is P=2erfcs 2Es η sin2 π √ 2M. Thus differential detection increases the power requirements by the factor 0 = sin2 π/M sin2 (π/ √ 2M) For m = 4, the increase in required power is about 2.5dB, which may be justified by the saving in equipment complexity.

In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a method of encoding digital data on multiple carrier frequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G mobile communications.

In coded orthogonal frequency-division multiplexing (COFDM), forward error correction (convolutional coding) and time/frequency interleaving are applied to the signal being transmitted. This is done to overcome errors in mobile communication channels affected by multipath propagation and Doppler effects. COFDM was introduced by Alard in 1986 for Digital Audio Broadcasting for Eureka Project 147. In practice, OFDM has become used in combination with such coding and interleaving, so that the terms COFDM and OFDM co-apply to common applications.

OFDM is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. OFDM was introduced by Chang of Bell Labs in 1966. Numerous closely spaced orthogonal sub-carrier signals with overlapping spectra are emitted to carry data. Demodulation is based on Fast Fourier Transform algorithms. OFDM was improved by Weinstein and Ebert in 1971 with the introduction of a guard interval, providing better orthogonality in transmission channels affected by multipath propagation. Each sub-carrier (signal) is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate. This maintains total data rates similar to conventional single-carrier modulation schemes in the same bandwidth.

Conceptually, OFDM is specialized frequency-division multiplexing (FDM) method, with the additional constraint that all subcarrier signals within a communication channel are orthogonal to one another.

In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that cross-talk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

The orthogonality requires that the sub-carrier spacing is Hertz, where T_U seconds is the useful symbol duration (the receiver-side window size), and k is a positive integer, typically equal to 1. This stipulates that each carrier frequency undergoes k more complete cycles per symbol period than the previous carrier. Therefore, with N sub-carriers, the total passband bandwidth will be $B= N*\Delta f$ (Hz).

The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e. near half the Nyquist rate for the double-sideband physical passband signal). Almost the whole available frequency band can be used. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users.

In radio, multiple-input and multiple-output, or MIMO, is a method for multiplying the capacity of a radio link using multiple transmission and receiving antennas to exploit multipath propagation. MIMO has become an essential element of wireless communication standards including IEEE802.11n (Wi-Fi), IEEE802.11ac (Wi-Fi), HSPA+ (3G), WiMAX (4G), and Long Term Evolution (LTE4G). More recently, MIMO has been applied to power-line communication for 3-wire installations as part of ITU G.hn standard and HomePlugAV2 specification.

At one time, in wireless, the term "MIMO" referred to the use of multiple antennas at the transmitter and the receiver. In modern usage, "MIMO" specifically refers to a practical technique for sending and receiving more than one data signal simultaneously over the same radio channel by exploiting multipath propagation. MIMO is fundamentally different from smart antenna techniques developed to enhance the performance of a single data signal, such as beamforming and diversity.

MIMO is often traced back to 1970s research papers concerning multi-channel digital transmission systems and interference (crosstalk) between wire pairs in a cable bundle: AR Kaye and DA George (1970), Branderburg and Wyner (1974), and W. van Etten (1975, 1976). Although these are not examples of exploiting multipath propagation to send multiple information streams, some of the mathematical techniques for dealing with mutual interference proved useful to MIMO development. In the mid-1980s Jack Salz at Bell Laboratories took this research a step further, investigating multi-user systems operating over "mutually cross-coupled linear networks with additive noise sources" such as time-division multiplexing and dually-polarized radio systems.

Methods were developed to improve the performance of cellular radio networks and enable more aggressive frequency reuse in the early 1990s. Space-division multiple access (SDMA) uses directional or smart antennas to communicate on the same frequency with users in different locations within a range of the same base station. An SDMA system was proposed by Richard Roy and Bjorn Ottersten, researchers at ArrayComm, in 1991. Their US patent (No. 5515378 issued in 1996) describes a method for increasing capacity using "an array of receiving antennas at the base station" with a "plurality of remote users."

Arogyaswami Paulraj and Thomas Kailath proposed an SDMA-based inverse multiplexing technique in 1993. Their US patent (No. 5,345,599 issued in 1994) described a method of broadcasting at high data rates by splitting a high-rate signal "into several low-rate signals" to be transmitted from "spatially separated transmitters" and recovered by the receive antenna array based on differences in "directions-of-arrival." Paulraj was awarded the prestigious Marconi Prize in 2014 for "his pioneering contributions to developing the theory and applications of MIMO antennas. His idea for using multiple antennas at both the transmitting and receiving stations – which is at the heart of the current high-speed WiFi and 4G mobile systems – has revolutionized high-speed wireless."

In an April 1996 paper and subsequent patent, Greg Raleigh proposed that natural multipath propagation can be exploited to transmit multiple, independent information streams using co-located antennas and multi-dimensional signal processing. The paper also identified practical solutions for modulation (MIMO-OFDM-IM), coding, synchronization, and channel estimation. Later that year (September 1996) Gerard J. Foschini submitted a paper that also suggested it is possible to multiply the capacity of a wireless link using what the author described as "layered space-time architecture."

Greg Raleigh, V. K. Jones, and Michael Pollack founded Clarity Wireless in 1996, and built and field-tested a prototype MIMO system. Cisco Systems acquired Clarity Wireless in 1998. Bell Labs built a laboratory prototype demonstrating its V-BLAST (Vertical-Bell Laboratories Layered Space-Time) technology in 1998. Arogyaswami Paulraj founded Iospan Wireless in late 1998 to develop MIMO-OFDM-IM products. Iospan was acquired by Intel in 2003. V-BLAST was never commercialized, and neither Clarity Wireless nor Iospan Wireless shipped MIMO-OFDM-IM products before being acquired.

A Massive MIMO system, shown in Figure 1, is a system comprising a relatively high number of M antennas (M> 10) at the base station [4, 2, 7]. This large number of radiating elements, each controlled numerically, will allow fine control of the overall radiation of the base station. Although quite suitable for point-to-point transmissions, this feature fact that this solution is often associated with multi-user techniques because of its potential to focus energy towards several particular positions of space. This characteristic is implemented by the precoding process, whose role is to exploit certain knowledge of the propagation channel to target multiple users and serve simultaneously. Each of them can then benefit from the totality bandwidth and get a very high bit rate.

Note that many studies consider single-antenna terminals [1, 5, 4] because all processing is performed at the base station, the user not having the information needed to perform post coding treatments. This focus on energy is often associated with the term energy efficiency which helps to make it a very appropriate solution for the future [3, 9]. Indeed, this focus results in a higher gain related to precoding without increasing the transmission power. In other words, a Massive MIMO system theoretically allows dividing the radio power necessary to obtain the same quality of service as a SISO system by a factor proportional to the number of antennas of the system (α M) [4,6]. Designed and properly used, a massive MIMO system can improve transmission throughput and reliability and provide a better compromise between energy use and signal spectral efficiency. Besides, a large-scale antenna system can eliminate the effects of small-scale fading and uncorrelated noise. Simple linear precoding and detection have been found to work optimally. The philosophy of Massive MIMO systems is therefore based on the use of a large number of transmit antennas to serve a limited number of users simultaneously.

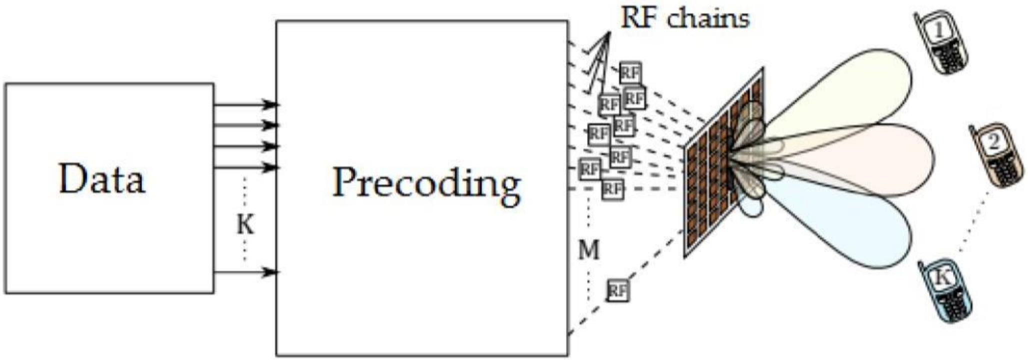

Figure 1.1 : Massive MIMO system

On the other hand, the number of users that can be supported simultaneously is closely dependent on the number of transmit antennas. Also, the performance of Massive MIMO systems is mainly related to the user selection method. In the literature, the problem of user scheduling in MIMO systems has been extensively studied. For example, the authors propose three heuristic scheduling algorithms for CDMA MIMO systems. In the massive context of MIMO, very few articles have addressed this problem. In, the authors propose to solve the problem of joint antenna selection and user planning, but in massive MIMO systems distributed under the constraint of capacity. The optimal strategy facing the problem of user scheduling is guaranteed by an exhaustive search (search by brute force), which generates a computationally prohibitive complexity.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE SURVEY

Beixiong Zheng et al.“Multiple-Input Multiple-Output OFDM with Index Modulation: Low-Complexity Detector Design”, in this paper proposed two low-complexity detectors derived from the SMC theory for the MIMO-OFDM-IM system. The first proposed subblock-wise detector draws samples at the subblock level, exhibiting near-optimal performance for the MIMO-OFDM-IM system. The second proposed subcarrier-wise detector draws samples at the subcarrier level, exhibiting substantially reduced complexity with a marginal performance loss. An effective legality examination method has been also developed to couple with the subcarrier wise detector. Computer simulation and numerical results have validated the outstanding performance and the low complexity of both proposed detectors.

Ertugrul Basar et al.“Multiple-Input Multiple-Output OFDM with Index Modulation”, A novel scheme called MIMO-OFDM-IM with index modulation has been proposed as an alternative multicarrier transmission technique for 5G networks. It has been shown via extensive computer simulations that the proposed scheme can provide significant BER performance improvements over classical MIMO-OFDM-IM for several different configurations. The following points remain unsolved in this study:

i) performance analysis,

ii) the selection of optimal N and K values,

iii) diversity techniques for MIMO-OFDM-IM, and

iv) Implementation scenarios for high mobility. Ertugrul Basar et al. “On Multiple-Input Multiple-Output OFDM with Index Modulation for Next Generation Wireless Networks”, In this study, the recently proposed MIMO-OFDM-IM scheme has been investigated for next-generation 5G wireless networks. For the MIMO-OFDM-IM scheme, new detector types such as ML, near-ML, simple MMSE, MMSE-LLR-OSIC detectors have been proposed and their ABEP has been theoretically examined. It has been shown via extensive computer simulations that the MIMO-OFDM-IM scheme provides an interesting trade-off between complexity, spectral efficiency and error performance compared to the classical MIMO-OFDM-IM scheme and it can be considered as a possible candidate for 5G wireless networks. The main features of MIMO-OFDM-IM can be summarized as follows:

i) better BER performance,

ii) flexible system design with a variable number of active OFDM subcarriers and

iii) better compatibility to higher MIMO setups. However, interesting topics such as diversity methods, generalized OFDM-IM cases, high mobility implementation and transmit antenna indices selection remain to be investigated for the MIMO-OFDM-IM scheme.

Ertugrul Bas¸ et al. “Performance of Multiple-Input Multiple-Output OFDM with Index Modulation”, In this paper, proposed ML and near-ML detectors for the recently introduced MIMO-OFDM-IM scheme to improve its error performance compared to MMSE based detection.

The ABEP upper bound of the MIMO-OFDM-IM scheme with ML detection has been derived and it has been shown that the derived theoretical upper bound can be used as an efficient tool to predict the BER performance of the MIMO-OFDM-IM scheme. It has been shown via computer simulations that the MIMO- FDM-IM scheme can provide significant improvements in BER performance over classical MIMO-OFDM-IM using a different type of detectors and MIMO configurations.

Beixiong Zheng et al. “Low-Complexity ML Detector and Performance Analysis for OFDM With In-Phase/Quadrature Index Modulation”, In this letter, we've planned a low-complexity detector supported the millilitre criterion, that dispenses with a priori data of the noise variance and also the potential realizations of the active subcarrier indices. supported the framework of OFDM-I/Q-IM using the planned millilitre detector, the straight line ABEP and also the actual coding gain achieved by OFDMI/Q-IM are derived, that matches the simulation results.

Moreover, the exact coding gain including the spectral efficiency price has provided a clear plan of a basic trade-off between the system performance and also the spectral efficiency of OFDM-I/Q-IM by the adjustment of the number of active subcarriers.

Sheng Wu et al.“Low-Complexity Iterative Detection for Large-Scale Multiuser MIMO-OFDM-IM Systems Using Approximate Message Passing”, For the detection of large-scale multiuser MIMO-OFDM-IM systems, we have proposed a range of low-complexity approximate message passing algorithms that can offer a desirable tradeoff between performance and complexity.

It is verified through extensive simulations that our proposed approximate message passing algorithms can achieve near-optimal performance with low complexity. Compared with existing turbo detection algorithms, the proposed schemes can achieve or even outperform the performance of some complex algorithms, such as the iterative decoding based on STS-SD and MMSESIC. In addition, the number of iterations required to achieve near-optimal performance is small and does not increase with the system dimension.

CHAPTER 3

SOFTWARE REQUIREMENTS

3.1 INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modelling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non-interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In the industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available to include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 THE MATLAB SYSTEM:

The MATLAB system consists of five main parts

- **Development Environment:**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigenvalues, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using the IMAGE PROCESSING toolbox.

3.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG file contains binary data that does not need to be parsed when the associated GUI-based M function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited and callback functions that are executed when a user interacts with GUI objects for example when a button is pushed.

To launch GUIDE from the MATLAB command window, type
guide filename
Where filename is the name of an existing FIG-file on the current path. If the filename is omitted, GUIDE opens a new (i.e., blank) window.

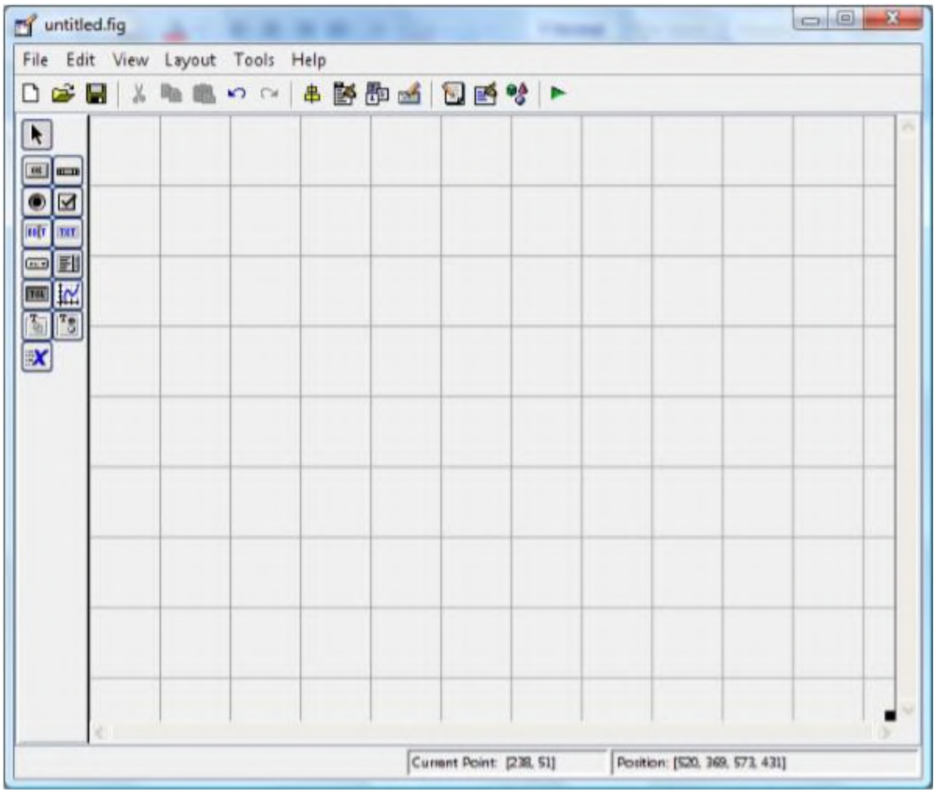

Figure 3.1 : Matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, pushbuttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.4.1 DESCRIPTION - describes the components of the MATLAB system.

3.4.2 DEVELOPMENT ENVIRONMENT - describes the MATLAB development environment, including information about tools and the MATLAB desktop.

3.4.3 MANIPULATING MATRICES - describes how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.4.4 GRAPHICS - describes MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images. 2.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.5 DEVELOPMENT ENVIRONMENT

3.5.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.5.2 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type Matlab

At the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup and reduce startup time in some situations.

3.5.3 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu on the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.5.4 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your LaunchPad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.5.5 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- LaunchPad
- Help Browser Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

LaunchPad

MATLAB's LaunchPad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the Help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name. Favourites tab - View a list of documents you previously designated as favourites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term on the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT file, which has a .mat extension. There are options for saving to different formats. To read in a MAT file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop.

CHAPTER 4
PROJECT DESCRIPTION

A typical FDD mode massive MIMO-OFDM-IM system was established. We consider a single-cell massive MIMO system consisting of one Base station equipped with M antennas and K single-antenna users, where M≫K. We propose the case of a single-cell system that means there is no interference co-channel. The downlink or broadcast system is described as follows. The base station with M antennas transmits data simultaneously to K active users chosen from a total of U users, each with one receive antenna. The base station separates the multiuser data streams by beamforming, i.e. assigning a beamforming vector to each of the K active users. The beamforming vectors $wn \;\; n$=1 M are selected from multiple sets of unitary orthogonal vectors following the beam and user selection algorithm. Equal power allocation over-scheduled users are considered. The received signal of u the scheduled user is expressed as:

$$y_u = \sqrt{\frac{P}{M}} h_k^* \sum_{n \in A} w_n x_n + v_u \qquad u \in A$$

Where we use the following notation: M: number of transmit antennas and also the number of scheduled users; hu (M × 1 vector) downlink channel; xu transmitted symbol with E[|xu|2] = 1; yu received symbol; wu (M × 1 vector) beamforming vector, A The index set of scheduled users, P: transmission power;

B. Zero-Forcing Beamforming Zero-forcing (ZF) decomposes the channel into several parallel scalar channels with only additive noise, and the interference is removed completely by transmitting beamforming techniques [8]. Suppose a base station with M transmit antennas transmits information to K users, each user is equipped with one single receive antenna. The received signal by the kth user is

$$y_k = h_k^H v_k x_k + h_k^H \sum_{j=1, j \neq k}^{K} v_j x_j + n_k \qquad 1 \leq k \leq K$$

ZF method transmits the signals towards the intended user with nulls steered in the direction of the other users, i.e., ($hj \;\; Hvk$ = 0 $\forall j \neq k$). The users will receive only the desired signal without any interference because of the perfect nulling. In this case, the received data at the kth user can be written

The corresponding vector equation is

$$y = HhVx + n \ (4)$$

Therefore, if the normalized transmit beamforming vector of the kth user is selected

Therefore, if the normalized transmit beamforming vector of the kth user is selected $vk\ ' = hk\ (\dagger)\ hk\ (\dagger)\ F\ 2$ (5) where $hk\ (\dagger)$ is the kth column of the pseudo inverse of H, denoted as H(y). Then it is shown that the interference can be cancelled completely.

4.1 MULTI INPUT-MULTI OUTPUT

The demand for high bit rate has increased in recent wireless communication networks. Theories by various engineers have proven that the Multiple Input Multiple Output (MIMO) technology can improve the problem of traffic capacity in wireless networks. MIMO systems can be defined as the use of multiple antennas at both the transmitting and receiving ends of a wireless communication network. The systems take advantage of multipath transmission paths. Although various efforts have been made by engineers to improve the data rate, the capacity is never enough for users. Users of mobile wireless devices like to be able to use their devices in streaming live programs, playing more online games and streaming an online movie which involves high data rates.

Telecommunication companies and Internet Service Providers (ISPs) as an example in Africa find it difficult to provide high data rate Internet services to their network users, especially mobile users, due to environmental factors. The only option for most of these companies is to provide the Internet with a high data rate wirelessly. With the limited bandwidth in space, MIMO technology will be of great benefit to these companies in providing high data rate Internet services to their customers. Currently, cellular systems, such as the third-generation (3G) cellular system, satellite communication systems and video broadcasting systems have experienced a great increase in capacity in the implementation of MIMO channel technology. Access point devices such as wireless local area networks (WLAN) routers have also experienced a great change in transmission techniques, with a few using MIMO technologies. The main goal of this project is to explain and illustrate the operation of MIMO channel technology.

4.1.1 Background of Multiple Input Multiple Output:

The multiple input multiple output channel technologies are aimed to increase the capacity in the wireless communication network. With the invention of MIMO, the technology seems to gain popularity as it is being implemented in the current commercial wireless products and networks such as broadband wireless access systems, wireless local area networks (WLAN), 3G networks, etc. Figure 1 shows a line of sight (LOS) antenna setup of a MIMO system.

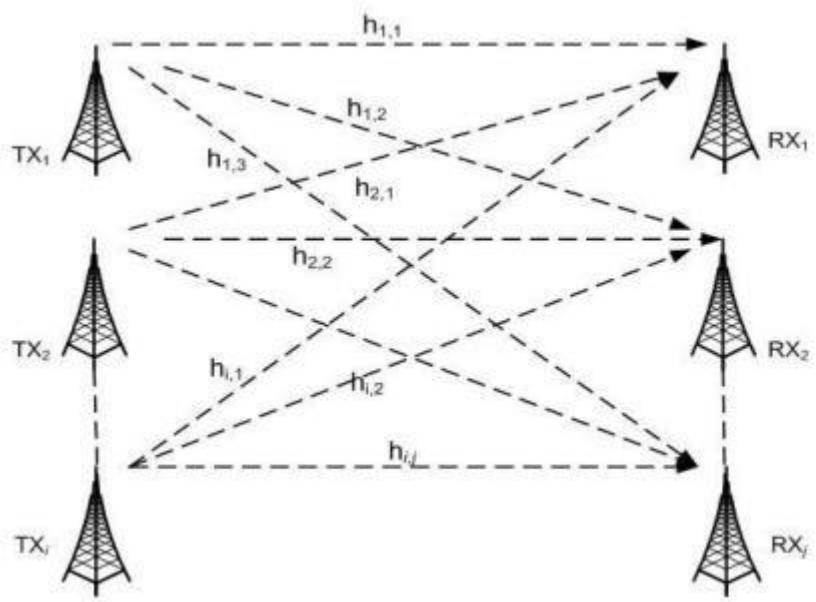

Figure 4.1 : A Generalized MIMO Wireless Communication System

The main idea behind MIMO is that the sampled signals in a spatial domain at both the transmitter and receiver end are combined so that they form effective multiple parallel spatial data streams which increase the data rate. The occurrence of diversity also improves the quality that is the bit-error-rate (BER) of the communication

4.1.2 SINGLE INPUT SINGLE OUTPUT VERSUS MIMO CHANNEL CAPACITY:

In communication systems, input discrete source symbols are mapped into a sequence of channel symbols which are then transmitted through the wireless channel. The transmission of channel symbols through the wireless channel is by nature random and random noise is added to the channel symbols. The measure of how much information can be transmitted and received with a minimum probability of error is called the channel capacity. A Single Input Single Output system involves the use of one antenna both at the transmitter and receiver end. To a telecommunications engineer, there exit a limit at which reliable transmission of information is not possible for a given transmission bandwidth and power. These limits were discovered by Claude Shannon in 1948 when he established the principles of information and communication theory in his various publications.

Shannon also established the conditions that enable the transmission of information over a noisy channel at a given rate, for a given power of the signal and noise. These limiting factors are the finite bandwidth and the S/N of the channel. This is because for a communication channel to accommodate the signal spectrum, enough transmission bandwidth is needed otherwise there will be distortion. “The higher data rate is to be transmitted, the shorter digital pulses must be used and the shorter digital pulses are used for transmission, the wider bandwidth is required”. For a deterministic channel with a bandwidth (B) with additive noise, Shannon proved that information with a rate of r bits per second (bps) can be transmitted with a small error probability provided that the bit rate is less than the capacity of the channel $r < C$. The Shannon formulae that can be applied to determine the maximum capacity C of the channel is of the form C = Blog[1 +T] [(bits s)/H T], where S/N, the signal-to-noise ratio and B the bandwidth of the transmission channel.

The above Equation informs us of how power and bandwidth are related. Assuming we have a channel with additive noise N and that we have some freedom of choosing the average transmission power S, to set up a reliable transmission link to send r bits per second. From the Shannon theorem, the data rate r cannot exceed capacity C, $r < C$ as in equation, but we still have one degree of freedom in the choice of bandwidth B and power S. It can be realized that, for a given signal-to-noise ratio S/N, if we wish to double C, we have to double the bandwidth B. On the other hand, if we double C, for a given B we have to evaluate the S/N.

4.1.3 WHAT IS MIMO?

MIMO (multiple inputs, multiple outputs) is an antenna technology for wireless communications in which multiple antennas are used at both the source (transmitter) and the destination (receiver). The antennas at each end of the communications circuit are combined to minimize errors and optimize data speed. MIMO is one of several forms of smart antenna technology, the others being MISO (multiple inputs, single output) and SIMO (single input, multiple outputs). In conventional wireless communications, a single antenna is used at the source, and another single antenna is used at the destination. In some cases, this gives rise to problems with multipath effects. When an electromagnetic field (EM field) is met with obstructions such as hills, canyons, buildings, and utility wires, the wavefronts are scattered, and thus they take many paths to reach the destination. The late arrival of scattered portions of the signal causes problems such as fading, cut-out (cliff effect), and intermittent reception (picket fencing). In digital communications systems such as wireless Internet, it can cause a reduction in data speed and an increase in the number of errors. The use of two or more antennas, along with the transmission of multiple signals (one for each antenna) at the source and the destination, eliminates the trouble caused by multipath wave propagation, and can even take advantage of this effect.

MIMO technology has aroused interest because of its possible applications in digital television (DTV), wireless local area networks (WLANs), metropolitan area networks (MANs), and mobile communications. In radio, multiple-input and multiple-output, or MIMO is a method for multiplying the capacity of a radio link using multiple transmission and receiving antennas to exploit multipath propagation. MIMO has become an essential element of wireless communication standards including IEEE 802.11n (Wi-Fi), IEEE 802.11ac (Wi-Fi), WiMAX, and Long-Term-Evolution. More recently, MIMO has been applied to power-line communication for 3-wire installations as part of the standard and Home Plug AV2 specification. At one time, in wireless, the term "MIMO" referred to the use of multiple antennas at the transmitter and the receiver. In modern usage, "MIMO" specifically refers to a practical technique for sending and receiving more than one data signal simultaneously over the same radio channel by exploiting multipath propagation. MIMO is fundamentally different from smart antenna techniques developed to enhance the performance of a single data signal, such as beamforming and diversity. MIMO technology has been standardized for wireless LANs, 3G mobile phone networks, and 4G mobile phone networks and is now in widespread commercial use. Greg Raleigh and V. K. Jones founded Airgo Networks in 2001 to develop MIMO-OFDM-IM chipsets for wireless LANs. The Institute of Electrical and Electronics Engineers (IEEE) created a task group in late 2003 to develop a wireless LAN standard delivering at least 100 Mbit/s of user data throughput. There were two major competing proposals: TGn Sync was backed by companies including Intel and Philips, and WWiSE was supported by companies including Airgo Networks, Broadcom, and Texas Instruments. Both groups agreed that the 802.11n standard would be based on MIMO-OFDM-IM with 20 MHz and 40 MHz channel options. TGn

Sync, WWiSE, and a third proposal (MITMOT, backed by Motorola and Mitsubishi) were merged to create what was called the Joint Proposal. In 2004, Airgo became the first company to ship MIMO-OFDM-IM products. Qualcomm acquired Airgo Networks in late 2006. The final 802.11n standard supported speeds up to 600 Mbit/s (using four simultaneous data streams) and was published in late 2009.

Surendra Babu Mandava and Arogyaswami Paulraj founded Beceem Communications in 2004 to produce MIMO-OFDM-IM chipsets for WiMAX. The company was acquired by Broadcom in 2010. Wi-MAX was developed as an alternative to cellular standards, is based on the 802.16e standard, and uses MIMO-OFDM-IM to deliver speeds up to 138 Mbit/s. The more advanced 802.16m standard enables download speeds up to 1 Gbit/s. A nationwide WiMAX network was built in the United States by Clear wire, a subsidiary of Sprint-Nextel, covering 130 million points of presence (PoP) by mid-2012. Sprint subsequently announced plans to deploy LTE (the cellular 4G standard) covering 31 cities by mid-2013 and to shut down its Wi-MAX network by the end of 2015.

The first 4G cellular standard was proposed by NTT DoCoMo in 2004. Long term evolution (LTE) is based on MIMO-OFDM-IM and continues to be developed by the 3rd Generation Partnership Project (3GPP). LTE specifies downlink rates up to 300 Mbit/s, uplink rates up to 75 Mbit/s, and quality of service parameters such as low latency. LTE Advanced adds support for picocells, femtocells, and multi-carrier channels up to 100 MHz wide. LTE has been embraced by both GSM/UMTS and CDMA operators.

The first LTE services were launched in Oslo and Stockholm by TeliaSonera in 2009. There are currently more than 360 LTE networks in 123 countries operational with approximately 373 million connections (devices).

4.1.4 FUNCTIONS OF MIMO:

Precoding is multi-stream beamforming, in the narrowest definition. In more general terms, it is considered to be all spatial processing that occurs at the transmitter. In (single-stream) beamforming, the same signal is emitted from each of the transmit antennas with appropriate phase and gain weighting such that the signal power is maximized at the receiver input. The benefits of beamforming are to increase the received signal gain by making signals emitted from different antennas add up constructively and to reduce the multipath fading effect. In line-of-sight propagation, beamforming results in a well-defined directional pattern. However, conventional beams are not a good analogy in cellular networks, which are mainly characterized by multipath propagation. When the receiver has multiple antennas, the transmit beamforming cannot simultaneously maximize the signal level at all of the receive antennas, and precoding with multiple streams is often beneficial. Note that precoding requires knowledge of channel state information (CSI) at the transmitter and the receiver.

Spatial multiplexing requires MIMO antenna configuration. In spatial multiplexing, a high-rate signal is split into multiple lower-rate streams and each stream is transmitted from a different transmit antenna in the same frequency channel. If these signals arrive at the receiver antenna array with sufficiently different spatial signatures and the receiver has accurate CSI, it can separate these streams into (almost) parallel channels. Spatial multiplexing is a very powerful technique for increasing channel capacity at higher signal-to-noise ratios (SNR). The maximum number of spatial streams is limited by the lesser the number of antennas at the transmitter or receiver. Spatial multiplexing can be used without CSI at the transmitter but can be combined with precoding if CSI is available. Spatial multiplexing can also be used for simultaneous transmission to multiple receivers, known as space-division multiple access or multi-user MIMO, in which case CSI is required at the transmitter. The scheduling of receivers with different spatial signatures allows good separability.

Diversity coding techniques are used when there is no channel knowledge at the transmitter. In diversity methods, a single stream (unlike multiple streams in spatial multiplexing) is transmitted, but the signal is coded using techniques called space-time coding. The signal is emitted from each of the transmit antennas with full or near orthogonal coding. Diversity coding exploits the independent fading in the multiple antenna links to enhance signal diversity. Because there is no channel knowledge, there is no beamforming or array gain from diversity coding. Diversity coding can be combined with spatial multiplexing when some channel knowledge is available at the transmitter. Electronic beam steering with greater efficiency is a vibrant feature of a phased array antenna, but for all the range cells, it is fixed at a specific angle. To mitigate this problem, a frequency diverse array (FDA) antenna was proposed. This study presents a review on the development of FDA technology in radar and navigation applications. FDA is different from a conventional phased array antenna radar in the sense that it uses a small frequency offset across the array, which helps to generate a range, angle and time-dependent beam pattern. This pattern assures the energy transmission towards the desired angle and range cell. In addition, this study also focuses the research on getting range-angle uncoupled beam patterns along with diverse hybrid cognitive FDA design, available in the literature, for improved radar performance. Radar systems provide an important remote sensing capability, and are crucial to the layered sensing vision; a concept of operation that aims to apply the right number of the right types of sensors, in the right places, at the right times for superior battlespace situational awareness. The layered sensing vision poses a range of technical challenges, including radar, that are yet to be addressed. To address the radar-specific design challenges, the research community responded with waveform diversity; a relatively new field of study which aims to reduce the cost of remote sensing while improving performance. Early work suggests that the frequency diverse array radar may be able to perform several remote sensing missions simultaneously without sacrificing performance. With few techniques available for modelling and characterizing the frequency diverse array, this research aims to specify, validate and characterize a waveform diverse signal model that can be used to model a variety of traditional and contemporary radar configurations, including frequency diverse array radars. To meet the aim of the research, a generalized radar array signal model is specified. A representative hardware system is built to generate the arbitrary radar signals, then the measured and simulated signals are compared to validate the model. Using the generalized model, expressions for the average transmit signal power, angular resolution, and the ambiguity function are also derived. The range, velocity and direction-of-arrival measurement accuracies for a set of signal configurations are evaluated to determine whether the configuration improves fundamental measurement accuracy.

The main importance of the MIMO channel technique is to improve the capacity of the channel and therefore it is important to compare the capacity of a SISO system to a MIMO system. In SISO a system, the Shannon formula in the equation can be applied to determine the capacity of the system. However, for a precise comparison, the MIMO system must be transmitting with power the same as that of a SISO system. Therefore if the power radiated by a SISO system is Ps (SNR), then the power radiated from each antenna of a MIMO system with NTX transmit antennas must be Ps/N.

Hence, for a MIMO system with NTX and MRX antennas using diversity at the transmitter and receiver end, the capacity of the system can be determined by the formula means transpose-conjugate of H and H is the M x N channel matrix. IM indicates the identity matrix of dimension N x M, in this case, M = N =2 or more. However, since signals transmitted over the MIMO channel have to be linearly independent and orthogonal, interference averages to zero. Hence from the equation, it can be seen that if the signal power Ps and the noise level N are the same then the more multiple antennas are used at the receiver, the more power is collected increasing the channel capacity and bandwidth.

4.1.5 REPRESENTATION OF MIMO CHANNEL:

The first channel model to be considered in this project will be a 2 x 2 MIMO system that is a system with 2 transmits (TX) and 2 receive (RX) antennas where different independent data streams are transmitted from multiple antennas to multiple receive antennas. This channel model will be extended to a 3 x 3 MIMO system and even more to illustrate the channel characteristics to the increase in the number of antennas. The signals considered in the MIMO systems of this project are baseband signals ignoring modulation processes and concentrating on the up and down frequency conversion. Therefore the signals on the i-th transmit antenna will be denoted x while the received signal on the j-th receive antenna denoted as y. Figure 2 shows the antenna set-up and the various unknown channel coefficients.

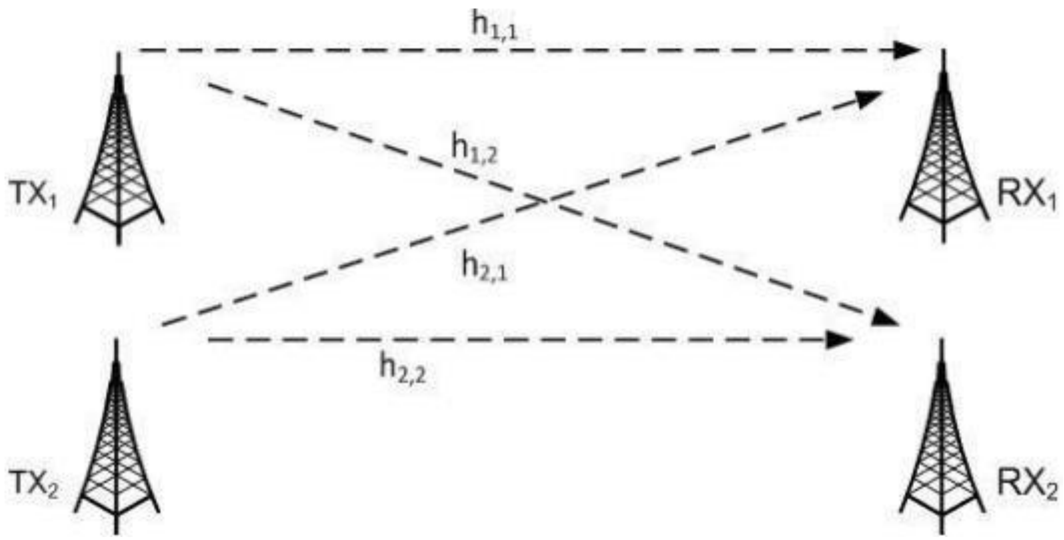

Figure 4.2 : Channel Characteristic of a 2 x 2 MIMO Wireless Communication System

Since the coefficient of the unknown in the channel matrix Wc and the number of transmitted signal X is equal to the number of received signal Y, the equation can be solved if the channel Wc is inversed which in this case a 2 x 2 matrix inversion.

4.1.6 OPERATIONAL PRINCIPLES OF A MIMO SYSTEM:

To derive the channel characteristics, the MIMO system transmits specified and known training signals regularly from all transmitters of the system and these transmitted signals are received at the receiver. Based on the received signals, the receiver calculates the characteristics of all channel paths from each transmitted antenna to each receiving antenna. To prove that MIMO work, the transmitted signal X has to be solved from the group of equations in the equation below. We also assume that the system is noise-free and line of sight (LOS). Reference to figure 3 below, if the transmitted signal is represented to be X and the received signal Y. If the channel characteristics matrix is Wc, we may write Y=X Wc. If the channel matrix has N rows as many as there are transmitting antennas with index i. Then transmitted signal vector is written as X = [x1, x2,…xN] . Also if the channel matrix has M columns, as there are receiving antennas with index j. Then the received signal vector is Y = [y1, y2,…yM]. These vectors are extended later to matrixes by inserting K samples into each column.

4.1.7 CHANNEL ESTIMATION PROCEDURE:

To estimate the channel characteristics, we expand each transmitted and received signals in time and write into signal matrix columns K discrete samples in time. The signals matrixes get K rows and as many columns as we have antennas, N or M. In general the MIMO system involves multiple antennas at the transmitting end and multiple receivers at the receiving end. Figure 4 show a general representation of a 3 x 3 general MIMO system.

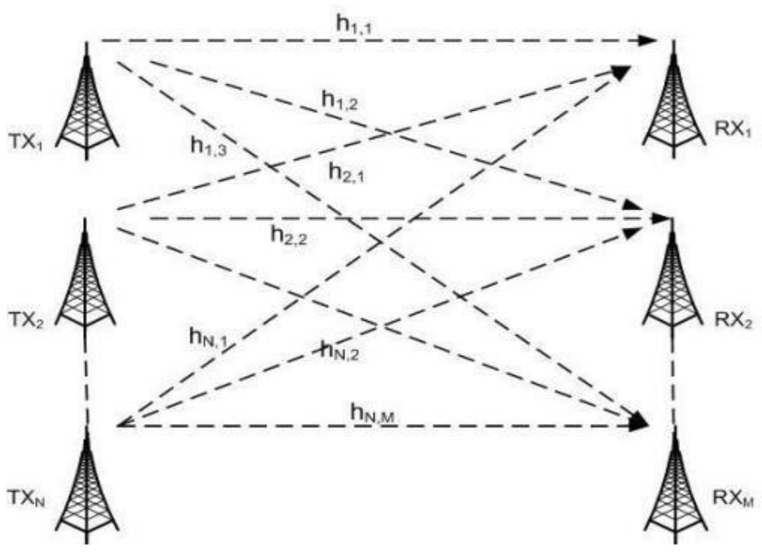

Figure 4.3 : General 3 x 3 MIMO System with Unknown Channel Characteristic

To determine the characteristic of the channel, both the transmitted signal X and the received signal Y have to be known. If the transmitted and received signals are of the form. If the channel transfer matrix Wc can be determined, then it means the transmitted signals can also be determined because the received signal Y is known. We may write the expression between these vector signals as Y = X Wc. To determine the transmitted signals, the channel transfer matrix, Wc -1 have to be inverted and then multiplied with the received signal matrix Y. X = Y Wc -1 The channel transfer matrix that we have to solve with the help of known training signal X and the received signal Y has the form. The channel transfer matrix is calculated periodically with the help of the known training signals and remains constant over information transmission time. It is then recalculated when new information is being transmitted. The channel characteristics in the equation are defined for each signal path at discrete time instants 1,2,...K. However, we need to derive Wc and this can be derived with the help of the transmitted signals X and the corresponding known received signals Y measured at the receiver. The equation expresses the channel matrix Wc which do not need to be a square matrix. Because, for example, if we have a 4x4 MIMO system with 100 samples, we do not need to have a 100x100 channel matrix. However, 5 samples can be transmitted from the four (4) antennas at a time. The next section explains the procedures required to estimate the channel transfer matrix.

4.1.8 CHANNEL IDENTIFICATION ALGORITHM:

To model the transfer channel a common space matrix (orthonormal basis matrix Ux) is first generated and then used to map both the transmitted and received signals that vary in space (multiple antennas) and in time (samples in time). This common orthonormal basis matrix is obtained by decomposing either the transmitted signal X or the received signal Y. Hence, the MIMO channel problem can be solved using a four-step approach under a condition where there is no noise (N = 0) and if the transmitted signals are orthogonal. These steps are summarized as follows:

(1) Finding an orthonormal basis Ux of the transmitted signal matrix X using the Gram-Schmidt procedure.

(2) In the K-dimensional signal vector space spanned by Ux, we express the N column vectors of the transmitted signal X by the projection onto the orthogonal axes of Ux. Wx = Ux X.

(3) In the K-dimensional signal vector space spanned by Ux, we express the M column vectors of the received signal matrix Y by their projection onto the orthogonal axes of Ux. Wy = Ux Y (4.2.2)

(4) Calculate the inverse of the pseudo inverse of the Fourier coefficients of the transmitted signal Wx and find an estimate of channel transfer matrix Oc = Wx -1 Wy or Oc = Wx + Wy.

4.1.9 ORTHONORMAL BASIS UX ESTIMATION:

To be able to estimate the transfer channel matrix Oc, a common space matrix is required to map both the transmitted signal X and the received signal Y together. The orthonormal base matrix Ux serves as the common space matrix needed to map the transmitted signal X to the received signal Y. It is important to know that, the orthonormal basis needed for the mapping can be derived either using the transmitted signal X or the received signal Y. Hence, the orthonormal basis Ux of the transmitted signal X is calculated by taking the matrix Ux obtained from the decomposition of transmitted signal X. In linear algebra, a matrix such as the transmitted signal X can be decomposition into the product X= Ux R where Ux is an orthogonal matrix in this case the orthonormal basis and R an upper triangular matrix. It should be noted that the format of matrix X is K-by-N while the size of the orthonormal base matrix Ux is always K-by-K. The Gram-Schmidt procedure is one way to decompose a column rank matrix and this procedure will be used in this project.

There are also other methods of decomposing a matrix such as QR-decomposition, LU decomposition, Cholesky decomposition, etc. See appendix 1 for the Gram-Schmidt process. Fourier coefficients of transmitted signal Wx After determining the orthonormal basis Ux, we have to map the known transmitted signal X to the orthonormal space matrix Ux and this is done by calculating the generalized Fourier coefficients of the transmitted signal Wx. The mapping of the transmitted signal X for the orthonormal basis Ux is expressed Wx = Ux X. The generalized Fourier coefficients are coefficients of any orthogonal set of functions over which signals are split up. Therefore the generalized Fourier coefficients of the transmitted signal Wx tell us how much each column (signal) of the transmitted signal X contains each orthogonal column component in the orthonormal base matrix Ux. In this case, we are splitting the transmitted signal with the help of the orthonormal basis Ux. It should be noted that the multiplication of Ux Ux T = I where I is a K-by-K identity matrix and the size of Wx is K-by-N.

Fourier coefficients of training (received) signal Wy The received signal Y is also mapped to the orthonormal space matrix Ux by multiplying the received signal Y with the orthonormal base matrix Ux. This means that we have to split the received signal Y with the help of the orthonormal basis Ux. Hence, the calculation of the Fourier coefficients of the received signal as Wy = Ux Y Where the size of Wy is K-by-M. Transfer channel matrix estimation Oc Finally, we derive the most favourable estimate of the channel transfer matrix from the expression Oc = Wx -1 Wy.

If the Fourier coefficient of the transmitted signal Wx is not a square matrix then we use the expression Oc = Wx + Wy where Wx + the pseudo inverse of Wx. This follows from the formula Y = X Oc Oc = X-1 Y =Wx -1 Ux Y =Wx -1 Ux Ux -1Wy = Wx -1 Wy From equation again it can be seen that to estimate the channel transfer matrix Oc, the inverse of the generalized Fourier coefficients of the transmitted signal Wx is needed since it is a square matrix. However, in the case where Wx is not a square matrix, the pseudo inverse of Wx is calculated. The orthonormal basis Ux plays an important role in determining the channel characteristics and therefore it is important to develop an algorithm to generate Ux. Not only to generate the orthonormal basis matrix but to illustrate the entire matrixes required to estimate the transfer channel. Hence, Microsoft Excel is used to develop an algorithm for the Gram-Schmidt procedure to generate Ux, the Fourier coefficients of both transmitted and received signals as well as the transfer channel. This algorithm can be accessed from a compact disk (CD) attached to this project. The next chapter explains with an example how to determine the orthonormal basis Ux using the Gram-Schmidt procedure by decomposing the transmitted signal X and applying this procedure to two different scenarios. First the calculation of the orthonormal basis Ux in the case where the transmitted signal X is a square matrix and in the second case where the transmitted signals X is not a square matrix.

4.1.10 ORTHONORMAL SPACE CONCEPT:

An orthonormal basis is a coordination system where we can present as many dimensions as is the maximum number of antennas of the transmitted and received signals. The main reason why we need the orthonormal base is to have a common coordinated system to combine the transmitted signal X and the received signal Y. The number of dimension of the orthonormal base matrix depends on the maximum number of antennas at both the transmitter and the receiver end of the MIMO system. It does not matter what kind of signal (X or Y) used in generating the orthonormal space but it is most convenient to use the transmitted training signal X which is defined to contain linearly independent column signals. Suppose K = 3-time samples per transmitted signal X and per received signal Y respectively of a 3 x 3 channel transmission system were observed. The figure shows a Line of Sight (LOS) MIMO system made up of three transmitters and three receivers. In figure 6, N = 3 transmitted signals and M = 3 received signals, the format of the unknown channel transfer matrix Oc would be 3 x 3. Assume that all signals are real-valued and the transmitted signals and received signals are observed as signal matrices. Then we need the orthonormal basis matrix Ux to solve for an estimated channel transfer matrix Oc. It is easier to calculate the orthonormal base matrix Ux of a square matrix; therefore in the next section, we estimate the channel model by calculating first the orthonormal basis matrix Ux of a simple 2 x 2 MIMO system and then proceed to a more complex 3 x 3 MIMO system.

This section explains how to calculate the orthonormal basis Ux of a 2 x 2 MIMO system with the help of the transmitted signal X. To demonstrate the steps in subchapter, we will have a numerical example to explain how to generate the orthonormal basis Ux of a full rank square matrix using linearly independent transmitted signals in X. The Gram-Schmidt procedure will be used in the decomposition of the transmitted signal X. See appendix 1 for the Gram-Schmidt procedure. The equation to decomposed in our calculation is of the form X = Ux R; R = Ux -1 X. In the equation, the transmitted signal X is divided into two components, Ux the orthonormal basis and R the upper triangular matrixes. The upper triangular matrix R is calculated by first finding the inverse of the orthonormal basis matrix Ux and multiplying it with the transmitted signal X. However, the upper triangular matrix R will is not needed in our analysis. The next very simple example explains how the Gram Schmidt procedure can be applied to generate orthonormal base Ux of the transmitted signal X.

The transmitted known training signals are used in modelling the transfer channel Oc as shown in examples. Therefore it is important to estimate the channel output if the transmitted signals are transmitted. The next example drives the received signal U in two different scenarios. In both scenarios, the transmitted signals are the same but different transfer channels. This will help us estimate the received signals produced by the different transfer channels.

To further understand the operational principles of the MIMO channel, we extend the same principles listed in subchapter 4.2 to a case of a 3 x 3 MIMO system where there are three antennas at both transmit and receive ends. Assuming three-column transmitted signals and three-column received signals each are observe over K uniformly spaced discrete time instances The channel can be estimated by first calculating the common signal space matrix (orthonormal base matrix). In the next example, the orthonormal base of the transmitted signal X is calculated using the Gram-Schmidt procedure

Based on the Gram Schmidt process, the orthonormal basis Ux matrix is an orthogonal matrix. The column signals of the orthonormal base Ux in the equation are orthogonal and the inner product of any pair of the column vectors result in zero. The column vectors are orthonormal and the norm of every column vector signal result in value 1. To prove that the column signals of the orthonormal base Ux are orthogonal, the inner product of these column signals. The results obtained from the inner product calculations prove that the column signals of the orthonormal base Ux are orthogonal. It should be noted that the results obtained in example (5.3.2) are not exactly zero due to the rounding of values in calculating the orthonormal basis matrix.

4.2 OFDM

OFDM has several significant benefits over single-carrier QAM modulation which has lead to its adoption in many of the modern wireless standards, including ADSL, European Digital Video Broadcast, IEEE 802.11a/g/n (WiFi), WiMax, and 3GPP Long Term Evolution (LTE). First of all, OFDM enables easy equalization, solving many of the equalization complexity issues we encountered for single-carrier QAM by working instead in the frequency domain. Second of all, the ability to control the size of the constellation on each subcarrier in OFDM also allows it to mimic the “water-filling” construction which maximizes the amount of information that can be reliably transmitted over the channel: subcarriers (frequencies) with better channel gains can utilize higher-order modulations and coding rates. A final significant benefit that we will encounter later in the course is that OFDM allows for an especially easy to implement and understand multiple access strategy OFDMA, in which different subcarriers (frequencies) are allocated to different users at different times. To understand how OFDM modems work, we must first revisit several properties of the discrete Fourier Transform and its efficient implementation of the Fast Fourier Transform.

The circular convolution between two length N signals x1[n] and x2[n], n ∈ {0, 1, . . . , N − 1}, is defined as x1[n] * x2[n] = N X−1 =0 x1*x2[((n −1))N] where ((n))N = N − n n < 0 n n ≥ 0 Circularly convolving two length N signals x1[n] and x2[n] is the same thing as multiplying their discrete Fourier transforms x1[n]* x2[n] DF T ←→ X1[k]X2[k] .The underlying principle of OFDM is based on this property of the DFT

The architecture of an OFDM transmitter and receiver pair is depicted in Fig. 1. First, during the th block, N QAM symbols c[k], k ∈ {0, . . . , N − 1} are mapped to "sub-carriers", one per subcarrier, which are the inputs to a size N IFFT, which computes the DFT shown below efficiently q[n] = N X−1 k=0 c[k]e j 2π N kn, n ∈ {0, . . . , N}

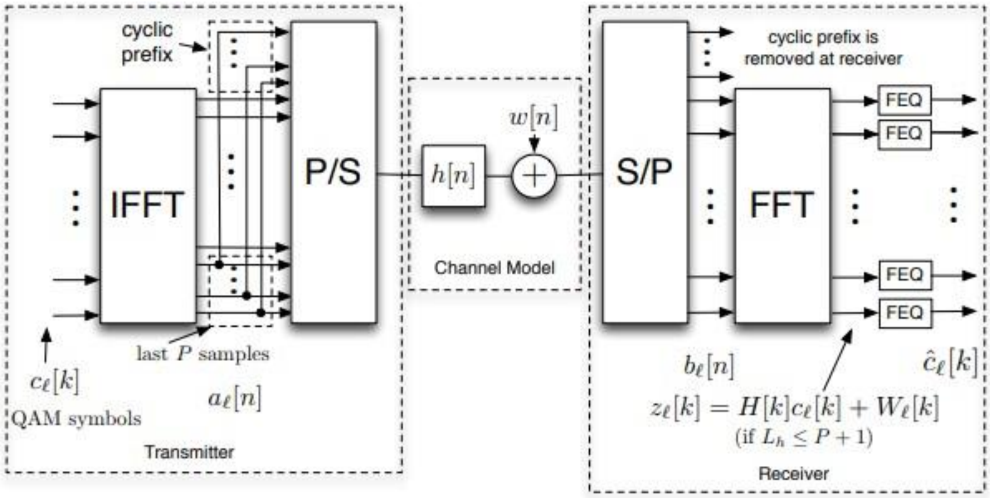

Figure 4.4 : An OFDM Transmitter, Channel model and Receiver

These OFDM blocks are then serialized to form xc[n] = a bn N+P c [n mod (N + P)] which is then put through a digital to analogue converter to form the complex baseband signal to be modulated by an ordinary quadrature modulator. As discussed in the previous notes on equalization, on its way from the transmitter to the receiver, the signal is subject to a multipath channel, as well as potentially some additive interference, and at the receiver, there is additive white Gaussian noise in the electronics. As discussed in the lecture on quadrature modulation, we can model the effects of this multipath channel by modelling the signal at the receiver, after demodulation and sampling as yc[n] = L Xh−1=0 h + w[n] where Δ indicates the delay before the channel is perceived as having any significant energy, and h[n] is the sampled impulse response of the channel, whose delay spread is Lh samples long, and w[n] is the additive white Gaussian noise. The receiver then proceeds to process this signal yc[n] in the exact opposite manner as at the transmitter. First the blocks are collected b[n] = yc[n + Δ + (N + P)], n ∈ {0, 1 . . . , N + P − 1} (8) then the cyclic prefix is removed r[n] = b[n + P], n ∈ {0, 1, . . . , N − 1} . The Fast Fourier transform is then taken, which calculates the DFT shown below efficiently z[k] = X N n=0 r[n]e −j 2π N kn.

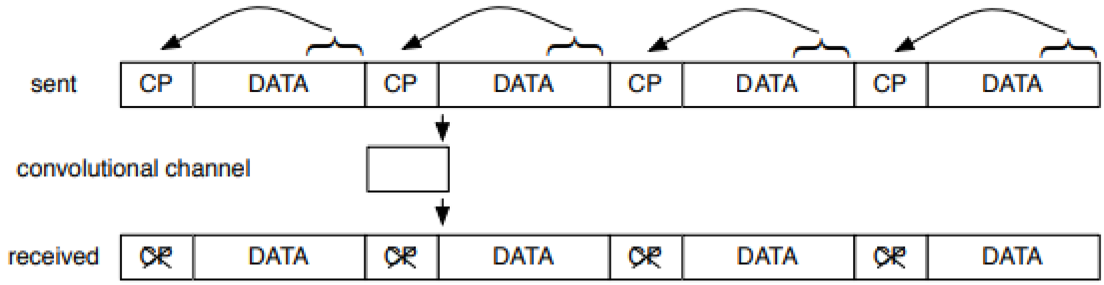

Figure 4.5 : Convolutional Channel

The Purpose of the Cyclic Prefix: Removing Inter-Block & Inter-Carrier Interference. The cyclic prefix allows an OFDM transmitter-receiver pair to accomplish important objectives, provided that the length of the multipath channel is less than or equal to the length of the cyclic prefix plus one:

1) it eliminates interblock interference, and

2) it enables easy equalization, as for the remainder of the block it makes the linear convolution with the ISI channel into a circular convolution. Indeed, as is indicated in Fig. 2, if we consider the output of the channel at times $n \in (\{0, \ldots, P-1\} + k(N+P)$, this will contain a contribution from both the previous OFDM symbol and the next one. However, if the channel length $Lh \leq P + 1$ then these are the only samples containing the inter-block interference, and hence, once we drop these samples at the receiver (when we remove the cyclic prefix), we will have no interblock interference. Additionally, under the same criterion $Lh \leq P + 1$ the remaining samples in each block after dropping the cyclic prefix will be the circular convolution of the channel with the associated transmitted block. Hence, by the circular convolution property of the DFT, when the FFT is taken of these received blocks, they will be the product of the FFT of the channel H[k] and the original QAM symbols, plus the FFT of the additive noise, as depicted in Fig 1. $z[k] = H[k]c[k] + w[k]$. The estimated QAM symbols can then be reconstructed by processing the subcarriers k individually by multiplying them with a frequency domain equalizer F[k] $c[k] = F[k]z[k]$ (12) where the F[k] can select as $H[k] * \ |H[k]|\ 2{+}\sigma2$, which minimizes the average magnitude squared error between c[k] and c[k], where σ 2 is the variance w[k]. These EQs F[k] can be estimated by placing training information, also called pilot signals or reference signals, agreed upon in advance between the transmitter and receiver, on various subcarriers k which are spread out in frequency. Because the channel is shorter than the cyclic prefix, and the cyclic prefix is

typically far shorter than the FFT size, the channel coefficients H[k] vary slowly with frequency k, and hence the channel estimates from the pilot signals can be interpolated to yield improved channel estimates for other carriers Considerations when Selecting a Cyclic Prefix Length and FFT Size There are two important considerations when selecting a cyclic prefix length and FFT size for an OFDM system in practice. We already noted that the cyclic prefix needs to be longer than one less than the length of the channel (its delay spread). As the cyclic prefix does not bear any extra information itself, it is desirable to select a very large FFT size so that the redundancy is introduced is low. However, the multipath channel must remain fixed over the entire duration of the OFDM symbol (i.e. the entire cyclic prefix and received data block), and this places an upper limit on the length of the FFT based on how quickly the channel is varying.

Bit-Loading & OFDMA Because the OFDM construction turns the wideband multipath channel into multiple parallel lower rate channels associated with evenly spaced frequencies within the band, it enables several intuitive other technologies. As mentioned in the introduction, those carriers k with a higher signal to noise ratios |H[k]| 2 σ2 can be given higher-order QAM symbols and higher code rates. This process is called bit-loading and adaptive modulation and coding in different contexts. Additionally, using OFDM modems also enable an especially intuitive form of multiple access. If the transmitter wishes to send individual messages to multiple receivers (as in a cellular system) listening to the same wideband channel, one can place information to be transmitted to different users on different subcarriers. Furthermore, since the multipath profiles H[k] of different receivers listening to the same transmitter will be different, if these multipath profiles are reliably fed back to the transmitter, it can also select those subcarriers for different users which they are receiving with high signal to noise ratios. On the other hand, if the multipath profiles are not fed back, or are varying too quickly, the transmitter can diversify which frequencies are used for different users by spreading the carriers/blocks of carriers given to each particular user out in frequency.

Finally, we note that you are likely to encounter at least two other variants of OFDM: discrete multitone (DMT) and SC-FDMA, both of which differ from pure OFDM solely by what is modulated on each of the subcarrier k (bins of the IFFT at the transmitter). Discrete multitone, which is used in ADSL systems, simply select the blocks of QAM symbols to be conjugate symmetric, so that their IFFT is real-valued, and hence only a single analog to digital converter is required at the receiver. An SC-FDMA transmitter selects a contiguous sub-block of subcarriers and places the result of the FFT of a sequence of QAM symbols of these subcarriers. This “spreading” of the inputs to the subcarriers with an FFT enables the peak to average power ratio of the output of the IFFT to be reduced, which allows the battery-operated power amplifiers in the analog RF front ends of the transmitters in mobiles to operate in more efficient regimes. SC-FDMA is used in the uplink of LTE (from mobile phones to the base stations), while OFDMA is used in the downlink (from base stations to mobile phones). Note that the overall effect of this operation is similar to pulse-shaping a single carrier QAM signal, since the zeros on the other subcarriers effectively determine a pulse shape, and which subcarriers are selected determine an effective overall carrier frequency. This is the reason this type of modulation is called “single-carrier FDMA” in the LTE standard.

Orthogonal frequency-division multiplexing (OFDM) is a method of digital signal modulation in which a single data stream is split across several separate narrowband channels at different frequencies to reduce interference and crosstalk. The original data stream bits -- that in a conventional single-channel modulation scheme would be sent serially (one after the other) -- are transmitted in parallel (several at once on separate channels) but at lower speed in each substream (a stream within another stream) relative to the original signal. This means symbols sent in the substreams are longer and spaced farther apart. In the original stream, each bit might be represented by a 1-nanosecond (ns) segment of the signal, with 0.25 ns spacing between bits. Splitting the signal across four component streams lets each bit be represented by 4 ns of the signal with 1ns spacing between. This reduces interference among symbols and makes it easier to receive each symbol accurately while maintaining the same throughput (in this example, 4 bits every 5 ns).

OFDM technology was first conceived in the 1960s and 1970s during research into minimizing interference among channels near each other in frequency and to achieve clean data transmission in situations prone to interference and signal corruption when more conventional modulation schemes are used.

OFDM is used in Wi-Fi, DSL internet access, 4Gwireless communications, and digital television and radio broadcast services

Orthogonal Frequency Division Multiplexing (OFDM) is a special form of multi-carrier modulation, patented in 1970. It is particularly suited for transmission over a dispersive channel. (See further discussion of MCM over the wireless channel.)

In a multipath channel, most conventional modulation techniques are sensitive to intersymbol interference unless the channel symbol rate is small compared to the delay spread of the channel. OFDM is significantly less sensitive to intersymbol interference because a special set of signals is used to build the composite transmitted signal. The basic idea is that each bit occupies a frequency-time window which ensures little or no distortion of the waveform. In practice, it means that bits are transmitted in parallel over several frequency-nonselective channels. Applications of OFDM are found in

- Digital Audio Broadcasting (DAB) and
- Digital Video Broadcasting over the terrestrial network: Digital Terrestrial Television Broadcasting (DTTB). In the DTTB OFDM transmission standard, about 2,000 to 8,000 subcarriers are used.
- UMTS. The UMTS Forum is selecting an appropriate radio solution for the third generation mobile standard, as a successor to GSM. OFDM is one of the five competing proposals.
- Wireless LANs. OFDM is used in HIPERLAN Phase II, which supports 20 Mbit/s in propagation environments with delay spreads up to 1 second.

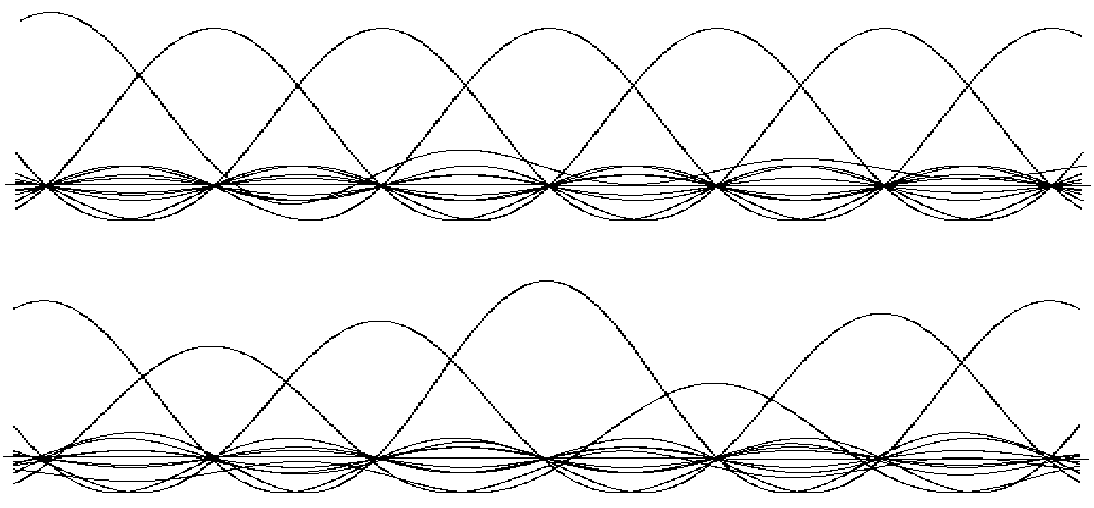

Figure 4.6 : Signal spectrum of an OFDM signal

which consists of the spectra of many bits, in parallel. Rectangular pulses in the time domain produce sinc-functions in the frequency domain.

- above: signal spectrum as transmitted.
- Below: as received in over a dispersive, time-invariant channel.

The effect of multipath scattering on OFDM differs from what happens to other forms of modulation. A qualitative description and mathematical description of OFDM is presented by Dusan Matic. Jean-Paul Linnartz reviews the effects of a Doppler spread and the associated rapid channel variations. Dusan Matic also studied the system design aspects of OFDM at mm-wavelengths.

4.2.1 CODED OFDM

Multi-Carrier Modulation on its own is not the solution to the problems of communication over unreliable multipath channels. The channel time dispersion will excessively attenuate some subcarriers such that the throughput on these sub-channels would be unacceptably small. Only if the joint signal of many subcarriers is processed appropriately, the diversity advantages of MCM can be exploited. The need for coding across subcarriers was addressed by Sari et al. warning against the overly enthusiastic pursuit of MCM. The advantages of frequency-domain implementations of equalizers (using an FFT) should not be mistaken for an "inherent" diversity gain of OFDM, which may not exist.

In an OFDM transmitter, blocks of k incoming bits are encoded into n channel bits. Before transmission, an n-point Inverse-FFT operation is performed. When the signals at the I-FFT output are transmitted sequentially, each of the n channel bits appears at a different (subcarrier) frequency. Such coding across subcarriers is necessary. If one subcarrier experiences deep fading, this leads to the erasure of the bit on this subcarrier.

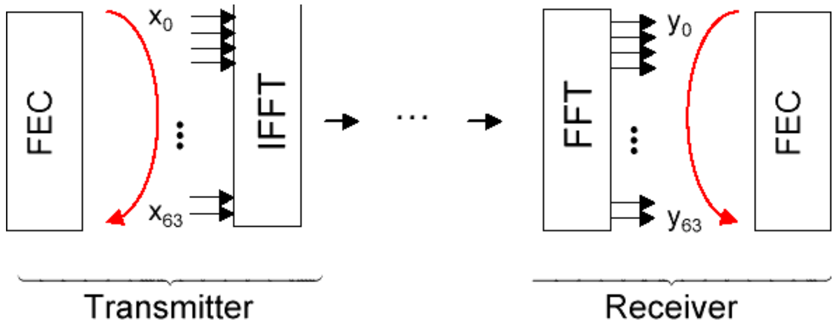

Figure 4.7 : OFDM Transmitter and Receiver

But of course, coding across subcarriers is not the only mechanism that can be invoked to combat dispersion or to exploit diversity. Other possibilities are

- Interleaving in frequency or time domain with coding in the other domain,
- The use of different signal constellations at different frequencies, i.e., adapting the subcarrier bit rate to the channel state,
- Signal to spread over various subcarriers, e.g., according to a linear matrix operation, as is proposed in Orthogonal Multi-Carrier Code Division Multiplexing.

If in a point-to-point MCM link, the receiver and the transmitter can cooperate by adaptively distributing their power budget over the individual subcarriers. For instance, the signal-to-noise ratios selected according to Gallager's water-pouring theorem can (under certain conditions) be proved to be optimum. Efficient loading of the various subcarriers can for instance significantly enhance the performance of MCM over twisted-pair telephone subscriber loops with crosstalk from other nearby copper pairs.

4.2.2 IMPLEMENTATIONAL ASPECTS

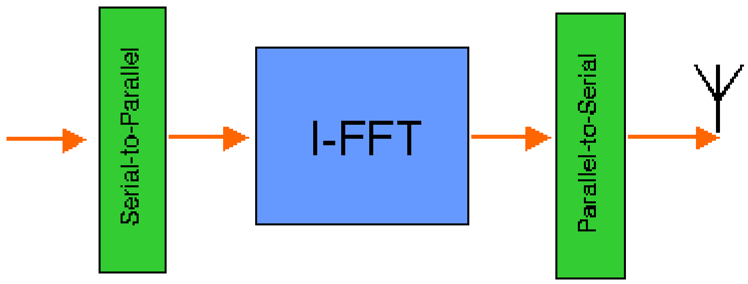

Figure 4.8 : OFDM transmitter using an (inverse) Fast Fourier Transform (FFT)

- OFDM is not a constant-envelope modulation method. Therefore transmit power amplifiers must be **highly linear**.

- OFDM receiver performance is very sensitive to phase noise.
- Synchronization to an OFDM signal also requires frame synchronization, to support an FFT operation at the receiver.

Single Frequency Networks:

OFDM allows very efficient frequency reuse. Transmitters broadcasting the same program can use the same frequency in a Single Frequency Network.

Code Division Multiple Access:

OFDM can be combined with CDMA transmission, e.g. in Multi-Carrier CDMA.
Channel Modeling:

Many channel simulation models follow the narrowband model. Wideband channels are often simulated by extending the model assuming multiple time-delayed resolvable paths. This allows the simulation of the channel impulse response, including its stochastic behaviour. To determine the performance of a multicarrier, OFDM or MC-CDMA system, another approach can be to model a set of fading subchannels. Considering a single subcarrier, the channel may be modelled as a narrowband fading channel, for instance with Rician or Rayleigh amplitude distributions. The collection of multiple subcarriers can be modelled as a set of mutually dependent fading channels. In such a model, it is important to address the correlation of the fading of various subchannels using the models of delay spread and coherence bandwidth. See a discussion of such a model. Also: read about the discrete-frequency model for OFDM with Delay spread and Doppler.

OFDM, Orthogonal Frequency Division Multiplexing is a form of signal waveform or modulation that provides some significant advantages for data links.

Accordingly, OFDM, Orthogonal Frequency Division Multiplexing is used for many of the latest wide bandwidth and high data rate wireless systems including Wi-Fi, cellular telecommunications and many more.

The fact that OFDM uses a large number of carriers, each carrying low bit rate data, means that it is very resilient to selective fading, interference, and multipath effects, as well as providing a high degree of spectral efficiency.

Early systems using OFDM found the processing required for the signal format was relatively high, but with advances in technology, OFDM presents few problems in terms of the processing required.

4.2.3 WHAT IS OFDM?

OFDM is a form of multicarrier modulation. An OFDM signal consists of several closely spaced modulated carriers. When modulation of any form - voice, data, etc. is applied to a carrier, then sidebands spread out either side. A receiver must be able to receive the whole signal to be able to successfully demodulate the data. As a result, when signals are transmitted close to one another they must be spaced so that the receiver can separate them using a filter and there must be a guard band between them. This is not the case with OFDM. Although the sidebands from each carrier overlap, they can still be received without the interference that might be expected because they are orthogonal to each other. This is achieved by having the carrier spacing equal to the reciprocal of the symbol period.

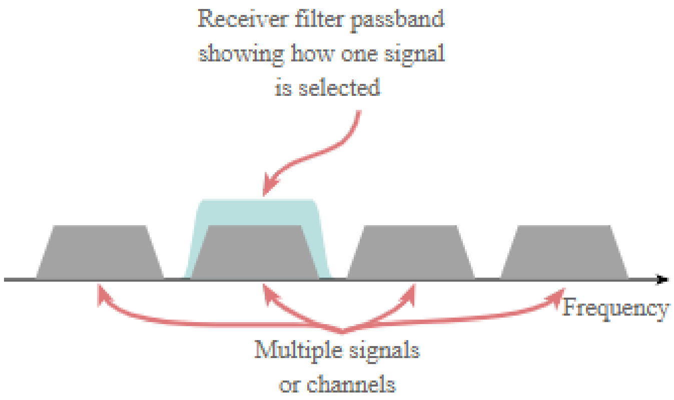

Figure 4.9 : Traditional Selection if signals on different channels

To see how OFDM works, it is necessary to look at the receiver. This acts as a bank of demodulators, translating each carrier down to DC. The resulting signal is integrated over the symbol period to regenerate the data from that carrier. The same demodulator also demodulates the other carriers. As the carrier spacing equal to the reciprocal of the symbol period means that they will have a whole number of cycles in the symbol period and their contribution will sum to zero - in other words, there is no interference contribution.

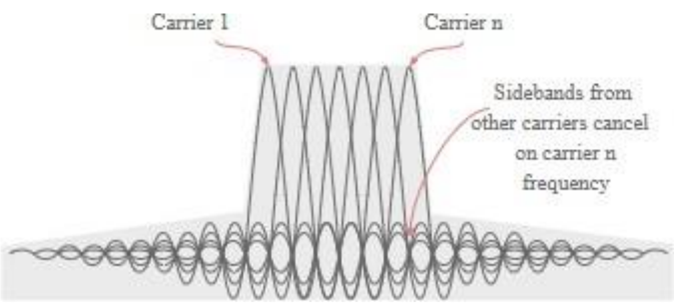

Figure 4.10 : Basic Concept of OFDM

One requirement of the OFDM transmitting and receiving systems is that they must be linear. Any non-linearity will cause interference between the carriers as a result of inter-modulation distortion. This will introduce unwanted signals that would cause interference and impair the orthogonality of the transmission. In terms of the equipment to be used the high peak to average ratio of multi-carrier systems such as OFDM requires the RF final amplifier on the output of the transmitter to be able to handle the peaks whilst the average power is much lower and this leads to inefficiency. In some systems the peaks are limited. Although this introduces distortion that results in a higher level of data errors, the system can rely on the error correction to remove them.

4.2.4 DATA ON OFDM

The data to be transmitted on an OFDM signal is spread across the carriers of the signal, each carrier taking part of the payload. This reduces the data rate taken by each carrier. The lower data rate has the advantage that interference from reflections is much less critical. This is achieved by adding a guard band time or guard interval into the system. This ensures that the data is only sampled when the signal is stable and no new delayed signals arrive that would alter the timing and phase of the signal.

4.2.5 GUARD INTERVAL ON OFDM SIGNALS

The distribution of the data across a large number of carriers in the OFDM signal has some further advantages. Nulls caused by multi-path effects or interference on a given frequency only affect a small number of the carriers, the remaining ones being received correctly. By using error-coding techniques, which does mean adding further data to the transmitted signal, it enables many or all of the corrupted data to be reconstructed within the receiver. This can be done because the error correction code is transmitted in a different part of the signal.

4.2.6 KEY FEATURES OF OFDM

The OFDM scheme differs from traditional FDM in the following interrelated ways:

- Multiple carriers (called subcarriers) carry the information stream
- The subcarriers are orthogonal to each other.
- A guard interval is added to each symbol to minimize the channel delay spread and intersymbol interference.

4.2.7 OFDM ADVANTAGES & DISADVANTAGES

4.2.7.1 OFDM ADVANTAGES

OFDM has been used in many high data rate wireless systems because of the many advantages it provides.

- **Immunity to selective fading**: One of the main advantages of OFDM is that is more resistant to frequency selective fading than single carrier systems because it divides the overall channel into multiple narrowband signals that are affected individually as flat fading sub-channels.
- **Resilience to interference**: Interference appearing on a channel may be bandwidth limited and in this way will not affect all the sub-channels. This means that not all the data is lost.
- **Spectrum efficiency:** Using close-spaced overlapping sub-carriers, a significant OFDM advantage is that it makes efficient use of the available spectrum.
- **Resilient to ISI:** Another advantage of OFDM is that it is very resilient to inter-symbol and inter-frame interference. This results from the low data rate on each of the sub-channels.
- **Resilient to narrow-band effects:** Using adequate channel coding and interleaving it is possible to recover symbols lost due to the frequency selectivity of the channel and narrowband interference. Not all the data is lost.
- **Simpler channel equalisation:** One of the issues with CDMA systems was the complexity of the channel equalisation which had to be applied across the whole channel. An advantage of OFDM is that using multiple sub-channels, the channel equalization becomes much simpler.

4.2.7.2 OFDM DISADVANTAGES

Whilst OFDM has been widely used, there are still a few disadvantages to its use that need to be addressed when considering its use.

- **High peak to average power ratio**: An OFDM signal has a noise like amplitude variation and has a relatively high large dynamic range, or peak to average power ratio. This impacts the RF amplifier efficiency as the amplifiers need to be linear and accommodate the large amplitude variations and these factors mean the amplifier cannot operate with a high-efficiency level.
- **Sensitive to carrier offset and drift**: Another disadvantage of OFDM is that is sensitive to carrier frequency offset and drift. Single carrier systems are less sensitive.

OFDM, orthogonal frequency division multiplexing has gained a significant presence in the wireless marketplace.

The combination of high data capacity, high spectral efficiency, and its resilience to interference as a result of multi-path effects means that it is ideal for the high data applications that have become a major factor in today's communications scene. The use of cyclic prefix is a key element of enabling the OFDM signal to operate reliably.

4.2.8 WHAT IS A CYCLIC PREFIX?

The basic concept behind the OFDM cyclic prefix is quite straightforward. The cyclic prefix performs two main functions.

- The cyclic prefix provides a guard interval to eliminate intersymbol interference from the previous symbol.

It repeats the end of the symbol so the linear convolution of a frequency-selective multipath channel can be modelled as circular convolution, which in turn may transform to the frequency domain via a discrete Fourier transform. This approach accommodates simple frequency-domain processing, such as channel estimation and equalization.

Different OFDM cyclic prefix lengths are available in various systems. For example within LTE a normal length and an extended length are available and after Release 8 a third extended length is also included, although not normally used.

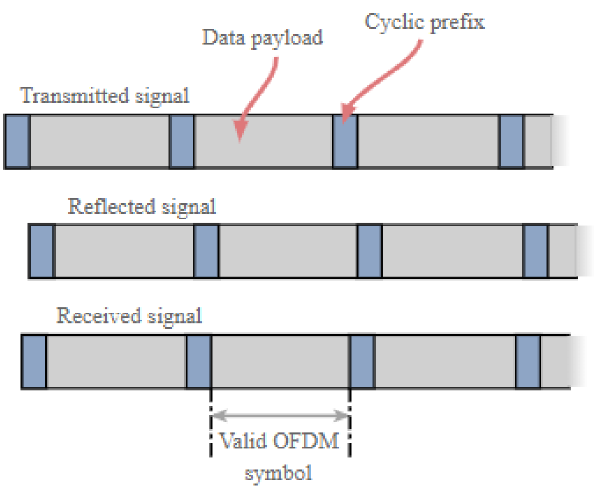

Figure 4.11 : OFDM Cyclic Prefix

4.2.9 CYCLIC PREFIX ADVANTAGES AND DISADVANTAGES

There are several advantages and disadvantages attached to the user for the cyclic prefix within OFDM.

4.2.9.1 ADVANTAGES

- **Provides robustness**: The addition of the cyclic prefix adds robustness to the OFDM signal. The data that is retransmitted can be used if required.
- **Reduces inter-symbol interference**: The guard interval introduced by the cyclic prefix enables the effects of inter-symbol interference to be reduced.

4.2.9.2 DISADVANTAGES

- **Reduces data capacity**: As the cyclic prefix re-transmits data that is already being transmitted, it takes up system capacity and reduces the overall data rate.

The use of a cyclic prefix is standard within OFDM and it enables the performance to be maintained even under conditions when levels of reflections and multipath propagation are high. One of the key requirements for optimum demodulation of OFDM signals is that there is the accurate frequency and timing synchronisation. Fortunately, good OFDM timing and frequency synchronisation are relatively easy to obtain as accurate signals are easy to derive.

Poor timing and frequency synchronisation result in significant levels of degradation to the signal, and as a result, this aspect of the signal chain is key to optimum performance.

4.2.10 OFDM SYNCHRONIZATION BASICS:

OFDM offers many advantages in terms of resilience to fading, reflections and the like. OFDM also offers a high level of spectrum efficiency. However to reap the rewards, it is necessary that the OFDM system operates correctly, and to achieve this, the OFDM synchronization must be effective.

There are many areas in which OFDM synchronisation is critical to the operation of the system:

- OFDM synchronization in terms of frequency offset: The frequencies must be accurately tracked to ensure that orthogonality is maintained.
- OFDM synchronisation in terms of clock accuracy: It is necessary that the sampling occurs at the correct time interval to ensure that the samples are synchronized and data errors are minimised. To ensure that the OFDM system works to its optimum, it is necessary to

ensure that there are schemes in place to ensure the OFDM synchronization is within the required limits.

4.2.11 FREQUENCY OFFSET OFDM SYNCHRONIZATION:

The demodulator in an OFDM receiver must be able to synchronize accurately with the carriers within the OFDM signal. Offsets may arise for many reasons including any frequency errors between the transmitter and the receiver and also as a result of Doppler shifts if there is movement between the transmitter and receiver.

If the frequency synchronisation is impaired, then the orthogonality of the carriers is reduced within the demodulation process and error rates increase. Accordingly, it is essential to maintain orthogonality to reduce errors and maintain the performance of the link.

First look at the way that sampling should occur. With the demodulator in synchronisation, all the contributions from the other carriers sum to zero as shown. In this way all the carriers are orthogonal and the error rate is at its minimum.

OFDM demodulation showing how the interference from other carriers is minimised at the centre of the carrier frequency. If a situation is encountered where the OFDM synchronisation for the frequency aspects are poor, then the demodulator will centre its samples away from the peak of the signal, and also at a point where the contributions from the other signals do not sum to zero. This will lead to a degradation of the signal which could, in turn, lead to an increase in the number of bit errors. OFDM demodulation where interference is high due to poor frequency synchronisation.

4.2.12 CLOCK OFFSET OFDM SYNCHRONIZATION

It is also necessary to maintain OFDM synchronization in terms of the clock. Gain if the clock synchronisation is not accurate, sampling will be offset and again orthogonality will be reduced, and data errors will increase.

When looking at OFDM synchronization concerning the clock offset, the carrier spacing used within the receiver for sampling the received signal will be based upon the internal clock rate. If this differs from that used within the transmitter, it will be found that even if the first carrier within the multiplex is correct, then there will be a growing discrepancy with each carrier away from the first one. Even small levels of discrepancy will cause the error rate to increase.

OFDM demodulation with clock synchronization misalignment: When using OFDM it is necessary to ensure that the synchronisation for both timing and frequency is accurate. By ensuring accurate synchronisation, it is possible to perform the optimum demodulation of the signal. Any misalignment causes the receiver to start to pick up the unwanted interference signals. Fortunately, it is relatively easy to obtain accurate synchronisation signals as these are available from the network, and short term synchronisation can be generated internally.

In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a method of encoding digital data on multiple carrier frequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G mobile communications.

In coded orthogonal frequency-division multiplexing (COFDM), forward error correction (convolutional coding) and time/frequency interleaving are applied to the signal being transmitted. This is done to overcome errors in mobile communication channels affected by multipath propagation and Doppler effects. COFDM was introduced by Alard in 1986 [1] [2][3] for Digital Audio Broadcasting for Eureka Project 147. In practice, OFDM has become used in combination with such coding and interleaving, so that the terms COFDM and OFDM co-apply to common applications.[4]

OFDM is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. OFDM was introduced by Chang of Bell Labs in 1966.[5][6][7] Numerous closely spaced orthogonal sub-carrier signals with overlapping spectra are emitted to carry data.[8] Demodulation is based on Fast Fourier Transform algorithms. OFDM was improved by Weinstein and Ebert in 1971 with the introduction of a guard interval, providing better orthogonality in transmission channels affected by multipath propagation.[9] Each sub-carrier (signal) is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate. This maintains total data rates similar to conventional single-carrier modulation schemes in the same bandwidth.

The main advantage of OFDM over single-carrier schemes is its ability to cope with severe channel conditions (for example, attenuation of high frequencies in a long copper wire, narrowband interference and frequency-selective fading due to multipath) without complex equalization filters. Channel equalization is simplified because OFDM may be viewed as using many slowly modulated narrowband signals rather than one rapidly modulated wideband signal. The low symbol rate makes the use of a guard interval between symbols affordable, making it possible to eliminate intersymbol interference (ISI) and use echoes and time-spreading (in analog television visible as ghosting and blurring, respectively) to achieve a diversity gain, i.e. a signal-to-noise ratio improvement. This mechanism also facilitates the design of single frequency networks (SFNs) where several adjacent transmitters send the same signal simultaneously at the same frequency, as the signals from multiple distant transmitters may be re-combined constructively, sparing interference of a traditional single-carrier system.

4.2.13 ORTHOGONALITY

Conceptually, OFDM is specialized frequency-division multiplexing (FDM) method, with the additional constraint that all subcarrier signals within a communication channel are orthogonal to one another.

In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that cross-talk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

The orthogonality requires that the sub-carrier spacing is Hertz, where T_U seconds is the useful symbol duration (the receiver-side window size), and k is a positive integer, typically equal to 1. This stipulates that each carrier frequency undergoes k more complete cycles per symbol period than the previous carrier. Therefore, with N sub-carriers, the total passband bandwidth will be $B = N*\Delta f$ (Hz).

The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e. near half the Nyquist rate for the double-sideband physical passband signal). Almost the whole available frequency band can be used. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users.

A simple example: A useful symbol duration T_U = 1 ms would require a sub-carrier spacing of (or an integer multiple of that) for orthogonality. N = 1,000 sub-carriers would result in a total passband bandwidth of $N\Delta f$ = 1 MHz. For this symbol time, the required bandwidth in theory according to Nyquist is (half of the achieved bandwidth required by our scheme), where R is the bit rate and where N = 1,000 samples per symbol by FFT. If a guard interval is applied (see below), the Nyquist bandwidth requirement would be even lower. The FFT would result in N = 1,000 samples per symbol. If no guard interval was applied, this would result in a baseband complex-valued signal with a sample rate of 1 MHz, which would require a baseband bandwidth of 0.5 MHz according to Nyquist. However, the passband RF signal is produced by multiplying the baseband signal with a carrier waveform (i.e., double-sideband quadrature amplitude-modulation) resulting in a passband bandwidth of 1 MHz. A single-sideband (SSB) or vestigial sideband (VSB) modulation scheme would achieve almost half that bandwidth for the same symbol rate (i.e., twice as high spectral efficiency for the same symbol alphabet length). It is however more sensitive to multipath interference.

OFDM requires very accurate frequency synchronization between the receiver and the transmitter; with frequency deviation the sub-carriers will no longer be orthogonal, causing inter-carrier interference (ICI) (i.e., cross-talk between the sub-carriers). Frequency offsets are typically caused by mismatched transmitter and receiver oscillators, or by Doppler shift due to movement. While Doppler shift alone may be compensated for by the receiver, the situation is worsened when combined with multipath, as reflections will appear at various frequency offsets, which is much harder to correct. This effect typically worsens as speed increases and is an important factor limiting the use of OFDM in high-speed vehicles. To mitigate ICI in such scenarios, one can shape each sub-carrier to minimize the interference resulting in a non-orthogonal subcarrier overlapping.[12] For example, a low-complexity scheme referred to as WCP-OFDM (Weighted Cyclic Prefix Orthogonal Frequency-Division Multiplexing) consists of using short filters at the transmitter output to perform a potentially non-rectangular pulse shaping and a near-perfect reconstruction using a single-tap per subcarrier equalization. Other ICI suppression techniques usually increase drastically the receiver complexity.

4.2.14 IMPLEMENTATION USING THE FFT ALGORITHM:

The orthogonality allows for efficient modulator and demodulator implementation using the FFT algorithm on the receiver side, and inverse FFT on the sender side. Although the principles and some of the benefits have been known since the 1960s, OFDM is popular for wideband communications today by way of low-cost digital signal processing components that can efficiently calculate the FFT.

The time to compute the inverse-FFT or FFT transform has to take less than the time for each symbol, which for example for DVB-T (FFT 8k) means the computation has to be done in 896 μs or less.

For an 8192-point FFT, this may be approximated to: MIPS = Million instructions per second

The computational demand approximately scales linearly with FFT size so a double size FFT needs double the amount of time and vice versa.[15]:83 As a comparison an Intel Pentium III CPU at 1.266 GHz can calculate an 8192 point FFT in 576 μs using FFTW. Intel Pentium M at 1.6 GHz does it in 387 μs Intel Core Duo at 3.0 GHz does it in 96.8 μs.

4.2.15 GUARD INTERVAL FOR THE ELIMINATION OF INTERSYMBOL INTERFERENCE

One key principle of OFDM is that since low symbol rate modulation schemes (i.e., where the symbols are relatively long compared to the channel time characteristics) suffer less from intersymbol interference caused by multipath propagation, it is advantageous to transmit several low-rate streams in parallel instead of a single high-rate stream. Since the duration of each symbol is long, it is feasible to insert a guard interval between the OFDM symbols, thus eliminating the intersymbol interference.

The guard interval also eliminates the need for a pulse-shaping filter, and it reduces the sensitivity to time synchronization problems.

The cyclic prefix, which is transmitted during the guard interval, consists of the end of the OFDM symbol copied into the guard interval, and the guard interval is transmitted followed by the OFDM symbol. The reason that the guard interval consists of a copy of the end of the OFDM symbol is so that the receiver will integrate over an integer number of sinusoid cycles for each of the multipath when it performs OFDM demodulation with the FFT.

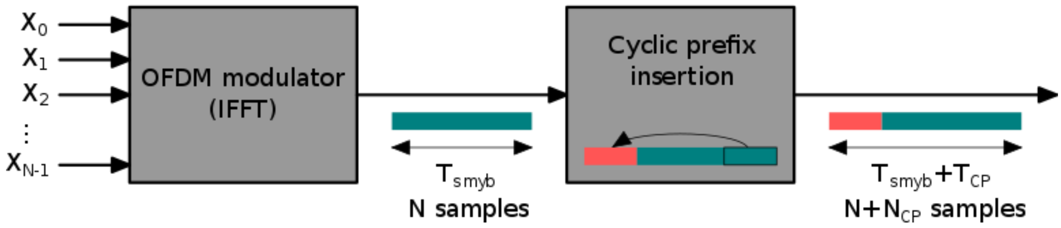

Figure 4.12 : OFDM Modulator

In some standards such as Ultrawideband, in the interest of transmitted power, a cyclic prefix is skipped and nothing is sent during the guard interval. The receiver will then have to mimic the cyclic prefix functionality by copying the end part of the OFDM symbol and adding it to the beginning portion.

4.2.16 SIMPLIFIED EQUALIZATION:

The effects of frequency-selective channel conditions, for example, fading caused by multipath propagation, can be considered as constant (flat) over an OFDM sub-channel if the sub-channel is sufficiently narrow-banded (i.e., if the number of sub-channels is sufficiently large). This makes frequency domain equalization possible at the receiver, which is far simpler than the time-domain equalization used in conventional single-carrier modulation.

In OFDM, the equalizer only has to multiply each detected sub-carrier (each Fourier coefficient) in each OFDM symbol by a constant complex number, or a rarely changed value. On a fundamental level, simpler digital equalizers are better because they require fewer operations, which translate to fewer round-off errors in the equalizer. Those round-off errors can be viewed as numerical noise and are inevitable.

Our example: The OFDM equalization in the above numerical example would require one complex-valued multiplication per subcarrier and symbol (i.e., complex multiplications per OFDM symbol; i.e., one million multiplications per second, at the receiver). The FFT algorithm requires [this is imprecise: over half of these complex multiplications are trivial, i.e. = to 1 and are not implemented in software or HW]. complex-valued multiplications per OFDM symbol (i.e., 10 million multiplications per second), at both the receiver and transmitter side. This should be compared with the corresponding one million symbols/second single-carrier modulation case mentioned in the example, where the equalization of 125 microseconds time-spreading using an FIR filter would require, in a naive implementation, 125 multiplications per symbol (i.e., 125 million multiplications per second). FFT techniques can be used to reduce the number of multiplications for an FIR filter-based time-domain equalizer to a number comparable with OFDM, at the cost of delay between reception and decoding which also becomes comparable with OFDM.

If differential modulation such as DPSK or DQPSK is applied to each sub-carrier, equalization can be completely omitted, since these non-coherent schemes are insensitive to slowly changing amplitude and phase distortion.

In a sense, improvements in FIR equalization using FFTs or partial FFTs leads mathematically closer to OFDM, but the OFDM technique is easier to understand and implement, and the sub-channels can be independently adapted in other ways than varying equalization coefficients, such as switching between different QAM constellation patterns and error-correction schemes to match individual sub-channel noise and interference characteristics.

Some of the sub-carriers in some of the OFDM symbols may carry pilot signals for measurement of the channel condition (i.e., the equalizer gain and phase shift for each sub-carrier). Pilot signals and training symbols (preambles) may also be used for time synchronization (to avoid intersymbol interference, ISI) and frequency synchronization (to avoid inter-carrier interference, ICI, caused by Doppler shift).

OFDM was initially used for wired and stationary wireless communications. However, with an increasing number of applications operating in highly mobile environments, the effect of dispersive fading caused by a combination of multipath propagation and Doppler shift is more significant. Over the last decade, research has been done on how to equalize OFDM transmission over doubly selective channels.

4.2.17 CHANNEL CODING AND INTERLEAVING

OFDM is invariably used in conjunction with channel coding (forward error correction), and almost always uses frequency and/or time interleaving.

Frequency (subcarrier) interleaving increases resistance to frequency-selective channel conditions such as fading. For example, when a part of the channel bandwidth fades, frequency interleaving ensures that the bit errors that would result from those subcarriers in the faded part of the bandwidth are spread out in the bitstream rather than being concentrated. Similarly, time interleaving ensures that bits that are originally close together in the bit-stream are transmitted far apart in time, thus mitigating against severe fading as would happen when travelling at high speed.

However, time interleaving is of little benefit in slowly fading channels, such as for stationary reception, and frequency interleaving offers little to no benefit for narrowband channels that suffer from flat-fading (where the whole channel bandwidth fades at the same time).

The reason why interleaving is used on OFDM is to attempt to spread the errors out in the bit-stream that is presented to the error correction decoder, because when such decoders are presented with a high concentration of errors the decoder is unable to correct all the bit errors, and a burst of uncorrected errors occurs. A similar design of audio data encoding makes compact disc (CD) playback robust.

A classical type of error correction coding used with OFDM-based systems is convolutional coding, often concatenated with Reed-Solomon coding. Usually, additional interleaving (on top of the time and frequency interleaving mentioned above) in between the two layers of coding is implemented. The choice for Reed-Solomon coding as the outer error correction code is based on the observation that the Viterbi decoder used for inner convolutional decoding produces short error bursts when there is a high concentration of errors, and Reed-Solomon codes are inherently well suited to correcting bursts of errors.

Newer systems, however, usually now adopt near-optimal types of error correction codes that use the turbo decoding principle, where the decoder iterates towards the desired solution. Examples of such error correction coding types include turbo codes and LDPC codes, which perform close to the Shannon limit for the Additive White Gaussian Noise (AWGN) channel. Some systems that have implemented these codes have concatenated them with either Reed-Solomon (for example on the MediaFLO system) or BCH codes (on the DVB-S2 system) to improve upon an error floor inherent to these codes at high signal-to-noise ratios.

4.2.18 ADAPTIVE TRANSMISSION

The resilience to severe channel conditions can be further enhanced if information about the channel is sent over a return channel. Based on this feedback information, adaptive modulation, channel coding and power allocation may be applied across all sub-carriers, or individually to each sub-carrier. In the latter case, if a particular range of frequencies suffers from interference or attenuation, the carriers within that range can be disabled or made to run slower by applying more robust modulation or error coding to those sub-carriers.

The term discrete multitone modulation (DMT) denotes OFDM-based communication systems that adapt the transmission to the channel conditions individually for each sub-carrier, utilizing so-called bit-loading. Examples are ADSL and VDSL.

The upstream and downstream speeds can be varied by allocating either more or fewer carriers for each purpose. Some forms of rate-adaptive DSL use this feature in real-time, so that the bitrate is adapted to the co-channel interference and bandwidth is allocated to whichever subscriber needs it most.

4.2.19 OFDM EXTENDED WITH MULTIPLE ACCESS

OFDM in its primary form is considered as a digital modulation technique, and not a multi-user channel access method since it is used for transferring one-bit stream over one communication channel using one sequence of OFDM symbols. However, OFDM can be combined with multiple access using time, frequency or coding separation of the users.

In orthogonal frequency-division multiple access (OFDMA), frequency-division multiple access is achieved by assigning different OFDM sub-channels to different users. OFDMA supports differentiated quality of service by assigning a different number of sub-carriers to different users in a similar fashion as in CDMA, and thus complex packet scheduling or Media Access Control schemes can be avoided. OFDMA is used in: the mobility mode of the IEEE 802.16 Wireless MAN standard, commonly referred to as WiMAX,

- the IEEE 802.20 mobile Wireless MAN standard, commonly referred to as MBWA,
- the 3GPP Long Term Evolution (LTE) fourth-generation mobile broadband standard downlink. The radio interface was formerly named High-Speed OFDM Packet Access (HSOPA), now named Evolved UMTS Terrestrial Radio Access (E-UTRA).
- the now-defunct Qualcomm/3GPP2 Ultra Mobile Broadband (UMB) project, intended as a successor of CDMA2000, but replaced by LTE.
- OFDMA is also a candidate access method for the IEEE 802.22 Wireless Regional Area Networks (WRAN). The project aims at designing the first cognitive radio-based standard operating in the VHF-low UHF spectrum (TV spectrum).

In multi-carrier code division multiple access (MC-CDMA), also known as OFDM-CDMA, OFDM is combined with CDMA spread spectrum communication for coding separation of the users. Co-channel interference can be mitigated, meaning that manually fixed channel allocation (FCA) frequency planning is simplified, or complex dynamic channel allocation (DCA) schemes are avoided.

4.2.20 SPACE DIVERSITY

In OFDM-based wide-area broadcasting, receivers can benefit from receiving signals from several spatially dispersed transmitters simultaneously, since transmitters will only destructively interfere with each other on a limited number of sub-carriers, whereas in general, they will reinforce coverage over a wide area. This is very beneficial in many countries, as it permits the operation of national single-frequency networks (SFN), where many transmitters send the same signal simultaneously over the same channel frequency.

SFNs use the available spectrum more effectively than conventional multi-frequency broadcast networks (MFN), where program content is replicated on different carrier frequencies. SFNs also result in a diversity gain in receivers situated midway between the transmitters. The coverage area is increased and the outage probability decreased in comparison to an MFN, due to increased received signal strength averaged over all sub-carriers.

Although the guard interval only contains redundant data, which means that it reduces the capacity, some OFDM-based systems, such as some of the broadcasting systems, deliberately use a long guard interval to allow the transmitters to be spaced farther apart in an SFN, and longer guard intervals allow larger SFN cell-sizes. A rule of thumb for the maximum distance between transmitters in an SFN is equal to the distance a signal travels during the guard interval — for instance, a guard interval of 200 microseconds would allow transmitters to be spaced 60 km apart.

A single frequency network is a form of transmitter macro-diversity. The concept can be further used in dynamic single-frequency networks (DSFN), where the SFN grouping is changed from timeslot to timeslot.

OFDM may be combined with other forms of space diversity, for example, antenna arrays and MIMO channels. This is done in the IEEE 802.11 Wireless LAN standards.

4.2.21 LINEAR TRANSMITTER POWER AMPLIFIER

An OFDM signal exhibits a high peak-to-average power ratio (PAPR) because the independent phases of the sub-carriers mean that they will often combine constructively. Handling this high PAPR requires:

A high-resolution digital-to-analogue converter (DAC) in the transmitter A high-resolution analogue-to-digital converter (ADC) in the receiver A linear signal chain Any non-linearity in the signal chain will cause intermodulation distortion that Raises the noise floor May cause inter-carrier interference Generates out-of-band spurious radiation

The linearity requirement is demanding, especially for transmitter RF output circuitry where amplifiers are often designed to be non-linear to minimise power consumption. In practical OFDM systems, a small amount of peak clipping is allowed to limit the PAPR in a judicious trade-off against the above consequences. However, the transmitter output filter which is required to reduce out-of-band spurs to legal levels has the effect of restoring peak levels that were clipped, so clipping is not an effective way to reduce PAPR.

Although the spectral efficiency of OFDM is attractive for both terrestrial and space communications, the high PAPR requirements have so far limited OFDM applications to terrestrial systems. The crest factor CF (in dB) for an OFDM system with n uncorrelated sub-carriers is where CF is the crest factor (in dB) for each sub-carrier. (CF is 3.01 dB for the sine waves used for BPSK and QPSK modulation).

For example, the DVB-T signal in 2K mode is composed of 1705 sub-carriers that are each QPSK-modulated, giving a crest factor of 35.32 dB. Many crest factor reduction techniques have been developed.

The dynamic range required for an FM receiver is 120 dB while DAB only requires about 90 dB. As a comparison, each extra bit per sample increases the dynamic range by 6 dB.

The performance of any communication system can be measured in terms of its power efficiency and bandwidth efficiency. Power efficiency describes the ability of a communication system.

Transmission Type	M in M-QAM	No. of Subcarriers	Bit rate	Fiber length	Power at the receiver (at BER of 10^{-9})	Bandwidth efficiency
single carrier	64	1	10 Gbit/s	20 km	-37.3 dBm	6.0000
multicarrier	64	128	10 Gbit/s	20 km	-36.3 dBm	10.6022

Table 4.1: Transmission Types

There is only a 1 dBm increase in receiver power, but we get a 76.7% improvement in bandwidth efficiency by using the multicarrier transmission technique.

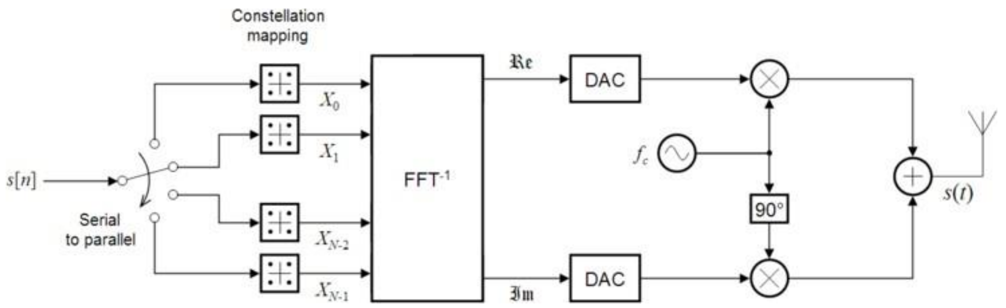

Figure 4.13 : Transmitter

An OFDM carrier signal is the sum of several orthogonal sub-carriers, with baseband data on each sub-carrier being independently modulated commonly using some type of quadrature amplitude modulation (QAM) or phase-shift keying (PSK). This composite baseband signal is typically used to modulate the main RF carrier.

OFDM is used by many powerline devices to extend digital connections through power wiring. Adaptive modulation is particularly important with such a noisy channel as electrical wiring. Some medium speed smart metering modems, "Prime" and "G3" use OFDM at modest frequencies (30–100 kHz) with modest numbers of channels (several hundred) to overcome the intersymbol interference in the power line environment. The IEEE 1901 standards include two incompatible physical layers that both use OFDM. The ITU-T G.hn standard, which provides high-speed local area networking over existing home wiring (power lines, phone lines and coaxial cables) is based on a PHY layer that specifies OFDM with adaptive modulation and a Low-Density Parity-Check (LDPC) FEC code.

An inverse FFT is computed on each set of symbols, giving a set of complex time-domain samples. These samples are then quadrature-mixed to passband in the standard way. The real and imaginary components are first converted to the analogue domain using digital-to-analogue converters (DACs); the analogue signals are then used to modulate cosine and sine waves at the carrier frequency, respectively. These signals are

then summed to give the transmission signal, .

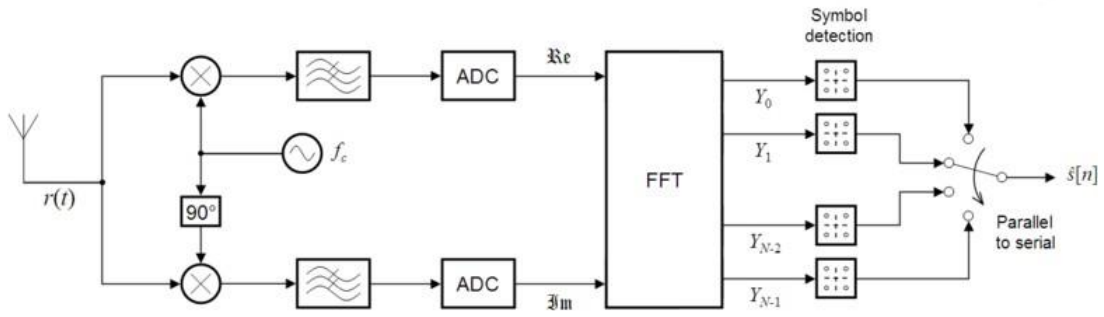

Figure 4.14 : Receiver

The receiver picks up the signal, which is then quadrature-mixed down to baseband using cosine and sine waves at the carrier frequency. This also creates signals centred on, so low-pass filters are used to reject these. The baseband signals are then sampled and digitised using analog-to-digital converters (ADCs), and a forward FFT is used to convert back to the frequency domain.

This returns parallel streams, each of which is converted to a binary stream using an appropriate symbol detector. These streams are then recombined into a serial stream, which is an estimate of the original binary stream at the transmitter.

4.2.22 ADSL

OFDM is used in ADSL connections that follow the ANSI T1.413 and G.dmt (ITU G.992.1) standards, where it is called discrete multitone modulation (DMT). DSL achieves high-speed data connections on existing copper wires. OFDM is also used in the successor standards ADSL2, ADSL2+, VDSL, VDSL2, and G.fast. ADSL2 uses variable sub-carrier modulation, ranging from BPSK to 32768QAM (in ADSL terminology this is referred to as bit-loading, orbit per tone, 1 to 15 bits per sub-carrier).

Long copper wires suffer from attenuation at high frequencies. The fact that OFDM can cope with this frequency-selective attenuation and with narrow-band interference are the main reasons it is frequently used in applications such as ADSL modems.

4.2.23 POWERLINE TECHNOLOGY

OFDM is used by many powerline devices to extend digital connections through power wiring. Adaptive modulation is particularly important with such a noisy channel as electrical wiring. Some medium speed smart metering modems, "Prime" and "G3" use OFDM at modest frequencies (30–100 kHz) with modest numbers of channels (several hundred) to overcome the intersymbol interference in the power line environment. The IEEE 1901 standards include two incompatible physical layers that both use OFDM. The ITU-T G.hn standard, which provides high-speed local area networking over existing home wiring (power lines, phone lines and coaxial cables) is based on a PHY layer that specifies OFDM with adaptive modulation and a Low-Density Parity-Check (LDPC) FEC code.

4.2.24 WIRELESS LOCAL AREA NETWORKS (LAN) AND METROPOLITAN AREA NETWORKS (MAN)

OFDM is extensively used in wireless LAN and MAN applications, including IEEE 802.11a/g/n and WiMAX.

IEEE 802.11a/g/n, operating in the 2.4 and 5 GHz bands, specifies per-stream airside data rates ranging from 6 to 54 Mbit/s. If both devices can use "HT mode" (added with 802.11n), the top 20 MHz per-stream rate is increased to 72.2 Mbit/s, with the option of data rates between 13.5 and 150 Mbit/s using a 40 MHz channel. Four different modulation schemes are used: BPSK, QPSK, 16-QAM, and 64-QAM, along with a set of error-correcting rates (1/2–5/6). The multitude of choices allows the system to adapt the optimum data rate for the current signal conditions.

4.2.25 WIRELESS PERSONAL AREA NETWORKS (PAN)

OFDM is also now being used in the WiMedia/Ecma-368 standard for high-speed wireless personal area networks in the 3.1–10.6 GHz ultrawideband spectrum (see MultiBand-OFDM).

- **Terrestrial digital radio and television broadcasting:**

Much of Europe and Asia have adopted OFDM for terrestrial broadcasting of digital television (DVB-T, DVB-H and T-DMB) and radio (EUREKA 147 DAB, Digital Radio Mondiale, HD Radio and T-DMB).

By Directive of the European Commission, all television services transmitted to viewers in the European Community must use a transmission system that has been standardized by a recognized European standardization body, and such a standard has been developed and codified by the DVB Project, Digital Video Broadcasting (DVB); Framing structure, channel coding and modulation for digital terrestrial television. Customarily referred to as DVB-T, the standard calls for the exclusive use of COFDM for modulation. DVB-T is now widely used in Europe and elsewhere for terrestrial digital TV.

- **SDARS**

The ground segments of the Digital Audio Radio Service (SDARS) systems used by XM Satellite Radio and Sirius Satellite Radio are transmitted using Coded OFDM (COFDM). The word "coded" comes from the use of forwarding error correction (FEC).

- **COFDM vs VSB**

The question of the relative technical merits of COFDM versus **8VSB** for terrestrial **digital television** has been a subject of some controversy, especially between European and North American technologists and regulators. The **United States** has rejected several proposals to adopt the COFDM-based **DVB-T** system for its digital television services and has instead opted for an **8VSB** (**vestigial sideband modulation**) operation.

One of the major benefits provided by COFDM is in rendering radio broadcasts relatively immune to multipath distortion and signal fading due to atmospheric conditions or passing aircraft. Proponents of COFDM argue it resists multipath far better than 8VSB. Early 8VSB DTV (digital television) receivers often had difficulty receiving a signal. Also, COFDM allows single-frequency networks, which is not possible with 8VSB.

However, newer 8VSB receivers are far better at dealing with multipath, hence the difference in performance may diminish with advances in equalizer design.

- **Digital radio**

COFDM is also used for other radio standards, for Digital Audio Broadcasting (DAB), the standard for digital audio broadcasting at VHF frequencies, for Digital Radio

Mondiale(DRM), the standard for digital broadcasting at shortwave and mediumwave frequencies (below 30 MHz) and DRM+ a more recently introduced standard for digital audio broadcasting at VHF frequencies. (30 to 174 MHz)

The USA again uses an alternate standard, a proprietary system developed by iBiquity dubbed HD Radio. However, it uses COFDM as the underlying broadcast technology to add digital audio to AM (medium wave) and FM broadcasts.

Both Digital Radio Mondiale and HD Radio are classified as in-band on-channel systems, unlike Eureka 147 (DAB: Digital Audio Broadcasting) which uses separate VHF or UHF frequency bands instead.

- **BST-OFDM used in ISDB**

The band-segmented transmission orthogonal frequency division multiplexing (BST-OFDM) system proposed for Japan (in the ISDB-T, ISDB-TSB, and ISDB-C broadcasting systems) improves upon COFDM by exploiting the fact that some OFDM carriers may be modulated differently from others within the same multiplex. Some forms of COFDM already offer this kind of hierarchical modulation, though BST-OFDM is intended to make it more flexible. The 6 MHz television channel may therefore be "segmented", with different segments being modulated differently and used for different services.

It is possible, for example, to send an audio service on a segment that includes a segment composed of many carriers, a data service on another segment and television service on yet another segment—all within the same 6 MHz television channel. Furthermore, these may be modulated with different parameters so that, for example, the audio and data services could be optimized for mobile reception, while the television service is optimized for stationary reception in a high-multipath environment.

- **ULTRA-WIDEBAND**

Ultra-wideband (UWB) wireless personal area network technology may also use OFDM, such as in Multiband OFDM (MB-OFDM). This UWB specification is advocated by the WiMedia Alliance (formerly by both the Multiband OFDM Alliance [MBOA] and the WiMedia Alliance, but the two have now merged), and is one of the competing UWB radio interfaces.

- **FLASH-OFDM**

Fast low-latency access with seamless handoff orthogonal frequency division multiplexing (Flash-OFDM), also referred to as F-OFDM, was based on OFDM and also specified higher protocol layers. It was developed by Flarion, and purchased by Qualcomm in January 2006. Flash-OFDM was marketed as a packet-switched cellular bearer, to compete with GSM and 3G networks. As an example, 450 MHz frequency bands previously used by NMT-450 and C-Net C450 (both 1G analogue networks, now mostly decommissioned) in Europe are being licensed to Flash-OFDM operators.

In Finland, the license holder Digita began deployment of a nationwide "@450" wireless network in parts of the country in April 2007. It was purchased by Datame in 2011. In February 2012 Datame announced they would upgrade the 450 MHz networks to competing for CDMA2000 technology

Slovak Telekom in Slovakia offers Flash-OFDM connections with a maximum downstream speed of 5.3 Mbit/s, and a maximum upstream speed of 1.8 Mbit/s, with a coverage of over 70% of the Slovak population The Flash-OFDM network was switched off in the majority of Slovakia on 30 September 2015.

T-Mobile Germany used Flash-OFDM to backhaul Wi-Fi HotSpots on the Deutsche Bahn's ICE high-speed trains between 2005 and 2015, until switching over to UMTS and LTE.

American wireless carrier Nextel Communications field-tested wireless broadband network technologies including Flash-OFDM in 2005. Sprint purchased the carrier in 2006 and decided to deploy the mobile version of WiMAX, which is based on Scalable Orthogonal Frequency Division Multiple Access (SOFDMA) technology.

Citizens Telephone Cooperative launched a mobile broadband service based on Flash-OFDM technology to subscribers in parts of Virginia in March 2006. The maximum speed available was 1.5 Mbit/s. The service was discontinued on April 30, 2009.

OFDM has become an interesting technique for power line communications (PLC). In this area of research, a wavelet transform is introduced to replace the DFT as the method of creating orthogonal frequencies. This is due to the advantages wavelets offer, which are particularly useful on noisy power lines.

Instead of using an IDFT to create the sender signal, the wavelet OFDM uses a synthesis bank consisting of a -band transmultiplexer followed by the transform function.

On the receiver side, an analysis bank is used to demodulate the signal again. This bank contains an inverse transform followed by another -band trans-multiplexer. The relationship between both transform functions is

An example of W-OFDM uses the Perfect Reconstruction Cosine Modulated Filter Bank (PR-CMFB) and Extended Lapped Transform (ELT) is used for the wavelet TF. Thus, and are given as

- **Advantages over standard OFDM**

W-OFDM is an evolution of the standard OFDM, with certain advantages.

Mainly, the sidelobe levels of W-OFDM are lower. This results in less ICI, as well as greater robustness to narrowband interference. These two properties are especially useful in PLC, where most of the lines aren't shielded against EM-noise, which creates noisy channels and noise spikes.

A comparison between the two modulation techniques also reveals that the complexity of both algorithms remains approximately the same.

In a sense, improvements in FIR equalization using FFTs or partial FFTs leads mathematically closer to OFDM, but the OFDM technique is easier to understand and implement, and the sub-channels can be independently adapted in other ways than varying equalization coefficients, such as switching between different QAM constellation patterns and error-correction schemes to match individual sub-channel noise and interference characteristics.

Some of the sub-carriers in some of the OFDM symbols may carry pilot signals for measurement of the channel condition (i.e., the equalizer gain and phase shift for each sub-carrier). Pilot signals and training symbols (preambles) may also be used for time synchronization (to avoid intersymbol interference, ISI) and frequency synchronization (to avoid inter-carrier interference, ICI, caused by Doppler shift).

OFDM was initially used for wired and stationary wireless communications. However, with an increasing number of applications operating in highly mobile environments, the effect of dispersive fading caused by a combination of multipath propagation and Doppler shift is more significant. Over the last decade, research has been done on how to equalize OFDM transmission over doubly selective channels.

4.2.26 CHANNEL CODING AND INTERLEAVING

OFDM is invariably used in conjunction with channel coding (forward error correction), and almost always uses frequency and/or time interleaving.

Frequency (subcarrier) interleaving increases resistance to frequency-selective channel conditions such as fading. For example, when a part of the channel bandwidth fades, frequency interleaving ensures that the bit errors that would result from those subcarriers in the faded part of the bandwidth are spread out in the bitstream rather than being concentrated. Similarly, time interleaving ensures that bits that are originally close together in the bit-stream are transmitted far apart in time, thus mitigating against severe fading as would happen when travelling at high speed.

CHAPTER-5

RESULTS ANALYSIS

5.1 Results

To evaluate its performances, we will simulate the behaviour of the massive MIMO-OFDM-IM system with the classic user selection techniques (ordinary MIMO system with a reduced antenna number at the base station) namely the Greedy algorithm, Random beamforming and SUBF where there is only user transmitting in the cell.

In Figure 5.1, it is the classical case when M=2, the sum rates of ZF (with and without Greedy algorithm as selection method) and RBF (with randomly generated codebooks) are compared for various values of SNR; It is seen that ZF when using a Greedy method maintains a significant advantage over normal ZF, RBF, and SUBF. At a small value of SNR, both schemes of RBF and normal ZF perform similarly, but SUBF gives the poorest performance in comparison with the other schemas.

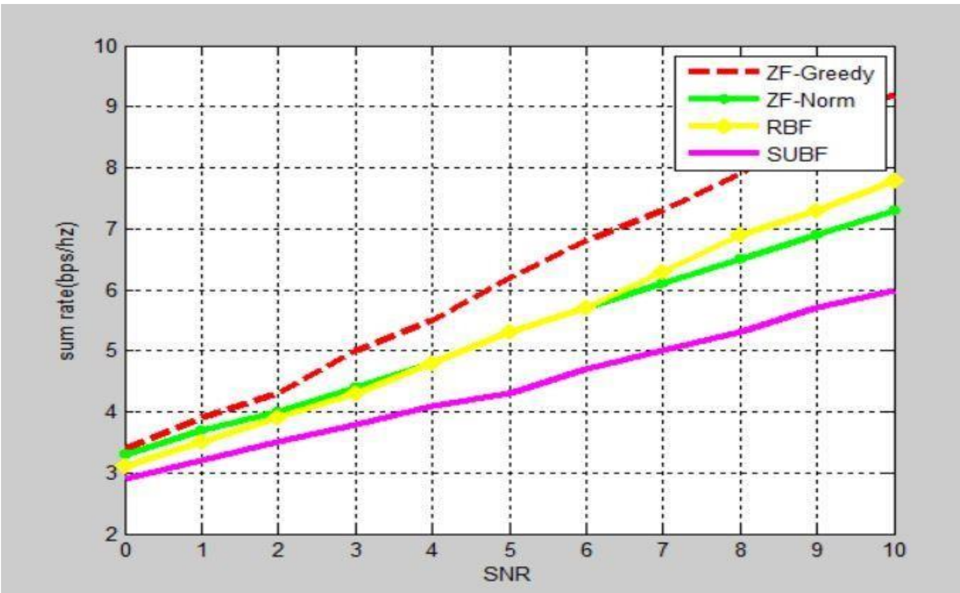

Figure 5.1 : Sum Rate vs SNR for M=2

In Figure 5.2, the same methods are simulated but for a large number of the antennas at the base station namely M = 50. We already notice the big difference between the case of a perfect CSIT and the beamforming random. Intuitively, the difference with perfect CSIT case in terms of sum rates is understandable if we consider the impact of the multiuser interference penalty term and the non-optimality of these algorithms on the other hand.

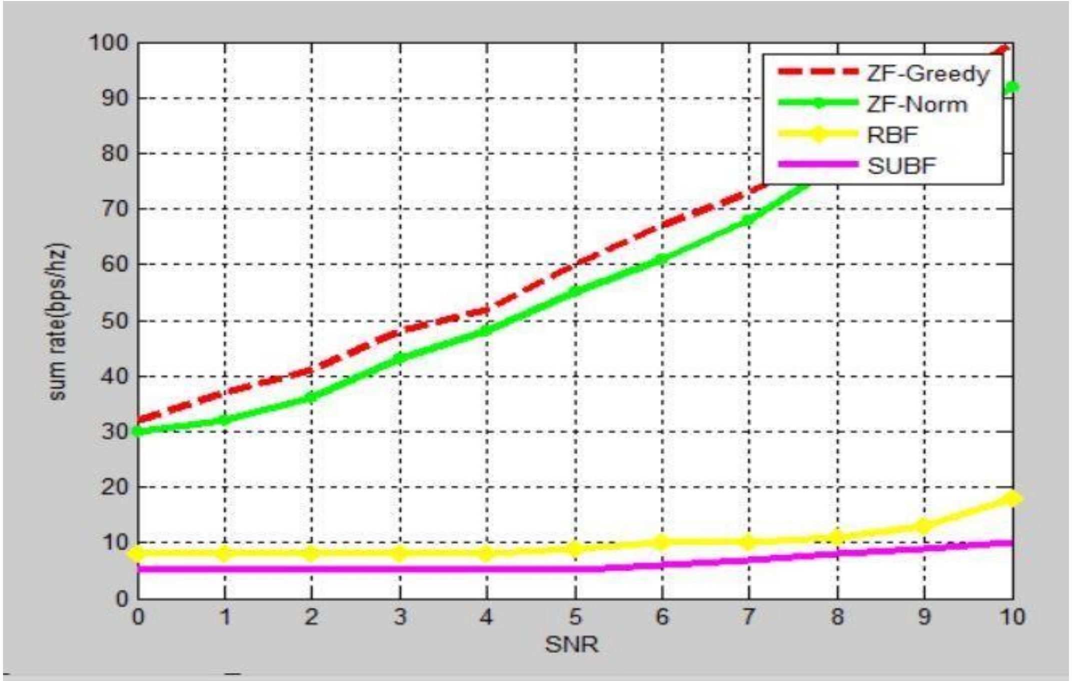

Figure 5.2 : Sum Rate vs SNR for M=50

Figure 5.3 compares the throughput of RBF and ZF for several values of M. The SNR = 10 dBm and feedback size is equal to T=100 bit. As observed from this figure, both RBF and SUBF achieves lower throughput than ZF over the range of M under consideration ($10 \leq M \leq 100$).

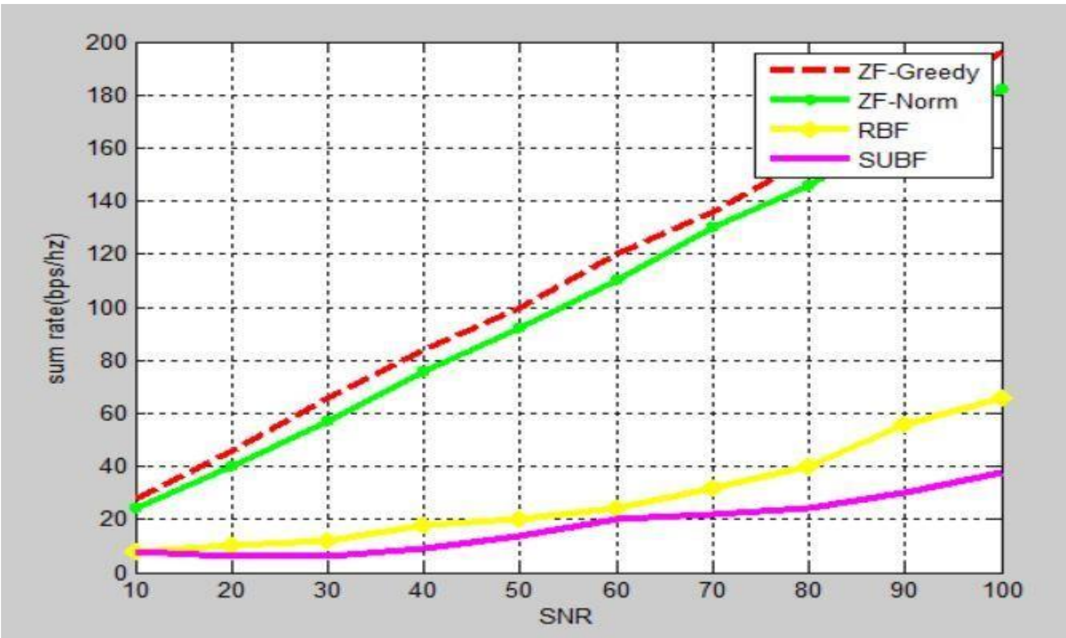

Figure 5.3 : Sum Rate vs Antenna Number; SNR=10, T=100

This should not prevent us from noticing the value of Sum rate in the case of a zero-forcing with the Greedy algorithm which resulted in a value almost equal to 200 bps / Hz for M = 100 which demonstrates the contribution of massive Mimo which intuitively waited.

5.2 Performance Evaluation

S.No	Parameters	Traditional MIMO-OFDM System	Massive MIMO-OFDM-IM
1	Antenna Number	≤8	≥100
2	Throughput	Low	High
3	Signal to Noise Ratio	Low	High
4	Data Rate	Low	High
5	Bit Error Rate	High	Low

Table 5.2: Performance Evaluation

CHAPTER 6

CONCLUSION

6.1 CONCLUSION

This project deals with the case of a downlink massive MIMO-OFDM-IM system in a single cell with a large number of users. Simulation results showed that the system efficiency in the sense of max rate is acceptable with the technique of zero-forcing except that it is very poor with the other classical techniques (like the RBF) especially if we consider the case of imperfect knowledge of the channel at the base station (which is the most realistic case already). These results are interpretable and explainable; indeed this is since that we did not take into account the spatial correlation between transmission antennas, which exists strongly considering a large number of antennas and consequently the minimal distance between them. In another part, pilot contamination has a major influence practically on spectral efficiency. Indeed, a massive MIMO system needs to estimate all the channels between the transmitter and the receivers. The number of these channels is much larger than in the case of conventional MIMO. We are more likely to have more pilots in MIMO systems which cause more interference between pilots as their distance is smaller in the case of MIMO. As perspectives, this aspect can be considered in future projects.

PUBLICATION

ic smec ece
to me

May 30, 2021, 12:11 AM

Dear Author(s),

Warm Greetings from St.Martins Engineering College.

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in the online mega International Conference on "Smart Modernistic in Electronics and Communication" (ICSMEC-21).

Paper ID:ICSMEC21-0033
Paper Title:Downlink user selection for massive MIMO-OFDM systems using ZF Preceding

Paper Accepted.

Please Send the final camera ready paper Paper After Registration

Please fill the below "**PAYMENT REGISTRATION FORM**" for completing registration process and follow the checklist to know what to attach to the mail to finish your registration process (**Mandatory to be completed within 5 days of receiving this mail**)

https://forms.gle/8zW1FvyK8XQFBiXQ9

Note: You are now requested to pay the conference registration fees at below mentioned details on or before 5 working days after receiving this email else your paper will not be considered for presentation as well as publication in the Journal. Follow the checklist given below for proceedings.

Account Details for Registration: (Current Account)
A/C Name: PRINCIPAL, St. Martin's Engineering College
Bank Name: SBI, Kukatpally, Hyderabad
Account No: 30667640268
IFSC code: SBIN0011664

Checklist to be followed after payment:

1. Final paper in MS Word and PDF (By mail)
2. Filled and scanned registration form

The project has been approved by international conference that is being conducted by out college i.e., ICSMEC-21 for publication.

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success**.**

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, our beloved **Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B. Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our department **Project Coordinator, Dr. A. Anand Kumar, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mrs. A. Soumya, Assistant Professor** Department of ECE and our project **Internal guide, Mrs. G. Vinatha, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

It has always been an arduous task for the election commission to conduct free and fair polls in our country, the largest democracy in the world. Crores of rupees have been spent on this to make sure that the elections are riot free. But, now- a -days it has become common for some forces to indulge in rigging which may eventually lead to a result contrary to the actual verdict given by the People.This project aims to present a new voting system employing biometrics in order to avoid rigging and to enhance the accuracy and speed of the process. The system uses thumb impression for voter identification as we know that the thumb impression of every human being has a unique pattern. Thus, it would have an edge over the present-day voting systems.

As a pre-poll procedure, a database consisting of the thumb impressions of all the eligible voters in a constituency is created. During elections, the thumb impression of a voter is entered as input to the system. This is then compared with the available records in the database. If the particular pattern matches with anyone in the available record, access to cast a vote is granted. But in case the pattern doesn't match with the records of the database or in case of repetition, access to cast a vote is denied or the vote gets rejected. Also, the police station nearby to the election poll booth is informed about the identity of the imposter.

LIST OF FIGURES

CHAPTER 1

INTRODUCTION

1.0 OVERVEIW OF THE PROJECT:

Biometrics is the science and technology of measuring and analyzing biological data. Biometrics refers to technologies that measure and analyze human body characteristics, such as DNA, fingerprints, eye retinas and irises, voice patterns, facial patterns and hand measurements, for authentication purposes. The field of biometrics was formed and has since expanded on to many types of physical identification. Among the several human fingerprints remain a very common identifier and the biometric method of choice among law enforcement. These concepts of human identification have lead to the development of fingerprint scanners that serve to quickly identify individuals and assign access privileges. The basic point of these devices is also to examine the fingerprint data of an individual and compare it to a database of other fingerprints . In our project we have used fingerprint for the purpose of voter identification or authentication. As the thumb impression of every individual is unique, it helps in minimizing the error. A database is created containing the fingerprint images of all the voters as required. Illegal votes and repetition of votes is checked for in this system with accurate coding. Hence with the application of this fingerprint based EVM system elections could be made fair and free from rigging. Further that the elections would are no longer a tedious and expensive job.

1.1 OBJECTIVES OF STUDY:

Tampering with the election process is not uncommon, even in some of the countries with strong rule of law. Ballot stuffing, voter suppression, multiple voting and destruction of legitimately cast ballot still covers the headlines of newspapers. Since every person has the unique fingerprint in this world, their fingerprint can be used to cast their vote with electronic fingerprint voting system. The proposed system is offline version. The finger-print voting system requires to register their fingerprint at the polling booth. The person can now vote on the Election Day just by verifying their identity using their fingerprint. The system uses Arduino and fingerprint technology. Voting does not 2 only include political but can be social, business and educational as well.

The development steps or method that outlines the way to achieve certain goal or in this case design and build a prototype Fingerprint voting system. In other words, it is a constructive framework. Below in figure , methodology flow block diagram of this project is shown.

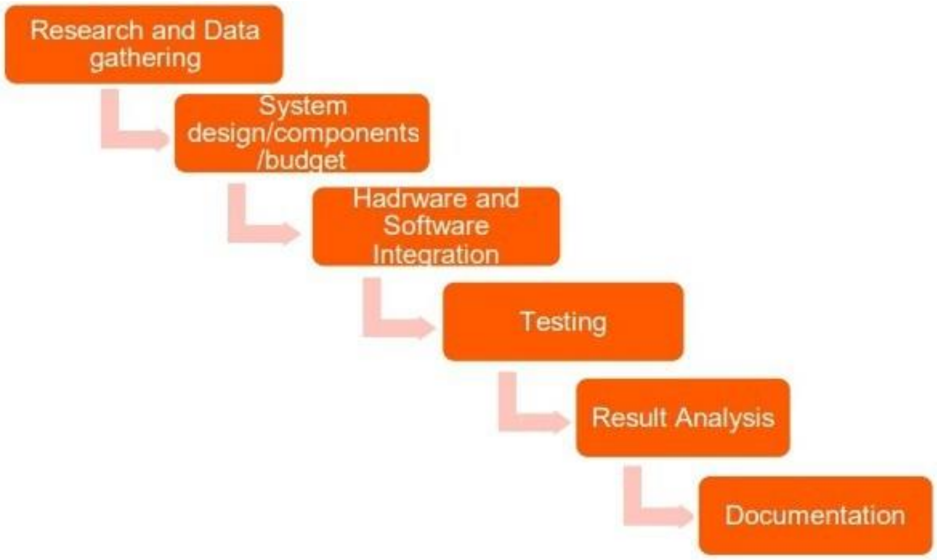

Fig 1.1: Flow diagram methodology

1.2 SCOPE OF THE STUDY:

Election is a feature of democratic government in which people govern themselves and are able to express their choices regarding various issues, such as constitutional amendments, piece of legislation or choosing the right person as their leader. An electoral system is present to layout the rules of the election. Political election is the most common form of election but there are many different fields where election is vital part of their organizational functions. Election is vital for business, informal organizations and nonprofit organizations. Election is the way of democratic world but conducting an election in fair manner has been the challenge of every electoral body especially in the country with high corruption, weak rule or law and less transparency. On the top of that conducting election cost millions and billions of dollars. This study report mainly focuses on developing a prototype of embedded system that deals with fingerprint voting system which can help in progression of election in robust and secure manner. The system integrates different hardware components like microcontroller, fingerprint module, LEDs, switches that facilitates a flawless voting system. For the implementation of this system, DY50 fingerprint sensor is used to take user finger print image and store in internal memory, these images are further processed and analyzed using Arduino. The user interface is implemented using LCD screen, which is mainly used to print user instructions during the execution of the voting process and the result.

1.3 MATERIALS REQUIREMENT:

1.3.1 HARDWARE COMPONENTS:

- ARDUINO UNO (ATMEGA328) MICROCONTROLLER BOARD

Fig:1.2 Arduino Uno board

- FINGER PRINT SCANNER ALONG WITH 3 PUSHBUTTONS

Fig:1.3 Fingerprint scanner

- LCD DISPLAY (16*2)

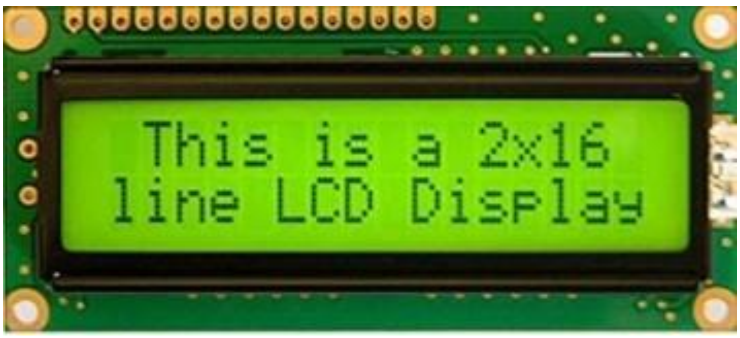

Fig:1.4 LCD Display

- POTENTIOMETER

Fig:1.5 POTENTIOMETER

- MB27L-12V PIEZO BUZZER

Fig:1.6 Piezo buzzer

1.3.2 SOFTWARE REQUIREMENTS:

1.3.2.1 ARDUINO IDE SOFTWARE:

This software is basically used for giving commands to ARDUNO Microcontroller**.**

STEPS FOR INSTALLING ARDUNO IDE SOFTWARE:

1. Download Arduino IDE Software in your PC.

2. When the download finishes, proceed with the installation.

3. Allow the driver installation process when you get a warning from the operating system.

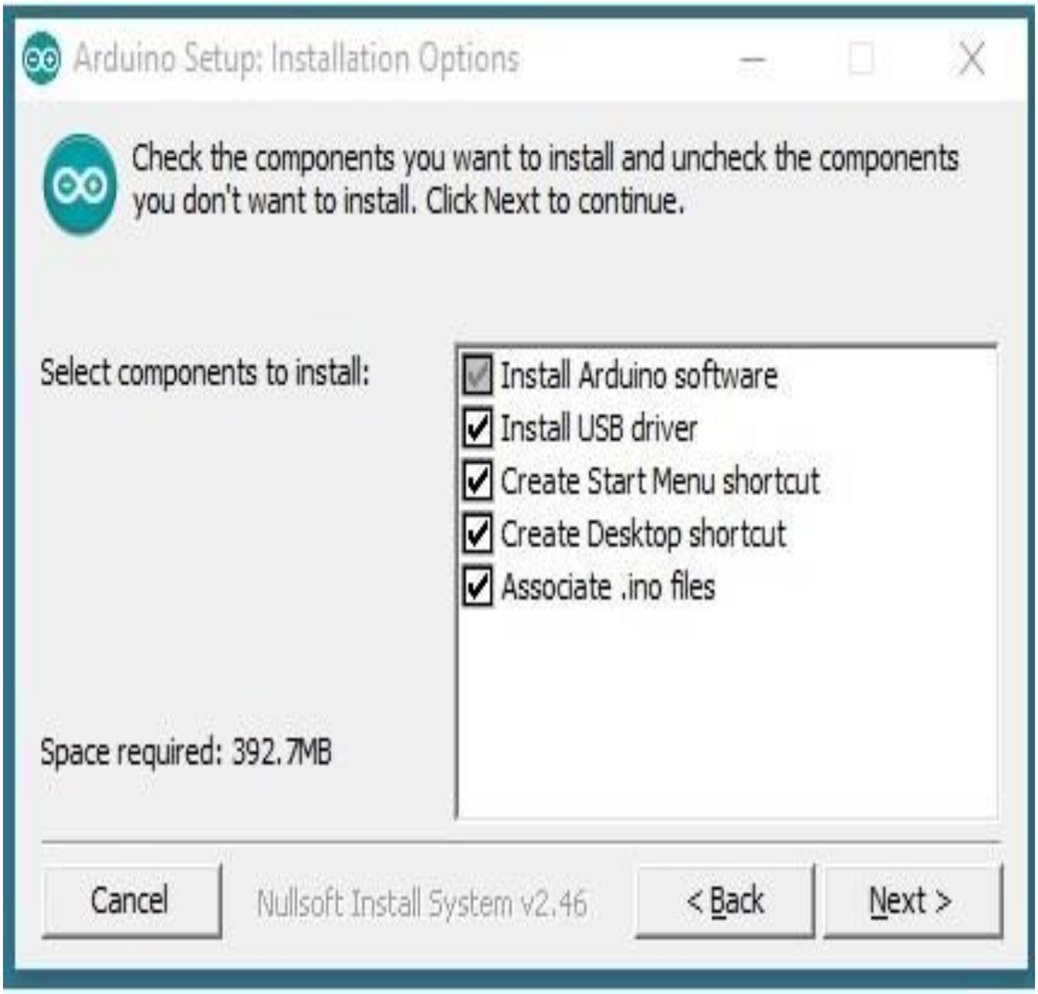

Fig:1.7 Installation process of driver

4. Choose the components to install

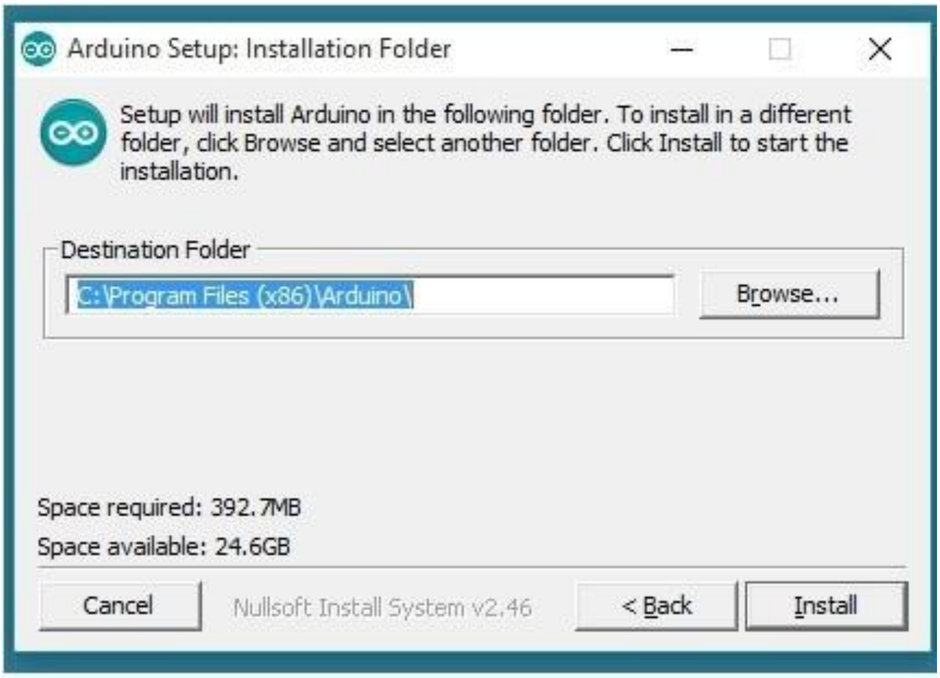

Fig 1.8 Setting destination folder

5. Choose the installation directory (we suggest to keep the default one)

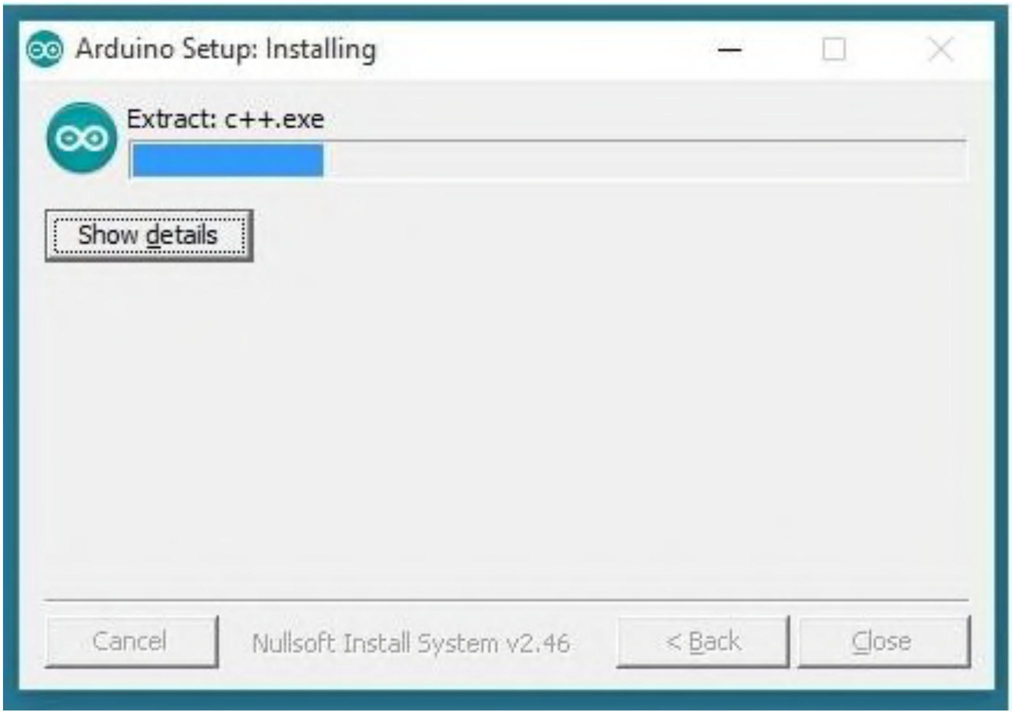

Fig:1.9 Installing directory

6. Successfully completed Installation of Software

7. Writing code on IDE platform

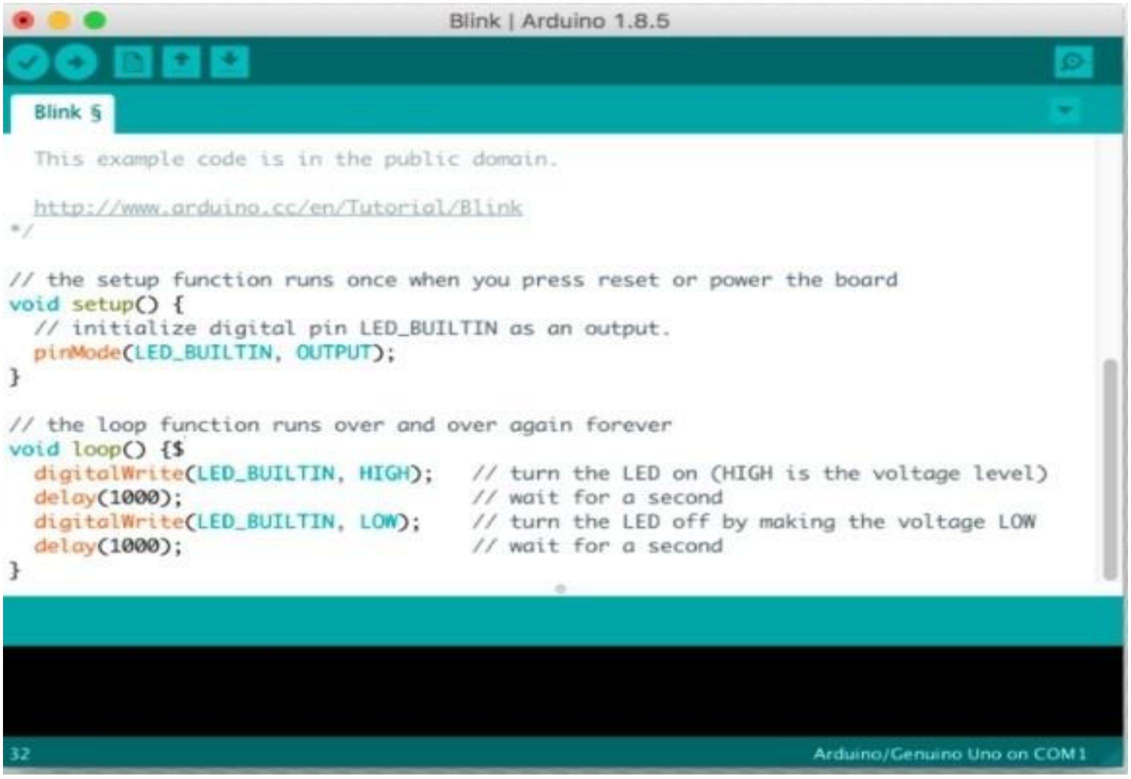

Fig:1.10 Source code written on IDE platform

1.3.2.2 PROTEUS SOFTWARE:

Through this software Schematic implementation of the embedded system will be done.

STEPS FOR DESIGNING SYSTEM ON PROTEUS DESIGN SUITE:

Step 1**:** Open ISIS software and select new design in File menu

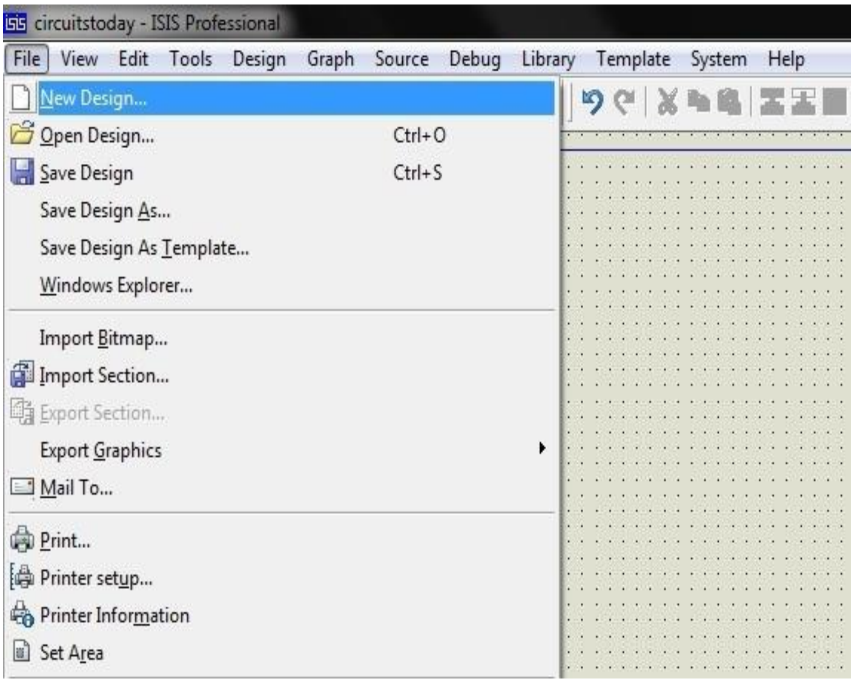

Fig:1.11 Simulation Procedure 1

Step 2**:** A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

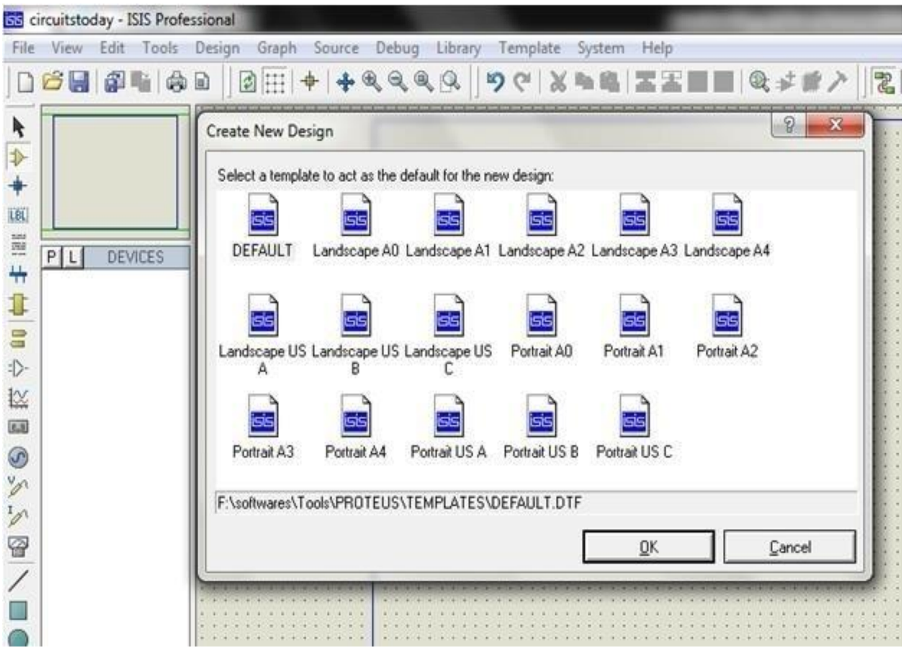

Fig:1.12 Simulation Procedure 2

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design.

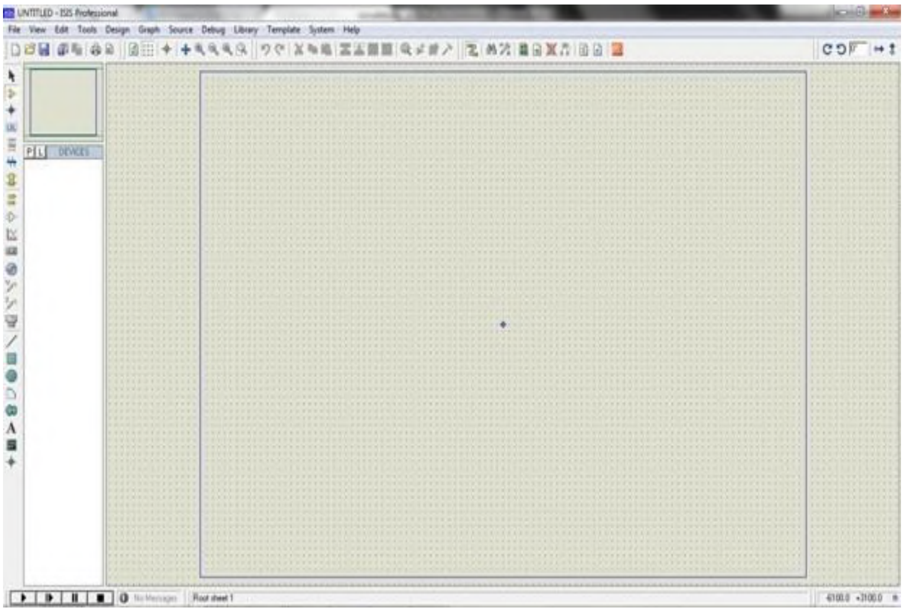

Fig:1.13 Simulation Procedure 3

Step 4: To Select components, Click on the component mode button.

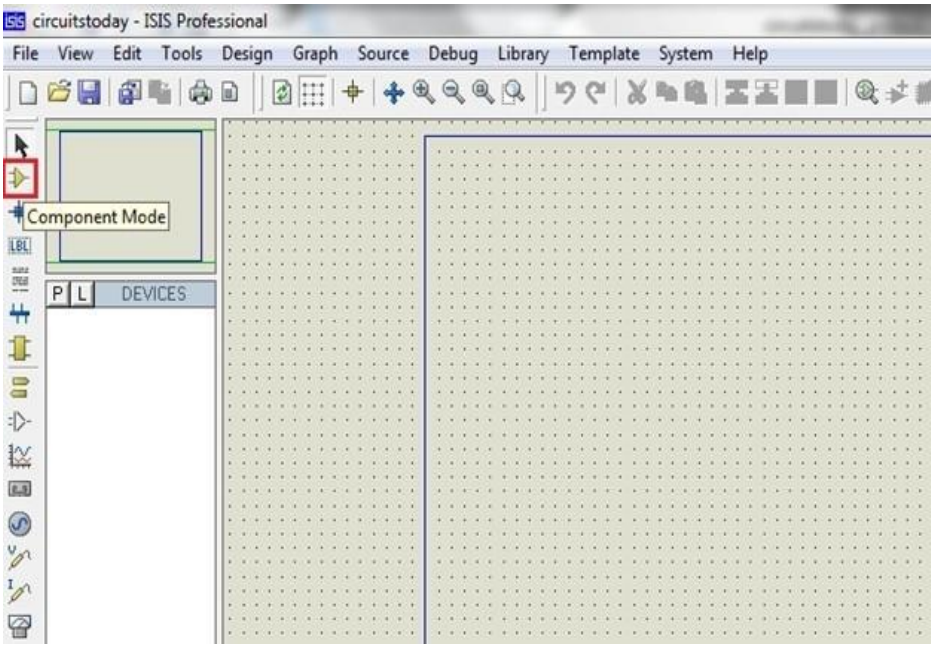

Fig:1.14 Simulation Procedure 4

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

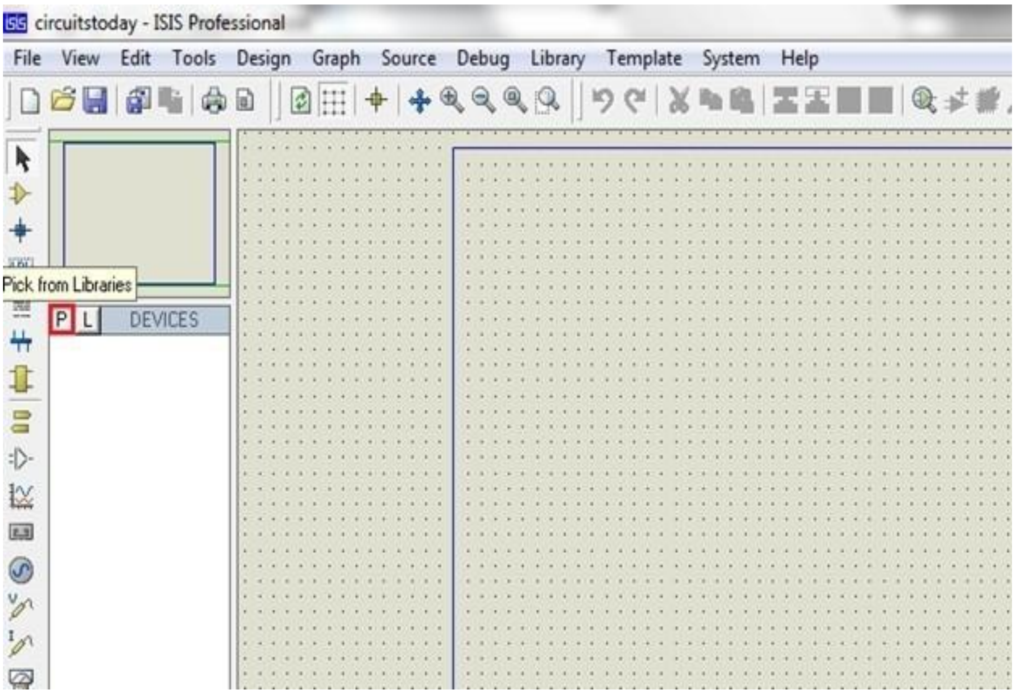

Fig:1.15 Simulation Procedure 5

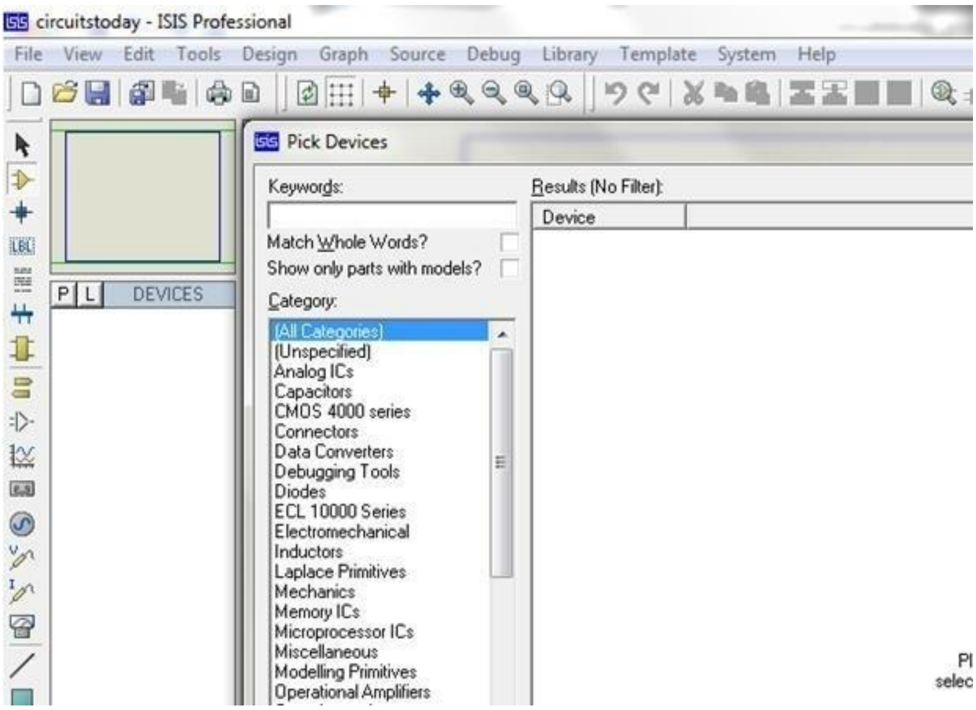
Fig:1.16 Simulation Procedure 6

Step 6: Select the components from categories or type the part name in Keyword's text box.



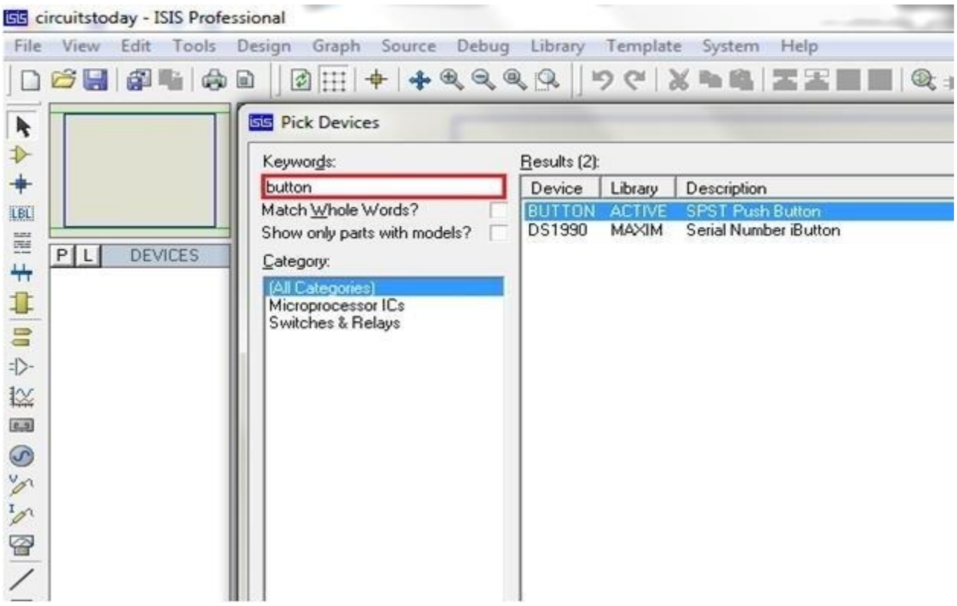


Fig:1.17 Simulation Procedure 7

Step 7**:** The selected components will appear in the devices list. Select the component and place it in the design sheet by left-cl.

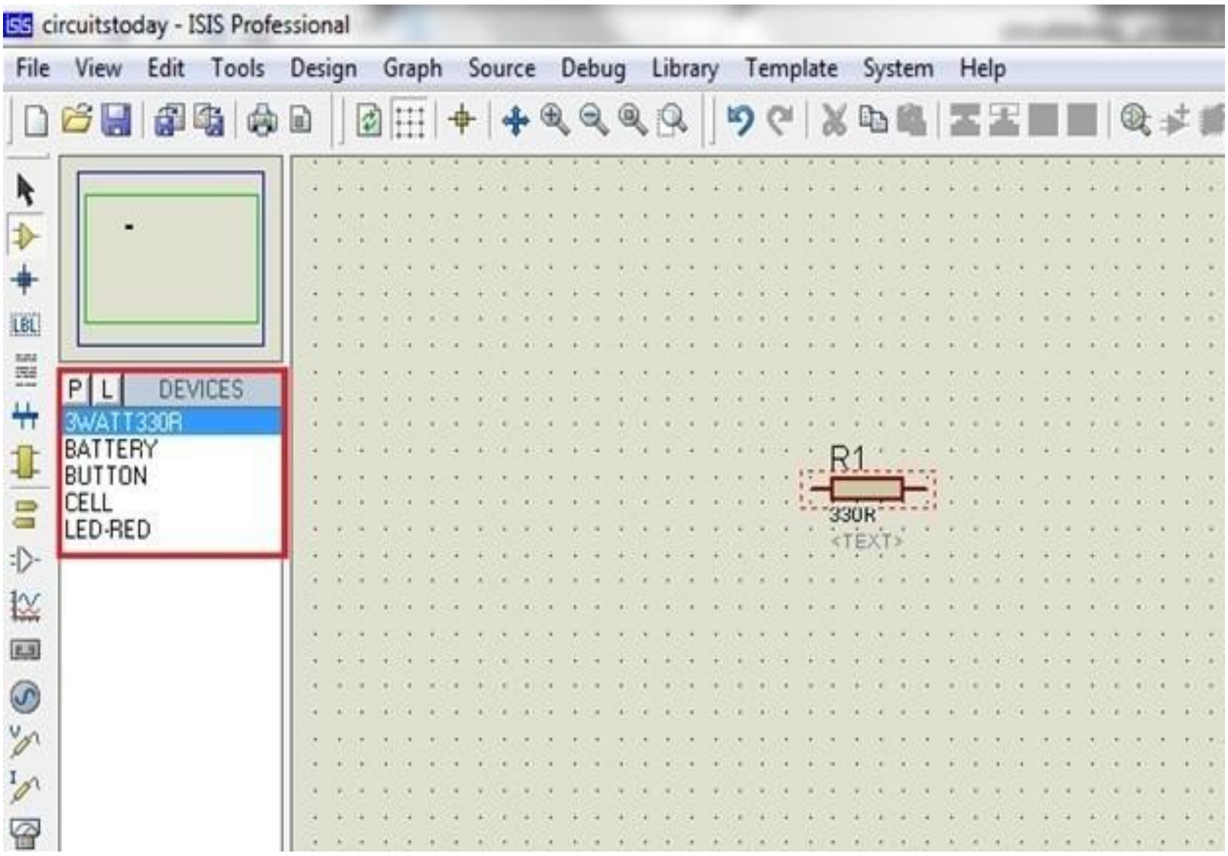

Fig:1.18 Simulation Procedure 8

Step 8: Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

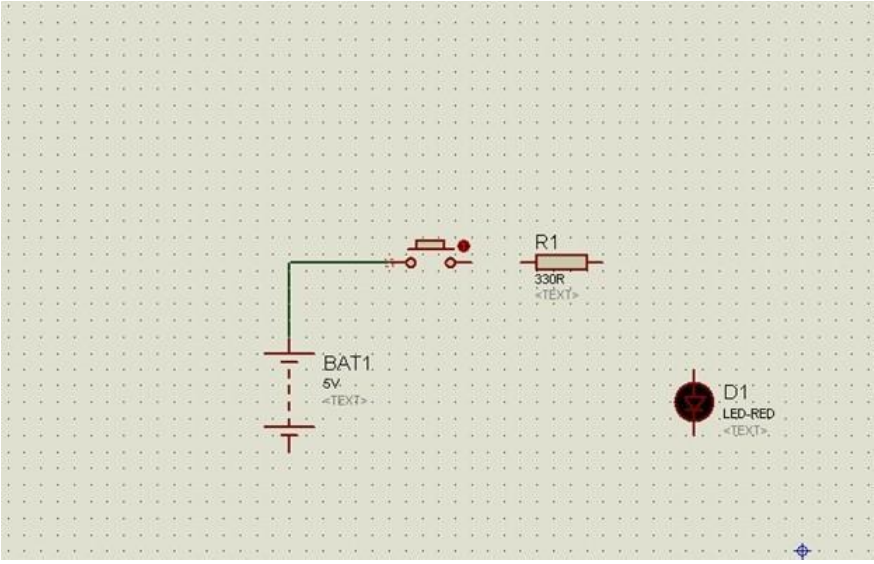

Fig:1.19 Simulation Procedure 9

Step 9: Double click on the component to edit the properties of the components and click on Ok.

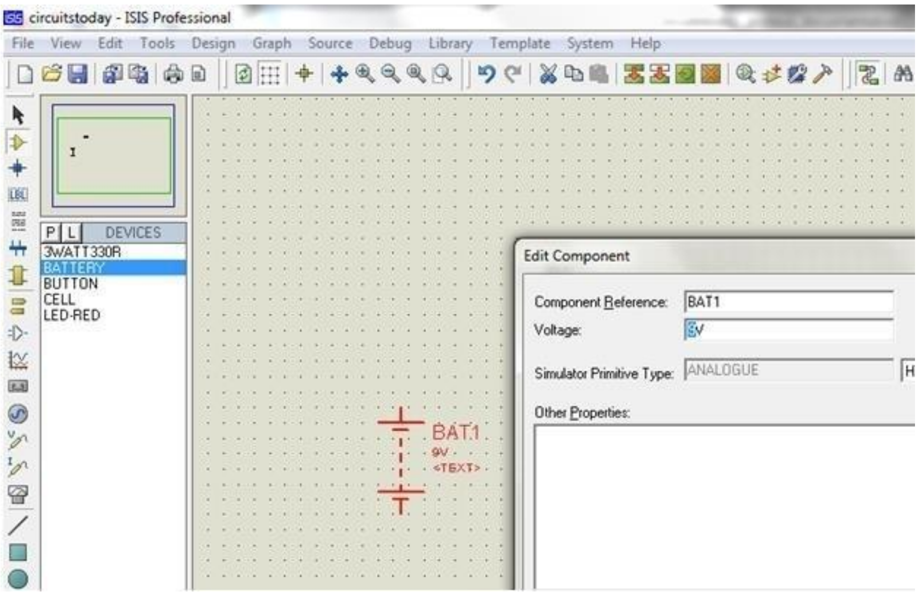

Fig.1.20 Simulation Procedure 10

Step 10: In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

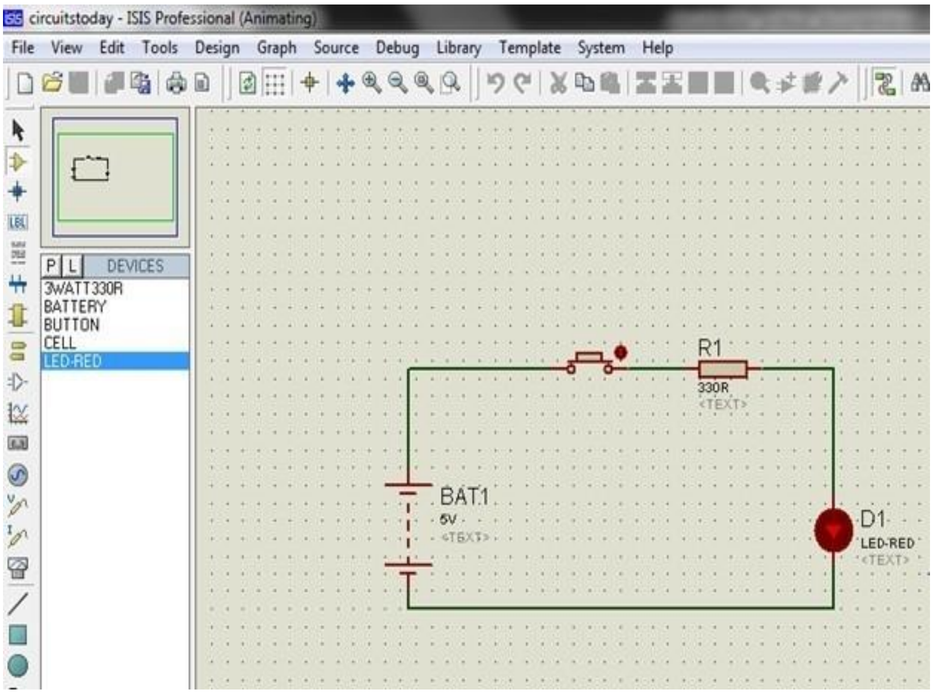

Fig:1.21 Simulation Procedure 11

Step 11: Simulation can be stepped, paused or stopped at any time.

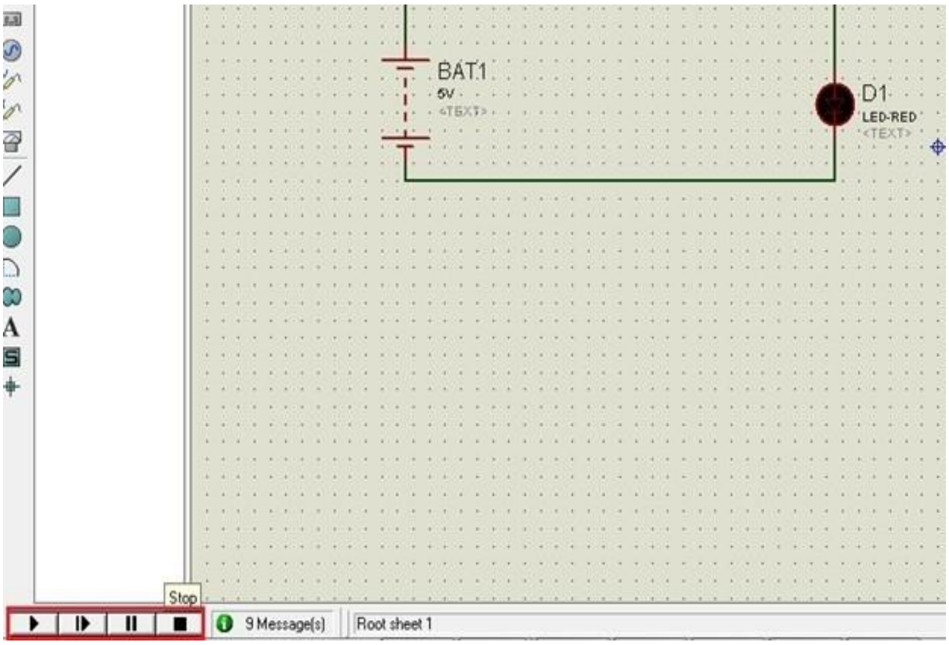

Fig:1.22 Simulation Procedure 12

1.4 PROCURMENT OF EQUIPMENT:

Fingerprints—the small ridges of skin on the fingertips which may enhance texture perception and grip friction—are unique to each person and have been used in identification for more than 100 years. Identification, the process of comparing a set of prints or a single print to others in a database, is used in many aspects of law enforcement and counterterrorism operations and investigations. Fingerprints may be compared to local and national databases for criminal history or to watch lists for border security. Latent prints from crime scenes are used in forensic investigations. Fingerprints can also be used to identify victims and for access control. Each application involves different processes for fingerprint capture and database searching and matching.

1.4.1 Components of Fingerprint Identification Systems

Fig:1.23 Finger print capture device

Fingerprint Capture the first step in fingerprint identification is obtaining an image of prints
interest. Fingerprints deliberately collected from an individual are called exemplar prints, and may include simultaneous four finger images or rolled prints, which capture an image of each side the fingernail to the other. Exemplar prints have historically been obtained using paper and ink, which must then be optically scanned for database input. Live scanners electronically capture and store a digital image, eliminating paper and ink. Digitized prints are transmitted electronically for AFIS searches. Most current live scanners are based on optical sensors. Emerging technologies include thermal, capacitive, and ultrasound sensors, and some have to use a striped pattern projected onto the fingertip to obtain a three-dimensional image.

Minutiae Encoding

The second step in fingerprint identification is to extract the fingerprints which are identifible characteristics to be used in a database search. Fingerprints can be sorted into general classification by

pattern type, such as arch, loop, or whorl, but minute details such as the ridge endings or burifications are unique to each individual. Software identifies
these minutiae and converts them into a system of numerical values. These minutiae templates are stored and used in searches instead of the whole image to reduce data and time requirements.

Recognition Software

An AFIS search involves the interaction of various databases where the minutiae are stored. Depending on the application, proprietary algorithms search segments of the database. For example, software may search the minutiae of two fingerprints of each subject, such as two index fingers, two thumbs, or a combination of finger and thumb. In other cases it may be necessary to search a database of all ten fingers. The simplest type of search is an identity verification used for access control or credentialing applications. Another identifier, such as a username, is submitted with a single fingerprint to specify who is attempting the authentication.

Certifications and Evaluations

A wide variety of fingerprint capture equipment and proprietary matching algorithms are commercially available. Interoperability is critical to the identification process and is achieved through standards and certification. The FBI has established image quality specifications for fingerprint images as well as data compression requirements for storage and transmission. The FBI certifies equipment compatible with the IAFIS, including live scanners, card scanners, and printers. Certified products are listed at https://www.fbibiospecs.org/IAFIS/Default.aspx. The National Institute of Standards and Technology (NIST) leads developments in automating fingerprint identification and conducts evaluations of hardware and software. Some examples are

Fast Capture, an initiative to improve technology to capture 10 rolledequivalent prints in less than 15 seconds in a portable, rugged system; the Minutiae Interoperability Exchange (MINEX), which tests the use of a standardized minutiae template, rather than entire fingerprint images, for exchange of data between 1:1 matching systems; and the Fingerprint Vendor Technology
Evaluation 2012, which assesses the performance of 1:N matching algorithms based on proprietary fingerprint templates using a database of millions of fingerprint sets, including live scan and scanned inked cards.

Standards

Two standards are currently used in FBI certification. The image quality specifications for interoperability with IAFIS for fingerprint scanners and printers are contained in Appendix F of IAFIS-DOC-01078-9.3 Criminal Justice Information Services Electronic Biometric Transmission Specification. Fingerprint verification using 1:1 matching is the focus of the standard PIV-071006.

Development of national and international standards for fingerprint technology is ongoing, and many other standards are available. For example, ANSI/INCITS 381-2004 specifies data compression for image storage and transmission, and ANSI/INCITS 378-2009 defines a fingerprint standard minutiae template.

1.5 ORGANISATION OF THE CHAPTERS

The Overall Overview of Documentation is:

1.5.1 INTRODUCTION

1.5.2 LITERATURE SURVEY

1.5.3 PROJECT DESIGN

1.5.4 PROJECT IMPLEMENTATION

1.5.5 CONCLUSION AND FUTURE ENHANCEMENT

CHAPTER 2

LITERATURE SURVEY

This chapter gives a brief overview of previous works done related to Fingerprint system.

2.0 INTRODUCTION:

The main idea of our project is to secure the places by using fingerprint sensor used to scan the finger of n the persons, the authorized people have to register their fingerprints to the system by using fingerprint sensor and each person is provided a particular ID which is stored in the data, Authorized people are the only eligible for vote, while the remaining people can't. For more security, the project is done along with buzzer indicator .

2.1 RELATED WORK:

Biometrics is a way used to recognize a person based on his physical nature. The fingerprint, iris, face, voice, etc. are the mainly used biometrics to recognize a person. There are two key functions for biometrics, first is one to one matching and other is one too many matchings. In one to many matching the biometric sample is compared with the already stored samples. In one to one matching, it compares with the previously stored sample. Biometric method results in a faster security, and more convenient method for user verification. Biometric method is better than password security. Fingerprint is unique for each individual so it can be used as a mark of signature, verification and authentication. Fingerprint is the biometric which is used in this project. Finger-print will be different for each individual. In this project, fingerprint is used for the authentication of the user and allows him to cast vote based on his fingerprint image. Finger-print matching can be divided into three types: correlationbased matching, minutiae-based matching, pattern-based (or image-based) matching. In correlationbased matching, two fingerprint images are superimposed and therefore the correlation between corresponding pixels is computed for various alignments. In minutiae-based matching, minutiae from the two fingerprints are extracted and stored in a two-dimensional plane as a set. This matching method consists of finding the alignment between the template and the input minutiae sets that result in the maximum number of minutiae pairings. In pattern-based (or image-based) matching method it compares with stored template and the candidate's fingerprint. This requires that the images to be aligned within the same orientation. To do this, the algorithm finds a central point within the fingerprint image and centers there on. In a pattern-based algorithm, the template contains the sort, size, and orientation of patterns within the aligned fingerprint image. Almost all the sectors are storing data digitally. To create digital India, most of the tasks are made through on-line. When the voting is made on-line, it helps the voters to vote from anywhere in the world. Thingspeak is one of the ways which helps in making voting on-line. Obtaining online result makes the system faster. Traditionally voting was done by marking with stamp casting vote for the corresponding candidate and then dropping the paper to a ballot box. To calculate the number of vote each vote must be calculated in each ballot box and then sum all the votes for each candidate and candidate who secured largest vote will be selected as the winner.

2.2 EXISTING METHODOLOGY:

Paper Ballots were used in India before 1997 for conducting the public elections. Even though this method gives uninterrupted voting, Votes captured in ballots can be stored for a very short period as the ink used in voting my discharge or ballot paper may lose its quality. Proper care has to be taken in maintaining these ballots to protect them from humidity, sunlight and other factors, which affect the ballot papers. Once the ballot is corrupted, we cannot recover the original data. After the election process, it takes more time and effort for counting the votes manually by checking each ballot paper. Paper is an Inflammable material accidentally I may catch fire in case all record will be lost and cannot be recovered and hence government has to spend extra money for conducting reelections. Bogus ballots can be made and in-numerous fake votes can be casted. Physically disabled peoples were facing difficulties in casting their votes, in those cases they need others help, but privacy while casting votes is vomited.

2.3 PROPOSED METHODOLOGY:

Fingerprint Based Voting Project is a application where the user is recognized by his finger pattern. Since the finger pattern of each human being is different, the voter can be easily authenticated. The system allow the voter to vote through his fingerprint. Finger print is used to uniquely identify the user. The finger print minutiae features are different for each human being. Finger print is used as a authentication of the voters. Voter can vote the candidate only once, the system will not allow the candidate to vote for the second time. The system will allow admin to add the candidate name and candidate photo who are nominated for the election. Admin only has the right to add candidate name and photo who are nominated. Admin will register the voters name by verifying voter. Admin will authenticate the user by verifying the user's identity proof and then admin will register the voter. The number of candidate added to the system by the admin will be automatically deleted after the completion of the election. Admin has to add the date when the election going to end. Once the user has got the user id and password from the admin the user can login and vote for the candidate who are nominated. The system will allow the user to vote for only one candidate. The system will allow the user to vote for one time for a particular election. Admin can add any number of candidates when the new election will be announced. Admin can view the election result by using the election id. Even user can view the election result.

CHAPTER 3

PROJECT DESIGN

3.0 OVERVEIW OF THE SYSTEM DESIGN

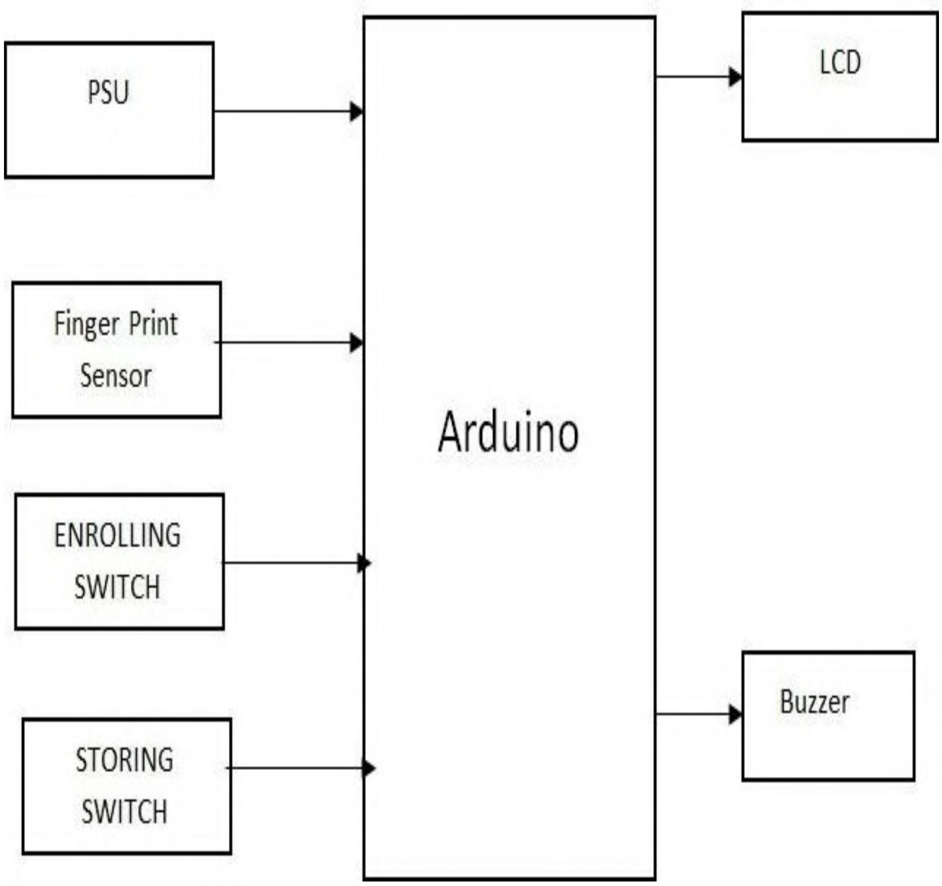

Fig:3.1 Block Diagram of finger print voting system

3.1 SCHEMATIC DIAGRAM:

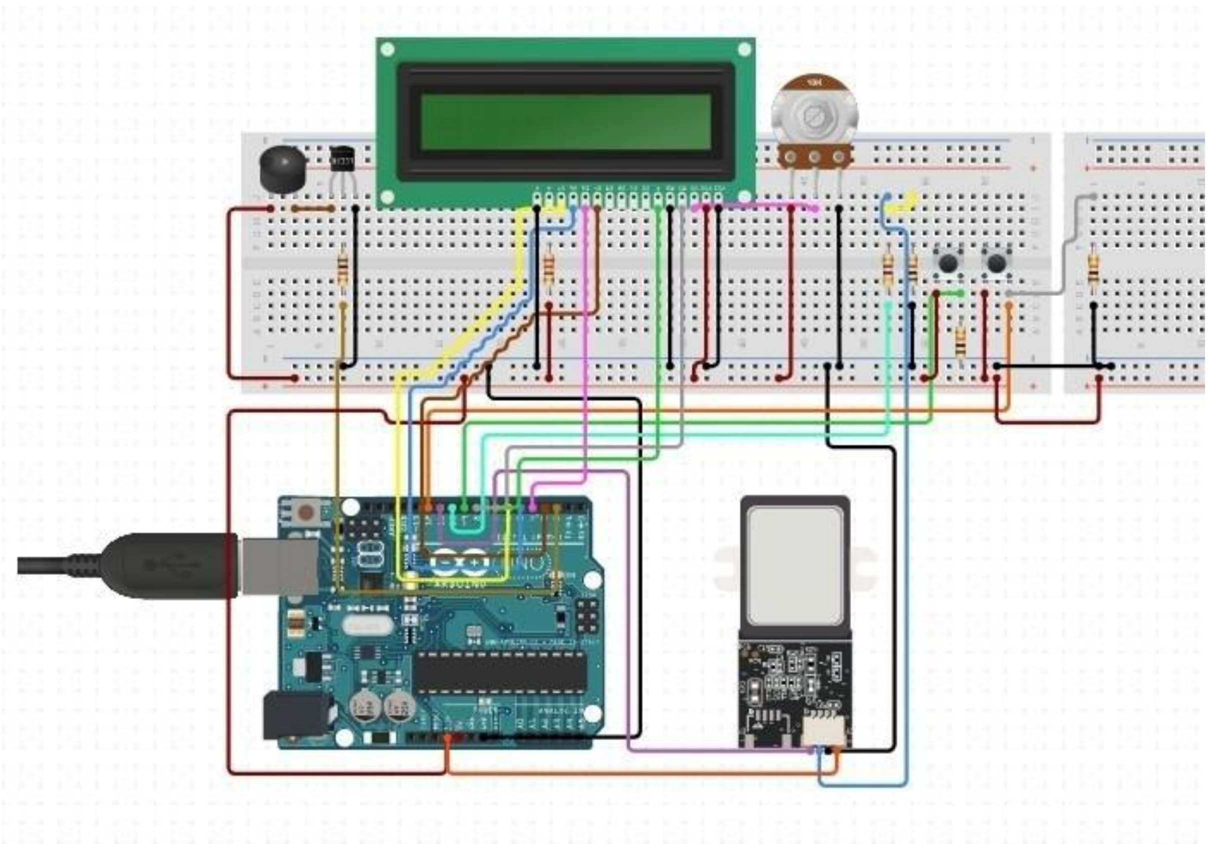

Fig:3.2 Simulation layout

The above schematic diagram of Finger Print Based Security System explains the interfacing section of each component with Arduino uno and input output modules

3.2 DEFINE THE MODULES:

3.2.1 FINGER PRINT MODULE:

Fingerprint Module consists of optical fingerprint sensor, high-speed DSP processor, highperformance fingerprint alignment algorithm, high-capacity FLASH chips and other hardware and software composition, stable performance, simple structure, with fingerprint entry, image processing, fingerprint matching, search and template storage and other functions. Fingerprint module has two interface TTL UART and USB2.0, USB2.0 interface are often connected to the computer; RS232 interface may be a TTL level, the default baud is 57600, can be changed, ask a communication protocol, microcontroller, like ARM, DSP and other serial devices with a connection, 3.3V- 5V microcontroller are often connected.

Fig 3.3 : Fingerprint module

Specifications:

Here's the specifications of the fingerprint sensor module we're using (you should check your sensor datasheet or the specifications provided by your supplier – they shouldn't be much different than these):

- Voltage supply: DC 3.6 to 6.0V
- Current supply: <120mA
- Backlight color: green
- Interface: UART
- Bad rate: 9600
- Safety level: five (from low to high: 1,2,3,4,5)
- False Accept Rate (FAR): <0.001% (security level 3)
- False Reject Rate (FRR): <1.0% (security level 3)
- Able to store 127 different fingerprints

3.2.2 LCD MODULE:

An LCD (Liquid Crystal Display) screen is an electronic display module and has a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. A 16x2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5x7 pixel matrix. The 16 x 2 intelligent alphanumeric dot matrix display is capable of displaying 224 different characters and symbols. This LCD has two registers, namely, Command and Data.

Command register stores various commands given to the display. Data register stores data to be displayed. The process of controlling the display involves putting the data that form the image of what you want to display into the data registers, then putting instructions in the instruction register. In your arduino project Liquid Crystal Library simplifies this for you so you don't need to know the low-level instructions. Contrast of the display can be adjusted by adjusting the potentiometer to be connected across VEE pin.

3.3 MODULES FUNCTIONALITIES:

3.3.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are :

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

3.3.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Table:3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB

3.3.1.2 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common

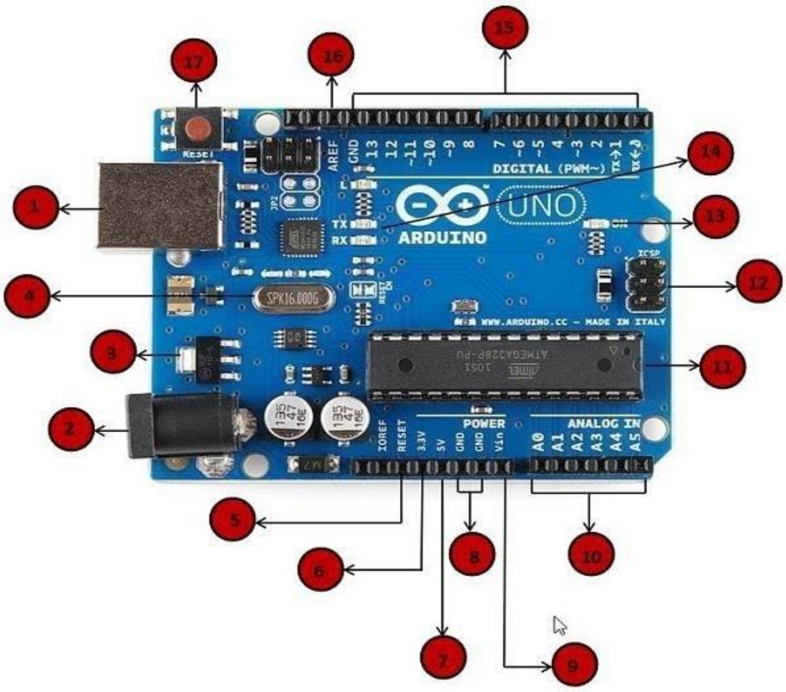

Fig:3.4 Board description of Arduino uno

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. GND (8) (Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.

10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

3.4 Liquid Crystal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to a controller is an LCD display. Some of the most common LCDs connected to the controllers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines (RS RW D7 D6 D5 D6).

When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller

3.4.1 Description of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So, what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

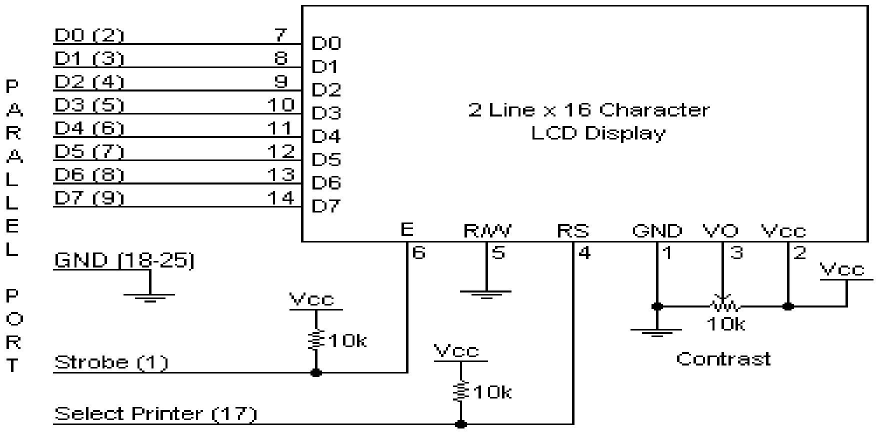

Fig 3.5: Schematic diagram

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

- We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use an onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

3.4.2 16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area.
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line.
- Can display 224 different symbols.
- Low power consumption (1 mA typical).
- Powerful command set and user-produced characters.
- TTL and CMOS compatible.
- Connector for standard 0.1-pitch pin headers.

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H, H->L	Enable

Table:3.5 16x2 LCD Features

3.4.3 FEATURES:

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Table:3.6 Data Location in LCD

3.4.4 Figure Address locations for a 1x16 line LCD

Even limited to character-based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one-, two- and four-line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

3.4.5 Pin Description In LCD:

Most LCDs with 1 controller have 14 Pins and LCDs with 2 controllers has 16 Pins (two pins are extra in both for back-light LED connections).

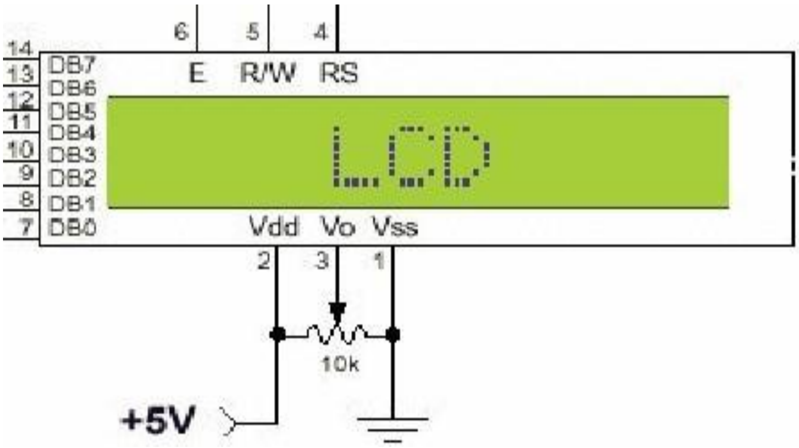

Fig:3.6 Pin Description of 1x16 lines

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table 3.7 Pin specifications

3.4.6 CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines

- E - 0 Access to LCD disabled.
- 1 Access to LCD enabled.
- R/W - 0 Writing data to LCD.
- 1 Reading data from LCD.
- RS - 0 Instructions.
- 1 Character.

Writing data to the LCD

- Set R/W bit to low.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Read data from data lines (if it is reading) on LCD

- Set R/W bit to high.
- Set RS bit to logic 0 or 1 (instruction or character).
- Set data to data lines (if it is writing).
- Set E line to high.
- Set E line to low.

Entering Text

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Table:3.8 LCD Commands

3.5 Fingerprint Sensor

The fingerprint sensor can read different fingerprints and store in its own flash memory. The sensor can perform three functions namely Add (Enroll), Empty Database or search database and return the ID of stored fingerprint. Any of three functions can be called simply by making the pin low of the sensor or pressing onboard three switches. The response is either error or ok which is indicated by onboard LED. The response is also returned as single serial data byte.

The return byte is a valid ID or error code. The response byte is a single byte at 9600 bps thus making whole sensor very easy to use. We have provided indicating LEDs and function switch already so it’s ready to use when you receive it. Just give power and start using the sensor using onboard switches. Then you can move on making external application using these functions.

3.5.1 Inputs and Outputs of Sensor

Input: Two ways to trigger the function of fingerprint sensor

- Onboard switch: Add, Empty or Search.
- Make pin low from external microcontroller for 5ms as per function required to be executed.

Output: Two ways to monitor output response after a function is executed

- Onboard LEDs: ERROR or OK.
- Read byte after executing function.

3.5.2 Types of Sensor Function

There are namely three functions you can call for the fingerprint sensor. We will see each in brief.

Add (Enroll) Function: Adds a fingerprint to database and return a byte of newly added ID. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function

Search Function: When a finger is put and search function is called, it returns a matching ID if found in its existing memory. Return values are from 0x00 to 0xFE. In case of error like no finger placed, return code is 0xFF. Here 0xFF means error executing function.

Empty Function: When you wish to empty all fingerprint, data stored on sensor you can use this function. After executing this function, you will get 0xCC as OK or 0xFF in case of error.

3.5.3 Fingerprint Recognition Sensor Module

The sensor is a solid-state fingerprint sensor that reliably captures fingerprint information. It is designed to integrate into devices for improved security and convenience. The sensor provides a reliable, quick and user-friendly alternative to passwords, PIN's and other forms of user authentication.

This fingerprint scanner is capable of gathering and storing unique finger prints. Simply hold your finger on the optical scanner, query the device over serial, and you will be issued a unique ID. Use that ID within your embedded system to determine access levels, time clocks, door locks, etc. Unit includes 4 pin connector cable to connect and read to controller. The outputs are TTL level serial data.

A biometric sensor, fingerprint sensor to be specific, also known as the fingerprint reader, is a fingerprint image capture device, the very front end of the biometric fingerprint identification/verification module. The fingerprint sensor captures the fingerprint images, matches the uniqueness of each print read by the sensor and compares it to the one stored in its module or local system database.

It consists of optical fingerprint sensor, high performance DSP processor and Flash. It boasts of functions such as fingerprint enrollment, fingerprint deletion, fingerprint verification, fingerprint upload, fingerprint download, etc.

3.5.4 Applications

- Computer peripherals – improves security and convenience
- Transportation systems – validation of operators, drivers and inspectors
- Medical equipment – authorization of operator or technician
- Physical access systems – approval for entry
- Kiosks and vending machines – confirmation of person receiving the selection
- Point of Sale terminals – authentication of tellers and cashiers

3.5.5 Features

- Rugged, solid-state optical fingerprint sensor
- High resolution 500 DPI imager
- Adapts to wet/dry fingers
- Simple Interfacing protocol

Fig:3.7 Fingerprint sensor

3.5.6 Specifications of Sensor

- Fingerprint enrollment time <250ms
- Fingerprint search time <1s（100 fingerprint, average value in test） Resolutions 500 DPI
- Security level 5, Adjustable Capacity 768 Templates
- FAR <0.0001%
- FRR <0.01%

- Power Supply 4.3V to 6V Working Current <80mA Peak Current <90mA Communication Interface TTL
- Communication Baud Rate 57600 bps Working Temperature -10 deg C to +40 deg C
- Working Humidity 40% RH to 85% TH (no dew) Module Dimensions 60x21x25 mm (LxWxH)

3.6 BUZZER:

3.6.1 Types of Buzzer

Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

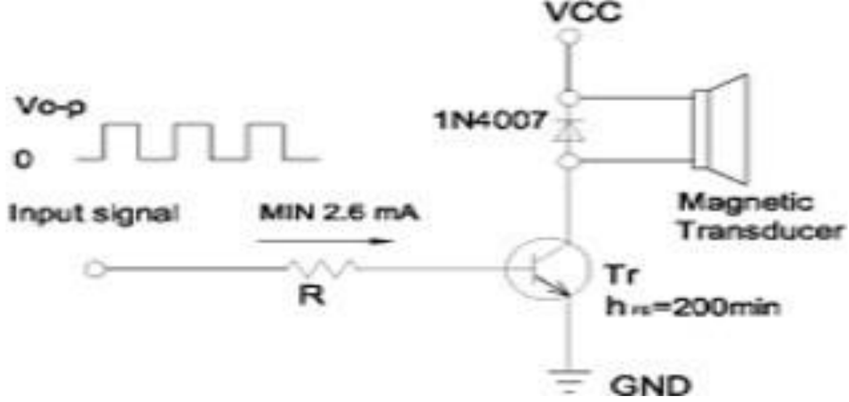

Fig:3.8 Driving Circuit for Magnetic Transducer

3.6.2 Specifications of buzzer:

- **Rated Voltage**: A magnetic buzzer is driven by 1/2 square waves (V o-p). **Operating Voltage**: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
- **Consumption Current**: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
- **Direct Current Resistance**: The direct current resistance is measured by ammeter directly. **Sound Output**: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
- **Rated Frequency**: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
- **Operating Temp**: Keep working well between -30℃ and +70℃.
- **Driving methods**: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.
- **Dimension**: Dimension affects frequency, small sizeresult in high frequency.
- **Voltage**: Depend on V o-p (1/2 square waves)
- **Fixed methods**: From the highest cost to the lowest- DIP, wires/ connector, SMD.

3.6.3 How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer starts to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer needs to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of silicon.

Fig:3.9 Buzzer

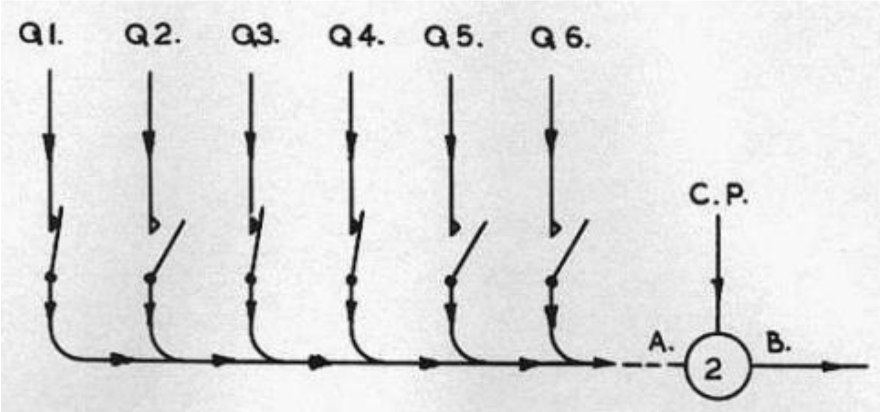

Fig:3.9 Pin Diagram of buzzer

3.7 Switches

A switch is an electrical component that can break an electrical circuit, interrupting the current or diverting it from one conductor to another. The most familiar form of switch is a manually operated electromechanical device with one or more sets of electrical contacts. Each set of contacts can be in one of two states: either 'closed' meaning the contacts are touching and electricity can flow between them, or 'open', meaning the contacts are separated and non-conducting.

Fig:3.10 Switches in a row

Switches with larger numbers of poles or throws can be described by replacing the "S" or "D" with a number or in some cases the letter "T" (for "triple"). In the rest of this article the terms *SPST*, SPDT and intermediate will be used to avoid the ambiguity in the use of the word "way".

3.7.1 Working of Switch

A pair of contacts is said to be "closed" when current can flow from one to the other. When the contacts are separated by an insulating air gap, an air space, they are said to be "open", and no current can flow at typical voltages.

Switches are classified according to the arrangement of their contacts in electronics. Electricians installing building wiring use different nomenclature, such as "one-way", "two- way", "three-way" and "four-way" switches

In a push-button type switch, in which the contacts remain in one state unless actuated, the contacts can either be normally open (abbreviated "no." or "no") until closed by operation of the switch, or normally closed ("n.c. or "nc") and opened by the switch action. A switch with both types of contact is called a changeover switch. These may be "make-before- break" which momentarily connect both circuits, or may be "break-before-make" which interrupts one circuit before closing the other

3.7.2 APPLICATIONS

- They are used for the given instructions to the required device like robot, driving the motor, etc.
- Switches can arrange in the matrix from or in the required from according to the application.
- **Reset circuit of the controller, motor also has the switches for its particular functioning.**

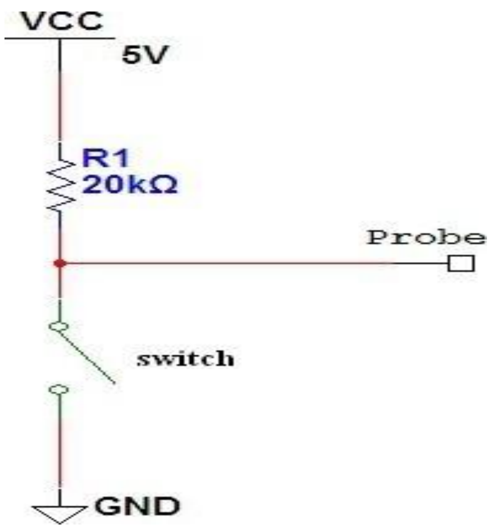

Fig:3.11 Circuit of Switch

From the above circuit it explains the working of the switch when supply is given to the circuit the resistor takes the current and oppose to the certain extend until the switch is pressed. These switches can be connected parallel or serial in required manner.

We can have resistor, capacitor, light resistor diode etc. as the combination of the switch. For example, w the reset circuit in which we the resistor and capacitor as the combination.

CHAPTER 4
PROJECT IMPLEMENTATION

4.0 IMPLEMENTATION STAGES:

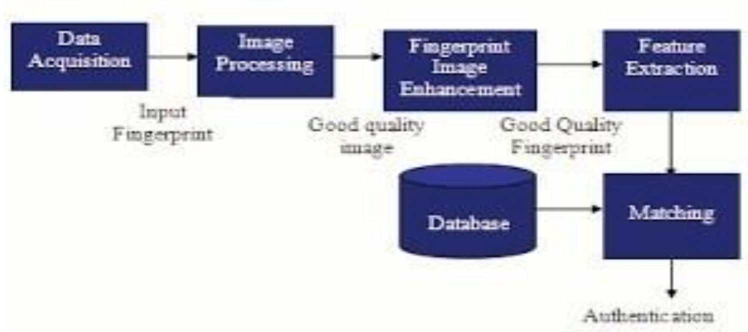

Fig:4.1 Implementation of Finger print voting system

1. Algorithm of Fingerprint Based Voting System:

Step 1: Start

Step 2: Users can register by giving their fingerprints. We use a microcontroller to store them.

Step 3: Scan your finger

Step 4: If match found goto step 5 else return to step3 Step 5: user checks their details

Step 6: cast your vote

Step 7: Press push-button for a party from the party list

Step 8: Vote counted

Step 9: Stop

2. Fingerprint Identification and Matching:

Fundamentally, we utilize advanced imaging innovation in securing, putting away, and dissecting the unique mark information.

1. Acquiring Images:

In the image identification process, the first step is to obtain an image as, withot it, we cannot perform further steps. To acquire an image of a fingerprint, the person needs to place their finger on the sensor. Once the voter places their finger,on one end of the prism, the total internal reflection occurs through which we can capture the image using the image sensor and lens from another end of the prism. But the image extracted in this step is unprocessed.

The position and placement of the finger play a prominent role in the process of capturing an impression. For intensifying the total internal reflection and capture a fingerprint of good quality with the image sensor, we need to make sure that the finger is placed correctly on the module.

2. Storing the images:

The unprocessed image acquired in the previous step is now processed using image segmentation.

Image Segmentation: The captured images may contain some redundant data and noise along with required data, so we use image segmentation in which we divide the image into many segments called pixels to remove the irrelevant data. To ease the process of image analysis, we use image segmentation.

We use the normalization of an image to get even pixels. Once the pixels are uniform, it results in the formation of an image, and then to reduce or remove the noise present in it, we use the Gabor filter. The thresholding technique is implemented on the filtered image to change it into a binary image, then we compare threshold values and pixel values, if the value is higher than the threshold value then we set the pixel value to 1 else 0. Next, to remove some pixels from the foreground, we implement the thinning process. Finally, all the segments form a single image.

3. Analyzing the Image:

Finally, it shows to whom the user cast the vote.

Using image analysis, we can retrieve all related data from the image for further use. Mostly some electrical machines are used to collect the required data. According to this project, the electrical machine is a fingerprint module through which we capture the fingerprint. The retrieved data from the image can be compared with data stored in different storage devices for identification, authentication, etc.

4.1 WORKING FLOW OF THE PROJECT:

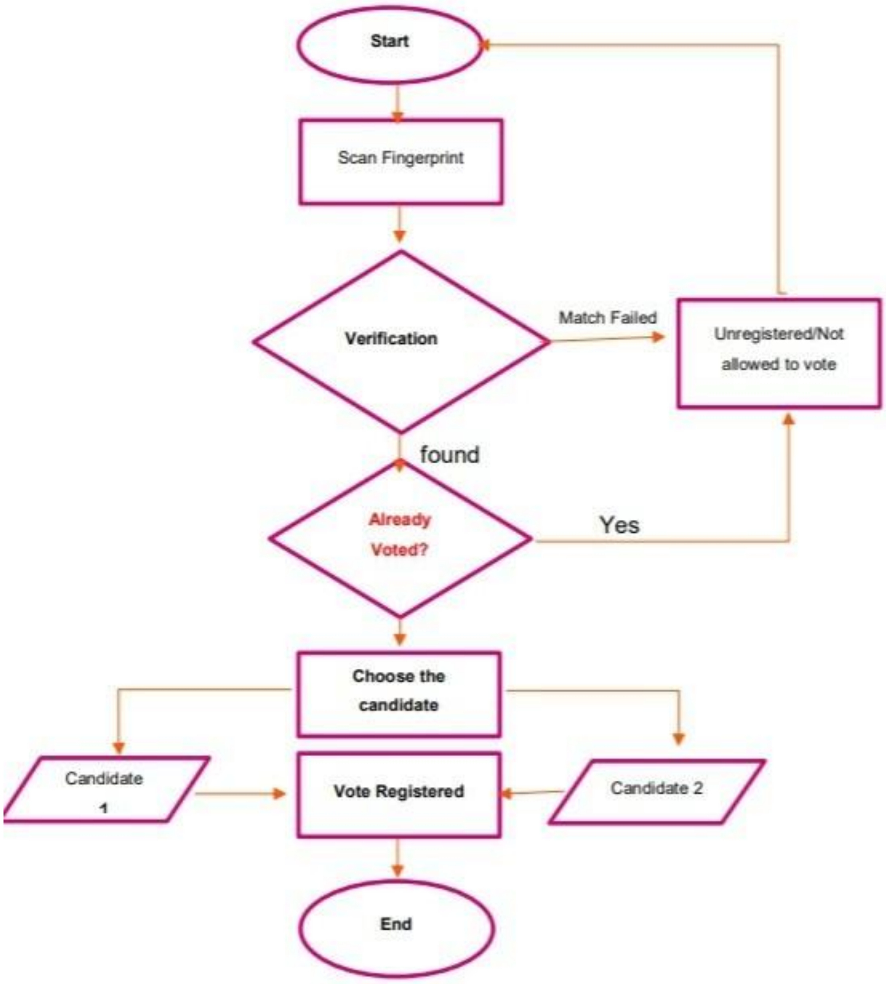

Fig:4.2 Working flow of Finger Print Based Voting System

4.2 EXPERIMENTAL RESULTS:

The Hardware setup gives us a brief idea to how the project ”Fingerprint voting system” works. The proposed system is implemented. There are mainly two units in this system, one for verification and other for voting. Arduino UNO was programmed using Arduino IDE. In the verification unit there are three scenarios- voting for first time, voting more than once, mismatch in fingerprint. If user attempts to vote for the first time, his fingerprint is compared with data in the database, if a match occurs, he can cast vote and message “Authenticated. Proceed” displays on the serial monitor of the arduino. If an authenticated user tries to cast vote more than once then a buzzer sound will be produced and “User not authorized” message displays on serial monitor. If the fingerprint of a person is not available in the database, he can’t cast his vote.Finally the authorized officer gets the summary of voting.

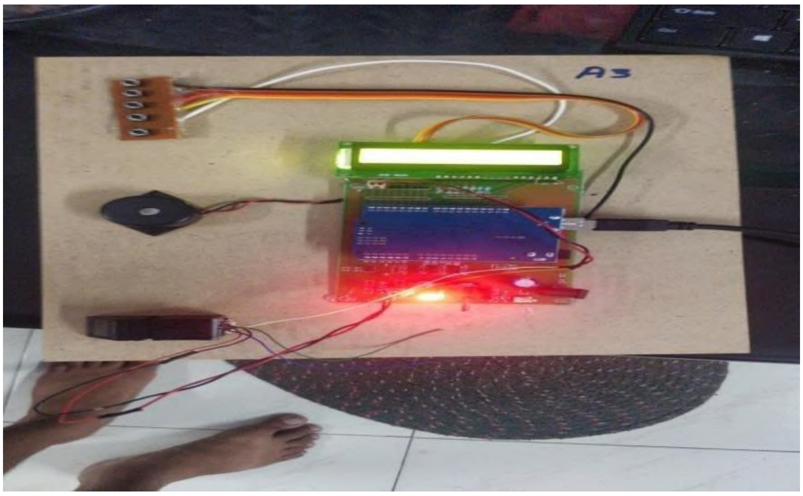

Fig 4.3:Overall design

4.2.1 INTERPRETING EXPERIMENTAL RESULTS:

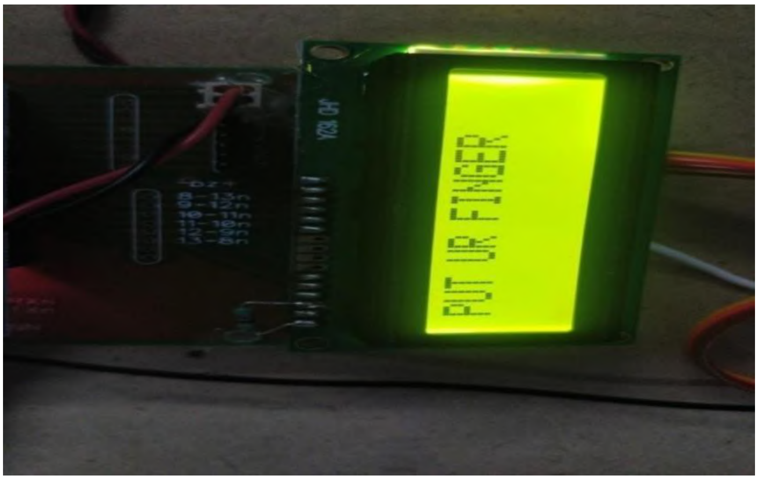

Fig:4.4 Displays Commands in LCD

Fig 4.5 Finger print Scanner

Fig:4.6 Displayed on LCD “User not authorized”

Fig:4.7 It shows the result obtained after voting

4.3 ADVANTAGES AND LIMITATIONS

ADVANTAGES

Some advantages of using this system are discussed below:

- Safe: It is an utmost important that the voting process be secure and no one should be able to tamper with the result before, during and after voting process. Since the system is not connected to internet, no online external influence can occur. Also, it is very easy for security personnel to secure the device if needed, since it is compact, and light compared to many ballot boxes.
- Cost: The conventional paper voting system used in Nepal is very expensive because of papers and printings, transportation, staff expenses and it takes several days to count the votes. On the other hand, the biometric fingerprint system is cheap, compact and can store any amount of data with proper upgrade.
- Accuracy and Reliability: The ink used to mark people who have voted already can be erased with modern technologies but the fingerprint voting system erases the chance of multiple voting and it is very precise. Also, there is a very slim chance of errors happening from electronic system so, people can rely on results to be accurate.
- Time Saving: It takes weeks to count the votes by election personnel sometimes. This time frame is not peaceful for that area so it is ideal to get result as soon as possible. The manual vote counting technique can be seen . With electronic device election results can be produced is minutes rather than days or weeks

LIMITATIONS

- The collection of fingerprints of all voters is little difficult.
- The personal details of the voter does not verifying in this system other than fingerprint.
- Only fingerprints of the voters is identified instead of identifying the person.

CHAPTER 5

APPLICATIONS

5.0 APPLICATIONS

This project can be used as a voting machine to prevent rigging, during the elections in the polling booths.

- Fast track voting which could be used in small scale elections, like resident welfare association, “panchayat” level election and other society level elections, where results can be instantaneous.

- It could also be used to conduct opinion polls during annual shareholders meeting.

- It could also be used to conduct general assembly elections where number of candidates are less than or equal to eight in the current situation, on a small scale basis

CHAPTER 6

CONCLUSION AND FUTURE SCOPE

6.0 CONCLUSION

The project "Fingerprint Based Voting Machine" was mainly intended to develop a fingerprint based advanced Electronic Voting Machine (EVM) which helps in free and fair way of conducting elections which are basis for democratic country like India. Fingerprint Based Voting Machine is designed to make the procedure of voting easier and more convenient as it is a modified system. It has proved to be very advantageous in providing security EVM is capable of saving considerable printing stationery and transport of large volumes of electoral material. It is easy to transport, store, and maintain. It completely rules out the chance of invalid votes. In total, the complete system (including all the hardware components and software routines) is working as per the initial specifications and requirements of our project. So certain aspects of the system can be modified as operational experience is gained with it. As the users work with the system, they develop various new ideas for the development and enhancement of the project. The proposed system has been designed and implemented successfully using a PIC microcontroller, which was shown to be superior over the existing Electronic Voting Machine. The proposed system has the benefit of using a biometric authentication and controls the process of voting avoiding unnecessary things like rigging, ballot papers, casings etc.

6.1 FUTURE SCOPE

- Number of active candidates may increase.
- It could be interfaced with the computer and results can be displayed quickly and easily or the result can be stored in the central server whose data can be stored in the backend servers.
- It could be interfaced with the printer so that the hardcopy of the data can be taken.
- It could make the results available at any corner of the world in minimum time.

PROJECT REPORT

ON

SATELLITE IMAGE ENHANCEMENT FOR SMALL PARTICLE OBSERVATION USING DECORRELATION STRETCHER

Submitted by

A.SURYATEJA REDDY	**(17K81A0404)**
CH.SIIDDARDHA REDDI	**(17K81A0412)**
S.VAMSHI	**(17K81A0445)**

In partial fulfillment for the award of the degree of

BACHELOR OF TECHNOLOGY

In

ELETRONICS AND COMMUNICATION ENGINEERING

Under the Guidance of

Mr.VENKANNA MOOD

M.Tech(Ph.D)

Associate professor

DEPARTMENT OF ELETRONICS AND COMMUNICATION ENGINEERING

ST. MARTIN’S ENGINEERING COLLEGE
(An Autonomous Institute)
Dhulapally,secunderbad-500 100

JUNE 2021

BONAFIDE CERTIFICATE

This is to certify that the project entitled "**Satellite Enhancement For Small Particle Observation Using Decorrelation Stretcher"**, is being submitted by **1.SuryaTeja reddy(17K81A0404), 2.Siiddardha reddi (17K81A0412), 3.Vamshi(17K81A0445)** in partial fulfillment of the requirement for the award of the degree of BACHELOR OF TECHNOLOGY "Electronics and Communication Engineering " is recorded of bonafide work carried out by them. The result embodied in this report have been verified and found satisfactory.

DECLARATION

We , the students of **“Bachelor of Technology in Department of Electronics and Communication Engineering”,** session: 2017-2021, **St. Martin’s Engineering College**, hereby declare that the project work Entitled **“Satellite Enhancement For Small Particle Observation Using Decorrelation Stretcher”** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. The result embodied in this project report has not been submitted in any university for award of any degree.

A.SURYATEJA REDDY 17K81A0404
CH.SIIDDARDHA REDDI 17K81A0412
S.VAMSHI 17K81A0445

ACKNOWLEDGEMENT

We sincerely thank the management of the college **ST . MARTIN'S ENGINEERING COLLEGE** for providing required facilities during our project work.

We derive our great pleasure in expressing our sincere gratitude and respect to our Principal **Dr.SANTHOSH KUMAR PATRA** for his timely suggestions, which helped us to complete the project successfully.

We would like to express our thanks and immense gratitude to Dr.B.HARIKRISHNA, Professor, Head of the Department, ECE for his consistent encouragement during the Progress of this project.

Our deep sense of gratitude to **Mr .VENKANNA MOOD**, Associate Professor ,our Project Mentor and Internal Guide, for the stimulating guidance and encouragement that we have received from him throughout the project.

We take it as a privilege to thank our project coordinator **Dr. A.ANAND** department of ECE for the ideas that lead to complete the project Work and we also thank him for the continuous guidance , support and unfailing patience, throughout the course of this work.

We would also like to thank all the staff of Department of ECE who has been helpful to complete the project successfully.

Abstract

In this research work, we have improved the image visual appearance using image decorrelation stretcher techniques. Landsat 8 images are used in this research work to show the improved visual presentation for the images. Landsat 8 images contain 11 different spectrum bands. The visual appearance of the images produces some specific details in terms of appearance, which were not present in the original image. Through the image decorrelation stretcher technique, the image quality is improved and enhanced.

Chapter 1

INTRODUCTION

The earth is associate aquatic planet and the maximum amount as eightieth of its surface is roofed by water.. Moreover, there is a strong interest in knowing what lies in underwater. Present days, an image of deep waters has a scope to large investigation to explore the underwater for sea floor expedition and navigation. Enthusiasm of underwater imaging includes the inspection of plants, seabed exploration, the search for wrecks up and to the exploration of natural resources. There were several issues faced by the human in the underwater, if he dives deep into the ocean and stay there for a long time to perform experimentation. [1]. Due to the above reasons, unmanned remote vehicles are used to sea floor exploration.

A. Historical Development

Underwater image quality improvement approaches present a path to magnify the object recognition in underwater surrounding. A heap of research started for the upgradation of image visual quality, but a little amount of work has been carried out in this area. In the deep waters, image quality is degrades due to poor illumination conditions and the light properties differ in water compared to air.[2]. There were several parameters which decreases the quality of an image in underground waters. So inorder to remove all these effects

there are several techniques has been implemented and practiced.

B. Need for Pre process

Initially processing is necessary for deep water images due to their poor quality during acquisition. Necessity for pre-processing of deep water images[1] are discussed below:

(i) Quality of images taken from deep water is deteriorated due to light ray attributes like scattering and absorption of light.

(ii) Specificity of surroundings such as lighting inequalities, water torridness, and blue complexion is more or less influential when vehicles move.

(iii) Video or image captured from deep waters like unknown rigid scene, and the depth of the scene and low light sensitivity due to Marine snow etc.

TRADITIONAL TECHNIQUES FOR IMAGE ENHANCEMENT

There are several techniques which are used very frequently for processing the image to improve the visual quality. Some of them are as follows:

(i) Contrast Stretching

(ii) Adaptive Histogram Equalization

A. Contrast stretching

The contrast stretching is a method to transform high intense region of image into more brighter and less intense region into more darker by using a predefined transformation function T(r) [2]. Generally, the underwater images will have less grey values. There are 256 grey values. '0' indicates black and '255' indicates white. In this method the current grey value of the image is stretched towards 255 i.e., from black to white, pixel by pixel. That means the contrast of the image is stretched, so that the quality of the image is improved for better vision.

For example:

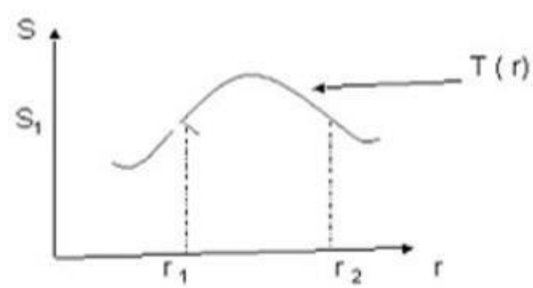

Fig.1. Two different gray levels look same

Here two different thresholds are considered for the entire image and the values between them are stretched to the maximum extent, so that the contrast increases. And more over by this method the entire global image contrast is enhanced.

Fig.2. (a) Raw image (b) Enhanced image

But the disadvantage here is that the transformation function is not unique. Depending on the application the suitable transformation function is chosen.

B. Adaptive histogram equalization

Adaptive histogram equalization is a PC based image processing technique which is used to improve the quality of image properties like contrast. It is similar to contrast stretching method but with a slight difference. It computes several intensities of specific gray value, each corresponding to a distinct portion of an image, and with the help of them intensities are rearranged by applying a suitable transformation function. For example, a simple transformation function such as each pixel transformed based on the histogram of a square surrounding the pixel [3]. Existing values will be mapped to new values keeping actual number of intensities in the resulting image equal or less than the original number of intensities. The transformation function applied on the histogram is proportional to the cumulative distributive function (CDF) of pixel values in the neighbourhood. Therefore it suits for enhancing the local details and enhancing the edge information of each region of an image.

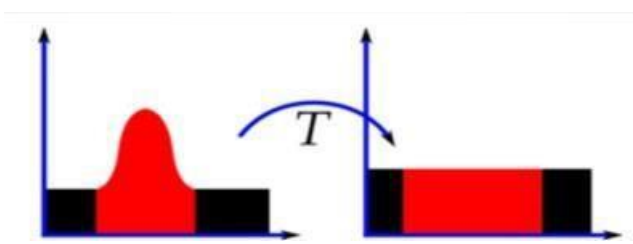

Fig.3. Histograms of an image before and after histogram equalization

Histogram equalization is a technique for changing the overall pixel intensities based on transformation function and contrast of an image. Histogram equalization is an effective technique which will benefit for the images with extreme contrast values. The limitation of this technique highlights the unwanted noise present in the background of an image and lead to loss in the information signal. It results in undesired effects in the resultant images [4].

Fig.4. (a) Raw image **(b) Enhanced image**

Here the noise in relatively homogeneous regions of the image are amplified which results in poor SNR. And also only the local objects of the image are enhanced and the background is left unenhanced.

Decorrelation can be understood as the process through which autocorrealtion within the signal and cross-correlation within the set of signals or images can be removed. During this process, all the other details of the image are conserved. There are many image improvement algorithms like Karhunen–Loève transform and discrete cosine transform (D.C.T.) . Decorrelation stretcher technique is applied in many fields like image processing, neuroscience, artificial neural network, cryptography and hardware number random generator. In simple words, decorrelation stretching can be understood as an artificial image contrast enhancement technique through which image contrast can be improved. The images on which these improvements can be implemented are digital images in communication and medicines (D.I.C.O.M.) images , satellite images , ultraviolet (U.V.) images, multispectral images etc.,.The purpose of performing decorrelation stretcher in an 8-bit image are as follows.

- We are changing the image pixel value distribution over the entire image with pixel values in the range of 0-255.
- These pixel values are utilized on the full range in a line fashion.
- Decorrelation Stretching is performed only on principal components of the image, not on the entire image.

Decorrelation Stretcher is used to improve the image quality to a great extend. The detailed review of the application of the Decorrelation Stretcher is as follows. Uji et al. used the Decorrelation Stretcher technique to improve the image quality and color of the images obtained from the "TRCNW8F Plus Mydriatic/Non-Mydriatic Retinal Camera" for the eye defect purpose. Their research concluded that the Decorrelation Stretcher has the ability to improve the image quality in color images. P. Sinha et al. used the Decorrelation Stretcher technique to enhance the visible image quality for sedimentary rock available in the Earth and the Mars surface. Thus the Decorrelation Stretcher technique can also be used for the image enhancement for the satellites and surface outside the Earth surface. G. Ch. Miliaresis used the Decorrelation Stretcher technique to enhance the visual appearance of the images having annual precipitation range on a 1 km grid for the state of "California, Nevada, Arizona, and Utah." A. Jellouli used the Decorrelation Stretcher technique to enhance the visual appearance of the Landsat 8 O.L.I. Images to enhance spatial, spectral, and radiometric characteristics of these images. E. Gürbüz used the Decorrelation Stretcher technique to improve the image quality for the multispectral image using ASTER data for the Turkey region by studying the vapourization of the minerals. An R Gillespie et al. used the image Decorrelation Stretcher technique on three different images, which are highly correlated with each other. They performed two different types of stretching on the models discussed as Decorrelation Stretch and saturation intensity stretching on the images to obtain superior results.

Image enhancement is performed to provide sufficient information that is hidden from human visual perception. There are several image enhancement techniques; one of the most popular image enhancement techniques is the grey level cooccurrence matrix (G.L.C. M) technique . In this technique, the changes developed in the images are quantified, and later for the visual image interpretation, a grey level image is created. The purpose of this image quantification and change detection represents the number of changes developed in the image. This techniques is used in medical image compression, satellite image analysis texture classification purposes etc

Chapter 2

LITERATURE SURVEY

There are many image improvement algorithms like Karhunen–Loève transform and discrete cosine transform (D.C.T.). Decorrelation stretcher technique is applied in many fields like image processing, neuroscience, artificial neural network, cryptography and hardware number random generator. In simple words, decorrelation stretching can be understood as an artificial image contrast enhancement technique through which image contrast can be improved. The images on which these improvements can be implemented are digital images in communication and medicines (D.I.C.O.M.) images , satellite images , ultraviolet (U.V.) images, multispectral images Uji et al. [7] used the Decorrelation Stretcher technique to improve the image quality and color of the images obtained from the "TRCNW8F Plus Mydriatic/Non-Mydriatic Retinal Camera" for the eye defect purpose.

Their research concluded that the Decorrelation Stretcher has the ability to improve the image quality in color images. P. Sinha et al. used the Decorrelation Stretcher technique to enhance the visible image quality for sedimentary rock available in the Earth and the Mars surface. Thus the Decorrelation Stretcher technique can also be used for the image enhancement for the satellites and surface outside the Earth surface. G. Ch. Miliaresis used the Decorrelation Stretcher technique to enhance the visual appearance of the images having annual precipitation range on a 1 km grid for the state of "California, Nevada, Arizona, and Utah." A. Jellouli used the Decorrelation Stretcher technique to enhance the visual appearance of the Landsat 8 O.L.I. Images to enhance spatial, spectral, and radiometric characteristics of these images. E. Gürbüz used the Decorrelation Stretcher technique to improve the image quality for the multispectral image using ASTER data for the Turkey region by studying the vapourization of the minerals. An R Gillespie et al. used the image Decorrelation Stretcher technique on three different images, which are highly correlated with each other

CHAPTER 3

INTRODUCTION TO IMAGE PROCESSING

INTRODUCTION

3.1.IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

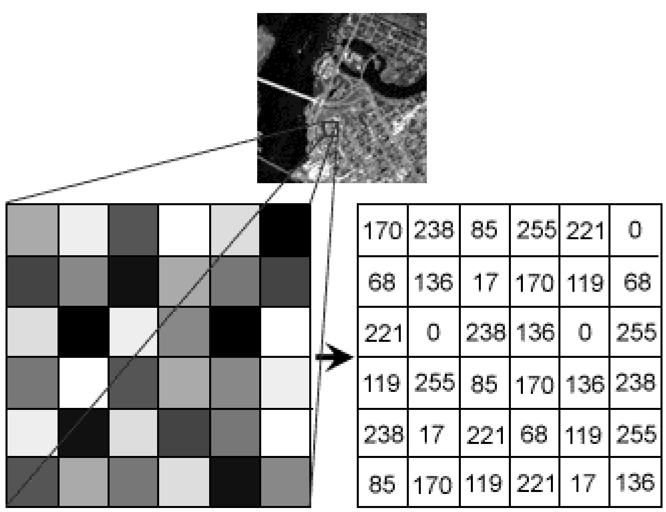

Fig 1.1 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1
Transparency	Red	Green	Blue

Fig1.2 Transparency image

3.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

3.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

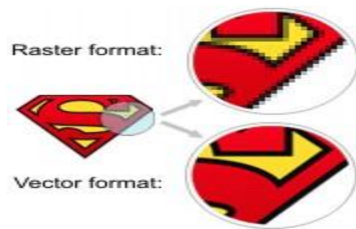

Fig1.3 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

3.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

  The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

  The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

  GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

3.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

3.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

3.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

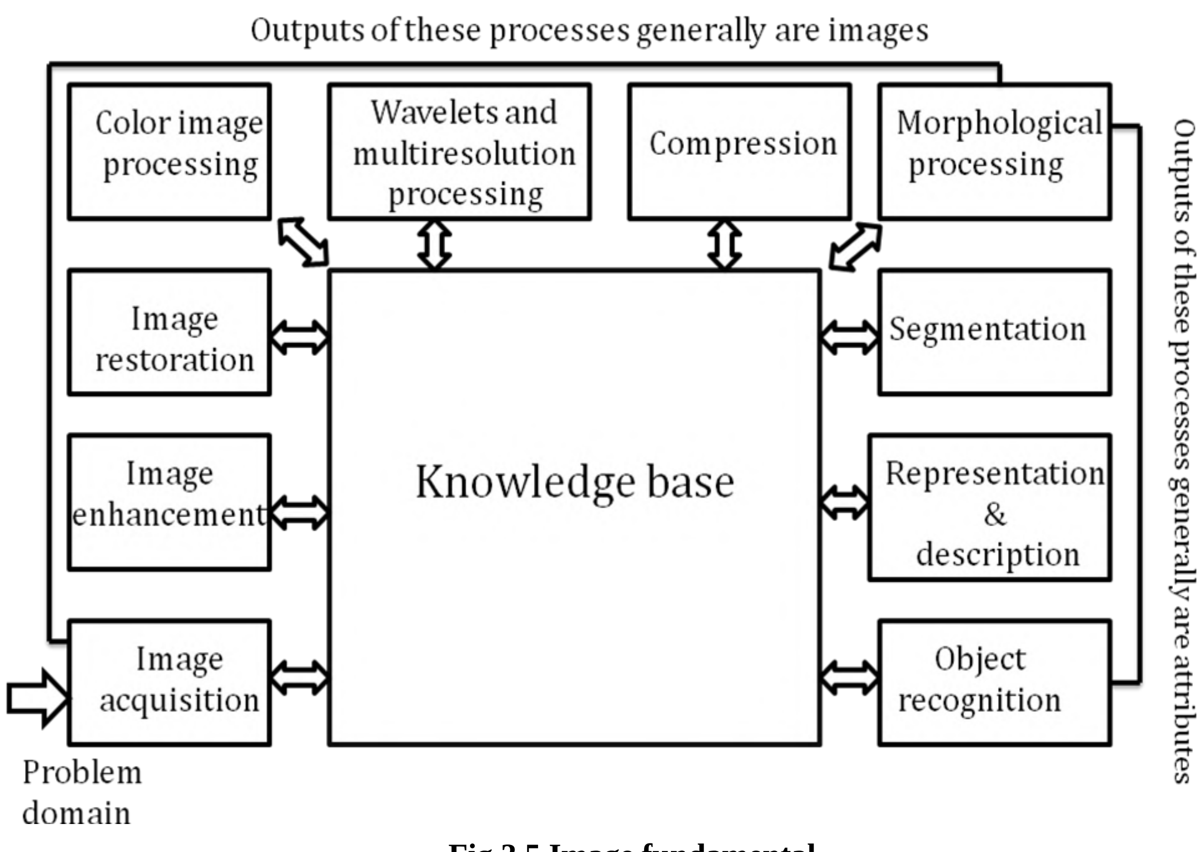

Fig 3.5 Image fundamental

3.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 3.5.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.5.2 digital camera cell

3.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 3.5.3 Image enhancement

3.5.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 3.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

3.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 3.5.5 Color & Gray scale image

3.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

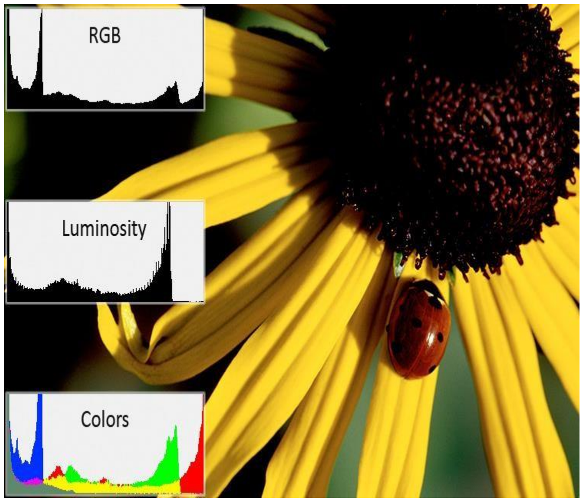

Fig 3.5.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

3.5.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

3.5.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 3.5.7 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

3.5.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

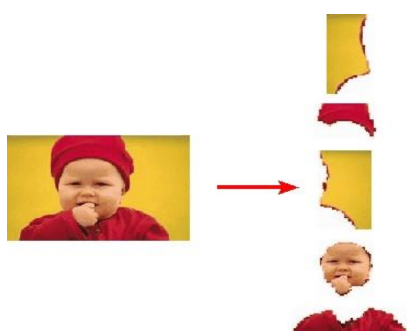

Fig 3.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

3.5.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

3.5.10 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

3.5.11 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

3.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

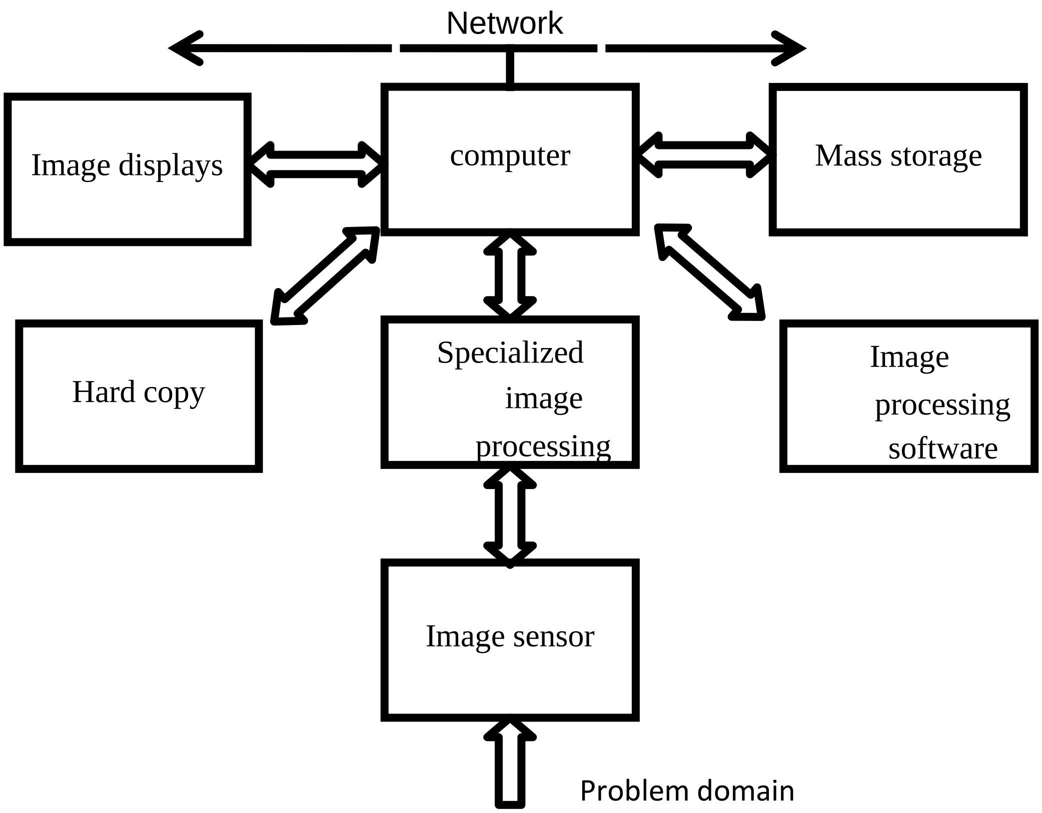

Fig 3.6 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

  Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

  Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

  Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

  Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \mathrm{Pr}((\mathrm{gl}\ \ \mathrm{gl}$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL}-1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i,j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i,j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image.

Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the

properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

G = Qs*Qv*H+Qv*s+V

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 \ \ if \ \ h \in [316,20] \\ 1 \ \ if \ \ h \in [21,40] \\ 2 \ \ if \ \ h \in [41,75] \\ 3 \ \ if \ \ h \in [76,155] \\ 4 \ \ if \ \ h \in [156,190] \\ 5 \ \ if \ \ h \in [191,270] \\ 6 \ \ if \ \ h \in [271,295] \\ 7 \ \ if \ \ h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \ \ if \ \ s \in [0,0.2) \\ 1 \ \ if \ \ s \in [0.2,0.7) \\ 2 \ \ if \ \ s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \ \ if \ \ v \in [0,0.2) \\ 1 \ \ if \ \ v \in [0.2,0.7) \\ 2 \ \ if \ \ v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

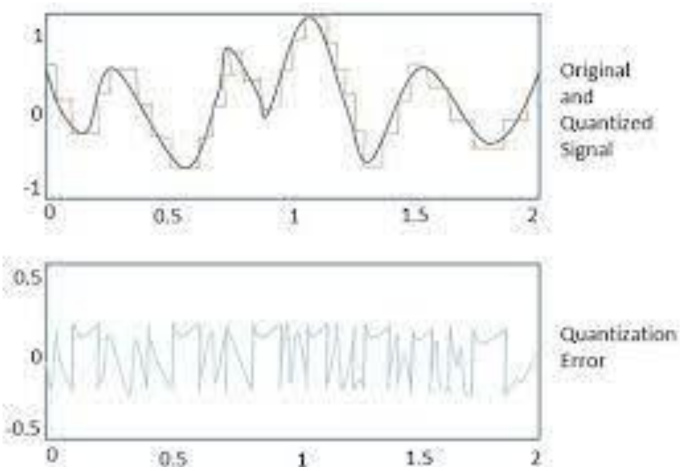

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

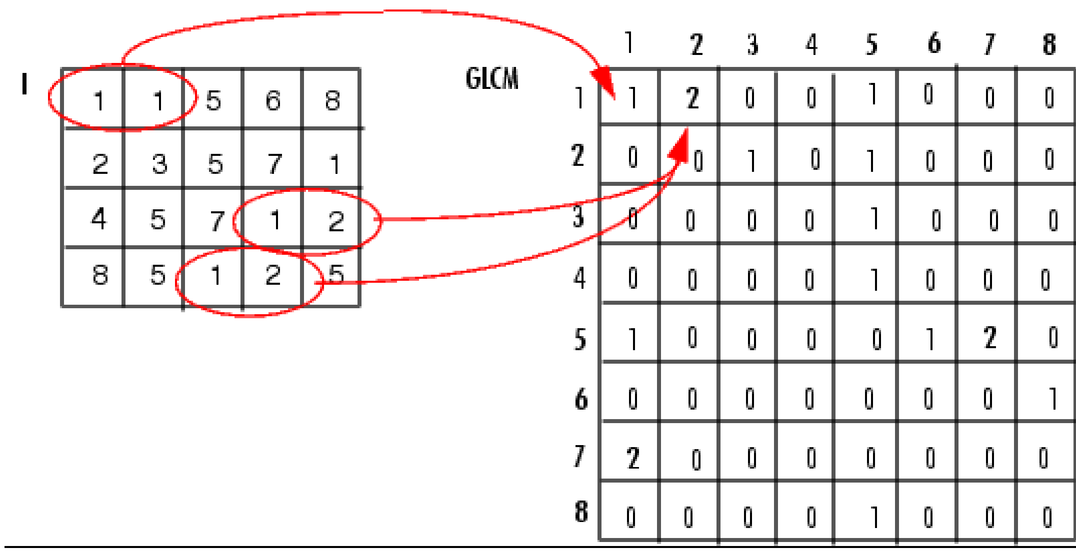
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



CHAPTER-4

DIGITAL IMAGE PROCESSING

Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of ‘f’ at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate’s values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

$$f\ (\text{xylem}) = \begin{matrix} f(0,0) & f(0,1) & \ldots\ldots\ldots & f(0,N-1) \\ f(1,0) & f(1,1) & \ldots\ldots\ldots & f(1,N-1) \\ . & . & & . \\ . & . & & . \\ f(M-1,0) & f(M-1,1) & \ldots\ldots\ldots & f(M-1,N-1) \end{matrix}$$

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.

A digital image can be represented naturally as a MATLAB matrix:

$$\begin{matrix} f(1,1) & f(1,2) \ldots\ldots\ldots & f(1,N) \\ f(2,1) & f(2,2) \ldots\ldots\ldots & f(2,N) \end{matrix}$$

.   .   .

f =   .   .   .

f (M,1) f(M,2) …….f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Format name	**Description**	**recognized extension**
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png

XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread ('8. jpg');

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name	**Description**
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255] (1byte per Element).

Uint16 unsigned 16_bit integers in the range [0, 65535] (2byte per element).

Uint 32 unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element). Int8 signed 8_bit integers in the range [-128,127] 1 byte per element)

Int 16 signed 16_byte integers in the range [32768, 32767] (2 bytes per element).

Int 32 Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER 5

Software Introduction:

5.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

5.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

  This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

  This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

  This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

  MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

5.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

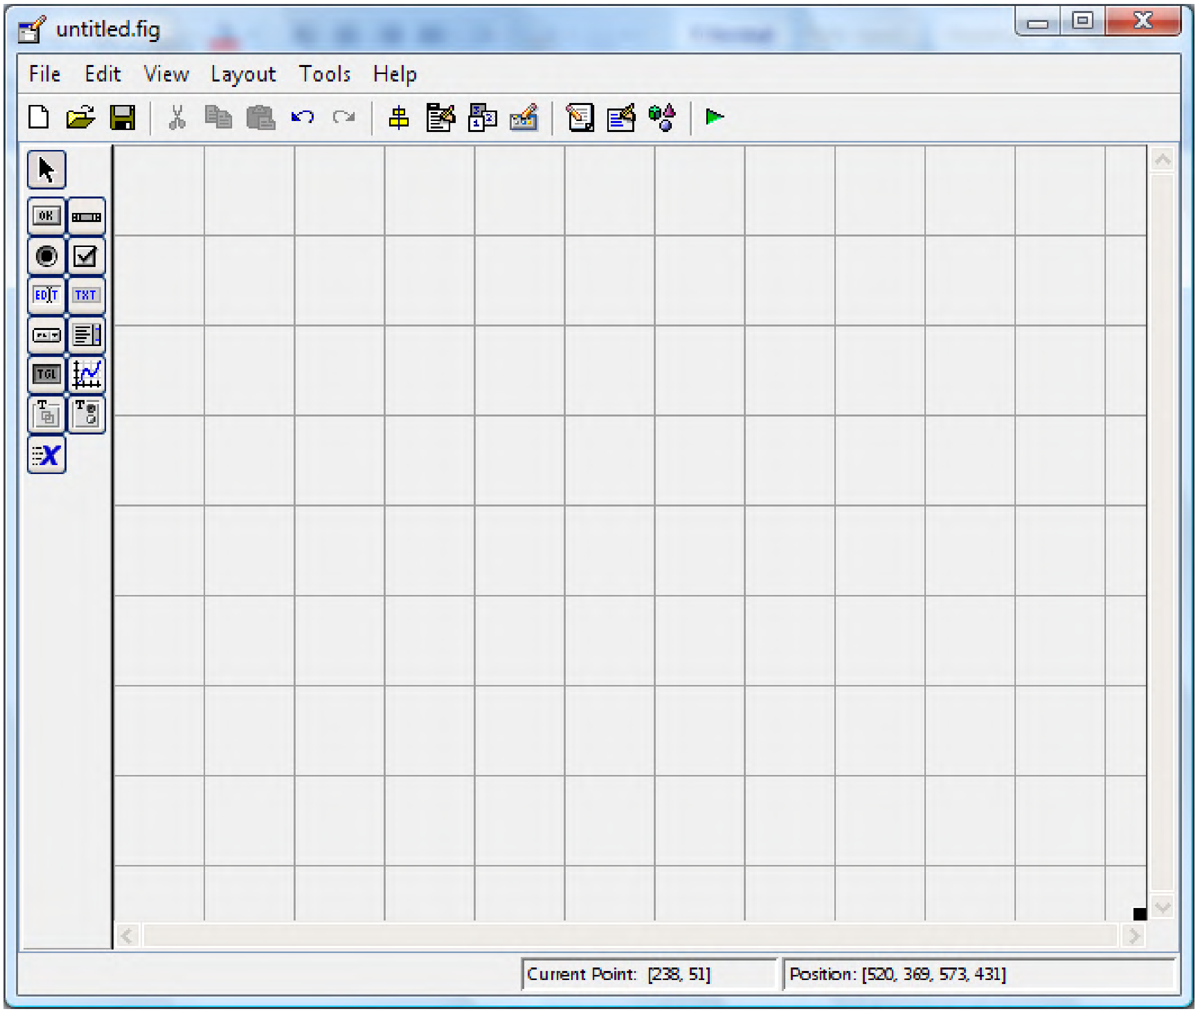
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

5.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator,

and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

5.4.1 Introduction - describes the components of the MATLAB system.

5.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

5.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

5.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

5.5 DEVELOPMENT ENVIRONMENT

5.5.1 Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

5.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

5.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

5.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

5.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

5.6 MANIPULATING MATRICES

5.6.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =
   16    3    2   13
    5   10   11    8
    9    6    7   12
    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

5.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example, num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

```
3               -99             0.0001
9.6397238       1.60210e-20     6.02252e23
1i              -3.14159j       3e5i
```

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

5.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

5.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

5.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

5.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

5.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

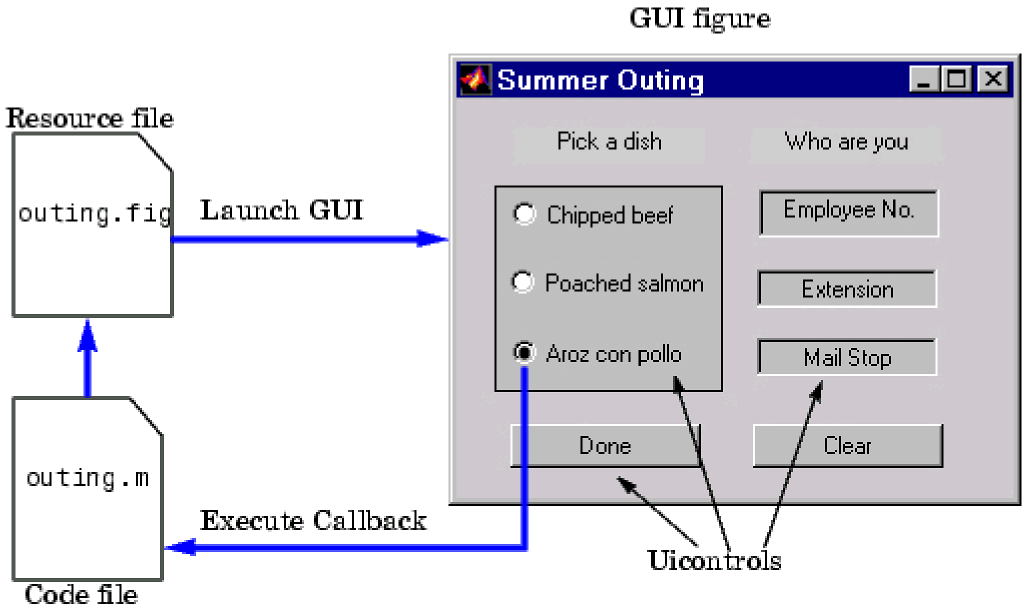


FIG 5.7 graphical user blocks

5.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

5.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

5.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus

- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)
button_state = get(h,'Value');
if button_state == get(h,'Max')
```

```
    % toggle button is pressed
elseif button_state == get(h,'Min')
    % toggle button is not pressed
end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)
set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)
off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
mutual_exclude(off)
% Continue with callback
   .
   .
   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
   errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

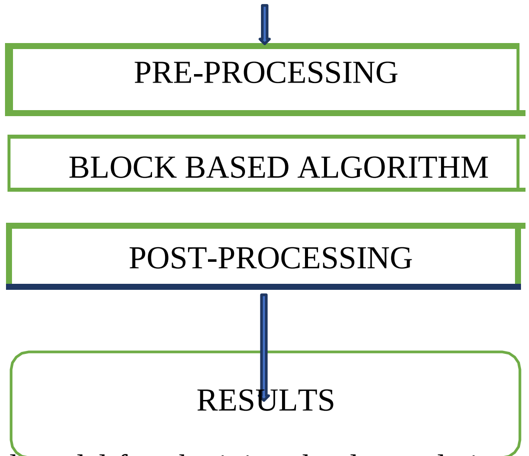
Chapter 6

Proposed method

Landsat 8 is one of the essential satellite programs of the National Aeronautics and Space Administration (N.A.S.A). This satellite is currently operational. This satellite consists of two different sensors "Thermal InfraRed Sensor (T.I.R.S.) and Operational Land Imager (O.L.I.)."b) At any point of time, for each IMF average value of the envelope computed from local maxima or local minima must be zero.

By considering the above two conditions, it came to know that IMFs are correlated to oscillatory modes in time series. Addition of all IMFs and the residual signal recovers the entire signal. The IMFs contain different frequency ranges, where the highest frequencies are usually found in the first IMF which contains the edge information with reference to image and lower frequencies in subsequent IMFs consists of spatial information of the image.

BLOCK DIAGRAM:



Now the mathematical model for obtaining the decorrelation stretcher can be understood from the following expressions. Let us assume that for the original image having (k, l) number of pixels. The decorrelation stretcher image has (k, m) number of pixels.

$$SUMX_{l,m} = \sum_{k=1}^{n} P_{k,l} * P_{k,m}$$

$$SUM_l = \sum_{k=1}^{n} P_{k,l}$$

Where Pk,l is the value of the kth pixel for the channel l.

The element of the covariance matrix

$$COV_{l,m=} \frac{1}{(n-1)}\left[SUMX_{l,m} - \frac{1}{n} * SUM_l * SUM_m\right]$$

For the correlation matrix element

$$COV_{l,m} = \frac{COV_{l,m}}{(COV_{l,l} * COV_{m,n})^{1/2}}$$

Table. 1 Landsat 8 Band Information [22]

S.No	Spectral Band	Wavelength	Resolution	Solar Irradiance
1	Band 1	0.433 – 0.453	30 *m*	2031 W/(m2μm)
2	Band 2	0.450 – 0.515	30 *m*	1925 W/(m2μm)
3	Band 3	0.525 – 0.600	30 *m*	1826 W/(m2μm)
4	Band 4	0.630 – 0.680	30 *m*	1574 W/(m2μm)
5	Band 5	0.845 – 0.885	30 *m*	955 W/(m2μm)
6	Band 6	1.560 – 1.660	30 *m*	242 W/(m2μm)
7	Band 7	2.100 – 2.300	30 *m*	82.5 W/(m2μm)
8	Band 8	0.500 – 0.680	15 *m*	1739 W/(m2μm)
9	Band 9	1.360 – 1.390	30 *m*	361 W/(m2μm)

Output Image (fig:7.1 & 7.2)

Chapter 8

CONCLUSION

In the proposed research work, we have presented a new approach for image enhancement. This image enhancement is based on an image decorrelation stretcher. This approach is suitable for mainly satellite images. Besides, this approach can be used for medical diagnostic purposes. In the World of today, image enhancement can also be used to provide information regarding Novel Coronavirus.

DECLARATION

We, the student of **Bachelor of Technology** in Department of Electronics And Communication Engineering’, session: <2017 – 2021>, St. Martin’s Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled IOT BASED COAL MINE SAFETY MONITORING AND ALERTING SYSTEM is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

D.Rishika (17K81A0414)
E.Joseph David (18K85A0410)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his in valuable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerableways.

We would like to express our gratitude to **B.HARI KRISHNA, Head&Professor**, the Dept. of Information Technology for his/her advice, supervision and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator A.ANAND** for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for along time to come.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

Coal mining is the process of extracting coal from the ground. Steel and cement industries use coal as a fuel for extraction of iron from iron ore and for cement production. Underground mining industry comes to the category, where each and every parameter such as methane gas, high temperature, fire accidents and so on has to be monitored regularly. Safe production level of coal mine is still low, disasters in coal mine occur frequently, which lead to great loss of possession and life. The disasters happening in coal mine are due to the complexity of mine environment and the variety of work carried out in coal mine, so it is very necessary to monitor the working environment of coal mine. To get over this problem, projects has proposed a wireless sensor network's application in coal mining safety system. In this wireless sensor network's application system there will, be master controllers and slave controllers. Slave controllers will detect the danger and give alert through RF to master controller and it will raise the alarm in all tunnels and also raise message on IOT, which will help to take action as soon as possible. This monitoring and alerting system is powered by Atmega328 microcontroller for master controller and rollers for slave controller and consists of temperature sensor, water sensor, methane and carbon dioxide sensor and RF transmitter which collects temperature, humidity and methane values underground of coal mine.

LIST OF TABLES

LIST OF FIGURES

CHAPTER 1

INTRODUCTION

1.1 OVERVEIW OF THE PROJECT:

Coal is one of the most important commodities and raw materials for a number of industries. It is used for power generation as well as the extraction of many by-product chemicals and materials. The extraction of coal from the coal mine is, however, a complex and dangerous process. Many accidents take place in the coal mines world over which causes fatalities and economic losses. The dangers and hazards can be reduced significantly by making use of the latest smart technologies.

1.2 OBJECTIVES OF THE PROJECT

The objective of developing this systems is to monitor and alerting the workers if there is any change in temperature and water level. This project is developed to provide a better safety to the coal mine workers**.**

1.3 SCOPE OF THE PROJECT

With the growing innovations future work of this experimentation may include, more development of the system by using other advanced sensors for monitoring the underground. Threats. Also, all the underground operations can be carried out from the ground surface. New developing communication technologies can be used for highspeed data transfer in integration with smart sensors for sensing the mine conditions. Also, more IOT enabled systems can be developed for more advanced functionality.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

1. Arduino UNO
2. LCD
3. Power Supply Unit
4. LM35
5. Water level indicator
6. RF Module
7. Wifi Module

8. Buzzer

ARDUINO

Arduino is open source software. Arduino Uno is a microcontroller, ATmega328Pcontain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

FIG.1.1 ARDUINO UNO

LCD

The LCD is used to display whenever there is a gas leakage or fire detected in the area. Whenever there is a gas leakage the Arduino that is connected to the sensor and LCD sends a message to LCD to display ‘Gas leakage’. When there is fire outbreak the Arduino again sends a message to LCD to display ‘Fire Detected’ notifying us if there is a gas leakage or fire detected in the vicinity.

FIG 1.2 LCD DISPLAY

POWER SUPPLY

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage 31 stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

LM35

LM35 is a precession Integrated circuit Temperature sensor, whose output voltage varies, based on the temperature around it. It is a small and cheap IC which can be used to measure temperature anywhere between -55°C to 150°C. There will be rise of 0.01V (10mV) for every degree Celsius rise in temperature.

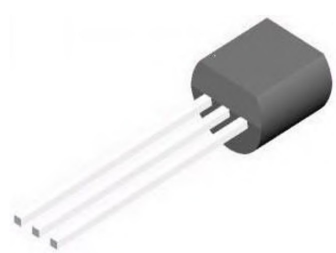

Fig 1.3 LM35

WATER LEVEL INDICATOR

A water level indicator is a system that relays information back to a control panel to indicate whether a body of water has a high or low water level. Some water level indicators use a combination of probe sensors or float switches to sense water levels. “The Water Level Indicator employs a simple mechanism to detect and indicate the water level in an overhead tank or any other water container.”

Fig.1.4 Water level indicator

RF MODULE

An RF module (short for radio-frequency module) is a (usually) small electronic device used to transmit and/or receive radio signals between two devices. In an embedded system it is often desirable to communicate with another device wirelessly. This wireless communication may be accomplished through optical communication or through radio frequency(RF) communication. For many applications, the medium of choice is RF since it does not require line of sight. RF communications incorporate a transmitter and a receiver. They are of various types and ranges. Some can transmit up to 500 feet. RF modules are typically fabricated using RF CMOS technology.

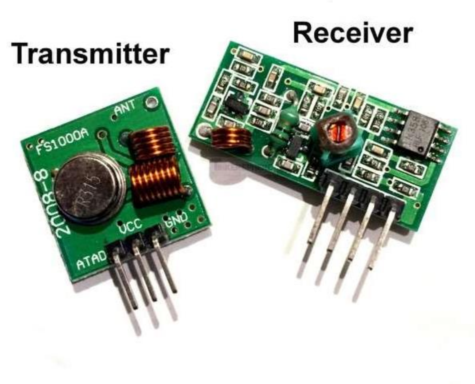

FIG 1.5 RF MODULE

WIFI MODULE(ESP-01)

The ESP8266 Wi-Fi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

1.4.2 SOFTWARE REQUIREMENTS:

1.4.2.1 ARDUNO IDE SOFTWARE:

This software is basically used for giving commands to ARDUNO Microcontroller**.**

STEPS FOR INSTALLING ARDUNO IDE SOFTWARE:

1. Download Arduino IDE Software in your PC.

2. When the download finishes, proceed with the installation.

3. Allow the driver installation process when you get a warning from the operating system.

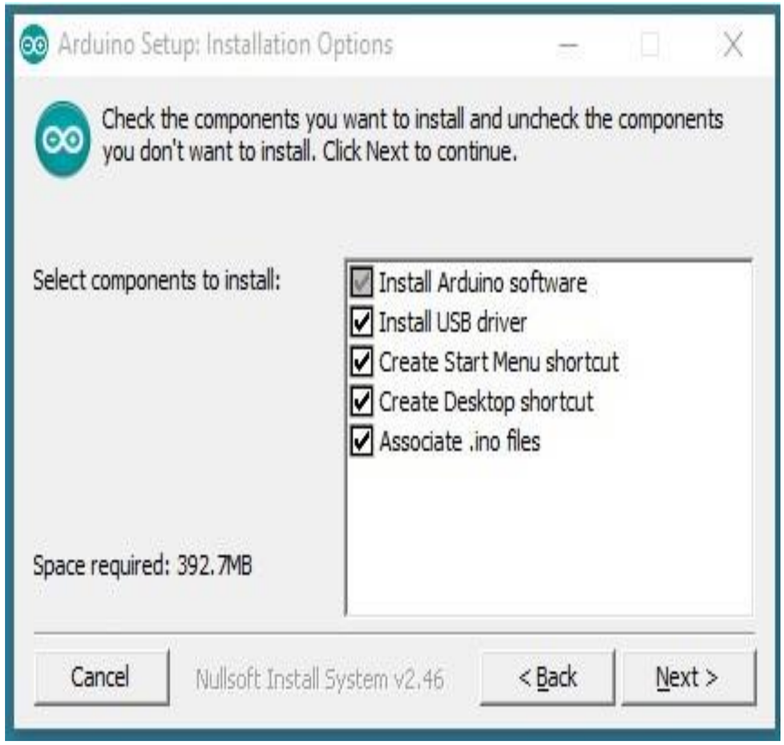

Fig:1.8 Installation process of driver

4. Choose the components to install

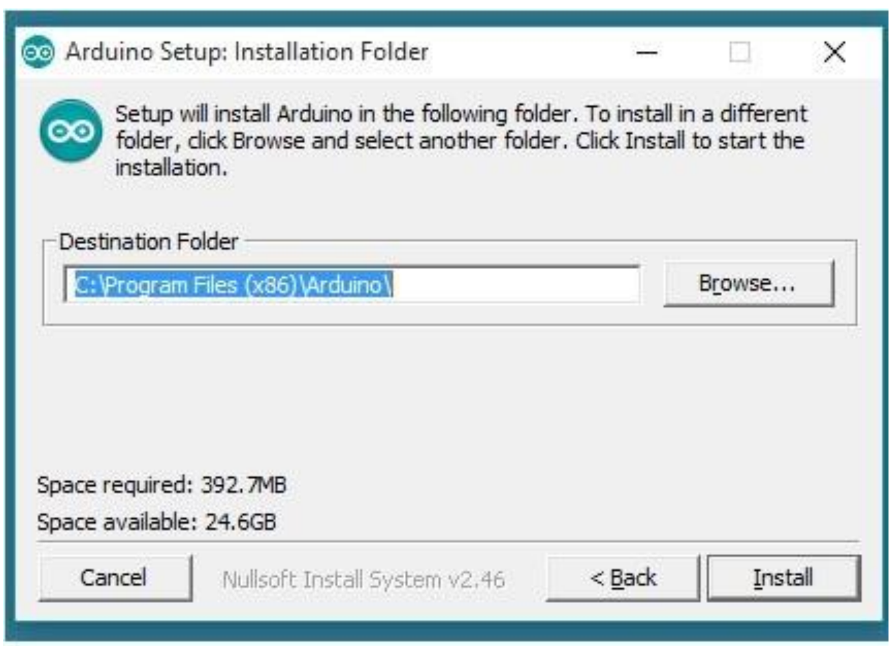

Fig 1.9 Setting destination folder

5. Choose the installation directory (we suggest to keep the default one)

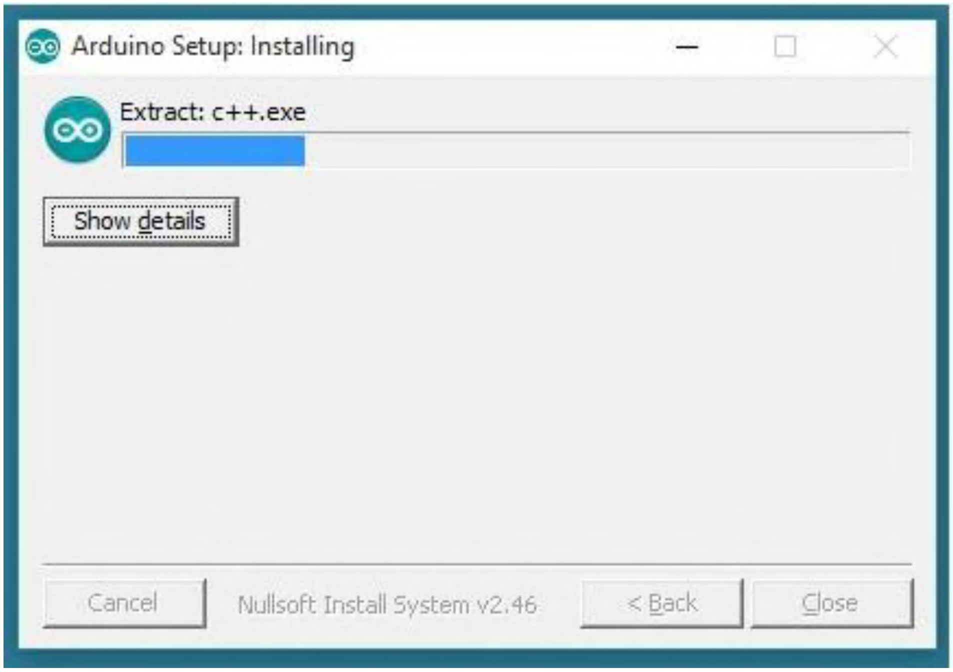

Fig:1.10 Installing directory

6. Successfully completed Installation of Software

7. Writing code on IDE platform

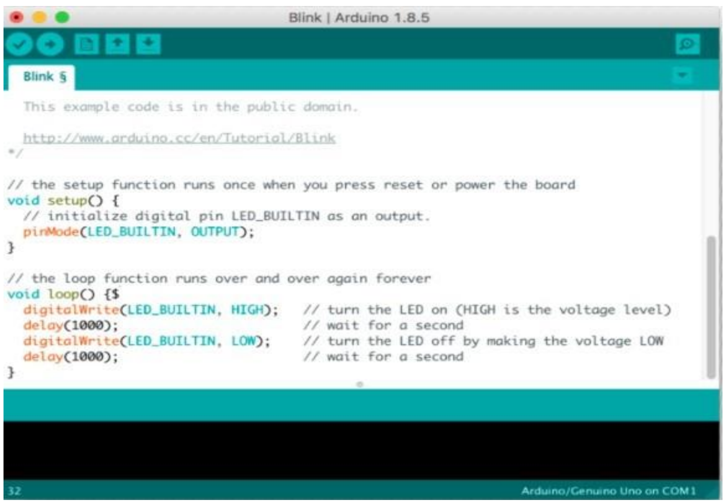

Fig:1.11 Source code written on IDE platform

1.4.2.2 PROTEUS SOFTWARE:

Through this software Schematic implementation of the embedded system will be done**.**

STEPS FOR DESIGNING SYSTEM ON PROTEUS DESIGN SUITE:

Step 1: Open ISIS software and select new design in File menu

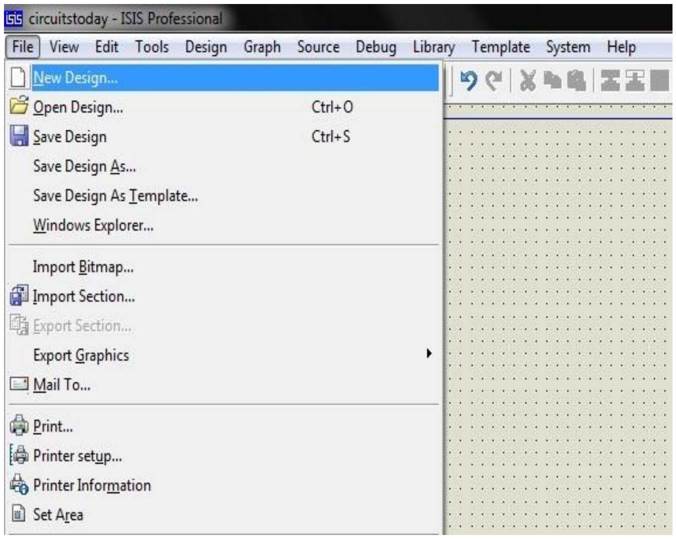

Fig:1.12 Simulation Procedure 1

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

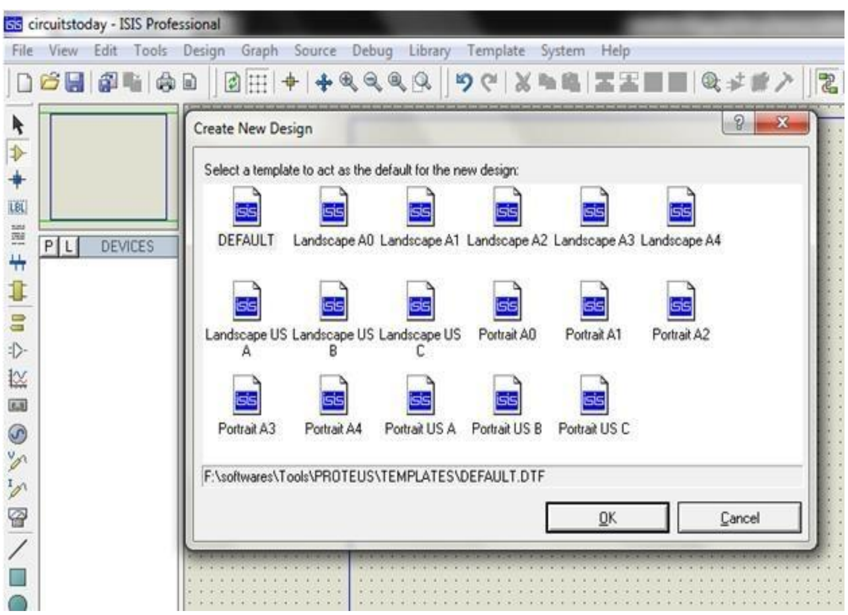

Fig:1.13 Simulation Procedure 2

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a

new folder for every layout as it generates other files supporting your design.

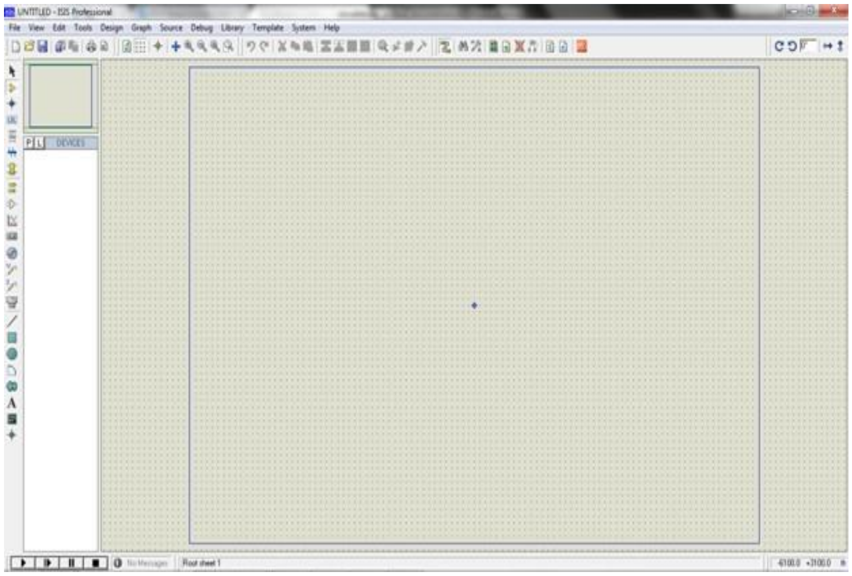

Fig:1.14 Simulation Procedure 3

Step 4: To Select components, Click on the component mode button.

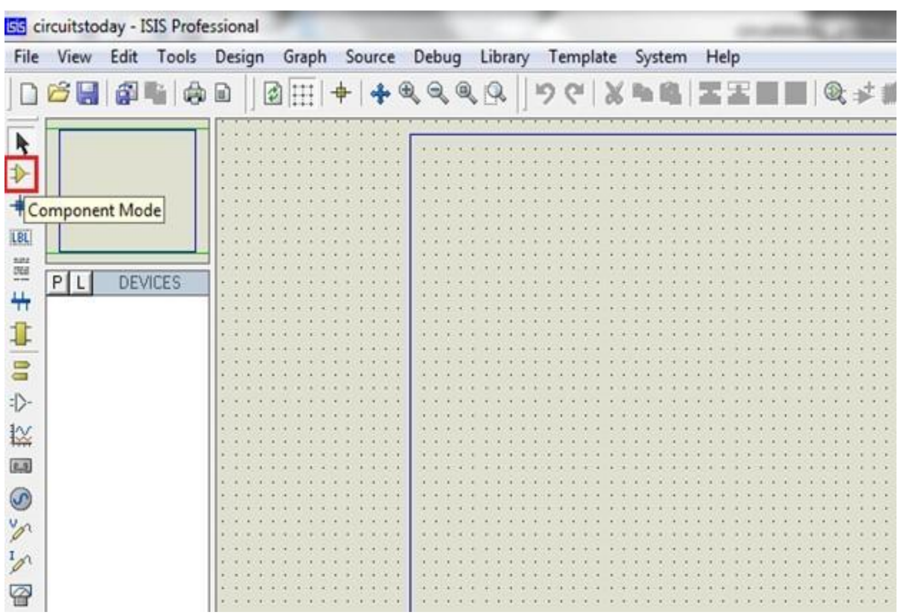

Fig:1.15 Simulation Procedure 4

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

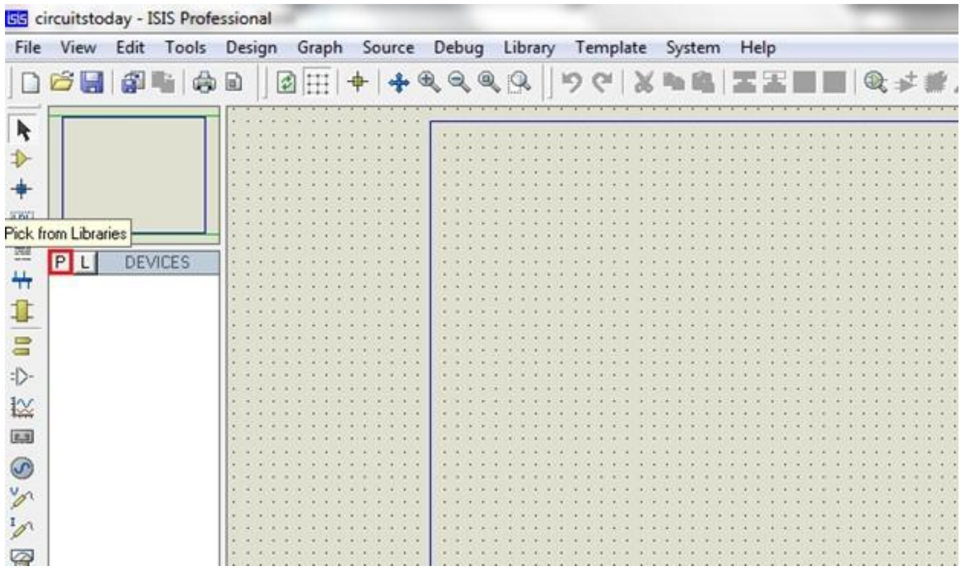

Fig:1.16 Simulation Procedure 5

Step 6: Select the components from categories or type the part name in Keyword's text box.

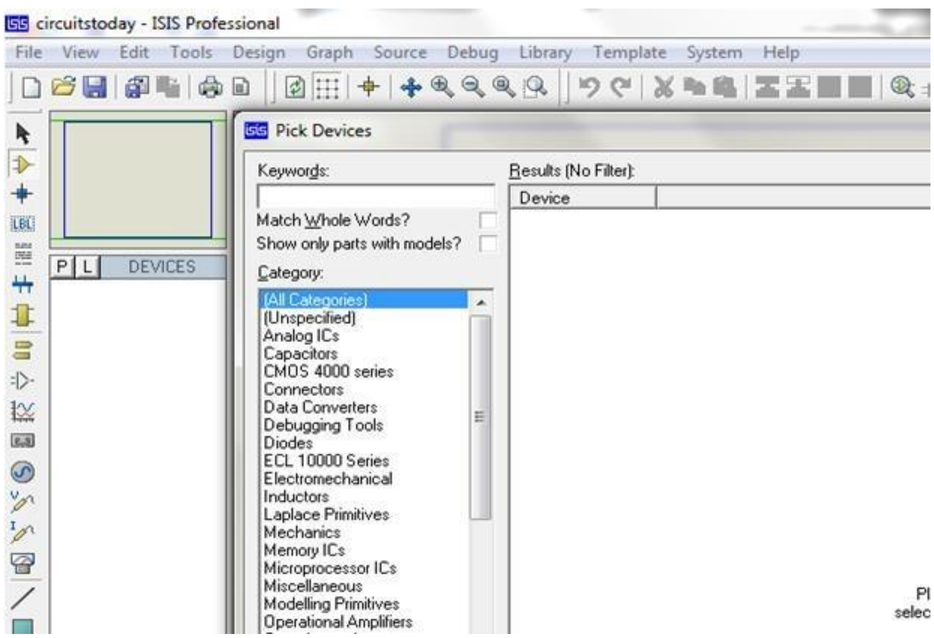

Fig:1.17 Simulation Procedure 6

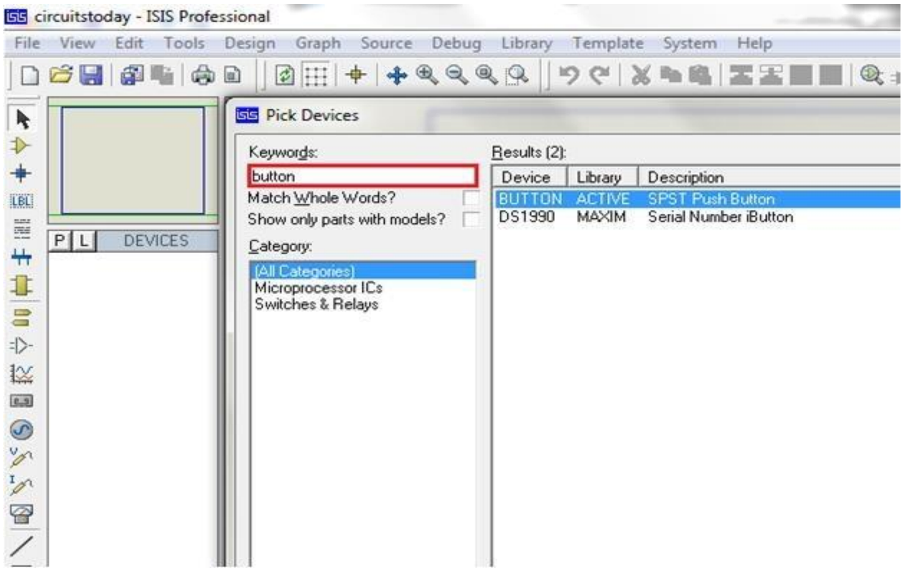

Fig:1.18 Simulation Procedure 7

Step 7: The selected components will appear in the devices list. Select the component and place itin the design sheet by left-cl.

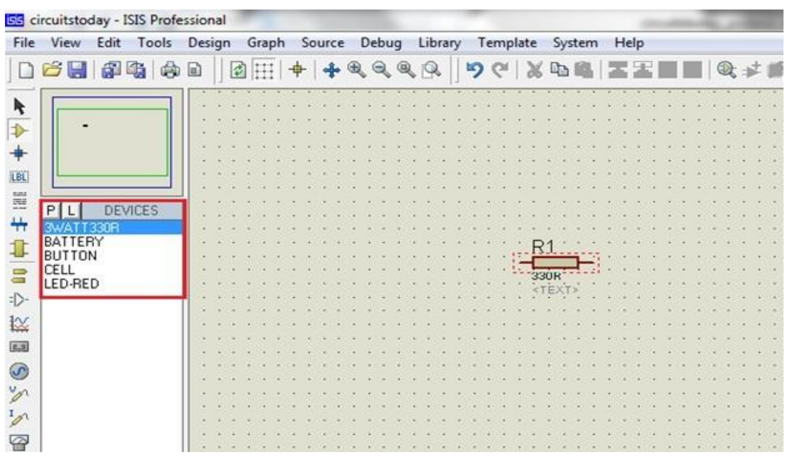

Fig.1.19 Simulation Procedure 8

Step 8: Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

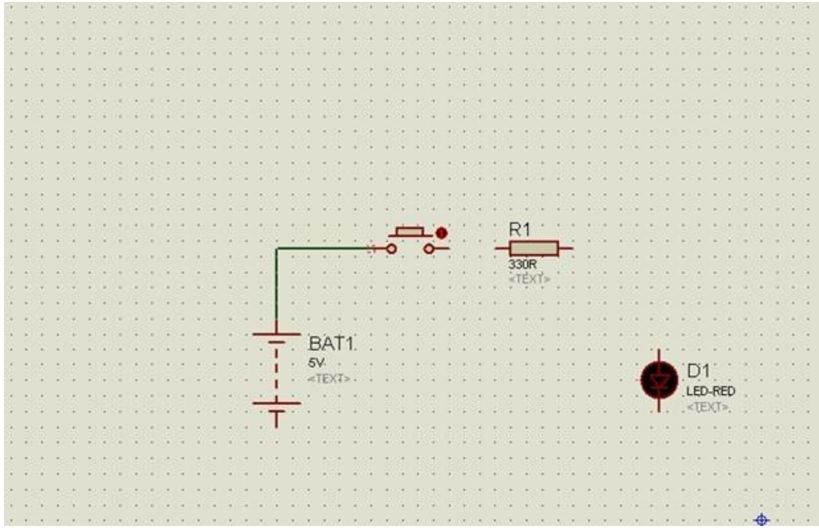

Fig:1.20 Simulation Procedure 9

Step 9: Double click on the component to edit the properties of the components and click on Ok.

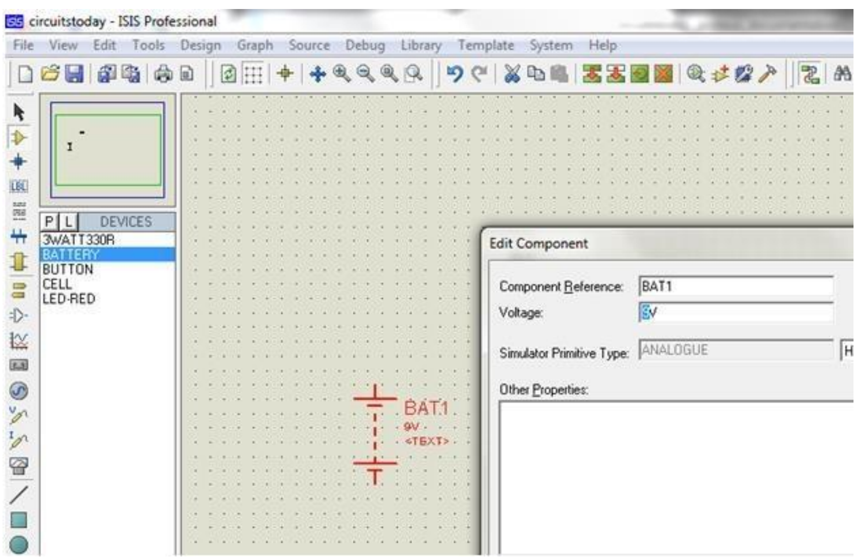

Fig.1.21 Simulation Procedure 10

Step 10: In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

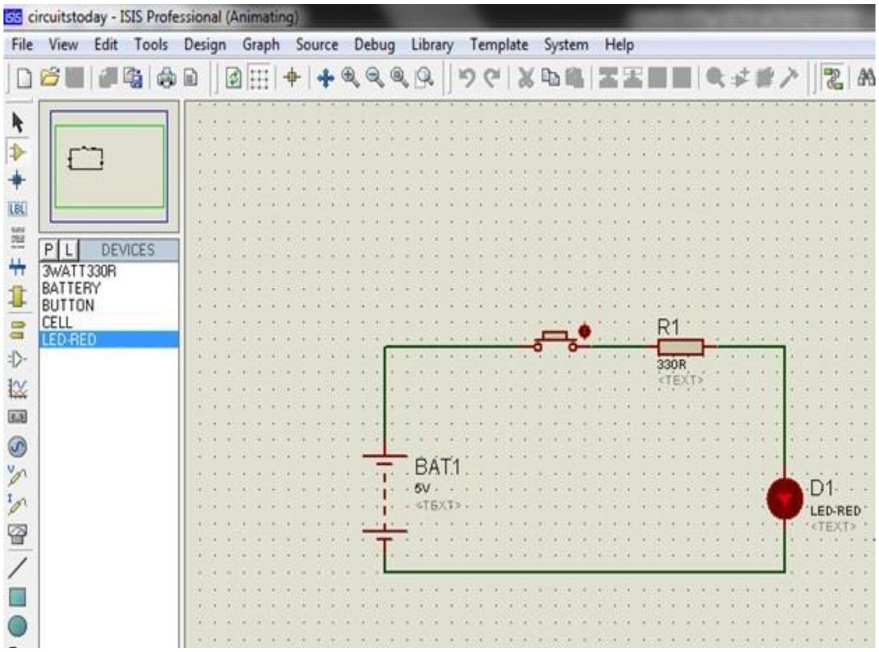

Fig:1.22 Simulation Procedure 11

Step 11: Simulation can be stepped, paused or stopped at any time.

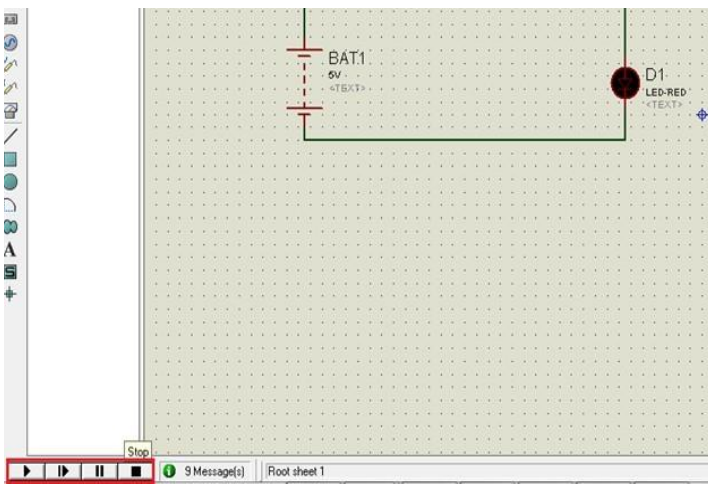

Fig:1.23 Simulation Procedure 12

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software. Now, we assembled all sensors and interfaced to Arduino

UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way. We observed temperature values and water level values inside the mine and all the information is sent to the online server.

CHAPTER 2

LITERATURE SURVEY AND EXISTING MODELS

2.1 RELATED WORK

Coal mining is the process of extracting coal from the ground. Steel and cement industries use coal as a fuel for extraction of iron from iron ore and for cement production. Underground mining industry comes to the category, where each and every parameter such as methane gas, high temperature, fire accidents and so on has to be monitored regularly. Safe production level of coal mine is still low, disasters in coal mine occur frequently, which lead to great loss of possession and life. The disasters happening in coal mine are due to the complexity of mine environment and the variety of work carried out in coal mine, so it is very necessary to monitor the working environment of coal mine. To get over this problem, projects has proposed a wireless sensor network's application in coal mining safety system. In this wireless sensor network's application system there will, be master controllers and slave controllers. Slave controllers will detect the danger and give alert through RF to master controller and it will raise the alarm in all tunnels and also raise message on IOT, which will help to take action as soon as possible. This monitoring and alerting system is powered by Atmega328 microcontroller for master controller and rollers for slave controller and consists of temperature sensor, water sensor, methane and carbon dioxide sensor and RF transmitter which collects temperature, humidity and methane values underground of coal mine.

2.2 EXISTING SYSTEM

In existing method, there is no data transmission from mine territory to watching station for checking the status of excavators and the environment. Difficult to screen each and every person to the barometrical status. There is no fast wellbeing endeavours available at the hour of emergency.

2.3 PROPOSED SYSTEM

IOT Based Coal Mine Safety Monitoring project consists of two hardware modules, one transmitter and one receiver. The main controller in both the modules is an Arduino board. The transmitter module is installed inside the coal mine. The transmitter module contains the smoke sensor, temperature sensor and methane sensor. The transmitter module also has an LCD, all the sensor data is displayed on the LCD screen by the Arduino controller. The RF transmitter present on the transmitter module sends the sensor data to the receiver module. The receiver module also has an Arduino controller, LCD display, and an RF receiver. The RF receiver receives the sensor values from the RF transmitter on the transmitter module. The received sensor values are displayed on the LCD screen. The Arduino also sends the sensor data to the remote IOT server using the WiFi module every two minutes. If any of the sensor values exceeds a particular threshold level, the buzzer is turned on to notify the concerned personnel. The remote server has an IOT platform installed on it which displays the relevant data using the GUI which helps the users in monitoring and system control.

3.3 MODULES FUNCTIONALITIES:

3.3.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

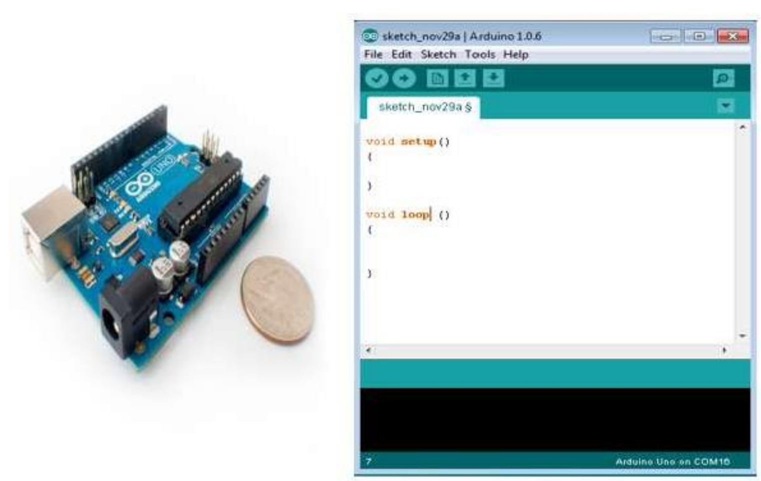

Figure 3.5 : Arduino UNO board

Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Table 3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

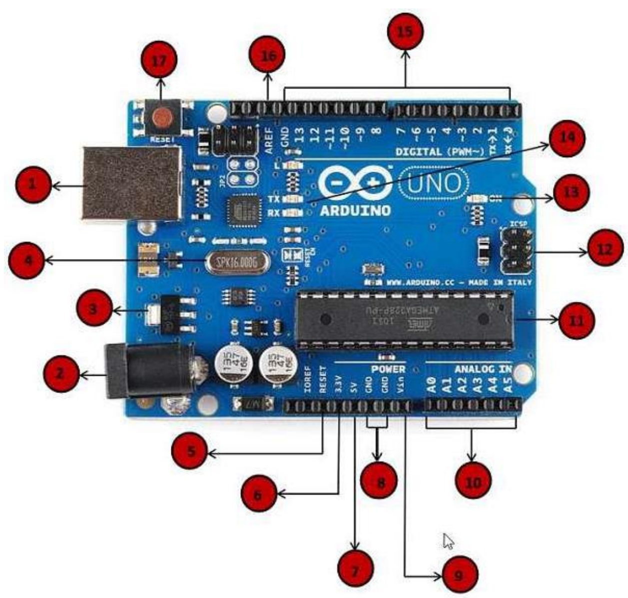

Figure 3.6 : Board description of Arduino Uno

	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.

13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.3.2 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

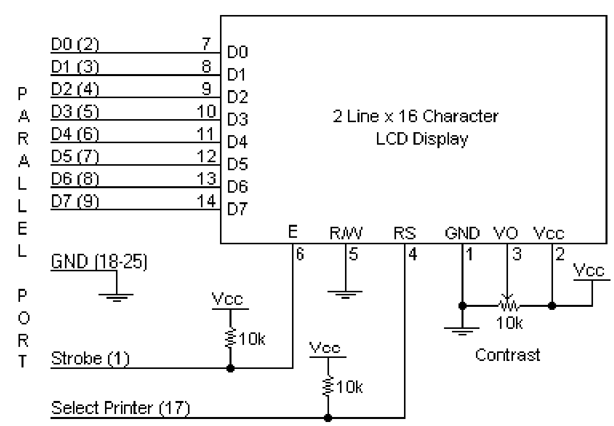

Figure 3.7: Schematic diagram of LCD

- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select SignalH: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode

15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8, 16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exist. “Supertwist” types, for example, offer improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

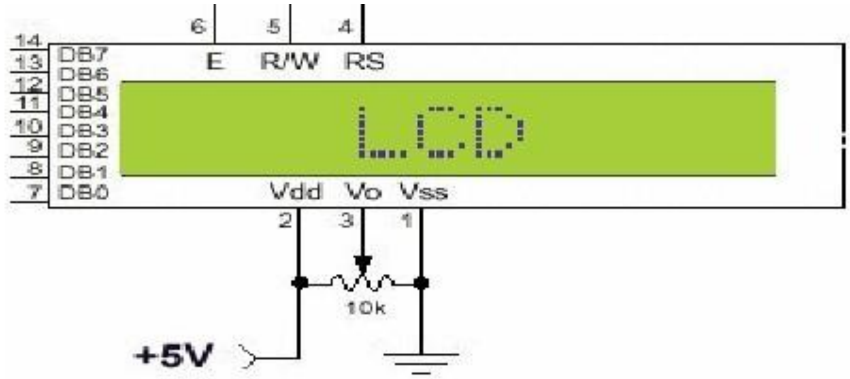

Figure3.8 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust

5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 3.9 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low.Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 3.5 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

3.3.3 TEMPERATURE SENSOR (LM35)

General Description:

The LM35 series are precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius (Centigrade) temperature. The LM35 thus has an advantage over linear temperature sensors calibrated in °Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1/4°C at room temperature and ±3/4°Cover a full −55 to +150°C temperature range. Low cost is assured by trimming and calibration at the wafer level. The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 µA from its supply, it has very low self-heating, less than 0.1°C in still air. The LM35 is rated to operate over a −55° to +150°C temperature range, while the LM35C is rated for a −40° to +110°C range (−10° with improved accuracy). The LM35 series is available packaged in hermetic TO-46 transistor packages, while the LM35C, LM35CA, and LM35D are also available in the plastic TO-92 transistor package. The LM35D is also available in an 8-lead surface mount small outline package and a plastic TO-220 package (Fig 3.2.1).

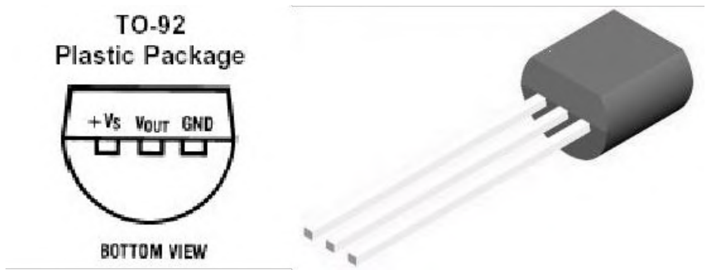

Fig 3.10 LM35

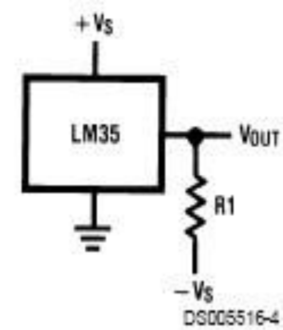
Applications:

The LM35 can be applied easily in the same way as other integrated-circuit temperature sensors. It can be glued or cemented to a surface and its temperature will be within about 0.01°C of the surface temperature. This presumes that the ambient air temperature is almost the same as the surface temperature; if the air temperature were much higher or lower than the surface temperature, the actual temperature of the LM35 die would be at an intermediate temperature between the surface temperature and the air temperature. This is especially true for the TO-92 plastic package, where the copper leads are the principal thermal path to carry heat into the device, so its temperature might be closer to the air temperature than to the surface temperature. To minimize this problem, be sure that the wiring to the LM35, as it leaves the device, is held at the same temperature as the surface of interest. The easiest way to do this is to cover up these wires with a bead of epoxy which will insure that the leads and wires are all at the same temperature as the surface, and that the LM35 die's temperature will not be affected by the air temperature. The TO-46 metal package can also be soldered to a metal surface or pipe without damage. Of course, in that case the V− terminal of the circuit will be grounded to that metal. Alternatively, the LM35 can be mounted inside a sealed-end metal tube, and can then be dipped into a bath or screwed into a threaded hole in a tank. As with any IC, the LM35 and accompanying wiring and circuits must be kept insulated and dry, to avoid leakage and corrosion. This is especially true if the circuit may operate at cold temperatures where condensation can occur. Printed-circuit coatings and varnishes such as Humiseal and epoxy paints or dips are often used to insure that moisture cannot corrode the

LM35 or its connections. These devices are sometimes soldered to a small light-weight heat fin, to decrease the thermal time constant and speed up the response in slowly-moving air. On the other

hand, a small thermal mass may be added to the sensor, to give the steadiest reading despite small deviations in the air temperature.



Choose $R_1 = -V_S/50\ \mu A$

$V_{OUT} = +1{,}500$ mV at +150°C

$= +250$ mV at +25°C

$= -550$ mV at −55°C

Features:

Calibrated directly in ° Celsius (Centigrade)

Linear + 10.0 mV/°C scale factor

0.5°C accuracy guaranteeable (at +25°C)

Rated for full −55° to +150°C range

Suitable for remote applications

Low cost due to wafer-level trimming

Operates from 4 to 30 volts

Less than 60 µA current drain

Low self-heating, 0.08°C in still air

Nonlinearity only ±1/4°C typical

Low impedance output, 0.1 W for 1 mA load

Testing of Temperature sensor LM35 using OP-AMP Circuit:

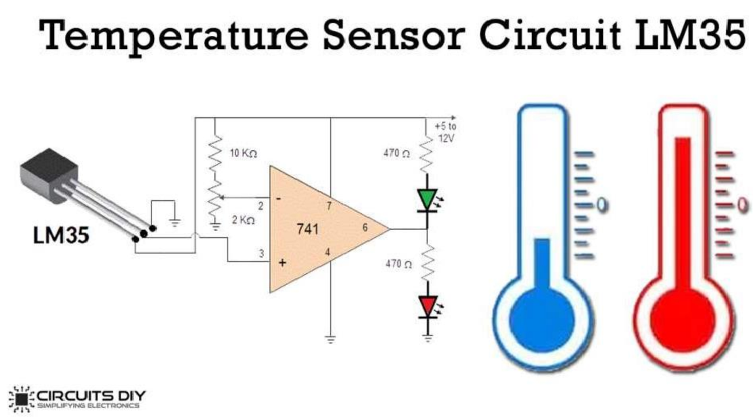


Fig3.11: LM35 testing circuit

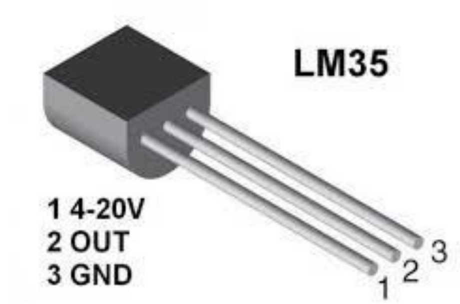
Gain calculation:

Gain A = 1+ R_f / R_1
If R_f =4k & R_1=1k Then Gain A=5

Output of LM35:

		Before Amplification,	After amplification With gain of 5
0^0 C	$\longrightarrow$	0V,	0V
1^0C	$\longrightarrow$	10mV,	50mV
25^0C	$\longrightarrow$	250mV,	1.25V
100^0C	$\longrightarrow$	1000mV,	5V



3.3.4 WIFI Module:

The ESP8266 is a low-cost Wi-Fi module that can be integrated easily into IoT devices. We’ve featured several projects using this module, such as **How To Make Smart Home Electronics: A Smart Mailbox** and **How To Read Your Arduino’s Mind: Building A Childproof Lock**. This tutorial will walk you through setting up ESP8266 Wi-Fi module which can be used with Arduino. The ESP8266 comes in many models with different functionalities. We’ll be focusing on the ESP8266 ESP-01 module, the most common and basic one available.

What is ESP8266?

The ESP8266 is a small Wi-Fi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module. In this tutorial, we hope to show you how to interface the ESP8266 with an Arduino and perform some basic functions like connecting it to a Wi-Fi network.

- & 0.4ms guard interval
  Wake up and transmit packets in < 2msStandby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you’ll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you’d like to make your prototyping more compact, you can also purchase breadboard breakouts forthe ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266’s pins are according to the foll

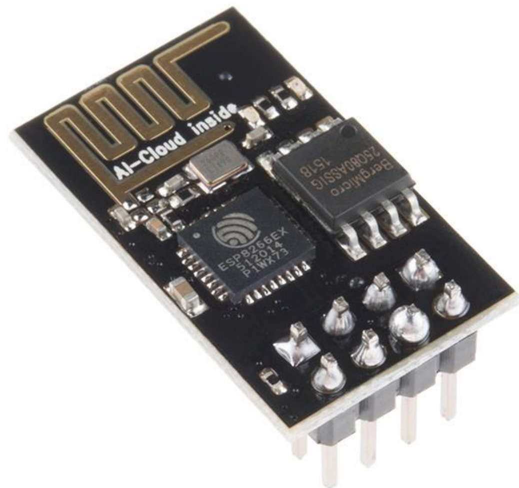


Fig 3.12 ESP8266 ESP-01 module / ©Sparkfun

ESP-01 Features – Spark fun**:**

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation

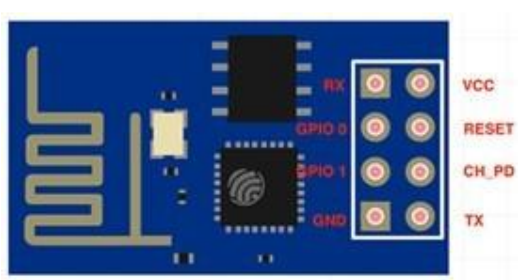

Fig 3.13. ESP8266 Pinout / ©Github.com/ydonnelly

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wifi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino.

Use the following diagram to connect the ESP8266 module to the Arduino:

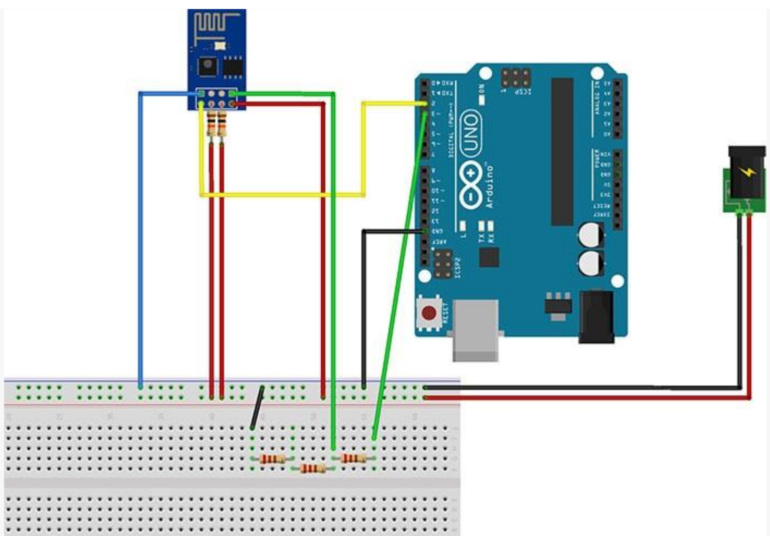

Figure 3.14. Connection between ESP8266 and Arduino Uno

You will need the following parts:

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider

3.3 V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)

- You can use something like this: https://www.sparkfun.com/products/114

- Breadboard and jumper wires
  - A couple of features of this circuit stand out immediately.

  - First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 voltscould fry the module! When connecting the ESP8266 to this power supply, you should not only connect the Vcc and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors

3.3.5 Water Level Indicator

Description

This is the circuit diagram of a simple **corrosion free water level indicator** for home and industries.In fact the the level of any conductive non corrosive liquids can be measured using this

circuit.The circuit is based on 5 transistor switches.Each transistor is switched on to drive the corresponding LED , when its base is supplied with current through the water through the electrode probes.

One electrode probe is (F) with 6V AC is placed at the bottom of tank. Next probes are placed step by step above the bottom probe. When water is rising the base of each transistor gets electrical connection to 6V AC through water and the corresponding probe. Which in turn makes the transistors conduct to glow LED and indicate the level of water. The ends of probes are connected to corresponding points in the circuit as shown in circuit diagram. Insulated Aluminium wires with end insulation removed will do for the probe. Arrange the probes in order on a PVC pipe according to the depth and immerse it in the tank.AC voltage is use to prevent electrolysis at the probes. So this setup will last really long. I guarantee at least a 2 years of maintenance free operation .That's what I got and is still going.

Components

T1 – T5 BC 548 or 2N2222 Transistors

R1-R5 2.2K 1/4 W Resistors

R6-R10 22K 1/4 W Resistors

D1 – D5 LED's (color your choice)

Notes:

Use a transformer with 6V 500 mA output for power supply. Do not use a rectifier! we need pure AC. Use good quality insulated Aluminium wire for probes. If Aluminium wires are not available try Steel or Tin. Copper is the worst. Try the circuit first on a bread board and if not working properly, make adjustments with the resistance values .This is often needed because conductivity of water changes slightly from place to place .The type number of the transistors used here are not critical and any small signal NPN transistor will do the job. Few other suitable type numbers are BC546, BC107, PN2222, BC337, BF494, ZTX300, BEL187 etc. The circuit can be enclosed in a plastic box with holes for revealing the LEDs .

Water Level Indicator Circuit Diagram and Sensor Arrangement

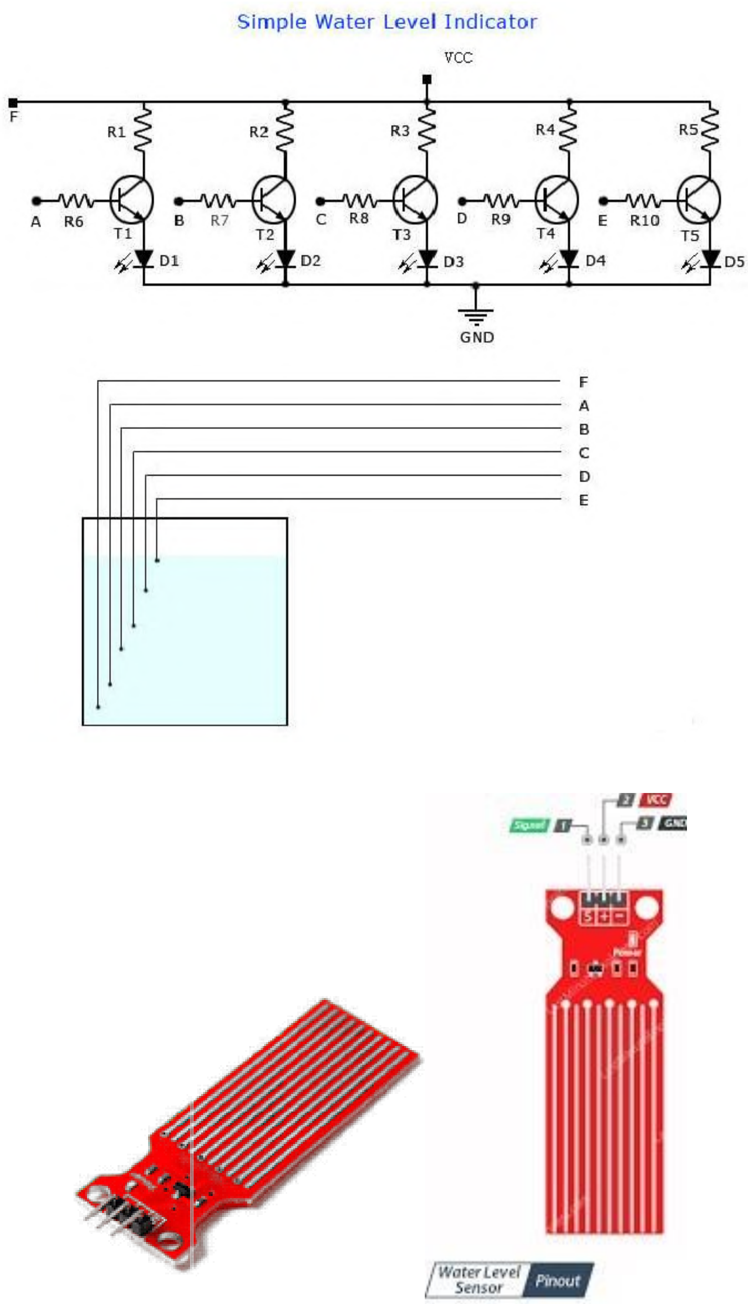

Figure 3.15 Water level indicator

3.3.6 Radio Frequency

The nRF24L01+ transceiver module is designed to operate in 2.4 GHz worldwide ISM frequency band and uses GFSK modulation for data transmission. The data transfer rate can be one of 250kbps, 1Mbps and 2Mbps.

WHAT IS 2.4GHZ ISM BAND?

2.4 GHz band is one of the Industrial, Scientific, and Medical (ISM) bands reserved internationally for the use of unlicensed low-powered devices. Examples are Cordless phones, Bluetooth devices, near field communication (NFC) devices, and wireless computer networks (WiFi) all use the ISM frequencies.

Power consumption

The operating voltage of the module is from **1.9 to 3.6V**, but the good news is that the **logic pins are 5-volt tolerant**, so we can easily connect it to an Arduino or any 5V logic microcontroller without using any logic level converter.

The module supports programmable output power viz. 0 dBm, -6 dBm, -12 dBm or -18 dBm and consumes unbelievably around **12 mA during transmission** at 0 dBm, which is even lower than a single LED. And best of all, it consumes 26 µA in standby mode and 900 nA at power down mode. That’s why they’re the go-to wireless device for low-power applications.

SPI Interface

The nRF24L01+ transceiver module communicates over a 4-pin Serial Peripheral Interface (**SPI**) with a maximum data rate of **10Mbps**. All the parameters such as frequency channel (125 selectable channels), output power (0 dBm, -6 dBm, -12 dBm or -18 dBm), and data rate (250kbps, 1Mbps, or 2Mbps) can be configured through SPI interface.

The SPI bus uses a concept of a Master and Slave, in most common applications our Arduino is the Master and the nRF24L01+ transceiver module is the Slave. Unlike the I2C bus the number of

slaves on the SPI bus is limited, on the Arduino Uno you can use a **maximum of two SPI slaves** i.e. two nRF24L01+ transceiver modules.

Here are complete specifications:

Frequency Range	2.4 GHz ISM Band
Maximum Air Data Rate	2 Mb/s
Modulation Format	GFSK

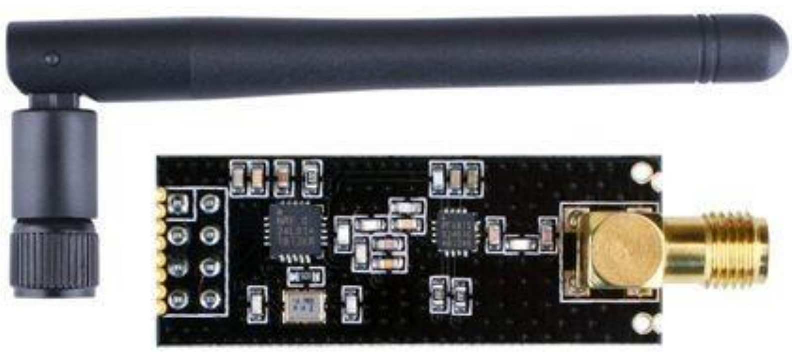
Max. Output Power	0 dBm
Operating Supply Voltage	1.9 V to 3.6 V
Max. Operating Current	13.5mA
Min. Current(Standby Mode)	26µA
Logic Inputs	5V Tolerant
Communication Range	800+ m (line of sight)

nRF24L01+ module Vs nRF24L01+ PA/LNA module

There are a variety of modules available based upon the nRF24L01+ chip. Below are the most popular versions.

nRF24L01+ Wireless Module

The first version uses on-board antenna. This allows for a more compact version of the breakout. However, the smaller antenna also means a lower transmission range. With this version, you'll be able to communicate over a distance of **100 meters**. Of course that is outdoors in an open space. Your range indoors, especially through walls, will be slightly weakened.

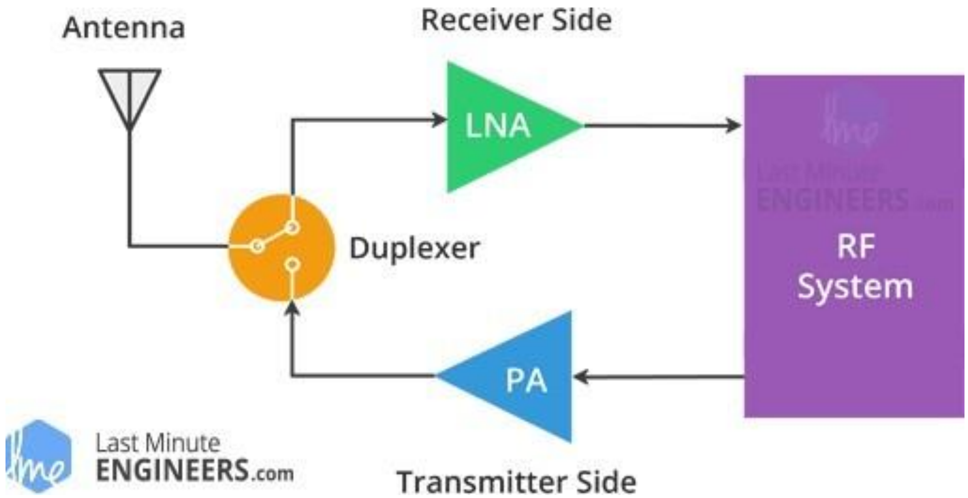


nRF24L01+ PA LNA Wireless Transceiver Module with External Antenna

The second version comes with a SMA connector and a duck-antenna but that's not the real difference. The real difference is that it comes with a special RFX2401C chip which integrates the PA, LNA, and transmit-receive switching circuitry. This range extender chip along with a duck-antenna helps the module achieve a significantly larger transmission range about **1000m**.

What is PA LNA?

The PA stands for **Power Amplifier**. It merely boosts the power of the signal being transmitted from the nRF24L01+ chip. Whereas, LNA stands for **Low-Noise Amplifier**. The function of the LNA is to take the



nRF24L01+ PA/LNA Block Diagram

extremely weak and uncertain signal from the antenna (usually on the order of microvolts or under -100 dBm) and amplify it to a more useful level (usually about 0.5 to 1V)

The low-noise amplifier (LNA) of the receive path and the power amplifier (PA) of the transmit path connect to the antenna via a duplexer, which separates the two signals and prevents the relatively powerful PA output from overloading the sensitive LNA input. For more information check out this article on digikey.com

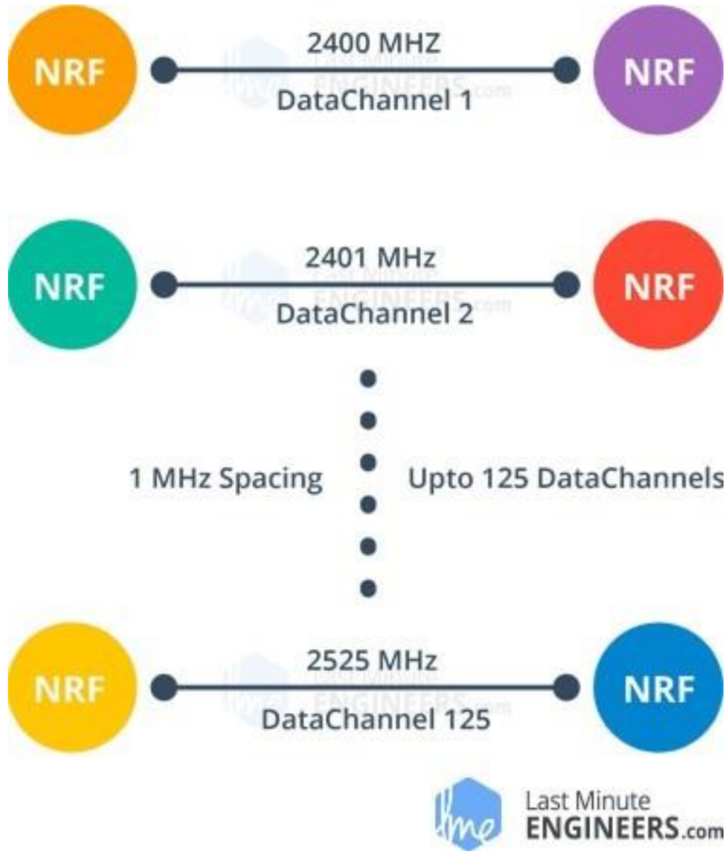
Except this difference, both modules are drop-in compatible. Meaning, if you build your project with one you can just unplug it and use another without need to make any changes to the system.

How nRF24L01+ transceiver module works?

RF Channel Frequency

The nRF24L01+ transceiver module transmits and receives data on a certain frequency called **Channel**. Also in order for two or more transceiver modules to communicate with each other, they need to be on the same channel. This channel could be any frequency in the 2.4 GHz ISM band or to be more precise, it could be between 2.400 to 2.525 GHz (2400 to 2525 MHz).

Each channel occupies a bandwidth of less than 1MHz. This gives us 125 possible channels with 1MHz spacing. So, the module can use 125 different channels which give a possibility to have a network of 125 independently working modems in one place.



The channel occupies a bandwidth of less than 1MHz at 250kbps and 1Mbps air data rate. However at 2Mbps air data rate, 2MHz bandwidth is occupied (wider than the resolution of RF channel frequency setting). So, to ensure non-overlapping channels and reduce cross-talk in 2Mbps mode, you need to keep 2MHz spacing between two channels.

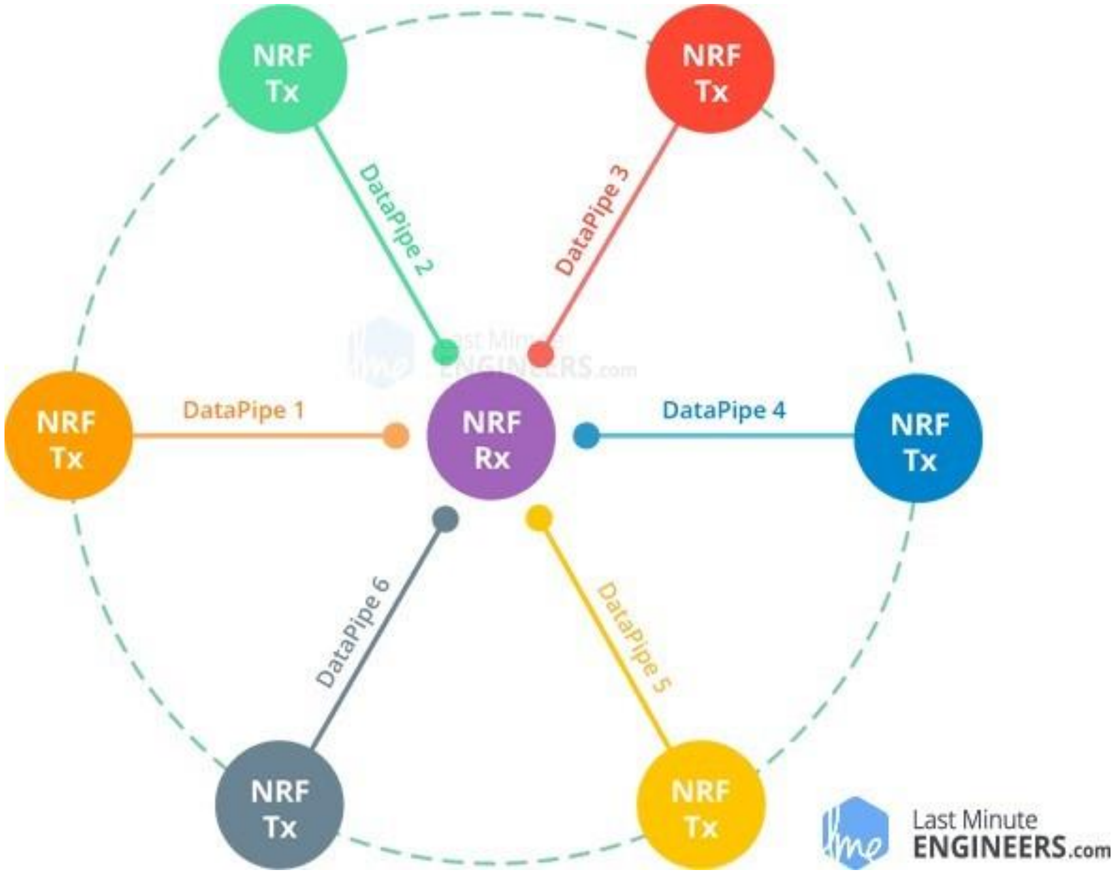
RF channel frequency of your selected channel is set according to the following formula:

$$Freq_{(Selected)} = 2400 + CH_{(Selected)}$$

For example, if you select 108 as your channel for data transmission, the RF channel frequency of your channel would be 2508MHz (2400 + 108)

nRF24L01+ Multiceiver Network

The nRF24L01+ provides a feature called **Multiceiver**. It’s an abbreviation for **Multi**ple Transmitters Single Re**ceiver**. In which each RF channel is logically divided into 6 parallel data channels called **Data Pipes**. In other words, a data pipe is a logical channel in the physical RF Channel. Each data pipe has its own physical address (Data Pipe Address) and can be configured. This can be illustrated as shown below.

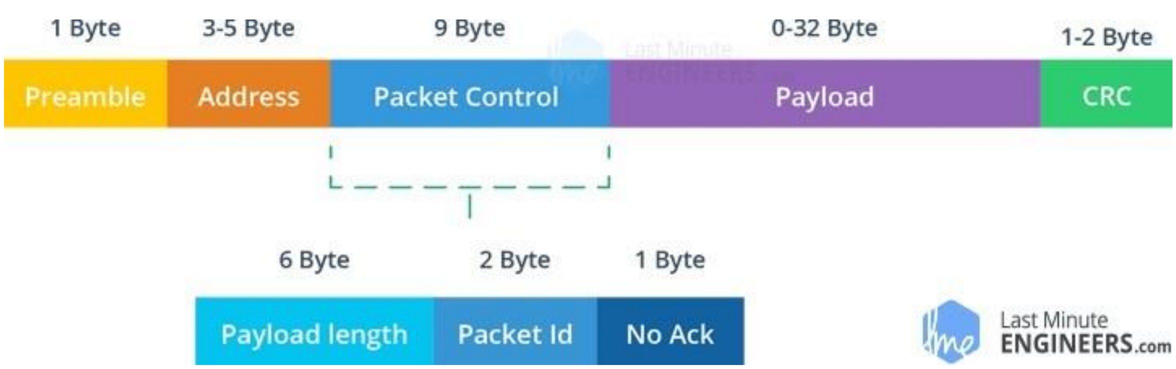


nRF24L01+ Multiceiver Network – Multiple Transmitters Single Receiver

To simplify the above diagram, imagine the primary receiver acting as a hub receiver collecting information from 6 different transmitter nodes simultaneously. The hub receiver can stop listening any time and acts as a transmitter. But this can only be done one pipe/node at a time.

Enhanced Shock Burst Protocol

The nRF24L01+ transceiver module uses a packet structure known as Enhanced ShockBurst. This simple packet structure is broken down into 5 different fields, which is illustrated below.



nRF24L01+ Enhanced Shock Burst Packet Structure

The original ShockBurst structure consisted only of Preamble, Address, Payload and the Cyclic Redundancy Check (CRC) fields. Enhanced Shock Burst brought about greater functionality for more enhanced communications using a newly introduced **Packet Control Field** (PCF).

This new structure is great for a number of reasons. Firstly, it allows for variable length payloads with a payload length specifier, meaning payloads can vary from 1 to 32 bytes.

Secondly, it provides each sent packet with a packet ID, which allows the receiving device to determine whether a message is new or whether it has been retransmitted (and thus can be ignored).

Finally, and most importantly, each message can request an acknowledgement to be sent when it is received by another device.

nRF24L01+ Automatic Packet Handling

Now, let's discuss three scenarios to get a better understanding of how two nRF24L01+ modules transact with each other.

Transaction with acknowledgement and interrupt This is an example of positive scenario. Here the transmitter starts a communication by sending a data packet to the receiver. Once the whole packet is transmitted, it waits (around 130 µs) for the acknowledgement packet (ACK packet) to receive. When the receiver receives the packet, it sends ACK packet to the transmitter. On receiving the ACK packet the transmitter asserts interrupt (IRQ) signal to indicate the new data is available.

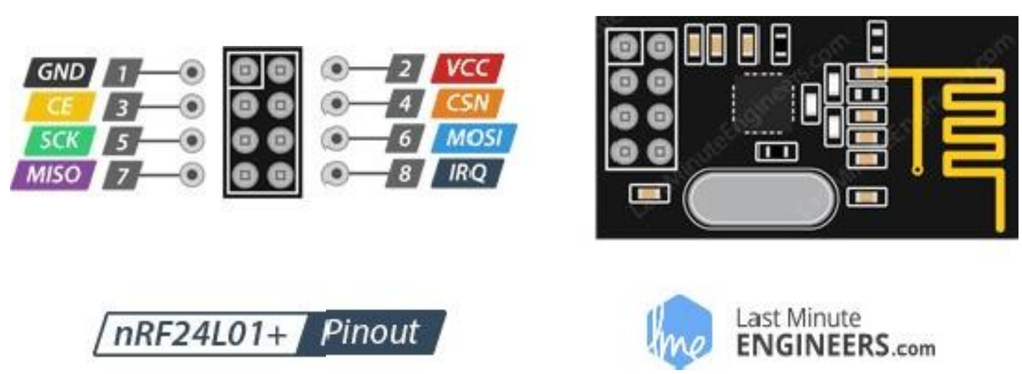
Transaction with data packet lost This is a negative scenario where a retransmission is needed due to loss of the packet transmitted. After the packet is transmitted, the transmitter waits for the ACK packet to receive. If the transmitter doesn't get it within Auto-Retransmit-Delay (ARD) time, the packet is retransmitted. When the retransmitted packet is receiv d by the receiver, the ACK packet is transmitted which in turn generates interrupt at the transmitter.

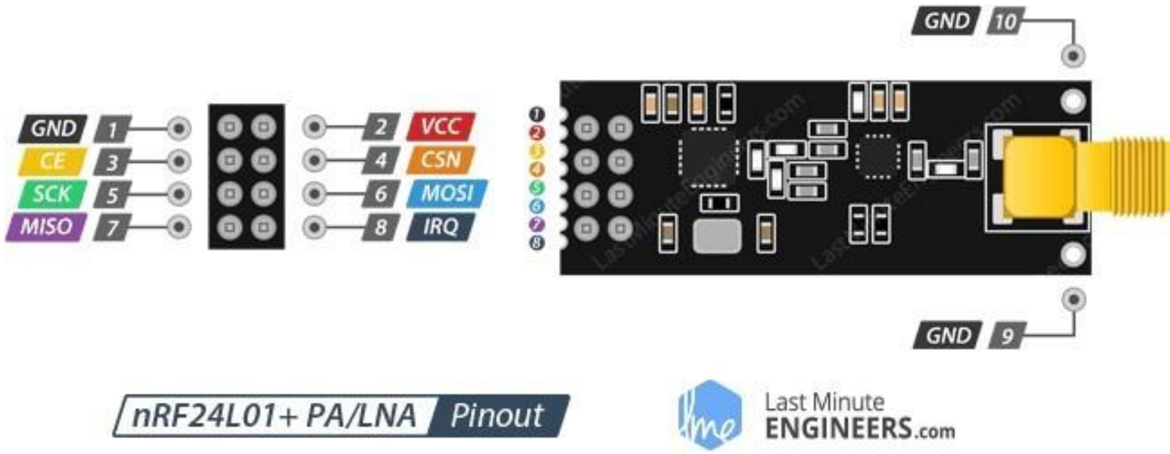
Transaction with acknowledgement lost This is again a negative scenario where a retransmission is needed due to loss of the ACK packet. Here even if the receiver receives the packet in the first attempt, due to the loss of ACK packet, transmitter thinks the receiver has not got the packet at all. So, after the Auto-Retransmit-Delay time is over, it retransmits the packet. Now when receiver receives the packet containing same packet ID as previous, it discards it and sends ACK packet again.

This whole packet handling is done automatically by the nRF24L 1+ chip without involvement of the microcontroller.

nRF24L01+ Transceiver Module Pinout

Let's have a look at the pinout of both the versions of nRF24L01+ transceiver Module.





GND is the Ground Pin. It is usually marked by encasing the pin in a square so it can be used as a reference for identifying the other pins.

VCC supplies power for the module. This can be anywhere from 1.9 to 3.9 volts. You can connect it to 3.3V output from your Arduino. Remember connecting it to 5V pin will likely destroy your nRF24L01+ module!

CE (Chip Enable) is an active-HIGH pin. When selected the nRF24L01 will either transmit or receive, depending upon which mode it is currently in.

CSN (Chip Select Not) is an active-LOW pin and is normally kept HIGH. When this pin goes low, the nRF24L01 begins listening on its SPI port for data and processes it accordingly.

SCK (Serial Clock) accepts clock pulses provided by the SPI bus Master.

MOSI (Master Out Slave In) is SPI input to the nRF24L01.

MISO (Master In Slave Out) is SPI output from the nRF24L01.

IRQ is an interrupt pin that can alert the master when new data is available to process

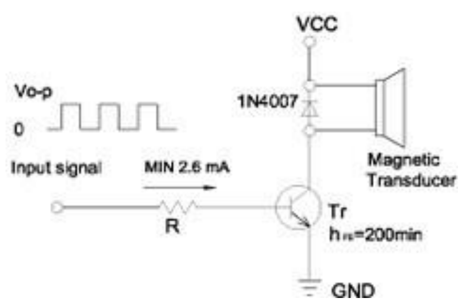
3.3.7 BUZZER:

Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.



Recommended Driving Circuit for Magnetic Transducer

Specifications:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Direct Current Resistance: The direct current resistance is measured by ammeter directly.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp: Keep working well between -30℃ and +70℃.

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self drive type to choose. Because of the internal set drive circuit, the self drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

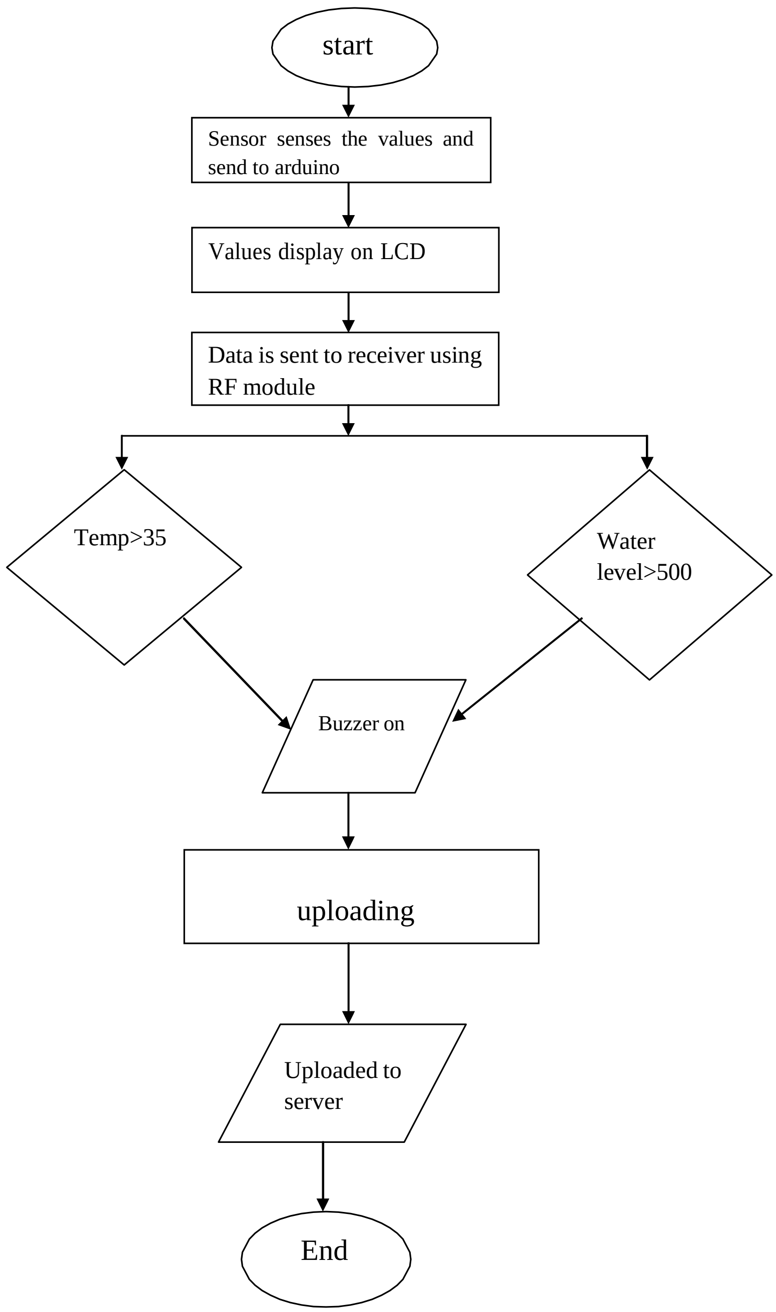
CHAPTER 4

PROJECT IMPLEMENTATION

4.1 IMPLEMENTATION STAGES



4.2 EXPERIMENTAL RESULTS:

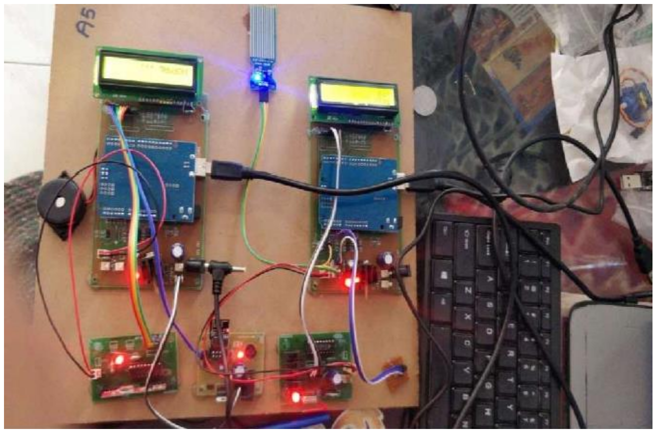


Figure 4.1: All the components connected on board

Figure 4.2 : Temperature and water level values displayed on LCD

Figure 4.3: "HIGH TEMPERATURE" displayed on LCD

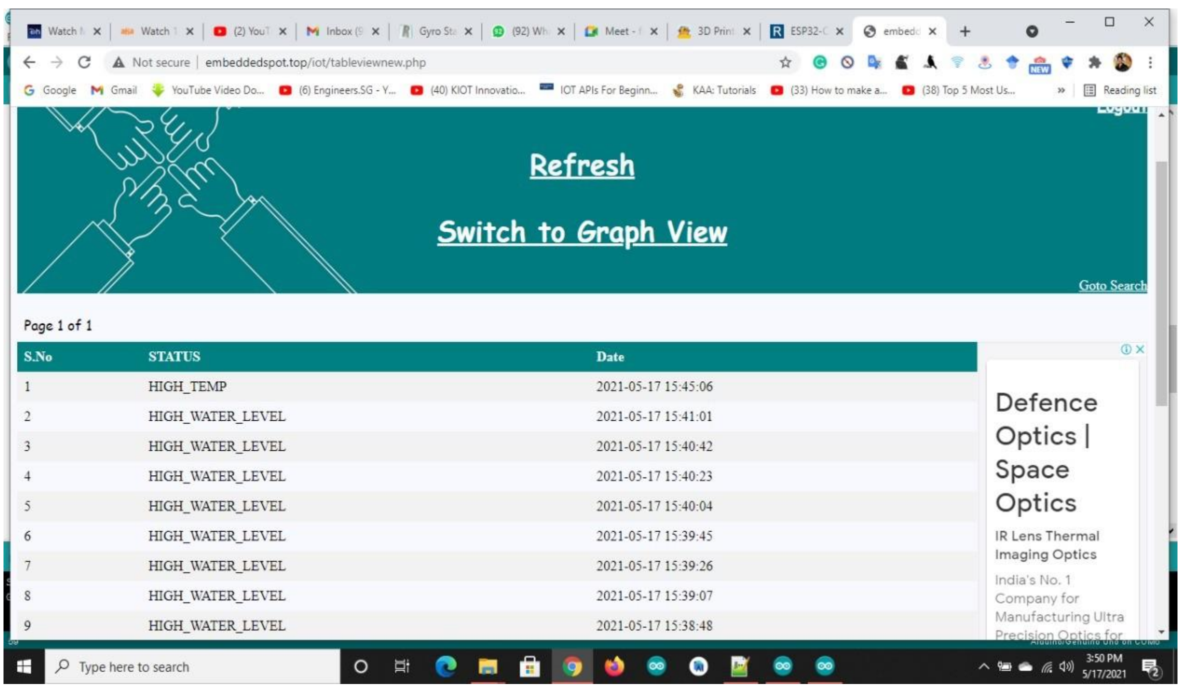

Figure 4.4: Message sent to Server

CHAPTER 5

ADVANTAGES AND APPLICATIONS

5.1 Advantages:

- The project is built from easily available and reasonably priced components. Therefore, the cost is reasonable and maintenance is easy.

5.2 Application

- This project is crucial in coal mining industry and is critical for the health and safety of the mine workers.

CHAPTER 6

CONCLUSION AND FUTURE SCOPE

6.1 CONCLUSION

This system is displaying the parameters on the monitoring unit; it will be helpful to all miners present inside the mine to save their life before any casualty occurs. Alarm triggers when sensor values crosses the threshold level. This system also stores all the data in the computer for future inspection.

6.2 FUTURE SCOPE

This is a safe critical project, therefore this system can be improved by making it fail-safe. We can implement the fail-safe operation using redundancy in the system. If the one module fails then the parallel module will take over the operation.

DECLARATION

We, the student of **Bachelor of Technology** in Department of ‘ELECTRONICS AND COMMUNICATION ENGINEERING’, session: 2017 – 2021, St. Martin’s Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled Application of MIMO-OFDM system in UAV communication network is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university foraward of any degree.

G. SAMYUKTHA (17K81A0416)
K. KUSUMA (17K81A0428)
K. VIJAY (18K85A0405)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **DR.A.Chaitanya Krishna, professor**, department of ECE and our class project coordinator **MS,A.Aleti Soumya, Assistant professor**, department of ECE for guidance and encouragement in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. G.Samyuktha (17K81A0416)
2. K.Kusuma (17K81A0428)
3. K.Vijay (18K85A0405)

ABSTRACT

With the application of various new mission loads in unmanned aerial vehicle (UAV), how to improve the communication quality of UAV data link has become a widespread concern. With the rapid development of UAV, multi-UAVs cooperative self-organizing network can accomplish tasks more reliably, efficiently and economically than a single large UAV. This paper analyzes the characteristics of mobile self-organizing network composed of multiple UAVs, and focuses on how to improve the communication quality of UAV network. After analyzing the technical principles and system models of multiple input multiple output (MIMO) and orthogonal frequency division multiplexing (OFDM) technologies, a MIMO-OFDM communication system is constructed. The simulation results show that the application of MIMO-OFDM technology in UAV communication network can effectively improve the data transmission ability.

TABLE OF CONTENTS

CHAPTER-1

1.1 OVERVIEW OF PROJECT

Choosing transmission technology is one of the key issues to improve the performance of UAV communication network. Multiple input multiple output (MIMO) technology can reduce the influence of multipath fading without increasing power and sacrificing bandwidth and make full use of the channel capacity of wireless communication system.

1.2 OBJECTIVES OF THE STUDY

At present, UAV and ground control center mainly use a single antenna for communication, whose channel capacity seriously restricts the maximum transmission rate, resulting in long transmission time. So, the main objective of this project is to overcome the drawbacks of existing system.

1.3 SCOPE OF PROJECT

This project is going to cover the technical properties of MIMO and OFDM systems and mostly focuses on combination of these two systems for the improvement of transmission ability.

1.4 ORGANISATION OF CHAPTERS

1.4.1 Introduction.

1.4.2 Literature survey.

1.4.3 Proposed system.

1.4.4 Main program.

1.4.5 Simulation results and analysis.

1.4.6 Conclusion and future enhancement.

1.4.1 INTRODUCTION

With the application of new mission loads in UAV, such as high-resolution photoelectric camera, infrared thermal imager and synthetic aperture radar, a large number of real time color images, thermal images, videos and other information will be generated, resulting in a geometric increase in the amount of returned information. How to improve the communication capacity of data link has become a hot issue in the development of UAV system. At present, UAV and ground control center mainly use a single antenna for communication, whose channel capacity seriously restricts the maximum transmission rate, resulting in long transmission time. Multiple input multiple output (MIMO) technology can reduce the influence of multipath fading without increasing power and sacrificing bandwidth and make full use of the channel capacity of wireless communication system, which can effectively overcome the problem of insufficient communication capacity and low transmission rate of UAV. UAV communication network requires multiple UAVs for data exchange and transmission, and wireless transmission technology is used as the underlying communication means. But the physical characteristics of wireless channel determine the network bandwidth it can provide. Due to the coupling of collision, signal attenuation, multipath interference and other factors generated by wireless channels, UAV terminals can only obtain a bandwidth much smaller than the theoretical maximum bandwidth value. Therefore, choosing the appropriate physical layer transmission technology is one of the key issues to improve the performance of UAV communication network. MIMO technology can greatly improve the quality and capacity of a communication system by implementing full diversity, and it can resist multipath fading to some extent, but it is powerless for frequency selective fading. Orthogonal frequency division multiplexing (OFDM) technology can effectively utilize spectrum resources and resist frequency selective fading. As a combination of MIMO and OFDM technology, MIMO-OFDM can not only improve the communication capacity, but also effectively combat frequency selective fading and improve the data transmission ability.

What is an UAV?

An unmanned aerial vehicle (UAV) or uncrewed aerial vehicle, commonly known as a drone, is an aircraft without a human pilot on board. UAVs are a component of an unmanned aircraft system (UAS), which include additionally a ground-based controller and a system of communications with the UAV

Fig: 1.1 UAV

The flight of UAVs may operate under remote control by a human operator remotely piloted aircraft (RPA) or with various degrees of autonomy, such as autopilot assistance, up to fully autonomous aircraft that does not allow human intervention. Compared to crewed aircraft, UAVs were originally used for missions too "dull, dirty or dangerous" for humans. While drones originated mostly in military applications, their use is rapidly finding many more applications including aerial photography, product deliveries, agriculture, policing and surveillance, infrastructure inspections, science, smuggling, and drone racing. Extremely small UAVs, in some cases hand-launched, are used to extend the vision of ground combat units beyond their front lines.

Applications of Unmanned Aerial Vehicle (UAV)

Some of the most common commercial applications and uses for UAV Drones are:

1. Aerial Photography & Videography
2. Real estate photography
3. Mapping & Surveying
4. Asset Inspection

5. Payload carrying
6. Agriculture
7. Bird Control
8. Crop spraying
9. Crop monitoring
10. Multispectral/thermal/NIR cameras
11. Live streaming events
12. Roof inspections
13. Emergency Response
14. Search and Rescue
15. Marine Rescue
16. Disaster zone mapping
17. Disaster Relief
18. Forensics
19. Mining
20. Firefighting
21. Monitoring Poachers
22. Insurance
23. Aviation
24. Meteorology
25. Product Deliver

ADVANTAGES OF UNMANNED AERIAL VEHICLE(UAV)

MAINTAINING SAFE ENVIRONMENT - UAVs are utilized in numerous occurrences due to their advancement in safety. With their remote control abilities, Drones monitor locations, communicate possible hazards, and notify threatening conditions .such as oil and gas refineries, pipelines and flare stacks. Not only this, Drone Technology is employed in the military during high-risk periods as well. Their features allow them to obtain real-time data to create and preserve a safe environment.

COST SAVING TECHNOLOGY - As drone's applicability becomes more extensive, their prices also drive towards being more pocket-friendly. People now acquire Drones not just for their industrial practices but also to fulfill their tech-savvy gadget's passion. UAVs are no longer equipped only for the military, law authorities, or the elite. Since UAVs take over several workforces, vehicles, and operation activities in commercial uses, many costs are preserved. For example, a Drone is more economical to buy, sustain, and fuel than airplanes for inspections. In addition you don’t need to hire a ladder, aerial lifts, and other heavy equipment.

QUALITY OF AERIAL IMAGING-AERIAL PHOTOGRAPHY With their high-resolution cameras furnished with top-notch sensors, UAVs can take excellent Aerial Photographs, aerial videos and accumulate large volumes of accurate data. The data obtained is transformed into detailed 3D Maps and 3D Models for a complete analysis. 3D Mapping is particularly relevant to disclose cracks, damages, or other hazardous elements in disaster areas. Drones, when paired along with high-resolution images or 4K video abilities, is well-known for live streaming significant events such as entertainment, personal, political, and global affairs.

PRECISION - UAVs appropriate GPS (the Global Positioning System) in their software, which is why they can be programmed and guided precisely to specific locations. For example, in Precision Agriculture, a Drone Aircraft is employed to perform many farming obligations like pesticide spraying, identification of weeds, monitoring crop health, crop damage, crop assessment, field soil analysis, Irrigation Monitoring etc. This feature of precision through the GPS conserves time and expenses for farmers.

EASY CONTROLLABLE OR DEPLOYABLE - The regular advancement in drone-control technology allows operators to quickly deploy and operate drones even with a relatively minimal technical background. With an extensive range of low-cost drones available for several purposes, drones are open to a broad spectrum of operators. Unmanned aerial vehicles (UAVs) have a more comprehensive range of movement, fly lower in all Directions, and can navigate effortlessly when contrasted to a crewed aircraft.

SECURITY - Another advantage that weighs out the pros and cons of a drone is the security centered on them. With relevant permissions and licenses, drone operators can utilize an Unmanned Aircraft System (UAS) to render safety and surveillance to private organizations, potential venues, and other expenses. Drones can also accumulate reliable information from natural catastrophes to support safety and recovery efforts.

MINIMIZES OBVIOUS DANGER AND HEALTH RISKS - With the support of a Drone, numerous dangers like elevation, wind, weather, and radiation that were earlier suffered by crew members have been replaced with more viable and safer alternatives. Drones facilitate straightforward and secure inspections of towering and complicated constructions like oil and gas refineries, flare stacks, and pipelines.

IN-DEPTH AND DETAIL DATA INPLACE - Many drone models are launched into the market with obstacle avoidance capacities. They can operate quite close to constructions, and this encourages them to seize precise data. They capture high-resolution images or 4K videos that explicitly reveal cracks, damages, displaced wires, and additional defects that we cannot detect through our naked eye. UAVs allow obtaining complete data without endangering inspection crew members of the company.

FLEXIBILITY FOR QUICK INSPECTIONS - Since Drones come with varied specifications, several can provide high or low altitude Inspections. The versatility of these characteristics empowers clients to customize the tools with ease for their projects. Drones are suitable for both regular and emergency scenarios, the Construction Industry abides by these advantages, especially building developers for Rooftop Inspections. Drones can carry out multiple roles, such as capturing high-quality photos, videos, thermal images, etc. This data is then transmitted and processed immediately, as opposed to the time- consuming conventional method.

REACH HAZARDOUS AREA - UAVs make obtaining efficient data from hard-to-reach locations a cakewalk for industry professionals. It is the most suitable alternative to overcome limitations of traditional methods regarding worker's safety, especially in hazardous situations like radiation monitoring, inspecting high-voltage lines. Drones also allow a more cost-effective approach toward inspections of these locations

DISADVANTAGES OF UNMANNED AERIAL VEHICLE (UAV)

PRIVACY - While drone's benefits are endless, drone technology has several downsides to it. UAVs can quickly fall prey to manipulation and trespass a group or individual's privacy. Though many desire to utilize drones for retaining safety, it could violate numerous individual liberties in the name of public security.

LEGISLATIVE UNCERTAINTY - The use of Unmanned Aircraft Systems (UAS) has become widespread; however, the law is still developing, considering it is a novel technology in the industry. Specific practices installed for tiny drones also apply to commercial and recreational applications but are still vague in several dimensions. Rules for the regulation of drone movement and property protection from aerial trespassing are still in the making; thus, UAV technology functions in a judicial gray zone. There are numerous frictions between governmental regulations and any state or city laws to manage airspace property rights, because of which drone operators may violate rules they didn't know about.

SAFETY - Safety is a fundamental element to prioritize when operating drone technology. UAVs outfitted with high-quality sensors recognize possible collisions and safely engineer their way around them, making them a significant trait. These drone capacities must resemble those of the manned aircraft navigators. It is commendable to hire professional drone service providers who can operate an aerial drone without crashing it. Drones operated in heavily-populated regions have an amplified risk of ground impact or damage, mainly due to system malfunction or hacking.

SOFTWARE ISSUES OR MALFUNCTION - There have previously been many drones that have fired weapons to commoners, generating a significant amount of casualties, injuries, and damages due to malfunctions or software blunders. Drone mishaps strike other military personnel's safety as well. Drones are still in the process of improvement to limit accidents or hazards that can affect the health and safety of human lives.

VULNERABLE TO WILD ANIMALS - Drones are susceptible to wild animal attacks and are sometimes also dangerous to nature. It is possible that when a drone operator is flying in a domain with a considerable number of wild animals, they crash against a tree or possibly conflict with a vulnerable animal. Large flying birds like eagles are regularly attacking and even capturing drones operating in their space to obtain crucial data.

SPYING – spying many offenders employ drones as a strategy to target their victims and to maintain a track on them. The blatant propeller noises are no longer a concern and are unnoticeable, enabling criminals to invade someone's privacy. Many drones furnished with thermal and night sensors identify life signs and efficiently target those currently of interest by the spy. Since UAVs can seize accurate data, they can register regular habits and recognize suspicious activities without permission.

EASY TO HACK - One substantial downside to drone technology's growth is its vulnerability. Hackers can quickly attack a drone's central control system and become the drone's original controller. The primary control system includes significant knowledge crucial for hackers to evade without the initial operator's awareness. Hackers can acquire private information, corrupt or damage the files, and leak data to unauthorized third parties.

WEATHER DEPENDENT - Drones are more vulnerable to weather conditions when contrasted to traditional aircraft. For example, if the climatic conditions are unfavorable, the UAV will not maneuver appropriately or gather reliable data or imagery. However, there are drones available that are more stable and can withstand gusts of wind successfully.

KNOWLEDGE AND SKILL - As discussed earlier, if one necessitates seizing accurate, high-quality data, they need to possess the demanded skillset. This specification would indicate that an average farmer would require comprehensive training or a third party drone service provider to capture, process, and analyze farming data. With expanding operators in the industry, drone costs and its accompanying resource expenses will gradually reduce.

DATA TRANSFER SPEED IS SLOW - One of the cons in expanding drone technology in precision agriculture is its data transmission speed, which some suppose could be a week. If the time necessitated for data delivery results in a farmers' unproductivity and damage to fertilizers, crops, or pesticides, the operation of the drone would be a waste in the end. Thus, if data transfer speed is slow, suffering and damage can occur in that period, following all efforts going to waste.

UAV communication network

UAV communications systems work by using one frequency to control the aerial vehicle from the ground via a remote pilot while the other frequency is used to beam data or relay First-Person View (FPV) video. By utilizing high-quality, reliable communications links, civilian UAVs are able to relay aerial visuals and data to those on the ground with ease, while still remaining in flight.

Since UAV can move quickly and flexibly, it is absolutely impossible to do the communication by using wire when they are flying. Even using wireless techniques, the flying attitude and the speed of UAV should be considered. However, there is also a number of advantages when UAV using wireless networking.

- UAVs can provide on-demand, high-quality communication due to line-of-sight signal propagation.
- UAVs can be sensing and data fusion nodes dynamically deployable in the region of interest.

- UAVs can tailor their flight paths to enhance the quality of wireless networking and communication.
- UAVs can themselves carry and forward huge amounts of data.

At present, the structure of UAV communication network usually adopts mobile self-organizing network, which is a kind of wireless communication network with special structure. Its communication is in response to the mutual cooperation between nodes, and is completed in the way of wireless multi hop. Each node in the network has a transceiver, which adopts distributed control. In addition, the node has the functions of a host and a router and can be quickly deployed without relying on pre-existing network infrastructure.

The mobile self-organizing network of UAV has strong anti-destroy ability. It can quickly and automatically form a network at any time and any place without the need of any other preset network facilities. It can dynamically change the network structure, and even if the UAV of one node is attacked, it can automatically reconstruct the network topology without affecting other nodes. The mobile self-organizing network of UAV has an efficient routing protocol algorithm, which can sense the network changes in time, automatically configure or reconstruct the network, ensure the real-time connectivity of the data link, and has a high degree of autonomy and adaptability. In addition, the mobile self-organizing network of UAV can realize information sharing, process the received information, make decision independently, and realize intelligent task.

MIMO (multiple input and multiple output)

Multiple-input and multiple-output, or MIMO is a method for multiplying the capacity of a radio link using multiple transmission and receiving antennas to exploit multipath propagation. MIMO has become an essential element of wireless communication standards including IEEE802.11n (Wi-Fi), IEEE802.11ac (Wi- Fi), HSPA+ (3G), WiMAX, and Long Term Evolution (LTE). More recently, MIMO has been applied to power-line communication for three-wire installations as part of the ITU G.hn standard and of the Home Plug AV2 specification.

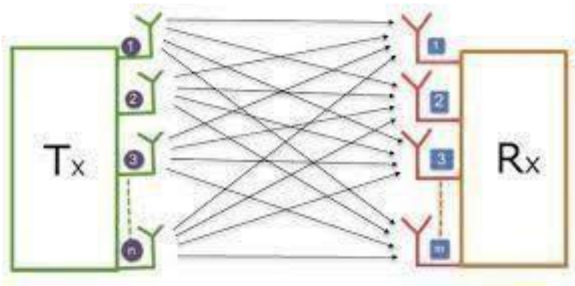

Fig: 1.2 Basic structure of MIMO

As a result of the use multiple antennas, MIMO wireless technology is able to considerably increase the capacity of a given channel while still obeying Shannon's law. By increasing the number of receive and transmit antennas it is possible to linearly increase the throughput of the channel with every pair of antennas added to the system. This makes MIMO wireless technology one of the most important wireless techniques to be employed in recent years. As spectral bandwidth is becoming an ever more valuable commodity for radio communications systems, techniques are needed to use the available bandwidth more effectively. MIMO wireless technology is one of these techniques.

Advantages of MIMO

- The higher data rate can be achieved with the help of multiple antennas and SM (Spatial Multiplexing) technique. This helps in achieving higher downlink and uplink throughput.
- It helps in achieving reduction in BER (Bit Error Rate) due to application of advanced signal processing algorithms on the received data symbols by multiple antennas.
- The techniques such as STBC (Space Time Block Coding) and BF (Beamforming) when employed in MIMO system helps in achieving extension of cell coverage.
- MIMO based system minimize fading effects seen by the information traveling from transmit to receive end. This is due to various diversity techniques such as time, frequency and space.
- There is lower susceptibility of tapping by unauthorized persons due to multiple antennas and algorithms.

- The systems with MIMO offers high QoS (Quality of Service) with increased spectral efficiency and data rates.
- The wide coverage supported by MIMO system helps in supporting large number of subscribers per cell.
- The MIMO based system is widely adopted in latest wireless standards viz. WLAN (802.11n, 802.11ac etc.), WiMAX (IEEE 802.16e), LTE, LTE-Advanced etc.

Disadvantages of MIMO

- The resource requirements and hardware complexity is higher compare to single antenna based system. Each antenna requires individual RF units for radio signal processing. Moreover advanced DSP chip is needed to run advanced mathematical signal processing algorithms.
- The hardware resources increase power requirements. Battery gets drain faster due to processing of complex and computationally intensive signal processing algorithms. This reduces battery lifetime of MIMO based devices.
- MIMO based systems cost higher compare to single antenna based system due to increased hardware and advanced software requirements

FUNCTIONS OF MIMO

Precoding is multi-stream beamforming, in the narrowest definition. In more general terms, it is considered to be all spatial processing that occurs at the transmitter. In (single-stream) beamforming, the same signal is emitted from each of the transmit antennas with appropriate phase and gain weighting such that the signal power is maximized at the receiver input. The benefits of beamforming are to increase the received signal gain by making signals emitted from different antennas add up constructively and to reduce the multipath fading effect. In line-of-sight propagation, beamforming results in a well-defined directional pattern. However, conventional beams are not a good analogy in cellular networks, which are mainly characterized by multipath propagation. When the receiver has multiple antennas, the transmit beamforming cannot simultaneously maximize the signal level at all of the receive antennas, and precoding with multiple streams is often beneficial. Note that precoding requires knowledge of channel state information (CSI) at the transmitter and the receiver.

Spatial multiplexing requires MIMO antenna configuration. In spatial multiplexing, a high-rate signal is split into multiple lower-rate streams and each stream is transmitted from a different transmit antenna in the same frequency channel. If these signals arrive at the receiver antenna array with sufficiently different spatial signatures and the receiver has accurate CSI, it can separate these streams into (almost) parallel channels. Spatial multiplexing is a very powerful technique for increasing channel capacity at higher signal-to-noise ratios (SNR). The maximum number of spatial streams is limited by the lesser of the number of antennas at the transmitter or receiver. Spatial multiplexing can be used without CSI at the transmitter, but can be combined with precoding if CSI is available. Spatial multiplexing can also be used for simultaneous transmission to multiple receivers, known as space-division multiple access or multi-user MIMO, in which case CSI is required at the transmitter. The scheduling of receivers with different spatial signatures allows good separability.

Diversity coding techniques are used when there is no channel knowledge at the transmitter. In diversity methods, a single stream (unlike multiple streams in spatial multiplexing) is transmitted, but the signal is coded using techniques called space-time coding. The signal is emitted from each of the transmit antennas with full or near orthogonal coding. Diversity coding exploits the independent fading in the multiple antenna links to enhance signal diversity. Because there is no channel knowledge, there is no beamforming or array gain from diversity coding. Diversity coding can be combined with spatial multiplexing when some channel knowledge is available at the transmitter. Electronic beam steering with greater efficiency is a vibrant feature of a phased array antenna, but for all the range cells, it is fixed at a specific angle. To mitigate this problem, frequency diverse array (FDA) antenna was proposed. This study presents a review on the development of FDA technology in radar and navigation applications. FDA is different from a conventional phased array antenna radar in a sense that it uses a small frequency offset across the array, which helps to generate a range, angle and time-dependent beam pattern. This pattern assures the energy transmission towards the desired angle and range cell. In addition, this study also focuses the research on getting range-angle uncoupled beam patterns along with diverse hybrid cognitive FDA design, available in the literature, for improved radar performance. Radar systems provide an important remote sensing capability and are crucial to the layered sensing vision; a concept of operation that aims to apply the right number of the right types of sensors, in the right places, at the right times for superior battle space situational awareness. The layered sensing vision poses a range of technical challenges, including radar, that are yet to be addressed. To address the radar-specific design challenges, the research community responded with waveform diversity; a relatively new field of study which aims reduce the cost of remote sensing while improving performance. Early work suggests that the frequency diverse array radar may be able to perform several remote sensing missions simultaneously without sacrificing performance. With few techniques available for modeling and characterizing the frequency diverse array, this research aims to specify, validate and characterize a waveform diverse signal model that can be used to model a variety of traditional and contemporary radar configurations, including frequency diverse array radars. To meet the aim of the research, a generalized radar array signal model is specified. A representative hardware system is built to generate the arbitrary radar signals, then the measured and simulated signals are compared to validate the model. Using the generalized model, expressions for the average transmit signal power, angular resolution, and the ambiguity function are also derived. The range, velocity and direction-of-arrival measurement accuracies for a set of signal configurations are evaluated to determine whether the configuration improves fundamental measurement accuracy.

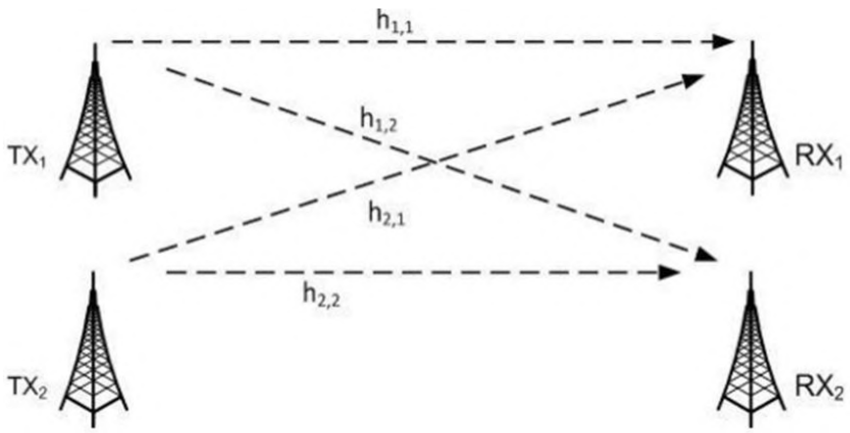
The main importance of MIMO channel technique is to improve the capacity of the channel and therefore it is important to compare the capacity of a SISO system to MIMO system. In SISO a system, the Shannon formula in equation can be applied to determine the capacity of the system. However, for a precise comparison, it is important that the MIMO system is transmitting with a power the same as that of a SISO system. Therefore, if the power radiated by a SISO system is Ps (SNR), then the power radiated from each antenna of a MIMO system with NTX transmit antennas must be Ps/N.

Hence, for a MIMO system with NTX and MRX antennas using diversity at transmitter and receiver end, the capacity of the system can be determined by the formula means transpose-conjugate of H and H is the M x N channel matrix. IM

Indicates the identity matrix of dimension N x M, in this case M = N =2 or more. However, since signals transmitted over MIMO channel have to be linearly independent and orthogonal, interference averages to zero. Hence from equation it can be seen that if the signal power Ps and the noise level N are the same then the more multiple antennas are used at the receiver, the more power is collected increasing the channel capacity and bandwidth.

Representation of MIMO channel:

The first channel model to be considered in this project will be a 2 x 2 MIMO system that is a system with 2 transmits (TX) and 2 receive (RX) antennas where different independent data streams are transmitted from multiple antennas to multiple receive antennas. This channel model will be extended to a 3 x 3 MIMO system and even more to illustrate the channel characteristics in relation to the increase in the number of antennas. The signals considered in the MIMO systems of this project are baseband signals ignoring modulation processes and concentrating on the up and down frequency conversion. Therefore, the signals on the i-th transmit antenna will be denoted x while the received signal on the j-th receive antenna denoted as y. Figure 1.3 shows the antenna set-up and the various unknown channel coefficients.



. Figure 1.3 antenna set-up

Since the coefficient of the unknown in the channel matrix Wc and the number of transmitted signal X is equal to the number of received signal Y, the equation can be solved if the channel Wc is inversed which in this case a 2 x 2 matrix inversion.

Operational principles of a MIMO system:

To derive the channel characteristics, MIMO system transmits specified and known training signals regularly from all transmitters of the system and these transmitted signals are received at the receiver. Based on the received signals, the receiver calculates the characteristics of all channel paths from each transmitted antenna to each receiving antenna. In order to prove that MIMO work, the transmitted signal X has to be solved from the group of equations in equation below. We also assume that the system is noise free and line of sight (LOS). Reference to figure 3 below, if the transmitted signal is represented to be X and the received signal Y. If the channel characteristics matrix is Wc, we may write Y=X Wc. If the channel matrix has N rows as many as there are transmitting antennas with index i. Then transmitted signal vector is written as X = [x1, x2…xN]. Also if the channel matrix has M columns, as there are receiving antennas with index j. Then the received signal vector is Y = [y1, y2…yM]. These vectors are extended later to matrixes by inserting K samples into each column.

Channel estimation procedure:

In order to estimate the channel characteristics, we expand each transmitted and received signals in time and write into signal matrix columns K discrete samples in time. The signals matrixes get K rows and as many columns as we have antennas, N or M. In general a MIMO system involves multiple antennas at the transmitting end and multiple receivers at the receiving end. Figure 1.4 show a general representation of a 3 x 3 general MIMO system.

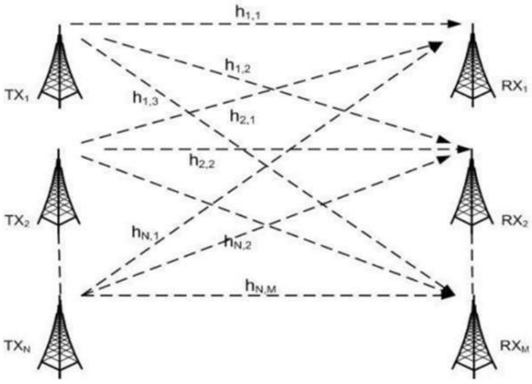


Figure 1.4 A general representation of a 3 x 3 general MIMO system

In order to determine the characteristic of the channel, both the transmitted signal X and the received signal Y have to be known. If the transmitted and received signals are of the form. If the channel transfer matrix Wc can be determine, then it means the transmitted signals can also be determine because the received signal Y is known. We may write the expression between these vector signals as Y = X Wc. In order to determine the transmitted signals, the channel transfer matrix, Wc -1 have to be inverted and then multiplied with the received signal matrix Y. X = Y Wc -1 The channel transfer matrix that we have to solve with the help of known training signal X and the received signal Y has the form. The channel transfer matrix is calculated periodically with the help of the known training signals and remains constant over information transmission time. It is then recalculated when new information is being transmitted. The channel characteristics in equation are defined for each signal path at discrete time instants 1,2,...K. However, we need to derive Wc and this can be derived with the help of the transmitted signals X and the corresponding known received signals Y measured at the receiver. Equation expresses the channel matrix Wc which do not need to be a square matrix. Because, for example if we have a 4x4 MIMO system with 100 samples, we do not need to have a 100x100 channel matrix. However, 5 samples can be transmitted from the four (4) antennas at a time. The next section explains the procedures required in order to estimate the channel transfer matrix.

Channel identification algorithm:

To model the transfer channel a common space matrix (orthonormal basis matrix Ux) is first generated and then used to map both the transmitted and received signals that vary in space (multiple antennas) and in time (samples in time). This common orthonormal basis matrix is obtained by decomposing either the transmitted signal X or the received signal Y. Hence, MIMO channel problem can be solved using four step approach under a condition where there is no noise (N = 0) and if the transmitted signals are orthogonal. These steps are summarized as follows:

(1) Finding an orthonormal basis Ux of the transmitted signal matrix X using the Gram-Schmidt procedure.

(2) In the K-dimensional signal vector space spanned by Ux, we express the N column vectors of the transmitted signal X by the projection onto the orthogonal axes of Ux. Wx = Ux X.

(3) In the K-dimensional signal vector space spanned by Ux, we express the M column vectors of the received signal matrix Y by their projection onto the orthogonal axes of Ux. Wy = Ux Y (4.2.2)

(4) Calculate the inverse or the pseudo inverse of the Fourier coefficients of the transmitted signal Wx and find an estimate of channel transfer matrix Oc = Wx -1 Wy or Oc = Wx + Wy.

OFDM (orthogonal frequency division multiplexing)

OFDM-Orthogonal Frequency Division Multiplexing, is a form of signal modulation that divides a high data rate modulating stream placing them onto many slowly modulated narrowband close-spaced subcarriers, and in this way is less sensitive to frequency selective fading. OFDM is a modulation format that is being used for many of the latest wireless and telecommunications standard.

OFDM is a form of multicarrier modulation. An OFDM signal consists of a number of closely spaced modulated carriers. When modulation of any form – voice, data, etc. is applied to a carrier, then sidebands spread out either side. It is necessary for a receiver to be able to receive the whole signal to be able to successfully demodulate the data. As a result when signals are transmitted close to one another they must be spaced so that the receiver can separate them using a filter and there must be a guard band between them. This is not the case with OFDM. Although the sidebands from each carrier overlap, they can still be received without the interference that might be expected because they are orthogonal to each another. This is achieved by having the carrier spacing equal to the reciprocal of the symbol period.

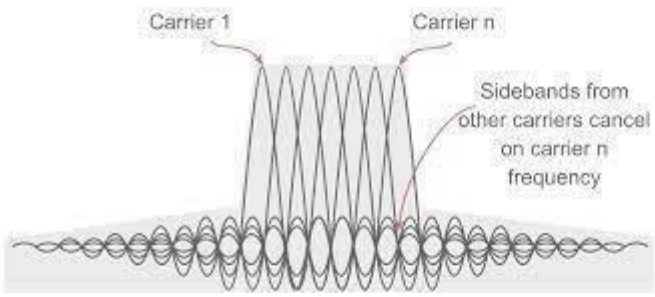

Fig: 1.5 OFDM Signal

The data to be transmitted on an OFDM signal is spread across the carriers of the signal, each carrier taking part of the payload. This reduces the data rate taken by each carrier. The lower data rate has the advantage that interference from reflections is much less critical. This is achieved by adding a guard band time or guard interval into the system. This ensures that the data is only sampled when the signal is stable and no new delayed signals arrive that would alter the timing and phase of the signal. The distribution of the data across a large number of carriers in the OFDM signal has some further advantages. Nulls caused by multi-path effects or interference on a given frequency only affect a small number of the carriers, the remaining ones being received correctly. By using error-coding techniques, which does mean adding further data to the transmitted signal, it enables many or all of the corrupted data to be reconstructed within the receiver. This can be done because the error correction code is transmitted in a different part of the signal.

OFDM advantages

- Immunity to selective fading: One of the main advantages of OFDM is that is more resistant to frequency selective fading than single carrier systems because it divides the overall channel into multiple narrowband signals that are affected individually as flat fading sub-channels.
- Resilience to interference: Interference appearing on a channel may be bandwidth limited and in this way will not affect all the sub-channels. This means that not all the data is lost.
- Spectrum efficiency: Using close-spaced overlapping sub-carriers, a significant OFDM advantage is that it makes efficient use of the available spectrum.
- Resilient to ISI: Another advantage of OFDM is that it is very resilient to inter-symbol and inter-frame interference. This results from the low data rate on each of the sub-channels.
- Resilient to narrow-band effects: Using adequate channel coding and interleaving it is possible to recover symbols lost due to the frequency selectivity of the channel and narrow band interference. Not all the data is lost.
- Simpler channel equalization: One of the issues with CDMA systems was the complexity of the channel equalization which had to be applied across the whole channel. An advantage of OFDM is that using multiple sub-channels, the channel equalization becomes much simpler.

OFDM disadvantages

Whilst OFDM has been widely used, there are still a few disadvantages to its use which need to be addressed when considering its use.

- High peak to average power ratio: An OFDM signal has a noise like amplitude variation and has a relatively high large dynamic range, or peak to average power ratio. This impacts the RF amplifier efficiency as the amplifiers need to be linear and accommodate the large amplitude variations and these factors mean the amplifier cannot operate with a high efficiency level.
- Sensitive to carrier offset and drift: Another disadvantage of OFDM is that is sensitive to carrier frequency offset and drift. Single carrier systems are less sensitive.

Applications of OFDM

- Digital Audio Broadcasting (DAB) and
- Digital Video Broadcasting over the terrestrial network: Digital Terrestrial Television Broadcasting (DTTB). In the DTTB OFDM transmission standard, about 2,000 to 8,000 subcarriers are used.
- UMTS. The UMTS Forum is selecting an appropriate radio solution for the third generation mobile standard, as a successor to GSM. OFDM is one of the five competing proposals.
- Wireless LANs. OFDM is used in HIPERLAN Phase II, which supports 20 Mbit/s in propagation environments with delay spreads up to 1 msecond.

Key features of OFDM

- The OFDM scheme differs from traditional FDM in the following interrelated ways:
- Multiple carriers (called subcarriers) carry the information stream
- The subcarriers are orthogonal to each other.
- A guard interval is added to each symbol to minimize the channel delay spread and inter symbol interference.

Data on OFDM

The data to be transmitted on an OFDM signal is spread across the carriers of the signal, each carrier taking part of the payload. This reduces the data rate taken by each carrier. The lower data rate has the advantage that interference from reflections is much less critical. This is achieved by adding a guard band time or guard interval into the system. This ensures that the data is only sampled when the signal is stable and no new delayed signals arrive that would alter the timing and phase of the signal.

Guard interval on OFDM signals

The distribution of the data across a large number of carriers in the OFDM signal has some further advantages. Nulls caused by multi-path effects or interference on a given frequency only affect a small number of the carriers, the remaining ones being received correctly. By using error-coding techniques, which does mean adding further data to the transmitted signal, it enables many or all of the corrupted data to be reconstructed within the receiver. This can be done because the error correction code is transmitted in a different part of the signal.

MIMO-OFDM SYSTEM

It combines multiple-input, multiple-output (MIMO) technology, which multiplies capacity by transmitting different signals over multiple antennas, and orthogonal frequency-division multiplexing (OFDM), which divides a radio channel into a large number of closely spaced sub channels to provide more reliable communications at high speeds.

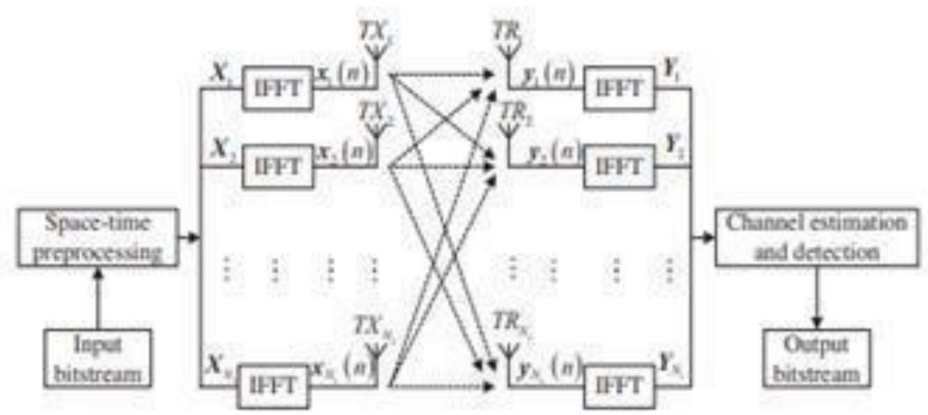

Fig: 1.6 The model of MIMO-OFDM system

The block diagram of the MIMO-OFDM transceiver is shown. We consider a MIMO system employing transmit and receive antennas. As seen from, for the transmission of each frame, a total of information bits enter the MIMO-OFDMtransmitter. These bits are first split into groups and the corresponding bits are processed in each branch of the transmitter by the OFDM index modulators. The incoming information bits are used to form the OFDM block, in each branch of the transmitter, where is the size of the fast Fourier transform (FFT). According to the OFDM principle, these bits are split into groups each containing bits, which are used to form OFDM sub blocks, of length N.

The corresponding bits, only out of available subcarriers are selected as active by the index selector at each sub block ,while the remaining subcarriers are inactive and set to zero. On the other hand, the remaining bits are mapped onto the considered M-ary signal constellation. Therefore, unlike classical MIMO-OFDM, contains some zero terms whose positions carry information for MIMO-OFDM. In this study, active subcarrier index selection is performed by the reference look-up tables at OFDM index modulators of the transmitter. The two active subcarriers out of four available sub carriers according to the reference look-up table of size. The OFDM index modulators in each branch of the transmitter obtain the OFDM sub blocks first and then concatenate these sub blocks to form the main OFDM blocks. In order to transmit the elements of the sub blocks from uncorrelated channels, block inter leavers are employed at the transmitter. The block interleaved OFDM frames are processed by the inverse FFT (IFFT) operators to obtain. We assume that the time- domain OFDM symbols are normalized to have unit energy, i.e., for all. After the addition of cyclic prefix of samples, parallel-to-serial and digital-to analog conversions, the resulting signals sent simultaneously from transmit antennas over a frequency selective Rayleigh fading MIMO channel, where represents the -tap wireless channel between the transmit antenna and the receive antenna ,whose elements are independent and identically distributed with. Assuming the wireless channels remain constant during the transmission of a MIMO-OFDM frame and , after removal of the cyclic prefix and performing FFT operations in each branch of the receiver, the input-output relationship of the MIMO-OFDM scheme in the frequency domain is obtained as for , where is the vector of the received signals for receive antenna , represents the frequency response of the wireless channel between the transmit antenna and receive antenna , and is the vector of noise samples. The elements of and follow and distributions, respectively, where denotes the variance of the noise samples in the frequency domain, which is related to the variance of the noise samples in the time domain as. We define the signal-to-noise ratio (SNR) as where [joules/bit] is the average transmitted energy per bit. The spectral efficiency of the MIMO-OFDM scheme is [bits/s/Hz], which is equal to times that of the OFDM scheme.

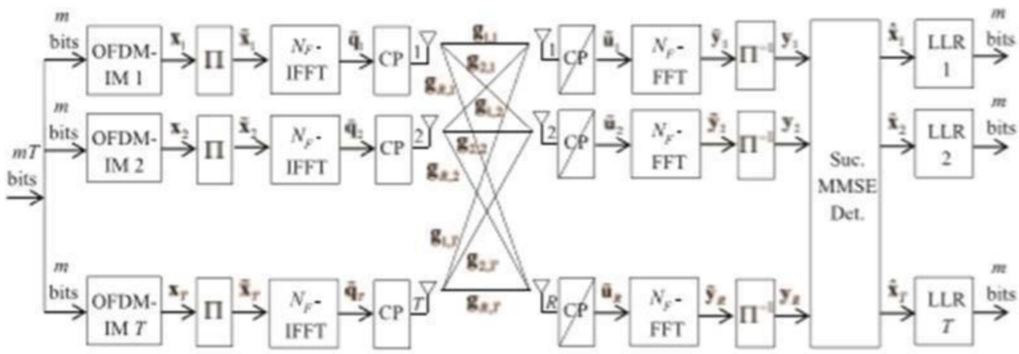

Fig: 1.7 The MIMO-OFDM transceiver

As seen from, the ML detector has to make a joint search overall transmit antennas due the interference between the sub blocks of different transmit antennas. Since has different realizations, the total decoding complexity of the ML detector in , in terms of complex multiplications (CMs), is per sub block, which becomes impractical for higher order modulations and MIMO systems. Instead of the exponentially increasing decoding complexity of the ML detector, we propose a novel MMSE detection and LLR calculation based detector, which has a linear decoding complexity as that of classical MIMO-OFDM with MMSE detection. For the detection of the corresponding OFDM sub blocks of different transmit antennas, the following MIMO signal model is obtained from for subcarrier of sub block where is the received signal vector, is the corresponding channel matrix which contains the channel coefficients between transmit and receive antennas and assumed to be perfectly known at the receiver, is the data vector which contains the simultaneously transmitted symbols from all transmit antennas and can have zero terms due to index selection in each branch of the transmitter and is the noise vector. For classical MIMO-OFDM, the data symbols can be simply recovered after processing the received signal vector with the MMSE detector. On the other hand, due to the index information carried by the sub blocks of the proposed scheme, it is not possible to detect the transmitted symbols by only processing for a given subcarrier in the MIMO-OFDM scheme. Therefore, successive MMSE detections are performed for the proposed scheme using the MMSE filtering matrix.

CHAPTER-2

LITERATURE SURVEY

Beixiong Zheng et al. "Multiple-Input Multiple-Output OFDM with Index Modulation"

Low-Complexity Detector Design", in this paper proposed two low-complexity detectors derived from the SMC theory for the MIMO-OFDMIM system. The first proposed sub block-wise detector draws samples at the sub block level, exhibiting near-optimal performance for the MIMO-OFDM system. The second proposed subcarrier-wise detector draws samples at the subcarrier level, exhibiting substantially reduced complexity with a marginal performance loss. An effective legality examination method has been also developed to couple with the subcarrier wise detector. Computer simulation and numerical results have validated the outstanding performance and the low complexity of both proposed detectors.

Ertugrul Basar et al. "Multiple-Input Multiple-Output OFDM with Index Modulation"

A novel scheme called MIMO-OFDM with index modulation has been proposed as an alternative multicarrier transmission technique for 5G networks. It has been shown via extensive computer simulations that the proposed scheme can provide significant BER performance improvements over classical MIMO-OFDM for several different configurations.

The following points remain unsolved in this study:

- performance analysis,
- the selection of optimal N and K values,
- diversity techniques for MIMO-OFDM-IM, and
- Implementation scenarios for high mobility.

In this study, the recently proposed MIMO-OFDM-IM scheme has been investigated for next generation 5G wireless networks. For the MIMO-OFDM-IM scheme, new detector types such as ML, near-ML, simple MMSE, MMSE-LLR-OSIC detectors have been proposed and their ABEP have been theoretically examined. It has been shown via extensive computer simulations that MIMO-OFDM-IM scheme provides an interesting trade-off between complexity, spectral efficiency and error performance compared to classical MIMO-OFDM scheme and it can be considered as a possible candidate for 5G wireless networks.

The main features of MIMO-OFDM-IM can be summarized as follows:

- better BER performance,
- flexible system design with variable number of active OFDM subcarriers and
- Better compatibility to higher MIMO setups.

However, interesting topics such as diversity methods, generalized OFDM-IM cases, high mobility implementation and transmit antenna indices selection still remain to be investigated for the MIMO-OFDM-IM scheme.

Ertugrul Bas et al. "Performance of Multiple-Input Multiple-Output OFDM with Index Modulation"

This paper, proposed ML and near-ML detectors for the recently introduced MIMO-OFDM-IM scheme to improve its error performance compared to MMSE based detection. The ABEP upper bound of the MIMO-OFDM-IM scheme with ML detection has been derived and it has been shown that the derived theoretical upper bound can be used as an efficient tool to predict the BER performance of the MIMO-OFDMIM scheme. It has been shown via computer simulations that MIMO- FDM-IM scheme can provide significant improvements in BER performance over classical MIMO-OFDM using different type of detectors and MIMO configurations.

Beixiong Zheng et al. "Low-Complexity ML Detector and Performance Analysis for OFDM with In-Phase/Quadrature Index Modulation".

In this letter, they've planned a low-complexity detector supported the milliliter criterion, that dispenses with a priori data of the noise variance and also the potential realizations of the active subcarrier indices. supported the framework of OFDM-I/Q-IM using the planned milliliter detector, the straight line ABEP and also the actual coding gain achieved by OFDMI/Q-IM are derived, that absolutely matches the simulation results. Moreover, the exact coding gain including the spectral efficiency price has provided a clear plan of a basic trade-off between the system

Performance and also the spectral efficiency of OFDM-I/Q-IM by the adjustment of the quantity of active subcarriers.

Sheng Wu et al. "Low-Complexity Iterative Detection for Large-Scale Multiuser MIMO-OFDM Systems Using Approximate Message Passing".

For the detection of large-scale multiuser MIMO-OFDM systems, we have proposed a range of low-complexity approximate message passing algorithms that can offer desirable tradeoff between performance and complexity. It is verified through extensive simulations that our proposed approximate message passing algorithms can achieve near optimal. Compared with existing turbo detection algorithms, the proposed schemes can achieve or even outperform the performance of some complex algorithms, such as the iterative decoding based on STS-SD and MMSESIC. In addition, the number of iterations required to achieve near-optimal performance is small and does not increase with the system dimension.

CHAPTER 3

PROPOSED METHOD

The proposed system of Application of MIMO-OFDM system in UAV communication system is shown with the help of a block diagram in the below figure. The methodology is carried out as shown in steps and each step of this system is discussed in detail in section below.

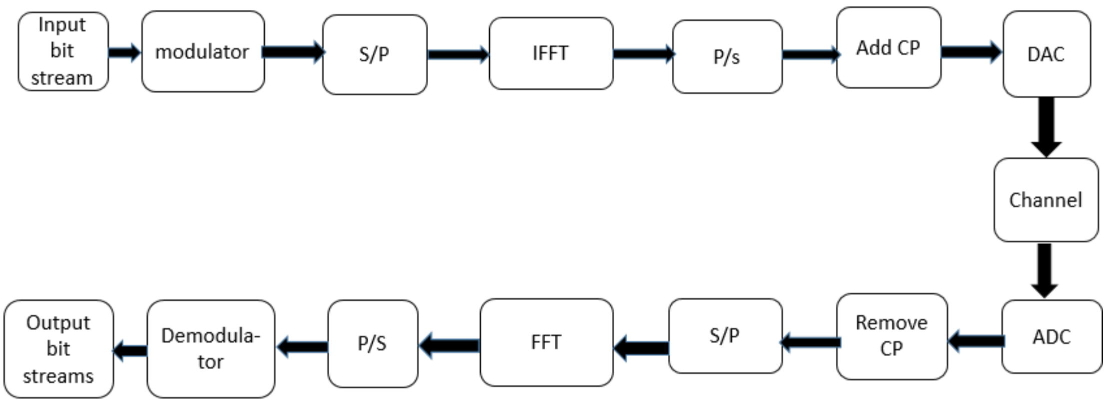

Fig: 3.1 Block diagram of MIMO-OFDM system

3.1 Modulator and demodulator

Quadrature Phase Shift Keying (QPSK) is a form of phase modulation technique, used in the above figure as modulator in which two information bits (combined as one symbol) are modulated at once, selecting one of the four possible carrier phase shift states.

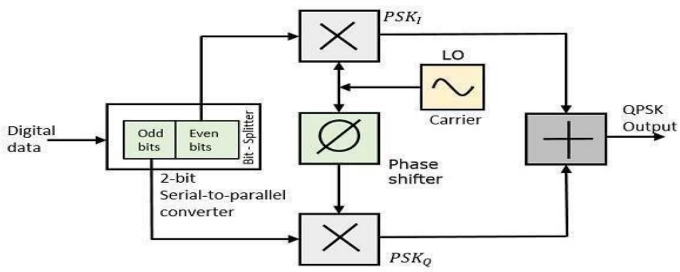

Fig: 3.2 Block diagram of QPSK modulator

The QPSK Demodulator is used as demodulator which uses two product demodulator circuits with local oscillator, two band pass filters, two integrator circuits, and a 2-bit parallel to serial converter.

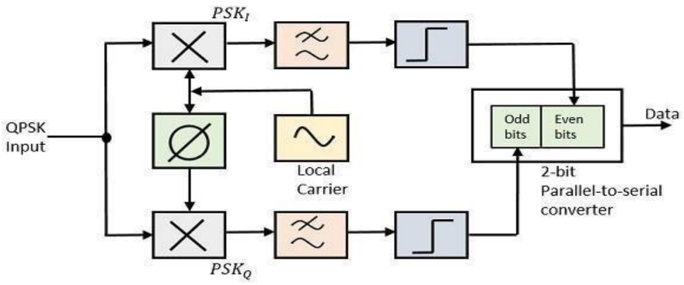

Fig: 3.3 Block diagram of QPSK demodulator

3.2 Serial to parallel converter(s/p)

A serial to parallel converter is a digital circuit where we feed the input data serially, and read the outputs in parallel fashion. A 4-bit serial-to-parallel shift register is one of the simplest types of circuits utilizing four D-type flip-flops. e.g. 2 bits/word for QPSK, and shifted into a parallel format. The data is then transmitted in parallel by assigning each data word to one carrier in the transmission.

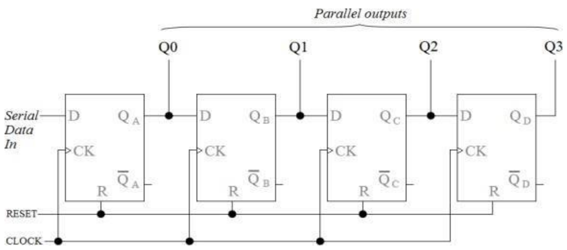

Fig: 3.4 serial to parallel converter

Parallel to serial converter (p/s)

A conversion process in which the stream of data elements received all at once is converted and sent as a stream of data at one bit at a time.

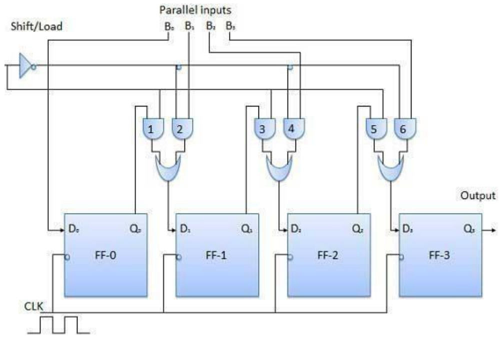

Fig: 3.5 Parallel to serial converter

3.3 FFT and IFFT

- FFT stands for Fast Fourier Transform.
- FFT converts time domain vector signal to frequency domain vector signal.
- It is used before demodulator block in the OFDM Receiver.

$$X(k) = \sum_{n=0}^{N-1} X(n) * e^{-i*2*pi*n*k/N} \quad \text{....... FFT Equation}$$

Where,

$X(n)$ -> Time Domain Samples

$X(k)$ -> Freq. Domain Samples

N -> FFT Size

k -> 0,1,2,........,N-1

Fig 3.6 FFT Equation

$$X(n) = \frac{1}{N} * \sum_{k=0}^{N-1} X(k) * e^{i*2*pi*n*k/N} \quad \text{... IFFT Equation}$$

Where,

$X(k)$ -> Freq. Domain Samples

$X(n)$ -> Time Domain Samples

N -> FFT Size

k -> 0,1,2,........,N-1

Fig 3.7 IFFT Equation

- IFFT stands for Inverse Fast Fourier Transform.
- IFFT converts frequency domain vector signal to time domain vector signal.
- It is used after the modulator block in the OFDM Transmitter

3.4 Add CP and Remove CP

The cyclic prefix provides a guard interval to eliminate inter symbol interference from the previous symbol. It repeats the end of the symbol so the linear convolution of a frequency-selective multipath channel can be modeled as circular

1convolution, which in turn may transform to the frequency domain via a discrete Fourier transform. This approach accommodates simple frequency domain processing, such as channel estimation and equalization. The cyclic prefix is created so that each OFDM symbol is preceded by a copy of the end part of that same symbol. Different OFDM cyclic prefix lengths are available in various systems. For example within LTE a normal length and an extended length are available and after Release 8 a third extended length is also included, although not normally used.

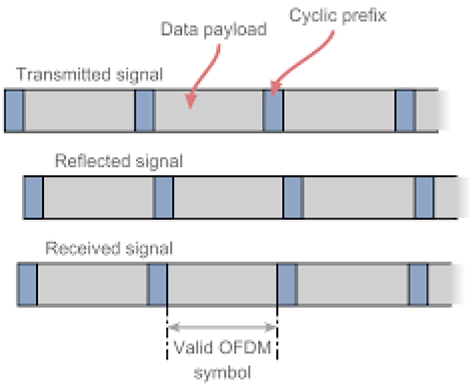

Fig: 3.8 cyclic prefix

Advantages of cyclic prefix

- Provides robustness: The addition of the cyclic prefix adds robustness to the OFDM signal. The data that is retransmitted can be used if required.
- Reduces inter-symbol interference: The guard interval introduced by the cyclic prefix enables the effects of inter-symbol interference to be reduced.

Disadvantages of cyclic prefix

- Reduces data capacity: As the cyclic prefix re-transmits data that is already being transmitted, it takes up system capacity and reduces the overall data rate.
- The use of a cyclic prefix is standard within OFDM and it enables the performance to be maintained even under conditions when levels of reflections and multipath propagation are high.

3.5 Analog to digital (ADC) and digital to analog converters (DAC)

Analogue to Digital Converter, or ADC, is a data converter which allows digital circuits to interface with the real world by encoding an analogue signal into a binary code

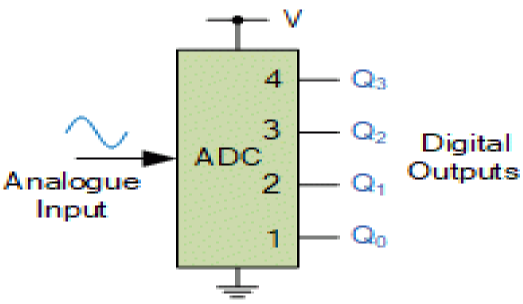

Fig: 3.9Analogue to Digital Converter

A Digital to Analog Converter (DAC) converts a digital input signal into an analog output signal. The digital signal is represented with a binary code, which is a combination of bits 0 and 1.

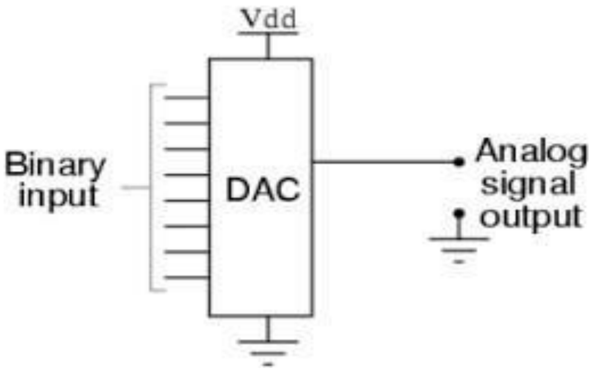

Fig: 3.10Digital to Analog Converter

The performance of ADCs and DACs mainly depends on their Resolution and Speed.

The Resolution of a converter is expressed in the number of Bit. For an ADC, the Resolution states the number of intervals or levels which can be divided from a certain analog input range. An n-bit ADC has the resolution of 1 / 2n. For example, the Resolution of a 16-bit ADC is 1 / 65536, since 216 = 65536. If the measuring voltage range is 10 V, then this input range can be resolved into 10 V / 65536 = 0.153 mV precision.

The Speed of a converter is expressed by the Sampling Frequency. It is the number of times that the converter samples the analog signal, its unit is Hertz (Hz). In audio signal processing, Sampling Frequencies of 44 kHz, 22 kHz and 11 kHz are mostly used. Using 44 kHz Sampling Frequency means the converter is sampling the analog audio signal and doing analog to digital conversion at 44000 times per second.

ADCs are used virtually everywhere, whenever an analog signal has to be transported, it is processed and stored in digital form. They are always used together with different transducers to convert physical sense and measurement such as temperature, pressure, humidity, speed, vibration, sound, picture etc. in digital signal for further processing by microprocessor.

3.6 FLOW CHART

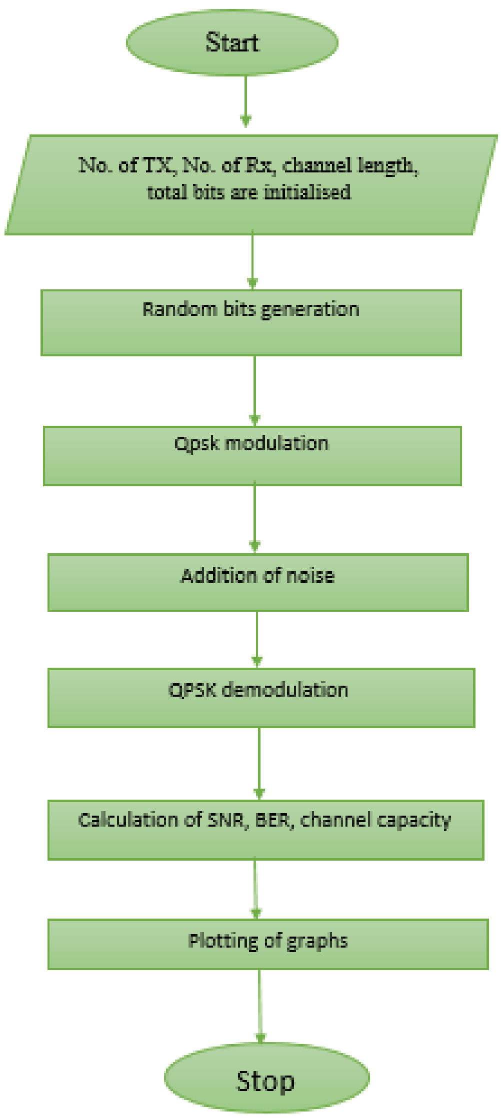

Fig: 3.11 flowchart of the program

3.7 ALGORITHM

- Firstly we will initialize the input data such as no.of transmitter ,receivers , channel length, total no.of bits etc.
- Then we create a iterative loop until it takes total no. of bits.

At the transmitter side

- We generate random bits from total no. of bits and modulate using QPSK modulation.
- We do the IFFT analysis.

At the receiver side

- We do the FFT analysis and extract real part of the signal.
- Next step is to count for the errors.
- Then calculate signal to noise ratio (SNR), channel capacity and bit error rate (BER) of the signal.
- Plotting the graph of SNR vs channel capacity.
- Plotting the semi log graph of SNR vs bit error rate.

CHAPTER 4

SIMULATION RESULTS AND ANALYSIS

The experimental environment of this project is based on MATLAB R2013a. The MIMO-OFDM communication system is constructed with MATLAB software. The Channel capacity and the bit error rate are used as main factors to prove the result.

Channel capacity

Channel capacity is a maximum information rate that a channel can transmit. It is measured in bits per second (bps). Channel capacity is a rough value as measuring takes into account only the whole amount of data transferred but leaves out of account communication quality.

It depends on three factors:

- The bandwidth available.
- The level of signal use.
- The quality of the channel (level of noise present).

Bit error rate

The bit error rate (BER) is the number of bit errors per unit time. The bit error ratio (also BER) is the number of bit errors divided by the total number of transferred bits during a studied time interval. Bit error ratio is a unit less performance measure, often expressed as a percentage**.** The BER may be improved by choosing a strong signal strength (unless this causes cross-talk and more bit errors), by choosing a slow and robust modulation scheme or line coding scheme, and by applying channel coding schemes such as redundant forward error correction codes**.**

If the medium between the transmitter and receiver is good and the signal to noise ratio is high, then the bit error rate will be very small - possibly insignificant and having no noticeable effect on the overall system However if noise can be detected, then there is chance that the bit error rate will need to be considered**.**

Signal-to-noise ratio (**SNR** or **S/N**)

It is a measure used in science and engineering that compares the level of a desired signal to the level of background noise. SNR is defined as the ratio of signal power to the noise power, often expressed in decibels. A ratio higher than 1:1 (greater than 0 dB) indicates more signal than noise. SNR, bandwidth, and channel capacity of a communication channel are connected by the Shannon–Hartley theorem.

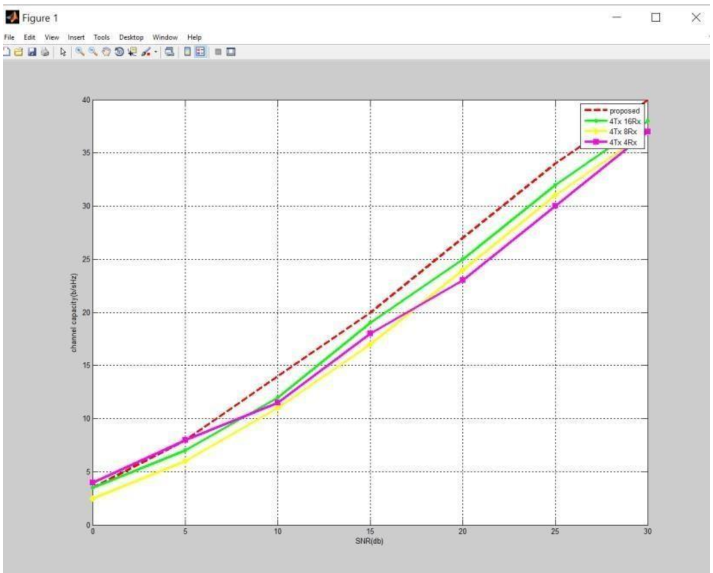

Fig: 4.1

Fig. 5.1 shows the channel capacity for different numbers of antennas. It can be seen from the figure that as the number of antennas increases, the channel capacity of the system increases.

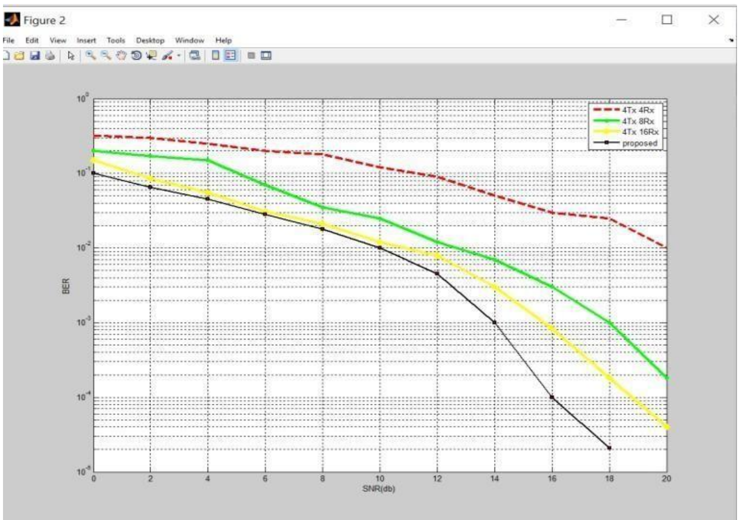

Fig: 4.2

Fig: 5.2 shows the bit error rate for different numbers of antennas. It can be seen from the figure that as the number of antennas increases, the bit error rate of the system decreases.

CHAPTER 5
CONCLUSION AND FUTURE ENHANCEMENT

Improving the communication quality of UAV communication network is an important topic in the field of UAV communication. In this paper, the characteristics of UAV communication network are analyzed. Based on the technical principle and system model of MIMO-OFDM, the MIMO-OFDM communication system is constructed. The simulation results show that MIMO-OFDM technology can effectively improve the channel capacity and reduce the bit error rate, which provides an effective solution for improving the communication quality of UAV communication network.

Acceptance Letter for online oral presentation & journal publication

Online Mega international Conference "Smart Modernistic in Electronics and Communication" *(ICSMEC–21) on 02nd & 03rd July 2021*

Dear G.Samyuktha, **K.Vijay**, **K.Kusuma, Dr.A.Chaithanya Krishna**:

Title of the paper: APPLICATION OF MIMO-OFDM TECHNOLOGY IN UAV COMMUNICATION NETWORK

Paper ID: ICSMEC21-0035

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in online mega International Conference on "Smart Modernistic in Electronics and Communication" ***(ICSMEC-21).***

ICSMEC-21 conference received over 400+ submissions from different parts of the world and regions so far, reviewed by international experts; the acceptance ratio is controlled below 20%. Your paper will be submitted for **Journal publications free of cost** in the appropriate given Journals after registration. **You will be given registration kit, International conference proceedings with ISBN (Soft copy), and international certificate of publication.**

You are now required to pay the conference registration fees (Faculty / Research Scholars: Rs.3500/-) as mentioned below A/C details on or before 5 working day after receiving this email else your paper will not be considered for presentation as well as publication in the Journal.

For PAYTM users

For NEFT/RTGS/IMPS

Account Details: (Current Account)

A/C Name: PRINCIPAL, St. Martin's Engineering College
Bank Name: SBI, Kukatpally, Hyderabad
Account No: 30667640268
IFSC code: SBIN0011664
Swift Code: SBININBB725 (Applicable for foreign author)

After payment, please send the registration form, payment proof and final paper in.doc/.docx format.

Your interest in *ICSMEC-21* is very much appreciated. Look forward to meeting you on the day of conference.

Yours sincerely,
ICSMEC- 21 Organizing Committees
icsmec21@smec.ac.in

(Organized by Department of ECE)

APPENDIX-A
MATLAB

What Is MATLAB?

MATLAB® is a excessive-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment wherein issues and answers are expressed in familiar mathematical notation. Typical uses encompass

Typical uses of MATLAB:

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data evaluation, exploration, and visualization
- Scientific and engineering pictures
- Application improvement, along with graphical consumer interface constructing.

Introduction

MATLAB is a immoderate-overall performance language for technical computing. It integrates computation, visualization, and programming in an clean-to-use surroundings wherein troubles and answers are expressed in acquainted mathematical notation. MATLAB stands for matrix laboratory, and become written first off to offer smooth get entry to matrix software application advanced by using LINPACK (linear system bundle) and EISPACK (Eigen system package deal) responsibilities.

MATLAB is consequently constructed on a basis of sophisticated matrix software program application in which the important element is array that does not require pre dimensioning which to resolve many technical computing issues, especially people with matrix and vector formulations, in a fragment of time. MATLAB talents a own family of programs specific answers referred to as toolboxes.

Very important to most customers of MATLAB, toolboxes permit analyzing and utilizing specialized era. These are complete collections of MATLAB features (M-documents) that growth the MATLAB environment to remedy unique commands of problems. Areas in which toolboxes are available embody sign processing, manipulate device, neural networks, fuzzy appropriate judgment, wavelets, simulation and plenty of others.

To resolve many technical computing issues, especially people with matrix and vector formulations, in a fragment of time.

Typical uses of MATLAB encompass: Math and computation, Algorithm improvement, Data acquisition, Modeling, simulation, prototyping, Data evaluation, exploration, visualization, Scientific and engineering pics, Application development, along with graphical character interface constructing. Boom the MATLAB environment to remedy unique commands of problems. Areas where in toolboxes are to be had embody signal processing, control device, neural networks, fuzzy appropriate judgment, wavelets, simulation and lots of others.

A.1 Basic Building Blocks of MATLAB

The fundamental building block of MATLAB is MATRIX. The essential information type is the array. Vectors, scalars, real matrices and complicated matrix are dealt with as particular magnificence of this fundamental information kind. The built in functions are optimized for vector operations. No size statements are required for vectors or arrays.

MATLAB Windows

The MATLAB works based totally on five windows: Command window, Workspace window, Current directory window, Command history window, Editor Window, Graphics window and Online-help window.

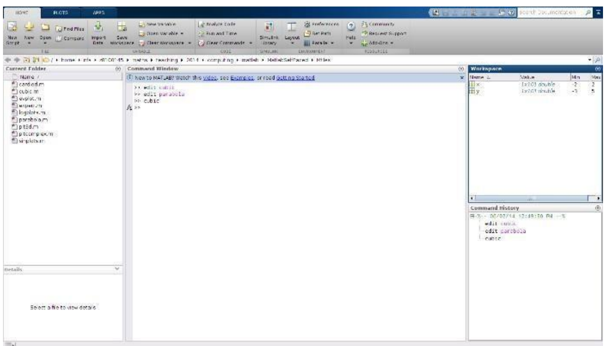

Fig: A.1 matlab window

Command Window

The command window is in which the person sorts MATLAB instructions and expressions on the spark off (>>) and in which the output of those commands is displayed. It is opened when the utility program is released. All instructions inclusive of user-written applications are typed in this window at MATLAB activate for execution.

Work Space Window

MATLAB defines the workspace as the set of variables that the person creates in a piece consultation. The workspace browser indicates these variables and a few records about them. Double clicking on a variable inside the workspace browser launches the Array Editor, which can be used to gain facts.

A.2 Three Current Directory Window

The present day Directory tab suggests the contents of the present day listing, whose route is hooked up inside the present day listing window. For example, within the domestic windows working tool the path is probably as follows: C:MATLABWork, indicating that directory “paintings” is a subdirectory of the precept list “MATLAB”; it's far mounted in pressure C. Clicking at the arrow in the contemporary listing window shows a listing of currently used paths. MATLAB uses a are in search of for route to discover M-files and different MATLAB related documents. Any document run in MATLAB need to live inside the modern listing or in a list that is on trying to find path.

Four Command History Window

The Command History Window consists of a file of the instructions someone has entered within the command window, which includes each modern and previous MATLAB periods. Previously entered MATLAB instructions may be selected and re-accomplished from the command records window through right clicking on a command or collection of commands. This is beneficial to pick out various alternatives further to executing the instructions and is useful characteristic while experimenting with numerous commands in a piece consultation.

Editor Window

The MATLAB editor is every a text editor specialized for growing M-documents and a graphical MATLAB debugger. The editor can seem in a window through the use of itself, or it may be a sub window inside the desktop. In this window you can clearly write, edit, create and preserve applications in documents called M-files.

MATLAB editor window has numerous pull-down menus for responsibilities collectively with saving, viewing, and debugging documents. Because it performs a few smooth assessments and additionally makes use of shade to differentiate among several factors of code, this newsletter editor is recommended because the device of desire for writing and improving M-functions.

Graphics or Figure Window

The output of all photo instructions typed inside the command window is seen in this window.

Online Help Window

MATLAB presents online assist for all its constructed in features and programming language constructs. The primary manner to get help on-line is to apply the MATLAB assist browser, opened as a separate window each with the useful resource of clicking on the question mark image (?) at the desktop toolbar, or with the aid of typing help browser at the activate inside the command window. The assist Browser is a web browser blanketed into the MATLAB computing tool that shows a HypertextMarkupLanguage (HTML) documents. The Help Browser includes planes, the assist navigator pane, used to find out statistics, and the display pane, used to view the statistics. Self-explanatory tabs other than navigator pane are used to carry out are seeking.

MATLAB Files

MATLAB has 3 varieties of files for storing facts. They are: M-documents and MAT-files.

These are wide spread ASCII text record with ‘m’ extension to the document call and growing own matrices using M-files, which are text documents containing MATLAB code. MATLAB editor or any other text editor is used to create a file containing the same statements which are typed at the MATLAB command line and save the record underneath a call that leads to .M. There are sorts of M-

Documents:

1. Script Files

It is an M-file with a hard and fast of MATLAB commands in it and is achieved by way of typing call of record on the command line. These documents paintings on worldwide variables presently found in that surroundings.

2. Function Files

A characteristic report is also an M-file besides that the variables in a feature record are all local. This type of files starts with a characteristic definition line.

MAT-Files

These are binary information documents with .Mat extension to the record which can be created through MATLAB when the records is saved. The information written in a unique format that only MATLAB can examine. These are located into MATLAB with ‘load’ command.

A.3 The MATLAB System:

The MATLAB machine consists of five important components:

Development Environment:

This is the set of tools and centers that assist you use MATLAB functions and files. Many of those gear are graphical person interfaces. It consists of the MATLAB computer and Command Window, a command history, an editor and debugger, and browsers for viewing assist, the workspace, files, and the quest path.

The MATLAB Mathematical Function:

This is a large series of computational algorithms ranging from elementary features like sum, sine, cosine, and complex mathematics, to greater sophisticated features like matrix inverse, matrix Eigen values, Bessel functions, and rapid Fourier transforms.

The MATLAB Language:

This is a excessive-stage matrix/array language with manage glide statements, capabilities, statistics systems, input/output, and item-orientated programming features. It lets in both "programming in the small" to rapidly create quick and dirty throw-away packages, and "programming within the massive" to create complete big and complicated software applications.

A.4.Four Graphics:

MATLAB has large centers for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It consists of high-degree features for two-dimensional and 3-dimensional statistics visualization, picture processing, animation, and presentation pics. It also includes low-level functions that let you fully customize the appearance of photographs as well as to build complete graphical consumer interfaces to your MATLAB packages.

THE MATLAB Application Program Interface (API):

This is a library that allows you to put in writing C and FORTRAN packages that have interaction with MATLAB. It consists of centers for calling exercises from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Workspace list the variables and describes their matrix size clear erases variables and functions from memory

Clear erases variables and functions from memory.

Clear x erases the matrix 'x' from your workspace close by itself, closes the current figure window figure creates an empty figure window.

Hold on holds the current plot and all axis properties so that subsequent graphing.

A.5 SOME BASIC PLOTCOMMANDS:

Kinds of plots:

Plot(x, y)	creates a Cartesian plot of the vectors x &y
Plot(y)	creates a plot of y vs.
Semilogy(x, y)	plots log(x) vs y.
Xlabel ('x-axis label')	generate labels along x-axis.
Ylabel ('y-axis label')	generate labels along y-axis.
Title	allows you to put a title on the graph.
Grid on	allows you to put the grid lines on the graph.

MATLAB provides eight basic color options for drawing graphs. The following table shows the colors and their codes

Table: A.1 Colors and codes used in MATLAB

CODE	**COLOUR**
w	White
k	Black
b	Blue
r	Red
c	Cyan
g	Green
m	Magenta
y	Yellow

A.6 ALGEBRIC OPERATIONS IN MATLAB:

Scalar Calculations:

+ Addition

- Subtraction

* Multiplication

/ Division

^ Exponentiation

Array products: Recall that addition and subtraction of matrices involved addition or subtraction of the character factors of the matrices. Sometimes it's far favored to definitely multiply or divide every element of an matrix by way of the corresponding element of any other matrix 'array operations”.

Array or detail-by way of-element operations are accomplished when the operator is preceded via a '.' (Period):

A.* B multiplies each detail of a by using the

respective element of b

A. / B divides each element of a by using the

respective detail of b

A. B divides every detail of b by using the respective detail of a

A. ^B raise each detail of a with the aid of the respective b element

A.7 MATLAB WORKING ENVIRONMENT

MATLAB DESKTOP

MATLAB Desktop is the principle MATLAB software program window. The laptop includes 5 sub domestic home windows, the command window, the workspace browser, the current list window, the command history window, and one or greater determine home windows, which can be tested most effective when the individual displays a photo.

The command window is in which the person kinds MATLAB instructions and expressions at the spark off (>>) and wherein the output of those commands is displayed. MATLAB defines the workspace as the set of variables that the patron creates in a work session. The cutting-edge Directory tab above the workspace tab suggests the contents of the present-day listing, whose path is shown in the current list window.

For example, in the domestic home windows running device the course is probably as follows: C: MATLAB Work, indicating that listing “art work” is a subdirectory of the primary listing “MATLAB”; WHICH IS INSTALLED IN DRIVE C.

Listing. MATLAB uses a are seeking for route to locate M-files and other MATLAB related files, which is probably arrange in directories within the laptop report system. Any document run in MATLAB want to are living inside the cutting-edge list or in a list this is on are seeking route. By default, the documents supplied with MATLAB and math works.

The simplest manner to look which directories are soon the quest path, or to characteristic or alter a seek direction, is to choose set path from the File menu the laptop, after which use the set direction communication box. It is right exercise to feature any normally used directories to the search course to avoid time and again having the change the cutting-edge list.

The Command History Window includes a file of the commands a consumer has entered in the command window, along with every modern and previous MATLAB periods. Previously entered MATLAB commands can be determined on and re-accomplished from the command history window by the use of right clicking on a command or sequence of commands.

This motion launches a menu from which to choose out numerous options further to executing the instructions. This is useful to choose out severa options in addition to executing the instructions. This is a beneficial feature at the same time as experimenting with various commands in a piece consultation.

A.7.1 Using the MATLAB Editor to create M-File:

The MATLAB editor is each a textual content editor specialized for growing M-files and a graphical MATLAB debugger. The editor can appear in a window via itself, or it could be a sub window within the laptop. M-files are denoted by using the usage of the extension .M, as in pixel The MATLAB editor window has numerous pull-down menus for tasks together with saving, viewing, and debugging files. Because it plays a few simple assessments and also makes use of coloration to distinguish among several elements of code, this newsletter editor is recommended due to the fact the tool of desire for writing and modifying M- abilities.

To open the editor, kind edit at the prompt opens the M-record filename in an editor window, equipped for enhancing. As stated earlier, the report must be inside the modern-day listing, or in a listing within the are looking for route.

A.8.Three Getting Help:

The most critical manner to get assist online is to use the MATLAB help browser, opened as a separate window either through clicking on the question mark symbol (?) at the computer toolbar, or through typing help browser on the set off in the command window. The help Browser is an internet browser incorporated into the MATLAB laptop that presentations a Hypertext Markup Language (HTML) files. The Help Browser includes two panes, the help navigator pane, used to find records, and the display pane, used to view the statistics. Self-explanatory tabs apart from navigator pane are used to carry out a search

.

Appendix B

INTRODUCTION TO DIGITAL COMMUNICATION

B.1 what is Digital Communication?

Digital communication systems, by definition, are communication systems that use such a digital sequence as an interface between the source and the channel input and similarly between the channel output and final destination.

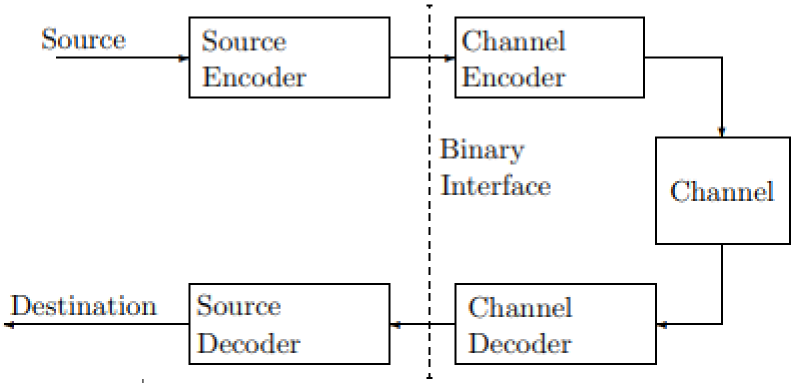

Fig: B.1block diagram of digital communication

Placing a binary interface between source and channel. The source en• coder converts the source output to a binary sequence and the channel encoder (often called a modulator) processes the binary sequence for transmission over the channel. The channel decoder (demodulator) recreates the incoming binary sequence (hopefully reliably), and the source decoder recreates the source output

WHY DIGITAL?

The telegraph, invented in the mid-nineteenth century, was the forerunner of digital communications. However, it is now that we can emphatically say digital is the pervasive technology of the twenty-first century and beyond, as the first generation of cellular phones in the late seventies was the last major analog communication invention. During the past three decades, communication networks, systems, and devices have all moved toward dig• ital. The primary examples are wireless networks, Internet, MP3 players, smart phones, HDTV, GPS, and satellite TV and radio. Digital communication technology will continue to bring about intelligent infrastructures and sophisticated end-user devices, through which a host of applications in entertainment, education, information, and business will be provided. The burgeoning field of digital communications will thus continue to affect almost all aspects of our contemporary life.

A basic definition of digital is the transmission of a message using binary digits (bits) or symbols from a finite alphabet during a finite time interval (bit or symbol duration). A bit or symbol occurring in each interval is mapped onto a continuous-time waveform that is then sent across the channel. Over any finite interval, the continuous-time waveform at the channel output belongs to a finite set of possible waveforms. This is in contrast to analog communications, where the output can assume any possible waveform. Digital can bring about many significant benefits, of course, at the expense of few shortcomings, for there is no free lunch in digital communications.

B.1.1 Advantages of Digital

- **Design efficiency:** Digital is inherently more efficient than analog in exchanging power for bandwidth, the two premium resources in communications. Since an essentially unlimited range of signal conditioning and processing options are available to the designer, effective trade-offs among power, bandwidth, performance, and complexity can be more readily accommodated. For any required performance, there is a three-way trade-off among power, bandwidth, and complexity (i.e., an increase in one means the other two will be reduced).

- **Versatile hardware:** The processing power of digital integrated circuits continues to approximately double every 18 months to 2 years. These programmable processors easily allow the implementation of improved designs or changed requirements. Digital circuits are generally less sensitive to physical effects, such as vibration, aging components, and external temperature. They also allow a greater dynamic range (the difference between the largest and the smallest signal values). Processing is now less costly than precious bandwidth and power resources. This in turn allows considerable flexibility in designing communication systems.

- **New and enhanced services:** In today's widely distributed way of life, Internet services, such as web browsing, e-mailing, texting, e-commerce, streaming and interactive multimedia services, have all become feasible and some even indispensable. It is also easier to integrate different services, with various modalities, into the same transmission scheme or to enhance services through transmission of some additional information, such as playing music or receiving a phone call with all relevant details.

- **Control of quality**: A desired distortion level can be initially set and then kept nearly fixed at that value at every step (link) of a digital communication path. This reconstruction of the digital signal is done by appropriately-spaced regenerative repeaters, which do not allow accumulation of noise and interference. On the other hand, once the analog signal is distorted, the distortion cannot be removed and a repeater in an analog system (i.e., an amplifier) regenerates the distortion together with the signal. In a way, in an analog system, the noises add, whereas in a digital system, the bit error rates add. In other words, with many regenerative repeaters along the path, the impact in an analog sys• tem is a reduction of many decibels (dBs) in the signal-to-noise ratio (SNR), whereas the effect in a digital system is a reduction of only a few dBs in the SNR.

- **Flexibility, compatibility, and switching**: Combining various digital signals and digitized analog signals from different users and applications into streams of different speeds and sizes—along with control and signaling information—can be much easier and more efficient. Signal storage, reproduction, interface with computers, as well as access and search of information in electronic data• bases can also be quite easy and inexpensive. Digital techniques allow the development of communication components with various features that can easily interface with a different component produced by a different manufacturer. Digital transmission brings about the great ability to dynamically switch and route messages of various types, thus offering an array of network connectivity's, including unicast, multicast, narrowcast, and broadcast.

B.2 Source coding

The source encoder in Figure B.1 has the function of converting the input from its original form into a sequence of bits. As discussed before, the major reasons for this almost universal conversion to a bit sequence are as follows: inexpensive digital hardware, standardized interfaces, layering, and the source/channel separation theorem.

The simplest source coding techniques apply to discrete sources and simply involve representing each successive source symbol by a sequence of binary digits. For example, letters from the 27• symbol English alphabet (including a space symbol) may be encoded into 5-bit blocks. Since there are 32 distinct 5-bit blocks, each letter may be mapped into a distinct 5-bit block with a few blocks left over for control or other symbols. Similarly, upper-case letters, lower-case letters, and a great many special symbols may be converted into 8-bit blocks ("bytes") using the standard ASCII code.

Treats coding for discrete sources and generalizes the above techniques in many ways. For example the input symbols might first be segmented into *m*-tuples, which are then mapped into blocks of binary digits. More generally yet, the blocks of binary digits can be generalized into variable-length sequences of binary digits. We shall find that any given discrete source, characterized by its alphabet and probabilistic description, has a quantity called entropy associated with it. Shannon showed that this source entropy is equal to the minimum number of binary digits per source symbol required to map the source output into binary digits in such a way that the source symbols may be retrieved from the encoded sequence.

Some discrete sources generate finite segments of symbols, such as email messages, that are statistically unrelated to other finite segments that might be generated at other times. Other discrete sources, such as the output from a digital sensor, generate a virtually unending sequence of symbols with a given statistical characterization. The most straightforward approach to analog source coding is called analog to digital (A/D) conversion. The source waveform is first sampled at a sufficiently high rate

Each sample is then quantized sufficiently finely for adequate reproduction. For example, in standard voice telephony, the voice waveform is sampled 8000 times per second; each sample is then quantized into one of 256 levels and represented by an

8-bit byte. This yields a source coding bit rate of 64 Kbps.

Beyond the basic objective of conversion to bits, the source encoder often has the further objective of doing this as efficiently as possible— *i.e.*, transmitting as few bits as possible, subject to the need to reconstruct the input adequately at the output. In this case source encoding is often called data compression. For example, modern speech coders can encode telephone-quality speech at bit rates of the order of 6-16 kb/s rather than 64 kb/s.

The problems of sampling and quantization are largely separable. Chapter 3 develops the basic principles of quantization. As with discrete source coding, it is possible to quantize each sample separately, but it is frequently preferable to segment the samples into *n*-tuples and then quantize the resulting *n*-tuples. As shown later, it is also often preferable to view the quantized output as a discrete source output and then to encode the quantized symbols

The purpose of sampling is to convert the analog source into a sequence of real-valued numbers, *i.e.*, into a discrete-time, analog-amplitude source. There are many other ways, beyond sampling, of converting an analog source to a discrete-time source. A general approach, which includes sampling as a special case, is to expand the source waveform into an orthonormal expansion and use the coefficients of that expansion to represent the source output. It forms the basis for the signal space approach to channel encoding/decoding.

B.3 Communication channels

We next discuss the channel and channel coding in a generic digital communication system.

In general, a channel is viewed as that part of the communication system between source and destination that is given and not under the control of the designer. Thus, to a source-code designer, the channel might be a digital channel with binary input and output; to a telephone- line modem designer, it might be a 4 KHz voice channel; to a cable modem designer, it might be a physical coaxial cable of up to a certain length, with certain bandwidth restrictions.

When the channel is taken to be the physical medium, the amplifiers, antennas, lasers, etc. that couple the encoded waveform to the physical medium might be regarded as part of the channel or as as part of the channel encoder. It is more common to view these coupling devices as part of the channel, since their design is quite separable from that of the rest of the channel encoder. This, of course, is another example of layering.

Channel encoding and decoding when the channel is the physical medium (either with or without amplifiers, antennas, lasers, etc.) is usually called (digital) modulation and demodulation respectively. The terminology comes from the days of analog communication where modulation referred to the process of combining a low pass signal waveform with a high frequency sinusoid, thus placing the signal waveform in a frequency band appropriate for transmission and regulatory requirements. The analog signal waveform could modulate the amplitude, frequency, or phase, for example, of the sinusoid, but in any case, the original waveform could be retrieved by demodulation.

As digital communication has increasingly replaced analog communication, the modulation/demodulation terminology has remained, but now refers to the entire process of digital encoding and decoding. In most such cases, the binary sequence is first converted to a baseband waveform and the resulting baseband waveform is converted to bandpass by the same type of procedure used for analog modulation. As will be seen, the challenging part of this problem is the conversion of binary data to baseband waveforms. Nonetheless, this entire process will be referred to as modulation and demodulation, and the conversion of baseband to passband and back will be referred to as frequency conversion.

As in the study of any type of system, a channel is usually viewed in terms of its possible inputs, it’s possible outputs, and a description of how the input affects the output. This description is usually probabilistic. If a channel were simply a linear time-invariant system (*e.g.*, a filter), then it could be completely characterized by its impulse response or frequency response. However, the channels here (and channels in practice) always have an extra ingredient – noise.

Suppose that there were no noise and a single input voltage level could be communicated exactly. Then, representing that voltage level by its infinite binary expansion, it would be possible in principle to transmit an infinite number of binary digits by transmitting a single real number. This is ridiculous in practice, of course, precisely because noise limits the number of bits that can be reliably distinguished.

Channel encoding (modulation)

Modulation is defined as a process through which an information-bearing message (i.e., modulating) signal is used to modify (i.e., modulate) some parameter (e.g., amplitude, frequency, phase) of a periodic (such as a high-frequency sinusoidal) signal known as a carrier wave, individually or in combination, to produce the modulated signal for transmission. This is similar to when a musician modulates a tone by varying its volume (amplitude), its timing (phase), and its pitch (frequency).

We have three distinct modulation categories: amplitude modulation (AM), frequency modulation (FM), and phase modulation (PM). However, in the context of digital communications, the term shift keying is generally used instead of the word modulation. To this effect, we have amplitude-shift keying (ASK), frequency-shift keying (FSK), and phase-shift keying (PSK). There is also another category in digital communications, which is a hybrid of ASK and PSK, known as quadrature amplitude modulation (QAM). It is important to note that PSK and QAM are used in digital communication systems far more often than ASK and FSK. In some cases, the modulated signal is simply related to the message signal, such as with ASK, and in some cases, the relationship is rather complicated, such as with QAM.

A modem is a device that provides two-way communications, and thus performs both modulation in the transmitter and demodulation (i.e., the inverse operation of modulation) in the receiver. Modulation is performed to achieve one or more of the following objectives

Modulation for efficient radio transmission: For radio communications, antennas are needed to radiate (transmit) and receive the modulated signal. The size of the antenna depends on the wavelength and the application. Modulation helps translate the message signal with low frequency components into a signal with much higher frequency components. The resulting modulated signal can thus possess a much smaller wavelength, and that in turn allows much smaller antennas. The signal

Wavelength λ can be found using λ ¼$_{f}^{c}$, where f is the signal frequency in Hertz (Hz), c is the speed of light in meters per second (MPs), and λ in meters (m). As an example, efficient electromagnetic radiation for line-of-sight radio propagation generally requires antennas whose physical dimensions are at least 10% of the signal's wavelength. Therefore, an audio signal with frequency components up to 100 Hz requires an antenna about 300 km, but with modulation at 300 MHz, the antenna needs to be only about 10 cm long. Another example is that for cellular mobile telephones, antennas are typically 25% of the signal wavelength, so for the above-mentioned audio signal, an antenna spanning 750 km would be required, but with modulation at 900 MHz, the equivalent antenna diameter would be only about 8 cm.

Modulation to match channel characteristics: Modulation allows modification of the message signal to a form suited to the characteristics of the transmission channel. The majority of practical channels have bandpass characteristics and modulation translates the frequency components of the low pass message signal to the passband range, so the spectrum of the transmitted signal can match the characteristics of the channel. Applications may include satellite TV, in which baseband video signals with frequency components up to 6 MHz are converted into RF signals operating at 14 GHz, and cellular phones, in which baseband speech signals with frequency components up to 4 kHz are converted into RF signals operating at 900 MHz

Modulation for frequency assignment: Modulation allows many radio and television stations to broadcast simultaneously in a given geographical area. Since each station has a different assigned carrier frequency, the desired broadcast signals can be separated from others by tuning the receiver to select different stations as required.

Modulation for multiplexing: When more than one signal needs to utilize a single channel, modulation may be used to translate different signals to different spectral locations. Applications include FM stereophonic broadcasting, in which the sum of the right-hand and left-hand signals and their differences are accommodated into a single channel, and cable TV, in which a number of TV channels along with the upstream and downstream Internet traffic are all integrated into a single channel.

Modulation to allow common processing: Sometimes the frequency range of the signal to be processed and the frequency range of the processing device do not match, and the processing device is complex. Modulation allows the processing equipment to operate in some fixed frequency range and instead translate the frequency range of the signal to correspond to the fixed frequency range of the processing equipment. This is the case when in a system, such as AM radio, all RF signals coming from various AM radio stations are converted to a certain intermediate-frequency (IF) in a receiver.

Modulation to overcome hardware limitations: The performance, design, and cost of some signal-processing devices, such as filters and amplifiers, often depend on the signal spectral location and the ratio of the highest to lowest signal frequencies. It is generally desirable to keep the ratio of signal bandwidth to its center frequency within 1–10%. Modulation can be therefore used to translate the signal to a location in the frequency domain where design requirements can be better met.

Modulation to reduce noise and interference: The effect of noise and interference cannot be completely eliminated in a communication system. However, by significantly expanding the bandwidth of the transmitted signal, the noise and interference immunity in some cases can be considerably enhanced. In other words, bandwidth increase is traded for noise and interference reduction. Applications include FM radio and spread spectrum techniques.

Modulation to allow design trade-offs: Modulation techniques, employing digital M-ary (vis-a`-vis binary) signaling, can provide a balancing act to optimally achieve digital communication design objectives, such as higher trans• mission rate, lower transmit power, smaller signal bandwidth, lower bit error rate, and more modest complexity. By increasing M, bandwidth can be saved at the expense of an increase in bit error rate. By using trellis-coded modulation, transmission rate can be enhanced, not with an increase in bandwidth but at the expense of increased modem complexity.

Error correction

Frequently the error probability incurred with simple modulation and demodulation techniques is too high. One possible solution is to separate the channel encoder into two layers, first an error-correcting code, and then a simple modulator.

As a very simple example, the bit rate into the channel encoder could be reduced by a factor of 3, and then each binary input could be repeated 3 times before entering the modulator. If at most one of the 3 binary digits coming out of the demodulator were incorrect, it could be corrected by majority rule at the decoder, thus reducing the error probability of the system at a considerable cost in data rate. The scheme above (repetition encoding followed by majority-rule decoding) is a very simple example of error-correction coding. Unfortunately, with this scheme, small error probabilities are achieved only at the cost of very small transmission rates

Digital interface

The interface between the source coding layer and the channel coding layer is a sequence of bits. However, this simple characterization does not tell the whole story. The major complicating factors are as follows:

Unequal rates: The rate at which bits leave the source encoder is often not perfectly matched to the rate at which bits enter the channel encoder.

Errors: Source decoders are usually designed to decode an exact replica of the encoded sequence, but the channel decoder makes occasional errors.

Networks: Encoded source outputs are often sent over networks, traveling serially over several channels; each channel in the network typically also carries the output from a number of different source encoders.

The first two factors above appear both in point-to-point communication systems and in net• works. They are often treated in an ad hoc way in point-to-point systems, whereas they must be treated in a standardized way in networks. The third factor, of course, must also be treated in a standardized way in networks.
The usual approach to these problems in networks is to convert the superficially simple binary interface above into multiple layers.

B.4 GUIDED-TRANSMISSION MEDIA

Information transmission across a communication network is accomplished in the physical layer by means of a transmission medium to convey the energy of a signal from a transmitter to a receiver. In telecommunications, transmission media can be divided into two broad categories: guided (wired) and unguided (radio). Guided-transmission media include twisted-pair cable, coaxial cable, and fiber-optic cable, as shown in and the unguided-transmission medium is the atmosphere or free space, through which electromagnetic waves are propagated to convey information.

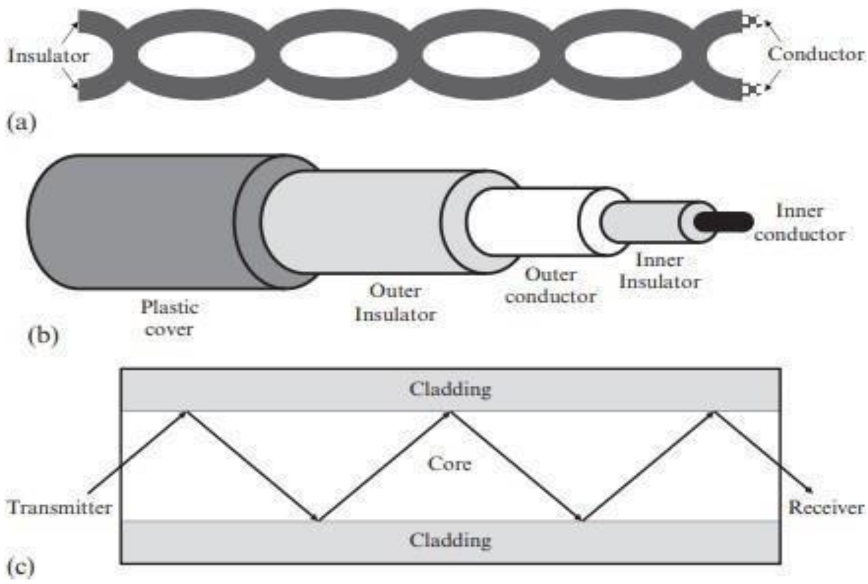

Fig: B.2 transmission media

Twisted-Pair Cable

Twisted-pair was designed and built mainly for speech communications. As shown in fig twisted-pair cable consists of two insulated conducting (typically copper) wires, closely twisted together to reduce the susceptibility to crosstalk (electrical signals from other adjacent wires) and noise. One of the wires is used to carry signals to the receiver, and the other is used only as a ground reference. The receiver detects the information signal by the voltage difference between the two.

A twisted-pair cable can pass a wide range of frequencies. At a given

Frequency, a higher gauge (thicker) wire yields a higher signal attenuation. The attenuation for twisted-pair, measured in dB per distance, sharply increases with frequencies above 100 kHz. Since the attenuation per distance is higher for higher frequencies, the bandwidth of twisted-pair decreases with distance. Depending on the gauge of the unshielded twisted-pair, the attenuation can roughly range between 1–4 dB/km at 4 kHz, between 5–10 dB/km at 100 kHz, and 10dB/km at 1 MHz For digital transmission over a twisted-pair cable, repeaters are required every couple of kilometers.

Twisted-pair cables are used in the telephone network to transmit voice. The local loop, the line connecting subscribers to the central office, consists of unshielded twisted-pair (UTP) cables. To improve voice transmission, the transmission frequencies are limited to 4 kHz to reduce the crosstalk and load• ing coils are added to provide a flatter transfer function. These factors, not the inherent bandwidth of twisted-pair, limit the digital transmission rate over tele• phone lines to below approximately 40 kbps.

However, a digital subscriber line (DSL), which uses a UTP cable, can provide much higher rates for short distances, provided that the user equipment and the interface at the central office are both changed to match the DSL transmission requirements. Besides distance, there are other factors, such as the size of the wire, the signaling type, crosstalk interference from other lines, and the SNR value, which can affect the available bandwidth and in turn the transmission rate. Moreover, twisted-pair cables are used in Ethernet LANs, such as 10Base-T at 10 Mbps, 100Base-TX at 100 Mbps, 1000Base-T at 1 Gbps, capable of carrying various modalities

.

Coaxial Cable

As shown in Figure coaxial cable consists of an inner (central) conductor of solid or stranded wire (usually copper) and an outer conductor of metal foil, braid, or a combination of two, separated by a dielectric insulating material. The outer conductor is also enclosed in an insulating sheath, and the whole cable can be protected by a plastic cover.

As opposed to twisted-pair cables, coaxial cables provide much better immunity to crosstalk and interference, offer much larger bandwidths (hundreds of MHz), but yield higher levels of attenuation. In other words, although coaxial cable has a much higher bandwidth, the signal weakens rapidly and requires the frequent use of repeaters, roughly every kilometer or so. The widest use of coaxial cable is for the distribution of television signals in cable TV systems, and it is also used for local area networks (LANs). Rates up to tens of Mbps are feasible using coaxial cables, with 10 Mbps being the standard. The attenuation can roughly range between 7–27 dB/km at 10 MHz

Fiber-Optic Cable

An optical fiber is a dielectric waveguide that transports light signals just as metallic (twisted-pair or coaxial) cable transports electrical signals. As shown in Figure, an optical fiber consists of a very fine cylinder of glass (core) surrounded by a con• centric layer of glass (cladding). The core has a slightly higher optical density (index of refraction) than the cladding. Therefore, when a ray of light from the core approaches the cladding, the ray is completely reflected back into the core, and the ray of light is guided within the fiber. Information is transmitted by varying the intensity of the light source with the message signal. The light in the fiber is periodically amplified and regenerated by repeaters along the transmission path, and at the receiver, the light intensity is detected by a photodiode.

There are two types of optical fibers, the low-cost multimode fibers and the low-loss single-mode fibers. A multimode fiber has a ray of light that can reach the receiver over multiple paths. Since each path has its own delay, the differences in delays cause interference. This limits the maximum bit rates that are achievable using multimode fibers. In a single-mode fiber where the core of fiber is much narrower, the single mode propagates with low loss and dispersion, thus requiring much fewer repeaters. Sources of noise in fiber-optic cables are photodiodes and electronic amplifiers. Optical fibers have unique characteristics, such as an enormous potential bandwidth, low transmission losses, immunity to electromagnetic interference, small size and weight, ruggedness, and flexibility. Optical fiber transmission systems are widely deployed in backbone net• works, and can provide nearly error-free transmission rates up to several hundred Gbps over tens of kilometers, as typical attenuation is about 0.2–0.5 dB/km.

RADIO TRANSMISSION

Radio encompasses the electromagnetic spectrum in the range of 3 kHz to 300 GHz. Radio transmission uses an unguided medium, and may possess principal benefits, but at the expense of some major shortcomings.

Radio Spectrum

It is imperative to highlight that spectrum is a very scarce commodity, and efficient use of any part of spectrum is of paramount importance. Radio spectrum refers to the part of the electromagnetic spectrum corresponding to radio frequencies i.e., frequencies lower than around 300 GHz (or, equivalently, wavelengths longer than about 1 mm). Frequency assignments and technical standards are set internationally by the International Telecommunications Union (ITU). The Radio communication Sector of ITU (ITU-R) provides frequency assignments and is concerned with the efficient use of the radio frequency spectrum.

Table B.1 shows the frequency bands and some of their major aspects. The frequency bands are designated in logarithmic frequency and the progression of frequency bands has increasingly larger bandwidths. For instance, the MF band (from 0.3–3 MHz) has a bandwidth of 2.7 MHz, whereas the VHF band (from 30–300 MHz) has a bandwidth of 270MHz. Higher bandwidths can generally lend themselves to higher system capacities and transmission rates as well as lower levels of interference and bit error rates, but at the expense of higher signal attenuation and equipment complexity.

Table B.1 Frequency bands and their major aspects

Frequency band	Frequency range	Wavelength range	Transmission media	Propagation mode
Extra-Low Frequency (ELF)	3–30 Hz	100,000–10,000 km	Wire pairs	Ground wave
Super-Low Frequency (SLF)	30–300 Hz	10,000–1,000 km	Wire pairs	Ground wave
Ultra-Low Frequency (ULF)	300–3 kHz	1,000–100 km	Wire pairs	Ground wave
Very-Low Frequency (VLF)	3–30 kHz	100–10 km	Wire pairs	Ground wave
Low Frequency (LF)	30–300 kHz	10–1 km	Wire pairs	Ground wave
Medium Frequency (MF)	0.3–3 MHz	1–0.1 km	Wire pairs & coaxial cable	Ground wave & sky wave
High Frequency (HF)	3–30 MHz	100–10 m	Coaxial cable	Sky wave
Very-High Frequency (VHF)	30–300 MHz	10–1 m	Coaxial cable	Sky wave & line of sight
Ultra-High Frequency (UHF)	0.3–3 GHz	1–0.1 m	Coaxial cable & waveguide	Line of sight
Super-High Frequency (SHF)	3–30 GHz	100–10 mm	Waveguide	Line of sight
Extra-High Frequency (EHF)	30–300 GHz	10–1 mm	Waveguide	Line of sight
Infrared	0.3–430 THz	1 mm–700 nm	Optical fibers	Laser beams
Visible Light	430–750 THz	700–400 nm	Optical fibers	Laser beams
Ultraviolet	0.75–30 PHz	400–10 nm	Optical fibers	Laser beams

Wave Propagation

Like light waves, radio signals by nature travel in a straight line, and therefore propagation beyond line of sight requires a means of deflecting the radio waves. The available methods are reflection (when the radio signal is bounced off a surface), refraction (when the radio signal bends due to a change in medium), diffraction (when the radio signal meets a sharp edge and redirects), and scattering (when the radio signal spreads out). For any type of radio communications, the signal disperses with distance. The signal attenuation in free space is inversely related to the square of the distance that the radio signal must travel as well as the square of the frequency that the radio signal is operating at.

Depending on the frequency and antenna, the radiated energy can propagate in either a unidirectional or omnidirectional fashion. In the former case, a properly-aligned antenna can receive the modulated signal, and in the latter case, any antenna in the area of coverage can receive the signal. In general, radio frequencies below 1 GHz or so are more suitable for omnidirectional applications and above 1 GHz or so are typically tailored for unidirectional applications. Also, at low and medium frequencies, radio waves can penetrate walls. This is viewed as an advantage when a signal is required to be received inside a building and is regarded as a disadvantage when it is required to isolate a communication to just inside or outside a building to reduce the level of interference.

The range of 300 MHz to 300 GHz is known as microwave radio frequencies. Rain attenuation, which refers primarily to the absorption of a microwave frequency signal by atmospheric rain, snow, or ice, is a dominant source of signal degradation. Rain attenuation is a function of many factors, such as location, distance, elevation angle, and frequency. Rain attenuation is directly related to frequency.

Radio waves at different frequencies propagate in different ways, there are three distinct methods for the transmission of radio signals: ground-wave propagation, sky-wave propagation, and line-of-sight propagation.

Ground-wave propagation: It is the dominant mode of propagation for frequencies below 2 MHz (all bands up to and including the lower part of MF band). In this frequency range, the Earth and the ionosphere (the layer of atmosphere where particles exist as ions) act as a waveguide for radio wave propagation. These low-frequency signals propagate (by diffraction) in all directions around the curved surface of the Earth for thousands of kilometers. Distance depends on the amount of power in the signal. Since the ground is not a perfect electrical conductor, ground waves are attenuated rapidly as they follow the Earth's surface. The signal attenuation is a function of time and the frequency band. Also, the atmospheric noise level is rather high. The channel bandwidths available in these frequency bands are rather modest and in turn yield rather low transmission speeds. Typical applications include long-range navigation and maritime communications, radio beacon, and AM radio broadcasting.

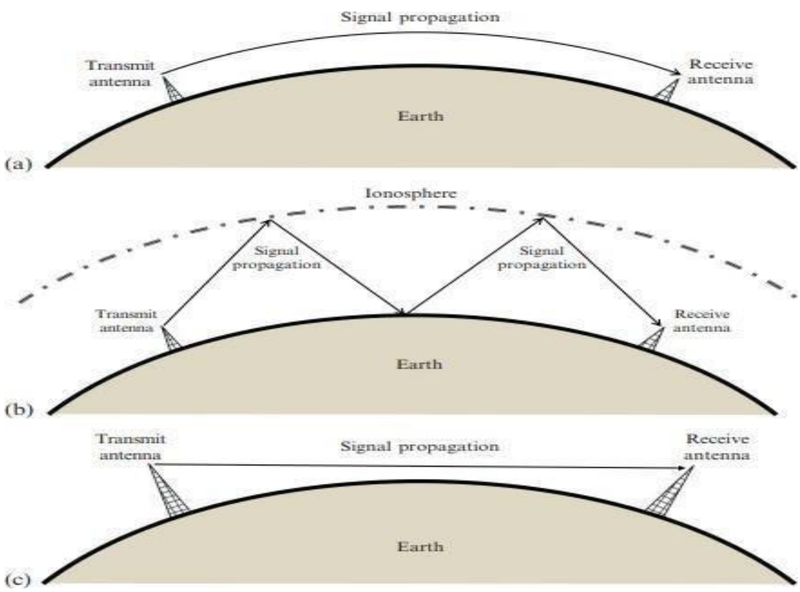

Fig: B.3 propagation of signal

Sky-wave propagation: It is the dominant mode of propagation in the frequency range of 2 MHz to about 30 MHz or in some cases 60 MHz (the upper part of MF band, HF band, and the lower part of VHF band). Sky-wave propagation results when the signal is reflected (bent or refracted) from the ionosphere (ionized layer of the upper atmosphere). In the HF band, signal multipath and fading can be a source of degradation. This impairment may be experienced when listening to a distant radio station at night when the sky-wave propagation is the dominant mode. The angle of reflection and the loss of signal at an ionospheric reflection point depend on the frequency, the time of the day, the season, and the sunspot activity. Ionosphere and troposphere scattering involves large signal propagation losses and requires a rather large amount of transmit power and relatively large antennas. The additive noise is a combination of atmospheric noise and thermal noise. Cosmic noise, which is random noise originating outside the Earth’s atmosphere, impacts sky-way propagation. The typical transmission range in sky-wave propagation can be in hundreds of kilometers. Typical applications include FM radio broadcasting, short-wave broadcasting, amateur radio, and CB radio.

Line-of-sight propagation: From the upper part of the VHF band up to and including the EHF band, signals must be transmitted in straight lines directly from antenna to antenna, hence the term line of sight. The transmit and receive antennas are required to be directional and facing each other. The direct path connecting the antennas in terrestrial communications can be affected by the curvature of the Earth. The distance between the transmitter and the receiver is therefore a function of the heights of the transmit and receive antennas. For this reason, television stations transmitting off-the• air signals or microwave radio relay systems mount their antennas on high towers or buildings to reach a broad coverage area. Specifically, for terrestrial communications, the maximum distance between transmit and receive antennas for direct line-of-sight radio propagation is about D ¼ 17 $H_T + H_R$, where H_T and H_R are the heights of transmit and receive antennas in meters, respectively, and D is the maximum distance in kilometers over which communications between them can take place by direct line-of-sight radio signals. Applications include off-the-air (VHF and UHF) TV broadcasting, which are examples of line-of-sight terrestrial communications, and satellite TV broad• casting and VSAT networks, which are examples of line-of-sight satellite communications.

A Major Project report on

JOINT CHANNEL ESTIMATION AND IMPULSIVE NOISE MITIGATION METHOD FOR OFDM SYSTEMS USING SPARSE BAYESIAN LEARNING

Submitted in partial fulfillment of the requirement for the award of degree of

BACHELOR OF TECHNOLOGY

IN

Electronics & Communication Engineering

Submitted By

K.Ravichandra (17K81A0422)

M.Vamshy (17K81A0433)

P.Varshini (17K81A0438)

Under the Guidance of

Mr. D. Prasad M.Tech

Assistant Professor

DEPARTMENT OF ELECTRONICS & COMMUNICATION ENGINEERING

ST. MARTIN'S ENGINEERING COLLEGE

UGC AUTONOMOUS

(Affiliated to Jawaharlal Nehru Technological University, Hyderabad)

Dhulapally, Secunderabad-500 100.

NBA & NAAC A+ Accredited

2020-2021

BONAFIDE CERTIFICATE

Certified that this project report titled "*JOINT CHANNEL ESTIMATION AND IMPLUSIVE NOISE MITIGATION METHOD FOR OFDM SYSTEMS USING SPARSE BAYESIAN LEARNING*", is a *bona fide* work of **1. Mr. K. Ravi Chandra (17K81A0422), 2. Mr. M. Vamshy (17K81A0433), 3. Ms. P. Varshini (17K81A0438), Dr. D. Prasad** who carried out the work under my supervision, for the partial fulfillment of the requirements for the award of the degree of *Bachelor of Technology* in *Electronics and Communication Engineering.* Certified further that to the best of my knowledge and belief, the work reported herein does not form part of any other thesis or dissertation on the basis of which a degree or an award was conferred on an earlier occasion.

ACKNOWLEGMENTS

While bringing out this project report to its final form, we came across a number of people whose contributions in various ways helped my field of research and they deserve special thanks. It is a pleasure to convey our gratitude to all of them.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. HariKrishna**, **Head &Professor**, the Dept. of electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr. A. Soumya** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr. D. Prasad**, **Assistant Professor**, Department of ECE and our class project coordinator **Ms. A. Soumya**, **Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

We are highly grateful and obliged to **our college level Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr. R. Santosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

The impulsive noise can deteriorate sharply the performance of orthogonal frequency division multiplexing (OFDM) systems. In this paper, we propose a novel joint channel impulse response estimation and impulsive noise mitigation algorithm based on compressed sensing theory. In this algorithm, both the channel impulse response and the impulsive noise are treated as a joint sparse vector. Then, the sparse Bayesian learning framework is adopted to jointly estimate the channel impulse response, the impulsive noise, and the data symbols, in which the data symbols are regarded as unknown parameters. The Cramér–Rao Bound is derived for the benchmark. Unlike the previous impulsive noise mitigation methods, the proposed algorithm utilizes all subcarriers without any a priori information of the channel and impulsive noise. The simulation results show that the proposed algorithm achieves significant performance improvement on the channel estimation and bit error rate performance.

ISP	Internet Service Providers
AWGN	Additive White Gaussian Noise
PS	Phase Shift Keying
BER	Bit Error Rate

CHAPTER 1

INTRODUCTION

1.1 OBJECTIVES OF THE STUDY

Orthogonal frequency division multiplexing (OFDM) has become the most popular multicarrier signaling format for high-speed wireless communications and has been included in many standards such as Long Term Evolution (LTE), IEEE 802.11 wireless local area network (WLAN) and digital video broadcasting (DVB). Due to its efficient implementation and robustness to the frequency selectivity, OFDM and its combination with multiple-input multiple-output (MIMO) system sun surprisingly appears as a strong alternative for 5G networks. OFDM with index modulation (OFDM-IM) is a recently proposed novel scheme which transmits information not only by M-ary constellation symbols, but also by the indices of the active subcarriers which are activated according to the incoming information bits. Subcarrier index modulation techniques for OFDM have attracted considerable attention from researchers and have been investigated in some recent studies due to interesting trade-offs they offer in error performance and spectral efficiency compared to classical OFDM systems. The bit error probability of OFDM-IM is analytically derived. The spectral efficiency of OFDM-IM is improved by selecting the active subcarriers in a more flexible way in, where index modulation is applied for both in-phase and quadrature components of the subcarriers. The authors deal with the problem of selecting the optimal number of active subcarriers in OFDM-IM. More recently, OFDM-I Mis-combined with coordinate interleaving to achieve additional diversity gains. However, the combination of OFDM-IM and MIMO transmission techniques remains an open and interesting research problem. Inthisstudy, we propose MIMO-OFDM with index modulation (MIMO-OFDM-IM) as an efficient alternative multicarrier transmission scheme for 5G networks by combining MIMO and OFDM-IM transmission techniques. In the proposed scheme, each transmit antenna transmits its own OFDM-IM frame as in Vertical Bell Labs layered space-time (V-BLAST) scheme, and at the receiver side, these OFDM-IM frames are separated and demodulated using a novel and low complexity minimum mean square error (MMSE) detection and log-likelihood ratio (LLR) calculation based detector. It is shown via computer simulations that the MIMO-OFDM-IM scheme achieves significantly better bit error rate (BER) performance than classical V-BLAST type MIMO-OFDM for several MIMO configurations. The rest of the letter is organized as follows. The system model of MIMO-OFDM-IM is presented,receiver structure of the MIMO –OFDM –I M-scheme is given. Simulation results are provided. we propose MIMO-OFDM with index modulation (MIMO-OFDM-IM) as an efficient alternative multicarrier transmission scheme for 5G networks by combining MIMO and OFDM-IM transmission techniques. In the proposed scheme, each transmit antenna transmits its own OFDM-IM frame as in Vertical Bell Labs layered space-time (V-BLAST) scheme, and at the receiver side, these OFDM-IM frames are separated and demodulated using a novel and low complexity minimum mean square error (MMSE) detection and log-likelihood ratio (LLR) calculation baseddetector. Orthogonal frequency division multiplexing (OFDM) has become one among the most common multicarrier transmission techniques for wideband wireless communications in recent years. Because of its benefits like efficient implementation and strength to frequency selective fading channels, OFDM has been enclosed in several standards like long term Evolution (LTE), IEEE 802.11x wireless local area network (LAN), digital video broadcasting (DVB) and IEEE 802.16e-WiMAX. Considering the benefits of multiple-input multiple-output (MIMO) systems over single antenna systems like improved rate and energy efficiency, the mixture of OFDM and MIMO transmission techniques seems as a robust different for future wireless standards like 5G and beyond. OFDM with index modulation (OFDM-IM) can be a new multicarrier transmission method that has been planned as another to classical OFDM. Stimulating from the SM conception, in OFDM-IM, index modulation techniques are applied for the indices of the offered subcarriers of an OFDM system. In OFDM-IM method, only a set of available subcarriers are preferred as active consistent with the data bits, whereas the remaining inactive subcarriers are set zero. In different words, the data is transmitted not only by the information symbols selected from M-ary signal constellations, however additionally by the indices of the active subcarriers. Not like classical OFDM, the quantity of active subcarriers may be adjusted within the OFDM-IM scheme, and this flexibility within the system style provides a stimulating trade-off between error performance and spectral efficiency. Moreover, it's been shown that OFDM-IM has the potential to realize a more robust error performance than classical OFDM for low-to-mid spectral efficiency values. Due to its adjustable range of active subcarriers, OFDM-IM may be a potential candidate not just for high speed wireless communications systems however additionally for machine-to-machine (M2M) communications systems that need low power consumption.

In statistics and signal processing, a minimum mean square error (MMSE) estimator is an estimation method which minimizes the mean square error (MSE), which is a common measure of estimator quality, of the fitted values of a dependent variable. In the Bayesian setting, the term MMSE more specifically refers to estimation with quadratic loss function. In such case, the MMSE estimator is given by the posterior mean of the parameter to be estimated. Since the posterior mean is cumbersome to calculate, the form of the MMSE estimator is usually constrained to be within a certain class of functions. Linear MMSE estimators are a popular choice since they are easy to use, easy to calculate, and very versatile. It has given rise to many popular estimators such as the Wiener–Kolmogorov filter and Kalman filter.

An M-ary transmission is a type of digital modulation where instead of transmitting one bit at a time, two or more bits are transmitted simultaneously. This type of transmission results in reduced channel bandwidth. This process is known as quadrature modulation.

M-ary Encoding. The word binary represents two-bits. ... This is the type of digital modulation technique used for data transmission in which instead of one-bit, two or more bits are transmitted at a time. As a single signal is used for multiple bit transmission, the channel bandwidth is reduced. An M-ary transmission is a type of digital modulation where instead of transmitting one bit at a time, two or more bits are transmitted simultaneously. This type of transmission results in reduced channel bandwidth. However, sometimes, two or more quadrature carriers are used for modulation. Multi-level modulation techniques permit high data rates within fixed bandwidth constraints. A convenient set of signals for M-ary PSK is

$\varphi i(t) = A \cos(\omega ct + \theta i), 0 < t \leq Ts,$

Where the M phase angles are $\theta i = 0, 2\pi M , . . ., 2(M - 1)\pi M$.

For equi probable ones and zeros the PSD for M-ary PSK is S

$\varphi(\omega) = A\ 2\ TsSa2(\omega - \omega c)\ Ts\ 2.$

The symbols in this case are of duration Ts, so the information (or bit) rate Tb satisfies Ts = Tb log2 M. The potential bandwidth efficiency of M-ary PSK can be shown to be fb B = log2 M bps/Hz.

All signals have the same energy Es over the interval (0, Ts), and each signal is correctly demodulated at the receiver if the phase is within ±π/M of the correct phase θi. No information is contained in the energy of the signal. A probability of error calculation involves analysing the received phase at the receiver (in the presence of noise), and comparing it to the actual phases. An exact solution is difficult to compute, but for P< 10−3 an approximate probability of making a symbol error is P 2erfcs 2Es η sin2 π M, M > 2. If a Gray code is used, then the corresponding bit error is approximately Pbe/ log2 M. Stremler provides a table of the SNR requirements of M-ary PSK for fixed error rates. The results indicate that for QPSK (M = 4) has definite advantages over coherent PSK (M = 2) the bandwidth efficiency is doubled for only about a 0.3dB increase in SNR. For higher-rate transmissions in band limited channels the choice M = 8 is often used. Values of M > 8 are seldom used due to excessive power requirements. M-ary PSK requires more complex equipment than BPSK signalling. Carrier recovery is also more complicated. The requirement that the carrier be recovered can be mitigated by using a comparison between the phases of two successive symbols. This leads to M-ary differential PSK, and is in principle similar to DPSK (which is differential PSK for M = 2). For large SNR the probability of error is P=2erfcs 2Es η sin2 π √ 2M .Thus differential detection increases the power requirements by the factor 0 = sin2 π/M sin2 (π/ √ 2M) For m = 4, the increase is required power is about 2.5dB, which may be justified by the saving in equipment complexity.

In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a method of encoding digital data on multiple carrierfrequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G mobile communications.

In coded orthogonal frequency-division multiplexing (COFDM), forward error correction (convolutional coding) and time/frequency interleaving are applied to the signal being transmitted. This is done to overcome errors in mobile communication channels affected by multipath propagation and Doppler effects. COFDM was introduced by Alard in 1986 for Digital Audio Broadcasting for Eureka Project 147. In practice, OFDM has become used in combination with such coding and interleaving, so that the terms COFDM and OFDM co-apply to common applications.

OFDM is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. OFDM was introduced by Chang of Bell Labs in 1966. Numerous closely spaced orthogonal sub-carrier signals with overlapping spectra are emitted to carry data. Demodulation is based on Fast Fourier Transform algorithms. OFDM was improved by Weinstein and Ebert in 1971 with the introduction of a guard interval, providing better orthogonality in transmission channels affected by multipath propagation. Each sub-carrier (signal) is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate. This maintains total data rates similar to conventional single-carrier modulation schemes in the same bandwidth.

Conceptually, OFDM is a specialized frequency-division multiplexing (FDM) method, with the additional constraint that all subcarrier signals within a communication channel are orthogonal to one another.

In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that cross-talk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

The orthogonality requires that the sub-carrier spacing is Hertz, where T_U seconds is the useful symbol duration (the receiver-side window size), and k is a positive integer, typically equal to 1. This stipulates that each carrier frequency undergoes k more complete cycles per symbol period than the previous carrier. Therefore, with N sub-carriers, the total passband bandwidth will be $B= N*\Delta f$ (Hz).

The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e. near half the Nyquist rate for the double-side band physical passband signal). Almost the whole available frequency band can be used. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users.

In radio, multiple-input and multiple-output, or MIMO, is a method for multiplying the capacity of a radio link using multiple transmission and receiving antennas to exploit multipath propagation. MIMO has become an essential element of wireless communication standards including IEEE802.11n (Wi-Fi), IEEE802.11ac (Wi-Fi), HSPA+ (3G), WiMAX (4G),and Long Term Evolution (LTE4G). More recently, MIMO has been applied to power-line communication for 3-wire installations as part of ITU G.hn standard and HomePlugAV2 specification.

At one time, in wireless the term "MIMO" referred to the use of multiple antennas at the transmitter and the receiver. In modern usage, "MIMO" specifically refers to a practical technique for sending and receiving more than one data signal simultaneously over the same radio channel by exploiting multipath propagation. MIMO is fundamentally different from smart antenna techniques developed to enhance the performance of a single data signal, such as beam forming and diversity.

MIMO is often traced back to 1970s research papers concerning multi-channel digital transmission systems and interference (crosstalk) between wire pairs in a cable bundle: AR Kaye and DA George (1970), Branderburg and Wyner (1974), and W. van Etten (1975, 1976). Although these are not examples of exploiting multipath propagation to send multiple information streams, some of the mathematical techniques for dealing with mutual interference proved useful to MIMO development. In the mid-1980s Jack Salz at Bell Laboratories took this research a step further, investigating multi-user systems operating over "mutually cross-coupled linear networks with additive noise sources" such as time-division multiplexing and dually-polarized radio systems.

Methods were developed to improve the performance of cellular radio networks and enable more aggressive frequency reuse in the early 1990s. Space-division multiple access (SDMA) uses directional or smart antennas to communicate on the same frequency with users in different locations within range of the same base station. An SDMA system was proposed by Richard Roy and Bjorn Ottersten, researchers at ArrayComm, in 1991. Their US patent (No. 5515378 issued in 1996) describes a method for increasing capacity using "an array of receiving antennas at the base station" with a "plurality of remote users."

ArogyaswamiPaulraj and Thomas Kailath proposed an SDMA-based inverse multiplexing technique in 1993. Their US patent (No. 5,345,599 issued in 1994) described a method of broadcasting at high data rates by splitting a high-rate signal "into several low-rate signals" to be transmitted from "spatially separated transmitters" and recovered by the receive antenna array based on differences in "directions-of-arrival." Paulraj was awarded the prestigious Marconi Prize in 2014 for "his pioneering contributions to developing the theory and applications of MIMO antennas. His idea for using multiple antennas at both the transmitting and receiving stations – which is at the heart of the current high speedWiFi and 4G mobile systems – has revolutionized high speed wireless."

In an April 1996 paper and subsequent patent, Greg Raleigh proposed that natural multipath propagation can be exploited to transmit multiple, independent information streams using co-located antennas and multi-dimensional signal processing. The paper also identified practical solutions for modulation (MIMO-OFDM), coding, synchronization, and channel estimation. Later that year (September 1996) Gerard J. Foschini submitted a paper that also suggested it is possible to multiply the capacity of a wireless link using what the author described as "layered space-time architecture."

Greg Raleigh, V. K. Jones, and Michael Pollack founded Clarity Wireless in 1996, and built and field-tested a prototype MIMO system. Cisco Systems acquired Clarity Wireless in 1998. Bell Labs built a laboratory prototype demonstrating its V-BLAST (Vertical-Bell Laboratories Layered Space-Time) technology in 1998. ArogyaswamiPaulraj founded Iospan Wireless in late 1998 to develop MIMO-OFDM products. Iospan was acquired by Intel in 2003. V-BLAST was never commercialized, and neither Clarity Wireless nor Iospan Wireless shipped MIMO-OFDM products before being acquired.

CHAPTER 2

LITERATURE SURVEY

In several applications of wireless communication technology (e.g., vehicular networks, smart grid, and shallow sea underwater networks), the transmission of data signals will be severely deteriorated by the impulsive noise (IN). The sources of impulsive noise are diverse, such as ignition noise in automobiles, switches for electrical equipments, various maritime operations, and so on. Compared to additive white Gaussian noise (AWGN), the impulsive noise arises randomly with short duration and high power impulses.

Orthogonal frequency division multiplexing (OFDM) technology has been widely adopted in most modern wireless communication standards. In conventional OFDM receivers, the time-domain received signal is convertedinto the frequency domain through a discrete Fourier transform (DFT), after which each subcarrier is demodulated independently. Such tone-by-tone demodulation achieves optimal maximum likelihood detection in AWGN and perfect channel state information. When the impulsive noise is present, however, the corresponding frequency-domain noise samples will be highly dependent, and tone-by-tone demodulation is no longer feasible since the complexity of performing joint-detection at the receiver increases exponentially with the number of subcarriers.

Recently, there has been growing interest in developing compressed sensing (CS) based impulsive noise mitigation methods that exploit the time-domain sparsity of impulsive noise. These methods all make use of the information of null tones (i.e., tones that do not carry data or pilots) of the received OFDM symbol to estimate the IN sample and then subtract it from the received signal. Furthermore, some of them have been extended for detecting bursty (i.e., block sparse) impulsive noise by using structured compressed sensing theory. Although these methods show obvious advantages over those based on nonlinear preprocessor, the common drawback of these algorithms is that their performances are mostly limited by the number of null tones. It is worth pointing out that these approaches also assume that the channel state information is already estimated perfectly before the impulsive noise removal and do not consider the severe impact of impulsive noise on the channel estimation.

The performance of the IN estimator can be improved by increasing the number of null tones. However having more null tones means reduced throughput. When the number of null tones is limited, it is desirable to exploit information available in all tones to improve the estimation performance of the impulsive noise. The difficulty for exploiting all tones, however, is how to simultaneously estimate the channel and impulsive noise. An approach for jointly estimating channel and IN is proposed in, but it requires that there is no overlap between the support of impulsive noise and channel impulse response. In, an iterative channel estimation and impulsive noise mitigation algorithm is proposed on the assumption that the length of channel impulse response is known in advance and that the channel is static for several OFDM symbols. In, generalized approximate message passing (GAMP) has been used to jointly estimate the channel taps, the impulse noise samples, symbols, and the unknown bits. This method requires the acquisition of a priori information of the channel and impulsive noise and does not offer rigorous convergence although it is lower in computational complexity. By assuming that the impulsive noise parameter distributions are known at the receiver, a joint channel estimation and data decoding algorithm is developed. By exploiting the sparsity of both them, the orthogonal matching pursuit(OMP) is adopted for joint channel and impulsive noise estimation in underwater acoustic OFDM systems. This algorithm needs to collectthe number and position of IN samples by applying a blanking operation.

In this paper, we propose two novel algorithms based on Sparse Bayesian Learning (SBL) framework to jointly estimate both the channel impulse response and impulsive noise by exploiting the sparsity of both them. Our algorithms can also be categorized as an extension of the method proposed.

CHAPTER 3

CONCLUSION ON REVIEWS

3.1 Introduction to OFDM

OFDM has several significant benefits over single carrier QAM modulation which has led to its adoption in many of the modern wireless standards, including ADSL, European Digital Video Broadcast, IEEE 802.11a/g/n (WiFi), WiMax, and 3GPP Long Term Evolution (LTE). First of all, OFDM enables easy equalization, solving many of the equalization complexity issues we encountered for single carrier QAM by working instead in the frequency domain. Second of all, the ability to control the size of the constellation on each subcarrier in OFDM also allows it to mimic the "waterfilling" construction which maximizes the amount of information which can be reliably transmitted over the channel: subcarriers (frequencies) with better channel gains can utilize higher order modulations and coding rates. A final significant benefit that we will encounter later in the course is that OFDM allows for an especially easy to implement and understand multiple access strategy OFDMA, in which different subcarriers (frequencies) are allocated to different users at different times. To understand how OFDM modems work, we must first revisit several properties of the discrete Fourier Transform, and its efficient implementation the Fast Fourier Transform.

The circular convolution between two length N signals x1[n] and x2[n], n ∈ {0, 1, . . . , N − 1}, is defined as x1[n] * x2[n] = N X−1 =0 x1*x2[((n −1))N] where ((n))N = N − n n< 0 n n ≥ 0 Circularly convolving two length N signals x1[n] and x2[n] is the same thing as multiplying their discrete Fourier transforms x1[n]* x2[n] DF T ←→ X1[k]X2[k] .The underlying principle of OFDM is based on this property of the DFT.

The architecture of an OFDM transmitter and receiver pair is depicted in Fig. 1. First, during the th block, N QAM symbols c[k], k ∈ {0, . . . , N − 1} are mapped to "sub-carriers", one per subcarrier, which are the inputs to a size N IFFT, which computes the DFT shown below efficiently q[n] = N X−1 k=0 c[k]e j 2π N kn, n ∈ {0, . . . , N}

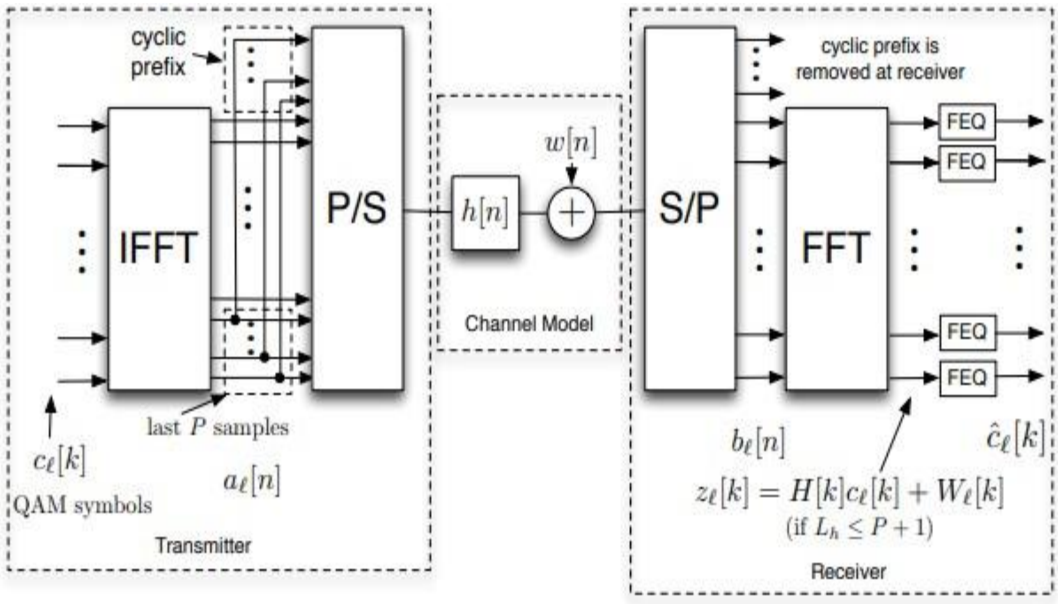

Fig.3.1.1 An OFDM transmitter,channel model and receiver.

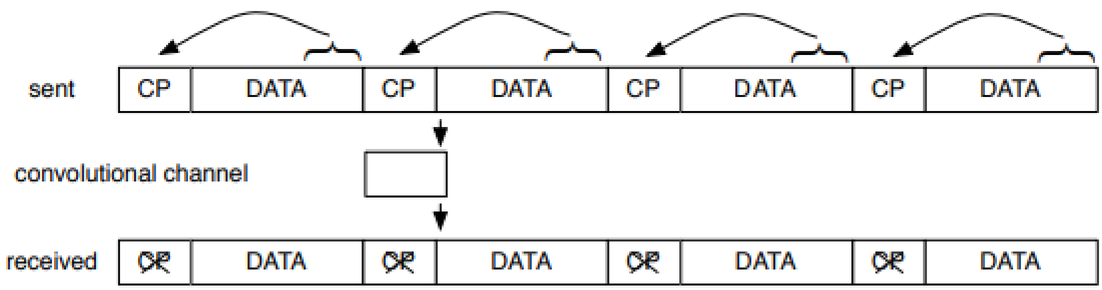
These OFDM blocks are then serialized to form xc[n] = a b n N+P c [n mod (N + P)] which is then put through an digital to analog convertor to form the complex baseband signal to be modulated by an ordinary quadrature modulator. As discussed in the previous notes on equalization, on its way from the transmitter to the receiver, the signal is subject to a multipath channel, as well as potentially some additive interference, and at the receiver there is additive white Gaussian noise in the electronics. As discussed in the lecture on quadrature modulation, we can model the effects of this multipath channel by modeling the signal at the receiver, after demodulation and sampling as yc[n] = L Xh−1=0 h + w[n] where Δ indicates the delay before the channel is perceived as having any significant energy, and h[n] is the sampled impulse response of the channel, whose delay spread is Lh samples long, and w[n] is the additive white Gaussian noise. The receiver then proceeds to process this signal yc[n] in the exact opposite manner as at the transmitter. First the blocks are collected b[n] = yc[n + Δ + (N + P)], n ∈ {0, 1 . . . , N + P − 1} (8) then the cyclic prefix is removed r[n] = b[n + P], n ∈ {0, 1, . . . , N − 1} . The Fast Fourier transform is then taken, which calculates the DFT shown below efficiently z[k] = X N n=0 r[n]e −j 2π N kn.



The Purpose of the Cyclic Prefix: Removing Inter-Block & Inter-Carrier Interference. The cyclic prefix allows an OFDM transmitter receiver pair to accomplish to important objectives, provided that the length of the multipath channel is less than or equal to the length of the cyclic prefix plus one:

1) It eliminates interblock interference, and

2) It enables easy equalization, as for the remainder of the block it makes the linear convolution with the ISI channel into a circular convolution. Indeed, as is indicated in Fig. 2, if we consider the output of the channel at times $n \in (\{0, \ldots, P-1\} + k(N + P)$, this will contain a contribution from both the previous OFDM symbol and the next one. However, if the channel length $Lh \leq P + 1$ then these are the only samples containing the inter-block interference, and hence, once we drop these samples at the receiver (when we remove the cyclic prefix), we will have no interblock interference. Additionally, under the same criterion $Lh \leq P + 1$ the remaining samples in each block after dropping the cyclic prefix will be the circular convolution of the channel with the associated transmitted block. Hence, by the circular convolution property of the DFT, when the FFT is taken of these received blocks, they will be the product of the FFT of the channel H[k] and the original QAM symbols, plus the FFT of the additive noise, as depicted in Fig 1. $z[k] = H[k]c[k] + w[k]$. The estimated QAM symbols can then be reconstructed by processing the subcarriers k individually by multiplying them with a frequency domain equalizer F[k] $c[k] = F[k]z[k]$ (12) where the F[k] can selected as $H[k] * \ |H[k]|\ 2+\sigma 2$, which minimizes the average magnitude squared error between c[k] and c[k], where σ 2 is the variance w[k]. These FEQs F[k] can be estimated by placing training information, also called pilot signals or reference signals, agreed upon in advance between the transmitter and receiver, on various subcarriers k which are spread out in frequency. Because the channel is shorter than the cyclic prefix, and the cyclic prefix is typically far shorter than the FFT size, the channel coefficients H[k] vary slowly with frequency k, and hence the channel estimates from the pilot signals can be interpolated to

yield improved channel estimates for other carriers Considerations when Selecting a Cyclic Prefix Length and FFT Size There are two important considerations when selecting a cyclic prefix length and FFT size for an OFDM system in practice. We already noted that the cyclic prefix needs to be longer than one less than the length of the channel (its delay spread). As the cyclic prefix does not bear any extra information itself, it is desirable to select a very large FFT size so that the redundancy is introduces is low. However, the multipath channel must remain fixed over the entire duration of the OFDM symbol (i.e. the entire cyclic prefix and received data block), and this places an upper limit on the length of the FFT based on how quickly the channel is varying.

Bit-Loading & OFDMA Because the OFDM construction turns the wideband multipath channel into multiple parallel lower rate channels associated with evenly spaced frequencies within the band, it enables several intuitive other technologies. As mentioned in the introduction, those carriers k with higher signal to noise ratios |H[k]| 2 σ2 can be given higher order QAM symbols and higher code rates. This process is called bit-loading and adaptive modulation and coding in different contexts. Additionally, using OFDM modems also enable an especially intuitive form of multiple access. If the transmitter wishes to send individual messages to multiple receivers (as in a cellular system) listening to the same wideband channel, one can place information to be transmitted to different users on different subcarriers. Furthermore, since the multipath profiles H[k] of different receivers listening to the same transmitter will be different, if these multipath profiles are reliably fed back to the transmitter, it can also select those subcarriers for different users which they are receiving with high signal to noise ratios. On the other hand, if the multipath profiles are not fed back, or are varying too quickly, the transmitter can diversify which frequencies are used for different users by spreading the carriers/blocks of carriers given to each particular user out in frequency.

Finally, we note that you are likely to encounter at least two other variants of OFDM: discrete multitone (DMT) and SC-FDMA, both of which differ from pure OFDM solely by what is modulated on each of the subcarrier k (bins of the IFFT at the transmitter). Discrete multitone, which is used in ADSL systems, simply selects the blocks of QAM symbols to be conjugate symmetric, so that their IFFT is realvalued, and hence only a single analog to digital convertor is required at the receiver. A SC-FDMA transmitter selects a contiguous sub-block of subcarriers, and places the result of the FFT of a sequence of QAM symbols of these subcarriers. This “spreading” of the inputs to the subcarriers with a FFT enables the peak to average power ratio of the output of the IFFT to be reduced, which allows the battery operated power amplifiers in the analog RF front ends of the transmitters in mobiles to operate in more efficient regimes. SC-FDMA is used in the uplink of LTE (from mobile phones to the base stations), while OFDMA is used in the downlink (from base stations to mobile phones). Note that the overall effect of this operation is the similar to pulse-shaping a single carrier QAM signal, since the zeros on the other subcarriers effectively determine a pulse shape, and which subcarriers are selected determine an effective overall carrier frequency. This is the reason this type of modulation is called "single carrier FDMA" in the LTE standard.

Orthogonal frequency-division multiplexing (OFDM) is a method of digital signal modulationin which a single data stream is split across several separate narrowband channels at different frequencies to reduce interference and crosstalk. The original data stream bits -- that in a conventional single-channel modulation scheme would be sent serially (one after the other) -- are transmitted in parallel (several at once on separate channels) but at lower speed in each substream (a stream within another stream) relative to the original signal. This means symbols sent in the substreams are longer and spaced farther apart. In the original stream, each bit might be represented by a 1-nanosecond (ns) segment of the signal, with 0.25 ns spacing between bits. Splitting the signal across four component streams lets each bit be represented by 4 ns of the signal with 1ns spacing between. This reduces interference among symbols and makes it easier to receive each symbol accurately while maintaining the same throughput (in this example, 4 bits every 5 ns).

OFDM technology was first conceived of in the 1960s and 1970s during research into minimizing interference among channels near each other in frequency and to achieve clean data transmission in situations prone to interference and signal corruption when more conventional modulation schemes are used.

OFDM is used in Wi-Fi, DSL internet access, 4Gwireless communications, and digital televisionand radio broadcast services

Orthogonal Frequency Division Multiplexing (OFDM) is special form of multi-carrier modulation, patented in 1970. It is particularly suited for transmission over a dispersive channel. (See further discussion of MCM over wireless channel.)

In a multipath channel, most conventional modulation techniques are sensitive to intersymbol interference unless the channel symbol rate is small compared to the delay spread of the channel. OFDM is significantly less sensitive to intersymbol interference, because a special set of signals is used to build the composite transmitted signal. The basic idea is that each bit occupies a frequency-time window which ensures little or no distortion of the waveform. In practice, it means that bits are transmitted in parallel over a number of frequency-nonselective channels.

3.2 Coded OFDM

Multi-Carrier Modulation on its own is not the solution to the problems of communication over unreliable multipath channels. The channel time dispersion will excessively attenuate some subcarriers such that the throughput on these sub-channels would be unacceptable small. Only if the joint signal of many subcarriers is processed appropriately, the diversity advantages of MCM can be exploited. The need for coding across subcarriers was addressed by Sari et al. warning against overly enthusiastic pursuit of MCM. The advantages of frequency-domain implementations of equalizers (using an FFT) should not be mistaken for an "inherent" diversity gain of OFDM, which may not exist.

In an OFDM transmitter, blocks of k incoming bits are encoded into n channel bits. Before transmission, an n-point Inverse-FFT operation is performed. When the signals at the I-FFT output are transmitted sequentially, each of the n channel bits appears at a different (subcarrier) frequency. Such coding across subcarriers is necessary. If one subcarrier experiences deep fading, this leads to erasure of the bit on this subcarrier.

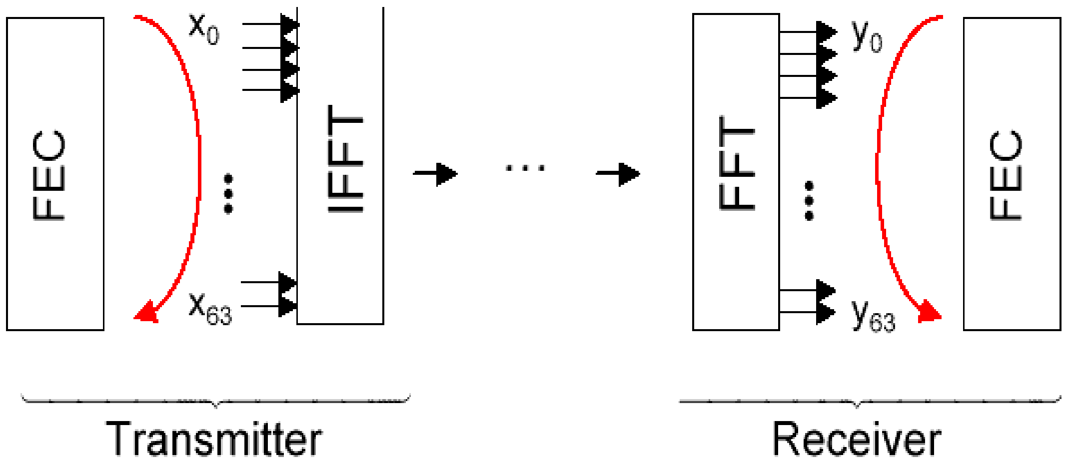


Fig 3.2.1 OFDM Transmitter and receiver

But of course coding across subcarriers is not the only mechanism that can be invoked to combat dispersion or to exploit diversity. Other possibilities are

- Interleaving in frequency or time domain with coding in the other domain,
- The use of different signal constellations at different frequencies, i.e., adapting the subcarrier bit rate to the channel state,
- Signal spreading over various subcarriers, e.g., according to a linear matrix operation, as is proposed in Orthogonal Multi-Carrier Code Division Multiplexing.

If in a point-to-point MCM link, the receiver and the transmitter can cooperate by adaptively distributing of their power budget over the individual subcarriers. For instance, the signal-to-noise ratios selected according to Gallager's water-pouring theorem can (under certain conditions) be proved to be optimum. Efficient loading of the various subcarriers can for instance significantly enhance the performance of MCM over twisted pair telephone subscriber loops with crosstalk from other nearby copper pairs.

Implementational Aspects

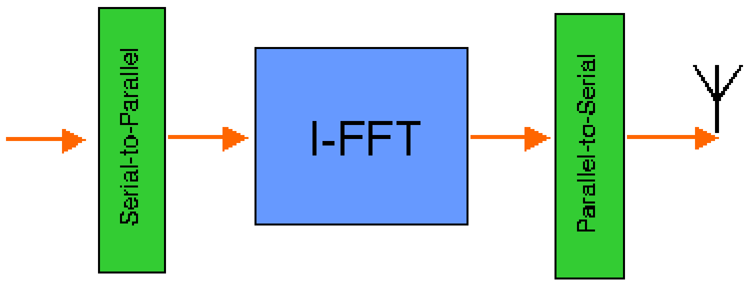

Figure 3.2.2 OFDM transmitter using an (inverse) Fast Fourier Transform (FFT).

- OFDM is not a constant-envelope modulation method. Therefore transmit power amplifiers must be highly linear.

- OFDM receiver performance is very sensitive to phase noise.
- Synchronization to an OFDM signal also requires frame synchronization, to support an FFT operation at the receiver.

Single Frequency Networks:

OFDM allows very efficient frequency reuse. Transmitters broadcasting the same program can use the same frequency in a Single Frequency Network.

Code Division Multiple Access:

OFDM can be combined with CDMA transmission, e.g. in Multi-Carrier CDMA.

3.3 Channel Modeling:

Many channel simulation models follow the narrowband model. Wideband channels are often simulated by extending the model assuming multiple time-delayed resolvable paths. This allows the simulation of the channel impulse response, including its stochastic behavior. To determine the performance of an multicarrier, OFDM or MC-CDMA system, another approach can be to model a set of fading subchannels. Considering a single subcarrier, the channel may be modelled as a narrowband fading channel, for instance with Rician or Rayleigh amplitude distributions. The collection of multiple subcarriers can be modelled as a set of mutually dependent fading channels. In such model, it is important to address correlation of the fading of various subchannels using the models of delay spread and coherence bandwidth. See a discussion of such model. Also: read about the discrete-frequency model for OFDM with Delay spread and Doppler.

OFDM, Orthogonal Frequency Division Multiplexing is a form of signal waveform or modulation that provides some significant advantages for data links.

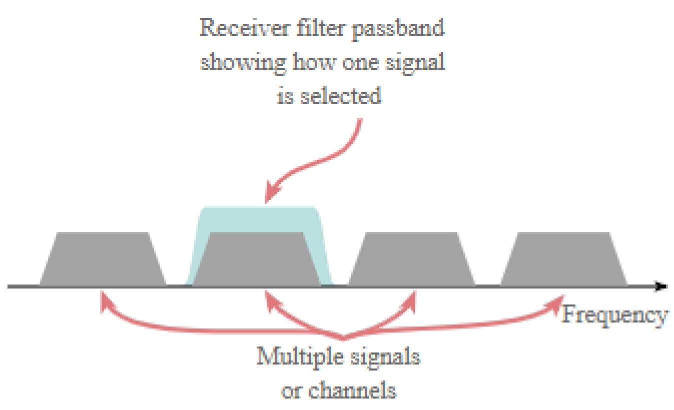
Accordingly, OFDM, Orthogonal Frequency Division Multiplexing is used for many of the latest wide bandwidth and high data rate wireless systems including Wi-Fi, cellular telecommunications and many more.

The fact that OFDM uses a large number of carriers, each carrying low bit rate data, means that it is very resilient to selective fading, interference, and multipath effects, as well providing a high degree of spectral efficiency.

Early systems using OFDM found the processing required for the signal format was relatively high, but with advances in technology, OFDM presents few problems in terms of the processing required.

3.4 What is OFDM?

OFDM is a form of multicarrier modulation. An OFDM signal consists of a number of closely spaced modulated carriers. When modulation of any form - voice, data, etc. is applied to a carrier, then sidebands spread out either side. It is necessary for a receiver to be able to receive the whole signal to be able to successfully demodulate the data. As a result when signals are transmitted close to one another they must be spaced so that the receiver can separate them using a filter and there must be a guard band between them. This is not the case with OFDM. Although the sidebands from each carrier overlap, they can still be received without the interference that might be expected because they are orthogonal to each another. This is achieved by having the carrier spacing equal to the reciprocal of the symbol period.



Traditional-slection if signals on different chanels

Figure 3.4.1 Traditional-selection if signals on different channels.

To see how OFDM works, it is necessary to look at the receiver. This acts as a bank of demodulators, translating each carrier down to DC. The resulting signal is integrated over the symbol period to regenerate the data from that carrier. The same demodulator also demodulates the other carriers. As the carrier spacing equal to the reciprocal of the symbol period means that they will have a whole number of cycles in the symbol period and their contribution will sum to zero - in other words there is no interference contribution.

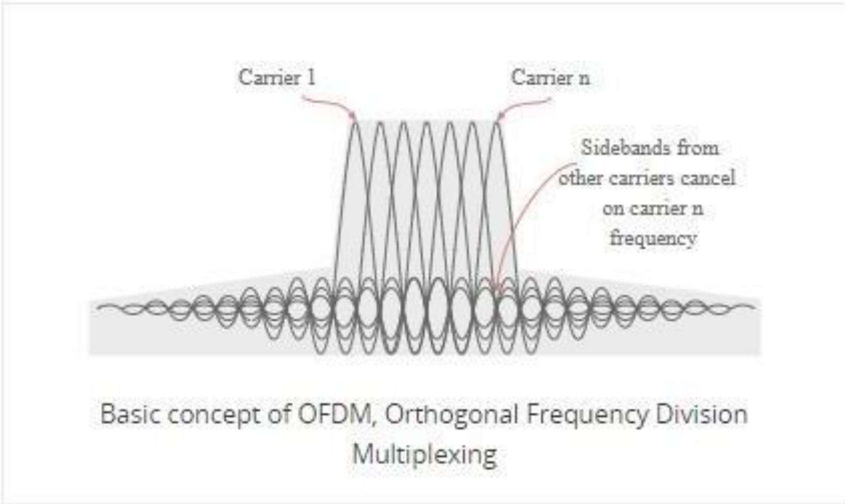


Figure 3.4.2 Basic concept of OFDM.

One requirement of the OFDM transmitting and receiving systems is that they must be linear. Any non-linearity will cause interference between the carriers as a result of inter-modulation distortion. This will introduce unwanted signals that would cause interference and impair the orthogonality of the transmission.

In terms of the equipment to be used the high peak to average ratio of multi-carrier systems such as OFDM requires the RF final amplifier on the output of the transmitter to be able to handle the peaks whilst the average power is much lower and this leads to inefficiency. In some systems the peaks are limited. Although this introduces distortion that results in a higher level of data errors, the system can rely on the error correction to remove them.

3.5 Data on OFDM

The data to be transmitted on an OFDM signal is spread across the carriers of the signal, each carrier taking part of the payload. This reduces the data rate taken by each carrier. The lower data rate has the advantage that interference from reflections is much less critical. This is achieved by adding a guard band time or guard interval into the system. This ensures that the data is only sampled when the signal is stable and no new delayed signals arrive that would alter the timing and phase of the signal.

3.6 Guard interval on OFDM signals

The distribution of the data across a large number of carriers in the OFDM signal has some further advantages. Nulls caused by multi-path effects or interference on a given frequency only affect a small number of the carriers, the remaining ones being received correctly. By using error-coding techniques, which does mean adding further data to the transmitted signal, it enables many or all of the corrupted data to be reconstructed within the receiver. This can be done because the error correction code is transmitted in a different part of the signal.

3.7 Key features of OFDM

The OFDM scheme differs from traditional FDM in the following interrelated ways:

- Multiple carriers (called subcarriers) carry the information stream
- The subcarriers are orthogonal to each other.

3.8 Applications of OFDM:

- Digital Video Broadcasting over the terrestrial network: Digital Terrestrial Television Broadcasting (DTTB). In the DTTB OFDM transmission standard, about 2,000 to 8,000 subcarriers are used.
- UMTS. The UMTS Forum is selecting an appropriate radio solution for the third generation mobile standard, as a successor to GSM. OFDM is one of the five competing proposals.
- Wireless LANs. OFDM is used in HIPERLAN Phase II, which supports 20 Mbit/s in propagation environments with delay spreads up to 1ms.

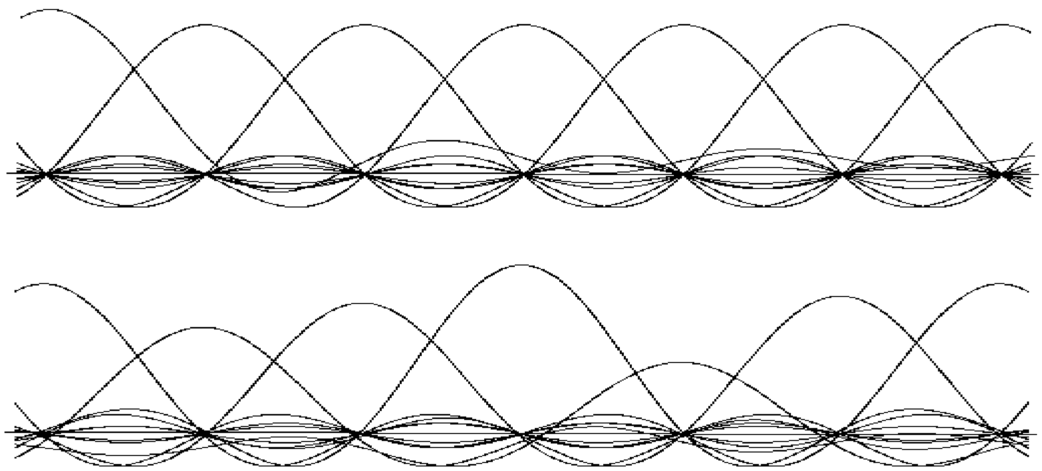

Figure 3.8.1 Signal spectrum of an OFDM signal, which consists of the spectra of many bits, in parallel. Rectangular pulses in time domain produce sinc-functions in frequency domain.

- Above: signal spectrum as transmitted.
- Below: as received in over a dispersive, time-invariant channel.

The effect of multipath scattering on OFDM differs from what happens to other forms of modulation. A qualitative description and mathematical description of OFDM is presented by Dusan Matic. Jean-Paul Linnartz reviews the effects of a Doppler spread and the associated rapid channel variations. Dusan Matic also studied the system design aspects of OFDM at mm-wavelengths.

3.9 OFDM advantages

OFDM has been used in many high data rate wireless systems because of the many advantages it provides.

- Immunity to selective fading: One of the main advantages of OFDM is that is more resistant to frequency selective fading than single carrier systems because it divides the overall channel into multiple narrowband signals that are affected individually as flat fading sub-channels.
- Resilience to interference: Interference appearing on a channel may be bandwidth limited and in this way will not affect all the sub-channels. This means that not all the data is lost.
- Spectrum efficiency: Using close-spaced overlapping sub-carriers, a significant OFDM advantage is that it makes efficient use of the available spectrum.
- Resilient to ISI: Another advantage of OFDM is that it is very resilient to inter-symbol and inter-frame interference. This results from the low data rate on each of the sub-channels.
- Resilient to narrow-band effects: Using adequate channel coding and interleaving it is possible to recover symbols lost due to the frequency selectivity of the channel and narrow band interference. Not all the data is lost.
- Simpler channel equalisation: One of the issues with CDMA systems was the complexity of the channel equalisation which had to be applied across the whole channel. An advantage of OFDM is that using multiple sub-channels, the channel equalization becomes much simpler.

3.10 OFDM disadvantages

Whilst OFDM has been widely used, there are still a few disadvantages to its use which need to be addressed when considering its use.

- High peak to average power ratio: An OFDM signal has a noise like amplitude variation and has a relatively high large dynamic range, or peak to average power ratio. This impacts the RF amplifier efficiency as the amplifiers need to be linear and accommodate the large amplitude variations and these factors mean the amplifier cannot operate with a high efficiency level.
- Sensitive to carrier offset and drift: Another disadvantage of OFDM is that is sensitive to carrier frequency offset and drift. Single carrier systems are less sensitive.

OFDM, orthogonal frequency division multiplexing has gained a significant presence in the wireless market place. The combination of high data capacity, high spectral efficiency, and its resilience to interference as a result of multi-path effects means that it is ideal for the high data applications that have become a major factor in today's communications scene.
Use of cyclic prefix is a key element of enabling the OFDM signal to operate reliably.

The cyclic prefix acts as a buffer region or guard interval to protect the OFDM signals from intersymbol interference. This can be an issue in some circumstances even with the much lower data rates that are transmitted in the multicarrier OFDM signal.

3.11 What is a cyclic prefix?

The basic concept behind the OFDM cyclic prefix is quite straightforward. The cyclic prefix performs two main functions.

- The cyclic prefix provides a guard interval to eliminate intersymbol interference from the previous symbol.

- It repeats the end of the symbol so the linear convolution of a frequency-selective multipath channel can be modeled as circular convolution, which in turn may transform to the frequency domain via a discrete Fourier transform. This approach accommodates simple frequency domain processing, such as channel estimation and equalization.

The cyclic prefix is created so that each OFDM symbol is preceded by a copy of the end part of that same symbol.Different OFDM cyclic prefix lengths are available in various systems. For example within LTE a normal length and an extended length are available and after Release 8 a third extended length is also included, although not normally used.

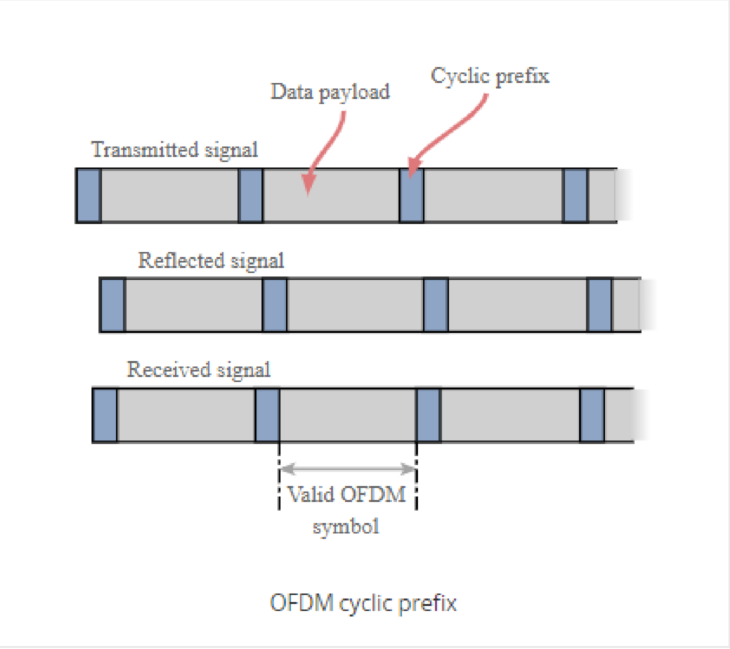

Figure 3.11.1 OFDM Cyclic prefix

3.12 Cyclic prefix advantages and disadvantages

There are several advantages and disadvantages attached to the use for the cyclic prefix within OFDM.

Advantages

- Provides robustness: The addition of the cyclic prefix adds robustness to the OFDM signal. The data that is retransmitted can be used if required.
- Reduces inter-symbol interference: The guard interval introduced by the cyclic prefix enables the effects of inter-symbol interference to be reduced.

Disadvantages

- Reduces data capacity: As the cyclic prefix re-transmits data that is already being transmitted, it takes up system capacity and reduces the overall data rate.

The use of a cyclic prefix is standard within OFDM and it enables the performance to be maintained even under conditions when levels of reflections and multipath propagation are high

One of the key requirements for optimum demodulation of OFDM signals is that there is accurate frequency and timing synchronisation.

Fortunately good OFDM timing and frequency synchronisation is relatively easy to obtain as accurate signals are easy to derive.

Poor timing and frequency synchronisation result in significant levels of degradation to the signal, and as a result this aspect of the signal chain is key to optimum performance.

3.13 OFDM synchronization basics:

OFDM offers many advantages in terms of resilience to fading, reflections and the like. OFDM also offers a high level of spectrum efficiency. However to reap the rewards, it is necessary that the OFDM system operates correctly, and to achieve this, it is necessary for the OFDM synchronization to be effective.

There are a number of areas in which the OFDM synchronisation is critical to the operation of the system:

- OFDM synchronization in terms of frequency offset: It is necessary that the frequencies are accurately tracked to ensure that orthogonality is maintained.
- OFDM synchronisation in terms of clock accuracy: It is necessary that the sampling occurs at the correct time interval to ensure that the samples are synchronized and data errors are minimised.

In order to ensure that the OFDM system works to its optimum, it is necessary to ensure that there are schemes in place to ensure the OFDM synchronization is within the required limits.

3.14 Frequency offset OFDM synchronization:

It is particularly important that the demodulator in an OFDM receiver is able to synchronize accurately with the carriers within the OFDM signal. Offsets may arise for a number of reasons including any frequency errors between the transmitter and the receiver and also as a result of Doppler shifts if there is movement between the transmitter and receiver.

If the frequency synchronisation is impaired, then the orthogonality of the carriers is reduced within the demodulation process and error rates increase. Accordingly it is essential to maintain orthogonality to reduce errors and maintain the performance of the link.

First look at the way that sampling should occur. With the demodulator in synchronisation, all the contributions from the other carriers sum to zero as shown. On this way all the carriers are orthogonal and the error rate is at its minimum.

OFDM demodulation showing how the interference from other carriers is minimized at the centre of the carrier frequency.
If a situation is encountered where the OFDM synchronisation for the frequency aspects are poor, then the demodulator will centre its samples away from the peak of the signal, and also at a point where the contributions from the other signals do not sum to zero. This will lead to a degradation of the signal which could in turn lead to an increase in the number of bit errors.

OFDM demodulation where interference is high due to poor frequency synchronization.

Clock offset OFDM synchronization

It is also necessary to maintain OFDM synchronization in terms of the clock. Gain if the clock synchronisation is not accurate, sampling will be offset and again orthogonality will be reduced, and data errors will increase.

When looking at OFDM synchronization with regard to the clock offset, the carrier spacing used within the receiver for sampling the received signal will be based upon the internal clock rate. If this differs from that used within the transmitter, it will be found that even if the first carrier within the multiplex is correct, then there will be a growing discrepancy with each carrier away from the first one. Even small levels of discrepancy will cause the error rate to increase.

OFDM demodulation with clock synchronization misalignment: When using OFDM it is necessary to ensure that the synchronisation for both timing and frequency is accurate. By ensuring accurate synchronisation, it is possible to perform the optimum demodulation of the signal. Any misalignment causes the receiver to start to pick up the unwanted interference signals. Fortunatelyit is relatively easy to obtain accurate synchronisation signals as these are available from the network, and short term synchronisation can be generated internally.

In telecommunications, orthogonal frequency-division multiplexing (OFDM) is a method of encoding digital data on multiple carrierfrequencies. OFDM has developed into a popular scheme for wideband digital communication, used in applications such as digital television and audio broadcasting, DSL internet access, wireless networks, power line networks, and 4G mobile communications.

In coded orthogonal frequency-division multiplexing (COFDM), forward error correction (convolutional coding) and time/frequency interleaving are applied to the signal being transmitted. This is done to overcome errors in mobile communication channels affected by multipath propagation and Doppler effects. COFDM was introduced by Alard in 1986 [1] [2][3] for Digital Audio Broadcasting for Eureka Project 147. In practice, OFDM has become used in combination with such coding and interleaving, so that the terms COFDM and OFDM co-apply to common applications.[4]

OFDM is a frequency-division multiplexing (FDM) scheme used as a digital multi-carrier modulation method. OFDM was introduced by Chang of Bell Labs in 1966.[5][6][7] Numerous closely spaced orthogonal sub-carrier signals with overlapping spectra are emitted to carry data.[8] Demodulation is based on Fast Fourier Transform algorithms. OFDM was improved by Weinstein and Ebert in 1971 with the introduction of a guard interval, providing better orthogonality in transmission channels affected by multipath propagation.[9] Each sub-carrier (signal) is modulated with a conventional modulation scheme (such as quadrature amplitude modulation or phase-shift keying) at a low symbol rate. This maintains total data rates similar to conventional single-carrier modulation schemes in the same bandwidth.

The main advantage of OFDM over single-carrier schemes is its ability to cope with severe channel conditions (for example, attenuation of high frequencies in a long copper wire, narrowband interference and frequency-selective fading due to multipath) without complex equalization filters. Channel equalization is simplified because OFDM may be viewed as using many slowly modulated narrowband signals rather than one rapidly modulated wideband signal. The low symbol rate makes the use of a guard interval between symbols affordable, making it possible to eliminate intersymbol interference (ISI) and use echoes and time-spreading (in analog television visible as ghosting and blurring, respectively) to achieve a diversity gain, i.e. a signal-to-noise ratio improvement. This mechanism also facilitates the design of single frequency networks (SFNs) where several adjacent transmitters send the same signal simultaneously at the same frequency, as the signals from multiple distant transmitters may be re-combined constructively, sparing interference of a traditional single-carrier system.

3.15 Orthogonality

Conceptually, OFDM is a specialized frequency-division multiplexing (FDM) method, with the additional constraint that all subcarrier signals within a communication channel are orthogonal to one another.

In OFDM, the sub-carrier frequencies are chosen so that the sub-carriers are orthogonal to each other, meaning that cross-talk between the sub-channels is eliminated and inter-carrier guard bands are not required. This greatly simplifies the design of both the transmitter and the receiver; unlike conventional FDM, a separate filter for each sub-channel is not required.

The orthogonality requires that the sub-carrier spacing is Hertz, where T_U seconds is the useful symbol duration (the receiver-side window size), and k is a positive integer, typically equal to 1. This stipulates that each carrier frequency undergoes k more complete cycles per symbol period than the previous carrier. Therefore, with N sub-carriers, the total passband bandwidth will be B = N*Δf (Hz).

The orthogonality also allows high spectral efficiency, with a total symbol rate near the Nyquist rate for the equivalent baseband signal (i.e. near half the Nyquist rate for the double-side band physical passband signal). Almost the whole available frequency band can be used. OFDM generally has a nearly 'white' spectrum, giving it benign electromagnetic interference properties with respect to other co-channel users.

A simple example: A useful symbol duration T_U = 1 ms would require a sub-carrier spacing of (or an integer multiple of that) for orthogonality. N = 1,000 sub-carriers would result in a total passband bandwidth of NΔf = 1 MHz. For this symbol time, the required bandwidth in theory according to Nyquist is (half of the achieved bandwidth required by our scheme), where R is the bit rate and where N = 1,000 samples per symbol by FFT. If a guard interval is applied (see below), Nyquist bandwidth requirement would be even lower. The FFT would result in N = 1,000 samples per symbol. If no guard interval was applied, this would result in a base band complex valued signal with a sample rate of 1 MHz, which would require a baseband bandwidth of 0.5 MHz according to Nyquist. However, the passband RF signal is produced by multiplying the baseband signal with a carrier waveform (i.e., double-sideband quadrature amplitude-modulation) resulting in a passband bandwidth of 1 MHz. A single-side band (SSB) or vestigial sideband (VSB) modulation scheme would achieve almost half that bandwidth for the same symbol rate (i.e., twice as high spectral efficiency for the same symbol alphabet length). It is however more sensitive to multipath interference.

OFDM requires very accurate frequency synchronization between the receiver and the transmitter; with frequency deviation the sub-carriers will no longer be orthogonal, causing inter-carrier interference (ICI) (i.e., cross-talk between the sub-carriers). Frequency offsets are typically caused by mismatched transmitter and receiver oscillators, or by Doppler shift due to movement. While Doppler shift alone may be compensated for by the receiver, the situation is worsened when combined with multipath, as reflections will appear at various frequency offsets, which is much harder to correct. This effect typically worsens as speed increases, and is an important factor limiting the use of OFDM in high-speed vehicles. In order to mitigate ICI in such scenarios, one can shape each sub-carrier in order to minimize the interference resulting in a non-orthogonal subcarriers overlapping.[12] For example, a low-complexity scheme referred to as WCP-OFDM (Weighted Cyclic Prefix Orthogonal Frequency-Division Multiplexing) consists of using short filters at the transmitter output in order to perform a potentially non-rectangular pulse shaping and a near perfect reconstruction using a single-tap per subcarrier equalization. Other ICI suppression techniques usually increase drastically the receiver complexity.

3.16 Implementation using the FFT algorithm:

The orthogonality allows for efficient modulator and demodulator implementation using the FFT algorithm on the receiver side, and inverse FFT on the sender side. Although the principles and some of the benefits have been known since the 1960s, OFDM is popular for wideband communications today by way of low-cost digital signal processing components that can efficiently calculate the FFT.

The time to compute the inverse-FFT or FFT transform has to take less than the time for each symbol, which for example for DVB-T (FFT 8k) means the computation has to be done in 896 μs or less.

For an 8192-point FFT this may be approximated to:

MIPS = Million instructions per second

The computational demand approximately scales linearly with FFT size so a double size FFT needs double the amount of time and vice versa.[15]:83 As a comparison an Intel Pentium III CPU at 1.266 GHz is able to calculate a 8192 point FFT in 576 μs using FFTW. Intel Pentium M at 1.6 GHz does it in 387 μs Intel Core Duo at 3.0 GHz does it in 96.8 μs.

Guard interval for elimination ofintersymbol interference

One key principle of OFDM is that since low symbol rate modulation schemes (i.e., where the symbols are relatively long compared to the channel time characteristics) suffer less from intersymbol interference caused by multipath propagation, it is advantageous to transmit a number of low-rate streams in parallel instead of a single high-rate stream. Since the duration of each symbol is long, it is feasible to insert a guard interval between the OFDM symbols, thus eliminating the intersymbol interference.

The guard interval also eliminates the need for a pulse-shaping filter, and it reduces the sensitivity to time synchronization problems.

The cyclic prefix, which is transmitted during the guard interval, consists of the end of the OFDM symbol copied into the guard interval, and the guard interval is transmitted followed by the OFDM symbol. The reason that the guard interval consists of a copy of the end of the OFDM symbol is so that the receiver will integrate over an integer number of sinusoid cycles for each of the multipaths when it performs OFDM demodulation with the FFT.

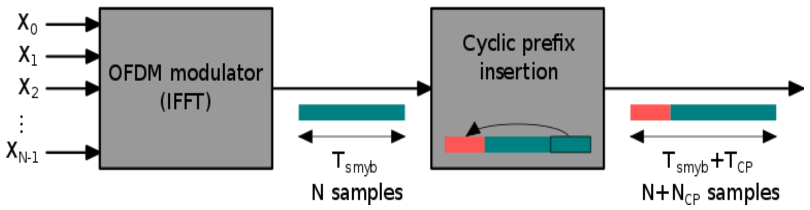

Figure 3.14.1 OFDM modulator and cyclic prefix insertion

In some standards such as Ultra wideband, in the interest of transmitted power, cyclic prefix is skipped and nothing is sent during the guard interval. The receiver will then have to mimic the cyclic prefix functionality by copying the end part of the OFDM symbol and adding it to the beginning portion.

3.17 Transmitter

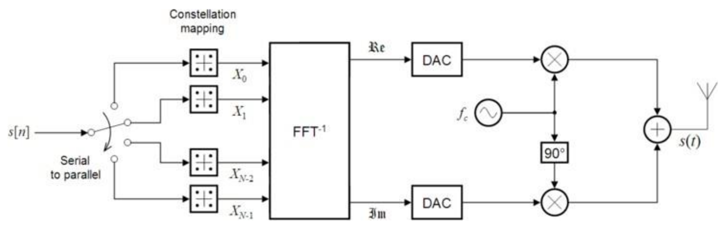

Figure 3.17.1 Transmitter

An OFDM carrier signal is the sum of a number of orthogonal sub-carriers, with baseband data on each sub-carrier being independently modulated commonly using some type of quadrature amplitude modulation (QAM) or phase-shift keying (PSK). This composite baseband signal is typically used to modulate a main RF carrier.

OFDM is used by many power line devices to extend digital connections through power wiring. Adaptive modulation is particularly important with such a noisy channel as electrical wiring. Some medium speed smart metering modems, "Prime" and "G3" use OFDM at modest frequencies (30–100 kHz) with modest numbers of channels (several hundred) in order to overcome the intersymbol interference in the power line environment. The IEEE 1901 standards include two incompatible physical layers that both use OFDM. The ITU-T G.hn standard, which provides high-speed local area networking over existing home wiring (power lines, phone lines and coaxial cables) is based on a PHY layer that specifies OFDM with adaptive modulation and a Low-Density Parity-Check (LDPC) FEC code.

An inverse FFT is computed on each set of symbols, giving a set of complex time-domain samples. These samples are then quadrature-mixed to passband in the standard way. The real and imaginary components are first converted to the analogue domain using digital-to-analogue converters (DACs); the analogue signals are then used to modulate cosine and sine waves at the carrier frequency, respectively. These signals are then

summed to give the transmission signal. .

3.18 Receiver

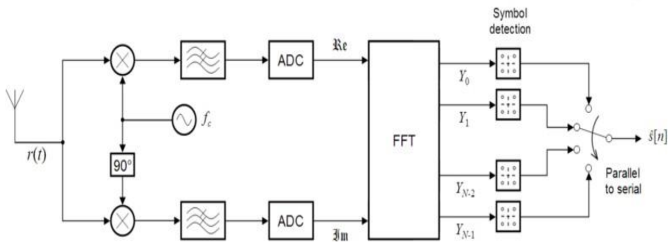

Figure 3.18.1 Receiver

The receiver picks up the signal, which is then quadrature-mixed down to baseband using cosine and sine waves at the carrier frequency. This also creates signals centered on, so low-pass filters are used to reject these. The baseband signals are then sampled and digitised using analog-to-digital converters (ADCs), and a forward FFT is used to convert back to the frequency domain.

This returns parallel streams, each of which is converted to a binary stream using an appropriate symbol detector. These streams are then re-combined into a serial stream, , which is an estimate of the original binary stream at the transmitter.

3.19 Wireless local area networks (LAN) and metropolitan area networks (MAN)

OFDM is extensively used in wireless LAN and MAN applications, including IEEE 802.11a/g/n and WiMAX.

IEEE 802.11a/g/n, operating in the 2.4 and 5 GHz bands, specifies per-stream airside data rates ranging from 6 to 54 Mbit/s. If both devices can use "HT mode" (added with 802.11n), the top 20 MHz per-stream rate is increased to 72.2 Mbit/s, with the option of data rates between 13.5 and 150 Mbit/s using a 40 MHz channel. Four different modulation schemes are used: BPSK, QPSK, 16-QAM, and 64-QAM, along with a set of error correcting rates (1/2–5/6). The multitude of choices allows the system to adapt the optimum data rate for the current signal conditions.

Wireless personal area networks (PAN)

OFDM is also now being used in the WiMedia/Ecma-368 standard for high-speed wireless personal area networks in the 3.1–10.6 GHz ultrawideband spectrum (see MultiBand-OFDM).

Terrestrial digital radio and television broadcasting:

Much of Europe and Asia has adopted OFDM for terrestrial broadcasting of digital television (DVB-T, DVB-H and T-DMB) and radio (EUREKA 147 DAB, Digital Radio Mondiale, HD Radio and T-DMB).

By Directive of the European Commission, all television services transmitted to viewers in the European Community must use a transmission system that has been standardized by a recognized European standardization body, and such a standard has been developed and codified by the DVB Project, Digital Video Broadcasting (DVB); Framing structure, channel coding and modulation for digital terrestrial television. Customarily referred to as DVB-T, the standard calls for the exclusive use of COFDM for modulation. DVB-T is now widely used in Europe and elsewhere for terrestrial digital TV.

SDARS

The ground segments of the Digital Audio Radio Service (SDARS) systems used by XM Satellite Radio and Sirius Satellite Radio are transmitted using Coded OFDM (COFDM).The word "coded" comes from the use of forward error correction (FEC).

CHAPTER 4

SOFTWARE USED

4.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

4.2 THE MATLAB SYSTEM:

The MATLAB system consists of five main parts

- Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- The MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for twodimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

4.3. GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based Mfunction is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

Guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

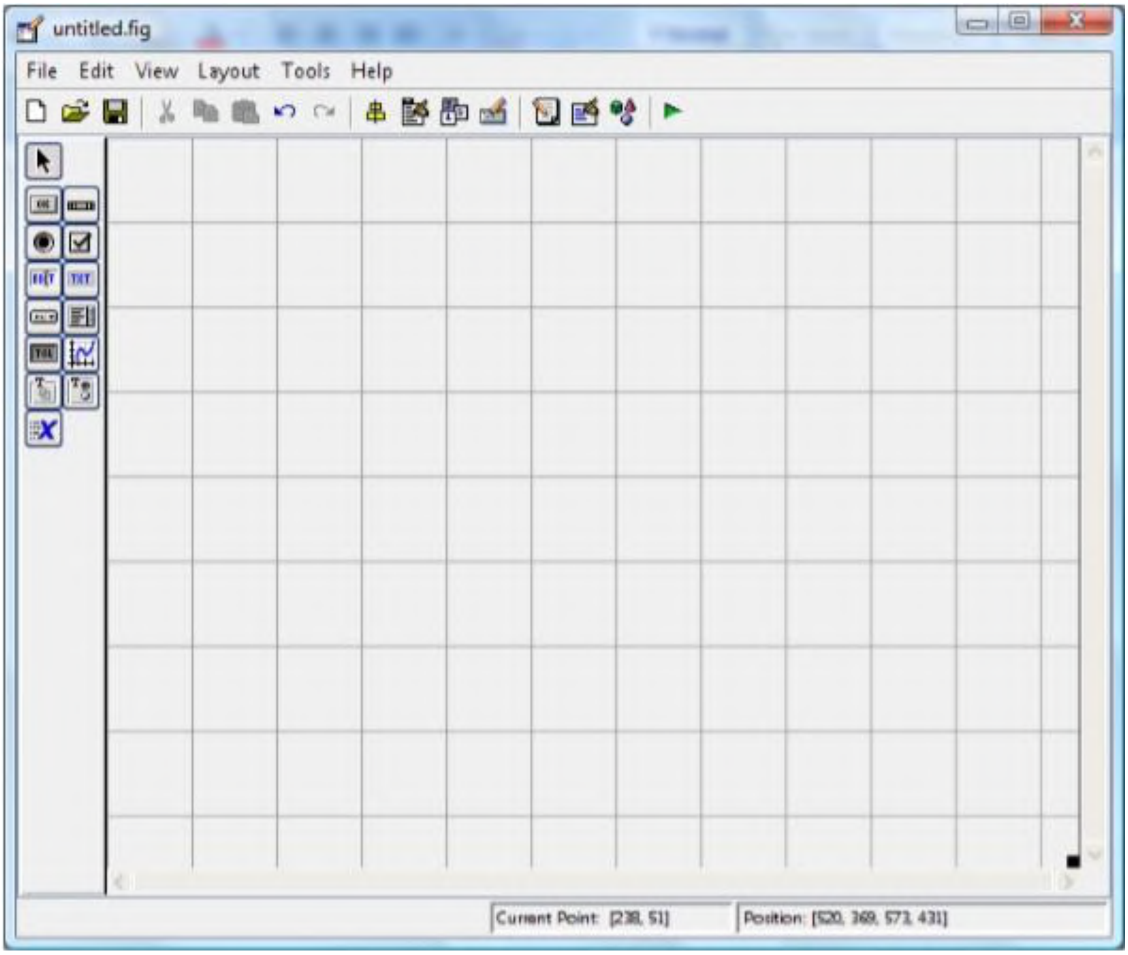

Figure 4.3.1:matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

4.4 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

4.4.1 INTRODUCTION - describes the components of the MATLAB system.

4.4.2 DEVELOPMENT ENVIRONMENT - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

4.4.3 MANIPULATING MATRICES - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

4.4.4 GRAPHICS - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images. 2.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

4.5 DEVELOPMENT ENVIRONMENT

4.5.1INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

4.5.2 STARTING MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab

At the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

4.5.3 QUITTING MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

4.5.4 MATLAB DESKTOP

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

4.5.5 DESKTOP TOOLS

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directorythat is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who’s.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic textediting, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB .

CHAPTER 5

PROJECT IMPLEMENTATION

5.1 Introduction to OFDM System

We consider an OFDM system with N subcarriers where M subcarriers are used for carrying pilot and $N - M$ subcarriers are used for sending data. In some case, we also considerthe system which has null subcarriers and then these subcarriers can also be considered as pilot subcarriers with setting pilot symbols as zero. At the transmitter, data symbols which are mapped from the source bits and known pilot symbols are joined as the frequency-domain OFDM symbol $x = (x_0, x_1, \ldots, x_{N-1})^T$. The OFDM modulator, as an inverse discrete Fourier transformation (IDFT), converts the frequency-domain OFDM symbols into the time-domain OFDM signals to which the cyclic prefix (CP) is prepended before feeding into the wireless channel. Assuming that inter-symbol interference is avoided by simply discarding the cyclic prefix at the receiver, the received time-domain signal is expressed as

$$r = HF^* x + u$$

Where H is a $N \times N$ circulant matrix whose first column is formed by the zero-padded channel impulse response vector $h = (h_0, h_1, \ldots, h_{L-1})^T$, L is the length of channel impulse response. F is the unitary N-point discrete Fourier transform (DFT) matrix with (m, n) element $[F]_{m,n} = \sqrt{\frac{1}{N}} e^{-j2\pi mn/N}$ with $m, n \in \{0, 1, \ldots, N-1\}$ and F^* is its conjugate transpose. $u = i + g$ is the additive noise term which includesi, denoting impulsive noise component, and g, denoting AWGN component.

$$y = Fr = FHF^* x + Fi + Fg = 3x + Fi + n$$

Where 3,diag($\check{h}$) is a diagonal matrix with the channel frequency response $\check{h}$ as its diagonal elements. The channel frequency response $\check{h}$ is the DFT of the channel impulse response h, namely $\check{h} = \sqrt{N} F_L h$, where $F_L \in C^{N\times L}$ is the submatrix selected from the first L columns of matrix F. n is the frequency-domain background noise vector which is still AWGN since F is unitary matrix. Gaussian-Mixture (GM), Middleton Class A (MCA), and Symmetric alpha stable are the three IN models most widely adopted in the literature. In this work, we use GM model to simulate the impulsive noise. In particular, aKcomponent GM is accepted for performance analysis. The probability density function(pdf) of a time-domain impulsive noise sample u is expressed as

$$p(\boldsymbol{u}) = \prod_{i=1}^{N} \sum_{k=1}^{K} \pi_k f_k(u_i)$$

5.2 JOINT CHANNEL AND IN ESTIMATION ALGORITHM USING PILOT SUBCARRIERS:

Let P and D denote the index set corresponding to the pilot subcarriers and data subcarriers, respectively. The part pertaining to the pilot subcarriers in can be written as

$$\boldsymbol{y}_P = \boldsymbol{\Phi}_P \boldsymbol{w} + \boldsymbol{n}_P$$

Where yP is a M × 1 vector containing the elements of y sampled at pilot locations, 8P is a M×(L+N) submatrix of 8 consisting of the rows corresponding to the pilot locations, and nP is also a M × 1 vector consisting of the components of n sampled at pilot locations. Since 8P is a known flat matrix and w is a sparse vector, we may use CS theory to estimate w directly.

Many CS algorithms have been proposed in the literatures. In practice, different CS algorithms will have different requirements on the matrix and the sparsity for a reliable recovery. In this paper, we adopt SBL to solve the problem. Compared with the greedy CS algorithm, the SBL algorithms have shown super recovery performance when the recovering signal is less sparsity or the measurement matrix is higher coherence, which could well fit our problem. Another advantage of SBL is that it is capable of handling partially unknown dictionary matrices by virtue of the EM framework, which leads to the solution. In the following, we derive the algorithm for joint channel and IN estimation using pilots based on SBL framework (JCI).For observation model , SBL imposes firstly a parameterized Gaussian prior on the vector w, given by

$$p(\boldsymbol{w}; 0, \boldsymbol{\Gamma}) = \prod_{i=0}^{N+L-1} (\pi \gamma_i)^{-1} \exp\left(-\frac{|w_i|^2}{\gamma_i}\right)$$

The computational complexity of the JCI is dominated by the matrix multiplication and inversion operations in, which has a complexity of O(M(N + L) 2) per iteration. After given the initial values of data symbols, the JCIS using all tones to estimate channel and IN has a complexity of O(N(N +L) 2) per iteration. So the total complexity of JCIS is O((N + M)(N + L) 2). Compared with JCI, the complexity of JCIS is higher. This means JCIS improves the performance at

TABLE 1. Parameters for simulations.

Parameter	Notation	Value
Subcarrier Interval	Δf	15kHz
Sampling Frequency	f_s	3.84MHz
OFDM symbol Duration	T_s	$83.3\mu s$
Guard Interval Duration	T_g	$16.6\mu s$
Total Number of Subcarriers	N	256
Cyclic Prefix Length	N_G	64
Channel Length	L	64

Figure 6.2.1 Parameters for simulations.

The expense of increasing complexity, which will be verified by simulation results in the next Section.

CHAPTER 6

SIMULATION AND RESULTS

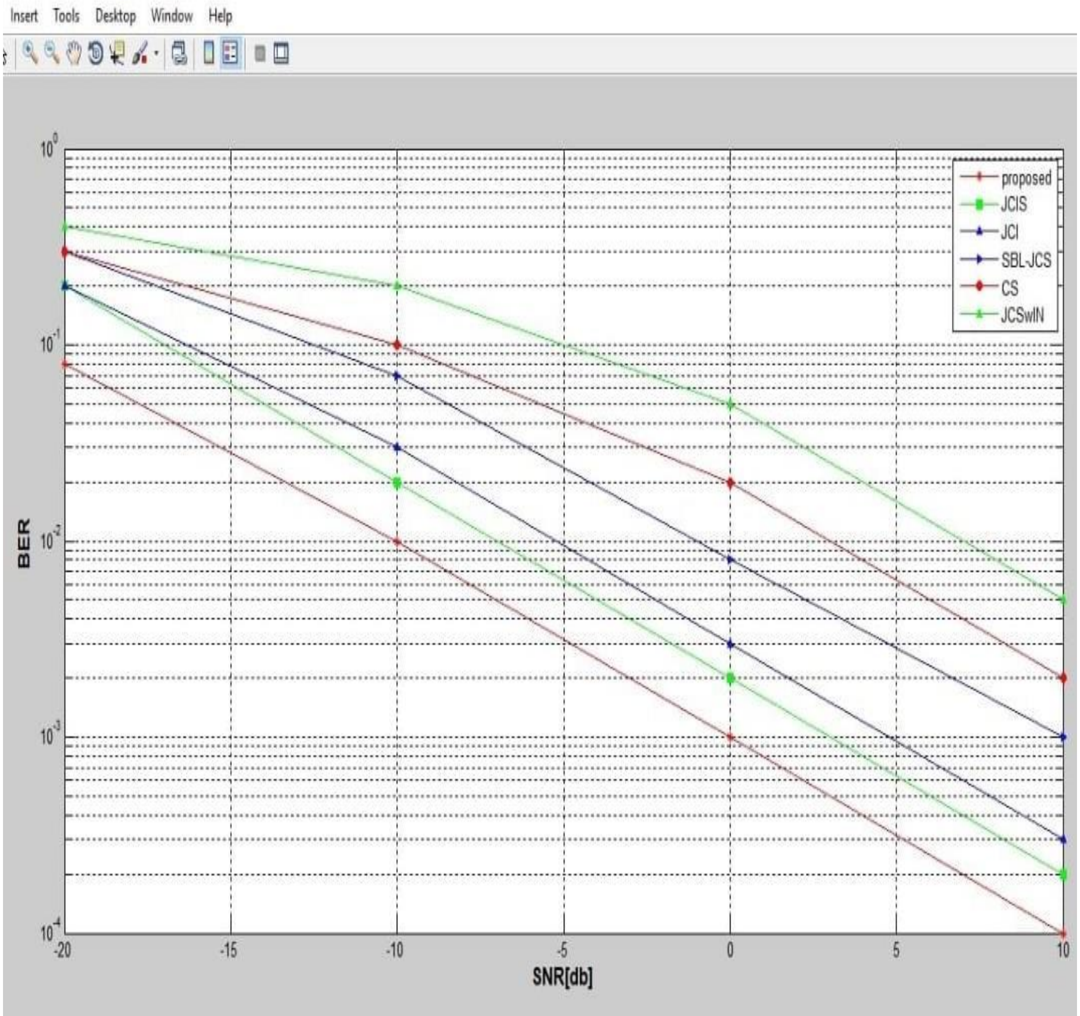

Figure 2: BER versus SNR in uncoded OFDM system. Number of pilot subcarriers 44 and number of null subcarriers 50.

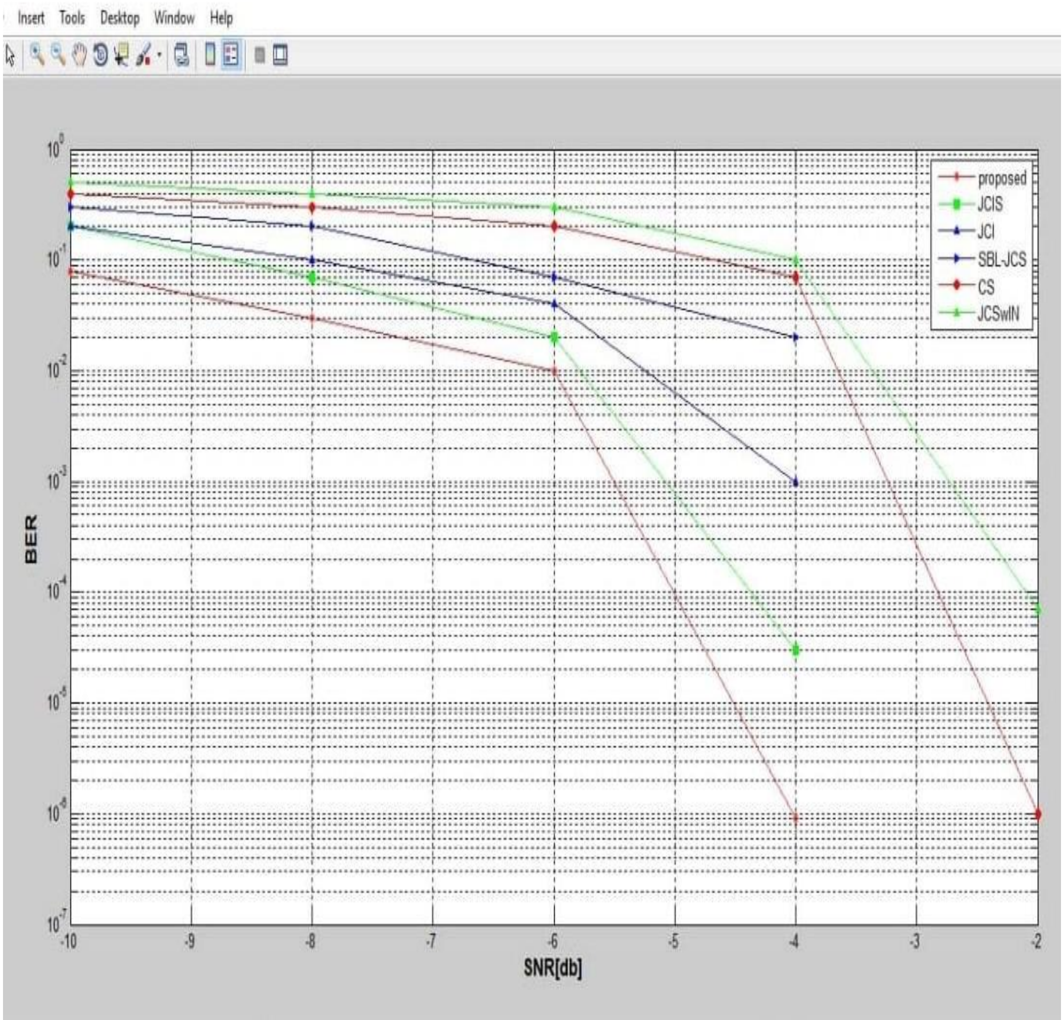

Figure 3: BER versus SNR in coded OFDM system. Number of pilot subcarriers 44 and number of null subcarriers 50

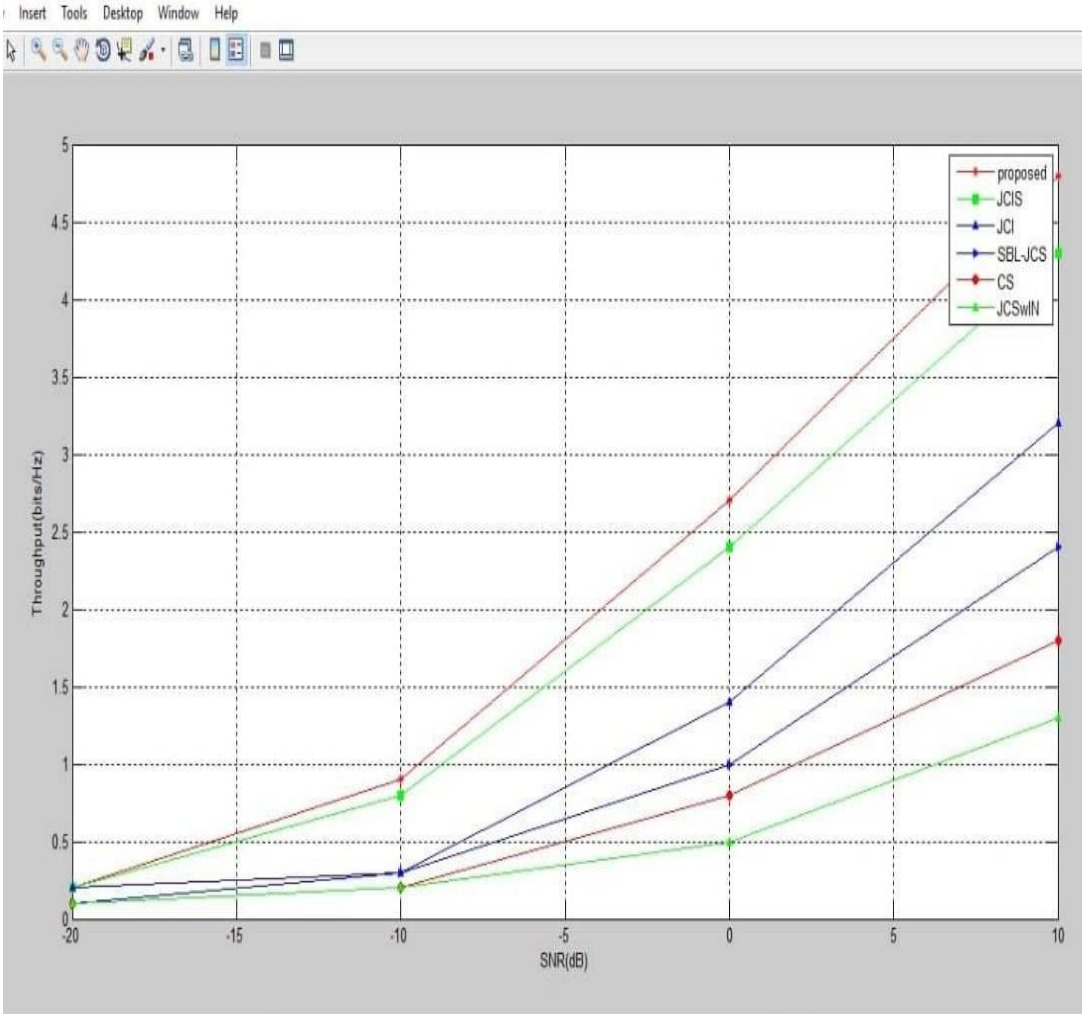

Figure 4: System throughput versus SNR.

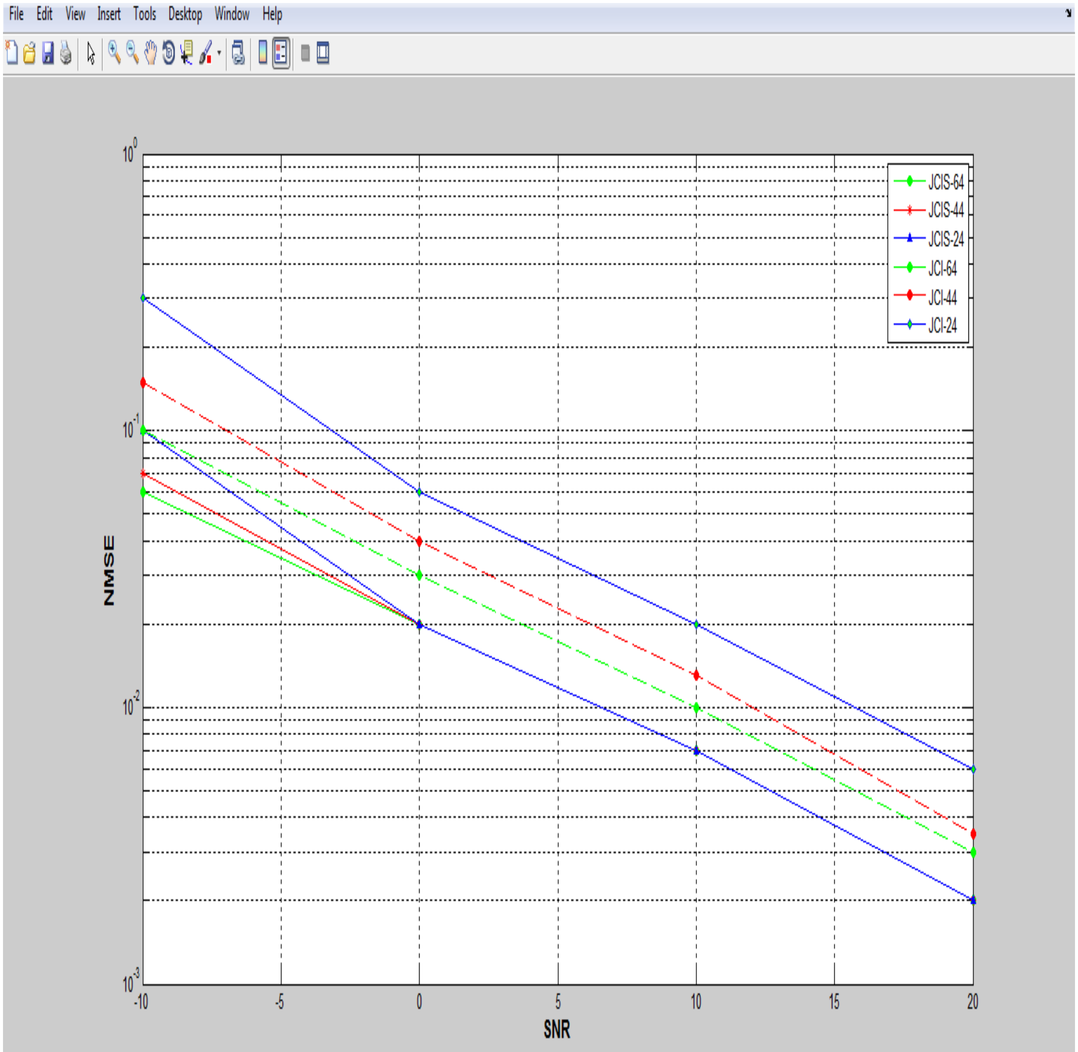

Figure 5: The MSE Performance Comparision between JCI and JCIS with various number of pilot tones.

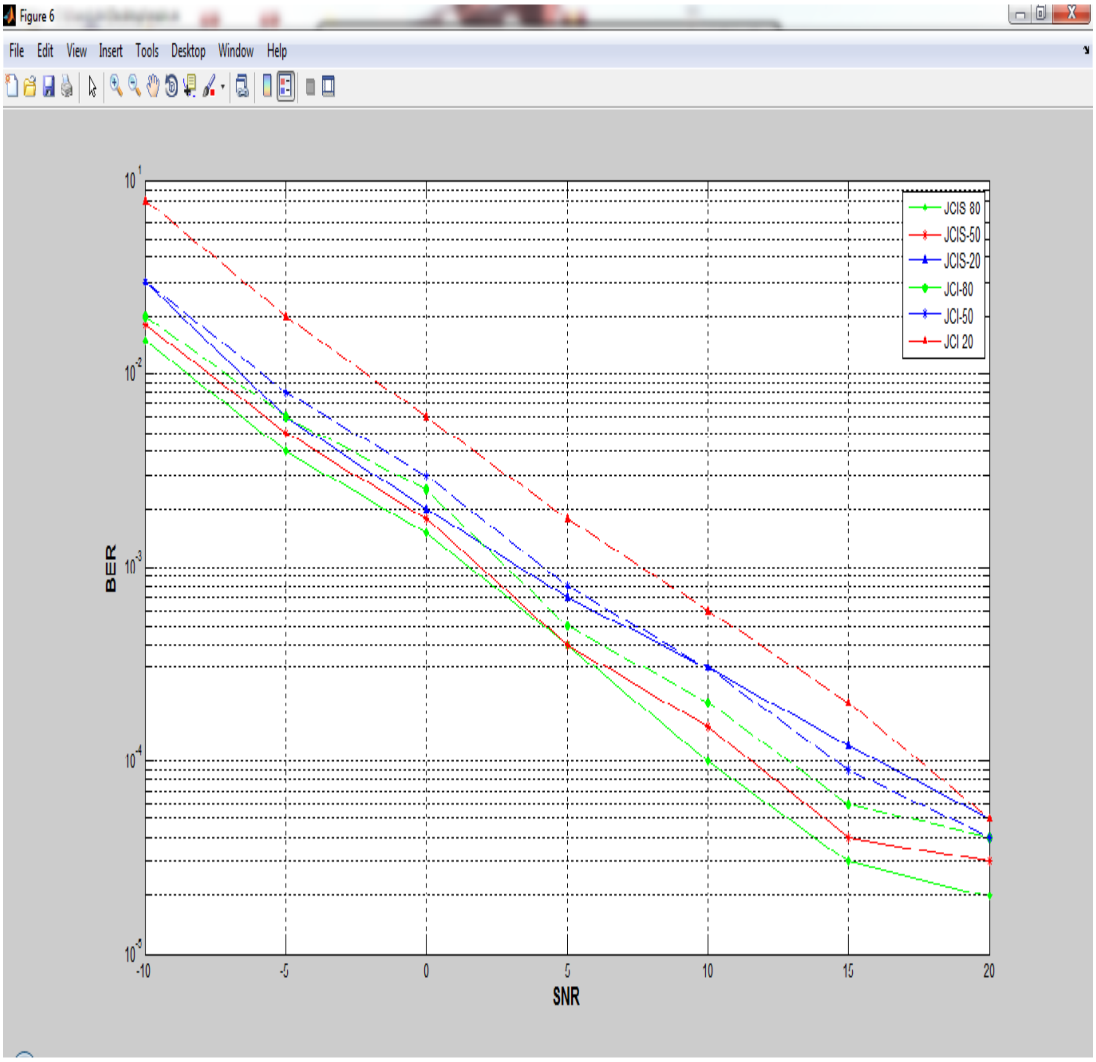

Figure 6: BER Versus SNR ratio with various number of null tones.

CHAPTER 7

CONCLUSION AND FUTURE SCOPE

In this paper, we consider the joint sparse channel estimation, impulsive noise mitigation, and data detection for OFDM systems. By observing the sparsity of channel and impulsive noise in the time domain, we construct an expanded sparse vector to represent the channel and impulsive noise together. To estimate the augmented vector, JCI algorithm is proposed which uses only the pilot and null subcarriers. Furthermore JCIS algorithm is developed to improve the performance of channel estimation and impulsive noise cancelation, which apply the data detection simultaneously. We derive the analytical expression of BCRB for JCIS algorithm as well. The MSE performance of our proposed scheme outperforms the conventional methods and is close to the lower bound. Moreover, simulation results show our methods can have a good BER performance with fewer pilot and null subcarriers and obtain better spectral efficiency.

Acceptance Letter for online oral presentation & journal publication

Online Mega international Conference "Smart Modernistic in Electronics and Communication" *(ICSMEC–21) on 02nd & 03rd July 2021*

Dear K.Ravi, M.Vamshy, P.Varshini,D.Prasad:

Title of the paper: JOINT CHANNEL ESTIMATION AND IMPULSIVE NOISE MITIGATION METHOD FOR OFDM SYSTEMS USING SPARSE BAYESIAN LEARNING

Paper ID: ICSMEC21-0023
With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in online mega International Conference on "Smart Modernistic in Electronics and Communication" ***(ICSMEC-21).***

ICSMEC-21 conference received over 400+ submissions from different parts of the world and regions so far, reviewed by international experts; the acceptance ratio is controlled below 20%. Your paper will be submitted for **Journal publications free of cost** in the appropriate given Journals after registration. **You will be given registration kit, International conference proceedings with ISBN (Soft copy), and international certificate of publication.**

You are now required to pay the conference registration fees (Faculty / Research Scholars: Rs.3500/-) as mentioned below A/C details on or before 5 working day after receiving this email else your paper will not be considered for presentation as well as publication in the Journal.

For NEFT/RTGS/IMPS
Account Details: (Current Account)
A/C Name: PRINCIPAL, St. Martin's Engineering College
Bank Name: SBI, Kukatpally, Hyderabad
Account No: 30667640268
IFSC code: SBIN0011664
Swift Code: SBININBB725 (Applicable for foreign author)

For PAYTM users

After payment, please send the registration form, payment proof and final paper in.doc/.docx format.
Your interest in *ICSMEC-21* is very much appreciated. Look forward to meeting you on the day of conference.

Yours sincerely,
ICSMEC- 21 Organizing Committees

// ACKNOWLEDGEMENT

The satisfaction and euphoria that accompany the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to our College Management for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to the principal **Dr. P. Santosh Kumar Patra**, for his invaluable encouragement, suggestions, and support from an early stage of this research and for providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna,** Professor & Head, the Department of Electronics & Communication Engineering for his advice, supervision, and vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our internal project coordinator **A. Soumya**, and the project coordinator of our department **Dr. A. Anand** for his involvement with originality has triggered and nourished the intellectual maturity that will help us for a long time to come.

ABSTRACT

The main objective of this project is to develop a Cloud integrated IoT-based sewage level monitoring system for a solid-liquid separator. The need to develop such a system is that there is a requirement to monitor sludge and liquid levels continuously. As a part of this product development, an interface is created with digital outputs, and the communication medium is the Internet. Having a simple yet optimised software-hardware interface and minimal hardware components, this system is not only very cost-effective but also very efficient with respect to the existing sewage level monitoring models. As technology continues to evolve and costs come down, these tools will provide more in-depth information and should be considered by designers, regulators, installers, and service providers. Sensors can be installed in septic tanks, pump tanks, and drain fields. The sensors are connected to a hub that uses the internet service in the home or business. Data from the sensors can be viewed in real-time from any internet-connected device, and all historical data is accessible for maintenance, decision-making, or time-of-property-transfer inspections. Warnings and critical alert notifications can be notified to the septic professional, system owner, regulator, or any other interested stakeholders. For product development, NodeMCU and HC-SR04 Ultrasonic Sensor Module are used. HTML and CSS are used to design the Webpages, while PHP is used as a connection between the Microcontroller (ESP8266) and the Cloud Database. The Cloud Database uses the standard Relational Database Model for storing data.

LIST OF OUTPUT SCREENS

1. INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Sewage Management is a very big problem today. There are multiple cons of unseen septic systems. Gases get developed, which may sometimes cause the chambers to explode, which may lead to the spread of several pathogens. Also, the sludge and the slime may overflow. The main objective is to develop a Cloud integrated IoT-based sewage level monitoring system. In the conventional case, the issue is that the sludge level must be continuously monitored, so that manually or automatically the sludge tank or chamber can be emptied so that the sludge chamber/ tank won't overflow and it could be reused. This can't be done as one doesn't wish to open the sludge chamber using their bare hands. Thus this task needs to be done remotely, and monitored as a graph or a digital value representing the solid level.

So as a part of this product development, a device is made which contains sensor(s) to calculate the level of the sludge, communicating with a controller which sends this data to the internet in digital format, and finally this data can be seen as entries in a cloud database, and on a website.

An interface is created with both analog and digital representations of level values, and a ready made cloud server is used, and the communication medium is the Internet.

1.2 OBJECTIVES OF THE STUDY:

With the increasing number of Sewage Explosion cases and the severities of it, there is an urgent need to have an efficient Sewage management system.

So the main objective of this project is to develop a Cloud integrated IoT-based sewage level monitoring system for a solid-liquid separator, and to make such a model as economical and simple as possible.

1.3 SCOPE OF THE STUDY:

This model could be installed in any Sludge Chamber/ Septic System, for Remote Monitoring.

This model can be further developed by integrating a liquid level monitoring system with it.

1.4 MATERIAL REQUIREMENT:

For materialising this project, primarily, a sensor and a microcontroller are needed. Also for the software development, a cloud server with database connectivity, and IDEs (Integrated Development Environments) are needed.

So, the hardware requirements include:

1. HC-SR04 Ultrasonic Sensor Module

2. ESP8266 NodeMCU Board.

Likewise, we have Software Requirements as well.

The software requirements include:

1. Arduino IDE

2. Code Editor for HTML, CSS, and PHP

3. Azure Data Studio Cloud Server

4. MySQL Database Connectivity

5. HTML, CSS, PHP supported Web Browser

1.5 PROCUREMENT OF EQUIPMENT:

Procuring the hardware tools was done due to their availability in the market, and software tools that are all open-source. The Hardware is purchased, assembled, connected to the Software via code in IDE and a Server that connects the entire system to the Cloud via Internet.

1.6.1 LITERATURE SURVEY

1.6.2 PROJECT DESIGN

1.6.3 PROJECT IMPLEMENTATION

1.6.4 PROJECT TESTING

1.6.5 CONCLUSION AND FUTURE ENHANCEMENT

2. LITERATURE SURVEY AND EXISTING MODELS

2.0 LITERATURE SURVEY ON SEWAGE MANAGEMENT:

In the articles about sewer gas explosion in public lavatory[1], emission of gases from the septic systems[2] & [3], estimated health risks due to these recreational waters[4], it is very clear how fatal the unmonitored sewage systems might be. Also from the article named Quantification of methane emissions from latrines, septic tanks, and stagnant, open sewers in the world[5], we can get the approximate quantified information about the amount of carbon emission. It says, open sewers and on-site wastewater treatment systems, including latrines and septic sewage tanks around the world may be a significant methane (CH_4) source that has previously received little attention. Combined global CH_4 emissions from latrines, septic sewage tanks, and stagnant, open sewers are estimated at 29 teragram per year (Tg/yr), with lower and upper bound ranges of 14 and 49 Tg/yr. Major uncertainties in the estimates are associated with the degree to which wastewater is treated in a specific system; the amount of wastewater that is discharged into stagnant, open sewers; and the degree to which anaerobic decomposition takes place. Latrines in rural areas of developing countries such as China and India are believed to be the single most significant source of CH_4, accounting for approximately 12 Tg/yr. Total CH_4 emissions from stagnant, open sewers are estimated at 10 Tg/yr. Considering these risks, many sewage monitoring, altering, and maintenance systems were developed. For instance, the paper on an IoT based sewage monitoring system[6] takes gases as references to estimate the fatality. And moreover to deal with the entire model, the components increase the costs and commercialising this prototype may not be an indispensable idea. So, keeping in mind all these factors, a comparatively inexpensive model of Sewage monitoring system is developed based on the fact that in a large flat-bottomed tank, the sludge rests and the sludge eventually gets flattened down to a nearly single surface level. So here, based on the observations from the articles, Obstacle detection using Ultrasonic Sensors[7], HC SR04 Ultrasonic Sensor[8], and Investigating the resolution ability of the HC-SR04 Ultrasonic Sensor[9], and the pricing of such products, HC-SR04 Ultrasonic sensor is considered to be a good fit for making an inexpensive yet efficient product. And based on the paper, Distance measurement using Ultrasonic Sensor and Node MCU[10], a basic level detecting system had been developed. Further, the model has to be used in a more complex system which communicates with the Cloud. So, the basic idea of this model was based on the conference papers, Internet of Things (IoT) enabled water monitoring system[11], and IoT Based Water Level Control System[12] using the Blynk IoT platform. Based on the articles, How to upload NodeMCU Temperature, Humidity data on ThingSpeak using Arduino IDE[13], ESP8266 Plot Sensor readings to Web Server in Real-Time Chart[14], and Great Projects: ESP8266 DHT11 SD Card WebServer[15], an integration between ESP8266/ NodeMCU, Thing Speak, and Web Server was made.

2.1 REVIEW OF RELATED LITERATURE:

In the existing system, we are using Water Level Monitoring Systems that are confined to only Water/ Liquid Level Monitoring. There is no perfect Cloud-and-IoT integration in any of the reviewed systems, which is actually essential for our project. But the reviewed literature provides a basic idea on how to connect ESP8266/ NodeMCU module to the Ultrasonic Sensor Module, and the Internet. Also, the papers and articles reviewed provide information on how to connect the NodeMCU board to the Cloud Server via the PHP functions and the Internet.

2.2 CONCLUSION ON REVIEWS:

In the existing system, we are using Water Level Monitoring Systems that are confined to only Water/ Liquid Level Monitoring. And in the conventional level monitoring and networking systems, we are having lengthy codes/ programs, larger delays, and the overall performance of the system is not upto the mark for commercial use. Also, the ThingSpeak and Blynk applications can not be used in commercial applications, as they are third party open-source tools.

So, keeping in mind the practical applications and the necessities, we couldn’t move forward with the existing systems.

3. PROJECT DESIGN

3.0 OVERVIEW OF THE DESIGN:

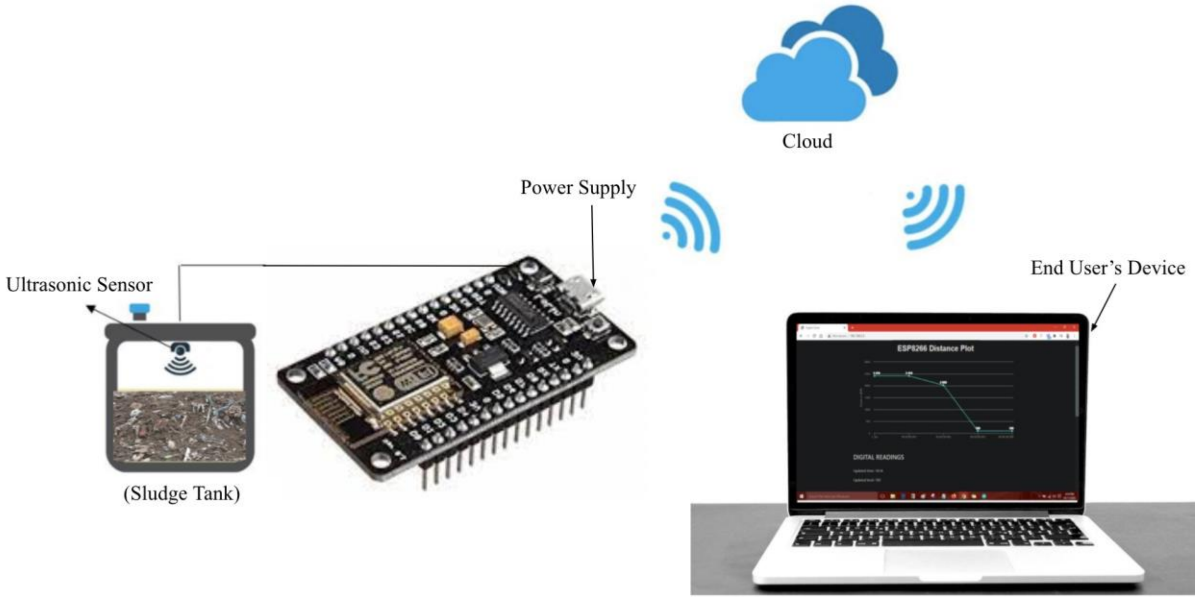

Fig 1: Schematic Block Diagram of the Project

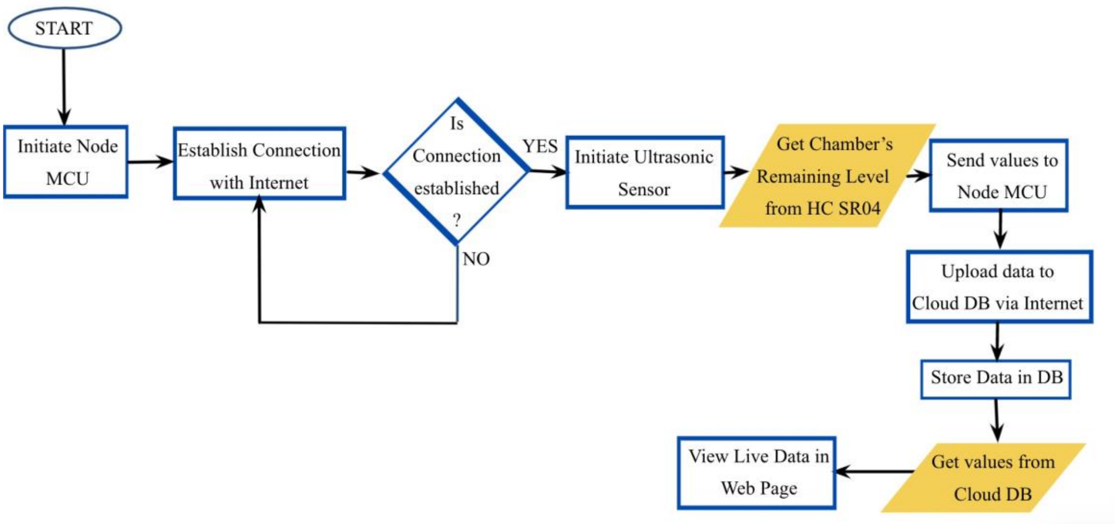

Fig 2: Flow Chart of the Project

3.0.1 Embedded Systems:

An embedded system is a computer system designed to perform one or a few dedicated functions often with real-time computing constraints. It is embedded as part of a complete device often including hardware and mechanical parts. By contrast, a general-purpose computer, such as a personal computer (PC), is designed to be flexible and to meet a wide range of end-user needs. Embedded systems control many devices in common use today.

Embedded systems are controlled by one or more main processing cores that are typically either microcontrollers or digital signal processors (DSP). The key characteristic, however, is being dedicated to handle a particular task, which may require very powerful processors. For example, air traffic control systems may usefully be viewed as embedded, even though they involve mainframe computers and dedicated regional and national networks between airports and radar sites. (Each radar probably includes one or more embedded systems of its own.)

Since the embedded system is dedicated to specific tasks, design engineers can optimise it to reduce the size and cost of the product and increase the reliability and performance. Some embedded systems are mass-produced, benefiting from economies of scale.

Physically embedded systems range from portable devices such as digital watches and MP3 players, to large stationary installations like traffic lights, factory controllers, or the systems controlling nuclear power plants. Complexity varies from low, with a single microcontroller chip, to very high with multiple units, peripherals and networks mounted inside a large chassis or enclosure.

In general, "embedded system" is not a strictly definable term, as most systems have some element of extensibility or programmability. For example, handheld computers share some elements with embedded systems such as the operating systems and microprocessors which power them, but they allow different applications to be loaded and peripherals to be connected. Moreover, even systems which don't expose programmability as a primary feature generally need to support software updates. On a continuum from "general purpose" to "embedded", large application systems will have subcomponents at most points even if the system as a whole is "designed to perform one or a few dedicated functions", and is thus appropriate to call "embedded". A modern example of embedded system is shown in fig: 2.1.

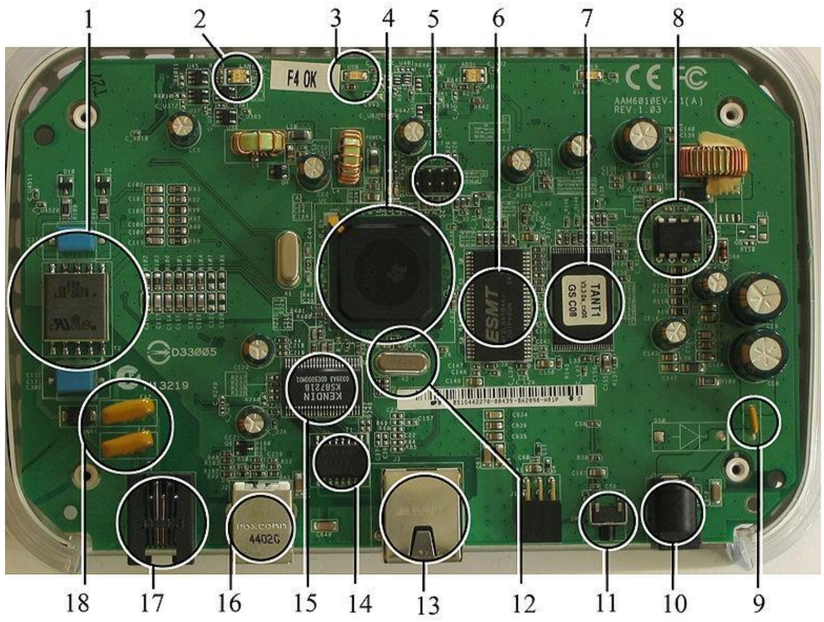

Fig 3: A modern example of embedded system

Labeled parts include microprocessor (4), RAM (6), flash memory (7).Embedded systems programming is not like normal PC programming. In many ways, programming for an embedded system is like programming PC 15 years ago. The hardware for the system is usually chosen to make the device as cheap as possible. Spending an extra dollar a unit in order to make things easier to program can cost millions. Hiring a programmer for an extra month is cheap in comparison. This means the programmer must make do with slow processors and low memory, while at the same time battling a need for efficiency not seen in most PC applications. Below is a list of issues specific to the embedded field.

3.0.2 History of Embedded Systems:

In the earliest years of computers in the 1930–40s, computers were sometimes dedicated to a single task, but were far too large and expensive for most kinds of tasks performed by embedded computers of today. Over time however, the concept of programmable controllers evolved from traditional electromechanical sequencers, via solid state devices, to the use of computer technology.

One of the first recognizably modern embedded systems was the Apollo Guidance Computer, developed by Charles Stark Draper at the MIT Instrumentation Laboratory. At the project's inception, the Apollo guidance computer was considered the riskiest item in the Apollo project as it employed the then newly developed monolithic integrated circuits to reduce the size and weight. An early mass-produced embedded system was the Autonetics D-17 guidance computer for the Minuteman missile, released in 1961. It was built from transistor logic and had a hard disk for main memory. When the Minuteman II went into production in 1966, the D-17 was replaced with a new computer that was the first high-volume use of integrated circuits.

3.0.3 Embedded Tools:

Embedded development makes up a small fraction of total programming. There's also a large number of embedded architectures, unlike the PC world where 1 instruction set rules, and the Unix world where there's only 3 or 4 major ones. This means that the tools are more expensive. It also means that they're lowering featured, and less developed. On a major embedded project, at some point you will almost always find a compiler bug of some sort.

Debugging tools are another issue. Since you can't always run general programs on your embedded processor, you can't always run a debugger on it. This makes fixing your program difficult. Special hardware such as JTAG ports can overcome this issue in part. However, if you stop on a breakpoint when your system is controlling real world hardware (such as a motor), permanent equipment damage can occur. As a result, people doing embedded programming quickly become masters at using serial IO channels and error message style debugging.

3.0.4 Embedded Systems - Resources:

To save costs, embedded systems frequently have the cheapest processors that can do the job. This means your programs need to be written as efficiently as possible. When dealing with large data sets, issues like memory cache misses that never matter in PC programming can hurt you. Luckily, this won't happen too often- use reasonably efficient algorithms to start, and optimise only when necessary. Of course, normal profilers won't work well, due to the same reason debuggers don't work well.

Memory is also an issue. For the same cost savings reasons, embedded systems usually have the least memory they can get away with. That means their algorithms must be memory efficient (unlike in PC programs, you will frequently sacrifice processor time for memory, rather than the reverse). It also means you can't afford to leak memory. Embedded applications generally use deterministic memory techniques and avoid the default "new" and "malloc" functions, so that leaks can be found and eliminated more easily. Other resources programmers expect may not even exist. For example, most embedded processors do not have hardware FPUs (Floating-Point Processing Unit). These resources either need to be emulated in software, or avoided altogether.

3.0.5 Real Time Issues with Embedded Systems:

Embedded systems frequently control hardware, and must be able to respond to them in real time. Failure to do so could cause inaccuracy in measurements, or even damage hardware such as motors. This is made even more difficult by the lack of resources available. Almost all embedded systems need to be able to prioritise some tasks over others, and to be able to put off/skip low priority tasks such as UI in favour of high priority tasks like hardware control.

3.0.6 Need For Embedded Systems:

The uses of embedded systems are virtually limitless, because every day new products are introduced to the market that utilises embedded computers in novel ways. In recent years, hardware such as microprocessors, microcontrollers, and FPGA chips have become much cheaper. So when implementing a new form of control, it's wiser to just buy the generic chip and write your own custom software for it. Producing a custom-made chip to handle a particular task or set of tasks costs far more time and money. Many embedded computers even come with extensive libraries, so that "writing your own software" becomes a very trivial task indeed. From an implementation viewpoint, there is a major difference between a computer and an embedded system. Embedded systems are often required to provide Real-Time response. The main elements that make embedded systems unique are its reliability and ease in debugging.

3.0.7 Embedded Systems - Debugging:

Embedded debugging may be performed at different levels, depending on the facilities available. From simplest to most sophisticate they can be roughly grouped into the following areas:

- Interactive resident debugging, using the simple shell provided by the embedded operating system (e.g. Forth and Basic)
- External debugging using logging or serial port output to trace operation using either a monitor in flash or using a debug server like the Remedy Debugger which even works for heterogeneous multi core systems.
- An in-circuit debugger (ICD), a hardware device that connects to the microprocessor via a JTAG or Nexus interface. This allows the operation of the microprocessor to be controlled externally, but is typically restricted to specific debugging capabilities in the processor.
- An in-circuit emulator replaces the microprocessor with a simulated equivalent, providing full control over all aspects of the microprocessor.
- A complete emulator provides a simulation of all aspects of the hardware, allowing all of it to be controlled and modified and allowing debugging on a normal PC.
- Unless restricted to external debugging, the programmer can typically load and run software through the tools, view the code running in the processor, and start or stop its operation. The view of the code may be as assembly code or source-code.

Because an embedded system is often composed of a wide variety of elements, the debugging strategy may vary. For instance, debugging a software(and microprocessor) centric embedded system is different from debugging an embedded system where most of the processing is performed by peripherals (DSP, FPGA, co-processor). An increasing number of embedded systems today use more than one single processor core. A common problem with multi-core development is the proper synchronisation of software execution. In such a case, the embedded system design may wish to check the data traffic on the busses between the processor cores, which requires very low-level debugging, at signal/bus level, with a logic analyser, for instance.

3.0.8 Reliability of Embedded Systems:

Embedded systems often reside in machines that are expected to run continuously for years without errors and in some cases recover by them if an error occurs. Therefore the software is usually developed and tested more carefully than that for personal computers, and unreliable mechanical moving parts such as disk drives, switches or buttons are avoided.

Specific reliability issues may include:

- The system cannot safely be shut down for repair, or it is too inaccessible to repair. Examples include space systems, undersea cables, navigational beacons, bore-hole systems, and automobiles.
- The system must be kept running for safety reasons. "Limp modes" are less tolerable. Often backups are selected by an operator. Examples include aircraft navigation, reactor control systems, safety-critical chemical factory controls, train signals, engines on single-engine aircraft.
- The system will lose large amounts of money when shut down: Telephone switches, factory controls, bridge and elevator controls, funds transfer and market making, automated sales and service.

A variety of techniques are used, sometimes in combination, to recover from errors—both software bugs such as memory leaks, and also soft errors in the hardware:

- Watchdog timer that resets the computer unless the software periodically notifies the watchdog
- Subsystems with redundant spares that can be switched over to
- software "limp modes" that provide partial function
- Designing with a Trusted Computing Base (TCB) architecture[6] ensures a highly secure & reliable system environment
- An Embedded Hypervisor is able to provide secure encapsulation for any subsystem component, so that a compromised software component cannot interfere with other subsystems, or privileged-level system software. This encapsulation keeps faults from propagating from one subsystem to another, improving reliability. This may also allow a subsystem to be automatically shut down and restarted on fault detection.
- Immunity Aware Programming

3.0.9 Explanation of Embedded Systems:

3.0.9.0 Software Architecture:

There are several different types of software architecture in common use.

- Simple Control Loop:

In this design, the software simply has a loop. The loop calls subroutines, each of which manages a part of the hardware or software.

- Interrupt Controlled System:

Some embedded systems are predominantly interrupt controlled. This means that tasks performed by the system are triggered by different kinds of events. An interrupt could be generated for example by a timer in a predefined frequency, or by a serial port controller receiving a byte. These kinds of systems are used if event handlers need low latency and the event handlers are short and simple.

Usually these kinds of systems run a simple task in a main loop also, but this task is not very sensitive to unexpected delays. Sometimes the interrupt handler will add longer tasks to a queue structure. Later, after the interrupt handler has finished, these tasks are executed by the main loop. This method brings the system close to a multitasking kernel with discrete processes.

- Cooperative Multitasking:

A non-preemptive multitasking system is very similar to the simple control loop scheme, except that the loop is hidden in an API. The programmer defines a series of tasks, and each task gets its own environment to “run” in. When a task is idle, it calls an idle routine, usually called “pause”, “wait”, “yield”, “nop” (stands for no operation), etc. The advantages and disadvantages are very similar to the control loop, except that adding new software is easier, by simply writing a new task, or adding to the queue-interpreter.

- Primitive Multitasking:

In this type of system, a low-level piece of code switches between tasks or threads based on a timer (connected to an interrupt). This is the level at which the system is generally considered to have an "operating system" kernel. Depending on how much functionality is required, it introduces more or less of the complexities of managing multiple tasks running conceptually in parallel.

As any code can potentially damage the data of another task (except in larger systems using an MMU) programs must be carefully designed and tested, and access to shared data must be controlled by some synchronisation strategy, such as message queues, semaphores or a non-blocking synchronisation scheme.

Because of these complexities, it is common for organisations to buy a real-time operating system, allowing the application programmers to concentrate on device functionality rather than operating system services, at least for large systems; smaller systems often cannot afford the overhead associated with a generic real time system, due to limitations regarding memory size, performance, and/or battery life.

- Microkernels And Exokernels:

A microkernel is a logical step up from a real-time OS. The usual arrangement is that the operating system kernel allocates memory and switches the CPU to different threads of execution. User mode processes implement major functions such as file systems, network interfaces, etc.

In general, microkernels succeed when the task switching and intertask communication is fast, and fail when they are slow. Exokernels communicate efficiently by normal subroutine calls. The hardware, and all the software in the system are available to, and extensible by application programmers. Based on performance, functionality, requirement the embedded systems are divided into three categories:

3.0.9.1 Stand Alone Embedded System:

These systems takes the input in the form of electrical signals from transducers or commands from human beings such as pressing of a button etc.., process them and produces desired output. This entire process of taking input, processing it and giving output is done in standalone mode. Such embedded systems comes under stand alone embedded systems

Eg: microwave oven, air conditioner etc..

3.0.9.2 Real-time embedded systems:

Embedded systems which are used to perform a specific task or operation in a specific time period those systems are called as real-time embedded systems. There are two types of real-time embedded systems.

- Hard Real-time embedded systems:

These embedded systems follow an absolute dead line time period i.e.., if the tasking is not done in a particular time period then there is a cause of damage to the entire equipment.

Eg: consider a system in which we have to open a valve within 30 milliseconds. If this valve is not opened in 30 ms this may cause damage to the entire equipment. So in such cases we use embedded systems for doing automatic operations.

- Soft Real Time embedded systems:

These embedded systems follow a relative dead line time period i.e.., if the task is not done in a particular time that will not cause damage to the equipment.

Eg: Consider a TV remote control system, if the remote control takes a few milliseconds delay it will not cause damage either to the TV or to the remote control. These systems which will not cause damage when they are not operated at considerable time period those systems comes under soft real-time embedded systems.

3.0.9.3 Network communication embedded systems:

A wide range network interfacing communication is provided by using embedded systems.

Eg:

- Consider a web camera that is connected to the computer with internet can be used to spread communication like sending pictures, images, videos etc.., to another computer with internet connection throughout anywhere in the world.
- Consider a web camera that is connected at the door lock.

Whenever a person comes near the door, it captures the image of a person and sends to the desktop of your computer which is connected to internet. This gives an alerting message with image on to the desktop of your computer, and then you can open the door lock just by clicking the mouse. Fig: 2.2 show the network communications in embedded systems.

Fig 4: Network communication embedded systems

3.0.9.4 Different types of processing units:

The central processing unit (c.p.u) can be any one of the following microprocessor, microcontroller, digital signal processing.

- Among these Microcontroller is of low cost processor and one of the main advantage of microcontrollers is, the components such as memory, serial communication interfaces, analog to digital converters etc.., all these are built on a single chip. The numbers of external components that are connected to it are very less according to the application.
- Microprocessors are more powerful than microcontrollers. They are used in major applications with a number of tasking requirements. But the microprocessor requires many external components like memory, serial communication, hard disk, input output ports etc.., so the power consumption is also very high when compared to microcontrollers.
- Digital signal processing is used mainly for the applications that particularly involved with processing of signals.

3.0.10 APPLICATIONS OF EMBEDDED SYSTEMS:

3.0.10.0 Consumer applications:

At home we use a number of embedded systems which include microwave oven, remote control, vcd players, dvd players, camera etc….

Fig 5: Automatic coffee maker equipment

3.0.10.1 Office automation:

We use systems like fax machine, modem, printer etc…

Fig 6: Fax machine **Fig 7: Printing machine**

3.0.10.2 Industrial automation:

Today a lot of industries are using embedded systems for process control. In industries we design the embedded systems to perform a specific operation like monitoring temperature, pressure, humidity ,voltage, current etc.., and basing on these monitored levels we do control other devices, we can send information to a centralized monitoring station.

Fig 8: Robot

In critical industries where human presence is avoided there we can use robot**s** which are programmed to do a specific operation.

3.0.10.3 Computer networking:

Embedded systems are used as bridges routers etc..

Fig 9: Computer networking

3.0.10.4 Tele communications:

Cell phones, web cameras etc.

Fig 10: Cell Phone **Fig 11: Web camera**

3.1 HARDWARE DESCRIPTION:

3.1.0 ESP8266/ NodeMCU:

NodeMCU is a low-cost open source IoT platform. It initially included firmware which runs on the ESP8266 Wi-Fi SoC from Espressif Systems, and hardware which was based on the ESP-12 module.

NodeMCU is an open source firmware for which open source prototyping board designs are available. The name "NodeMCU" combines "node" and "MCU" (micro-controller unit). The term "NodeMCU" strictly speaking refers to the firmware rather than the associated development kits.

Both the firmware and prototyping board designs are open source.

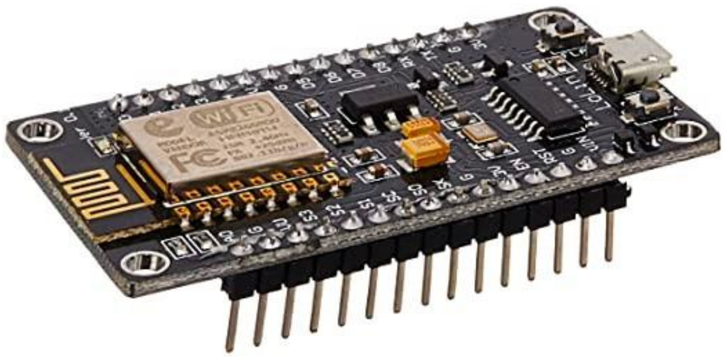

Fig 12: ESP 8266/ Node MCU

The firmware uses the Lua scripting language. The firmware is based on the eLua project, and built on the Espressif Non-OS SDK for ESP8266. It uses many open source projects, such as lua-cjson and SPIFFS. Due to resource constraints, users need to select the modules relevant for their project and build a firmware tailored to their needs. Support for the 32-bit ESP32 has also been implemented.

The prototyping hardware typically used is a circuit board functioning as a dual in-line package (DIP) which integrates a USB controller with a smaller surface-mounted board containing the MCU and antenna. The choice of the DIP format allows for easy prototyping on breadboards. The design was initially based on the ESP-12 module of the ESP8266, which is a Wi-Fi SoC integrated with a Tensilica Xtensa LX106 core, widely used in IoT applications.

3.1.1 Regulated power supply:

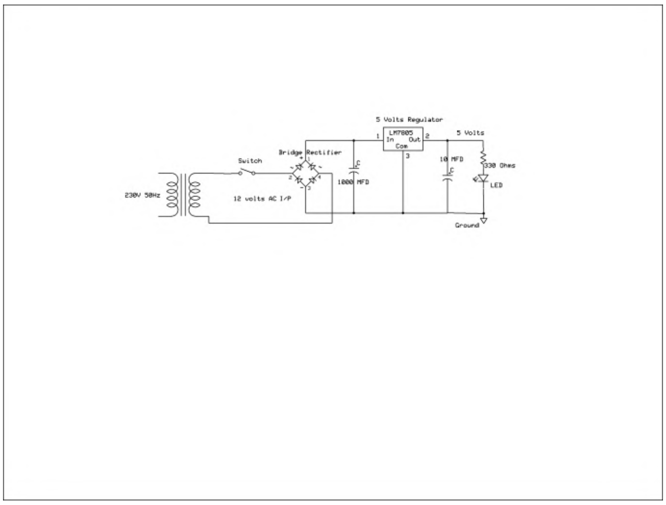

Fig 13: Circuit diagram of Regulated Power Supply with LED connection

The components mainly used in above figure are:

- 230V AC MAINS
- TRANSFORMER
- BRIDGE RECTIFIER (DIODES)
- CAPACITOR
- VOLTAGE REGULATOR (IC 7805)
- RESISTOR
- LED (LIGHT EMITTING DIODE)

The detailed explanation of each and every component mentioned above is as follows:

Transformation: The process of transforming energy from one device to another is called transformation. For transforming energy we use transformers.

Transformers: A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors without changing its frequency. A varying current in the first or primary winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the secondary winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

If a load is connected to the secondary, an electric current will flow in the secondary winding and electrical energy will be transferred from the primary circuit through the transformer to the load. This field is made up from lines of force and has the same shape as a bar magnet.

If the current is increased, the lines of force move outwards from the coil. If the current is reduced, the lines of force move inwards.

If another coil is placed adjacent to the first coil then, as the field moves out or in, the moving lines of force will "cut" the turns of the second coil. As it does this, a voltage is induced in the second coil. With the 50 Hz AC mains supply, this will happen 50 times a second. This is called MUTUAL INDUCTION and forms the basis of the transformer.

The input coil is called the PRIMARY WINDING; the output coil is the SECONDARY WINDING. Fig: 3.3.4 shows step-down transformer. The voltage induced in the secondary is determined by the TURNS RATIO.

$$\frac{\text{primary voltage}}{\text{secondary voltage}} = \frac{\text{number of primary turns}}{\text{number of secondary turns}}$$

For example, if the secondary has half the primary turns; the secondary will have half the primary voltage.

Another example is if the primary has 5000 turns and the secondary has 500 turns, then the turn's ratio is 10:1.

If the primary voltage is 240 volts then the secondary voltage will be x 10 smaller = 24 volts. Assuming a perfect transformer, the power provided by the primary must equal the power taken by a load on the secondary. If a 24-watt lamp is connected across a 24 volt secondary, then the primary must supply 24 watts.

To aid magnetic coupling between primary and secondary, the coils are wound on a metal CORE. Since the primary would induce power, called EDDY CURRENTS, into this core, the core is LAMINATED. This means that it is made up from metal sheets insulated from each other. Transformers to work at higher frequencies have an iron dust core or no core at all.

Note that the transformer only works on AC, which has a constantly changing current and moving field. DC has a steady current and therefore a steady field and there would be no induction.

Some transformers have an electrostatic screen between primary and secondary. This is to prevent some types of interference being fed from the equipment down into the mains supply, or in the other direction. Transformers are sometimes used for IMPEDANCE MATCHING.

We can use the transformers as step up or step down.

Step Up transformer:

In case of step up transformer, primary windings are every less compared to secondary winding.

Because of having more turns secondary winding accepts more energy, and it releases more voltage at the output side.

Step down transformer:

Incase of step down transformer, Primary winding induces more flux than the secondary winding, and secondary winding is having less number of turns because of that it accepts less number of flux, and releases less amount of voltage.

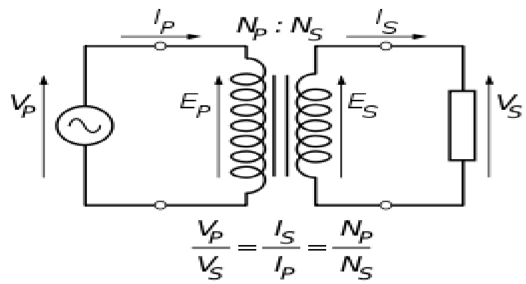

Fig 14: Step-Down Transformer

Battery power supply:

A battery is a type of linear power supply that offers benefits that traditional line-operated power supplies lack: mobility, portability and reliability. A battery consists of multiple electrochemical cells connected to provide the voltage desired. Fig: 3.3.5 shows Hi-Watt 9V battery

Fig 15: Hi-Watt 9V Battery

The most commonly used dry-cell battery is the carbon-zinc dry cell battery. Dry-cell batteries are made by stacking a carbon plate, a layer of electrolyte paste, and a zinc plate alternately until the desired total voltage is achieved. The most common dry-cell batteries have one of the following voltages: 1.5, 3, 6, 9, 22.5, 45, and 90. During the discharge of a carbon-zinc battery, the zinc metal is converted to a zinc salt in the electrolyte, and magnesium dioxide is reduced at the carbon electrode. These actions establish a voltage of approximately 1.5 V.

The lead-acid storage battery may be used. This battery is rechargeable; it consists of lead and lead/dioxide electrodes which are immersed in sulphuric acid. When fully charged, this type of battery has a 2.06-2.14 V potential (A 12 volt car battery uses 6 cells in series). During discharge, the lead is converted to lead sulphate and the sulphuric acid is converted to water. When the battery is charging, the lead sulphate is converted back to lead and lead dioxide A nickel-cadmium battery has become more popular in recent years. This battery cell is completely sealed and rechargeable. The electrolyte is not involved in the electrode reaction, making the voltage constant over the span of the batteries long service life. During the charging process, nickel oxide is oxidised to its higher oxidation state and cadmium oxide is reduced. The nickel-cadmium batteries have many benefits. They can be stored both charged and uncharged. They have a long service life, high current availabilities, constant voltage, and the ability to be recharged. Fig: 3.3.6 shows pencil battery of 1.5V.

Fig 16: Pencil Battery of 1.5V

RECTIFICATION:

The process of converting an alternating current to a pulsating direct current is called as rectification. For rectification purpose we use rectifiers.

Rectifiers:

A rectifier is an electrical device that converts alternating current (AC) to direct current (DC), a process known as rectification. Rectifiers have many uses including as components of power supplies and as detectors of radio signals. Rectifiers may be made of solid-state diodes, vacuum tube diodes, mercury arc valves, and other components.

A device that it can perform the opposite function (converting DC to AC) is known as an inverter.

When only one diode is used to rectify AC (by blocking the negative or positive portion of the waveform), the difference between the term diode and the term rectifier is merely one of usage, i.e., the term rectifier describes a diode that is being used to convert AC to DC. Almost all rectifiers comprise a number of diodes in a specific arrangement for more efficiently converting AC to DC than is possible with only one diode. Before the development of silicon semiconductor rectifiers, vacuum tube diodes and copper (I) oxide or selenium rectifier stacks were used.

Bridge full wave rectifier:

The Bridge rectifier circuit is shown in fig: 3.3.7, which converts an ac voltage to dc voltage using both half cycles of the input ac voltage. The Bridge rectifier circuit is shown in the figure. The circuit has four diodes connected to form a bridge. The ac input voltage is applied to the diagonally opposite ends of the bridge. The load resistance is connected between the other two ends of the bridge.

For the positive half cycle of the input ac voltage, diodes D1 and D3 conduct, whereas diodes D2 and D4 remain in the OFF state. The conducting diodes will be in series with the load resistance R_L and hence the load current flows through R_L.

For the negative half cycle of the input ac voltage, diodes D2 and D4 conduct whereas, D1 and D3 remain OFF. The conducting diodes D2 and D4 will be in series with the load resistance R_L and hence the current flows through R_L in the same direction as in the previous half cycle. Thus a bi-directional wave is converted into a unidirectional wave.

Input Output

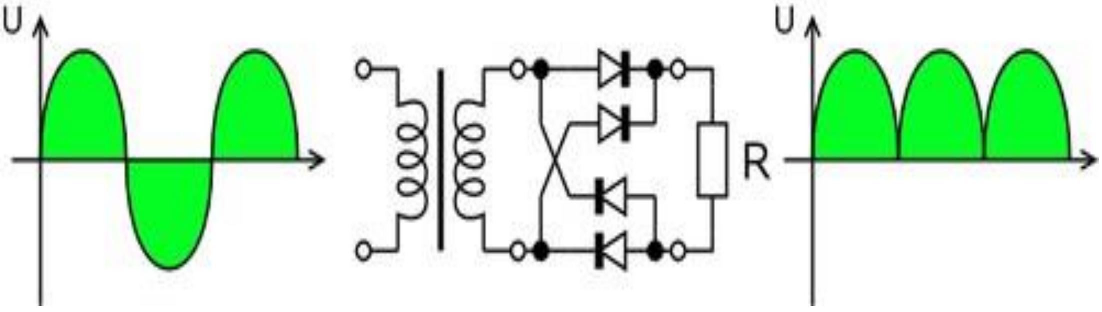

Fig 17: Bridge rectifier: a full-wave rectifier using 4 diodes

DB107:

Now -a -days Bridge rectifier is available in IC with a number of DB107. In our project we are using an IC in place of bridge rectifier. The picture of DB 107 is shown in fig: 3.3.8.

Features:

- Good for automation insertion
- Surge overload rating - 30 amperes peak
- Ideal for printed circuit board
- Reliable low cost construction utilizing molded
- Glass passivated device
- Polarity symbols molded on body
- Mounting position: Any
- Weight: 1.0 gram

Fig 18: DB107

Filtration:

The process of converting a pulsating direct current to a pure direct current using filters is called as filtration.

Filters:

Electronic filters are electronic circuits, which perform signal-processing functions, specifically to remove unwanted frequency components from the signal, to enhance wanted ones.

Introduction to Capacitors:

The Capacitor or sometimes referred to as a Condenser is a passive device, and one which stores energy in the form of an electrostatic field which produces a potential (static voltage) across its plates. In its basic form a capacitor consists of two parallel conductive plates that are not connected but are electrically separated either by air or by an insulating material called the Dielectric. When a voltage is applied to these plates, a current flows charging up the plates with electrons giving one plate a positive charge and the other plate an equal and opposite negative charge. This flow of electrons to the plates is known as the Charging Current and continues to flow until the voltage across the plates (and hence the capacitor) is equal to the applied voltage Vcc. At this point the capacitor is said to be fully charged and this is illustrated below. The construction of capacitor and an electrolytic capacitor are shown in figures 3.3.9 and 3.3.10 respectively.

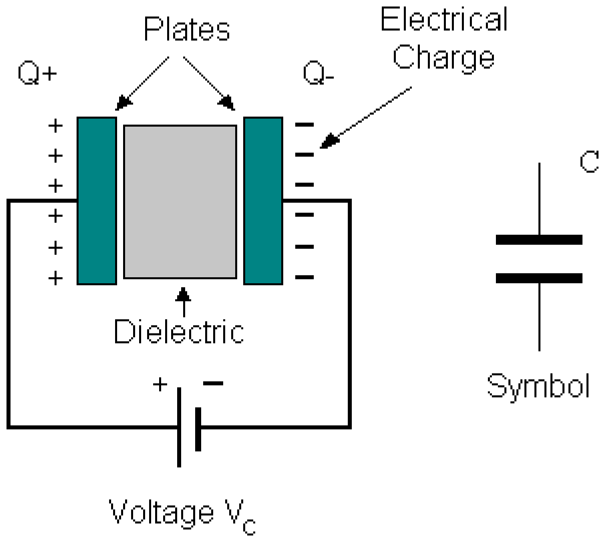

Fig 19: Construction Of a Capacitor

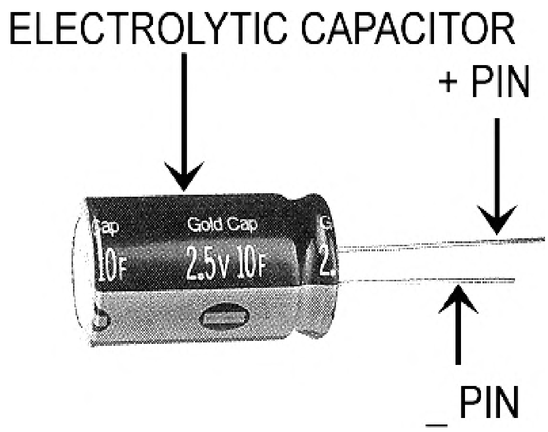

Fig 20: Electrolytic Capacitor

Units of Capacitance:

Microfarad (µF) 1µF = 1/1,000,000 = 0.000001 = 10^{-6} F

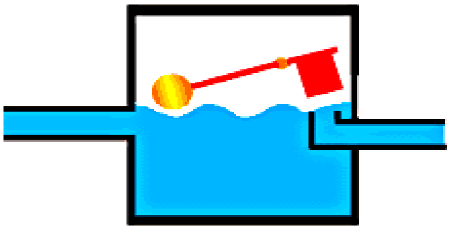
Nanofarad (nF) 1nF = 1/1,000,000,000 = 0.000000001 = 10^{-9} F

Pico farad (pF) 1pF = 1/1,000,000,000,000 = 0.000000000001 = 10^{-12} F

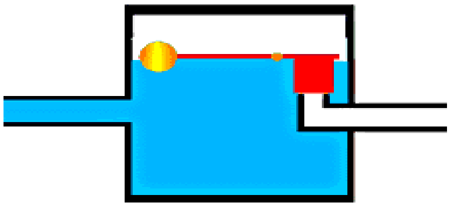
Operation of Capacitor:

Think of water flowing through a pipe. If we imagine a capacitor as being a storage tank with an inlet and an outlet pipe, it is possible to show approximately how an electronic capacitor works.

First, let's consider the case of a "coupling capacitor" where the capacitor is used to connect a signal from one part of a circuit to another but without allowing any direct current to flow.



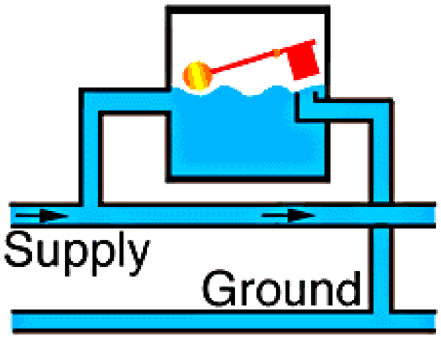
If the current flow is alternating between zero and a maximum, our "storage tank" capacitor will allow the current waves to pass through.



However, if there is a steady current, only the initial short burst will flow until the "floating ball valve" closes and stops further flow.

So a coupling capacitor allows "alternating current" to pass through because the ball valve doesn't get a chance to close as the waves go up and down. However, a steady current quickly fills the tank so that all flow stops.

A capacitor will pass alternating current but (apart from an initial surge) it will not pass d.c.



Where a capacitor is used to decouple a circuit, the effect is to "smooth out ripples". Any ripples, waves or pulses of current are passed to ground while d.c. Flows smoothly.

Regulation:

The process of converting a varying voltage to a constant regulated voltage is called as regulation. For the process of regulation we use voltage regulators.

Voltage Regulator:

A voltage regulator (also called a ‘regulator’) with only three terminals appears to be a simple device, but it is in fact a very complex integrated circuit. It converts a varying input voltage into a constant ‘regulated’ output voltage. Voltage Regulators are available in a variety of outputs like 5V, 6V, 9V, 12V and 15V. The LM78XX series of voltage regulators are designed for positive input. For applications requiring negative input, the LM79XX series is used. Using a pair of ‘voltage-divider’ resistors can increase the output voltage of a regulator circuit.

It is not possible to obtain a voltage lower than the stated rating. You cannot use a 12V regulator to make a 5V power supply. Voltage regulators are very robust. These can withstand over-current draw due to short circuits and also over-heating. In both cases, the regulator will cut off before any damage occurs. The only way to destroy a regulator is to apply reverse voltage to its input. Reverse polarity destroys the regulator almost instantly. Fig: 3.3.11 shows voltage regulator.

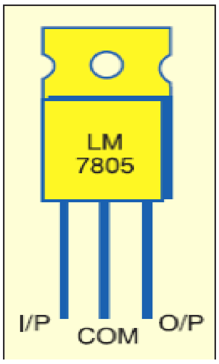


Fig 21: Voltage Regulator

Resistors:

A resistor is a two-terminal electronic component that produces a voltage across its terminals that is proportional to the electric current passing through it in accordance with Ohm's law:

$$V = IR$$

Resistors are elements of electrical networks and electronic circuits and are ubiquitous in most electronic equipment. Practical resistors can be made of various compounds and films, as well as resistance wire (wire made of a high-resistivity alloy, such as nickel/ chrome).

The primary characteristics of a resistor are the resistance, the tolerance, maximum working voltage and the power rating. Other characteristics include temperature coefficient, noise, and inductance. Less well-known is critical resistance, the value below which power dissipation limits the maximum permitted current flow, and above which the limit is applied voltage. Critical resistance is determined by the design, materials and dimensions of the resistor.

Resistors can be made to control the flow of current, to work as Voltage dividers, to dissipate power and it can shape electrical waves when used in combination of other components. Basic unit is ohms.

Theory of operation:

Ohm's law:

The behaviour of an ideal resistor is dictated by the relationship specified in Ohm's law:

$$V = IR$$

Ohm's law states that the voltage (V) across a resistor is proportional to the current (I) through it where the constant of proportionality is the resistance (R).

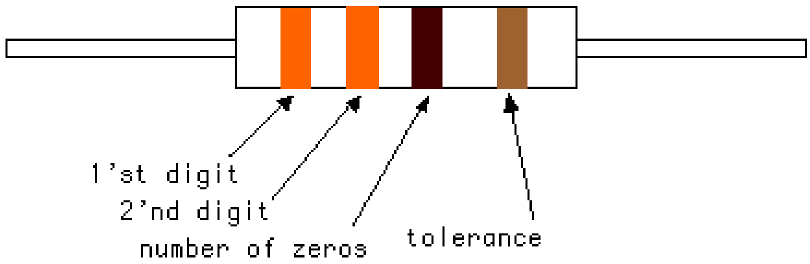
Power dissipation:

The power dissipated by a resistor (or the equivalent resistance of a resistor network) is calculated using the following:

$$P = I^2 R = IV = \frac{V^2}{R}$$

Fig 22: Resistor

Resistor color Coding



Digit	color	Tolerance	color
0	Black	20%	nothing
1	Brown	10%	Silver
2	Red	5%	Gold
3	Orange	2%	Red
4	Yellow	1%	Brown
5	Green		
6	Blue		
7	Violet		
8	Grey		
9	White

3.1.2 HC-SR04 Ultrasonic Distance Measurement Sensor:

Ultrasonic transducers and ultrasonic sensors are devices that generate or sense ultrasound energy. They can be divided into three broad categories: transmitters, receivers and transceivers. Transmitters convert electrical signals into ultrasound, receivers convert ultrasound into electrical signals, and transceivers can both transmit and receive ultrasound.

In a similar way to radar and sonar, ultrasonic transducers are used in systems which evaluate targets by interpreting the reflected signals. For example, by measuring the time between sending a signal and receiving an echo the distance of an object can be calculated. Passive ultrasonic sensors are basically microphones that detect ultrasonic noise that is present under certain conditions.

The design of transducer can vary greatly depending on its use: those used for medical diagnostic purposes, for example the range-finding applications listed above, are generally lower power than those used for the purpose of changing the properties of the liquid medium, or targets immersed in the liquid medium, through chemical, biological or physical (e.g. erosive) effects. The latter class include ultrasonic probes and ultrasonic baths, which apply ultrasonic energy to agitate particles, clean, erode, or disrupt biological cells, in a wide range of materials.

Fig 24: An Ultrasonic Distance/Depth Measuring Sensor (HC-SR04)

3.2 SOFTWARE DESCRIPTION:

3.2.0 Arduino IDE (Integrated Development Environment):

Arduino IDE is an open source software that is mainly used for writing and compiling the code into the Arduino Module. It is an official Arduino software, making code compilation too easy that even a common person with no prior technical knowledge can get their feet wet with the learning process. It is easily available for operating systems like Mac, Windows, Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital role for debugging, editing and compiling the code in the environment.

A range of Arduino modules available including Arduino Uno, Arduino Mega, Arduino Leonardo, Arduino Micro and many more. Each of them contains a microcontroller on the board that is actually programmed and accepts the information in the form of code. The main code, also known as a sketch, created on the IDE platform will ultimately generate a Hex File which is then transferred and uploaded in the controller on the board.

The IDE environment mainly contains two basic parts: Editor and Compiler where former is used for writing the required code and later is used for compiling and uploading the code into the given Arduino Module. This environment supports both C and C++ languages.

What exactly is Arduino?

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing.

Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals - has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike.

Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open-source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why use Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community.

There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Netmedia's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than $50

Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

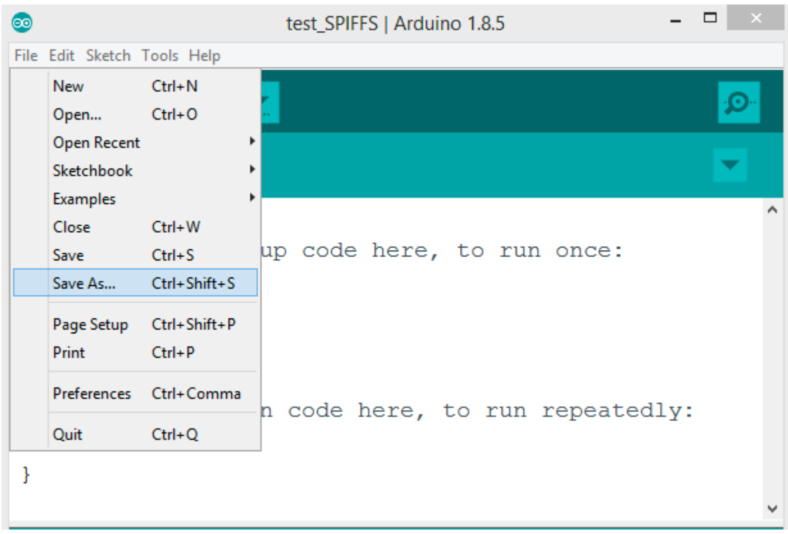
Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

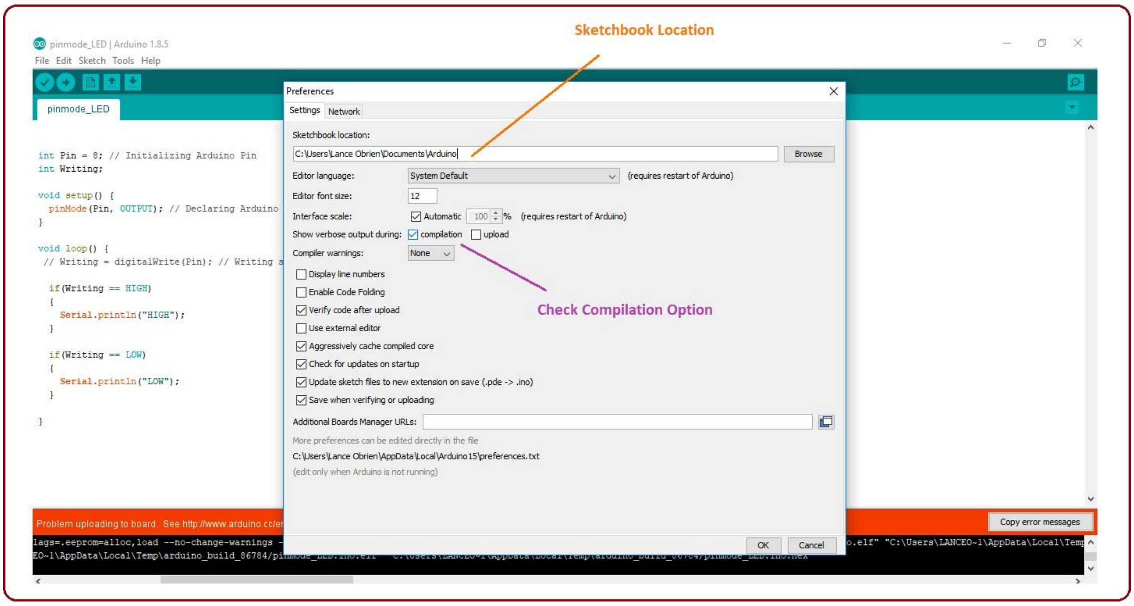
Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money.

The IDE environment is mainly distributed into three sections:

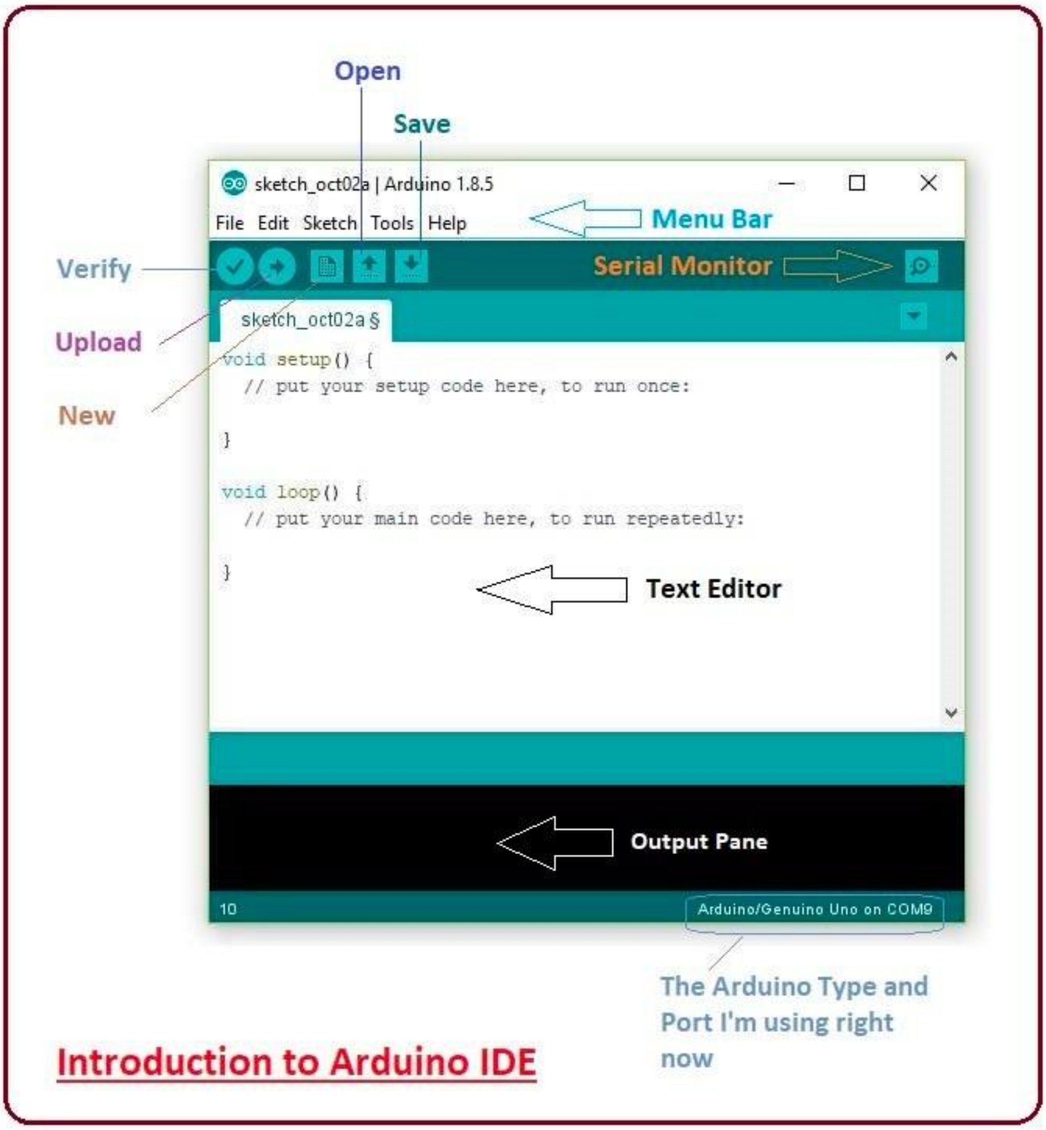
- Menu Bar
- Text Editor
- Output Pane
- File: We can open a new window for writing the code or open an existing one. Following table shows the number of further subdivisions the file option is categorised into.



As we go to the preference section and check the compilation section, the Output Pane will show the code compilation as we click the upload button.



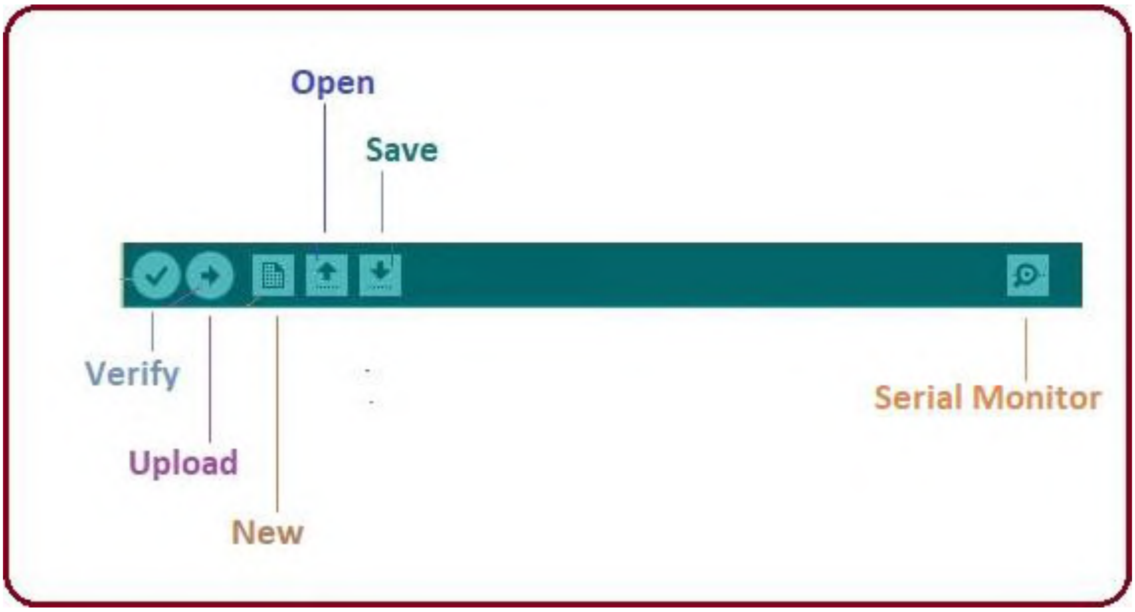
- And at the end of compilation, it will show us the hex file it has generated for the recent sketch that will send to the Arduino Board for the specific task we aim to achieve.



- **Edit** - Used for copying and pasting the code with further modification for font
- **Sketch** - For compiling and programming

- **Tools** - Mainly used for testing projects. The Programmer section in this panel is used for burning a boot-loader to the new microcontroller.
- **Help** - In case you are feeling skeptical about software, complete help is available from getting started to troubleshooting.

The **Six Buttons** appearing under the Menu tab are connected with the running program as follow.



The check mark appearing in the circular button is used to verify the code. Click this once you have written your code.

The arrow key will upload and transfer the required code to the Arduino board.

The dotted paper is used for creating a new file.

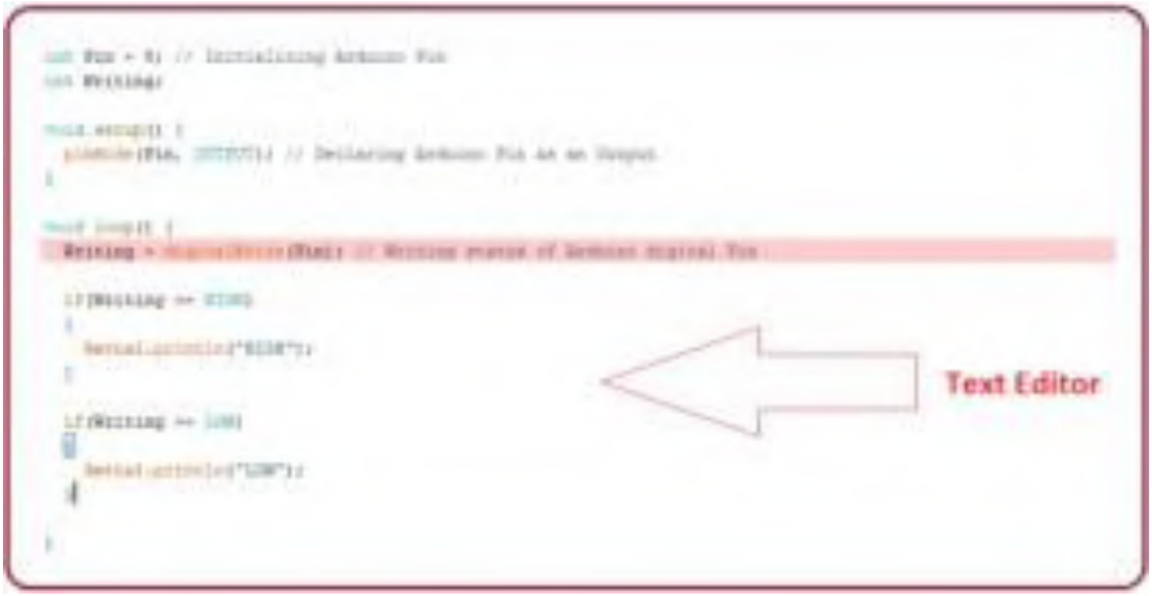
The upward arrow is reserved for opening an existing Arduino project.

The downward arrow is used to save the current running code.

The button appearing on the top right corner is a **Serial Monitor** - A separate pop-up window that acts as an independent terminal and plays a vital role for sending and receiving the Serial Data. You can also go to the Tools panel and select Serial Monitor, or pressing Ctrl+Shift+M all at once will open it instantly. The Serial Monitor will actually help to debug the written Sketches where you can get a hold of how your program is operating. Your Arduino Module should be connected to your computer by USB cable in order to activate the Serial Monitor.

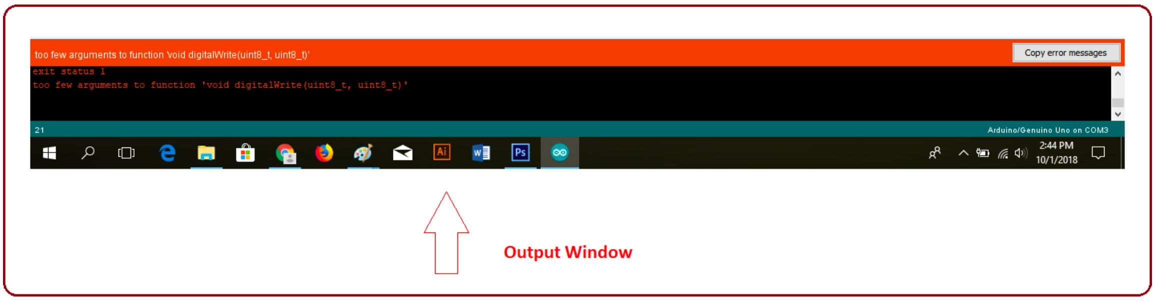
We need to select the baud rate of the Arduino Board we are using right now. For my Arduino Uno Baud Rate is 9600, as we write the following code and click the Serial Monitor, the output will show as the image below.

The main screen below the Menu bard is known as a simple text editor used for writing the required code.



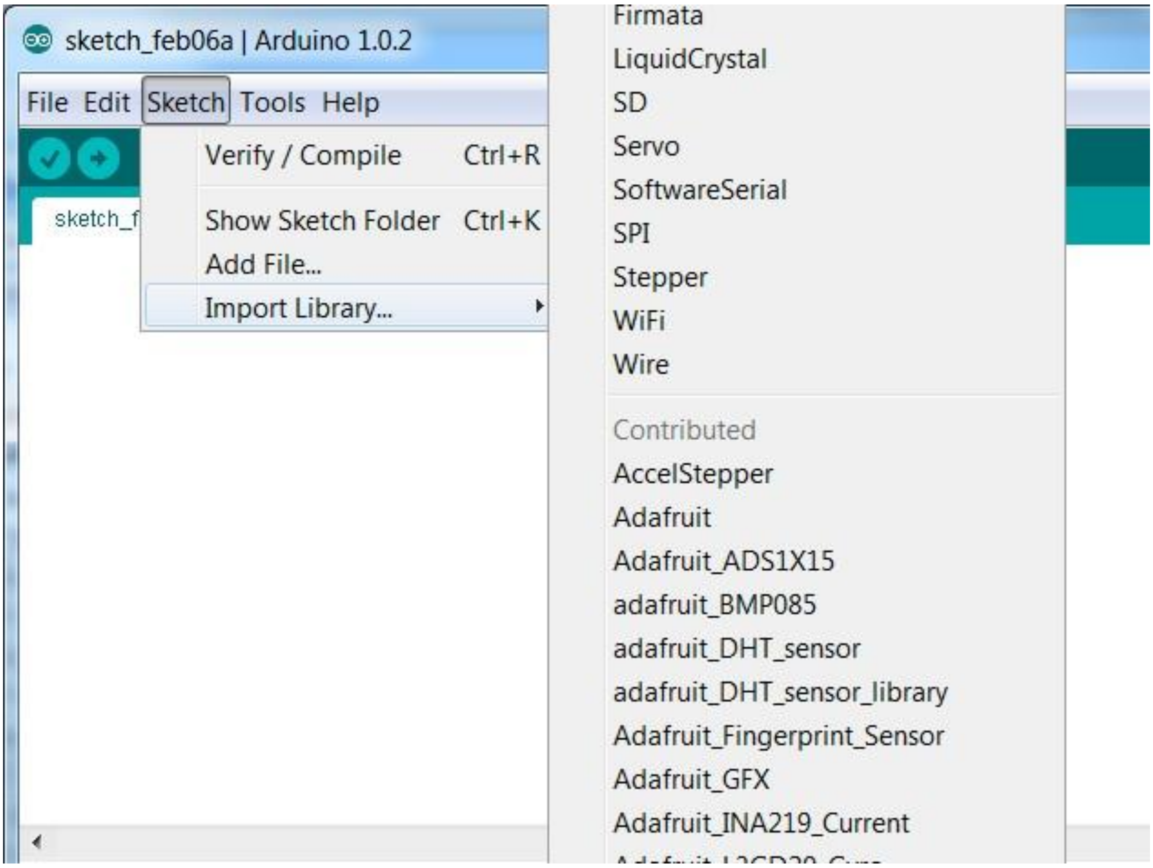
The bottom of the main screen is described as an Output Pane that mainly highlights the compilation status of the running code: the memory used by the code, and errors occurred in the program. You need to fix those errors before you intend to upload the hex file into your Arduino

Module.



More or less, Arduino C language works similar to the regular C language used for any embedded system microcontroller, however, there are some dedicated libraries used for calling and executing specific functions on the board.**Libraries**

Libraries are very useful for adding the extra functionality into the Arduino Module. There is a list of libraries you can add by clicking the Sketch button in the menu bar and going to Include Library.



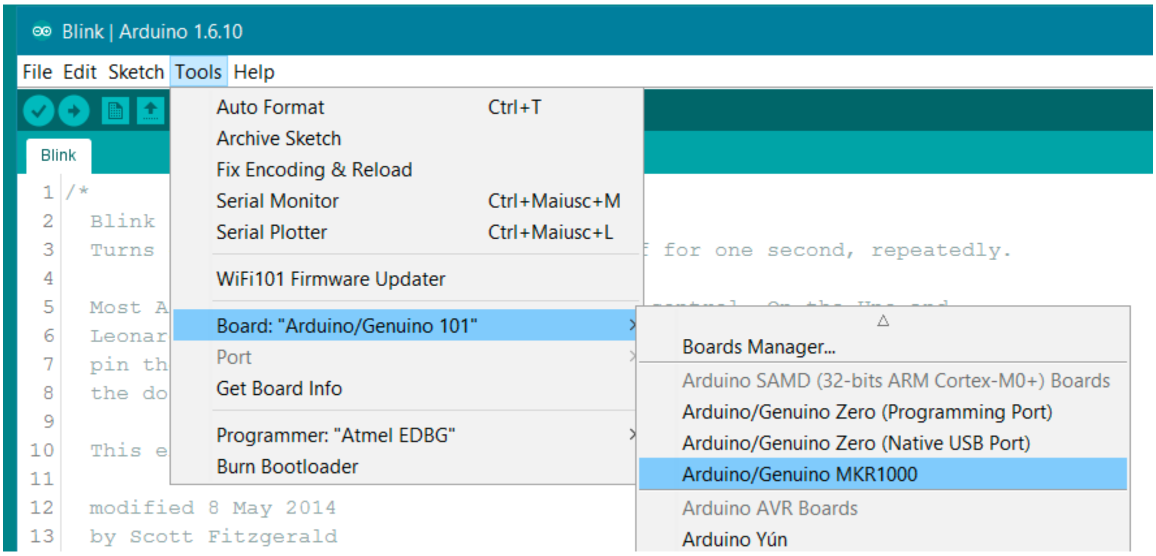
As we click the Include Library and Add the respective library it will on the top of the sketch with a #include sign. Suppose, I Include the EEPROM library, it will appear on the text editor as

#include <EEPROM.h>.

Most of the libraries are preinstalled and come with the Arduino software. However, we can also download them from the external sources.**Making Pins Input or Output**

The digitalRead and digitalWrite commands are used for addressing and making the Arduino pins as an input and output respectively. These commands are text sensitive i.e. we need to write them down the exact way they are given like digitalWrite starting with small "d" and write with capital "W". Writing it down with Digitalwrite or digitalwrite won't be calling or addressing any function.**How to Select the Board**

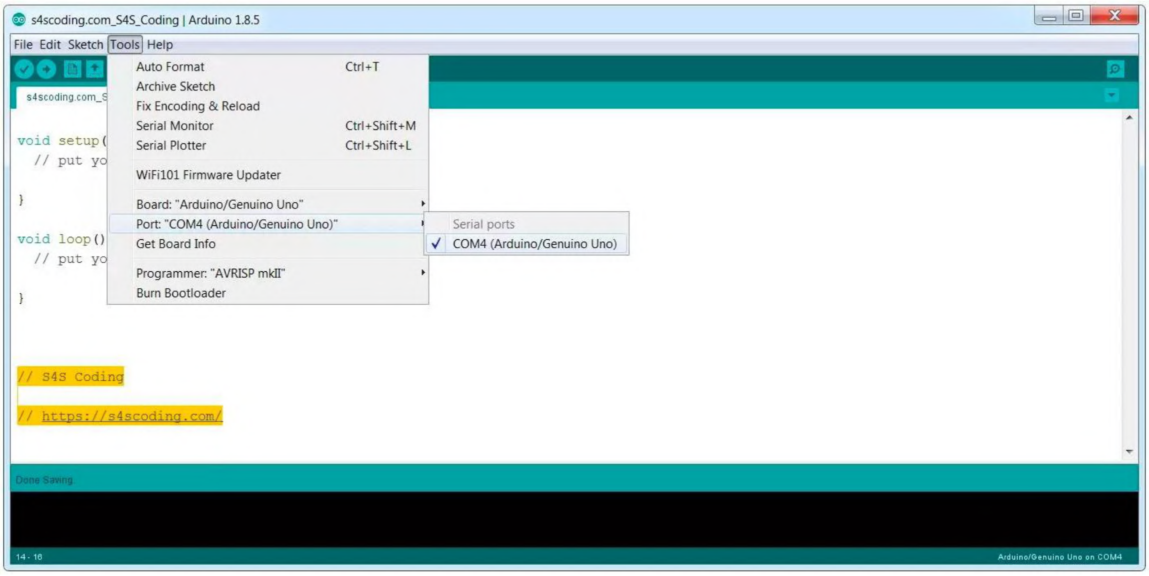
In order to upload the sketch, we need to select the relevant board we are using and the ports for that operating system. As we click the Tools on the Menu, it will open like the figure below.



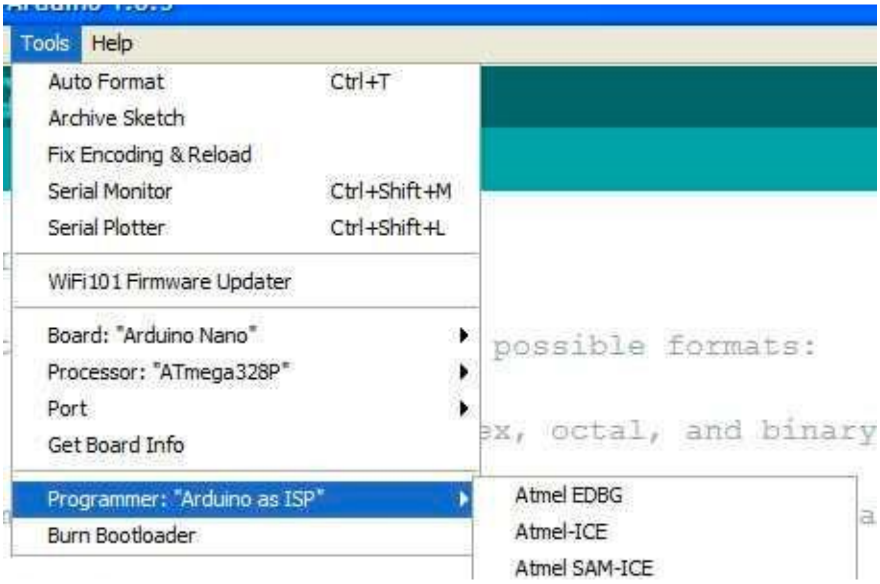
- Just go to the "Board" section and select the board we aim to work on. Similarly, COM1, COM2, COM4, COM5, COM7 or higher are reserved for the serial and USB board. We can look for the USB serial device in the ports section of the Windows Device Manager.

Following figure shows the COM4, indicating the Arduino Uno with COM4 port at the right bottom corner of the screen.

- After correct selection of both Board and Serial Port, click the verify and then upload button appearing in the upper left corner of the six button section or we can go to the Sketch section and press verify/compile and then upload.



- The sketch is written in the text editor and is then saved with the file extension .ino.



It is important to note that the recent Arduino Modules will reset automatically as we compile and press the upload button the IDE software, however, older version may require the physical reset on the board.

- Once we upload the code, TX and RX LEDs will blink on the board, indicating the desired program is running successfully.
- As we go to the Tools section, we will find a boot-loader at the end. It is very helpful to burn the code directly into the controller, setting us free from buying the external burner to burn the required code.

When we buy the new Arduino Module, the bootloader is already installed inside the controller. However, if we intend to buy a controller and put in the Arduino module, we need to burn the bootloader again inside the controller by going to the Tools section and selecting the burn bootloader.

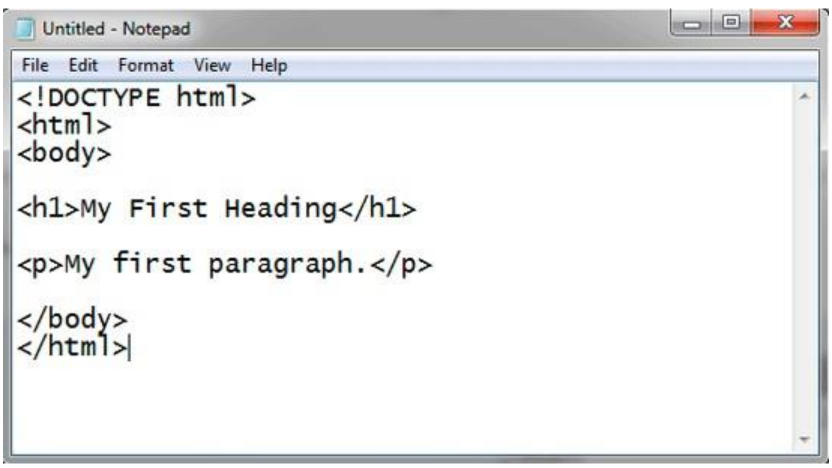
3.2.1 HTML, CSS, and PHP:

HTML (Hyper Text Markup Language):

Hypertext Markup Language (HTML) is the standard markup language for documents designed to be displayed in a web browser. It can be assisted by technologies such as Cascading Style Sheets (CSS) and scripting languages such as JavaScript.

Web browsers receive HTML documents from a web server or from local storage and render the documents into multimedia web pages. HTML describes the structure of a web page semantically and originally included cues for the appearance of the document.

HTML elements are the building blocks of HTML pages. With HTML constructs, images and other objects such as interactive forms may be embedded into the rendered page. HTML provides a means to create structured documents by denoting structural semantics for text such as headings, paragraphs, lists, links, quotes and other items. HTML elements are delineated by tags, written using angle brackets. Tags such as <img /> and <input /> directly introduce content into the page. Other tags such as <p> surround and provide information about document text and may include other tags as sub-elements. Browsers do not display the HTML tags, but use them to interpret the content of the page.



HTML can embed programs written in a scripting language such as JavaScript, which affects the behaviour and content of web pages. Inclusion of CSS defines the look and layout of content. The World Wide Web Consortium (W3C), former maintainer of the

HTML and current maintainer of the CSS standards, has encouraged the use of CSS over explicit presentational HTML since 1997.

Markup:

HTML markup consists of several key components, including those called tags (and their attributes), character-based data types, character references and entity references. HTML tags most commonly come in pairs like <h1> and </h1>, although some represent empty elements and so are unpaired, for example <img>. The first tag in such a pair is the start tag, and the second is the end tag (they are also called opening tags and closing tags).

Another important component is the HTML document type declaration, which triggers standards mode rendering.

The following is an example of the classic "Hello, World!" program:

```
<!DOCTYPE html>
<html>
  <head>
    <title>This is a title</title>
  </head>
  <body>
    <div>
        <p>Hello world!</p>
    </div>
  </body>
</html>
```

The text between <html> and </html> describes the web page, and the text between <body> and </body> is the visible page content. The markup text <title>This is a title</title> defines the browser page title, and the tag <div> defines a division of the page used for easy styling.

The Document Type Declaration <!DOCTYPE html> is for HTML5. If a declaration is not included, various browsers will revert to "quirks mode" for rendering.

Elements:

HTML documents imply a structure of nested HTML elements. These are indicated in the document by HTML tags, enclosed in angle brackets thus: <p>.

In the simple, general case, the extent of an element is indicated by a pair of tags: a "start tag" <p> and "end tag" </p>. The text content of the element, if any, is placed between these tags.

Tags may also enclose further tag markup between the start and end, including a mixture of tags and text. This indicates further (nested) elements, as children of the parent element.

The start tag may also include attributes within the tag. These indicate other information, such as identifiers for sections within the document, identifiers used to bind style information to the presentation of the document, and for some tags such as the <img> used to embed images, the reference to the image resource in the format like this: <img src="example.com/example.jpg">

Some elements, such as the line break <br>, or <br /> do not permit any embedded content, either text or further tags. These require only a single empty tag (akin to a start tag) and do not use an end tag.

Many tags, particularly the closing end tag for the very commonly used paragraph element <p>, are optional. An HTML browser or other agent can infer the closure for the end of an element from the context and the structural rules defined by the HTML standard. These rules are complex and not widely understood by most HTML coders.

The general form of an HTML element is therefore: <tag attribute1="value1" attribute2="value2">"content"</tag>. Some HTML elements are defined as empty elements and take the form <tag attribute1="value1" attribute2="value2">. Empty elements may enclose no content, for instance, the <br> tag or the inline <img> tag. The name of an HTML element is the name used in the tags. Note that the end tag's name is preceded by a slash character, /, and that in empty elements the end tag is neither required nor allowed. If attributes are not mentioned, default values are used in each case.

Paragraphs:

`<p>Paragraph 1</p> <p>Paragraph 2</p>`

Line breaks: `<br>`. The difference between `<br>` and `<p>` is that `<br>` breaks a line without altering the semantic structure of the page, whereas `<p>` sections the page into paragraphs. The element `<br>` is an empty element in that, although it may have attributes, it can take no content and it may not have an end tag.

```
<p>This <br> is a paragraph <br> with <br> line breaks</p>
```

This is a link in HTML. To create a link the `<a>` tag is used. The href attribute holds the URL address of the link.

```
<a href="https://www.wikipedia.org/">A link to Wikipedia!</a>
```

Inputs:

There are many possible ways a user can give input/s like:

```
<input type="text" /> <!-- This is for text input -->

<input type="file" /> <!-- This is for uploading files -->

<input type="checkbox" /> <!-- This is for checkboxes —>
```

Comments:

```
<!-- This is a comment -->
```

Comments can help in the understanding of the markup and do not display in the webpage.

There are several types of markup elements used in HTML:

Structural markup indicates the purpose of text

For example, <h2>Golf</h2> establishes "Golf" as a second-level heading. Structural markup does not denote any specific rendering, but most web browsers have default styles for element formatting. Content may be further styled using Cascading Style Sheets (CSS). [72]

Presentational markup indicates the appearance of the text, regardless of its purpose

For example, bold text indicates that visual output devices should render "boldface" in bold text, but gives little indication what devices that are unable to do this (such as aural devices that read the text aloud) should do. In the case of both bold text and <i>italic text</i>, there are other elements that may have equivalent visual renderings but that are more semantic in nature, such as strong text and emphasized text respectively. It is easier to see how an aural user agent should interpret the latter two elements. However, they are not equivalent to their presentational counterparts: it would be undesirable for a screen-reader to emphasize the name of a book, for instance, but on a screen such a name would be italicized. Most presentational markup elements have become deprecated under the HTML 4.0 specification in favor of using CSS for styling.

Hypertext markup makes parts of a document into links to other documents

An anchor element creates a hyperlink in the document and its href attribute sets the link's target URL. For example, the HTML markup Wikipedia, will render the word "Wikipedia" as a hyperlink. To render an image as a hyperlink, an img element is inserted as content into the a element. Like br, img is an empty element with attributes but no content or closing tag. <img src="image.gif" alt="descriptive text" width="50" height="50" border="0">.

Attributes:

Most of the attributes of an element are name-value pairs, separated by = and written within the start tag of an element after the element's name. The value may be enclosed in single or double quotes, although values consisting of certain characters can be left unquoted in HTML (but not XHTML). Leaving attribute values unquoted is considered unsafe. In contrast with name-value pair attributes, there are some attributes that affect the element simply by their presence in the start tag of the element,[6] like the ismap attribute for the img element.

There are several common attributes that may appear in many elements :

- The id attribute provides a document-wide unique identifier for an element. This is used to identify the element so that stylesheets can alter its presentational properties, and scripts may alter, animate or delete its contents or presentation. Appended to the URL of the page, it provides a globally unique identifier for the element, typically a sub-section of the page. For example, the ID "Attributes" in https://en.wikipedia.org/wiki/HTML#Attributes.

- The class attribute provides a way of classifying similar elements. This can be used for semantic or presentation purposes. For example, an HTML document might semantically use the designation <class="notation"> to indicate that all elements with this class value are subordinate to the main text of the document. In presentation, such elements might be gathered together and presented as footnotes on a page instead of appearing in the place where they occur in the HTML source. Class attributes are used semantically in microformats. Multiple class values may be specified; for example <class="notation important"> puts the element into both the notation and the important classes.
- An author may use the style attribute to assign presentational properties to a particular element. It is considered better practice to use an element's id or class attributes to select the element from within a stylesheet, though sometimes this can be too cumbersome for a simple, specific, or ad hoc styling.
- The title attribute is used to attach subtextual explanation to an element. In most browsers this attribute is displayed as a tooltip.
- The lang attribute identifies the natural language of the element's contents, which may be different from that of the rest of the document. For example, in an English-language document:<p>Oh well, c'est la vie, as they say in France.</p>

The abbreviation element, abbr, can be used to demonstrate some of these attributes:

<abbr id="anId" class="jargon" style="color:purple;" title="Hypertext Markup Language">HTML</abbr>

This example displays as HTML; in most browsers, pointing the cursor at the abbreviation should display the title text "Hypertext Markup Language."

Most elements take the language-related attribute dir to specify text direction, such as with "rtl" for right-to-left text in, for example, Arabic, Persian or Hebrew.

Data types:

HTML defines several data types for element content, such as script data and stylesheet data, and a plethora of types for attribute values, including IDs, names, URIs, numbers, units of length, languages, media descriptors, colors, character encodings, dates and times, and so on. All of these data types are specializations of character data.

Document type declaration:

HTML documents are required to start with a Document Type Declaration (informally, a "doctype"). In browsers, the doctype helps to define the rendering mode—particularly whether to use quirks mode.

The original purpose of the doctype was to enable parsing and validation of HTML documents by SGML tools based on the Document Type Definition (DTD). The DTD to which the DOCTYPE refers contains a machine-readable grammar specifying the permitted and prohibited content for a document conforming to such a DTD. Browsers, on the other hand, do not implement HTML as an application of SGML and by consequence do not read the DTD.

HTML5 does not define a DTD; therefore, in HTML5 the doctype declaration is simpler and shorter:

```
<!DOCTYPE html>
```

An example of an HTML 4 doctype:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "https://www.w3.org/TR/html4/strict.dtd">
```

This declaration references the DTD for the "strict" version of HTML 4.01. SGML-based validators read the DTD in order to properly parse the document and to perform validation. In modern browsers, a valid doctype activates standards mode as opposed to quirks mode.

In addition, HTML 4.01 provides Transitional and Frameset DTDs, as explained below. Transitional type is the most inclusive, incorporating current tags as well as older or "deprecated" tags, with the Strict DTD excluding deprecated tags. Frameset has all tags necessary to make frames on a page along with the tags included in transitional type.

Semantic HTML:

Semantic HTML is a way of writing HTML that emphasizes the meaning of the encoded information over its presentation (look). HTML has included semantic markup from its inception,[82] but has also included presentational markup, such as `<font>`, `<i>` and `<center>` tags. There are also the semantically neutral span and div tags. Since the late 1990s, when Cascading Style Sheets were beginning to work in most browsers, web authors have been encouraged to avoid the use of presentational HTML markup with a view to the separation of presentation and content.[83]

In a 2001 discussion of the Semantic Web, Tim Berners-Lee and others gave examples of ways in which intelligent software "agents" may one day automatically crawl the web and find, filter and correlate previously unrelated, published facts for the benefit of human users.[84] Such agents are not commonplace even now, but some of the ideas of Web 2.0, mashups and price comparison websites may be coming close. The main difference between these web application hybrids and Berners-Lee's semantic agents lies in the fact that the current aggregation and hybridization of information is usually designed in by web developers, who already know the web locations and the API semantics of the specific data they wish to mash, compare and combine.

An important type of web agent that does crawl and read web pages automatically, without prior knowledge of what it might find, is the web crawler or search-engine spider. These software agents are dependent on the semantic clarity of web pages they find as they use various techniques and algorithms to read and index millions of web pages a day and provide web users with search facilities without which the World Wide Web's usefulness would be greatly reduced.

In order for search-engine spiders to be able to rate the significance of pieces of text they find in HTML documents, and also for those creating mashups and other hybrids as well as for more automated agents as they are developed, the semantic structures that exist in HTML need to be widely and uniformly applied to bring out the meaning of published text.

Presentational markup tags are deprecated in current HTML and XHTML recommendations. The majority of presentational features from previous versions of HTML are no longer allowed as they lead to poorer accessibility, higher cost of site maintenance, and larger document sizes.

Good semantic HTML also improves the accessibility of web documents (see also Web Content Accessibility Guidelines). For example, when a screen reader or audio browser can correctly ascertain the structure of a document, it will not waste the visually impaired user's time by reading out repeated or irrelevant information when it has been marked up correctly.

Delivery:

HTML documents can be delivered by the same means as any other computer file. However, they are most often delivered either by HTTP from a web server or by email.

HTTP:

The World Wide Web is composed primarily of HTML documents transmitted from web servers to web browsers using the Hypertext Transfer Protocol (HTTP). However, HTTP is used to serve images, sound, and other content, in addition to HTML. To allow the web browser to know how to handle each document it receives, other information is transmitted along with the document. This meta data usually includes the MIME type (e.g., text/ html or application/xhtml+xml) and the character encoding (see Character encoding in HTML).

In modern browsers, the MIME type that is sent with the HTML document may affect how the document is initially interpreted. A document sent with the XHTML MIME type is expected to be well-formed XML; syntax errors may cause the browser to fail to render it. The same document sent with the HTML MIME type might be displayed successfully, since some browsers are more lenient with HTML.

The W3C recommendations state that XHTML 1.0 documents that follow guidelines set forth in the recommendation's Appendix C may be labeled with either MIME Type. XHTML 1.1 also states that XHTML 1.1 documents should be labeled with either MIME type.

HTML e-mail:

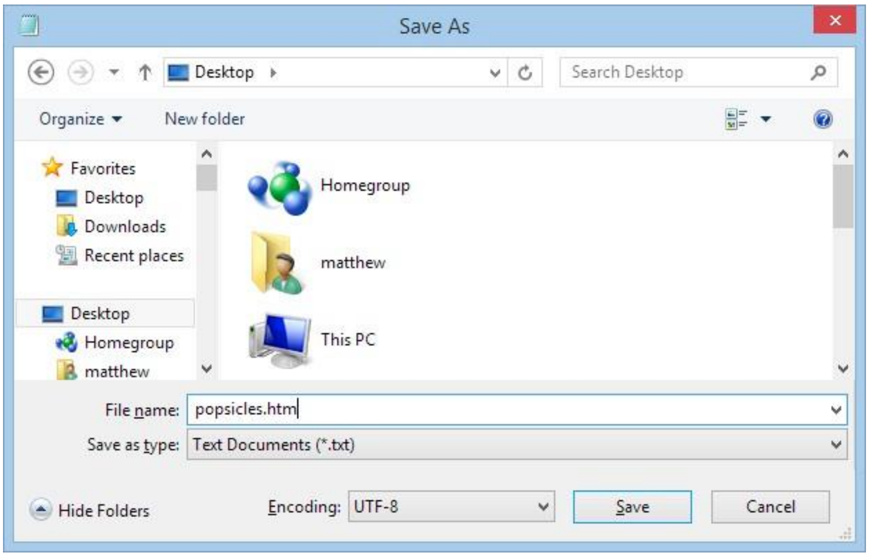
Most graphical email clients allow the use of a subset of HTML (often ill-defined) to provide formatting and semantic markup not available with plain text. This may include typographic information like coloured headings, emphasized and quoted text, inline images and diagrams. Many such clients include both a GUI editor for composing HTML e-mail messages and a rendering engine for displaying them. Use of HTML in e-mail is criticized by some because of compatibility issues, because it can help disguise phishing attacks, because of accessibility issues for blind or visually impaired people, because it can confuse spam filters and because the message size is larger than plain text.

Naming conventions:

The most common filename extension for files containing HTML is .html. A common abbreviation of this is .htm, which originated because some early operating systems and file systems, such as DOS and the limitations imposed by FAT data structure, limited file extensions to three letters.

HTML Application:

An HTML Application (HTA; file extension ".hta") is a Microsoft Windows application that uses HTML and Dynamic HTML in a browser to provide the application's graphical interface. A regular HTML file is confined to the security model of the web browser's security, communicating only to web servers and manipulating only web page objects and site cookies. An HTA runs as a fully trusted application and therefore has more privileges, like creation/editing/removal of files and Windows Registry entries. Because they operate outside the browser's security model, HTAs cannot be executed via HTTP, but must be downloaded (just like an EXE file) and executed from local file system.



CSS (Cascaded Style Sheets):

Cascading Style Sheets is a style sheet language used for describing the presentation of a document written in a markup language such as HTML. CSS is a cornerstone technology of the World Wide Web, alongside HTML and JavaScript.

Example:

```
body {
  background-color: lightblue;
}

h1 {
```

```
  color: white;
  text-align: center;
}

p {
  font-family: verdana;
  font-size: 20px;
}
```

PHP (Hypertext Preprocessor):

PHP (recursive acronym for PHP: Hypertext Preprocessor) is a widely-used open source general-purpose scripting language that is especially suited for web development and can be embedded into HTML.

Example:

```
<!DOCTYPE html>
<html>
    <head>
        <title>Example</title>
    </head>
    <body>
        <?php
          echo "Hi, I'm a PHP script!”;
        ?>
    </body>
</html>
```

Instead of lots of commands to output HTML (as seen in C or Perl), PHP pages contain HTML with embedded code that does "something" (in this case, output "Hi, I'm a PHP script!"). The PHP code is enclosed in special start and end processing instructions <?php and ?> that allow you to jump into and out of "PHP mode."

What distinguishes PHP from something like client-side JavaScript is that the code is executed on the server, generating HTML which is then sent to the client. The client would receive the results of running that script, but would not know what the underlying code was. You can even configure your web server to process all your HTML files with PHP, and then there's really no way that users can tell what you have up your sleeve.

The best things in using PHP are that it is extremely simple for a newcomer, but offers many advanced features for a professional programmer. Don't be afraid reading the long list of PHP's features. You can jump in, in a short time, and start writing simple scripts in a few hours.

Although PHP's development is focused on server-side scripting, you can do much more with it. PHP is mainly focused on server-side scripting, so you can do anything any other CGI program can do, such as collect form data, generate dynamic page content, or send and receive cookies. But PHP can do much more. There are three main areas where PHP scripts are used.

- **Server-side scripting:** This is the most traditional and main target field for PHP. You need three things to make this work: the PHP parser (CGI or server module), a web server and a web browser. You need to run the web server, with a connected PHP installation. You can access the PHP program output with a web browser, viewing the PHP page through the server. All these can run on your home machine if you are just experimenting with PHP programming.

- **Command line scripting:** You can make a PHP script to run it without any server or browser. You only need the PHP parser to use it this way. This type of usage is ideal for scripts regularly executed using cron (on *nix or Linux) or Task Scheduler (on Windows). These scripts can also be used for simple text processing tasks.

- **Writing desktop applications:** PHP is probably not the very best language to create a desktop application with a graphical user interface, but if you know PHP very well, and would like to use some advanced PHP features in your client-side applications you can also use PHP-GTK to write such programs. You also have the ability to write cross-platform applications this way. PHP-GTK is an extension to PHP, not available in the main distribution.

PHP can be used on all major operating systems, including Linux, many Unix variants (including HP-UX, Solaris and OpenBSD), Microsoft Windows, macOS, RISC OS, and probably others. PHP also has support for most of the web servers today. This includes Apache, IIS, and many others. And this includes any web server that can utilise the FastCGI PHP binary, like lighttpd and nginx. PHP works as either a module, or as a CGI processor.

So with PHP, you have the freedom of choosing an operating system and a web server. Furthermore, you also have the choice of using procedural programming or object oriented programming (OOP), or a mixture of them both.

With PHP you are not limited to output HTML. PHP's abilities includes outputting images, PDF files and even Flash movies (using libswf and Ming) generated on the fly. You can also output easily any text, such as XHTML and any other XML file. PHP can autogenerate these files, and save them in the file system, instead of printing it out, forming a server-side cache for your dynamic content.

One of the strongest and most significant features in PHP is its support for a wide range of databases. Writing a database-enabled web page is incredibly simple using one of the database specific extensions (e.g., for mysql), or using an abstraction layer like PDO, or connect to any database supporting the Open Database Connection standard via the ODBC extension. Other databases may utilise cURL or sockets, like CouchDB.

PHP also has support for talking to other services using protocols such as LDAP, IMAP, SNMP, NNTP, POP3, HTTP, COM (on Windows) and countless others. You can also open raw network sockets and interact using any other protocol. PHP has support for the WDDX complex data exchange between virtually all Web programming languages. Talking about interconnection, PHP has support for instantiation of Java objects and using them transparently as PHP objects.

PHP has useful text processing features, which includes the Perl compatible regular expressions (PCRE), and many extensions and tools to parse and access XML documents. PHP standardises all of the XML extensions on the solid base of libxml2, and extends the feature set adding SimpleXML, XMLReader and XMLWriter support.

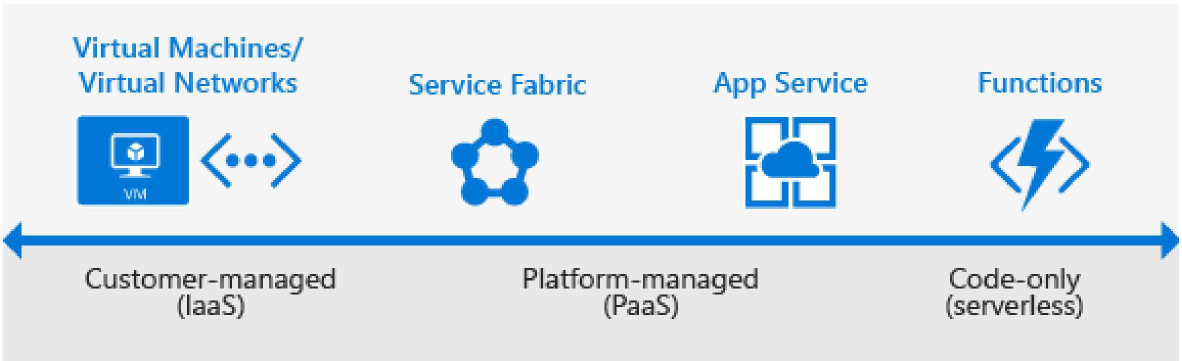
And many other interesting extensions exist, which are categorised both alphabetically and by category. And there are additional PECL extensions that may or may not be documented within the PHP manual itself, like XDebug.

3.2.2 Azure Cloud:

Azure is a complete cloud platform that can host your existing applications and streamline new application development. Azure can even enhance on-premises applications. Azure integrates the cloud services that you need to develop, test, deploy, and manage your applications, all while taking advantage of the efficiencies of cloud computing. By hosting your applications in Azure, you can start small and easily scale your application as your customer demand grows. Azure also offers the reliability that's needed for high-availability applications, even including failover between different regions. The Azure portal lets you easily manage all your Azure services. You can also manage your services programmatically by using service-specific APIs and templates.

Application hosting:

Azure provides several cloud-based compute offerings to run your application so that you don't have to worry about the infrastructure details. You can easily scale up or scale out your resources as your application usage grows. Azure offers services that support your application development and hosting needs. Azure provides Infrastructure as a Service (IaaS) to give you full control over your application hosting. Azure's Platform as a Service (PaaS) offerings provide the fully managed services needed to power your apps. There's even true server-less hosting in Azure where all you need to do is write your code.



Azure App Service:

When you want the quickest path to publish your web-based projects, consider Azure App Service. App Service makes it easy to extend your web apps to support your mobile clients and publish easily consumed REST APIs. This platform provides authentication by using social providers, traffic-based autoscaling, testing in production, and continuous and container-based deployments. You can create web apps, mobile app back ends, and API apps. Because all three app types share the App Service runtime, you can host a website, support mobile clients, and expose your APIs in Azure, all from the same project or solution.

App Service has been designed with DevOps in mind. It supports various tools for publishing and continuous integration deployments. These tools include GitHub webhooks, Jenkins, Azure DevOps, TeamCity, and others.

When to use: Use App Service when you're migrating existing web applications to Azure, and when you need a fully-managed hosting platform for your web apps. You can also use App Service when you need to support mobile clients or expose REST APIs with your app.

Azure Virtual Machines:

As an Infrastructure as a Service (IaaS) provider, Azure lets you deploy to or migrate your application to either Windows or Linux VMs. Together with Azure Virtual Network, Azure Virtual Machines supports the deployment of Windows or Linux VMs to Azure. With VMs, you have total control over the configuration of the machine. When using VMs, you're responsible for all server software installation, configuration, maintenance, and operating system patches.

Because of the level of control that you have with VMs, you can run a wide range of server workloads on Azure that don't fit into a PaaS model. These workloads include database servers, Windows Server Active Directory, and Microsoft SharePoint.

Azure Functions (serverless):

Rather than worrying about building out and managing a whole application or the infrastructure to run your code, you could just write your code and have it run in response to events or on a schedule. Azure Functions is a "server-less"-style offering that lets you write just the code you need. With Functions, you can trigger code execution with HTTP requests, webhooks, cloud service events, or on a schedule. You can code in your development language of choice, such as C#, F#, Node.js, Python, or PHP. With consumption-based billing, you pay only for the time that your code executes, and Azure scales as needed.

Azure Service Fabric:

Azure Service Fabric is a distributed systems platform. This platform makes it easy to build, package, deploy, and manage scalable and reliable micro-services. It also provides comprehensive application management capabilities such as:

- Provisioning
- Deploying
- Monitoring

- Upgrading/patching
- Deleting

Apps, which run on a shared pool of machines, can start small and scale to hundreds or thousands of machines as needed. Service Fabric supports WebAPI with Open Web Interface for .NET (OWIN) and ASP.NET Core. It provides SDKs for building services on Linux in both .NET Core and Java.

Azure Spring Cloud:

Azure Spring Cloud is a server-less micro-services platform that enables you to build, deploy, scale and monitor your applications in the cloud. Use Spring Cloud to bring modern micro-service patterns to Spring Boot apps, eliminating boilerplate code to quickly build robust Java apps.

- Leverage managed versions of Spring Cloud Service Discovery and Config Server, while we ensure those critical components are running in optimum conditions.
- Focus on building your business logic and we will take care of your service runtime with security patches, compliance standards and high availability.
- Manage application lifecycle (e.g.: deploy, start, stop, scale) on top of Azure Kubernetes Service.
- Easily bind connections between your apps and Azure services such as Azure Database for MySQL and Azure Cache for Redis.
- Monitor and troubleshoot microservices and applications using enterprise-grade unified monitoring tools that offer deep insights on application dependencies and operational telemetry.

Hosted storage and data access:

Most applications must store data, so however you decide to host your application in Azure, consider one or more of the following storage and data services.

- **Azure Cosmos DB:** A globally distributed, multi-model database service. This database enables you to elastically scale throughput and storage across any number of geographical regions with a comprehensive SLA.
- **Azure Storage:** Offers durable, highly available storage for blobs, queues, files, and other kinds of non-relational data. Storage provides the storage foundation for VMs.

- **Azure SQL Database:** An Azure-based version of the Microsoft SQL Server engine for storing relational tabular data in the cloud. SQL Database provides predictable performance, scalability with no downtime, business continuity, and data protection.

You can use Azure Data Factory to move existing on-premises data to Azure. If you aren't ready to move data to the cloud, Hybrid Connections in Azure App Service lets you connect your App Service hosted app to on-premises resources. You can also connect to Azure data and storage services from your on-premises applications.

Docker support:

Docker containers, a form of OS virtualization, let you deploy applications in a more efficient and predictable way. A containerized application works in production the same way as on your development and test systems. You can manage containers by using standard Docker tools. You can use your existing skills and popular open-source tools to deploy and manage container-based applications on Azure.

Azure provides several ways to use containers in your applications.

- **Azure Kubernetes Service:** Lets you create, configure, and manage a cluster of virtual machines that are preconfigured to run containerized applications. To learn more about Azure Kubernetes Service, see Azure Kubernetes Service introduction.
- **Docker Machine:** Lets you install and manage a Docker Engine on virtual hosts by using docker-machine commands.
- **Custom Docker image for App Service:** Lets you use Docker containers from a container registry or a customer container when you deploy a web app on Linux.

Authentication:

It's crucial to not only know who is using your applications, but also to prevent unauthorized access to your resources. Azure provides several ways to authenticate your app clients.

- **Azure Active Directory (Azure AD):** The Microsoft multitenant, cloud-based identity and access management service. You can add single-sign on (SSO) to your applications by integrating with Azure AD. You can access directory properties by using the Azure AD Graph API directly or the Microsoft Graph API. You can integrate with Azure AD support for the OAuth2.0 authorization framework and Open ID Connect by using native HTTP/REST endpoints and the multiplatform Azure AD authentication libraries.

- **App Service Authentication:** When you choose App Service to host your app, you also get built-in authentication support for Azure AD, along with social identity providers—including Facebook, Google, Microsoft, and Twitter.

Monitoring:

With your application up and running in Azure, you need to monitor performance, watch for issues, and see how customers are using your app. Azure provides several monitoring options.

- **Application Insights:** An Azure-hosted extensible analytics service that integrates with Visual Studio to monitor your live web applications. It gives you the data that you need to improve the performance and usability of your apps continuously. This improvement occurs whether you host your applications on Azure or not.
- **Azure Monitor:** A service that helps you to visualize, query, route, archive, and act on the metrics and logs that you generate with your Azure infrastructure and resources. Monitor is a single source for monitoring Azure resources and provides the data views that you see in the Azure portal.

DevOps integration:

Whether it's provisioning VMs or publishing your web apps with continuous integration, Azure integrates with most of the popular DevOps tools. You can work with the tools that you already have and maximize your existing experience with support for tools like:

- Jenkins
- GitHub
- Puppet
- Chef
- TeamCity

- Ansible
- Azure DevOps

Command-line interfaces and PowerShell:

Azure provides two ways to manage your applications and services from the command line. You can use tools like Bash, Terminal, the command prompt, or your command-line tool of choice. Usually, you can do the same tasks from the command line as in the Azure portal—such as creating and configuring virtual machines, virtual networks, web apps, and other services.

- **Azure Command-Line Interface (CLI):** Lets you connect to an Azure subscription and program various tasks against Azure resources from the command line.
- **Azure PowerShell:** Provides a set of modules with cmdlets that enable you to manage Azure resources by using Windows PowerShell.

Azure portal:

The Azure portal is a web-based application. You can use the Azure portal to create, manage, and remove Azure resources and services. It includes:

- A configurable dashboard
- Azure resource management tools
- Access to subscription settings and billing information. For more information, see the Azure portal overview.

REST APIs:

Azure is built on a set of REST APIs that support the Azure portal UI. Most of these REST APIs are also supported to let you programmatically provision and manage your Azure resources and applications from any Internet-enabled device.

APIs:

Along with REST APIs, many Azure services also let you programmatically manage resources from your applications by using platform-specific Azure SDKs, including SDKs for the following development platforms:

- .NET
- Node.js
- Java

- PHP
- Python
- Ruby
- Go

Services such as Mobile Apps and Azure Media Services provide client-side SDKs to let you access services from web and mobile client apps.

Azure Resource Manager:

Running your app on Azure likely involves working with multiple Azure services. These services follow the same life cycle and can be thought of as a logical unit. For example, a web app might use Web Apps, SQL Database, Storage, Azure Cache for Redis, and Azure Content Delivery Network services. Azure Resource Manager lets you work with the resources in your application as a group. You can deploy, update, or delete all the resources in a single, coordinated operation.

Along with logically grouping and managing related resources, Azure Resource Manager includes deployment capabilities that let you customize the deployment and configuration of related resources. For example, you can use Resource Manager deploy and configure an application. This application can consist of multiple virtual machines, a load balancer, and a database in Azure SQL Database as a single unit.

You develop these deployments by using an Azure Resource Manager template, which is a JSON-formatted document. Templates let you define a deployment and manage your applications by using declarative templates, rather than scripts. Your templates can work for different environments, such as testing, staging, and production. For example, you can use templates to add a button to a GitHub repo that deploys the code in the repo to a set of Azure services with a single click.

When to use: Use Resource Manager templates when you want a template-based deployment for your app that you can manage programmatically by using REST APIs, the Azure CLI, and Azure PowerShell.

3.2.3 Azure Databases:

Azure SQL:

Azure SQL is a family of managed, secure, and intelligent products that use the SQL Server database engine in the Azure cloud.

- **Azure SQL Database:** Support modern cloud applications on an intelligent, managed database service, that includes serverless compute.
- **Azure SQL Managed Instance:** Modernize your existing SQL Server applications at scale with an intelligent fully managed instance as a service, with almost 100% feature parity with the SQL Server database engine. Best for most migrations to the cloud.
- **SQL Server on Azure VMs:** Lift-and-shift your SQL Server workloads with ease and maintain 100% SQL Server compatibility and operating system-level access.

Azure SQL is built upon the familiar SQL Server engine, so you can migrate applications with ease and continue to use the tools, languages, and resources you're familiar with. Your skills and experience transfer to the cloud, so you can do even more with what you already have.

Learn how each product fits into Microsoft's Azure SQL data platform to match the right option for your business requirements. Whether you prioritize cost savings or minimal administration, this article can help you decide which approach delivers against the business requirements you care about most.

Overview:

In today's data-driven world, driving digital transformation increasingly depends on our ability to manage massive amounts of data and harness its potential. But today's data estates are increasingly complex, with data hosted on-premises, in the cloud, or at the edge of the network. Developers who are building intelligent and immersive applications can find themselves constrained by limitations that can ultimately impact their experience. Limitations arising from incompatible platforms, inadequate data security, insufficient resources and price-performance barriers create complexity that can inhibit app modernisation and development.

One of the first things to understand in any discussion of Azure versus on-premises SQL Server databases is that you can use it all. Microsoft's data platform leverages SQL Server technology and makes it available across physical on-premises machines, private cloud environments, third-party hosted private cloud environments, and the public cloud.

Fully managed and always up to date:

Spend more time innovating and less time patching, updating, and backing up your databases. Azure is the only cloud with evergreen SQL that automatically applies the latest updates and patches so that your databases are always up to date—eliminating end-of-support hassle. Even complex tasks like performance tuning, high availability, disaster recovery, and backups are automated, freeing you to focus on applications.

Protect your data with built-in intelligent security:

Azure constantly monitors your data for threats. With Azure SQL, you can:

- Remediate potential threats in real time with intelligent advanced threat detection and proactive vulnerability assessment alerts.
- Get industry-leading, multi-layered protection with built-in security controls including T-SQL, authentication, networking, and key management.
- Take advantage of the most comprehensive compliance coverage of any cloud database service.

Azure SQL Database:

Azure SQL Database is a relational database-as-a-service (DBaaS) hosted in Azure that falls into the industry category of *Platform-as-a-Service (PaaS)*.

- Best for modern cloud applications that want to use the latest stable SQL Server features and have time constraints in development and marketing.
- A fully managed SQL Server database engine, based on the latest stable Enterprise Edition of SQL Server. SQL Database has two deployment options built on standardised hardware and software that is owned, hosted, and maintained by Microsoft.

With SQL Server, you can use built-in features and functionality that requires extensive configuration (either on-premises or in an Azure virtual machine). When using SQL Database, you pay-as-you-go with options to scale up or out for greater power with no interruption. SQL Database has some additional features that are not available in SQL Server, such as built-in high availability, intelligence, and management.

Azure SQL Database offers the following deployment options:

- As a *single database* with its own set of resources managed via a logical SQL server. A single database is similar to a contained database in SQL Server. This option is optimised for modern application development of new cloud-born applications. Hyperscale and serverless options are available.
- An *elastic pool*, which is a collection of databases with a shared set of resources managed via a logical SQL server. Single databases can be moved into and out of an elastic pool. This option is optimised for modern application development of new cloud-

born applications using the multi-tenant SaaS application pattern. Elastic pools provide a cost-effective solution for managing the performance of multiple databases that have variable usage patterns.

Azure SQL Managed Instance:

Azure SQL Managed Instance falls into the industry category of *Platform-as-a-Service (PaaS)*, and is best for most migrations to the cloud. SQL Managed Instance is a collection of system and user databases with a shared set of resources that is lift-and-shift ready.

- Best for new applications or existing on-premises applications that want to use the latest stable SQL Server features and that are migrated to the cloud with minimal changes. An instance of SQL Managed Instance is similar to an instance of the Microsoft SQL Server database engine offering shared resources for databases and additional instance-scoped features.
- SQL Managed Instance supports database migration from on-premises with minimal to no database change. This option provides all of the PaaS benefits of Azure SQL Database but adds capabilities that were previously only available in SQL Server VMs. This includes a native virtual network and near 100% compatibility with on-premises SQL Server. Instances of SQL Managed Instance provide full SQL Server access and feature compatibility for migrating SQL Servers to Azure.

SQL Server on Azure VM:

SQL Server on Azure VM falls into the industry category *Infrastructure-as-a-Service (IaaS)* and allows you to run SQL Server inside a fully managed virtual machine (VM) in Azure.

- SQL Server installed and hosted in the cloud runs on Windows Server or Linux virtual machines running on Azure, also known as an infrastructure as a service (IaaS). SQL virtual machines are a good option for migrating on-premises SQL Server databases and applications without any database change. All recent versions and editions of SQL Server are available for installation in an IaaS virtual machine.
- Best for migrations and applications requiring OS-level access. SQL virtual machines in Azure are lift-and-shift ready for existing applications that require fast migration to the cloud with minimal changes or no changes. SQL virtual machines offer full

administrative control over the SQL Server instance and underlying OS for migration to Azure.

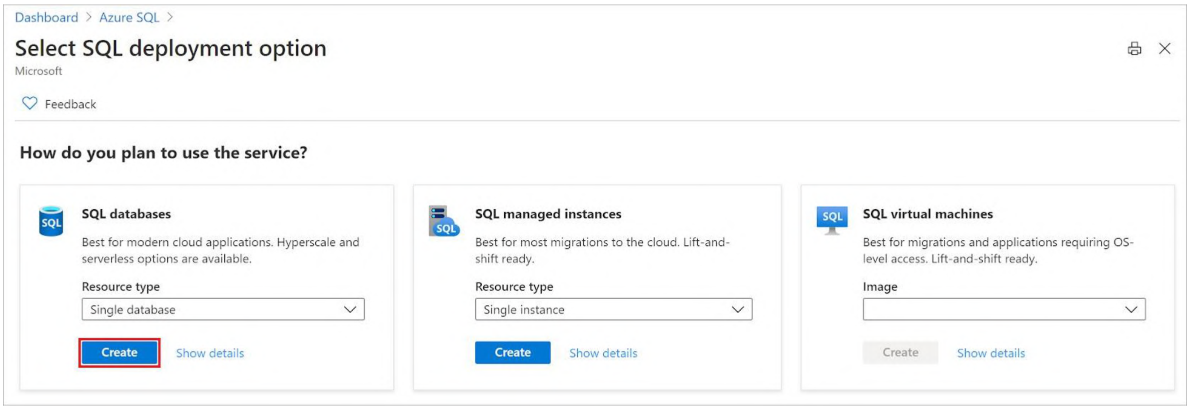
- The most significant difference from SQL Database and SQL Managed Instance is that SQL Server on Azure Virtual Machines allows full control over the database engine. You can choose when to start maintenance/patching, change the recovery model to simple or bulk-logged, pause or start the service when needed, and you can fully customise the SQL Server database engine. With this additional control comes the added responsibility to manage the virtual machine.
- Rapid development and test scenarios when you do not want to buy on-premises non-production SQL Server hardware. SQL virtual machines also run on standardised hardware that is owned, hosted, and maintained by Microsoft. When using SQL virtual machines, you can either pay-as-you-go for a SQL Server license already included in a SQL Server image or easily use an existing license. You can also stop or resume the VM as needed.
- Optimised for migrating existing applications to Azure or extending existing on-premises applications to the cloud in hybrid deployments. In addition, you can use SQL Server in a virtual machine to develop and test traditional SQL Server applications. With SQL virtual machines, you have the full administrative rights over a dedicated SQL Server instance and a cloud-based VM. It is a perfect choice when an organisation already has IT resources available to maintain the virtual machines. These capabilities allow you to build a highly customised system to address your application's specific performance and availability requirements.

AZURE PORTAL: General Steps to Follow:

To create a single database in the Azure portal:

1. Browse to the Select SQL Deployment option page.

2. Under SQL databases, leave Resource type set to Single database, and select Create.



3. On the Basics tab of the Create SQL Database form, under Project details, select the desired Azure Subscription.

4. For Resource group, select Create new, enter *myResourceGroup*, and select OK.

5. For Database name enter *mySampleDatabase*.

6. For Server, select Create new, and fill out the New server form with the following values:

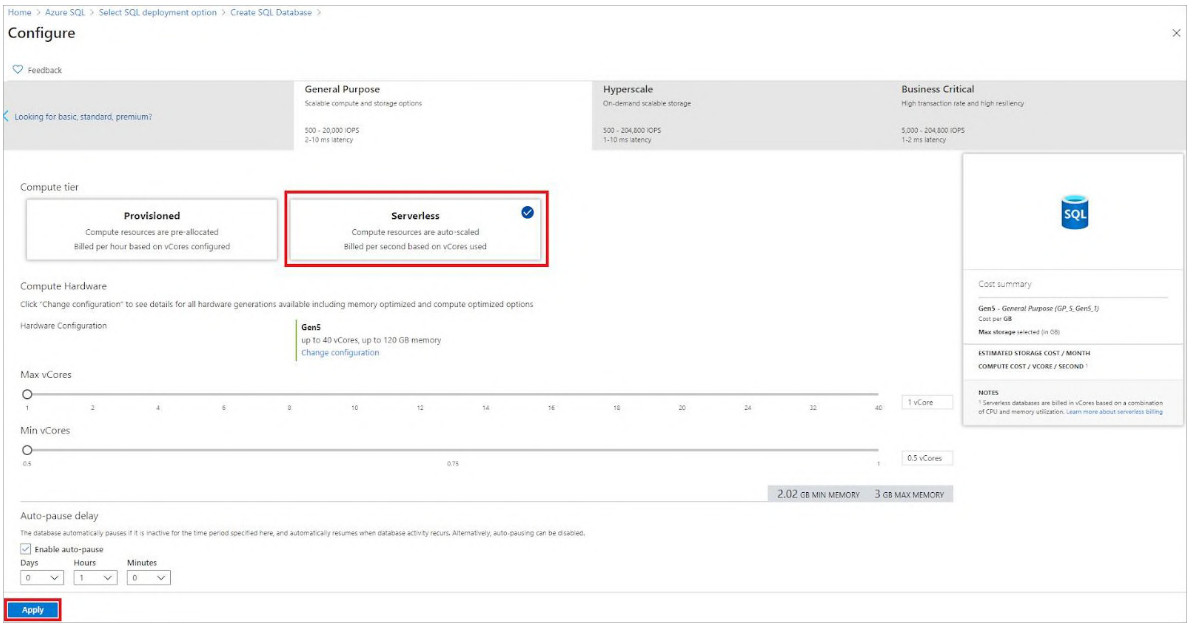
- **Server name:** Enter *mysqlserver*, and add some characters for uniqueness. We can't provide an exact server name to use because server names must be globally unique for all servers in Azure, not just unique within a subscription. So enter something like mysqlserver12345, and the portal lets you know if it is available or not.
- **Server admin login:** Enter *azureuser*.
- **Password:** Enter a password that meets requirements, and enter it again in the Confirm password field.
- **Location:** Select a location from the dropdown list.

7. Select OK.

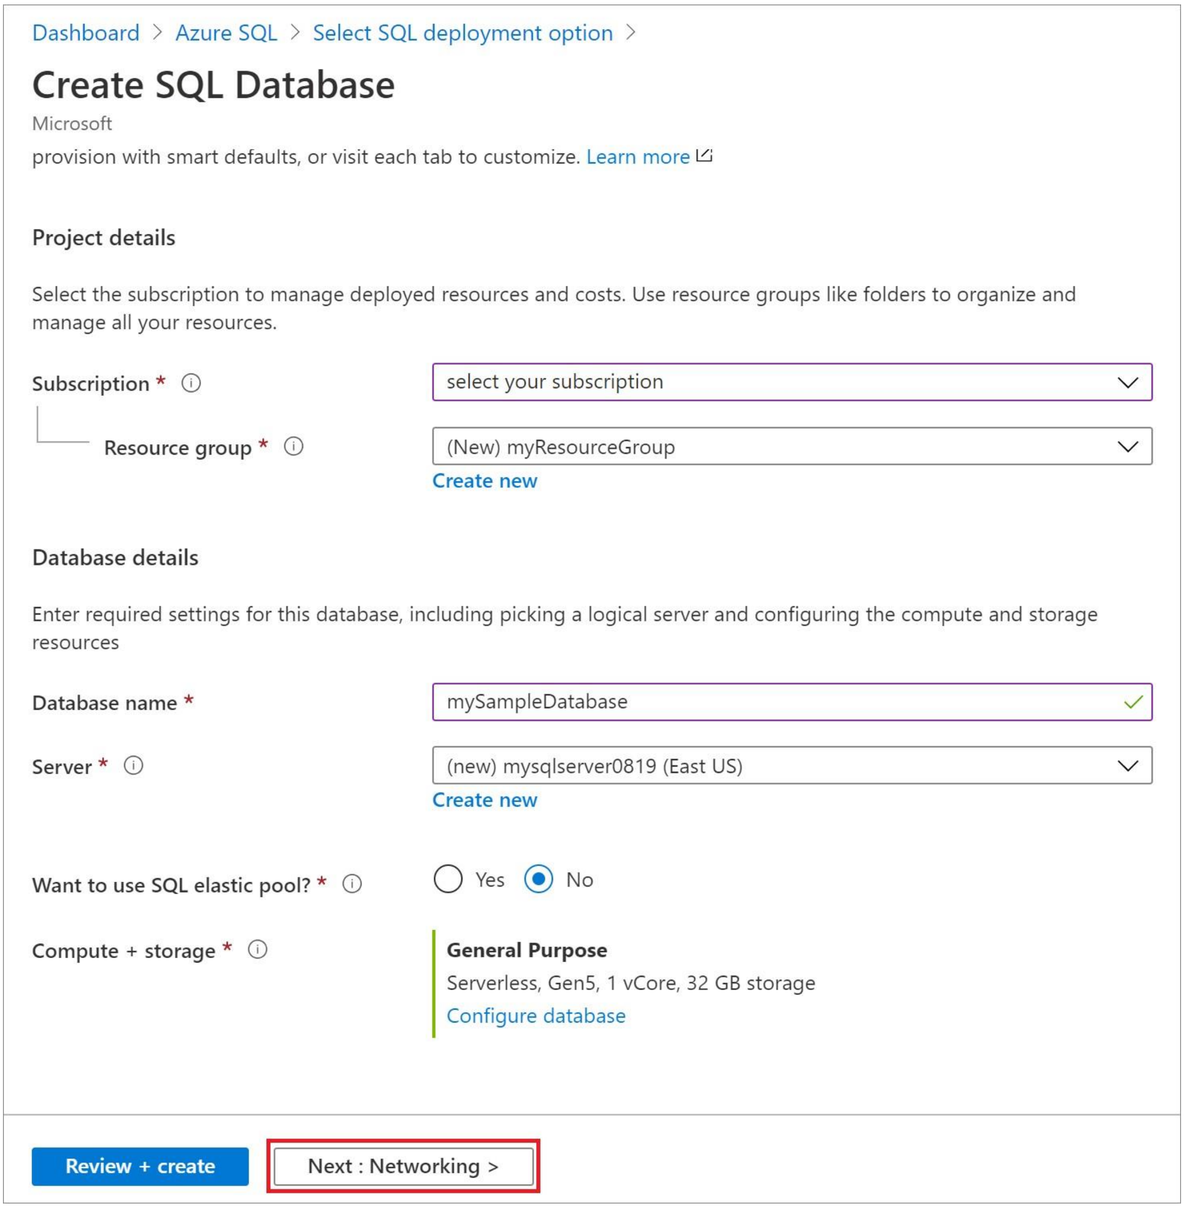
8. Leave Want to use SQL elastic pool set to No.

9. Under Compute + storage, select Configure database.

10. This quickstart uses a serverless database, so select Serverless, and then select Apply.



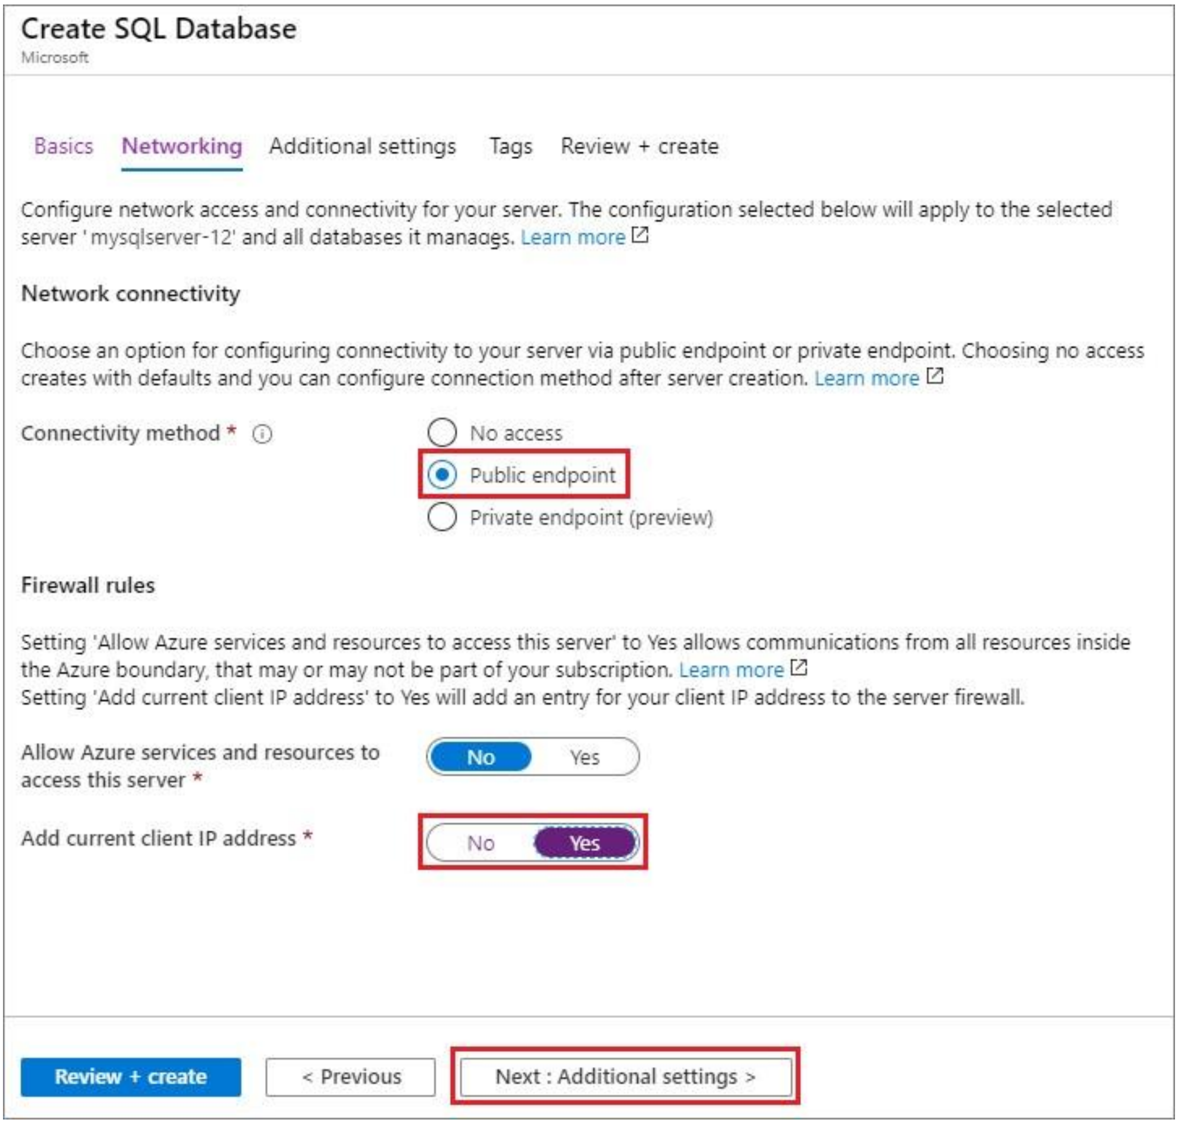
11. Select Next: Networking at the bottom of the page.



12. On the Networking tab, for Connectivity method, select Public endpoint.

13. For Firewall rules, set Add current client IP address to Yes. Leave Allow Azure services and resources to access this server set to No.

14. Select Next: Additional settings at the bottom of the page.

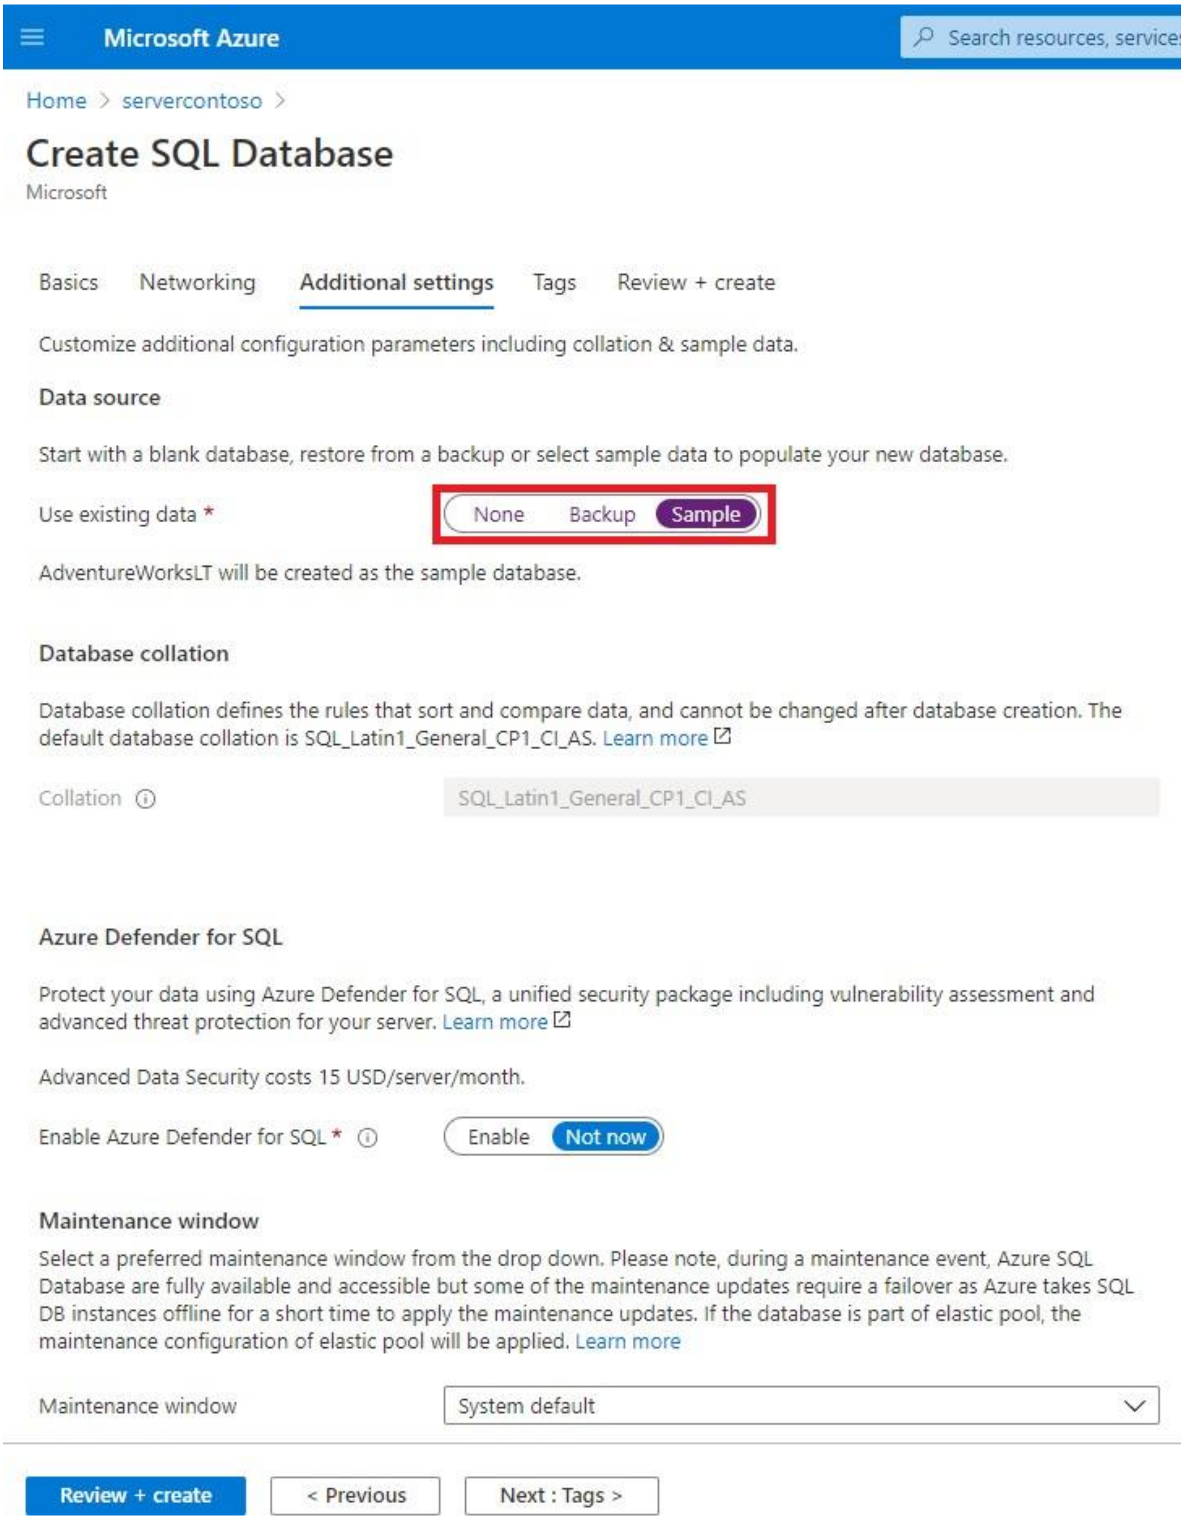


15. On the Additional settings tab, in the Data source section, for Use existing data, select Sample. This creates an AdventureWorksLT sample database so there's some tables and data to query and experiment with, as opposed to an empty blank database.

16. Optionally, enable Azure Defender for SQL.

17. Optionally, set the maintenance window so planned maintenance is performed at the best time for your database.

18. Select Review + create at the bottom of the page:



19. On the Review + create page, after reviewing, select Create.

Query the database:

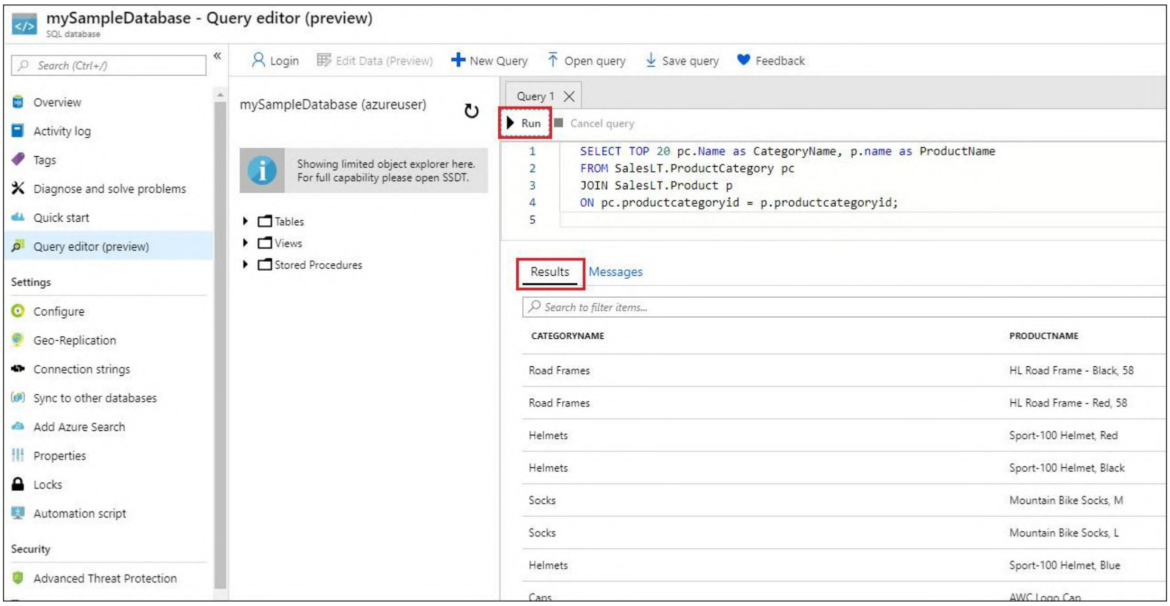
Once your database is created, you can use the Query editor (preview) in the Azure portal to connect to the database and query data.

1. In the portal, search for and select SQL databases, and then select your database from the list.

2. On the page for your database, select Query editor (preview) in the left menu.

3. Enter your server admin login information, and select OK.

4. Select Run, and then review the query results in the Results pane.



5. Close the Query editor page, and select OK when prompted to discard your unsaved edits.

Next Steps:

Connect and query your database using different tools and languages:

- SQL Server Management Studio
- Azure Data Studio

4. PROJECT IMPLEMENTATION

4.0 SYSTEM DESCRIPTION

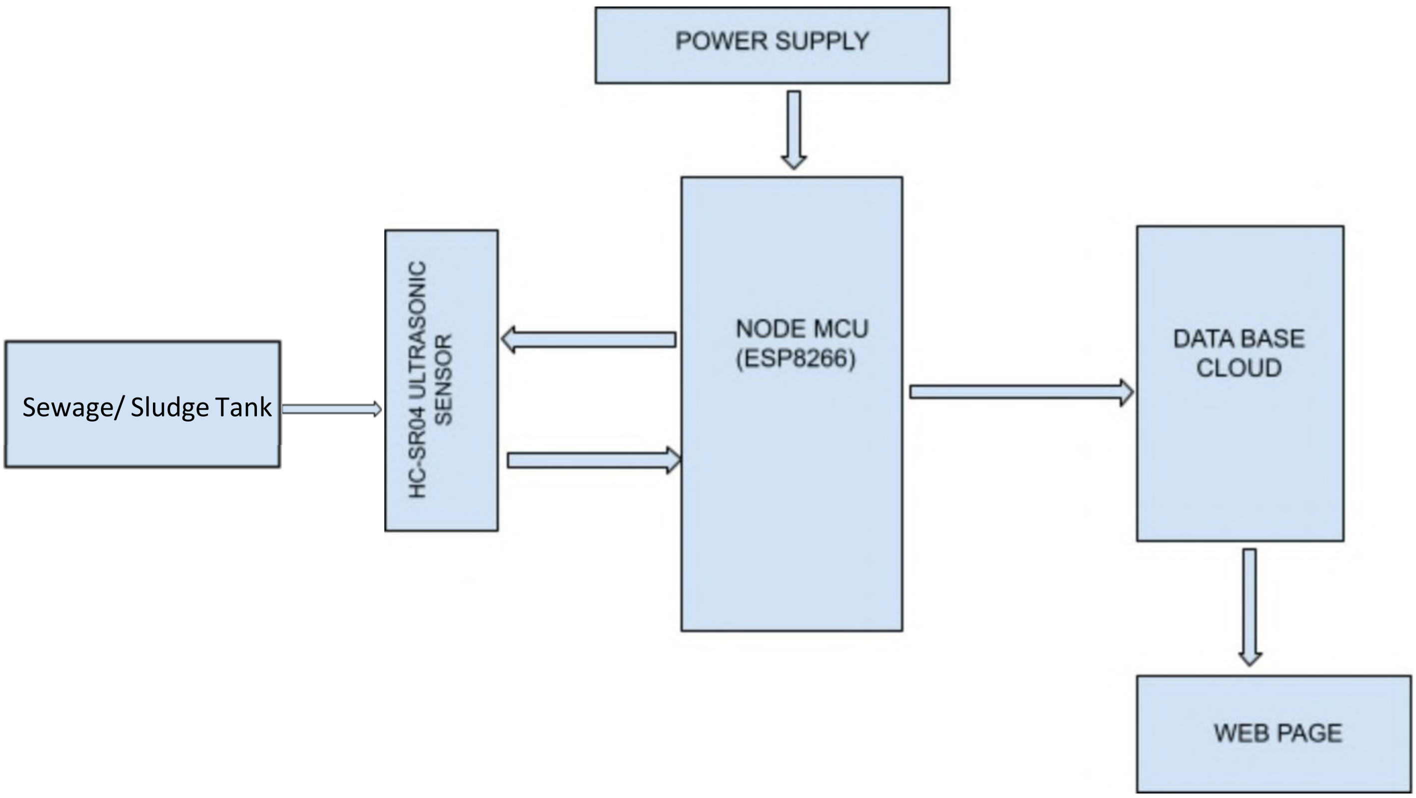


Fig 25: Block Schematic for the Project

- First, on powering the set, the NodeMCU starts connecting to a network (previously setup in the code).
- HC-SR04 Ultrasonic Sensor detects the remaining level, and continuously sends these values to Node MCU.
- Node MCU sends the data to the Cloud DB, through WiFi module which uses PHP Read and PHP Write.
- This data is stored in the Cloud, in an SQL database, which is retrieved using a Webpage. HTML’s High-charts class in the Webpage processes the data, and displays it as a Chart, and as Digital Readings.

4.1 CIRCUIT DIAGRAM

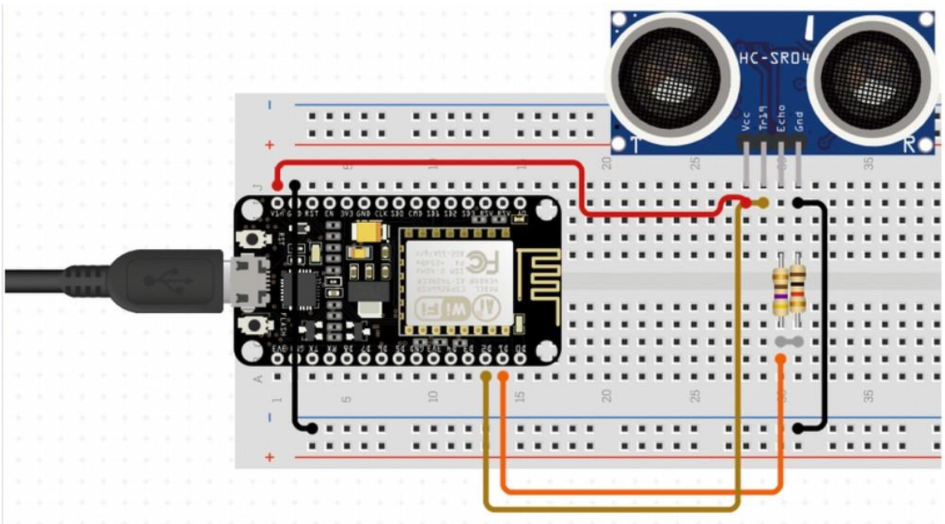

Fig 26: Circuit Schematic for the Project

4.2 RESULTS

The project "**Sewage Level Monitoring System using IoT**" is done. This system provides continuous monitoring-both analog and digital to our sludge tanks. Here is a low-cost, efficient circuit to monitor your sludge level in the chamber/tank. An Ultrasonic distance measuring sensor and an ESP8266 module, which are easily available in the market, can be used to build this device. Now there's no concern that the sludge-tank overflows. To perform this entire task using ESP8266 microcontroller, code is written in embedded C language (for Networking) and HTML (for Monitoring over the Web or App).

Fig 27: Final Model

5. PROJECT TESTING

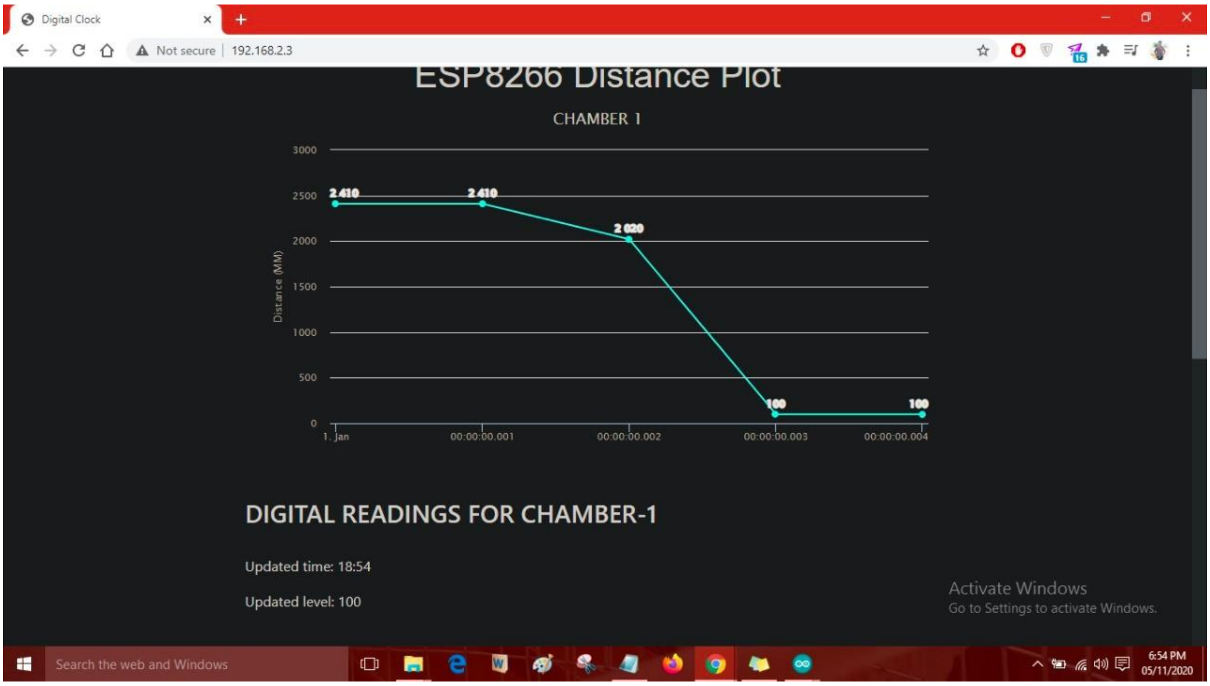

Fig 28: Output Screen for Webpage displaying the level

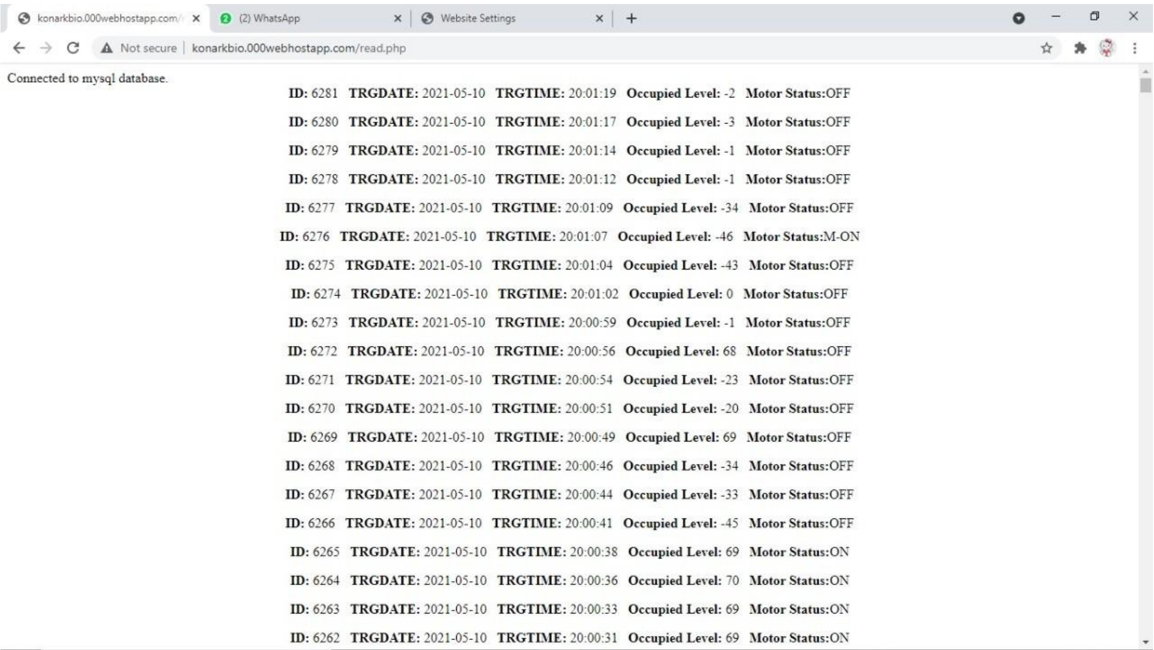

Fig 29: Output Screen for Cloud DB page displaying the levels with respective timestamp

6. CONCLUSION AND FUTURE ENHANCEMENT

6.0 Conclusion:

Integrating features of the hardware components used have been developed in it. Presence of every module has been reasoned out and placed carefully, thus contributing to the best working of the unit. Secondly, using highly advanced IC's with the help of growing technology, the project has been successfully implemented. Thus the project has been successfully designed and tested.

6.1 Future Scope:

Our project "**Sewage Level Monitoring System using IoT**" consists of NodeMCU microcontroller. As of now, an Ultrasonic distance measuring sensor is interfaced to the Arduino microcontroller.

6.1.0 GSM Message Alert System as a Backup for Active Internet Connection:

But this model could be further enhanced by integrating an Optical Ultrasonic sensor (for maximum precision) or even a Radar system. And integrating a GSM module helps in sending emergency SMS alerts in case of chances of overflowing, if any. As an ESP8266 module consists of 17 (D0 to D16) [all are usable] GPIO pins, hence 8 slave devices (Sensors) could be connected to the same master (NodeMCU). Hence more number of tanks could be monitored using a single controller, making the effective cost of the setup lesser than ever.

Fig 30: GSM Module (SIM 900)

6.1.1 Liquid Level Monitoring System:

Also, the same approach could be used for Liquid Sewage's Level Monitoring.

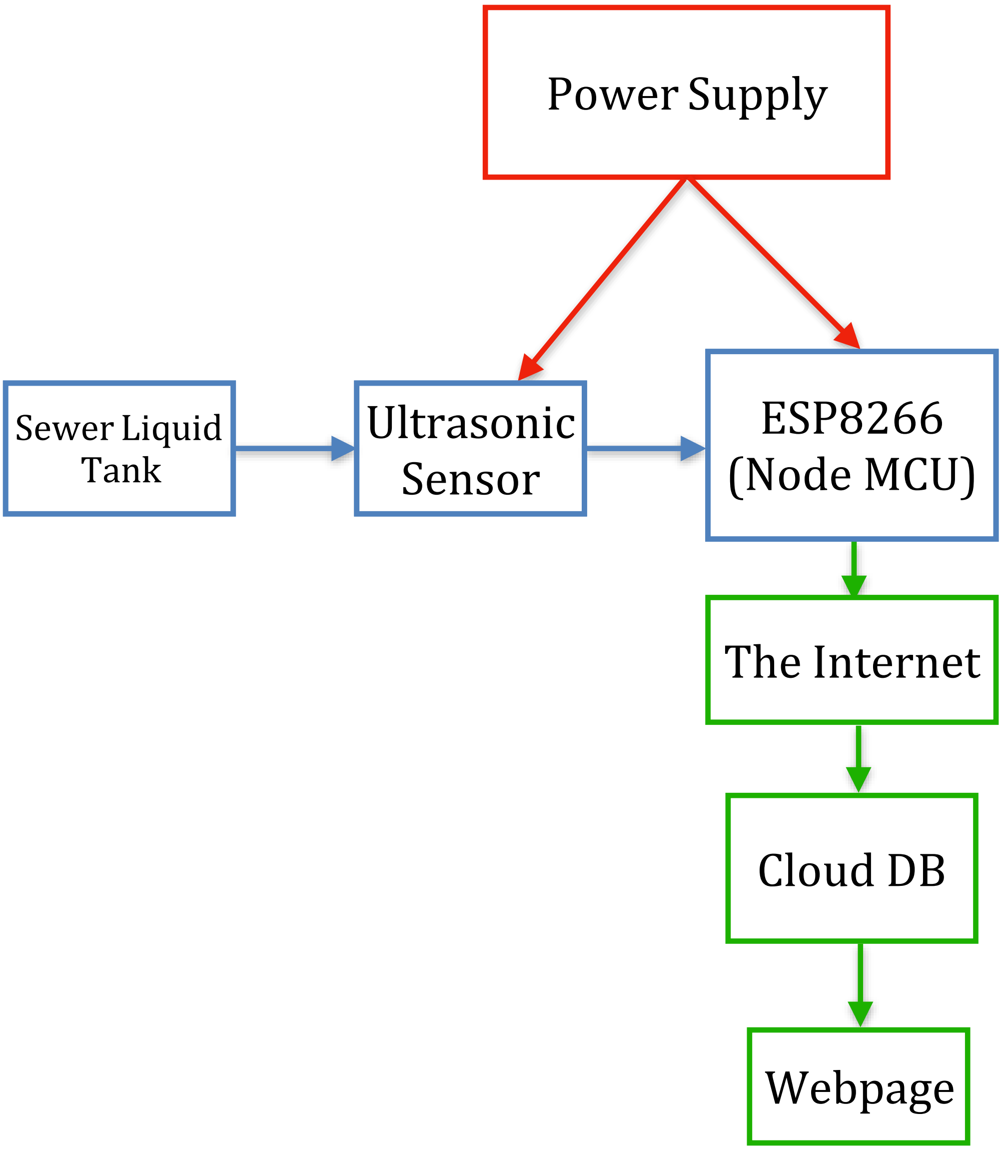

Fig 31: Block Schematic for the Liquid Level Monitoring System

PUBLICATION

Submitted paper in the Conference ICSMEC-21 with Paper ID (ICSMEC21-0074) and got Acceptance for the Paper.

APPENDICES

This project aims to measure and analyse the real-time levels of sewage. This project attempts to device an IoT technology that shall measure the sludge level while keeping a record of the data history in a Cloud Database. It can be accessed by using Web Browser and Cloud Database on the connected devices of the authorised people who are remotely located.

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to Dr.B.Hari Krishna, **Head &Professor**, the Dept. of Electronics and Communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.Anand,** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Ms.D.Kirtana Assistant Professor** ,Department of ECE and our class coordinator **Mrs.A.Soumya**, **Assistant Professor**, Department of ECE and for guidance and encouragement in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalayadri, Professor in IT and Dr.R.Santosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

TABLE OF CONTENTS

LIST OF FIGURES

ABSTRACT

We here propose an automatic dam water level monitor and controller system. Our proposed project uses sensors to sense the water level and then opens the dam gate (motor used to demonstrate as dam gate) according to the water level. Our system uses multiple water level sensors (float sensors) for this purpose. The sensor are mounted at three different levels in order to check water level and provide signals accordingly. When water reaches first level it is sensed by it and displayed. When water reaches second level it provides a signal to the microcontroller and it opens the dam gate partially. As soon as the water level reaches the third position, it signals the microcontroller and the microcontroller then signals the motor to run, which is demonstrated as opening the dam gate fully. Thus, our proposed system allows for automatic dam gate opening based on water level sensing.

CHAPTER 1
INTRODUCTION
1.1 PROJECT OVERVIEW:

A Microcontroller is a computer-on-a-chip or a single-chip computer that contains the processor (the CPU), non-volatile memory for the program (ROM or flash), volatile memory for input and output (RAM), a clock and an I/O control unit. Micro suggests that the device is small and controller tells that the device might be used to control objects, processes or events. Another term is Embedded Microcontroller tells that it support circuits are often built into or embedded in the devices for control. You find microcontroller in all kinds of things never days. It is used for measures, controls, stores or displays information by placing microcontroller inside any device. The largest single use for microcontroller in automobiles-car manufactured today includes at least one microcontroller for engine control and more to control additional systems. In desktop computer, you may find microcontrollers inside keyboards, modems, printers, and other peripherals. In test equipment, microcontrollers make things easier to store measurement, to create and store user routines, and to display messages and waveforms. Consumer products like cameras, video recorders, compact-disk players, and ovens. And they are so many applications where we use microcontrollers. A micro controller is similar to the microprocessor inside a personal computer. Examples are Intel's 8086, Zilog's Z80. Both microprocessors and microcontrollers contain CPU. The CPU executes instructions that perform the basic logic, math, and data moving functions of a computer. To make a complete computer, a microprocessor require memory for storing data and programs, and I/O interfaces for connecting external devices like keyboard and displays. In contrast, microcontrollers are a single chip computer because it contains memory and I/O interfaces in addition to the CPU. It tends to limit the amount of memory and interfaces that can fit on single chip, microcontrollers tend to be used in smaller system. Examples of popular microcontrollers are Intel's 8052, 89C052, Motorola's 68HC11 and Zilog's Z8. The following are some of the capabilities of 8051 microcontroller:

- Internal ROM and RAM
- I/O ports with programmable pins
- Timers and counters

Serial data communication Motion control, in electronic terms, means to accurately control the movement of an object based on speed, distance, load, inertia or a combination of all these factors. There are numerous types of motion control systems, including; Stepper

Motor, Linear Step Motor, DC Brush, Brushless Servo and more. This document will concentrate on Step Motor technology. Like many conventional electric motors, a “stepper motor consists of a magnet and coils of wire. Whereas conventional motors spin continuously, a stepper motor moves around one small step at a time (hence the name). A stepper motor is a marvel in simplicity. It has no brushes, or contacts. Basically, it’s a synchronous motor with the magnetic field electronically switched to rotate the armature magnet around. “The stepper motor is an electromagnetic device that converts digital pulses into mechanical shaft or spindle rotation”. The shaft or spindle of a stepper motor rotates in discrete step increments when electrical command pulses are applied to it in the proper sequence. The motors rotation has several direct relationships to these applied input pulses. The sequence of the applied pulses is directly related to the direction of motor shafts rotation. The speed of the motor shafts rotation is directly related to the frequency of the input pulses and the length of rotations applied. The simplest way to think of a stepper motor is a bar magnet and four coils.

CHAPTER 2

EMBEDDED SYSTEMS

PROJECT DESIGN:

2.1 EMBEDDED DESIGN:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

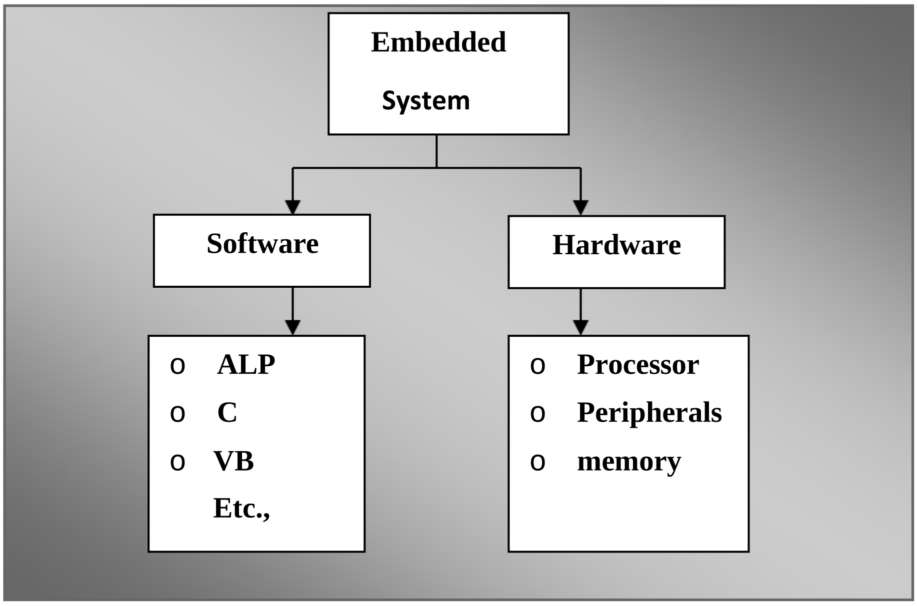

Figure 2.1 Block diagram of Embedded System

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

Micro Processor (μp):

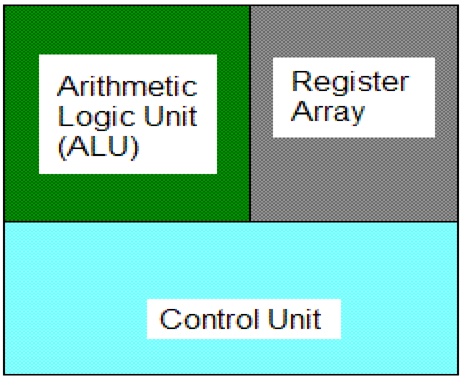
A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).



Three Basic Elements of a Microprocessor

Micro Controller (μc):

A microcontroller is a small computer on a single **integrated circuit** containing a processor core, memory, and programmable **input/output** peripherals. Program memory in the form of **NOR flash** or **OTP ROM** is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the **microprocessors** used in **personal computers** or other general purpose applications.

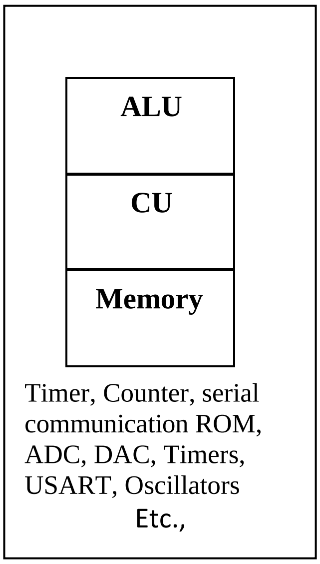


Figure 2.2 Block Diagram of Micro Controller (μc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program

- ➢ Analog circuits to provide clocks and interface to the real world which is analog in nature
- ➢ I/Os to connect to external components like LEDs, memories, monitors etc.

2.2 Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and
2. CISC (Complex Instruction Set computer)

2.2.1 Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- ➢ A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- ➢ Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.
- ➢ The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

2.2.2 RISC characteristics

- ➢ **Simple instruction set:**

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- ➢ **Same length instructions.**

Each instruction is the same length, so that it may be fetched in a single operation.

- ➢ **1machine-cycleinstructions.**

Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

2.2.3 Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generationof computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.

➢ CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

2.3 Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

2.3.1 Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The **Harvard architecture** is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

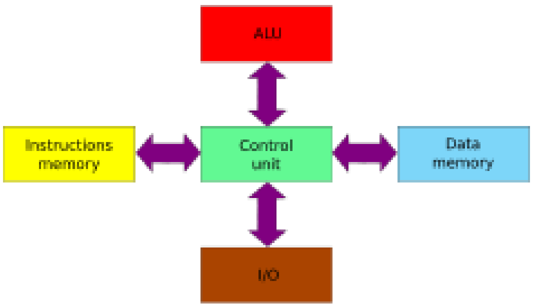

Figure 2.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.
- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.3.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

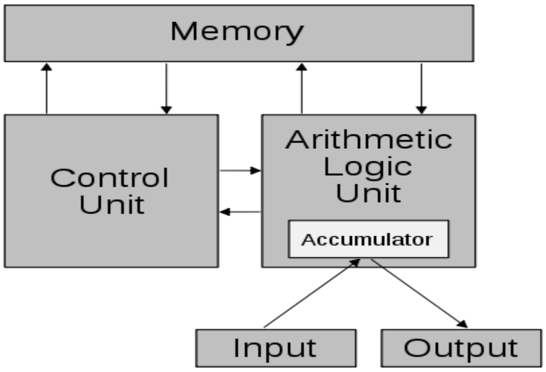

Figure 2.4 Schematic of the Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER 3

POWER SUPPLY

3.1 Block Diagram

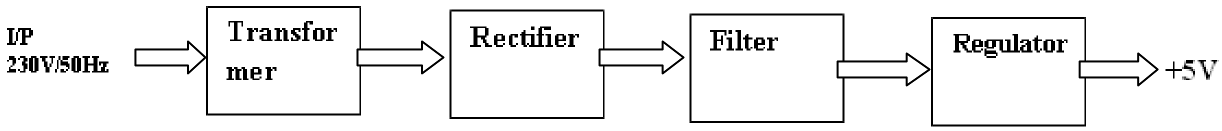

Figure 3.1 Power Supply

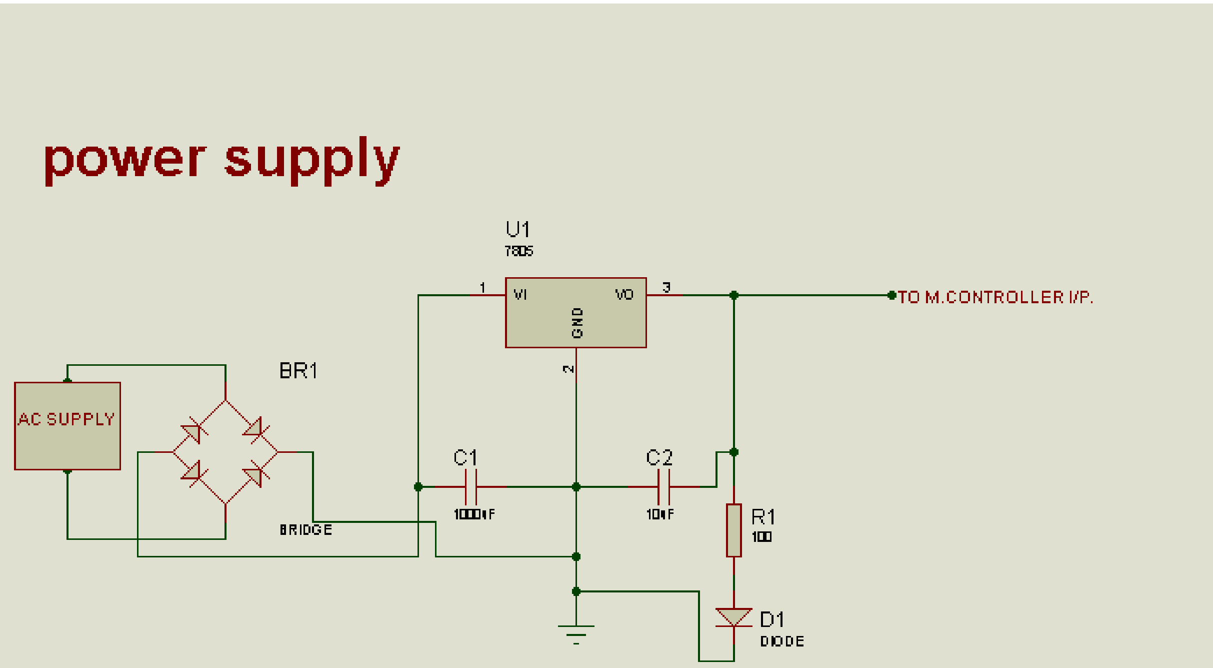
3.2 Circuit Diagram



Description

3.2.1 Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

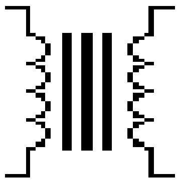


Figure: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

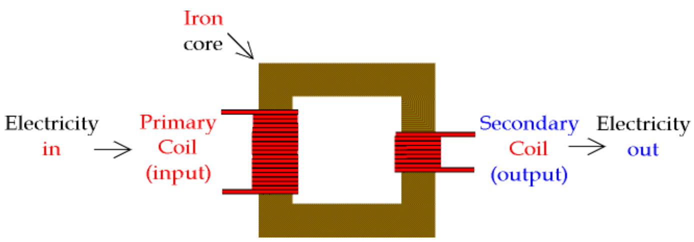

Figure 3.2 Transformer

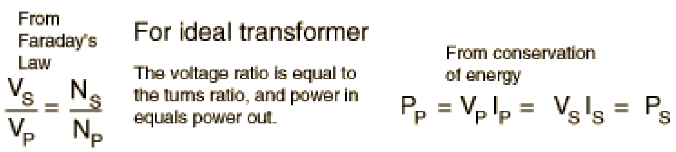
Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.



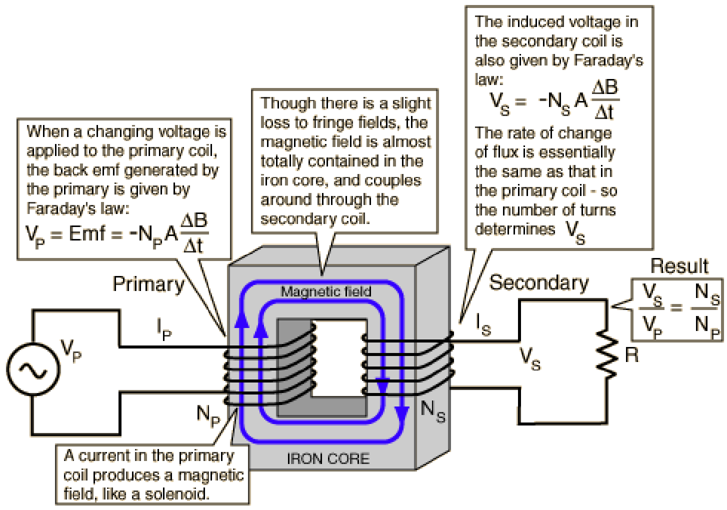


Figure: Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

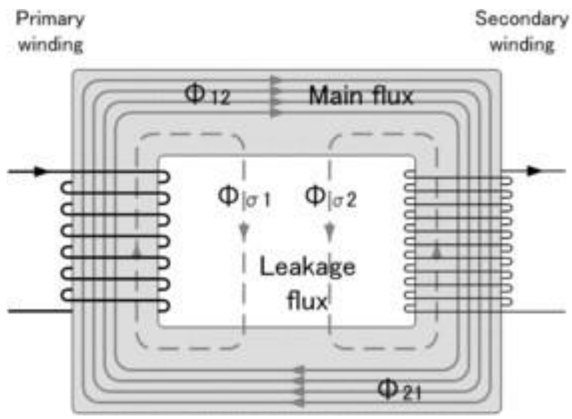

Figure: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

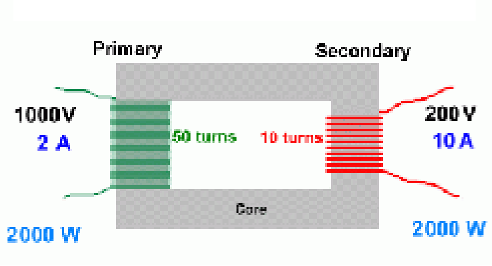

Figure: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

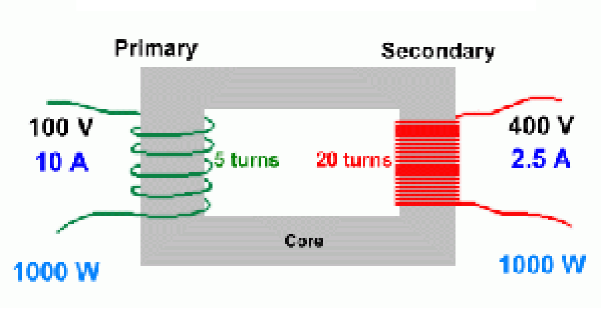

Figure: Step-Up Transformer

Applications

Generally these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

3.2.2 Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

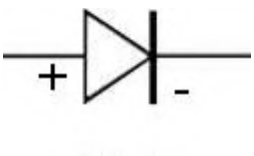

Figure 3.3 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.2.3 Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-wave Rectifier

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure .

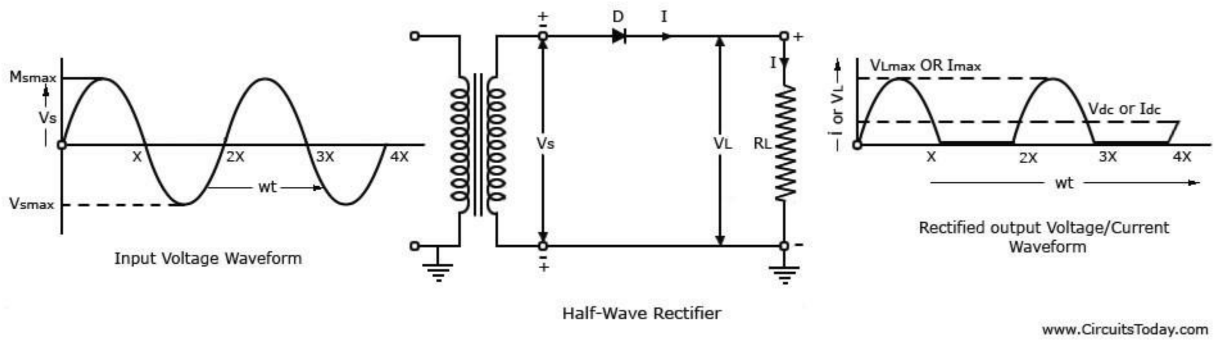

Figure 3.4 Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

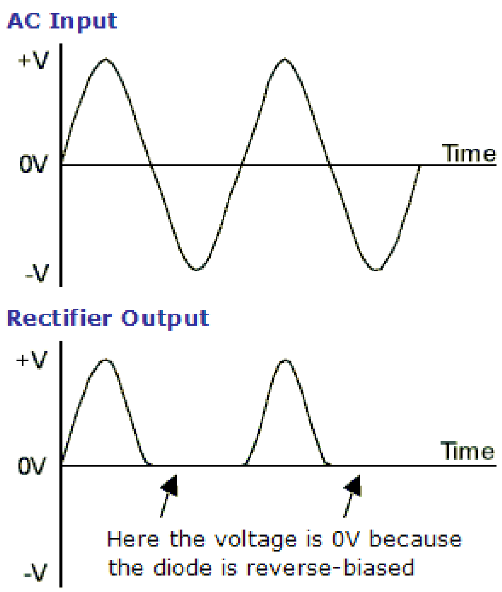

Figure 3.5 Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 4.

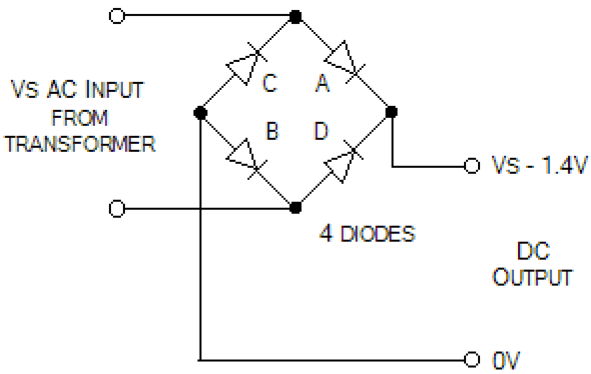

Figure Full-Wave Rectifier

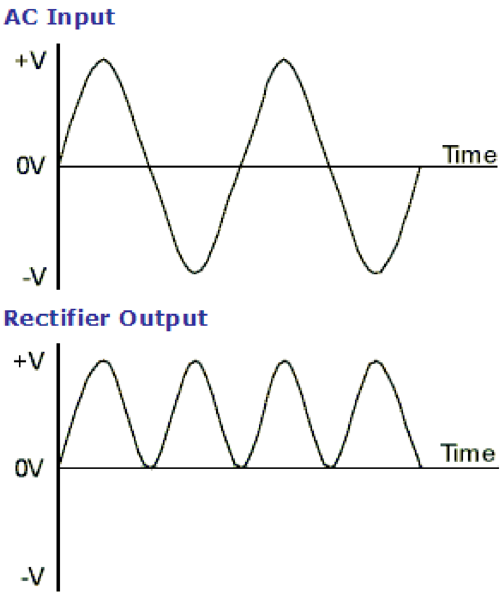

Figure Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

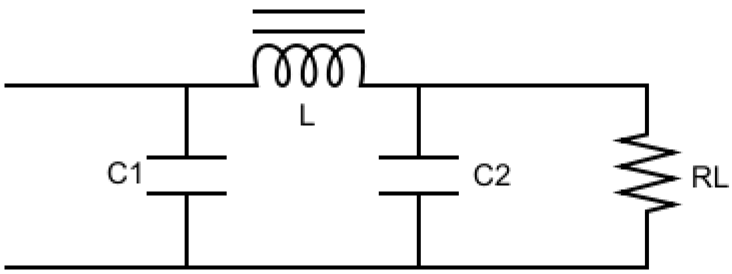

Figure: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an

appreciable amount of the AC component while the DC component continues its journey to the inductor L

2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

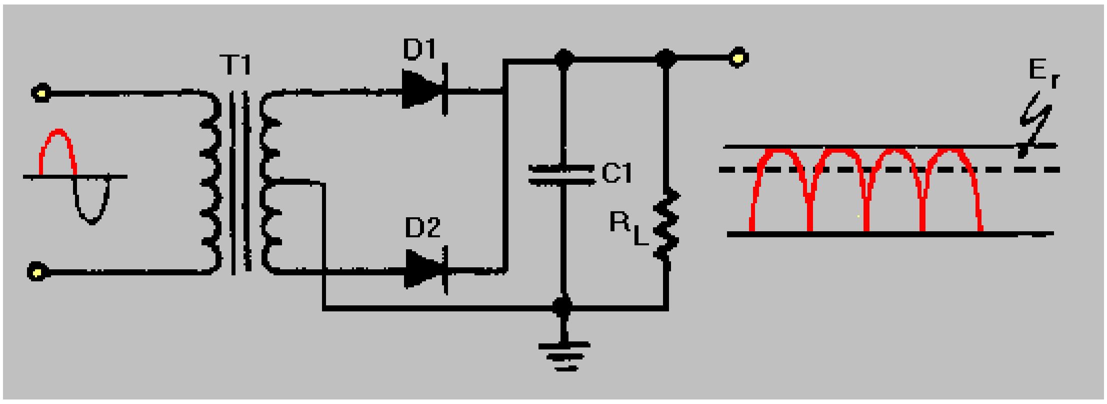

Figure: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.2.4 Voltage Regulator:

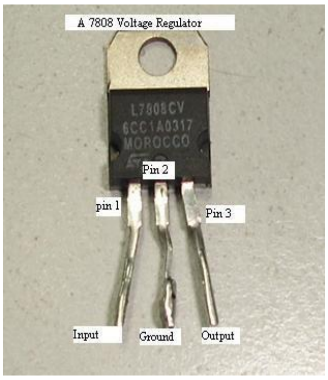
A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05' indicates the regulator output is -5V.

These regulators consists the three pins there are



Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

Figure 3.6 Regulator

CHAPTER 4

SOFTWARE

4.1 Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.1.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

4.1.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.2 Starting New Design

Step 1: Open ISIS software and select New design in File menu

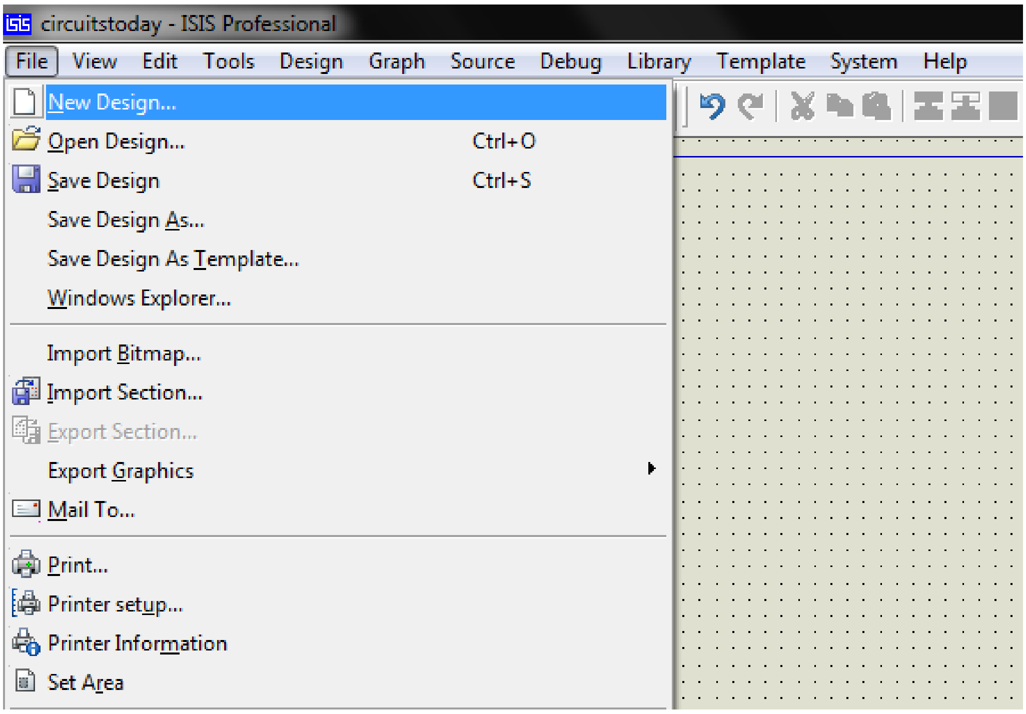


Figure 4.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

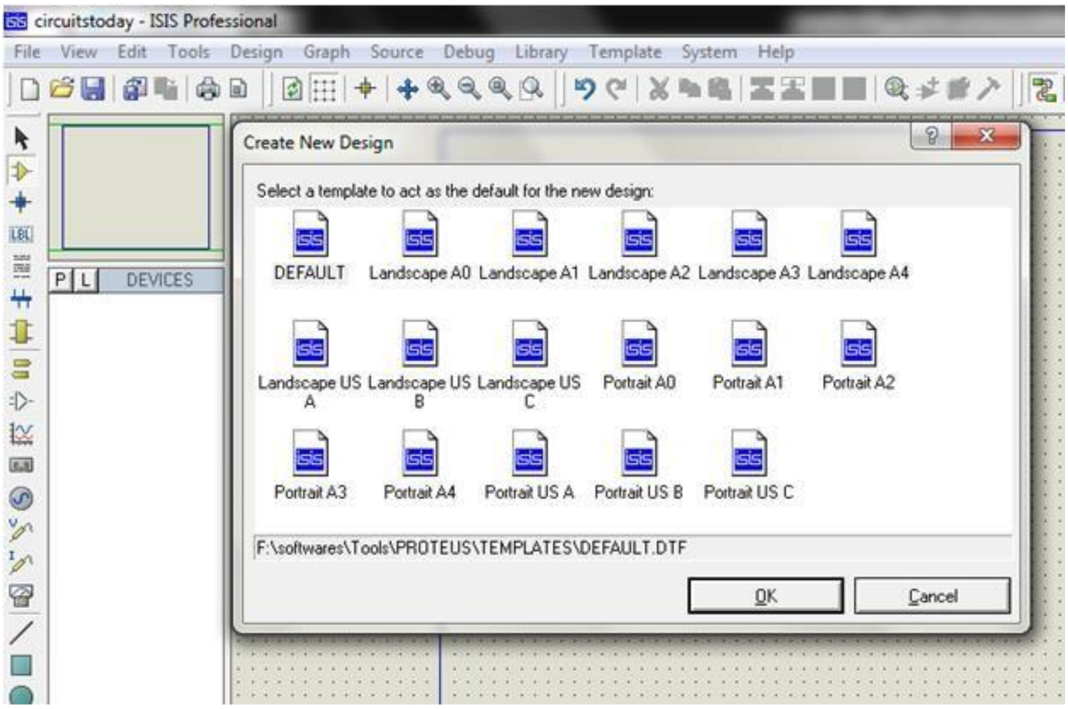

Figure 4.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

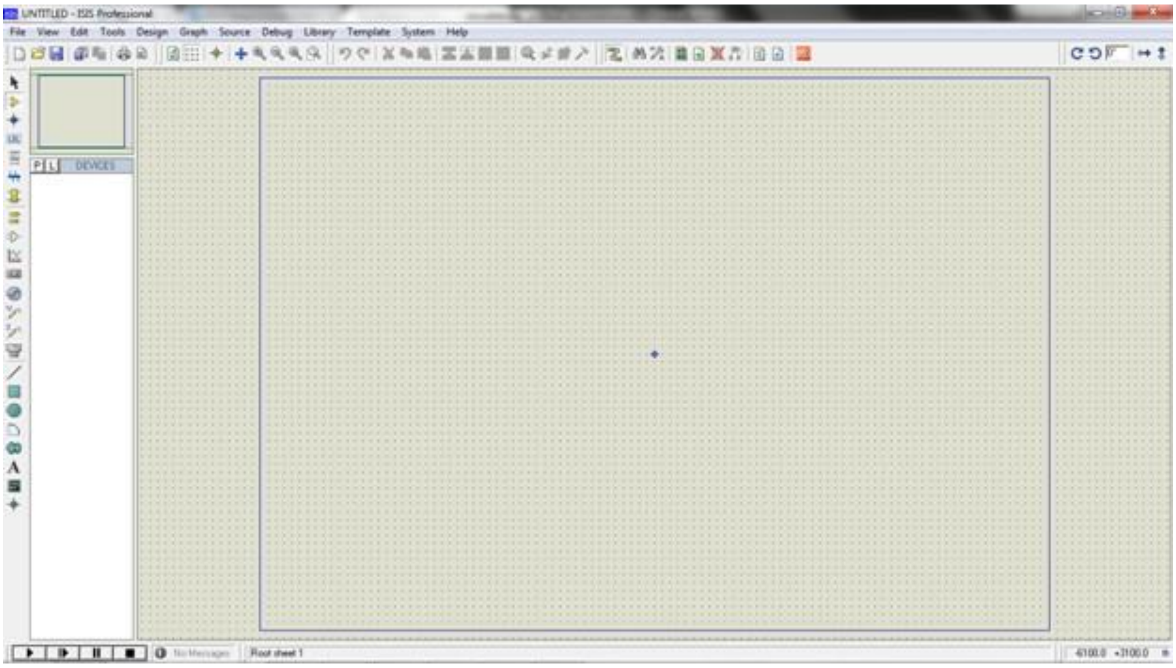

Figure 4.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

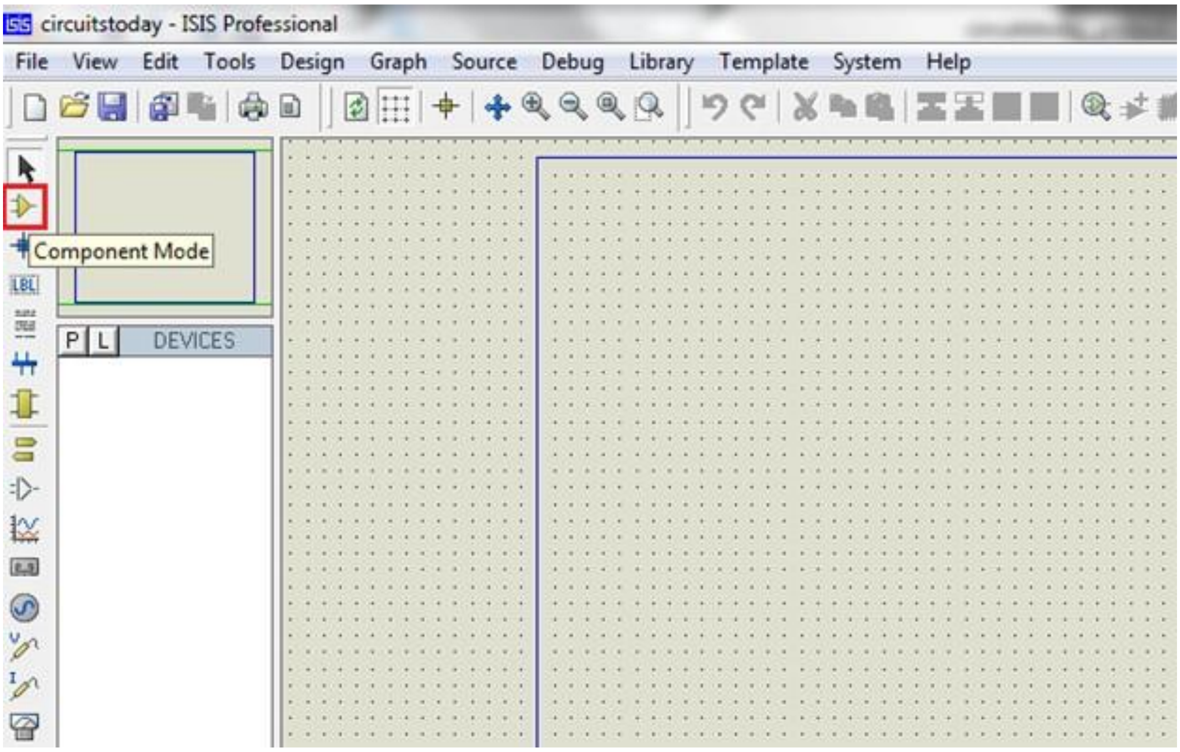

Figure 4.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

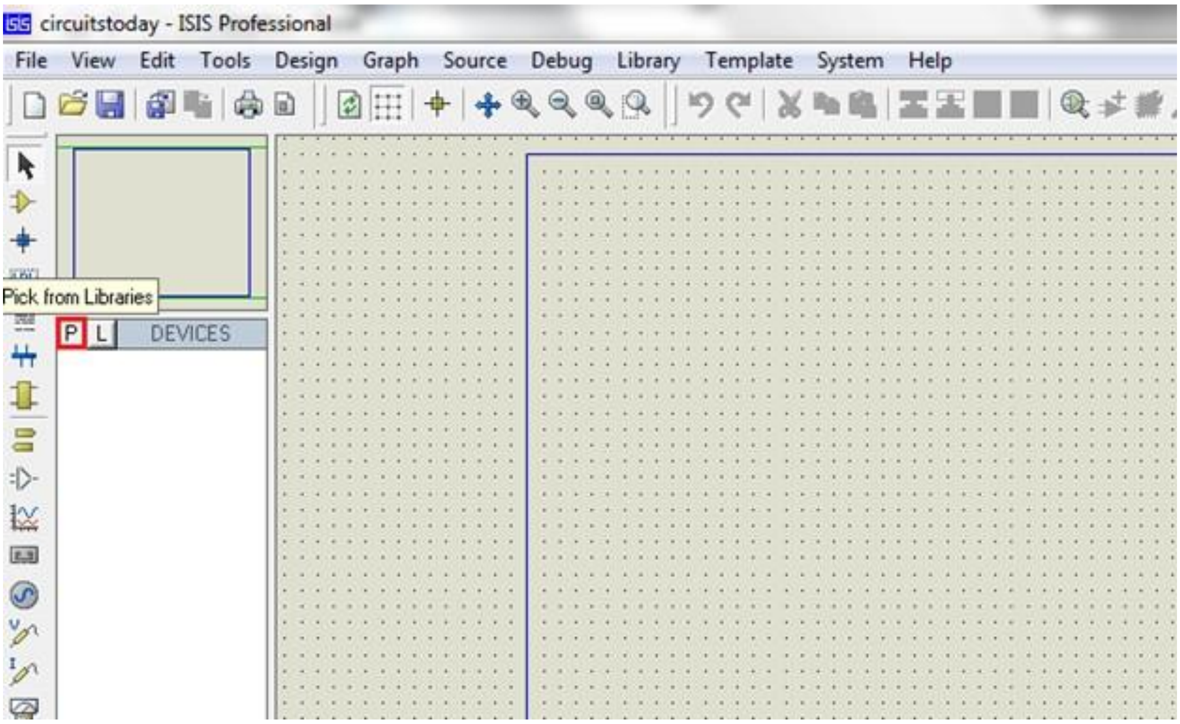

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

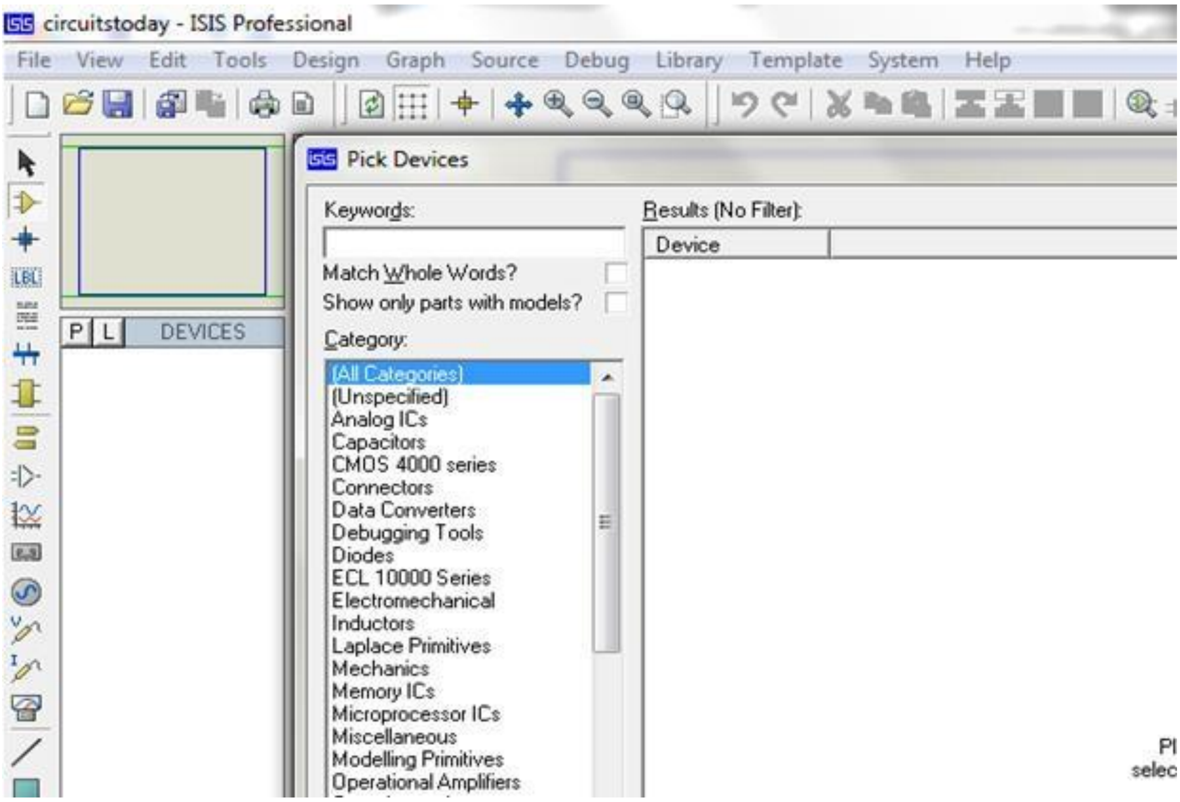

Figure 4.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

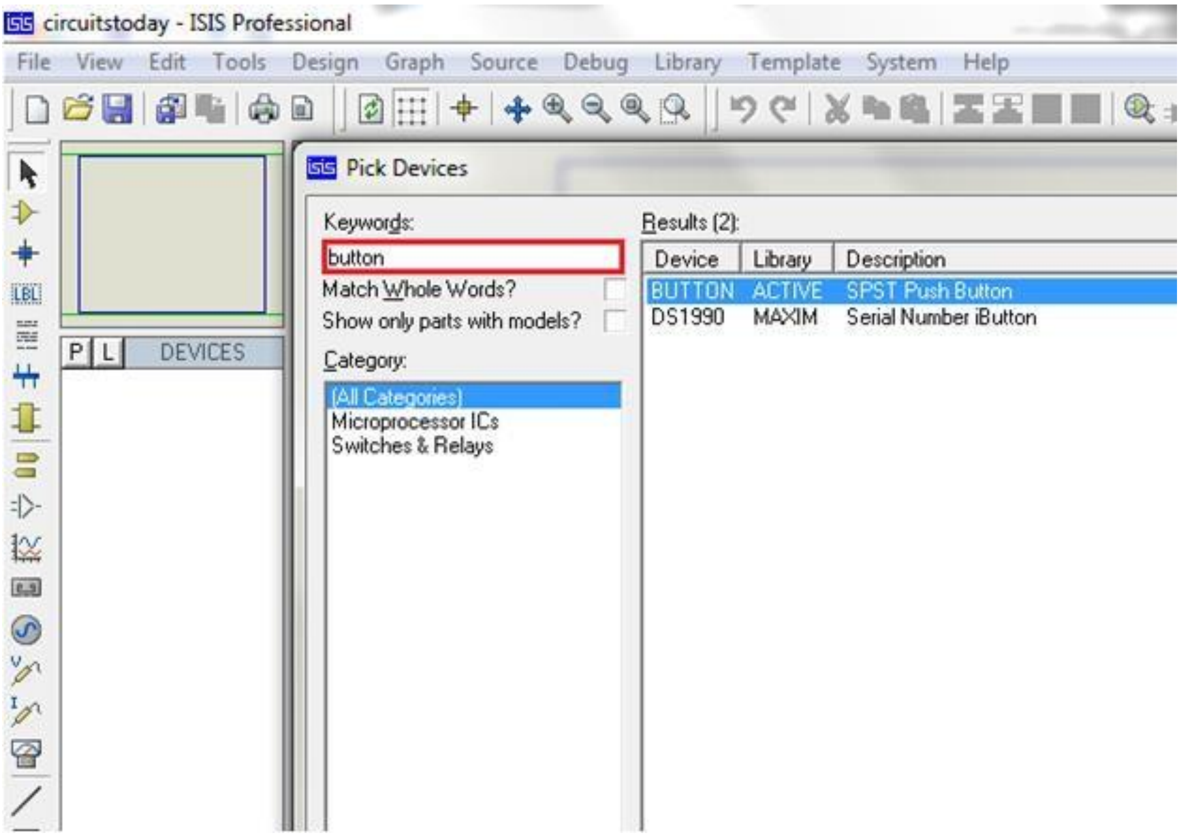

Figure 4.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

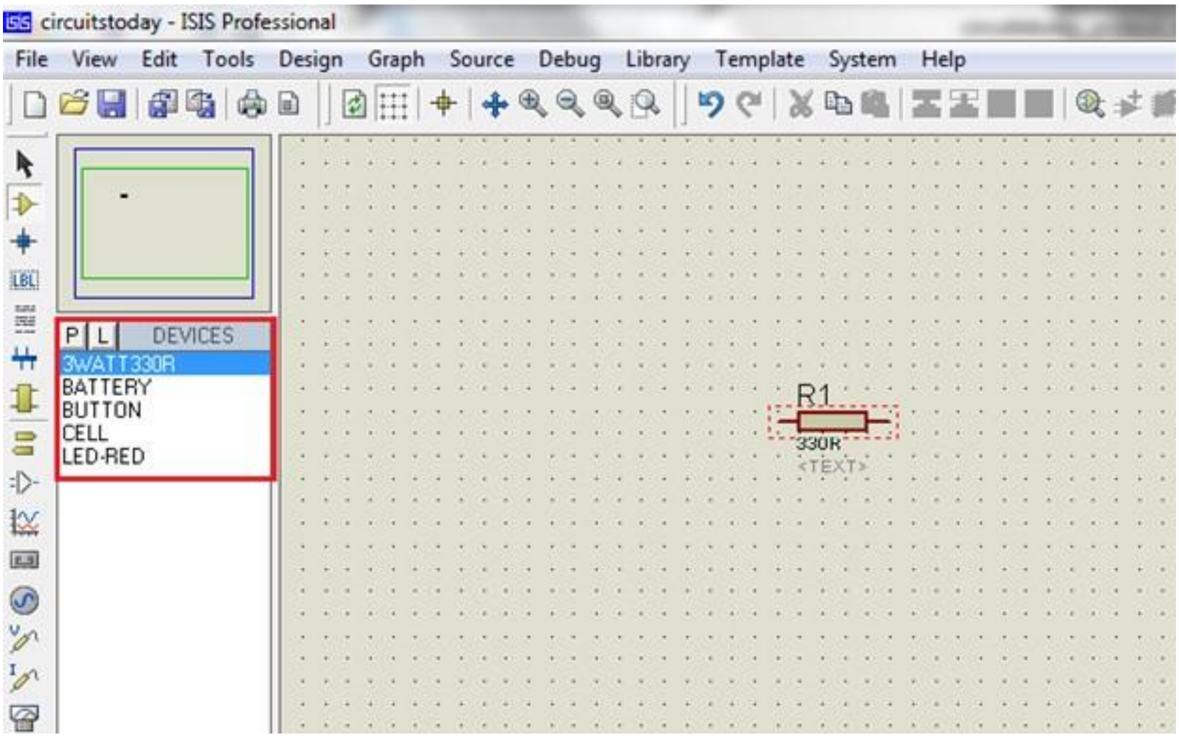

Figure 4.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

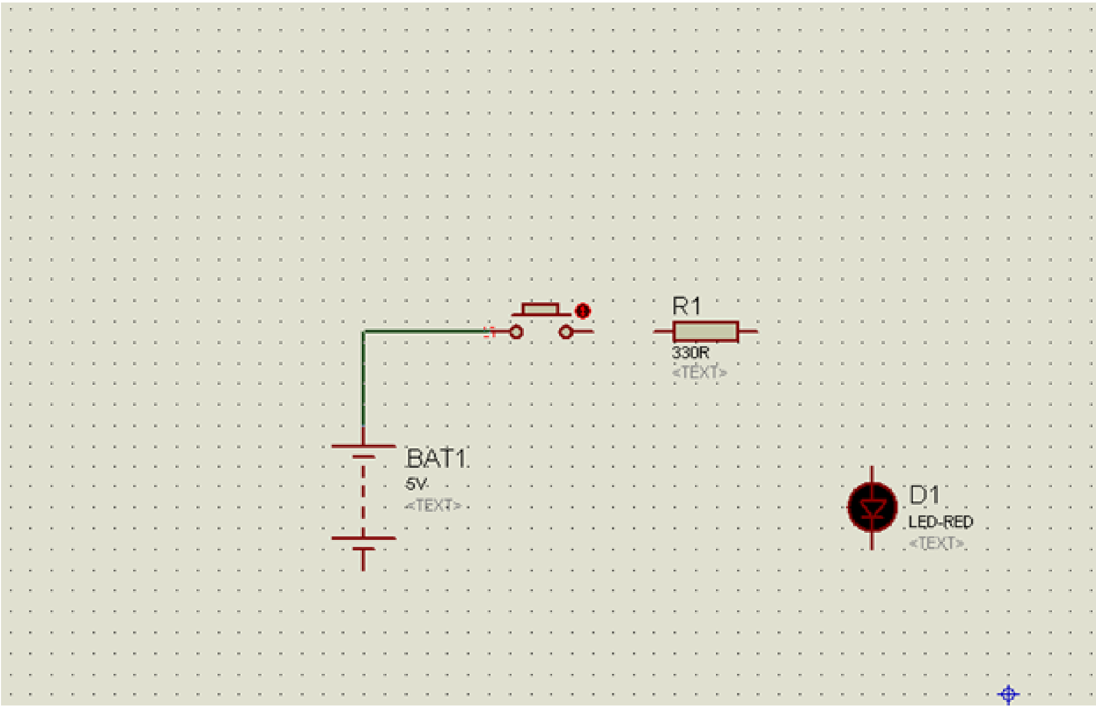

Figure 4.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

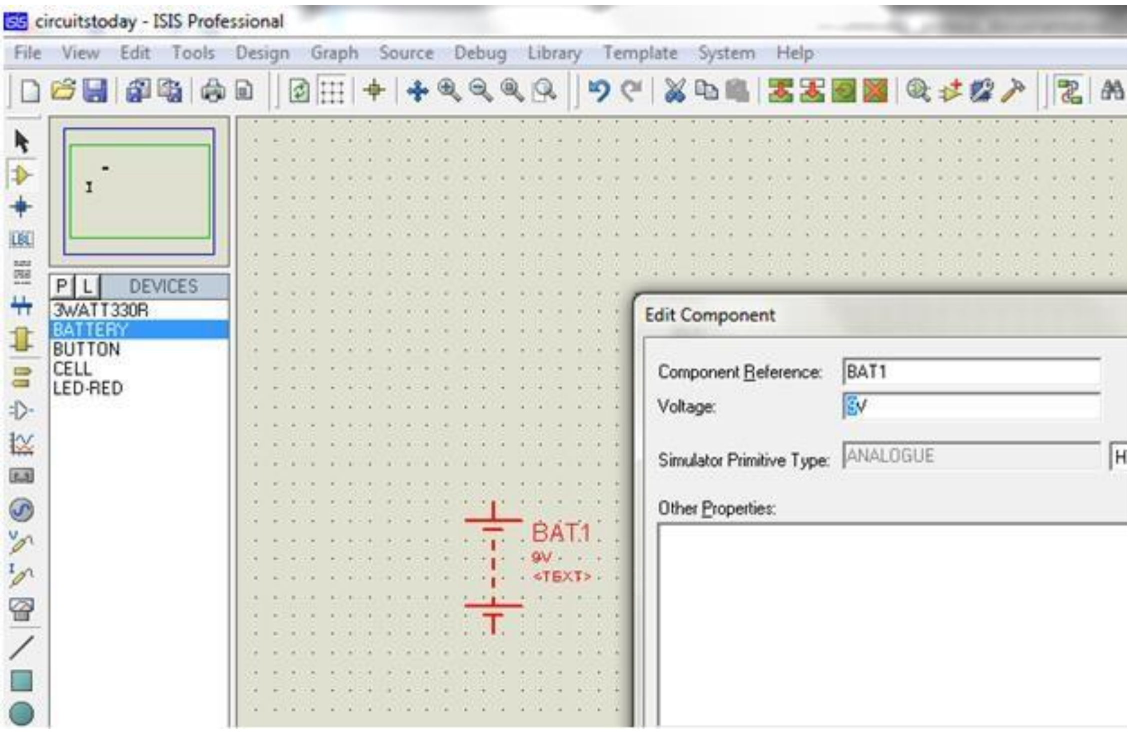

Figure 4.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

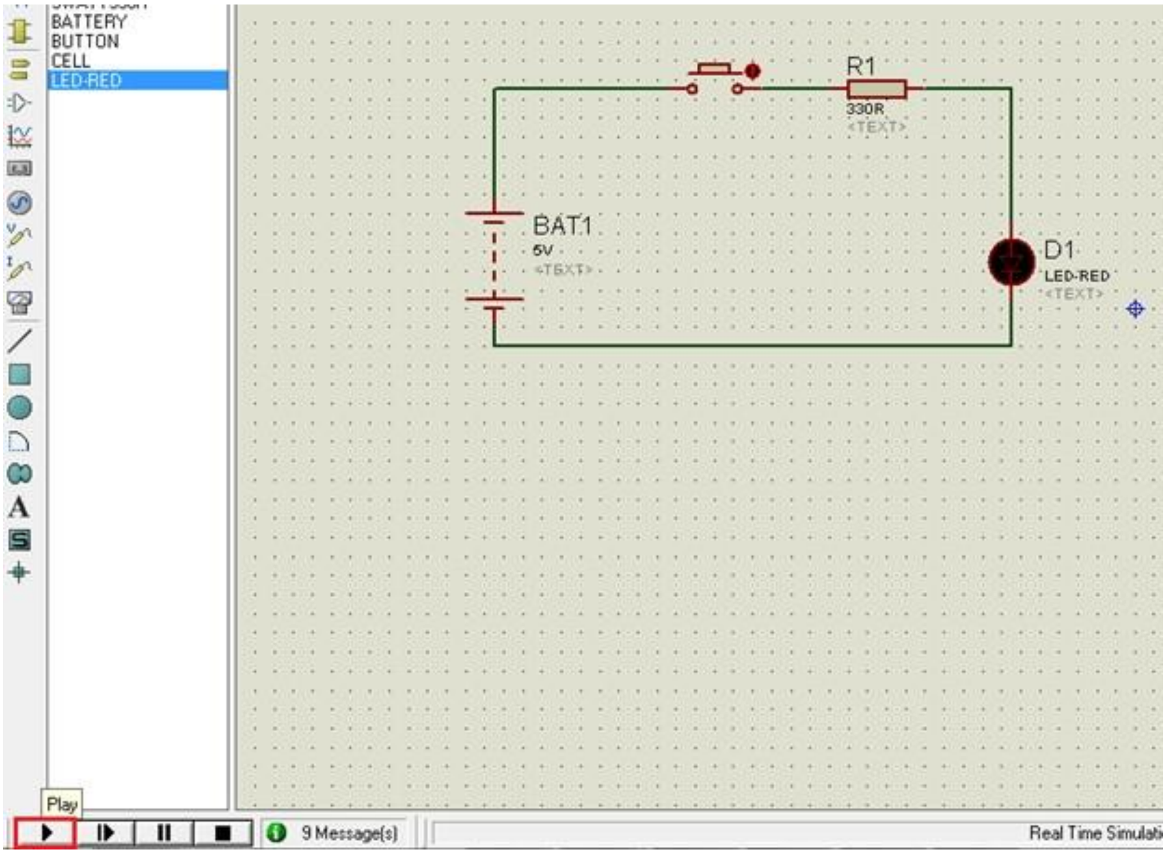

Figure 4.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

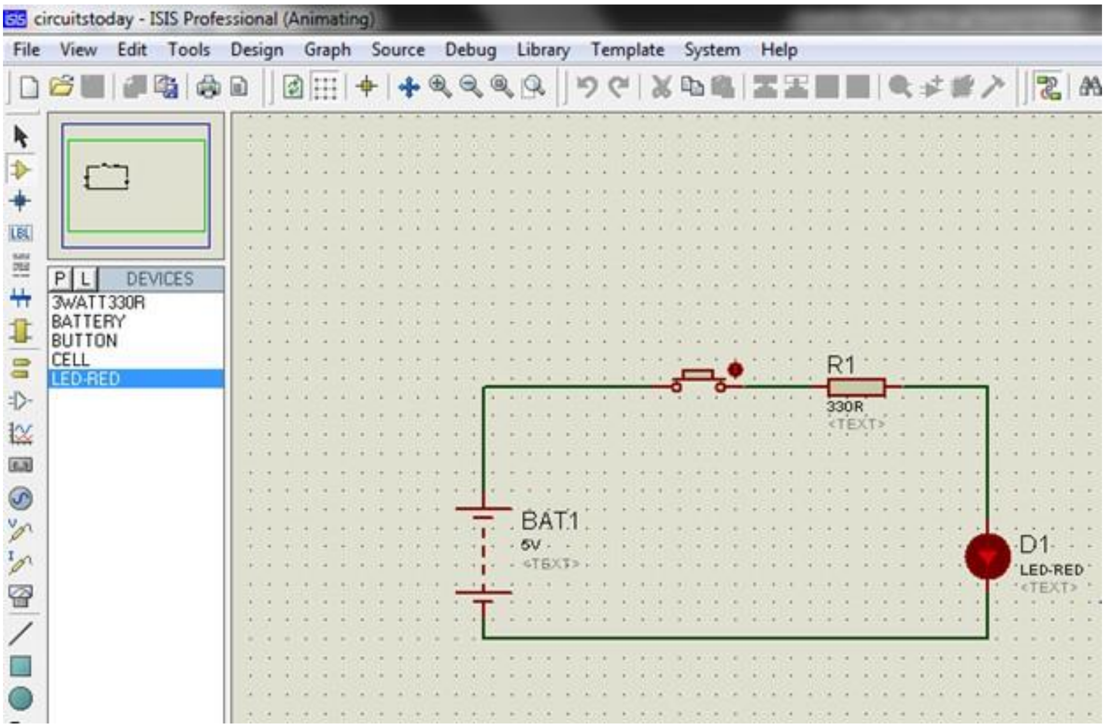

Figure 4.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

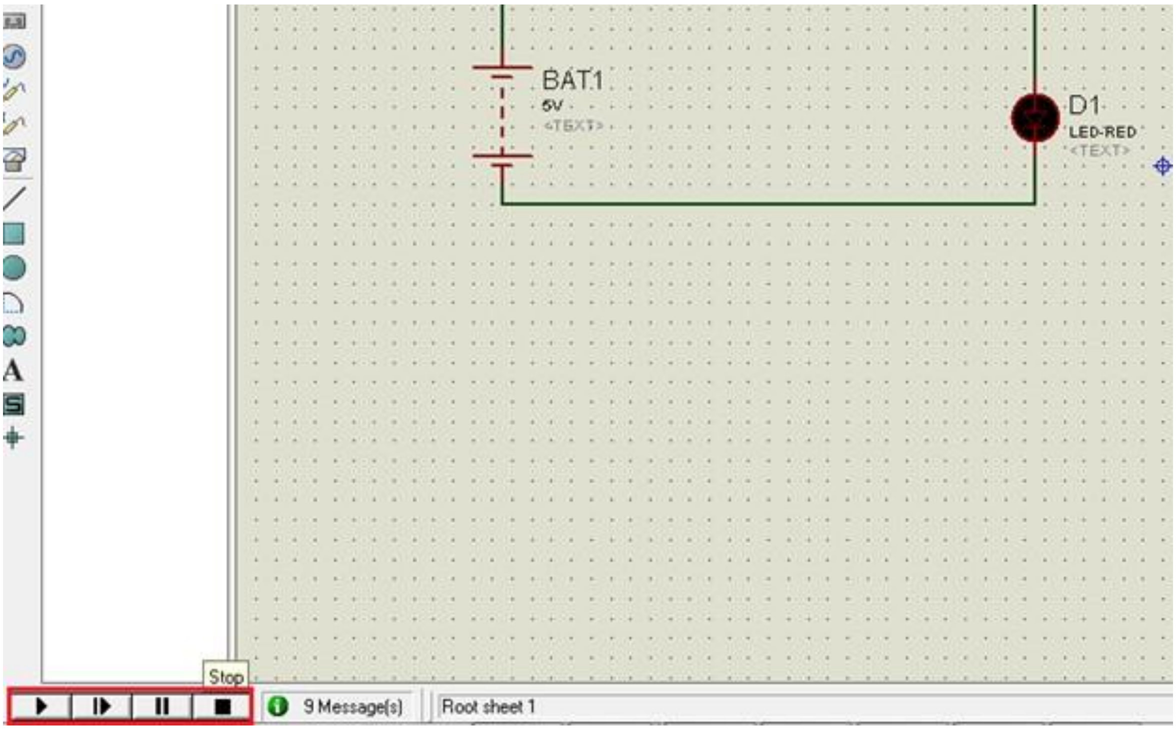

Figure 4.13 Simulation Step-Pause-Stop Buttons

4.3 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE	
Developer(s)	Arduino Software
Preview release	v0.0.2 / 28 October 2019; 3 months ago[8]

Repository	github.com/arduino/Arduino
Written in	C, C++
Operating system	Windows, macOS, Linux
Platform	IA-32, x86-64, ARM
Type	Integrated development environment
License	LGPL or GPL license
Website	blog.arduino.cc/2019/10/18/arduino-pro-ide-alpha-preview-with-advanced-features/

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging[9] and other advanced features.

After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

4.3.1 Installation

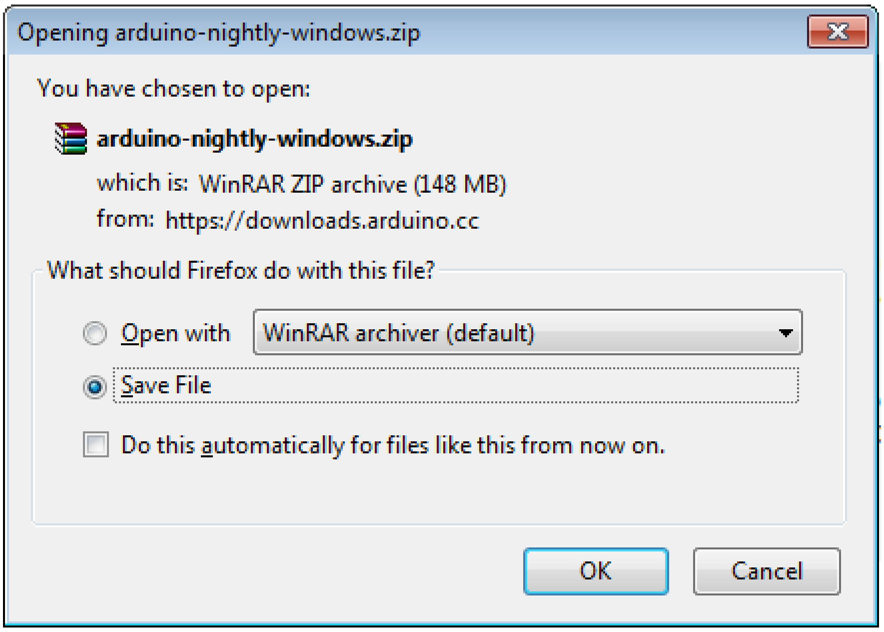
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



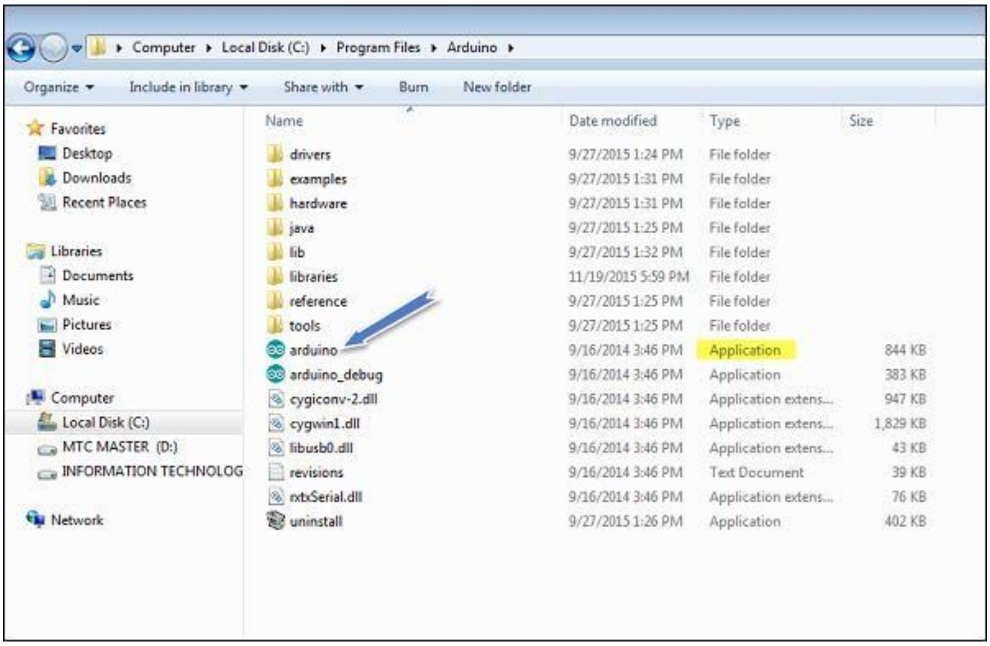
Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

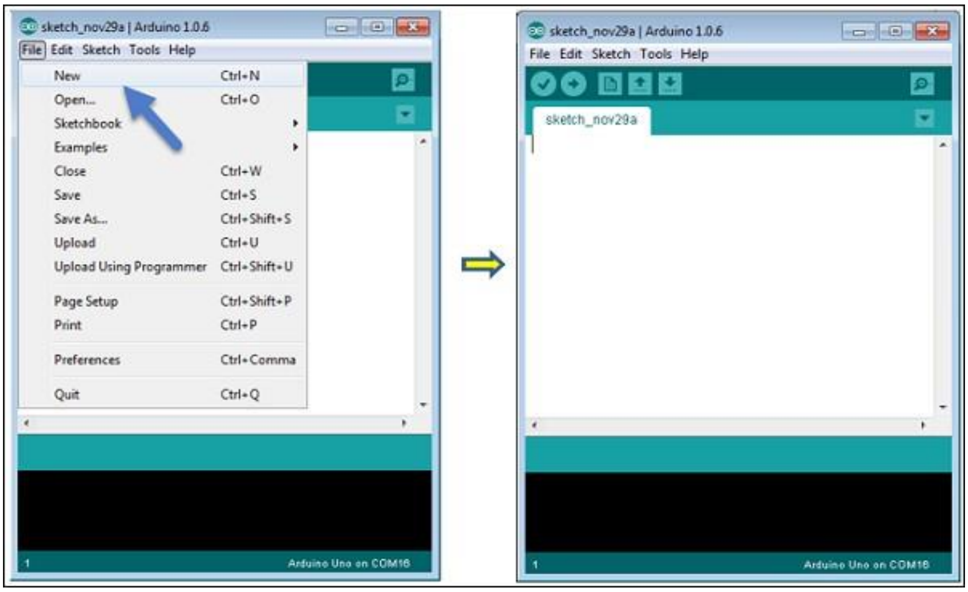


Step 5 − Open your first project.

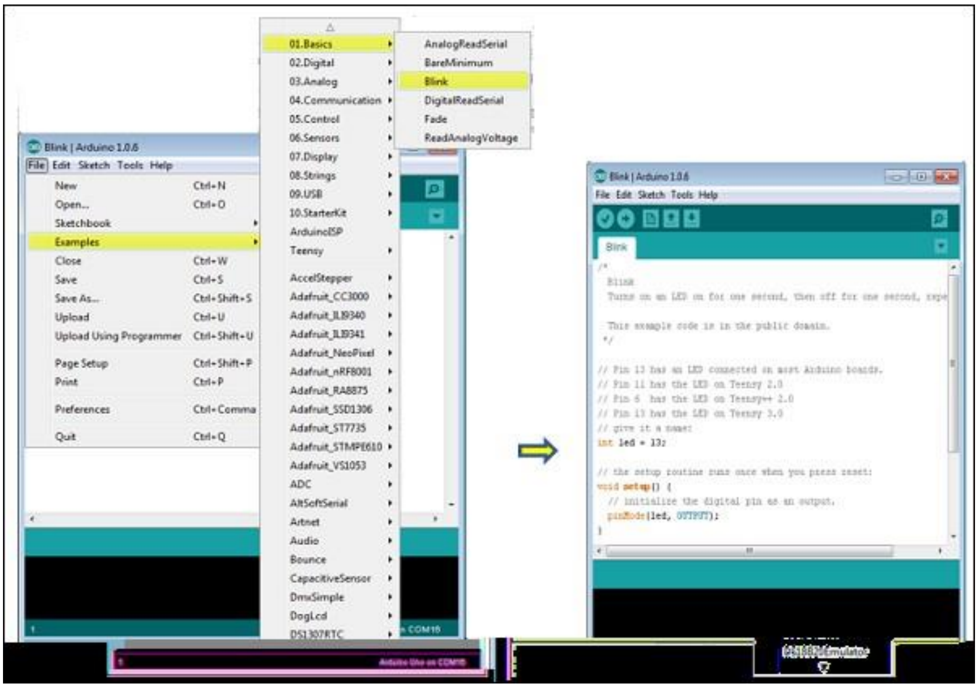
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

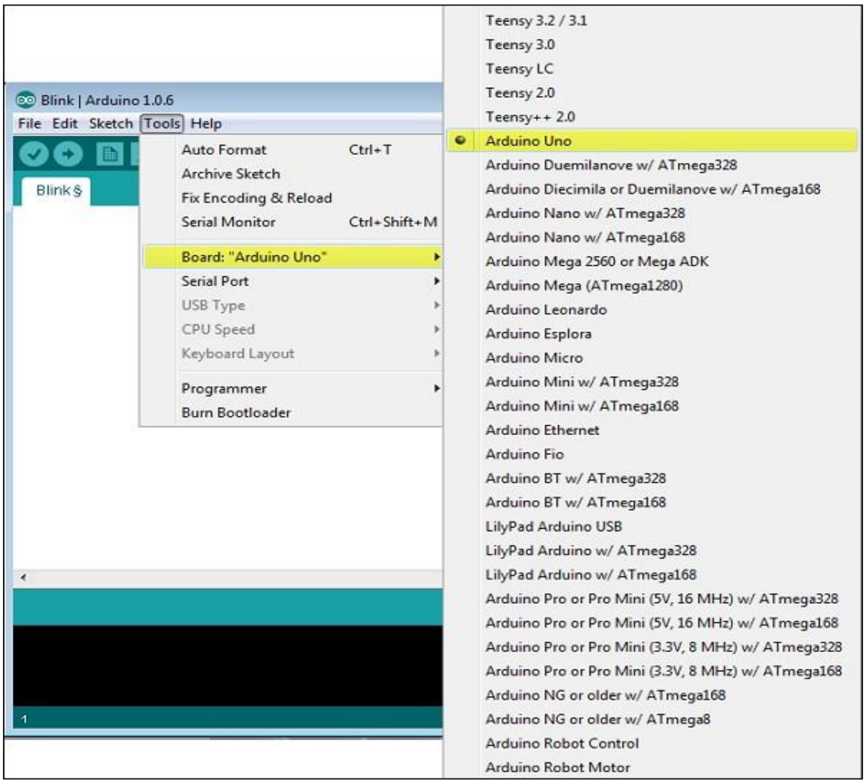


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

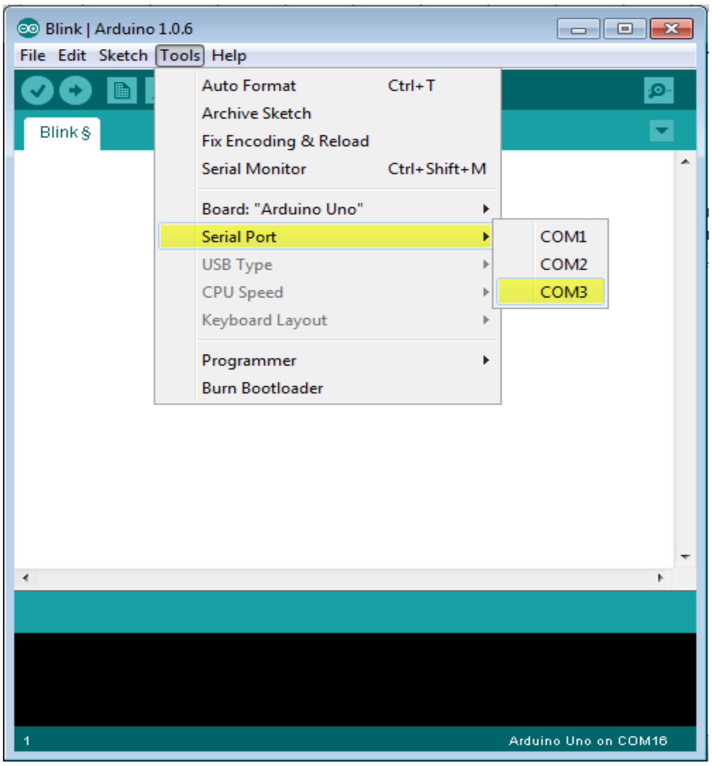
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

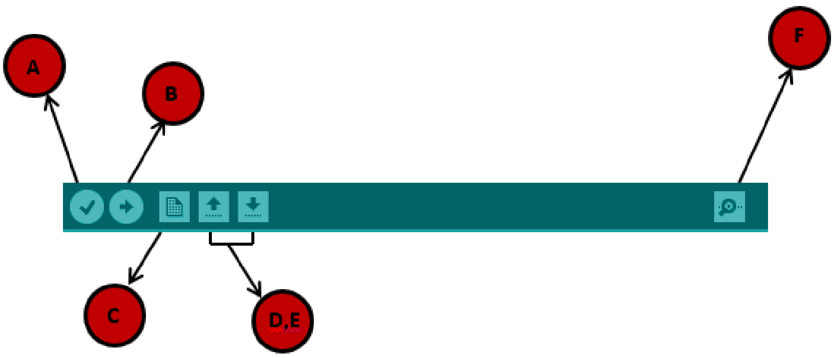
Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

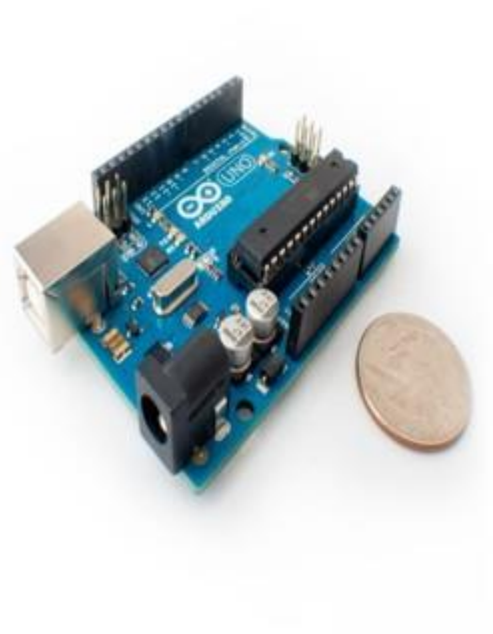
CHAPTER 5
HARDWARE

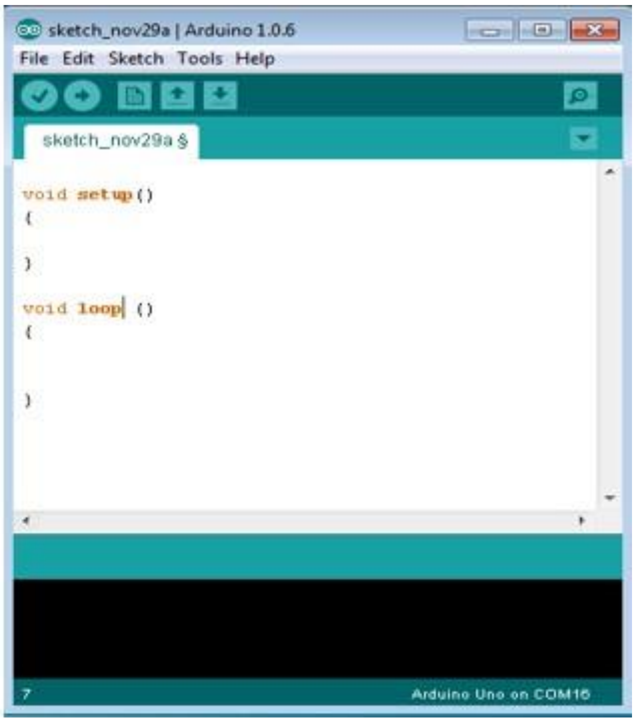
5.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.





5.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 5.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 5.2Arduino boards based on ATMEGA32u4 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB
Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

5.3 Arduino boards based on ATMEGA2560 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	5V	16MHz	54	16	14	4	USB via ATMega16U2B
Mega Pro 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

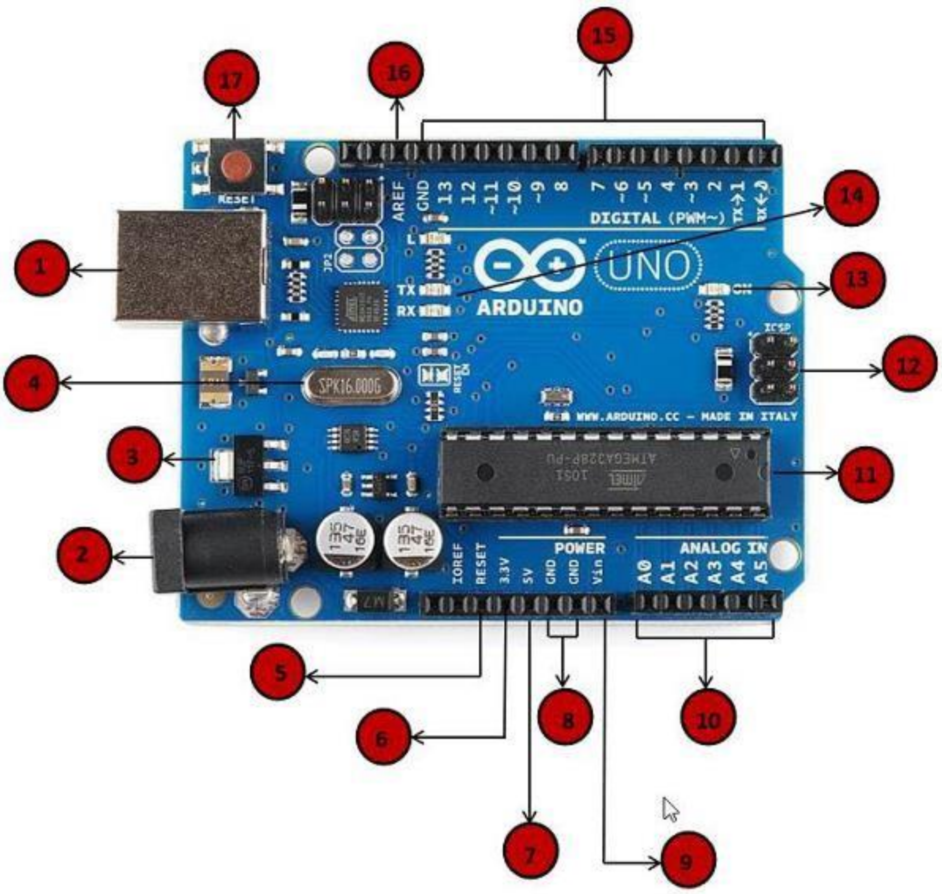
Mega Pro 5V	5V	16MHz	54	16	14	4	FTDI-Compatible Header
Mega Pro Mini 3.3V	3.3V	8MHz	54	16	14	4	FTDI-Compatible Header

5.4 Arduino boards based on AT91SAM3X8E microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Mega 2560 R3	3.3V	84MHz	54	12	12	4	USB native

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.

11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

5.2 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

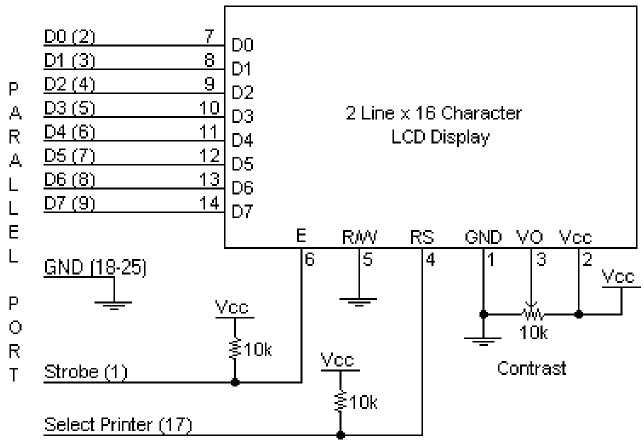
A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

5.2.1 Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram



- Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

FEATURES:

- 5 x 8 dots with cursor
- Built-in controller (KS 0066 or Equivalent)
- \+ 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

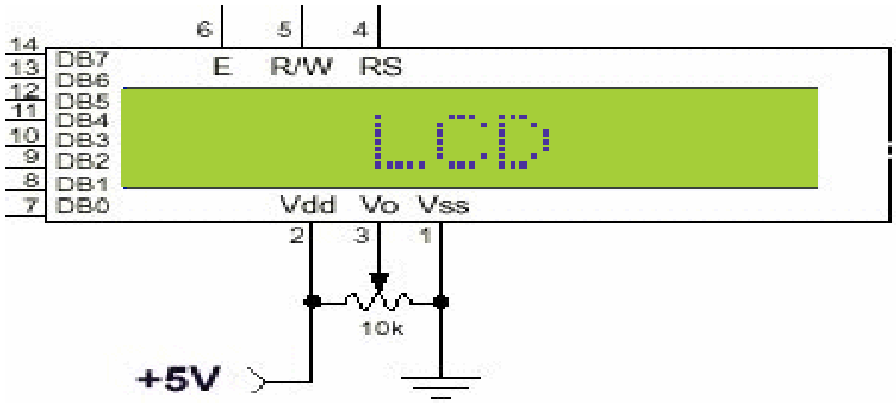


Figure 5.1 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 5.2 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 5.5 Commands

Hex Code	Command to LCD Instruction Register

Description

This is the circuit diagram of a simple **corrosion free water level indicator** for home and industries. In fact the level of any conductive non corrosive liquids can be measured using this circuit. The circuit is based on 5 transistor switches. Each transistor is switched on to drive the corresponding LED , when its base is supplied with current through the water through the electrode probes.

One electrode probe is (F) with 6V AC is placed at the bottom of tank. Next probes are placed step by step above the bottom probe. When water is rising the base of each transistor gets electrical connection to 6V AC through water and the corresponding probe. Which in turn makes the transistors conduct to glow LED and indicate the level of water. The ends of probes are connected to corresponding points in the circuit as shown in circuit diagram. Insulated Alluminium wires with end insulation removed will do for the probe. Arrange the probes in order on a PVC pipe according to the depth and immerse it in the tank.AC voltage is use to prevent electrolysis at the probes. So this setup will last really long. I guarantee at least a 2 years of maintenance free operation. That’s what I got and is still going.

Components

T1 – T5 BC 548 or 2N2222 Transistors

R1-R5 2.2K 1/4 W Resistors

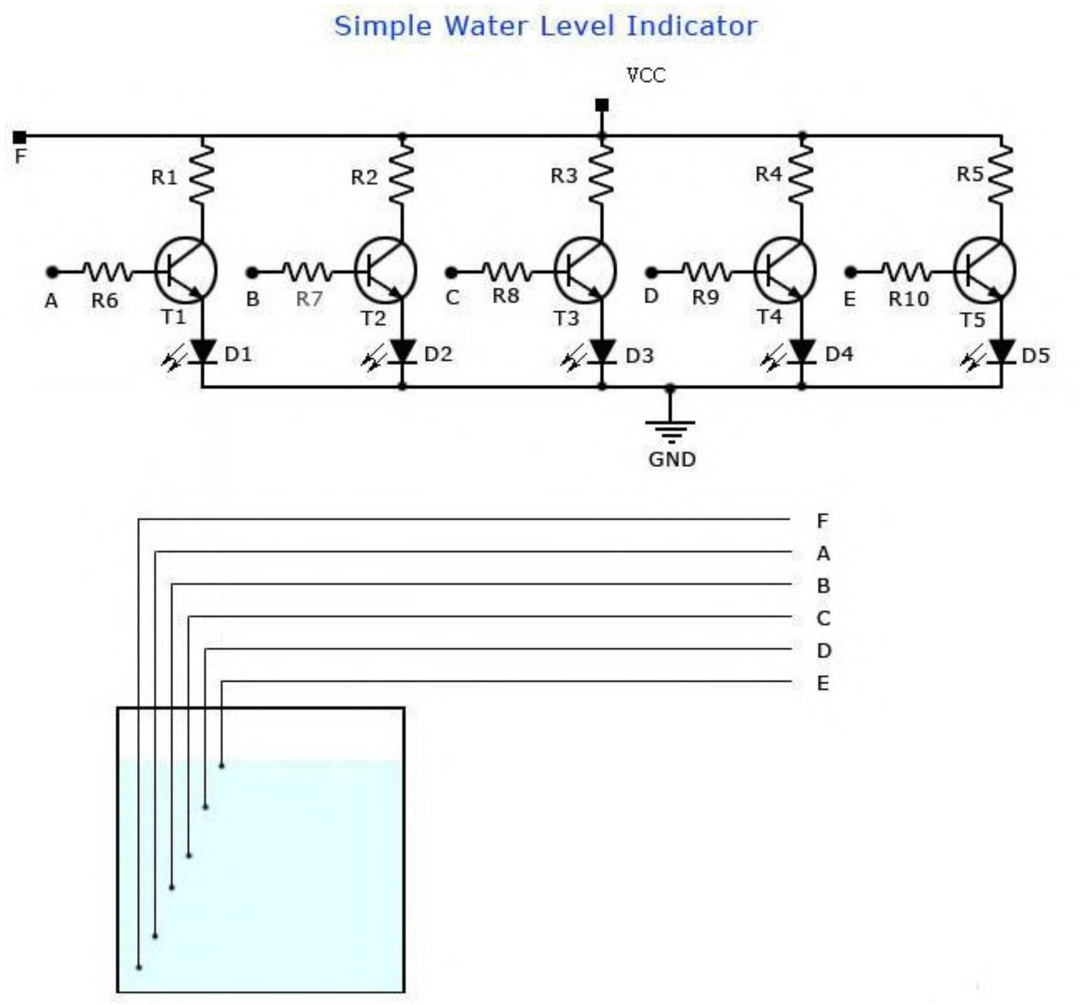
R6-R10 22K 1/4 W Resistors

D1 – D5 LED’s (color your choice)

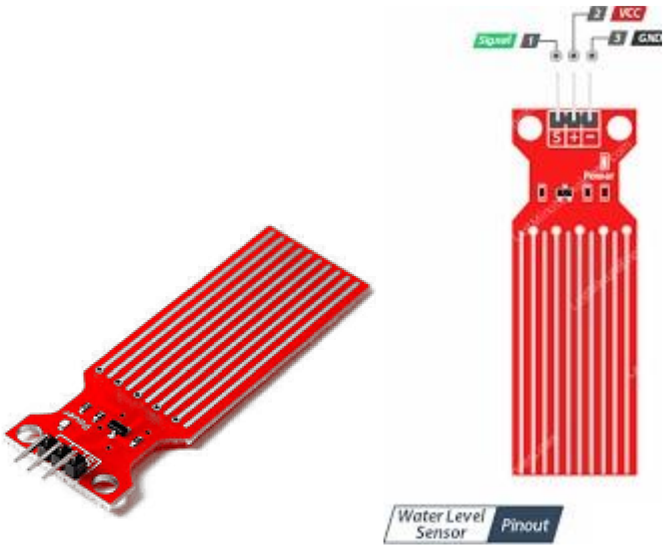
Notes:

Use a transformer with 6V 500 mA output for power supply.Do not use a rectifier! we need pure AC. Use good quality insulated Aluminum wire for probes.If Aluminum wires are not available try Steel or Tin.Copper is the worst.Try the circuit first on a bread board and if not working properly, make adjustments with the resistance values .This is often needed because conductivity of water changes slightly from place to place.The type number of the transistors used here are not critical and any small signal NPN transistor will do the job. Few other suitable type numbers are BC546, BC107, PN2222, BC337, BF494, ZTX300, BEL187 etc. The circuit can be enclosed in a plastic box with holes for revealing the LEDs .

Water Level Indicator Circuit Diagram and Sensor Arrangement.



Water Level Indicator



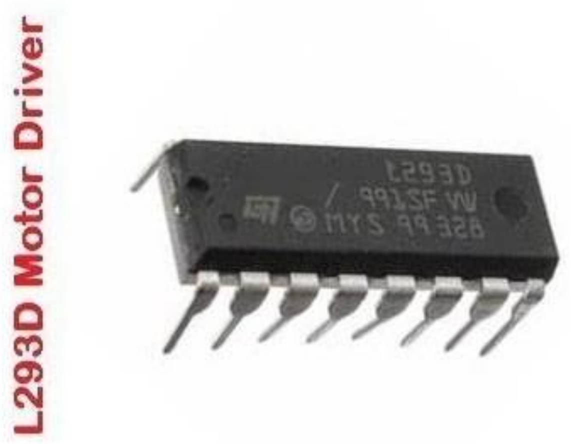
L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to builtin H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

Introduction to L293D

L293D is basically a motor driver or controller. It has two builtin H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large inpu voltage supply range, large output current high noise immunity input signals etc. Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.



1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

3. L293D Pinout

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.
- L293D pinout diagram is shown in the figure given below.

DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjuntion with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher. Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparible AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

Easy to control torque

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

Simple, cheap drive design

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

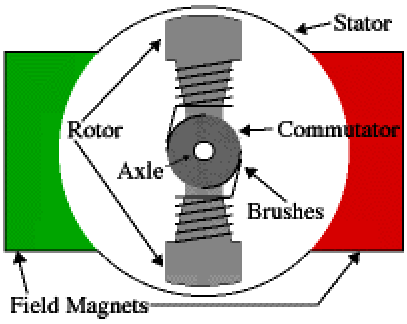
Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance tradeoffs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

Disadvantages

- Expensive to produce
- Can't reliably control at lowest speeds
- Physically larger
- High maintenance
- Dust

WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.



Principle

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously.

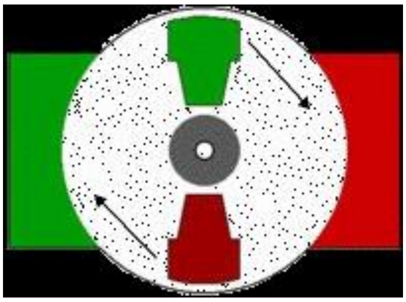
When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the

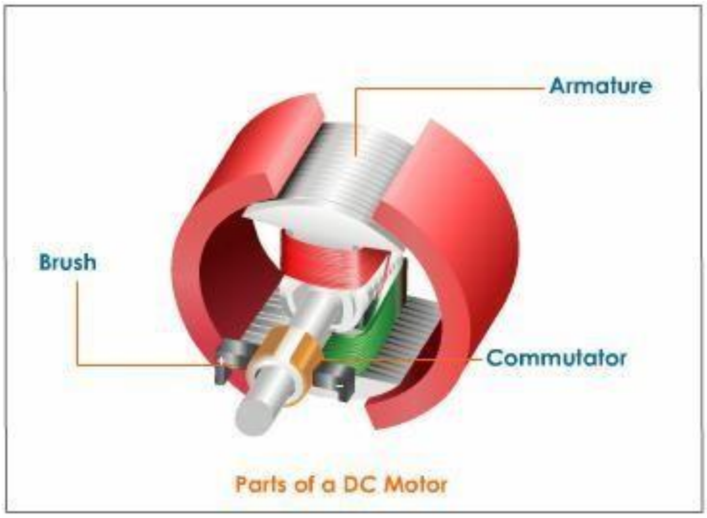
external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator. You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).



Construction and Working



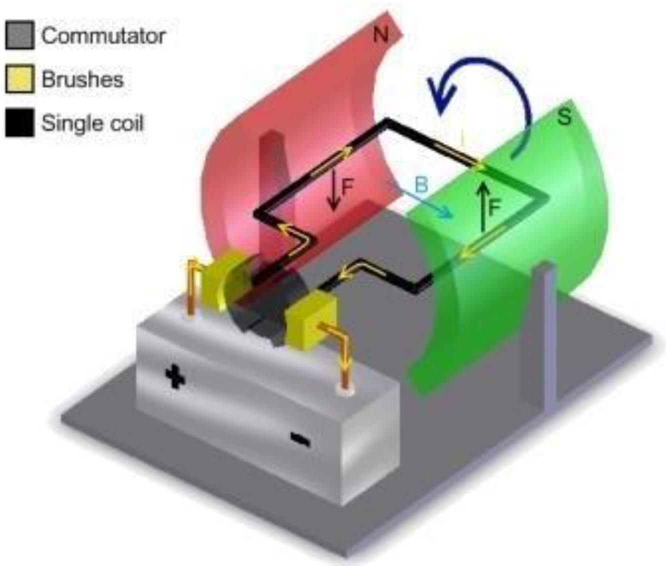
Parts of a DC Motor

Armature

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

Commutator

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.



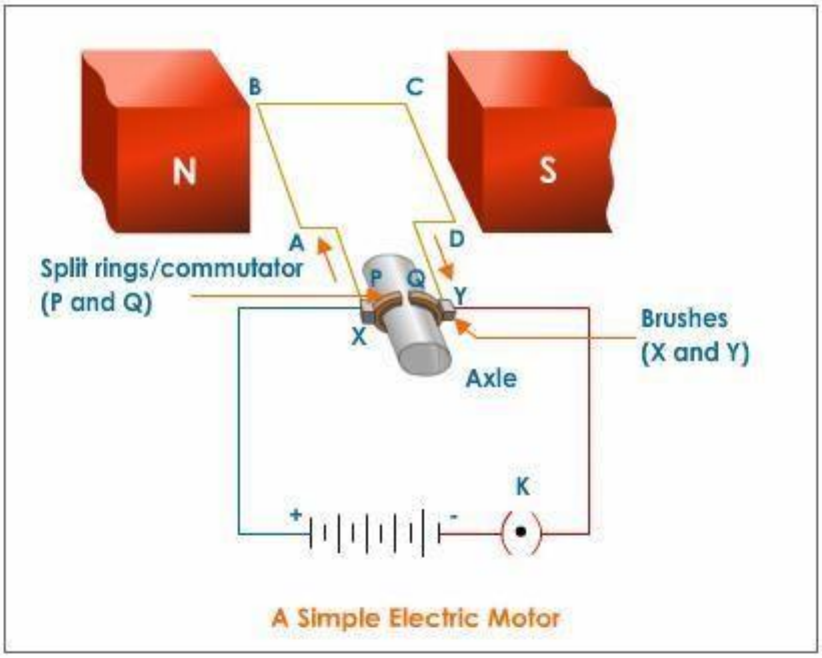
Brushes

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

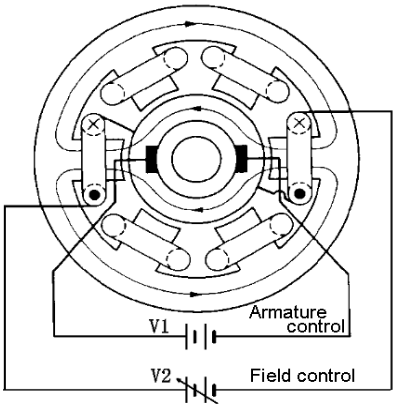
Working of a DC Motor

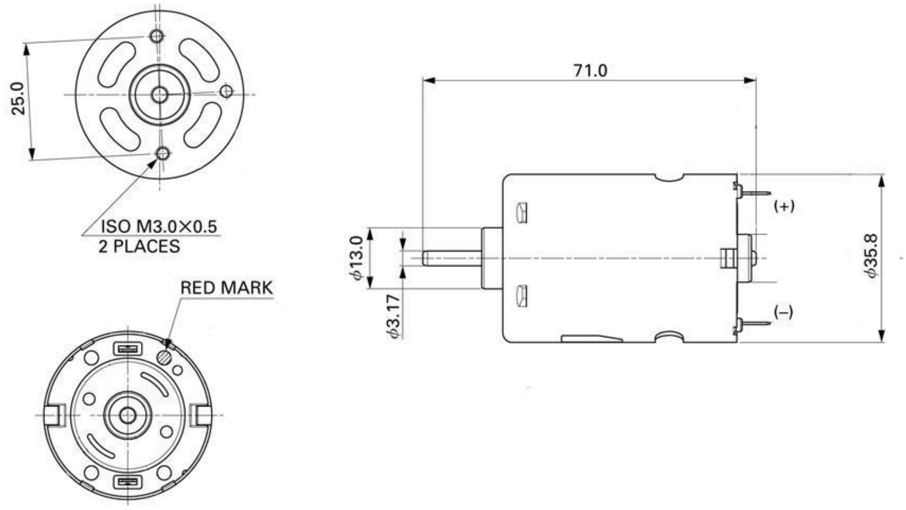
When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.



When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.



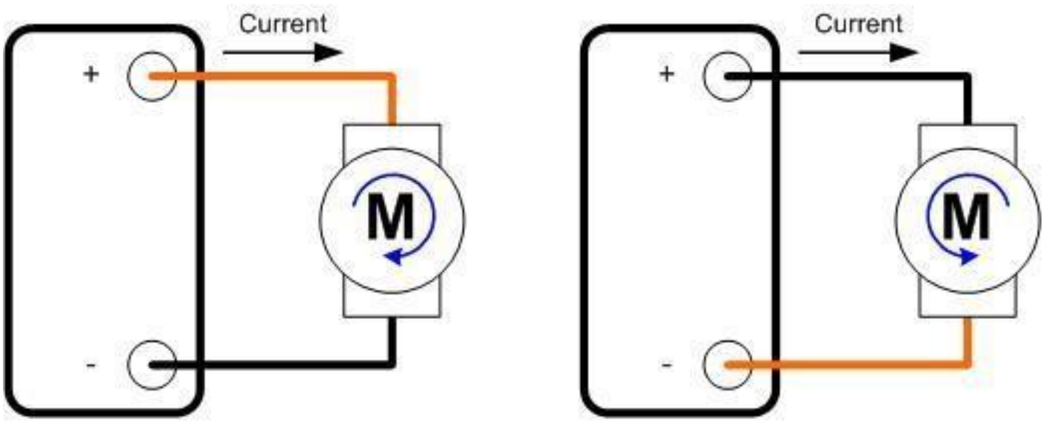


PARAMETRS OF THE DC MOTRS

1. Direction of rotation
2. Motor Speed
3. Motor Torque
4. Motor Start and Stop

Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.



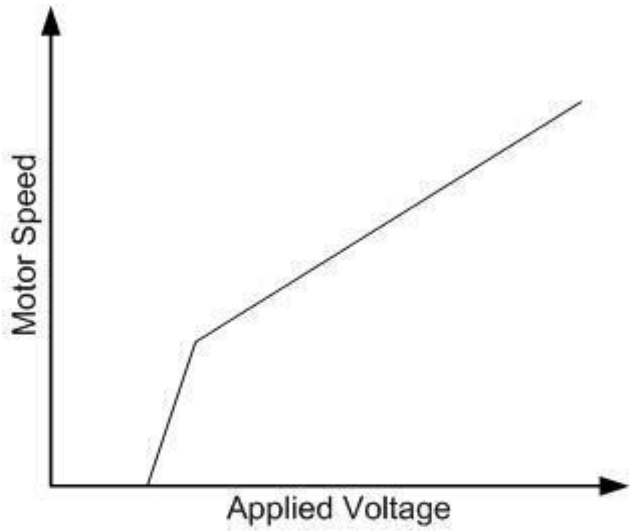
DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.
- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

DC Motor Speed

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as atract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attaction will try to take place. As a result, motor speed is directly proportional to applied voltage.



Motor Speed Curve

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will simply not move. This is because the magnetic field strength is not enough to overcome friction. Once friction is overcome, motor speed will start to increase as voltage increase.

The following video shows the concept of speed control and offers some ideas on how this can be achieved.

Motor Torque

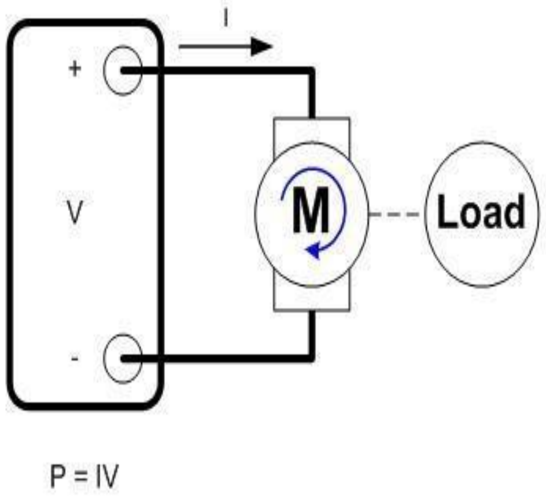
In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.

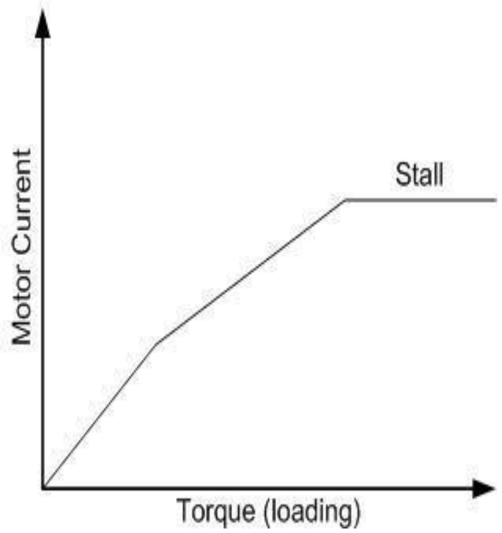
Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy can not be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

$$P = IV$$

Where P is power, I is motor current and V is motor voltage

Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current. As you increase load (or torque requirements) current must also increase.





Motor Loading

One aspect about DC motors which we must not forget is that loading or increase of torque can not be infinite as there is a point in which the motor simply can not move. When this happens, we call this loading "Stalling Torque". At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

Motor Start and Stop

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current can not change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.

Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.

Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs. The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back EMF is directly proportional to speed, making Back EMF = 0, also means making speed = 0.

Truth Table

High Left	High Right	Low Left	Low Right	Description
On	Off	Off	On	Motor runs clockwise
Off	On	On	Off	Motor runs anti-clockwise
On	On	Off	Off	Motor stops or decelerates
Off	Off	On	On	Motor stops or decelerates

As already said, H-bridge can be made with the help of transistors as well as MOSFETs, the only thing is the power handling capacity of the circuit. If motors are needed to run with high current then lot of dissipation is there. So, head sinks are needed to cool the circuit. Now you might be thinking in why i did not discuss the cases like High side left on and Low side left on or high side right on and low side right on. Clearly seen in the diagram, you don't want to burn your power supply by shorting them. So that is why those combinations are not discussed in the truth table.

CONCLUSION

In order to complete the project, the hardware is initially tested on bread board. Subsequently, the hardware is wired on general purpose PCB. This software is written in C language and simulation is tested on pc. Afterwards the code is dumped into a micro controller. The integrated hardware and software are tested successfully. The principle proved thorough this project can be utilized in many real time applications.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept . project coordinator Dr.A.Anand,Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr.K.Nishakar** , **Assosciate Professor**, Department of Electronics and Communication Engineering and our class project coordinator **Ms.P.Pushpa, Assistant Professor** ,Department of ECE for guidance and encouragement in carrying out the project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

A green house is where plants such as flowers and vegetables are grown. During the day the greenhouses warm up when the sun-rays penetrates through it , which then heats the plant, soil and structure. Green houses help to protect the crops from many diseases, particularly those that are soil borne and splash onto plants in the rain. Greenhouse effect is a natural phenomenon and beneficial to human being. Numerous farmers fail to get good profits from the greenhouse crops for the reason that they can't manage two essential factors, which determines plant growth as well as productivity. Green house temperature should not go below a certain degree, High humidity can result to crop transpiration, condensation of water vapor on various greenhouse surfaces, and water evaporation from the humid soil. To overcome such challenges, this greenhouse monitoring and control system comes to rescue. This project demonstrates the design and implementation of a various sensors for greenhouse environment monitoring and controlling. This greenhouse control system is powered by Atmega328 microcontroller it consists of temperature sensor, light sensor, soil moisture sensor, LDR sensor, LCD display module, 12v DC fan, Bulb and pump. Temperature sensor, senses the level of temperature. if it goes high DC fans gets on and when the temperature goes low the fan gets off. Soil moisture sensor, senses the water level as the level decreases the pumps gets on. In the absence of light, the LDR sensor senses and the bulb starts glowing. By this way it will become easy to monitor and control the system.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

GLOSSARY OF COMMONLY USED TERMS

AODTPC: Adaptive on demand transmission control protocol is a key technique to save the energy of a sensor node in wireless sensor network.Power level regulation of a sensor node in time varying propagation environment still needs deep investigation due to uncertain behaviour of wireless fading channel**.**

GREENHOUSE: A greenhouse is a structure with walls and roof made chiefly of transparent material, such as glass, in which plants requiring regulated climatic conditions are grown. These structures range in size from small sheds to industrial-sized buildings.

NEXT GENERATION NETWORK: It is a packet based network able to provide services including telecommunication services and able to make use of multiple broadband.

TCP/IP PROTOCOL: The **Internet protocol suite** is the conceptual model and set of communications protocols used in the Internet and similar computer networks. It is commonly known as **TCP/IP** because the current foundational protocols in the suite are the Transmission Control Protocol (TCP) and the Internet Protocol (IP). During its development, versions of it were known as the **Department of Defense** (**DoD**) **model** because the development of the networking method was funded by the United States Department of Defense. Its implementation is a protocol stack.

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

We live in the world where everything can be controlled and operated automatically, but there are still few sectors in our country where automation hasnot been adopted or not being put to a full-fledged use, perhaps because of several reason one such reason is cost and one such field is ‘agriculture’. Agriculture has been one of the primary occupations of man since early civilization and even today manual interventions in farming are inevitable. Greenhouse form an important part of the agriculture and horticulture sectors in the country as they can be used to grow plants under controlled climatic conditions for optimal growth. Greenhouse technology is the technique of providing favorable environmental conditions for plants . It replaces the direct supervision. Now a day, due to urbanization and lack of land availability there is a great need to construct the greenhouse, which will be revered mainly for growing crops. Greenhouse monitoring and controlling projects is used to measure the various parameters like temperature , light, moisture content and to display them on LED. Continuous monitoring of these environmental factors gives relevant information pertaining to the individual effects of the various factors towards obtaining effects of the various factors towards obtaining maximum crop production. Unlike open farming where natures control takes the upper hand, green house prevents a closed environment that can be strictly controlled by humans in order to provide optimal conditions for the growth of plants . The effectiveness in greenhouse crop production depends significantly on the modification of optimal growth conditions to achieve high yield at lower costs, good quality and low environmental load.

1.2 OBJECTIVE

The main objective of the this project is to design and implement an efficient monitoring system through which the required parameters are monitored remotely using internet and the data gathered from the sensors are stored in the cloud and to project the estimated trend on the web browser. A solution for monitoring the temperature, moisture content in soil and light intensity value crossing its threshold value ranges, for example temperature levels in the air, moisture content in soil and light intensity in the greenhouse exceeding the normal levels etc., in the environment using wireless embedded computing system is proposed in this paper. The solution also provides an intelligent remote monitoring for a particular area of interest. The embedded system is an integration of sensor devices, wireless communication which enables the user to remotely access the various parameters and store the data in cloud.

1.3 SCOPE

The automated greenhouse is applicable for domestic usage. If the scale of usage is to be increased ,there would be a need of more requirement of components to measure the desired parameters. In this project the temperature, light intensity and soil moisture content are measured. It does not cover all the factors that can be taken into consideration to create a favorable environment .Other factor includes ph level of the soil or the humidity content in the greenhouse. The values for when the soil is considered to be too wet or too dry is dependent on the type of soil used. In those cases the values have to be set individually with the help of tests.

1.4 MATERIAL REQUIREMENT

1.4.1 HARDWARE REQUIREMENT:

1. **ARDUINO UNO**: It is a microprocessor which is used to transfer data from Temperature sensor to LCD and Wifi module. Ardunio takes the input from Temperature Sensor in Analog form and converts it into digital form. This converted data is sent to the Wifi module. The Ardunio sents the power required by the Temperature Sensors. So Arduino gets power from Wifi module to work and arduino works according to the code dump.

2. **TEMPERATURE SENSOR**: The temperature sensor senses the temperature around it. The temperature sensor senses the temperature in mechanical form. The temperature sensor changes this mechanical form into Analog form as the Arduino does not takes the input in mechanical form.

3. **LIGHT SENSOR:** Photo resistors, also known as light dependent resistors (LDR), are light sensitive devices most often used to indicate the presence or absence of light, or to measure the light intensity. In the dark, their resistance is very high, sometimes up to 1MΩ, but when the LDR sensor is exposed to light, the resistance drops dramatically, even down to a few ohms, depending on the light intensity. LDRs have a sensitivity that varies with the wavelength of the light applied and are nonlinear devices. They are used in many applications but are sometimes made obsolete by other devices such as photodiodes.

4.**SOIL MOISTURE SENSOR:** The soil moisture sensor is used to measure the values of the volumetric water content in soil. Since the direct gravimetric measurement of free soil and weighing of a sample, soil moisture sensors measure the volumetric water content indirectly by using some other property of the soil, such as electrical resistance, dielectric constant, or interaction with neutrons, as a proxy for the moisture content.

5.**ESP8266 WI-FI MODULE:** The wifi module in the circuit helps in connecting the microcontroller with the wifi network. The data received by the Wifi module is sent to the TELNET app where we can see the variations in the graph due to changes in the temperature.The ESP8266 Wi-Fi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network.The ESP8266 is capable highly of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

6. **LCD** : The LCD we used here is 16x2 display LCD. The LCD helps us to know the data is getting transferred or uploaded to TELNET app or not.

7. **DC FAN** : The direct current fans, or DC fans, are powered with a potential of fixed value such as the voltage of a battery. Typical voltage values for DC fans are 5V, 12V, 24V and 48V. In contrast, the alternating current fans, or AC fans, are most powered with a changing voltage of positive

8.**BULB**:A light-bulb produces light from electricity.In addition to lighting a dark space, they can be used to show an electronic device is on, to direct traffic, for heat, and for many other purposes

9.**WATER PUMP:** DC 5V operated submersible water pump is ideal for making automatic plant watering system using Arduino and esp8266 with the wifi module.

10.**POWER SUPPLY UNIT:** The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

1.4.2 SOFTWARE REQUIREMENT :

1.**ARDUINO IDE**: Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs.

2.**PROTEUS SOFTWARE:** Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".It is a proprietry software tool suite used primarily for electronic design engineers and technicians to create schematics and electronic prints for manufacturing printed circuit boards.

1.5 PROCUMENT OF EQUIPMENT

All the required hardware components were procured from an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, individual sensors were connected to Arduino in Proteus Software and understood the working of every individual sensor in Proteus Software. Then assembled all the sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and wrote the program to make work all the hardware sensors in Arduino IDE and understood the working of all sensors practically. Later fixed the threshold limit for the temperature sensor and all the information was sent to the IOT Platform.

1.5.0 INTRODUCTION TO EMBEDDED SYSTEMS

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip"), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware. Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

- ### MICRO PROCESSOR (µp)

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel- injection systems for automobiles

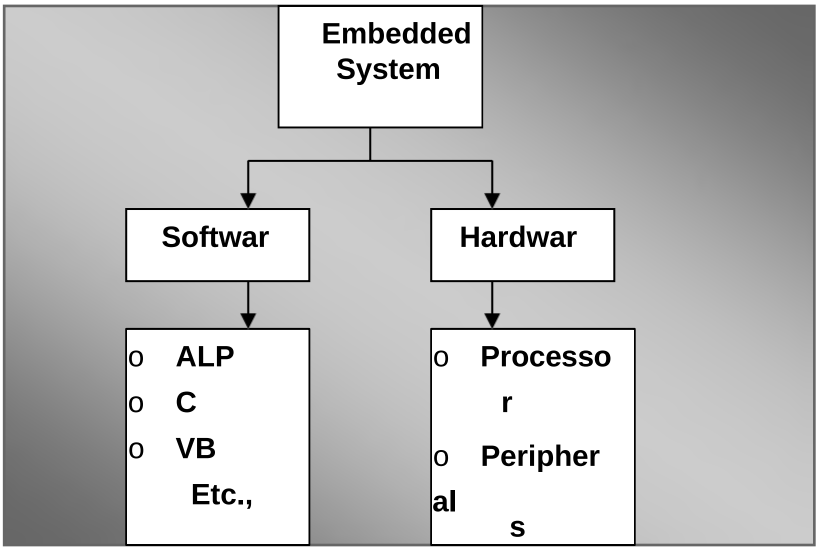

Fig.1.1 Block Diagram of Embedded System

➢ CLASSIFICATION OF PROCESSORS

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processo1r (DSP)
- Application Specific Integrated Circuits (ASIC)

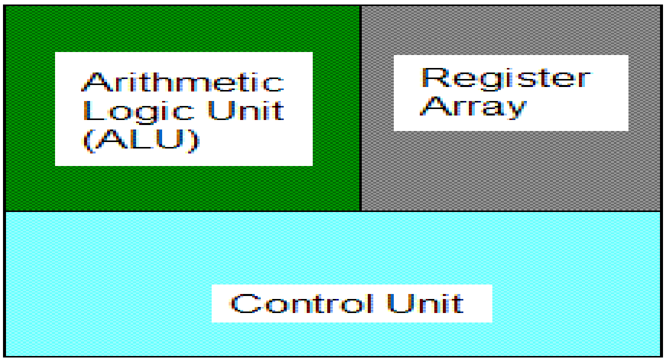

Fig.1.2 Three Basic Elements of a Microprocessor

1.5.1 HARVARD ARCHITECTURE

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

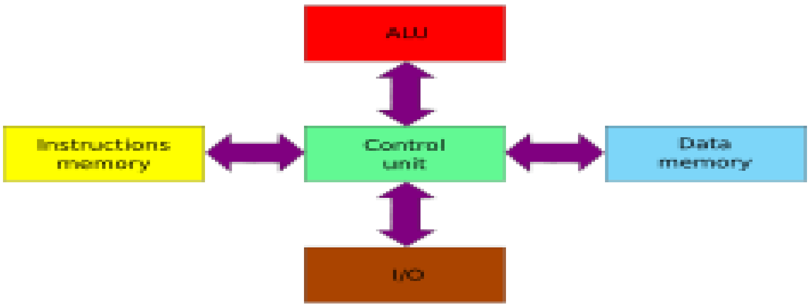

Fig.1.3 Harvard Architecture

1.5.2 VON-NEUMANN ARCHITECTURE

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

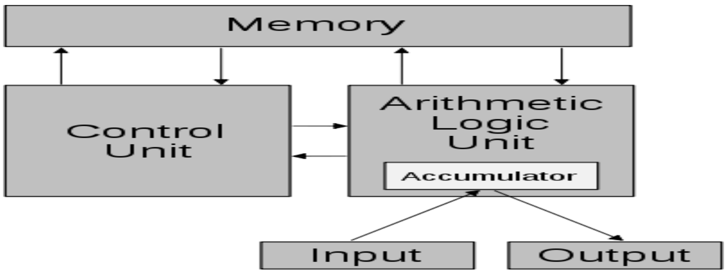

Fig.1.4 Schematic of the Von-Neumann Architecture

• USES OF THE HARVARD ARCHITECTURE

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc.

1.5.3 BASIC DIFFERENCES BETWEEN HARVARD AND VON-NEUMANN ARCHITECTURE

- The primary difference between Harvard architecture and the Von Neumann architecture is Von Neumann architecture data and programs are stored in the same memory and managed by the same memory and managed by the same information and handling system. Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

1.6 INTRODUCTION TO IOT

The Internet of things (IoT) describes the network of physical objects—a.k.a. "things"—that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the Internet.Things have evolved due to the convergence of multiple technologies, real-time analytics, machine learning, ubiquitous computing, commodity sensors, and embedded systems.[1] Traditional fields of embedded systems, wireless sensor networks, control systems, automation (including home and building automation), and others all contribute to enabling the Internet of things. In the consumer market, IoT technology is most synonymous with products pertaining to the concept of the "smart home", including devices and appliances (such as lighting fixtures, thermostats, home security systems and cameras, and other home appliances) that support one or more common ecosystems, and can be controlled via devices associated with that ecosystem, such as smartphones and smart speakers. The IoT can also be used in healthcare systems. Internet of Things (IOT) is a network of devices that connect directly with each other to capture and share data through a secure service layer that connects to a central command and control server in the cloud. The closure\look suggest that the way people collect, record and analyze data—not just in health care but in every industry today. The idea of devices connecting directly with each other is basically called Internet of Things. The Internet of Things also a called the Internet of Objects, refers to a wireless network between objects, usually the network will be wireless and self-configuring. Internet of Things (IOT) is one of the major component advances in present time that links the internet with everyday sensor and working devices. Smart objects play an important role in the Internet of Things vision, since embedded communication and information technology would have the potential to change the utility of these objects. Using sensors they are able to recognize their condition, and via built-in connecting power they would be able to interact with each other.

➢ BENEFITS OF IOT

UBIQUITOUS NETWORKS -: Personal Wi-Fi on your smart phones and on many of the other devices. Everyone (and everything) wants as well as needs to be connected.

Connected computing -:We want all of the devices, smart phones, televisions(colored or black and white), dvd players, vehicles etc. to keep record of what we are doing, seeing, reading, and/or listening to as we sway through the day, from one place to another – the handoffs from device to device is happening already.

ANALYTICS-AS-A-SERVICE-: The API and App economies are already wide and growing which enables to “do something interesting” as long as it can be connected to an API or can invoke an App that carries out a network-based service. The thing is a data generator as well as collector that learns from, makes forecast, and maybe even takes data-driven actions in response to the data that are collected too.

MARKETING AUTOMATION-: Smart phone customer engagement, geological-location, Apple’s iBeacon etc. are all developing a network of knowledge and information regarding customers’ locations, intentions, preferences, as well as buying patterns. Obviously, the degree of geological location-based knowledge needs to maintain the right balance between user privacy as well as the timely delivery of important and significant products and services to the particular user.

SUPPLY CHAIN ANALYTICS-: Delivering the just-in-time products at the time of need (inclusive of the use of RFID-based tracking). Significantly, everything is a customer (inclusive of machines, automobiles, manufacturing plants, ATM machines, etc.), as well as the IOT is monitoring, watching, as well as waiting for the product needs to arise.

1.7 LITERATURE SURVEY

Since 1990‟s, for greenhouse and environment monitoring various kinds of systems have been developed. But due to lack of awareness, cost and implementation factors, these systems were left behind. Later a DSP based prototype Greenhouse Environment Monitoring system developed in 2010. The newer scenario of decreasing water tables, drying up of rivers and tanks, unpredictable environment presents urgent need for proper utilization of water. To cope up with this use of temperature and moisture sensor at suitable locations for monitoring of crops is implemented in. . We also visited few greenhouses and observed and recorded the working methods of the framers, which provided me a very clear idea how the maintenance and monitoring activities. Proposed the techniques for selection hardware ,provided basics and reference models on which an IoT system can be based and developed. Comparative study of some existing systems provided insights provides the first node to start, already available systems in IoT-powered gardening and agriculture, like Bitponics, and Harvest Geek are either not available in India or are very costly which add up a considerable production cost overhead on the crops or Agro-based products.

CHAPTER-2

LITERATRE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

1) "Greenhouse Monitoring System Using IoT," proposed by M. Krishna Mohan, JakkulaLikhitha, TejaswyYamarthi, KagithaSravani on 02, March 2017 : This system is mainly applicable for greenhouses .Various sensors are deployed for sensing illumination,temparature and moisture content .The system uses IOT and is hosted on server .The technology used is ARM7 and WiFi.This can work as both web based and also based on mobile application.Future research proposed to this is to find which part of plant is having dead cells and which part is healthy.Also to calculate the amount of chemicals required for plant growth.

2) "IoT Based Smart Greenhouse Automation Using Arduino, proposed by D.O.Shirsath, Punam Kamble, Rohini Mane, Ashwini Kolap, R. S. More " IJIRCST, Volume-5, Issue-2, March 2017 : This system is mainly applicable for greenhouses .Various sensors are deployed for sensing humidity, temparature and moisture content .The system uses IOT and is hosted on server .The technology used is arduino controlling and remote monitoring using wireless communication. This can work as both web based and also based on mobile application. Future research proposed to this is to provide more security to the data stored in the IOT.

3)"An IoT-based wireless imaging and sensor node system for remote greenhouse pest monitor- ing," Chemical Engineering Transactions, 58, 2017.pp 601-606 was proposed by Dan JericArcegaRustia , Ta-Te Lin. This system is implemented using various sensors that are used to detect the crucial parameters of the plant such as atmospheric pressure and light intensity. The technology used is image processing and k-means algorithm. This system is purely web based. Future research proposed is to deploy more nodes in different location for pest monitoring.

4)A decision support system based on multi sensor data fusion for sustainable greenhouse management ," Jour- nal of Cleaner Production, Feb 2017, pp. 1-9. proposed by Giuseppe Aiello , Irene Giovino , MariangelaVallone , Pietro Cata- nia ,AntonellaArgento,". The system is mainly applicable for agricultural sector. This system helps in detecting humidity and temparature of the greenhouse. Alogorithm used here is data fusion algorithm.

2.2 REVIEW ON RELATED LITERATURE:

Idea of growing plants in environmentally controlled areas has existed since roman times. In the 13thcentury, greenhouses were built in Italy. They were originally called giardini botanici(botanical gardens).Then, in 1450, sanga yorok written description of greenhouses which was designed to regulate the temperature and humidity requirements of plants & crops. As the time passed, every country adopts the greenhouse system with some enhancement. Due to development in agriculture field, there are many ways to monitor & control the various parameters like temperature, humidity, soil moisture, light intensity. System can be wired or wireless. In the wired system, power source is wire. This system more reliable but complex to handle. When in wireless sensor network, power source of node is battery but it has also a drawback relative to battery which is of limited capacity. To overcome this drawback AODTPC protocol with kalman estimator is used. [5] IoT Technology has been used to reduce the distance between the staff in the article “Things” and its digital impersonation in data frameworks. It’s seen as the NGN of the internet [1]. The IoT is driven by an extension of the Internet through the incorporation of physical articles joined with a capacity to provide more quick-witted administrations to the earth as more information ends up noticeably accessible. Several application areas going from Green-IT and vitality effectiveness to coordination’s are now beginning to profit by Internet of Things ideas [2]. A Greenhouse provides basic methods for employment to its proprietor and must be financially pragmatic for the specific atmosphere in which it stands. Also, Greenhouse could be defined as advanced Innovation for Protected Horticulture addresses the major natural elements of light, temperature, and irrigation [3]. This paper investigates the usefulness of using the IoT based on the greenhouse to utilize low-cost tools and decrease the effort of the Pleasants. This could be implemented by including the automation in irrigation process, conserving temperature, and the degree of brightness inside the greenhouse structure .More recent attention has been focused on the provision of improvement on the Internet of things (IoT) and how to utilize it with the various applications. The IoT is interesting subject that recently whiteness very large number of papers that aimed to develop this technology. in next paragraphs, several papers about the greenhouse with IoT should be presented .In 2013, C. wenshun et al. published a paper in which they described the structure of services platform, even operating layer, collecting, and control layer, arrange transport layer and etc. then described the functions of Zhuangluo sunlight greenhouse. Finally, how to run interface and working condition of the system[4]. T. Quynh et al. (2015) suggest an article that analyzes various models of greenhouse in Vietnam and monitoring parameters required and proposes to apply single-path and multiple-path routing protocol in order to improve the IoT monitoring performance[6].

J. Zhao et al. (2010) proposes a paper that studies the integration of control networks and information networks in IoT in practical agriculture production. They also suggest a method that combines the remote monitoring system and wireless communications [7].

This paper has been written to show that IoT save peasants efforts and make the work much easier when the IoT used in Greenhouse applications. Also, this paper tries to provide a solution for some network problems such as dynamic Internet Protocol (IP) and global IP.

The proposed greenhouse has been implemented with three intelligent control systems. These system could be controlled by an intelligent Fuzzy controllers that providing the best performance. The Fuzzy controllers must be resided completely inside Microcontroller chip without require any extra processing. This development feature leads to the more sophisticated improvements of fuzzy systems in practical environments.

2.3 CONCLUSION ON REVIEWS:

Hence as the technology is advancing day by day at a faster pace and helps make the lives easier ,hence in the system internet of things is used for makings things smarter. Here in the proposed system it consists of two parts– in the first part consists of controlling.Controlling is achieved by connecting the sensors to the Arduino uno and the sensors senses the level of the parameters being measured and sends the data collected to Arduino uno. In the second part ,the sytem is monitored remotely. The recieved data is then sent to the cloud and stored and could be retrieved anytime from anywhere.

CHAPTER-3
PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

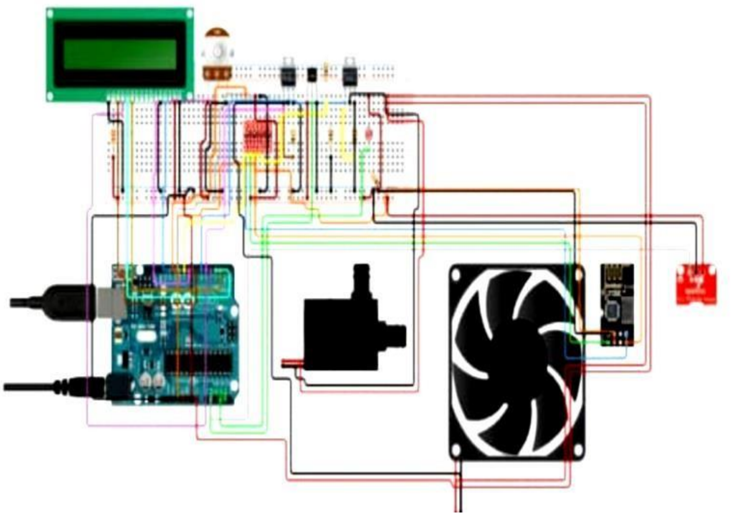

Fig 3.1 Overview of the Design

The temperature sensors output pin is connected to A0 and A1 of arduino analog pins. The Vcc and ground of Temperature Sensors is connected to 5V and ground of Arduino. The transmitter and receiver of Arduino are connected to the receiver and transmitter of Wifi module respectively. The VSS, VEE, RW, D0- D3 pins of LCD are grounded. The RS, E, D4-D7 pins of LCD are connected to 13-8 digital pins of Arduino.

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION

It is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A

Power barrel jack, an ICSP header and a reset button.

- The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.
- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

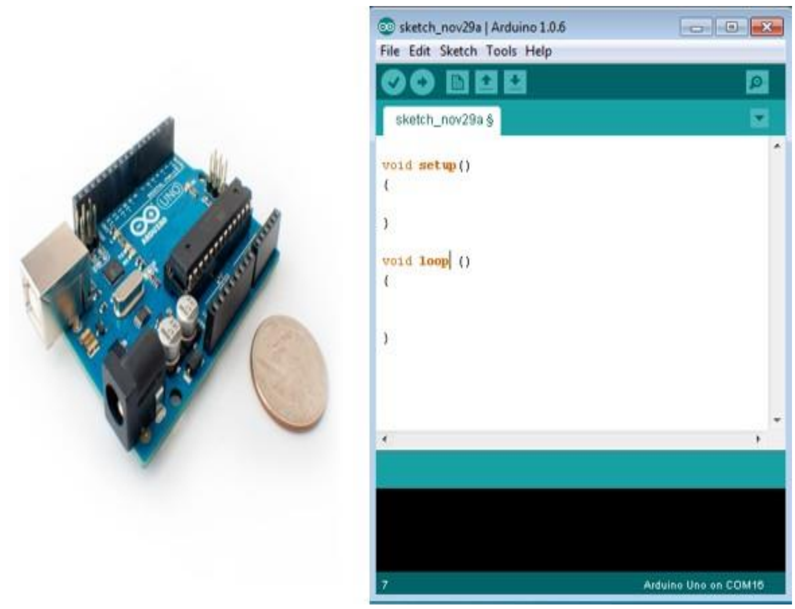

Fig.3.2 Arduino UNO

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE. The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Table 3.1 Arduino Boards based on ATMEGA328 Microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3.5 Arduino Boards based on AT91SAM3X8E microcontroller

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.

5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that

	your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.3 Board Description

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most of them remain the same.

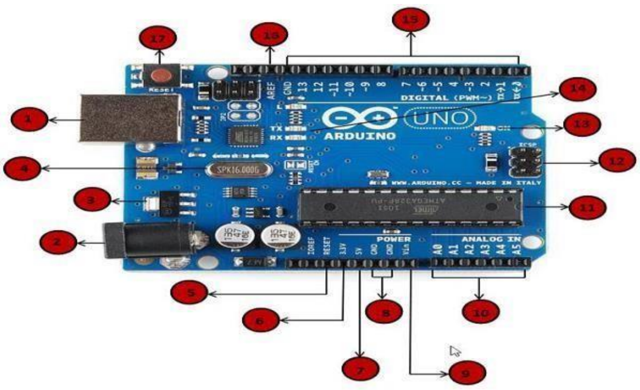

Fig.3.3 Arduino UNO Pin Description

Table 3.6 Arduino UNO Pin Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.

11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality.

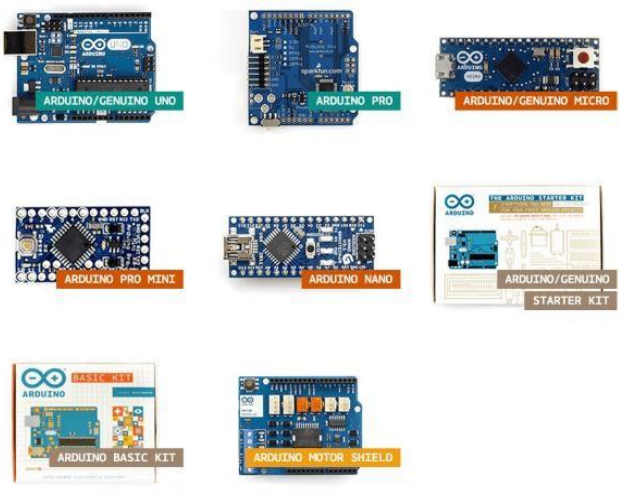

Fig.3.4 Arduino Family

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality.

3.2.1.5 Shields

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

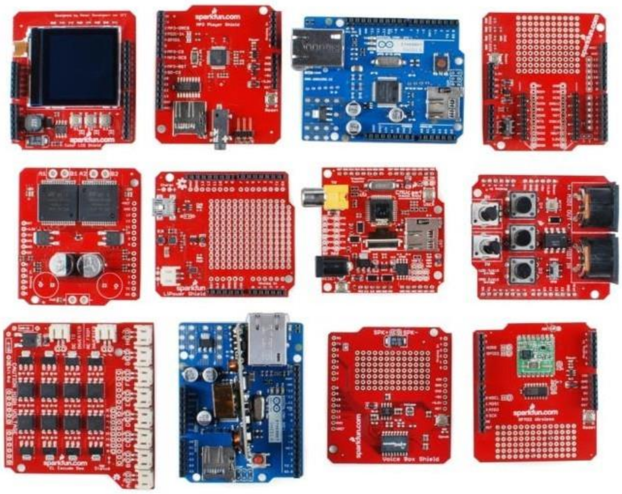

Fig.3.5 Arduino Shields

3.2.1.6Pin description of atmega328

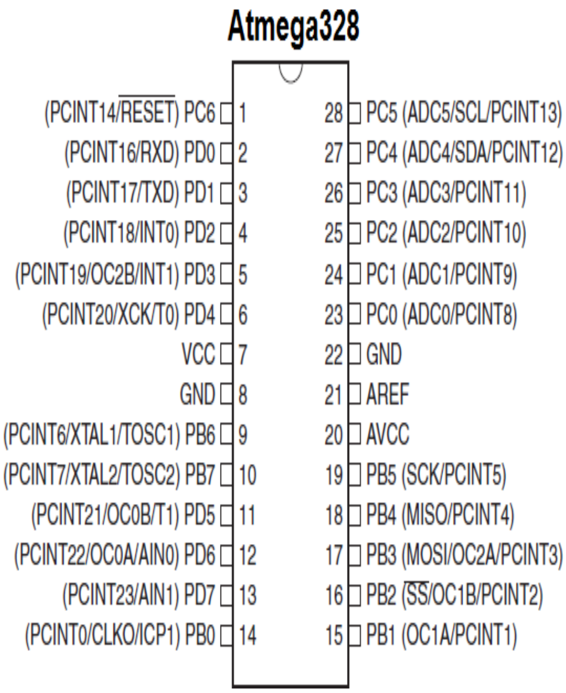

Fig.3.6 Pin Diagram of ATMEGA32

The 14 digital input/output pins can be used as input or output pins by using pinMode(), digitalRead() and digitalWrite() functions in arduino programming. Each pin operate at 5V and can provide or receive a maximum of 40mA current, and has an internal pull-up resistor of 20-50 KOhms which are disconnected by default. Out of these 14 pins, some pins have specific functions as listed below:

Serial Pins 0 (Rx) and 1 (Tx): Rx and Tx pins are used to receive and transmit TTL serial data. They are connected with the corresponding ATmega328P USB to TTL serial chip.

External Interrupt Pins 2 and 3: These pins can be configured to trigger an interrupt on a low value, a rising or falling edge, or a change in value.

PWM Pins 3, 5, 6, 9 and 11: These pins provide an 8-bit PWM output by using analogWrite() function.

SPI Pins 10 (SS), 11 (MOSI), 12 (MISO) and 13 (SCK): These pins are used for SPI communication.

In-built LED Pin 13: This pin is connected with an built-in LED, when pin 13 is HIGH – LED is on and when pin 13 is LOW, its off.

Along with 14 Digital pins, there are 6 analog input pins, each of which provide 10 bits of resolution, i.e. 1024 different values. They measure from 0 to 5 volts but this limit can be increased by using AREF pin with analog Reference() function.

Analog pin 4 (SDA) and pin 5 (SCA) also used for TWI communication using Wire library. Arduino Uno has a couple of other pins as explained below:

AREF: Used to provide reference voltage for analog inputs with analogReference() function.

Reset Pin: Making this pin LOW, resets the microcontroller.

➢ Advantages of arduino

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

➢ Applications

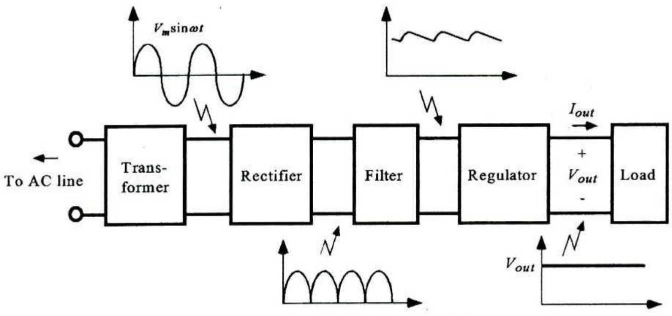
ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low-powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model.

3.2.2 REGULATED POWER SUPPLY*:*

3.2.2.1 INTRODUCTION

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

3.2.2.2 Block diagram of power supply:



Components of a typical linear power supply

Fig.3.7 Block Diagram of Power Supply

3.2.2.3 Description of power supply:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy. A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.2.2.4 Transformer

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or primary winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the secondary winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

➢ Basic Principle of Transformer

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa. It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.For beginners, it is very simple to use.

➢ Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

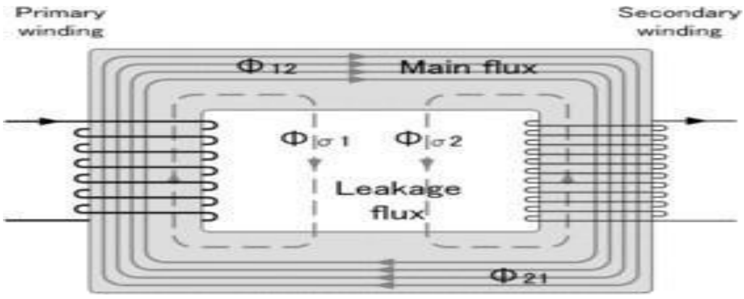


Fig.3.8 Basic Transformer

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.2.2.5 CLASSIFICATION OF TRANSFORMER

1. Step-Up Transformer
2. Step-Down Transformer

(I) Step-Down Transformer*:*

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply. Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

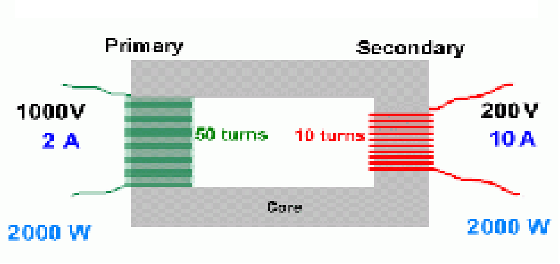

Fig.3.9 Step-Down Transformer

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of thisit is possible to do some non-standard applications using standard transformers.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

(II) Step-up transformer

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input. Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage. The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

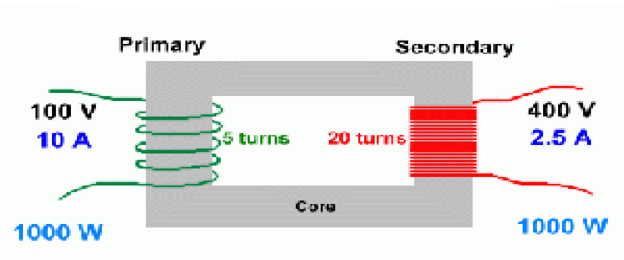

Fig.3.10 Step-Up Transformer

3.2.2.6 RECTIFIER:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as 'half-wave' and 'full-wave' rectifiers. Both use components called diodes to convert **AC** into DC.

- **The Half-Wave Rectifier*:***

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

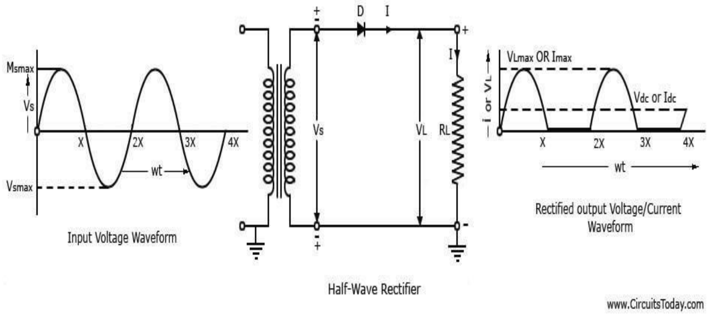

Fig 3.11 Half Wave Rectifier

Figure shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward- biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs. While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all. The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

- **The Full-wave Rectifier:**

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

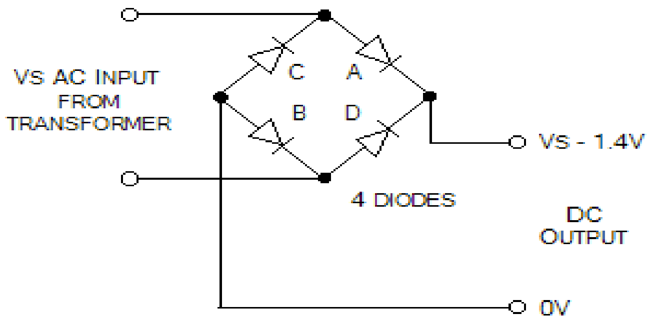

Fig.3.12 Full-Wave Rectifier

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half- wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V.

3.2.3 LIQUID CRISTAL DISPLAY

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other. A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively. Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4).

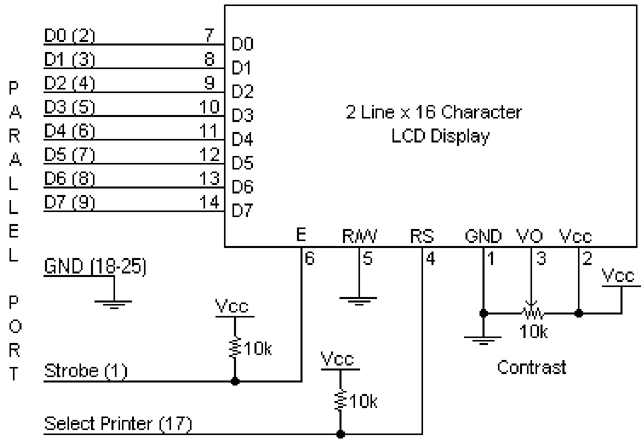

Fig.3.13 Schematic Diagram Of LCD

➢ DESCRIPTION OF 16X2

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

- Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the R/W line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

3.2.3.1 PIN DESCRIPTION

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

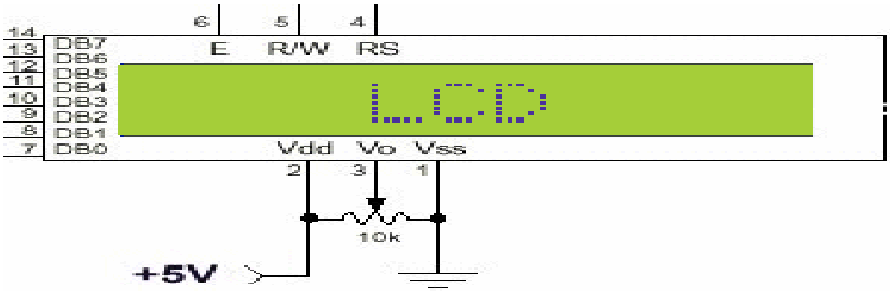

Fig4.20 Pin Diagram Of 1x16 Lines LCD

Table 3.7 16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

Table 3.8 Pin Specifications

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

3.2.4 LIGHT DEPENDENT RESISTOR

A photoresistor or light dependent resistor or cadmium sulfide (CdS) cell is a resistor whose resistance decreases with increasing incident light intensity. It can also be referred to as a photoconductor. A photo resistor is made of a high resistance semiconductor. If light falling on the device is of high enough frequency, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, there by lowering resistance. A photoelectric device can be either intrinsic or extrinsic. An intrinsic semiconductor has its own charge carriers and is not an efficient semiconductor, e.g., silicon. In intrinsic devices the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electron across the entire bandgap. Extrinsic devices have impurities, also called dopants, added whose ground state energy is closer to the conduction band; since the electrons do not have as far to jump, lower energy photons (i.e., longer wavelengths and lower frequencies) are sufficient to trigger the device. If a sample of silicon has some of its atoms replaced by phosphorus atoms (impurities), there will be extra electrons available for conduction. This is an example of an extrinsic semiconductor.

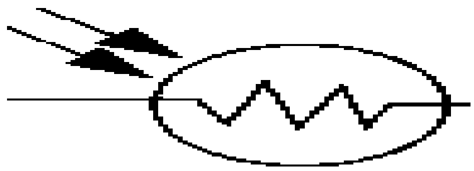

Fig.3.15 The Symbol For A Photoresistor

LDRs or Light Dependent Resistors are very useful especially in light/dark sensor circuits. Normally the resistance of an LDR is very high, sometimes as high as 1000 000 ohms, but when they are illuminated with light resistance drops dramatically. The animation opposite shows that when the torch is turned on, the resistance of the LDR falls, allowing current to pass through it.

- **Basic Structure**

Although there are many ways in which LDR's or photo resistors can be manufactured, ther are naturally a few more common methods that are seen. Essentially the LDR or photo resistor consists of a resistive material sensitive to light that is exposed to light. The photo resistive element comprises section of material with contacts at either end. Although many of the material used for light dependent resistors are semiconductors, when used as photo resistors, they are used only as a resistive element and there are no p-n junctions. Accordingly, the devices purely passive. A typical structure for a Light Dependent Resistor uses an active semiconductor layer that is deposited on an insulating substrate. The semiconductor is normally lightly doped to enable it to have the required level of conductivity. Contacts then placed either side of the exposed area. In many instances the area between the contacts is in the form of zig zag, or inter digital pattern. This maximizes the exposed area and by keeping the distance between the contacts small it enhances the gain. It also possible to use a poly crystalline semiconductor that is deposited onto a substrate such as ceramic. This makes for a very low cost light dependent resistor.

- **Operation**

Light Dependent Resistor made of a high resistance semiconductor, if light falling on the is of high enough efficiently, photon absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electron (and its hole partner) conduct electricity, thereby lowering resistance. In intrinsic devices, the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electrons across the entire band gap. Extrinsic devices have impurities added, which have a ground state energy closer to the conduction band, since the electrons don't have so far to jump, lower energy photons (i.e., longer wavelengths and lower frequencies) will suffice to trigger the device.

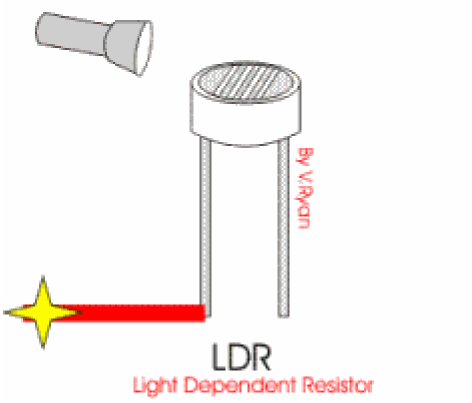

Fig.3.16 LDR Sensor

3.2.5 TEMPERATURE SENSOR (LM35)

3.2.5.1 GENERAL DESCRIPTION:

The LM35 series are precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius (Centigrade) temperature. The LM35 thus has an advantage over linear temperature sensors calibrated in °Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°Cover a full −55 to +150°C temperature range. Low cost is assured by trimming and calibration at the wafer level. The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 µA from its supply, it has very low self-heating, less than 0.1°C in still air. The LM35 is rated to operate over a −55° to +150°C temperature range, while the LM35C is rated for a −40° to +110°C range (−10° with improved accuracy). The LM35 series is available packaged in hermetic TO-46 transistor packages, while the LM35C, LM35CA, and LM35D are also available in the plastic TO-92 transistor package. The LM35D is also available in an 8-lead surface mount small outline package and a plastic TO-220 package (Fig 3.2.1).

Fig.3.17 Temperature Sensor

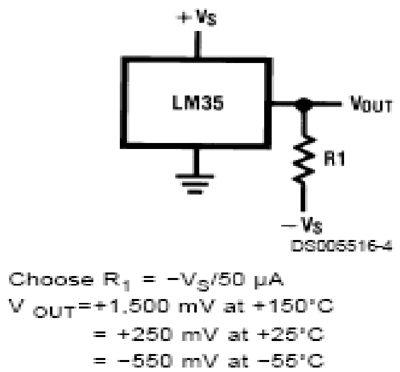

Fig.3.18 LMS

➢ Features

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteeable (at +25°C)
- Rated for full −55° to +150°C range

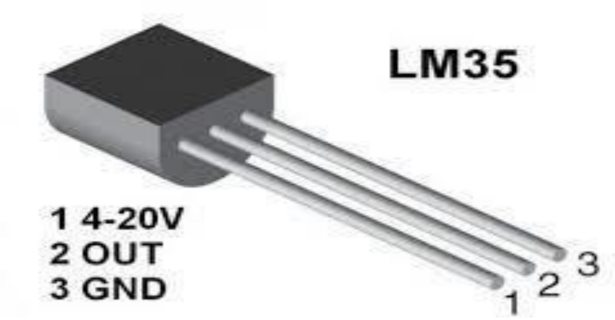

Fig.3.19 LM35

3.2.6 SOIL SENSOR

The moisture of the soil plays an essential role in the irrigation field as well as in gardens for plants. As nutrients in the soil provide the food to the plants for their growth. Supplying water to the plants is also essential to change the temperature of the plants. The temperature of the plant can be changed with water using the method like transpiration. And plant root systems are also developed better when rising within moist soil. Extreme soil moisture levels can guide to anaerobic situations that can encourage the plant's growth as well as soil pathogens. This article discusses an overview of the soil moisture sensor, working and it's applications.

3.2.6.1 What is a Soil Moisture Sensor?

The soil moisture sensor is one kind of sensor used to gauge the volumetric content of water within the soil. As the straight gravimetric dimension of soil moisture needs eliminating, drying, as well as sample weighting. These sensors measure the volumetric water content not directly with the help of some other rules of soil like dielectric constant, electrical resistance, otherwise interaction with neutrons, and replacement of the moisture content. The relation among the calculated property as well as moisture of soil should be adjusted & may change based on ecological factors like temperature, type of soil, otherwise electric conductivity. The microwave emission which is reflected can be influenced by the moisture of soil as well as mainly used in agriculture and remote sensing within hydrology.

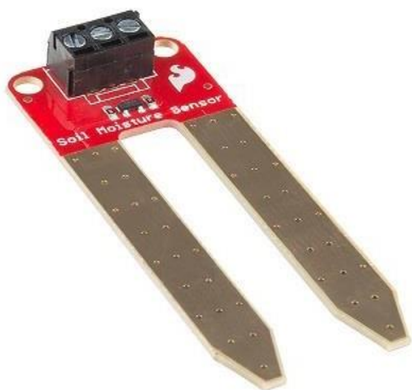

Fig.3.20 Soil Moisture Sensor Device

Fig.3.21 Soil Moisture Sensor FC-28

3.2.6.2 SOIL MOISTURE SENSOR PIN CONFIGURATION

The FC-28 soil moisture sensor includes 4-pins

VCC pin is used for power

- A0 pin is an analog output
- D0 pin is a digital output
- GND pin is a Ground

This module also includes a potentiometer that will fix the threshold value, & the value can be evaluated by the comparator-LM393. The LED will turn on/off based on the threshold value.

3.2.6.3 WORKING PRINCIPLE

This sensor mainly utilizes capacitance to gauge the water content of the soil (dielectric permittivity). The working of this sensor can be done by inserting this sensor into the earth and the status of the water content in the soil can be reported in the form of a percent. This sensor makes it perfect to execute experiments within science courses like environmental science, agricultural science, biology, soil science, botany, and horticulture.

➢ **Specifications**

The specification of this sensor includes the following.

- The required voltage for working is 5V
- The required current for working is <20mA
- Type of interface is analog
- The required working temperature of this sensor is 10°C~30°C

3.3 SOFTWARE COMPONENTS

- Proteus simulation
- Arduino software
- Programming language

3.3.1 Arduino Software

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs.

3.3.1.2 Arduino

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

1) Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50

2) Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to windows.

3) Simple, clear programming environment - The Arduino Software (IDE) is easy- to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

4) Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

5) Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

6) Getting Started with Arduino and Genuino products:- Install the Arduino Software (IDE) on Windows PCs This document explains how to install the Arduino Software (IDE) on Windows machines.

7) Download the Arduino Software(IDE).

➢ How to Download the Arduino Software (IDE)

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

3.3.1.3 INSTALLATION

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.22 cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.3.23 Mini-B Cable

Step 2 − Download Arduino IDE Software

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

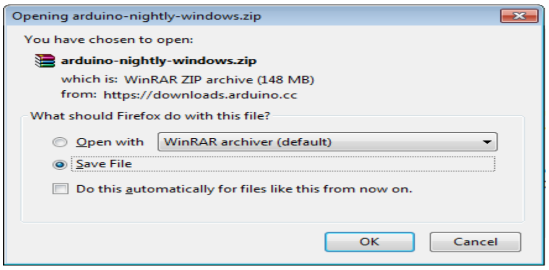

Fig.3.24 Arduino IDE Software

Step 3 − Power Up Your Board

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port. Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE

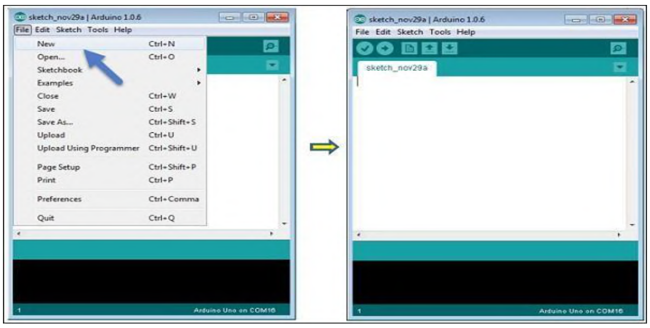
After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

Step 5 − Open Your First Project

Once the software starts, you have two options −

Create a new project.

Open an existing project example.



.

Fig.3.25 Creating New File

Step 6 – Select Your Arduino Board

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

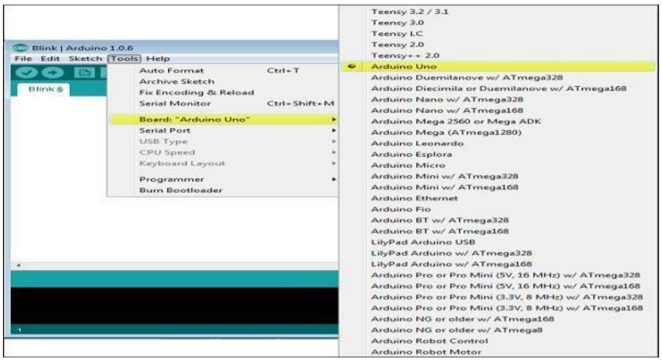


Fig.3.26 Tools Board

Step 7 – Select Your Serial Port

Select the serial device of the Arduino board. Go to Tools → Serial Port menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

Step 8 – Upload The Program To Your Board

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

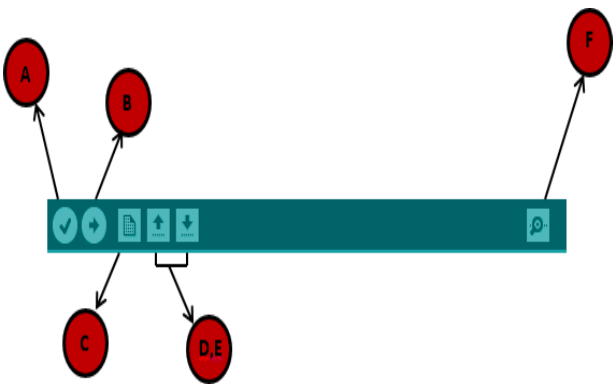

Fig.3.27 Uploading Program

A − Used to check if there is any compilation error. **B** − Used to upload a program to the Arduino board. **C** − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar. If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

- **Connecting a Battery**

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs.

- **Moving On**

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run. Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs. In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
 void setup()
{
Serial.begin(9600); Serial.println("Hello World");
            } void loop() {}
```

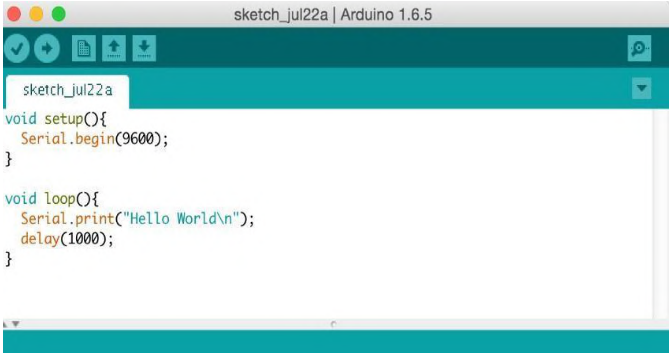

Fig.3.28 Arduino

3.3.2 PROTEUS*:*

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

3.3.2.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

3.3.2.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc. ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

3.3.2.3 Starting New Design

Step 1: Open ISIS software and select New design in File menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

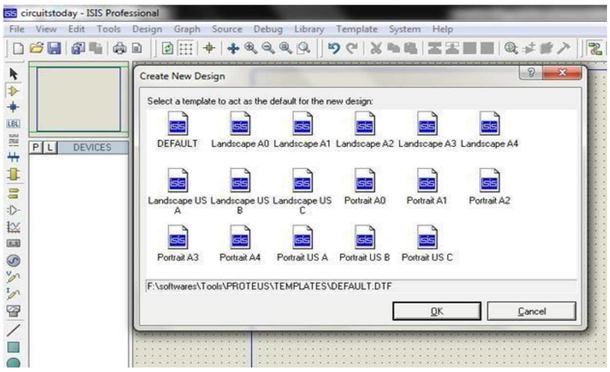

Fig.3.29 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

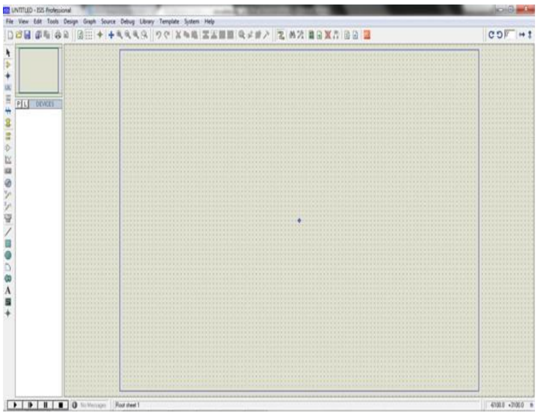

Fig.3.30 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

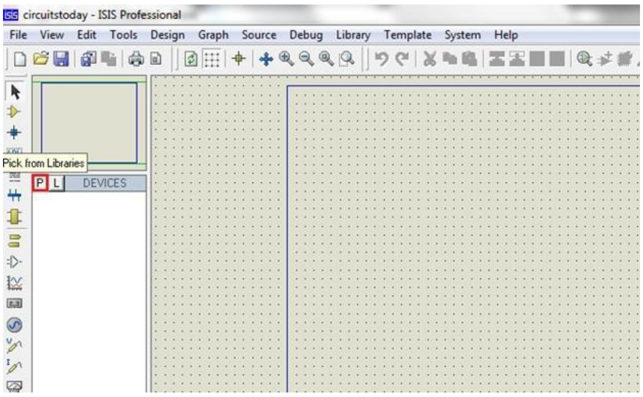

Fig.3.31 Pick From Libraries

Step 6: Select the components from categories or type the part name keyword.

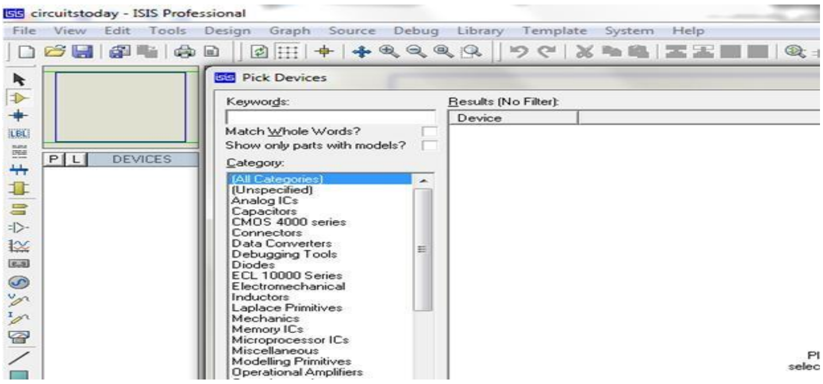

Fig.3.32 Key Word Textbox

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click. Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively. Double click on the component to edit the properties of the components and click on Ok.

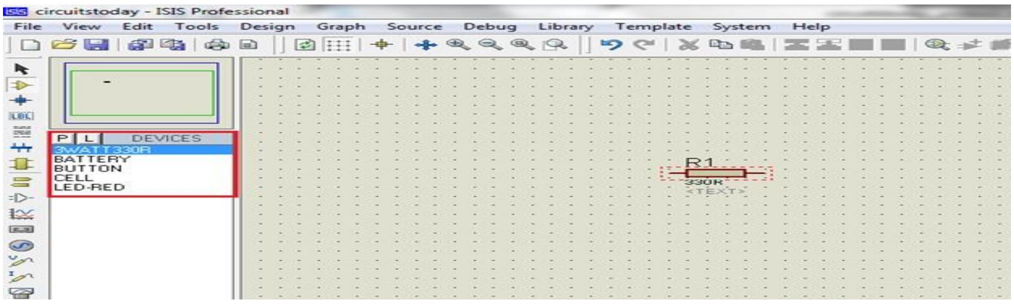

Fig.3.33 Component Selection

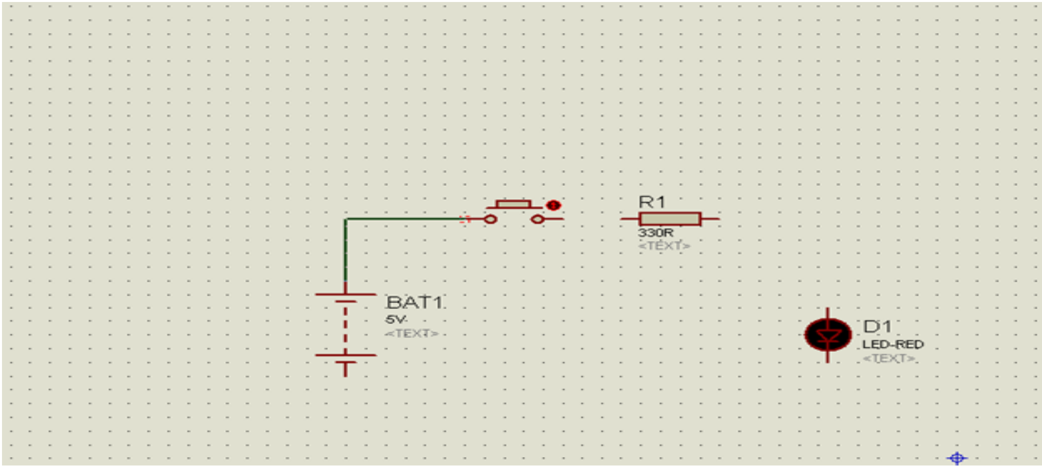

Fig.3.34 Simulation

Step 8: After connecting the circuit, click on the play button to run the simulation. Simulation can be stepped, paused or stopped at any time. In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

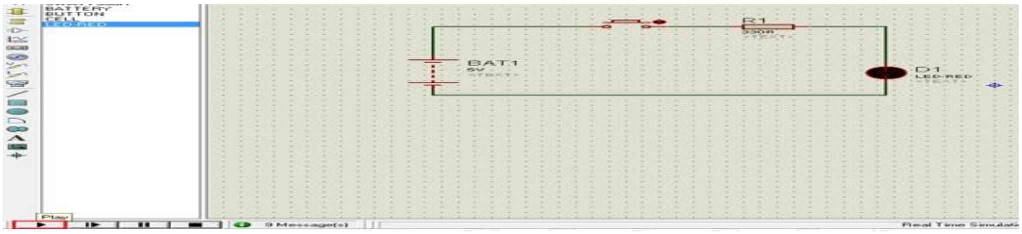

Fig.3.35 Simulation Run

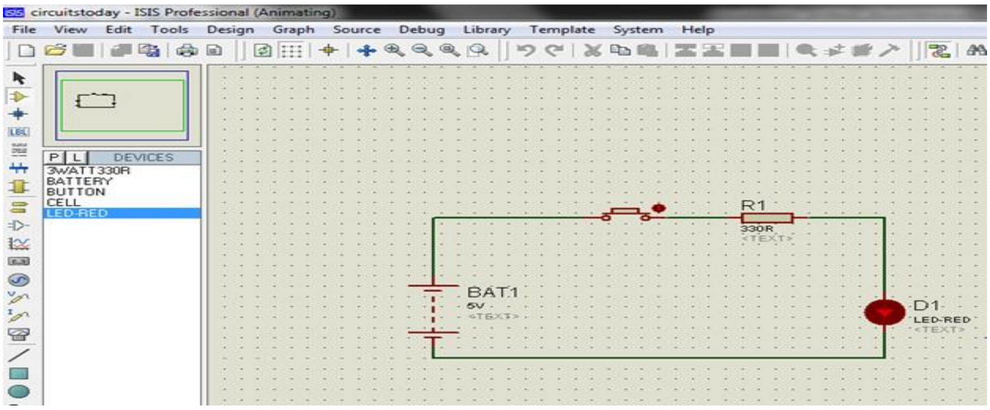

Fig .3.36 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

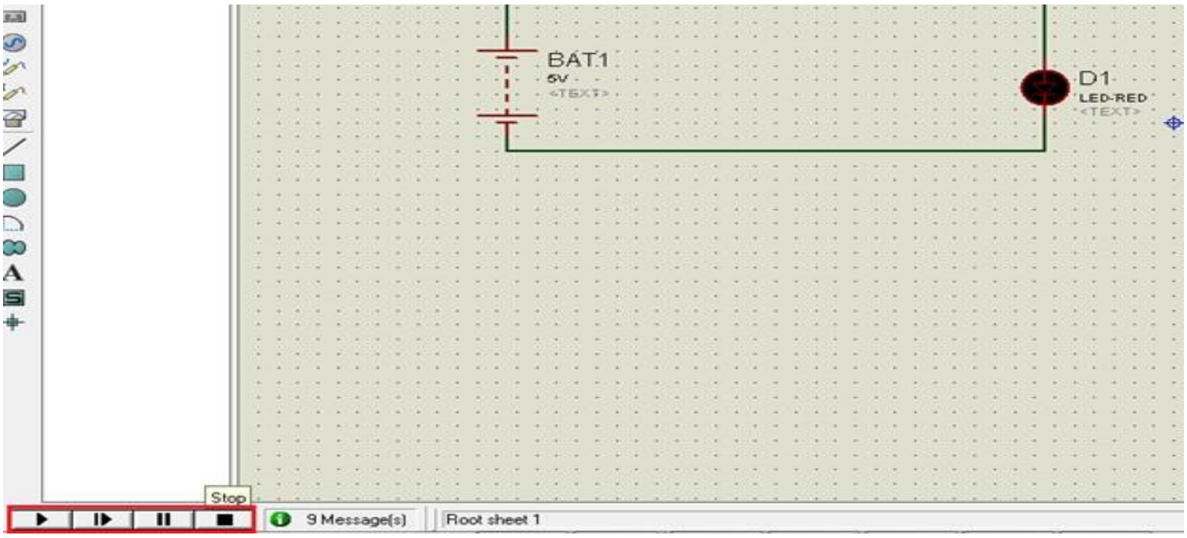

Fig. 3.37 Simulation Step-Pause-Stop Buttons

3.3.3 TELNET MOBILE APP:

Telnet is a client-server protocol, based on a reliable connection-oriented transport. Typically, this protocol is used to establish a connection to TCP port number 23, where a Telnet server application (telnetd) is listening. Telnet, however, predates TCP/IP and was originally NCP protocols.

Even though Telnet was an ad hoc protocol with no official definition until March 5, 1973,[3] the name actually referred to Teletype Over Network Protocol as the RFC 206 (NIC 7176) on Telnet makes the connection clear:[4]

The TELNET protocol is based upon the notion of a virtual teletype, employing a 7-bit ASCII character set. The primary function of a User TELNET, then, is to provide the means by which its users can 'hit' all the keys on that virtual teletype. Essentially, it used an 8-bit channel to exchange 7-bit ASCII data. Any byte with the high bit set was a special Telnet character. On March 5, 1973, a Telnet protocol standard was defined at UCLA with the publication of two NIC documents: Telnet Protocol Specification, NIC 15372, and Telnet Option Specifications, NIC 15373. Many extensions were made for Telnet because of its negotiable options protocol architecture. Some of these extensions have been adopted as Internet standards, IETF documents STD 27 through STD 32. Some extensions have been widely implemented and others are proposed standards on the IETF standards track. Telnet is best understood in the context of a user with a simple terminal using the local Telnet program (known as the client program) to run a logon session on a remote computer where the user's communications needs are handled by a Telnet server program. When Telnet was initially developed in 1969, most users of networked computers were in the computer departments of academic institutions, or at large private and government research facilities. In this environment, security was not nearly as much a concern as it became after the bandwidth explosion of the 1990s. The rise in the number of people with access to the Internet, and by extension the number of people attempting to hack other people's servers, made encrypted alternatives necessary.

3.4 DEFINE THE MODULES:

3.4.1 WIFI MODULE

The ESP8266 is a low-cost WiFi module that can be integrated easily into IoT devices. The ESP8266 is a small WiFi module built around the ESP8266 chip that can connect your microcontroller to the internet wirelessly for a very small cost. It can be a great option for Internet of Things (IoT) projects, but can be difficult to work with for beginner hobbyists who do not have prior experience with the module.

Fig.3.38 ESP8266 ESP-01 Module

3.3.2 ESP-01 Features

- 802.11 b/g/n
- Wi-Fi Direct (P2P), soft-AP
- Integrated TCP/IP protocol stack
- Integrated TR switch, balun, LNA, power amplifier and matching network
- Integrated PLLs, regulators, DCXO and power management units
- +19.5dBm output power in 802.11b mode
- Power down leakage current of <10uA
- 1MB Flash Memory
- Integrated low power 32-bit CPU could be used as application processor
- SDIO 1.1 / 2.0, SPI, UART
- STBC, 1×1 MIMO, 2×1 MIMO
- A-MPDU & A-MSDU aggregation & 0.4ms guard interval
- Wake up and transmit packets in < 2ms
- Standby power consumption of < 1.0mW (DTIM3)

The first feature to notice about the ESP8266 is its awkwardly spaced header pins. The module has 8 pins that serve different functions, but they are packed in a 4×2 arrangement that makes plugging the module into a breadboard impossible. This means that to prototype projects on a breadboard, you'll need male-female jumper wires to connect the pins on the ESP8266 to rows on the breadboard. If you'd like to make your prototyping more compact, you can also purchase breadboard breakouts for the ESP8266 such as this one. For prototyping, I chose to just use jumper wires.

The pinout for the ESP8266's pins are according to the following diagram:

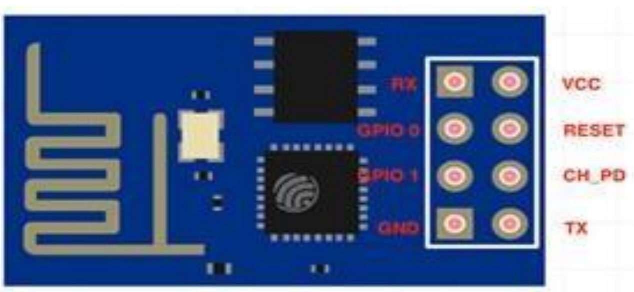

Fig.3.39 ESP8266 Pinout

RX: UART serial communication receive pin

GPIO 0: GPIO pin (unused in this project)

GPIO 1: GPIO pin (unused in this project)

GND: Connection to Ground

VCC: Connection to 3.3V Vcc (Vcc cannot exceed 3.3V!)

RESET: Reset pin (pull down to reset)

CH_PD: Chip enable and power down pin

TX: UART serial communication transmit pin

Note that the maximum voltage input for the ESP8266 is 3.3V. Any input voltage greater than 3.3V will damage the module! To program settings on the ESP8266, we'll first need to connect it to a serial terminal on a computer through which we can send it special commands. Settings that we'll have to program include, for example, the SSID and password for the wifi network the module will be connected to. To connect the ESP8266 to a computer and configure its settings, we'll need a USB to serial adapter with 3.3V logic, along with a serial terminal program. Fortunately for us, we have the Arduino and the Arduino IDE's serial monitor! This means that we'll just have to connect the ESP8266 module to the Arduino and upload a custom sketch to the Arduino. Use the following diagram to connect the ESP8266 module to the Arduino:

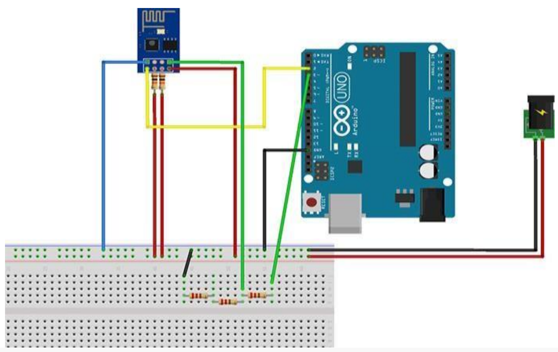

Fig.3.40 Connection Between ESP8266 and Arduino Uno

- Arduino Uno or similar module
- ESP8266 ESP-01 module
- 2 x 1kΩ resistors for CH_PD and RESET pull-up
- 3 x 220Ω resistors for serial line voltage divider
- 3.3V regulated power supply for ESP8266 (you cannot plug the power line into the Arduino's 3.3V out pin because the ESP8266 draws a lot of current!)
- Breadboard and jumper wires

First, the ESP8266 module is powered by a 3.3V regulated power supply. As described earlier, the ESP8266 has a maximum voltage input rating of 3.3 volts. Using a power supply rated higher than this recommended 3.3 volts could fry the module! When connecting the ESP8266 to this power supply, you should not only connect the Vcc and Ground pins to the power supply lines, but also connect the power supply's ground line to the Arduino's ground pin. Since the Arduino will be powered by the USB connection to the laptop, creating a common ground essentially creates a common reference (you can think of it as a baseline) to compare voltages and thereby interpret digital high and low signals.

Second, the receive (RX) line for the ESP8266 module is connected to the output of a resistor voltage-divider circuit. We do this to shift the serial communication logic level (the highs and lows of the digital signals that make up the serial communications) from a logic high of 5 volts on the Arduino to a logic high of 3.3 volts on the ESP8266 module. Again, the ESP8266 is specified with 3.3V logic, so connecting the module's receive line directly to the Arduino's transmit line could damage the device. We do not need to shift levels on the ESP8266's transmit line because the module's 3.3V logic high is a high enough voltage to also register as a logic high on the Arduino.

Finally, there are two pull-up resistors on the ESP8266's CH_PD and RESET pins. These are specified by the module's creators to ensure that the device functions properly while it is being used. To reset the ESP8266 or disable it, these pins must be pulled down, but since we do not want those processes to occur, we will instead pull these pins high through some 10kΩ pull-up resistors.

3.4.3 STRUCTURE AND CONFIGURATION:

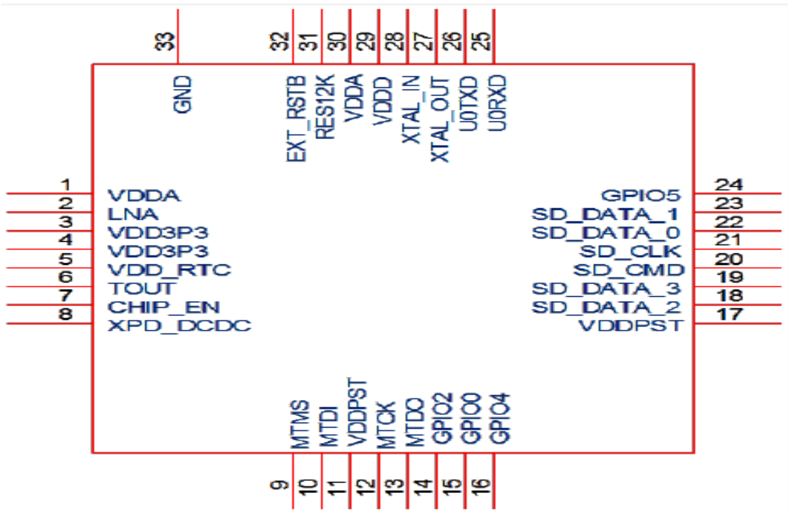

Fig.3.41 Structure and configuration

3.5 MODULE FUNCTIONALITIES:

3.5.1 ESP8266 WIFI MODULE

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community. This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts. There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM

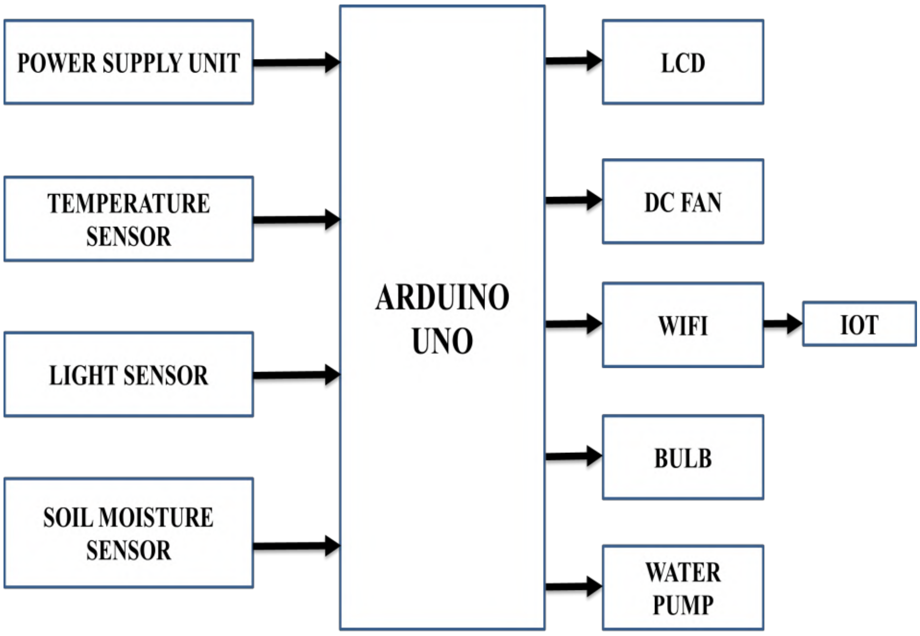

Fig.4.1 Block Diagram

The system consists of three input sensors to detect temperature,light intensity and soil moisture sensor.Corresponding load is given to the arduino uno as DC fan,bulb and water pump respectively.The data sensed is sent to the microcontroller and it controls the load according to the varying parameter.At the same time ,data regarding these parameters are sent to IOT module .WiFi module is used to establish connection between microcontroller and the WiFi network and make TCP/IP connections and sends the data to the IOT.

4.2 FLOW CHART

The system is turned on. The parameters such as temperature, light intensity and soil moisture is read using the temperature sensor, LDR and soil moisture sensor respectively. The read parameters are then sent to arduino .If the temperature exceeds the threshold value then the fan is turned on to cool the system. When the temperature becomes normal the fan gets turned off automatically. Initially the light sensor is kept low. Hence when the sensor detects no light the bulb is turned off. The data collected from the soil moisture sensor is sent to the microcontroller and it performs the operation of turning the pump on if the soil is detected as dry,else turned off if the soil retains the moisture content. The sensed data is constantly sent to the IOT where the WiFi module establishes a connection and the user retrieves the data.

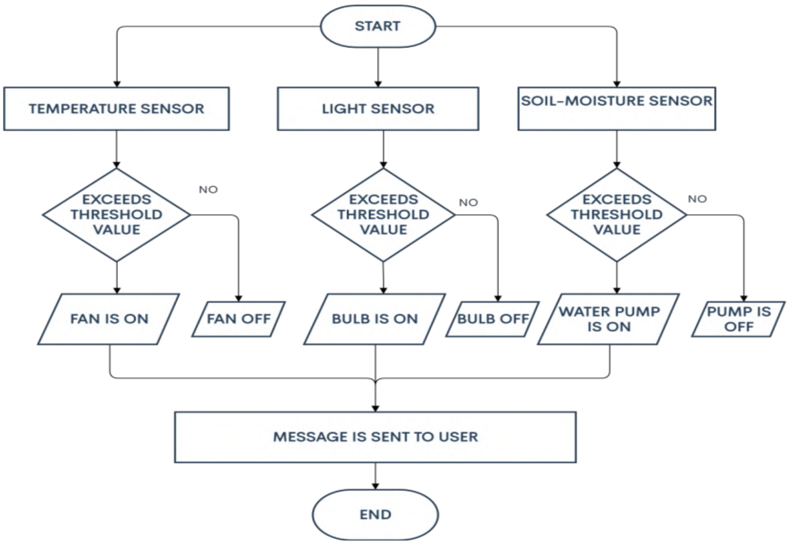

Fig 4.2 Flow Chart

4.3 IMPLEMENTATION STAGES

Stage-1: Firstly on lcd the message is displayed showing IOT Based Greenhouse indicating the succesful turning on of the system.

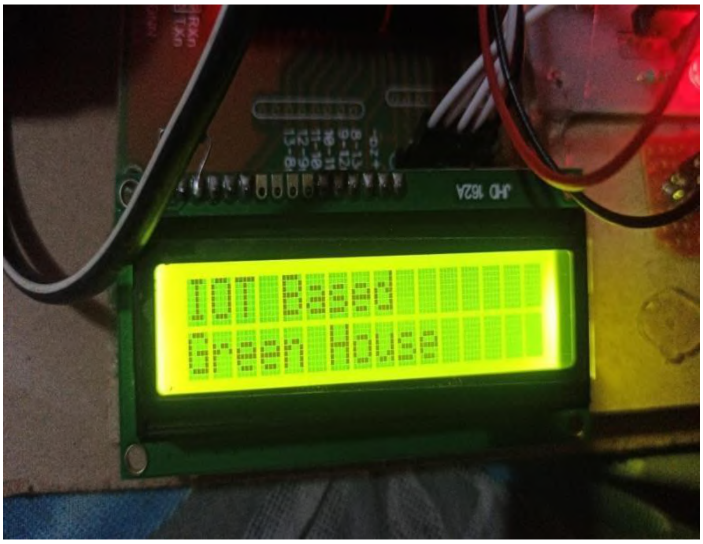

Fig.4.3 LCD Display When The System Is Turned On

Stage-2: Secondly on lcd receive a message displaying waiting for link that indicates the wifi is not yet connected.

Fig.4.4 Waiting For Link

Stage-3: In Mobile Telnet App, message such as welcome is shown when the wifi is connected to ESP8266 WIFI Module.

Fig.4.5 Welcome Message Displayed

Stage-4: After the system is turned on,the detected parameters are shown on the LCD

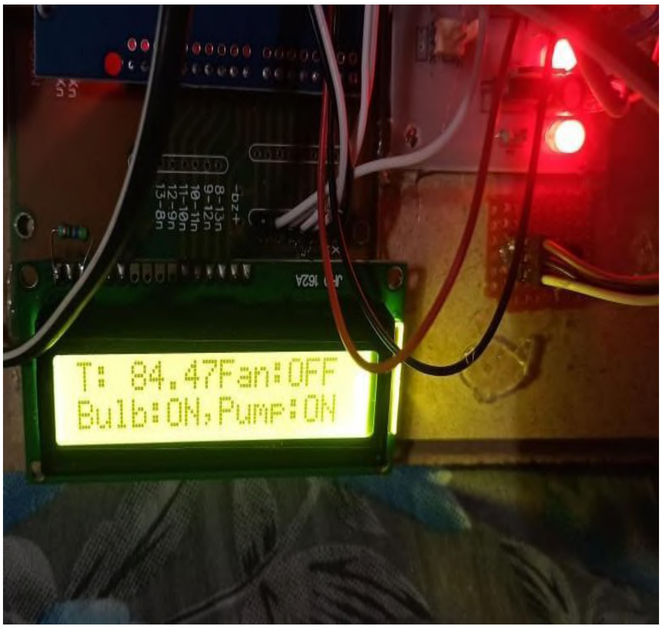

Fig.4.6 System Working During Night With Normal Temperature And Dry Soil

Stage-5: The soil is made wet and then parameter gets displayed on the LCD.

Fig.4.7 Result When Soil Is Wet

Stage-6: When the temperature inside the greenhouse structure rises,the message displayed on LCD is noted indicating the fan is turned on to cool the system.

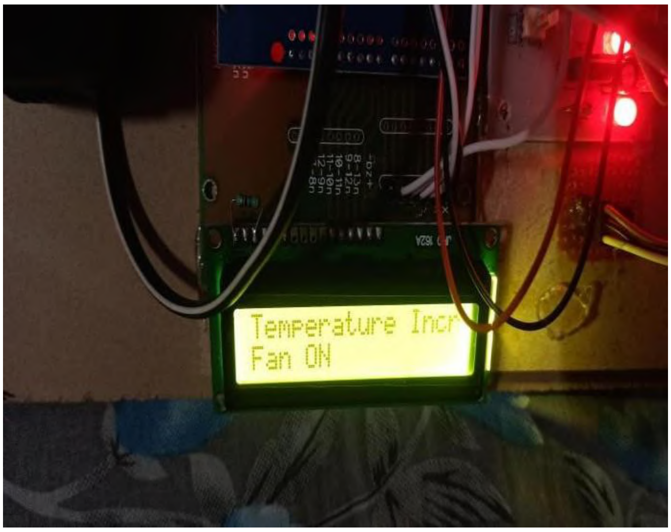

Fig.4.8 When The Temperature Exceeds The Set Threshold Value

Stage-7-Finally,the system is tested during the day indicating the presence of light which in turn puts on the bulb.

Fig.4.9 Result during Day Time

4.5 RESULTS

This hardware setup gives a brief idea as to how the project “Greenhouse Monitoring And Control System Using IOT” works. In the hardware implementation, all the sensors used are connected to the microcontroller. The system has been wired using jumper cables. A DC power supply of 5V is given to the microcontroller and to the sensors. Besides, 9V DC power supply is provided for light, fan and the water pump. An LCD is mounted on the board. The connections are made between the microcontroller and the sensors. The WiFi module establishes a path between the microcontroller and the user's device to get the sensor value in order to monitor and control the system. If the values of the parameters exceeds the load connected to it gets automatically turned on and when the value is in normal condition the fan, light and the motor remains off. The system is capable of sending the measured values to the user's device such as a mobile via wireless connection. Thus controlling and monitoring occurs simultaneously.

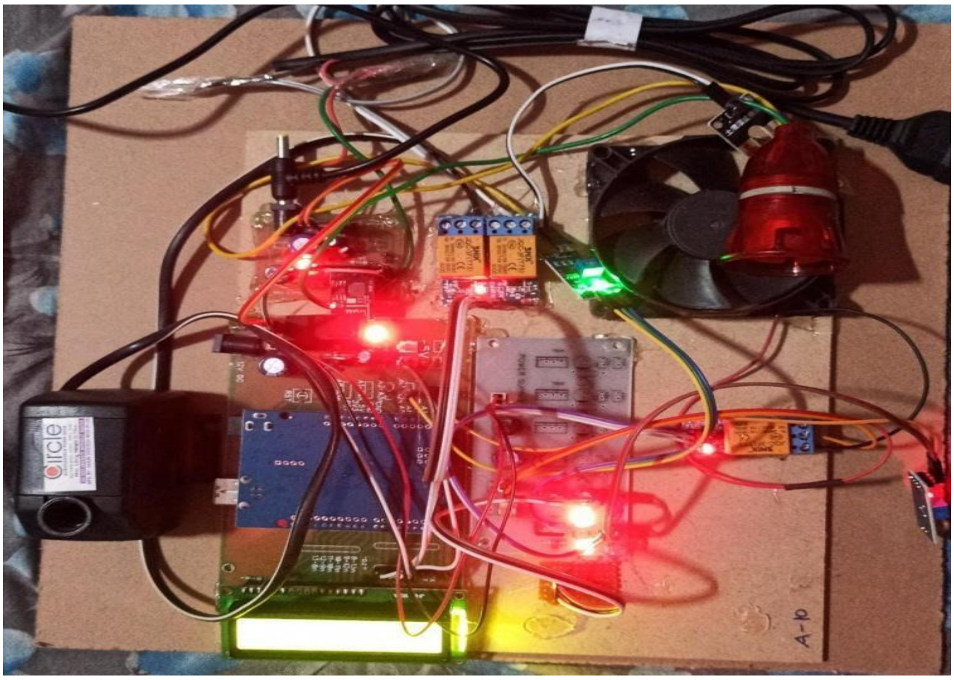

Fig.4.10 Final Output

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Today, government wants to take the greenhouse monitoring and control system one step further, with more sophisticated systems included in it to increase the cultivation and the production rate.Department of Agriculture and Cooperation has been promoting capital investment and has been extending financial assistances for the building of greenhouse structures.It is thus obvious that for ensuring rapid growth of quality infrastructure for protected cultivation.This has necessitated prescribing technical standards specifications and linking the same with normative costs in larger cost in large interest of the industry and user farmers.

Security: IoT is a combination of physical objects (“things”), sensors, embedded software and keeps a goal of effective connectivity and faithful data exchange.
The current graphs imply that IoT market growing at remarkable rate. However, some of these devices suffer from limited memory, power consumption and processing power.

These issues may cause IoT to become penetrable and hence security is at utmost priority to IoT domain.

As stated in a 2015 report by Hewlett-Packard on IoT research [3]:
1. Per 100, 70 devices still use un-encrypted network services
2. Per 100, 90 devices collected at least one piece of personally identifiable information (via device, cloud or mobile app)
3. Per 100, 70 devices (with cloud and mobile app components) enabled an attacker to identify valid user accounts through enumeration.
4. 80% of devices (with cloud and mobile app components) failed to require passwords of sufficient complexity
5.Behind every 10 device every 6 devices user interfaces (UI) were vulnerable

Following are the vulnerabilities of the IoT as per The Open Web Application Security Project (OWASP)

1) Insufficient protection compositions.
2) Dubiously secured Software/Firmware
3) Doubtful Network Services
4) Doubtful Web Interface
5) Worst Physical Security
6) Doubtful Cloud Interface
7) Doubtful Mobile Interface
8) Privacy Concerns
9) Doubtful Authentication/Authorization
10) Inadequate Transport Encryption Ongoing approaches to secure IoT have attempted to put a grip on communication protocol-based mechanisms, such as encryption for data-at-rest or in-transit.

But this itself is doubtful if the respective endpoints themselves are capable of being modified either by local access or remote connections.

Gartner claims that by year 2020 more than 25% of identified attacks in a particular company will be on IoT devices or systems, even though IoT will only contribute to less than 10% of IT security budgets.

The testing methods of the project which is Greenhouse Monitoring and Controlling System using IoT is it requires a mobile app, wifi connection . Firstly on lcd we recieve a message displaying waiting for link that indicates the wifi is not yet connected.In Mobile Telnet App, we will get a message like welcome when the wifi is connected to ESP8266 WIFI Module.After the wifi is connected,we will get a message on LCD displaying Please Scan UR Card.When we scan the card, if sufficient amount is available, we will get a message access granted for person and remaining balance will be displayed on LCD.When we scan the card, if sufficient amount is not available, we will get a message access denied for person and balance will be displayed on LCD.When card is recharged, amount will be added to card and display’s person recharge done on LCD Screen.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION:

Currently the existing system have limitation of not being able to simultaneously measure the parameters. This system enables people to monitor and manage growing conditions of their greenhouses. The use of modern sensors with integration of internet will deliver real-time updates about the crops and help people grow their plants more effectively and increase the yields. With all the tests results it can be concluded that the project will provide a solution for automating greenhouse activities and irrigation activities. Implementation of such systems can definitely help in overall production .The IOT used in the system enables the conveyance of the information gathered about greenhouse to the user..The project depicts how technology reduces human efforts.

6.2 FUTURE ENHANCEMENT:

- The system performance can be further expanded by increasing operating speed, memory capacity and instruction cycle period of microcontroller.
- To operate multiple greenhouses concurrently ,a multi-controller system can be developed. Connection establishment of WiFi with other devices like MODEM or cellular phones can be introduced apart from android phones.
- Greenhouses with high value crops are vulnerable targets for thieves. So security systems can be implemented by adding on surveillance networks with CCTV.
- More sensors can be added in addition to the ones already used like rain sensors.
- Time bound administration of fertilizers, insecticides and pesticides can be introduced.
- A multi controller system can be developed that will enable a master controller along with its slave controllers to automate multiple greenhouses simultaneously.

PUBLICATION

Submitted Paper in the Conference ICSMEC - 21 with Paper ID (ICISEC21-0053) and got Acceptance for the Paper.

DECLARATION

We, the students of **Bachelor of Technology** in Department of **Electronics and Communication Engineering**, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **'Real Time Vehicle Theft Control System Using Engine Temperature Measurement'** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

G.Jeevani (17K81A0418)
P.Keerthi (17K81A0436)
K.Supriya (18K85A0406)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide **Mr.G.Ramesh, Assistant Professor**, Department of ECE and our class project coordinator **Ms.A.Sowmya, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

REAL TIME VEHICLE THEFT CONTROL SYSTEM USING ENGINE TEMPERATURE MEASUREMENT

ABSTRACT

This project deals with the design and development of a theft control system for an automobile, which is being used to prevent or control the theft of a vehicle. The developed system makes use of an embedded system based on GSM technology. The designed and developed system is installed in the vehicle. An interfacing mobile is also connected to the microcontroller, which is in turn, connected to the engine. Once, the vehicle is being stolen, the information is being used by the vehicle owner for further processing. The information is passed onto the central processing system. By reading the signals received by the mobile, one can control the ignition of the engine; say to lock it or to stop the engine immediately.

CHAPTER 1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

This project is used when the vehicle is stolen i.e., when the temperature in the engine varies the information is passed onto the central processing system, whereby sitting at a remote place, a particular number is dialed by them to the interfacing mobile that is with the hardware kit which is installed in the vehicle.The owner can say to lock it or to stop the engine immediately. Again, it will come to the normal condition only after entering a secured password. The owner of the vehicle & the central processing system will know this secured password. The main concept in this design is introducing the mobile communications into the embedded system. The designed unit is very simple & low cost. The entire designed unit is on a single chip. When the vehicle is stolen, owner of vehicle may inform to the central processing system, then they will stop the vehicle by just giving a text to that secret number and with the help of SIM tracking knows the location of vehicle and informs to the local police or stops it from further movement. Here temperature sensor is used to know the engine position with help of heat dissipated in it.

1.2 OBJECTIVES OF THE STUDY

The main objective of this project is to develop a automatic ignition control system of vehicle for detecting theft. Here are some of the methods to provide safety measures at low cost. Theft prevention and safety measures can be provided by using Digital Ignition lock with highly efficient sensors like MEMS. This project designs an automatic ignition control system of vehicle which monitors abnormal situations. Many ideas were either proposed or formulated to provide safety to the vehicles by using the combination of pattern ignition with the MEMS to protect the vehicles from theft.

1.3 SCOPE OF THE STUDY

The vehicle theft and tracking machine is an essential kit to reduce the no. of increased theft of vehicles which is commonly known as antitheft kit. Most of the theft cases are occurred due to the Hot wiring, Hijacking and opportunistic theft. Certain safety measures are only available at high cost. These GSM and GPS tracking systems for cars project significantly reduce the time, manpower and operates without interference of humanoid. In the modern world, there are various new technologies like GPS, GSM, RFID, Biometric Recognition. Mobile communication has been integrated into vehicles for security purposes. In this project GPS technology is used to find the exact location of the vehicle and GSM is used to send the message to the owner of the vehicle.

1.4 MATERIAL REQUIREMENT

HARDWARE REQUIREMENT :

- Arduino Uno
- Power Supply Unit
- Temperature Sensor
- GPS Module
- LCD
- L293D
- DC Motor
- GSM Module

SOFTWARE REQUIREMENT :

- Arduino IDE
- Proteus

1.5 PROCUMENT OF EQUIPMENT

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- We can control board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. We can simply use a USB cable.
- The Arduino IDE uses a simplified version of C++, making it easier to learn to program.

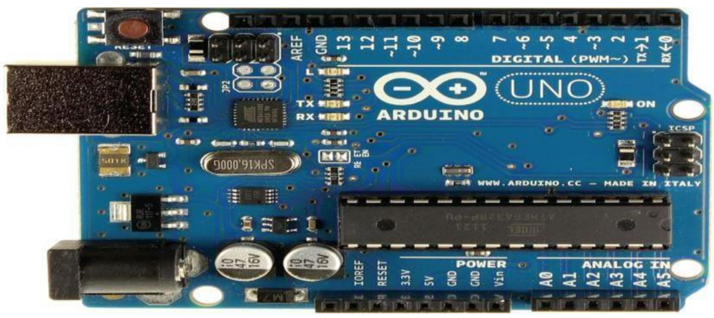

Fig 1.1: Arduino Uno

GPS:

The Global Positioning System (GPS), is one of the global navigation satellite systems (GNSS) that provides geolocation and time information to a GPS receiver anywhere on or near the Earth where there is an unobstructed line of sight to four or more GPS satellites. The GPS does not require the user to transmit any data, and it operates independently of any telephonic or internet reception, though these technologies can enhance the usefulness of the GPS positioning information. The GPS provides critical positioning capabilities to military, civil, and commercial users around the world.

Fig 1.2: GPS Module

GSM Module:

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services.GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot.

Fig 1.3: GSM Module

TEMPERATURE SENSOR (LM35):

LM35 is a temperature sensor that outputs an analog signal which is proportional to the instantaneous temperature. The output voltage can easily be interpreted to obtain a temperature reading in Celsius. The advantage of lm35 over thermistor is it does not require any external calibration. The coating also protects it from self-heating. Low cost and greater accuracy made it popular . LM35 can measure from -55 degrees centigrade to 150-degree centigrade. The accuracy level is very high if operated at optimal temperature and humidity levels. The conversion of the output voltage to centigrade is also easy and straight forward.

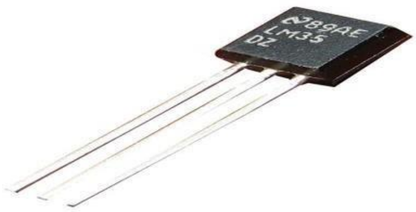

Fig 1.4: Temperature Sensor

Proteus:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It is a software suite containing schematic,simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.
The designer can also develop 2D drawings for the product.

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components.

CHAPTER 2

LITERATURE SURVEY

2.0 LITERATURE REVIEW ON RESEARCH AREA

In India according to vehicle theft, burglary census from 2013 the vehicle thefts are increasing nearly 8.47 % on an average, for this situation the technology to avoid the theft of the vehicle must also be increased, Microcontroller based real time vehicle theft detection and prevention system provide solution for this problem. The Global system of mobile (GSM) communication is a globally accepted standard for cellular communication. The vehicle owner uses Subscriber Identity Module (SIM) inserted with in his mobile phone to send messages to GSM modem and GPS system which is a part of the vehicle theft prevention system that is attached to vehicle. This system is used for any vehicle like bus, bikes or cars and is cost effective. Some people uses the GPS system only to the vehicle to trace the vehicle location like the latitude, longitude and speed of the vehicle but not useful for controlling the vehicle. Some people uses only GSM for controlling the vehicle but not useful to trace the vehicle, some researchers uses GSM, GPS system to control the vehicle as well as to trace its location. The literature review of the work is as follows.

A researcher developed an anti-burglary vehicle security system, which uses thumb impression to start the vehicle. The authorized persons thumb impressions are stored in the database of the system. The vehicle is started if the finger print of the database is matched. If anyone accessed the vehicle by chance then the fuel tank will be emptied through the relay bolt fitted to the tank at the same time it gives alarm that the vehicle is theft so that the unauthorized person cannot refill the emptied fuel tank.

Some researchers uses GSM, GPS & RFID security system for taxi like vehicles. For starting the vehicle the worker must use the RFID card in which the identification number is provided such that the identification numbers already preloaded in to the database of the system, If the number is matched, GPS and GSM comes in to play and sends SMS to the vehicle owner the location like latitude and longitude of the vehicle. If the owner detected theft

by chance then he sends the SMS to the GSM such that it will lock the doors of the vehicle.

A researcher used GSM system, Microcontroller, and relay switch for the ignition system. It theft is detected the Microcontroller activates the GSM system to send SMS to the owner, If the owner gives reply to the SMS then the relay switch is activated and it deactivate the ignition system.

Another researcher used GPS-GSM system that uses Google earth application. The system contains GPS module provided in the vehicle, this GPS module exchanges information with the GSM system to send SMS to the owner. After getting SMS to the owner, he can trace the latitude, longitude and speed of the vehicle using Google earth application.

2.1 REVIEW ON RELATED LITERATURE

Vehicle tracking has become necessary in this modern age due to the fact that several vehicles have been stolen and are still being stolen. The owners of these vehicles often find it very challenging to locate and recover their vehicles. But with the advent of vehicle tracking technologies, it has become quite easier to locate these vehicles. It is not just enough to recover the stolen vehicle but there is a need to ensure that the identity of the thief is also captured by a camera so that he can be arrested and penalized. This act will serve as a deterrent to many vehicle thieves. Some of the anti-vehicle theft control systems that have been designed include:

A GPS–GSM Based Tracking System: The system uses the global positioning system to determine the precise location of an object, person or other asset to which it is attached and using GSM modem this information could then be transmitted to a remote user. It provides tele-monitoring system for inter-cities transportation vehicles such as taxis and buses. This system contains single-board embedded system that is equipped with GPS and GSM modems along with ARM processor that is installed in the vehicle. During object motion, its location can be reported by SMS message. This system finds its application in real time traffic surveillance. The result achieved by this project is the fact that positional data (in terms of latitude and longitude) of objects carrying the system can easily be retrieved. Also a stolen vehicle could be immobilised remotely by sending an SMS to the SIM number in the GSM module. However this is not without limitations. There is no way the thief can be identified so that he could be arrested after he had stolen the vehicle.

In a GSM and GPS based vehicle location and tracking system using AT89S52 microcontroller was developed.

In a Remote Vehicle Tracking and Driver Health Monitoring System Using GSM Modem and Google Maps was developed. The GSM modem at the control centre receives the coordinates through Short Message Service (SMS) and updates the main database. The information then is accessed through the website and the position of the vehicle is displayed through the Google Maps application.

In 'Vehicle tracking system with GPS GSM Interface and Self-Created Map' was carried out basically to provide remote monitoring capabilities by the owner or company manager. The Geographical Information system (GIS) was incorporated into the design to give exact or nearby location of vehicle on a map that was self-created. In order to get the position on Google map, Google API was used.

In a GSM and GPS based system for Vehicle Tracking and Employee Security System was proposed. It consisted of a car unit, emergency button and company unit. Car unit was placed inside the car. When the car picked up the employee; he/she had to swap an RFID card. The micro controller then matched the RFID card number with its database records and sends the employee's identity, cab identity & the cab position co-ordinates to the company unit via GSM module. Emergency button is a part of the car unit. There are three to four emergency buttons in the car. These buttons were placed at such position so that an employee can access them easily i.e. near the door unlocking handle. If employee found himself/herself in a problem, he/she would press the button. Microcontroller then detects the action & sends a signal to the GSM which will coordinate with the company unit and police. Microcontroller also sent a signal to the relay which will turn off the car ignition & stop the car.

2.2 CONCLUSIONS ON REVIEWS

Chen, H., Chiang "Real Time Vehicle Ceasing and Tracking Using GSM and GPS Technology" described to track the theft vehicle by using GPS and GSM technology. This system puts into the sleeping mode after the vehicle gets handled by the owner or authorized persons through the reset button over it.

Ramani, S.Valarmathy "Vehicle Tracking and Locking System Based on GSM and GPS" described When the theft identified, the responsible people send SMS to the micro controller, then issue the control signals to stop the engine motor. This design will continuously watch a moving Vehicle and report the status of the Vehicle on demand

Ch. Bhanu Prakash "Design and Implementation of a Vehicle Theft Control Unit using GSM and CAN Technology" described the present security system that will warn the owner of the vehicle by sending SMS when there has been an intrusion into the vehicle. SMS is a good choice of the communication to replace the conventional alarm.

CHAPTER 3

PROJECT DESIGN

3.0 OVERVIEW OF THE DESIGN

The main scope of this project is to send an alert message to the owner of the vehicle when the vehicle is stolen. This project includes a GSM modem, GPS system, microcontroller, buzzer and solenoid valve for fuel cut-off and a sensor to detect vehicle theft. When someone tries to steal the vehicle then microcontroller gets interrupted and orders GSM Modem to send the SMS, the owner receives a SMS that his car is being stolen and also the exact location of the vehicle through GPS system. With a message from owner mobile, the ignition system and fuel supply to the vehicle is cut off and the buzzer gets off.

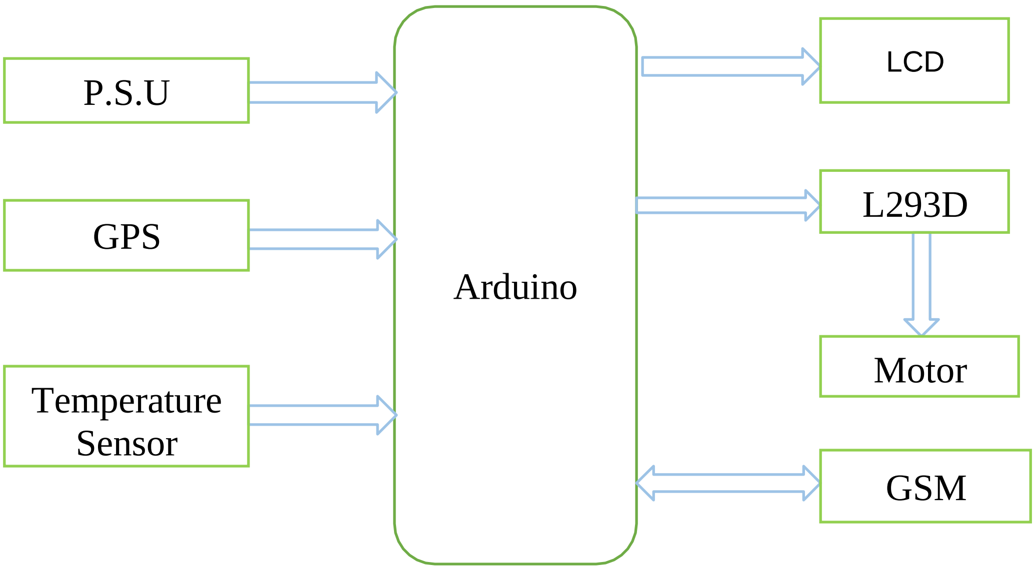

Fig 3.1: Block Diagram

While we go for work after riding the vehicle, the antitheft system must be kept in the active mode with the help of a switch present in the system. If anyone by chance starts the vehicle which is already in active mode, the voltage in the circuit becomes high which gives the signal to the microcontroller. This microcontroller again sends signal to the GSM, GPS to send SMSto the owner, and also its location like Longitude and Latitude of the vehicle through GPS to GSM and GSM sends the SMS to the owner. If the owner finds any threat to the vehicle then the owner with the help of SMS he will cut off the ignition.

3.1 EQUIPMENT ANALYSIS

Every lab running some kind of behavioral research makes use of several types of equipment and software for experimental control. The goal is typically to record events (behavioral or physiological) and generate signals (i.e., to control or synchronize different machines). Such tasks, in most cases, require millisecond-to-millisecond accuracy and thus require particular attention, since modern operating systems (OS) are not designed to operate in real-time and with such accuracy therefore, several different approaches are used, such as programming the experimental I/O task via dedicated and optimized software packages (i.e., E-Prime, Presentation, Psychophysics Toolbox for MATLAB, etc.) or devolving critical tasks to dedicated hardware with internal high precision clocks (i.e., external I/O boards from National Instruments, Measurement Computing, Cambridge Electronics Devices, etc.). In both cases, the solution tends to be expensive (especially for external boards), suboptimal insofar as it relies heavily on the OS's accuracy (this holds for all experimental control software), or unsuited for specific experiments.

In some cases, however, many low-level I/O tasks do not need specific software packages or expensive boards. For example, if the experimenter wants an event to be triggered when an event is detected via some sensors (i.e., touch sensor, force sensor, etc.), it is not necessary to use expensive hardware or software. In fact, simple and cheap microcontroller boards may solve many of these laboratory I/O tasks. Such boards are physical computing platforms based on a simple microcontroller and a development environment for writing software. These devices can be used to develop interactive objects, taking inputs from a variety of switches or sensors and controlling a variety of lights, motors, and other physical outputs. Projects of this kind can usually be stand-alone, or they can communicate with software running on a computer. Such boards have been around for several years and typically offer similar characteristics differing only in processor architecture (ARM, ATMEL, etc.), programming language (C/C++, BASIC, etc.), or other features (i.e., number of I/O channels, presence of analog channels, etc.). Several manufacturers have proposed quite popular solutions such as Parallax Inc., Coridium Corporation, FTDI, Picaxe, Arduino, as well as many others. All of these boards cost is very high . However, programming these boards can be quite complicated, and the user requires at least some basic electronics knowledge. Thus, the main obstacle to widespread use of these boards in psychological and neurophysiological labs is the steep learning curve.

However, Arduino boards offer one critical advantage: the open source philosophy (both hardware and software), which capitalizes on the massive nonexpert community that has flourished around the Arduino concept. A very rough estimate of the size of the community can be gleaned from a Google search reporting more than 12 million hits for "arduino." In fact, a large user base and the growing market have shown increasing interest around the Arduino concept. There are hundreds of open-source projects one can use or modify according to specific (experimental) needs. Many web tutorials cover basic programming and electronics issues, and there are active forums for help. Thus, learning to use Arduino boards may be a lot easier than learning to use similar products from other manufacturers. Given the available support from the Arduino community, even researchers with little programming and electronics background should consider using Arduino rather than other similar boards.

Arduino hardware consists of an open hardware design with an Atmel AVR processor. Arduino boards can be purchased preassembled, but hardware design information is also available for those willing to build or modify them . Several third-party makers have produced Shields (add-on boards) that are able to extend the basic capabilities of an Arduino . Among these shields, it is worth mentioning that the Motor Control Shield allows the control of DC motors and read encoders, the Xbee shield allows multiple Arduino boards to communicate wirelessly, and the Critical Velocity Accelerometer Shield integrates a 3-axis accelerometer. Additionally, third parties (+30) have released several variations based on the Arduino concept. These are companies building boards (typically with better specs or lower price) using the Arduino software.

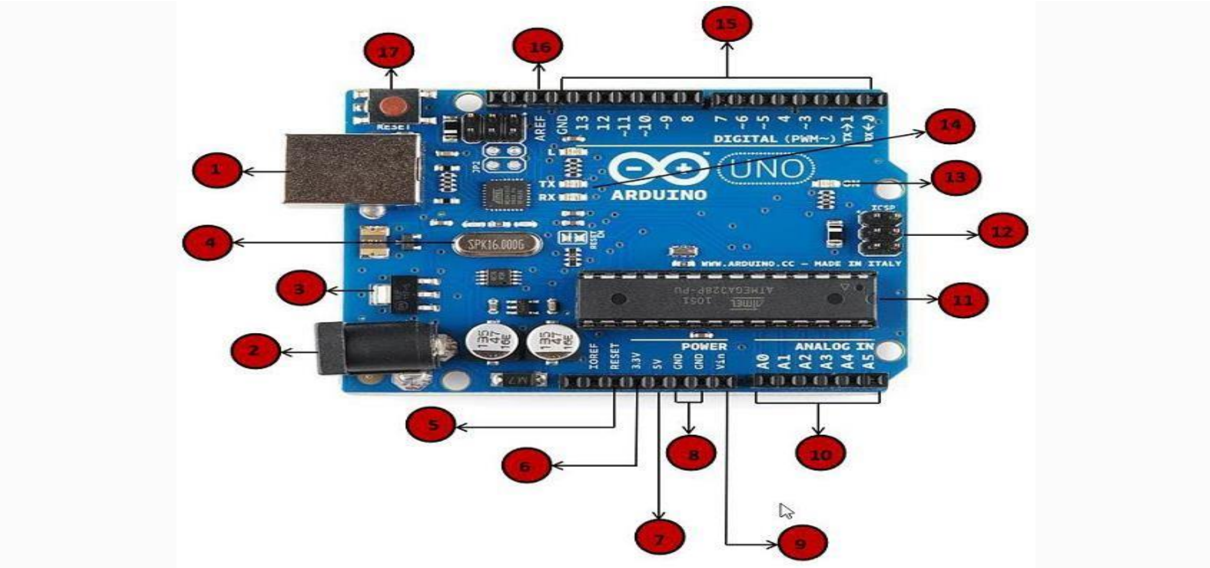

Fig 3.2: Arduino Board Pins

Table 3.1: Pin Description of Arduino

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).

6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

15	**Digital I/O** The ArduinoUNO board has14 digital I/O pins(15)(of which 6 provide PWM (Pulse Width Modulation)output.These pins can be configured to work as input digital pins to read logic values(0 or 1)or as digital output pins to drive different modules like LEDs, relays, etc.The pins labeled “~”can be used to generatePWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

The software consists of a standard programming language and a firmware that runs on the board. Arduino hardware is programmed using a language that is simplified C++, in a processing-based IDE. The software is then compiled and loaded on board. Arduino boards are compatible also with Flash, Processing, MaxMSP, and MATLAB, and a few lines of code often suffice to enable quite powerful behaviors . The basic programming structure of an Arduino is composed of at least two parts. These are the setup and the loop components. In the set-up, which runs at the beginning and only once to set pin mode or serial communication, the variables are declared. The second part runs in a loop that enables the script to change, to respond, and to control the Arduino board. After declaring variables, controlling the Arduino involves classic control structures (IF, IF…ELSE, FOR, etc.), arithmetic operators (+, -, /, *, etc.), and comparison operators (>, <, etc.) or boolean (AND, OR, etc.). There is also a set of commands for analog and digital read and write such as digitalwrite() or digitalread(). Furthermore, other commands can set temporal delays in milliseconds, perform basic mathematical and trigonometry operations (min/max, absolute value, square root, sine, cosine, etc.), or generate random numbers.

Design of power supply:

Power supply is the major concern for every electronic device .Since the controller and other devices used are low power devices there is a need to step down the voltage and as well as rectify the output to convert the output to a constant dc. Power supply unit is the basic requirement for electronic devices.

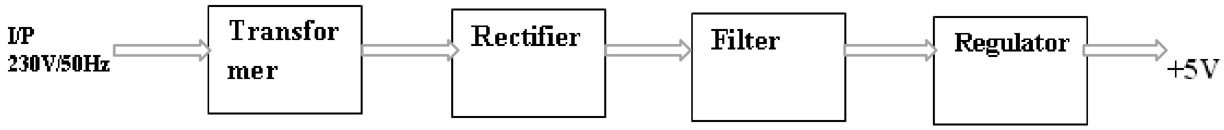

Fig 3.3: Power Supply

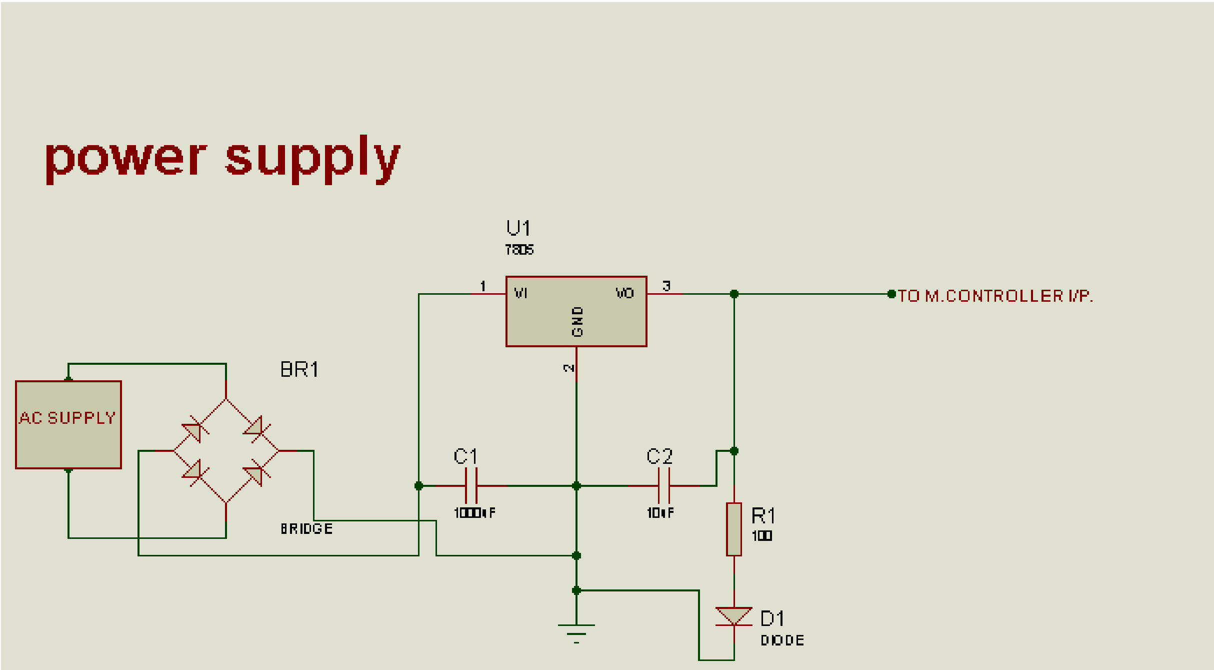

Fig 3.4: Circiut Diagram of power supply

Arduino IDE

The Arduino **Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards.

The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So we are interfacing a 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

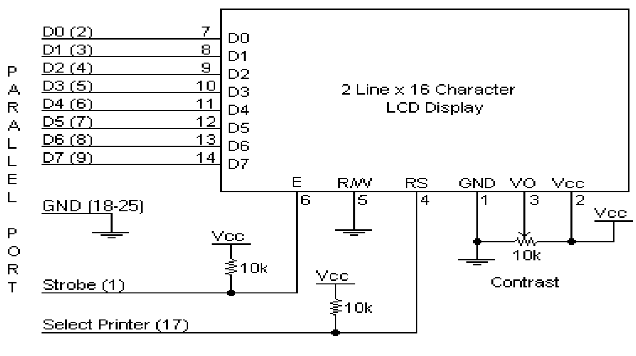

Fig 3.5: Schematic of LCD

Above is the quite simple schematic. The LCD panel's *Enable* and *Register Select* is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output

L293D is basically a motor driver or controller. It has two builtin H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large inpu voltage supply range, large output current high noise immunity input signals etc. Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

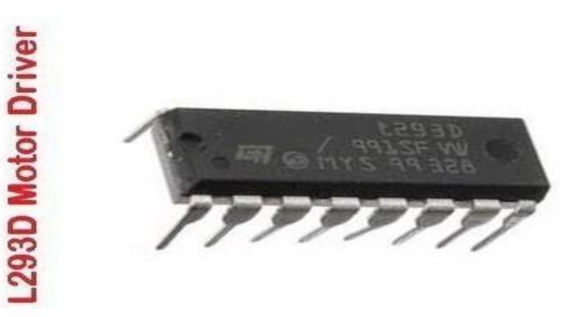

Fig 3.6: L293D Motor Driver

L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

Table 3.2: Pin Description of L293D

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND

DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion

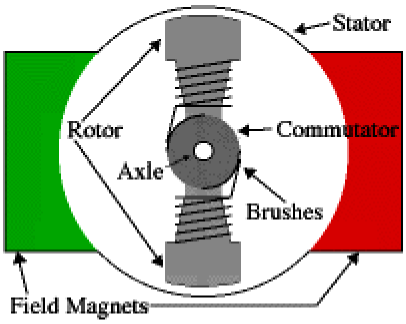

Fig 3.7: DC Motor Internal View

3.2 DEFINE THE MODULES

An efficient automotive security system is implemented for anti-theft using arduino with Global System for Mobile Communication (GSM). As far as vehicle security is concerned many options are available depending upon the technology being adopted. With the development and applications of lots of embedded techniques, car security system design and analyses are continually improving. Many new techniques, such as biometric recognition technique, image processing technique, communication technique and so on, have been included into car security systems. Statistics show that the number of cars is growing rapidly and so is the number of car theft attempts, locally and internationally. Although there are a batch of car security systems that had been produced lately, but the result is still unsatisfactory as the number of car theft cases still increases. The thieves are inventing cleverer and stronger stealing techniques that need extra powerful security systems.

This proposed project presents an anti-theft-control system for automobiles that tries to stop a vehicle from being stolen. In present days, vehicle theft is increasing rapidly and people have started using anti- theft-control systems in different automobiles systems. These anti-theft control systems are very expensive, but this project is designed cost-effectively by using arduino along with the GSM. GSM system is also installed in the vehicle for sending the information to the owner.The system contains

- GSM Module
- GPS Module
- Temperature Sensor
- DC Motor
- LCD Display

3.3 MODULE FUNCTIONALITIES

FUNCTIONALITY OF GSM MODULE:

A GSM modem or GSM module is a hardware device that uses GSM mobile telephone technology to provide a data link to a remote network. From the view of the mobile phone network, they are essentially identical to an ordinary mobile phone, including the need for a SIM to identify themselves to the network. GSM modems typically provide TTL-level serial interfaces to their host. They are usually used as part of an embedded system

GSM technology was developed as a digital system using the time division multiple access (TDMA) technique for communication purposes. A GSM digitizes and reduces the data, then sends it down through a channel with two different streams of client data, each in its own particular time slot. The digital system has the ability to carry 64 kbps to 120 Mbps of data rates.

There are various cell sizes in a GSM system such as macro, micro, pico, and umbrella cells. Each cell varies as per the implementation domain. There are five different cell sizes in a GSM network macro, micro, pico, and umbrella cells. The coverage area of each cell varies according to the implementation environment.

The time division multiple access (TDMA) technique relies on assigning different time slots to each user on the same frequency. It can easily adapt to data transmission and voice communication and can carry 64kbps to 120Mbps of data rate.

GSM Technology Architecture:

The main elements in the GSM architecture include the following.

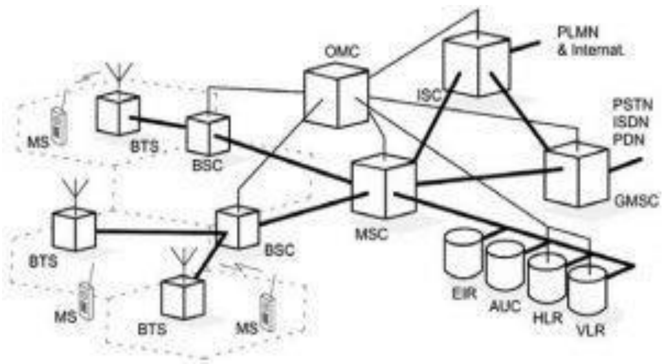

Fig 3.8: Architecture of GSM

- Network and Switching Subsystem (NSS)
- Base-Station Subsystem (BSS)
- The mobile station (MS)
- Operation and Support Subsystem (OSS)

Network Switching Subsystem (NSS)

In GSM system architecture, it includes different elements, which are frequently known as the core system/network. Here, it is basically a data network including a variety of units to provide the major control as well as interfacing of the entire mobile network system. The core network includes the major elements which are discussed below.

Base Station Subsystem (BSS)

It acts as an interface between the mobile station and the network subsystem. It consists of the Base Transceiver Station which contains the radio transceivers and handles the protocols for communication with mobiles. It also consists of the Base Station Controller which controls the Base Transceiver station and acts as an interface between the mobile station and mobile switching center.

Mobile Station

It is the mobile phone which consists of the transceiver, the display, and the processor and is controlled by a SIM card operating over the network.The MS (Mobile stations) or ME (mobile equipment) are most generally identified through cell otherwise mobile phones which are the part of a GSM mobile communications n/w that the operator observes & operates. At present, their dimension has reduced radically whereas the functionality level has very much increased. And one more benefit is that the time among charges has drastically enlarged. There are different elements to the mobile phone, though the two essential elements are the hardware & the SIM.

Operation and Support Subsystem (OSS)

The operation support subsystem (OSS) is a part of the complete GSM network architecture. This is connected to the NSS & the BSC components. This OSS is mainly used to control the GSM network & the BSS traffic load. It should be noted down that when the number of BS enhances through the subscriber population scaling then some of the preservation tasks are moved to the base transceiver stations so that the ownership cost of the system can be reduced.

Features of GSM Module:

- The features of the GSM module include the following.
- Improved spectrum efficiency
- International roaming
- Compatibility with integrated services digital network (ISDN)
- Support for new services.
- SIM phonebook management
- Fixed dialing number (FDN)
- Real-time clock with alarm management
- High-quality speech
- Uses encryption to make phone calls more secure
- Short message service (SMS)

Working of GSM Module

From the below circuit, a GSM modem duly interfaced to the MC through the level shifter IC Max232. The SIM card mounted GSM modem upon receiving digit command by SMS from any cell phone sends that data to the MC through serial communication. While the program is executed, the GSM modem receives the command ‘STOP’ to develop an output at the MC, the contact point of which are used to disable the ignition switch.

The command so sent by the user is based on an intimation received by him through the GSM modem ‘ALERT’ a programmed message only if the input is driven low. The complete operation is displayed over a 16×2 LCD display.

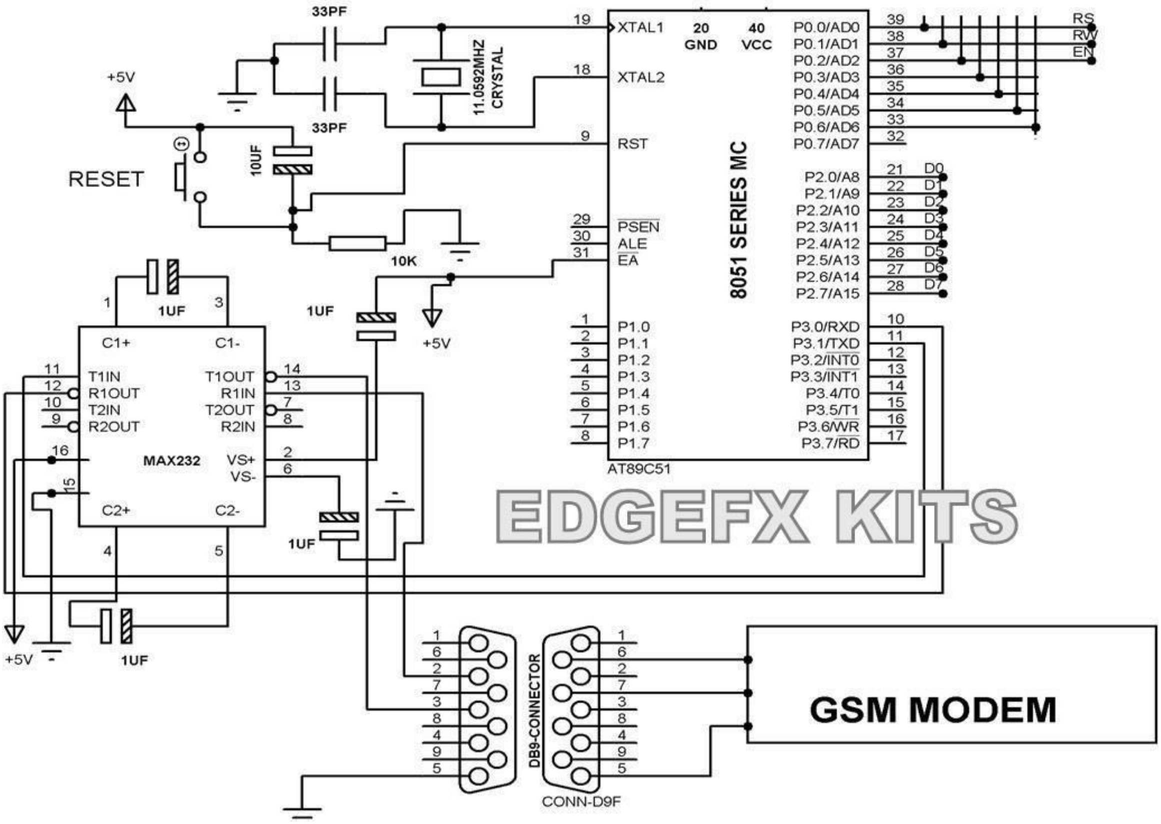

Fig 3.9: GSM Modem Circuit

FUNCTIONALITY OF GPS MODULE

GPS stands for Global Positioning System by which anyone can always obtain the position information anywhere in the world.GPS consists of the following three segments.

Space segment (GPS satellites):

A number of GPS satellites are deployed on six orbits around the earth at the altitude of approximately 20,000 km (four GPS satellites per one orbit), and move around the earth at 12-hour-intervals.

Control segment (Ground control stations):

Ground control stations play roles of monitoring, controlling and maintaining satellite orbit to make sure that the deviation of the satellites from the orbit as well as GPS timing are within the tolerance level.

User segment (GPS receivers): For receiving the signals

GPS positioning:

Firstly, the signal of time is sent from a GPS satellite at a given point. Subsequently, the time difference between GPS time and the point of time clock which GPS receiver receives the time signal will be calculated to generate the distance from the receiver to the satellite. The same process will be done with three other available satellites. It is possible to calculate the position of the GPS receiver from distance from the GPS receiver to three satellites. However, the position generated by means of this method is not accurate, for there is an error in calculated distance between satellites and a GPS receiver, which arises from a time error on the clock incorporated into a GPS receiver. For a satellite, an atomic clock is incorporated to generate on-the-spot time information, but the time generated by clocks incorporated into GPS receivers is not as precise as the time generated by atomic clocks on satellites. Here, the fourth satellite comes to play its role: the distance from the fourth satellite to the receiver can be used to compute the position in relations to the position data generated by distance between three satellites and the receiver, hence reducing the margin of error in position accuracy.

Factors that trigger GPS position errors:

Ionosphere :

The ionosphere is a portion of the upper atmosphere, between the thermosphere and the exosphere. When GPS signals pass through this layer, the propagation velocity of the GPS signal goes slower, hence causing propagation error.

Troposphere:

The troposphere is the lowest portion of Earth's atmosphere. Radio reflections caused by dry atmosphere and water vapor within provoke GPS position error.

Multipath propagation:

GPS signal is not immune to reflection when it hits on the ground, structures and many others. This phenomenon is called multipath propagation, one of the causes of GPS position errors.

State of reception of GPS depends upon the number of satellites tracked for positioning.If the number of the tracked satellites is great, GPS positioning becomes greater, but if there were a fewer satellites tracked for positioning, it would be difficult to generate GPS position.

3.4 RELATED DESIGNS

This project is developed to provide security for the vehicles and also it is designed with less complexity.The following figure shows the schematic diagram of the project.

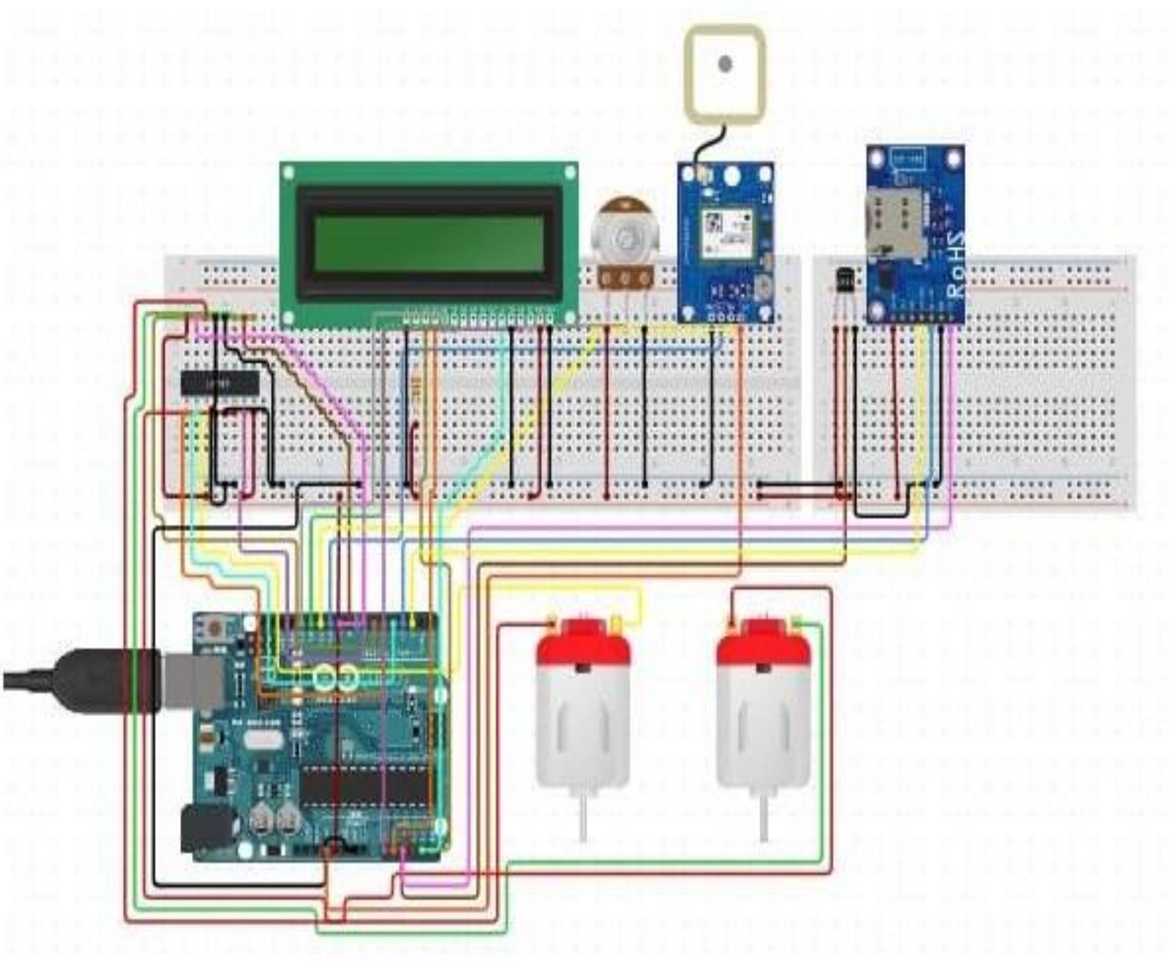

Fig 3.10: Schematic Diagram

CHAPTER 4

PROJECT IMPLEMENTATION

4.0 IMPLEMENTATION STAGES

The steps to implement this project are

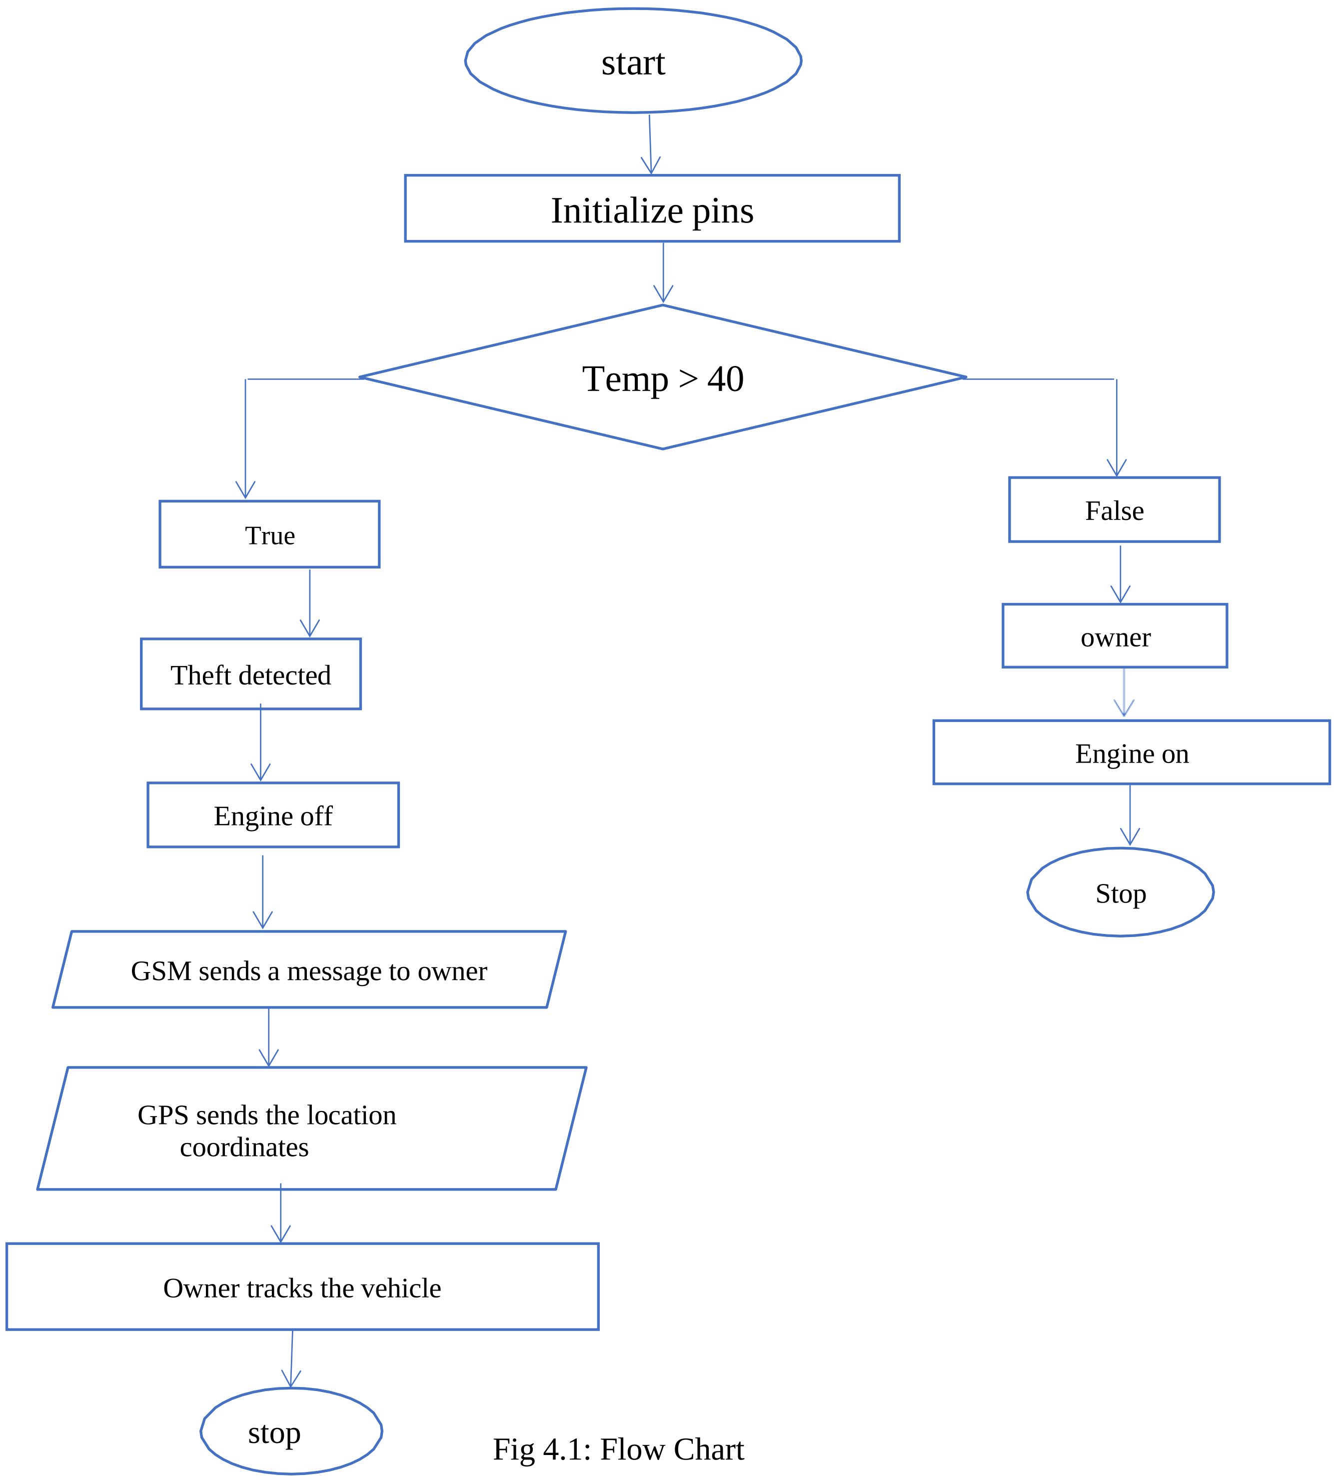

Fig 4.1: Flow Chart

The basic idea for this project is such that when the engine temperature increases beyond certain value then it will go into off position. The vehicle can be restarted by entering the secured password which is only known to the owner of the vehicle.The above mentioned stages in the flow chart are the different implementation stages to perform the project.

4.1 RESULTS

The proposed system is described that integrates new technologies offering a tracking of stolen vehicle by using GPS and GSM technology and provides vehicle security.The trainer kit of the proprosed system is designed as follows.

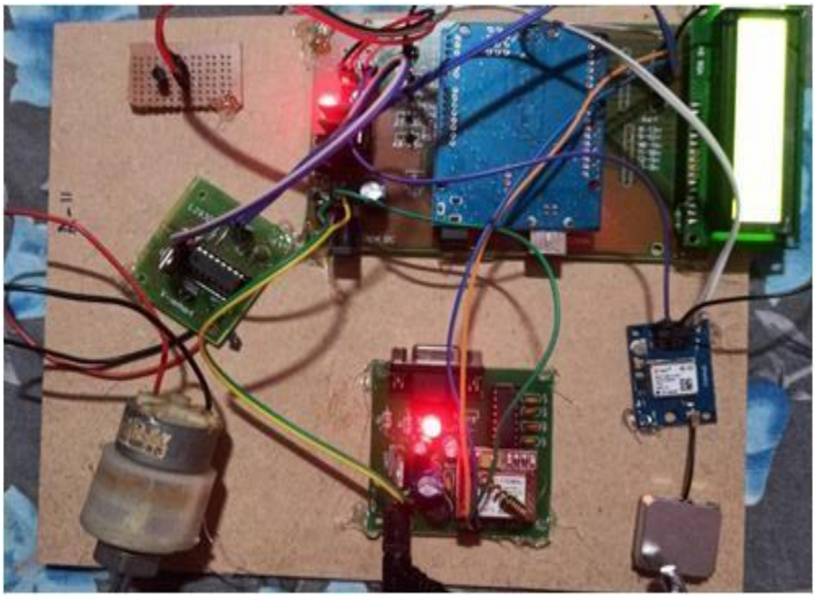

Fig 4.2: Final Outcome

The above figure depicts that the system is in tracking mode indicated by the red LED lighting up.

The system has an advantage of real time tracking of stolen vehicle and also it is easy to access.

The following are the figures on the LCD display that shows the engine position whether it is on or off and also it displays the location coordinates in the form of latitude and longitude by using the GPS module.

Fig 4.3: LCD Display

The messages that are sent to the owner mobile about the location coordinates are shown in the following figure.

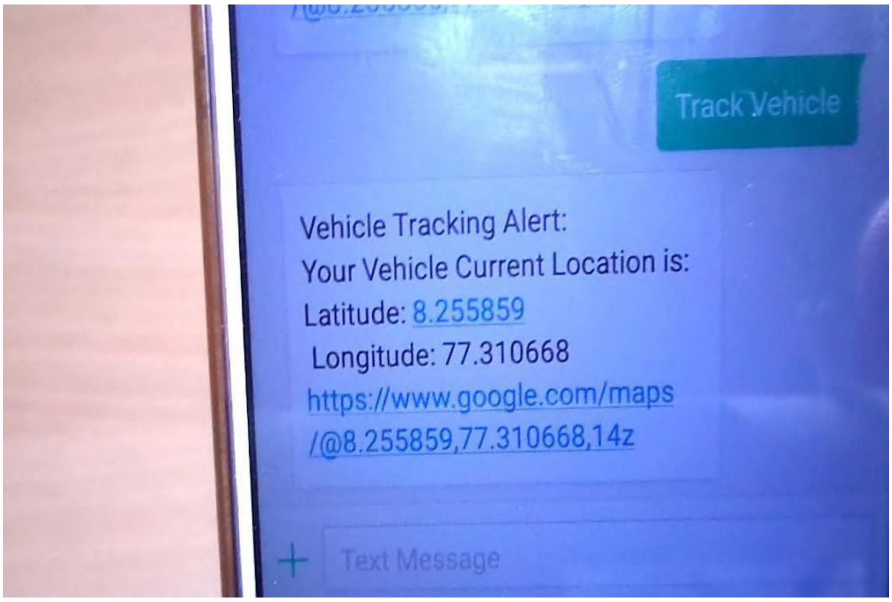

Fig 4.4: Messages sent to owner

CHAPTER 5

PROJECT TESTING

5.0 OVERVIEW OF TESTING METHODS

In this project, we are interfacing GSM Module to Arduino. There are different kinds of GSM modules available. We are using the most popular module based on Simcom SIM300 and Arduino Uno for this project. Interfacing a GSM module to Arduino is pretty simple. We should only make 3 connections between the gsm module and arduino.

A GSM Module is basically a GSM Modem (like SIM 300) connected to a PCB with different types of output taken from the board – say TTL Output (for Arduino, 8051 and other microcontrollers) and RS232 Output to interface directly with a PC (personal computer). The board will also have pins or provisions to attach mic and speaker, to take out +5V or other values of power and ground connections. These type of provisions vary with different modules.

For our project of connecting a gsm modem or module to arduino and hence send and receive sms using arduino – its always good to choose an arduino compatible GSM Module – that is a GSM module with TTL Output provisions.

We use SIM300 GSM Module – This means the module supports communication in 300MHz band.

GSM modules are manufactured by different companies. They all have different input power supply specs. We need to double check our GSM modules power requirements.

Note: GSM Modules are manufactured by connecting a particular GSM modem to a PCB and then giving provisions for RS232 outputs, TTL outputs, Mic and Speaker interfacing provisions etc. The most popular modem under use is SIM 900 gsm modem from manufacturer SIMCom. They also manufacture GSM Modems in bands 850, 300 and other frequency bands.

We can feed the data from gsm module directly to Arduino only if the module is enabled with TTL output pins. Otherwise we have to convert the RS232 data to TTL using MAX232 IC and feed it to Arduino. Most of the gsm modules are equipped with TTL output pins.

Booting the GSM Module:

1. Insert the SIM card to GSM module and lock it.

2. Connect the adapter to GSM module and turn it ON!

3. Now wait for some time (say 1 minute) and see the blinking rate of ‘status LED or ‘network LED’ (GSM module will take some time to establish connection with mobile network)

4. Once the connection is established successfully, the status/network LED will blink continuously every 3 seconds. We may try making a call to the mobile number of the sim card inside GSM module. If we hear a ring back, the gsm module has successfully established network connection.

Now let’s see how to connect a gsm module to Arduino

Connecting GSM Module to Arduino:

There are two ways of connecting GSM module to arduino. In any case, the communication between Arduino and GSM module is serial. So we are supposed to use serial pins of Arduino (Rx and Tx). So if we are going with this method, we may connect the Tx pin of GSM module to Rx pin of Arduino and Rx pin of GSM module to Tx pin of Arduino. GSM Tx –> Arduino Rx and GSM Rx –> Arduino Tx. Now connect the ground pin of arduino to ground pin of gsm module. We made 3 connections and the wiring is over. Now we can load different programs to communicate with gsm module and make it work.

In the coding part,the program has two objectives as described below:

1 Send SMS using Arduino and GSM Module – to a specified mobile number inside the program

2. Receive SMS using Arduino and GSM Module – to the SIM card loaded in the GSM Module.

TESTING METHOD OF GPS:

As GPS technology becomes more common, GPS receiver manufacturers, OEM integrators, and contract manufacturers struggle to determine the appropriate standard tests to verify GPS receiver performance. Verification procedures require a controlled environment that facilitates precise repeatability. In most cases, using actual GPS satellite signals received through an antenna does not provide such an environment. This excerpt from Agilent's GPS Receiver Testing white paper introduces a real-time GPS signal simulation technique capable of generating the required GPS signals for a repeatable and flexible test environment.

GPS Test Requirements:

The GPS user experience for commercial applications is affected by several factors. GPS devices which provide an enhanced user experience will sell better, so manufacturers are looking for factors to differentiate their receivers. Typical factors which determine the outcome of the user experience include the following factors:

When a GPS device is turned on, how long is it until the position of the receiver is determined?

When a weak or poor signal area is encountered, can the receiver still determine its position?

If the signal is interrupted and then restored, how long does it take for the receiver to recover and resume calculating its position?

Accuracy of the calculated location.

There are of course other factors such as cost, user interface, turn-by- turn navigation, spoken directions, and so forth that are important to users, but these are not so dependent on the GPS receiver performance.For commercial or military applications, there may be many other kinds of GPS conditions that are important, such as:

How accurately can a position or time be determined?

How repeatable is the solution?

How sensitive is the receiver to interference or jamming?

How rapidly can the receiver report its position (if the receiver is moving rapidly – such as in an airplane)?

Here are five steps to testing GPS receivers.These steps need to be completed in the sequential order as listed. Not following the numbered sequence will often force us to repeat tests in the event changes are made to the system.

Step 1: Antenna Testing

The first step in receiver testing is to ensure our antennas work properly. This consists of ensuring the antennas are tuned on-frequency

Step 2: Conducted Receiver Sensitivity Testing

The next step in system testing is conducting receive sensitivity testing, and it is the first time we actually test the receiver itself. There are a number of problems that can impact receiver performance such as conducted power supply noise, power supply errors (such as voltage or current problems), firmware setup, and module management errors. Conducted receive sensitivity testing is the responsibility of the radio integrator.

Step 3: Residual Error Test

With residual error, a conducted RF test is done with signal levels turned up so a signal is strong. It should not be so strong that it might impact the linearity of the receiver. It should be sufficiently strong so there is no ambiguity that the signal the receiver is seeing is well within the sensitivity range. For most modern GPS modules a number of approximately – 100dBm seen at the RF input of the module would be a good starting point. Set the GPS signal generator up, let the GPS get a fix and then start examining the test cases.

Step 4: Radiated receiver sensitivity testing

With radiated receiver sensitivity testing the entire receive system is being tested, as it would work in the field, with the exception that it is being done in a controlled and repeatable RF environment. Testing of this kind is done in an anechoic RF chamber with a GPS signal generator. It cannot be done using the real satellite constellation because we cannot control the signal levels of the satellites. In order to know the path loss of the test setup, typically a network analyzer is used to measure this.

Step 5: Self-quieting

All wireless devices emit radio energy. The amplitude and frequency of these emissions are directly related to the circuitry chosen and how it is implemented. Because a GPS receiver is so sensitive, it takes deliberate attention to noise suppression to have a chance of keeping the rest of our electronics quiet enough, from a radio standpoint, so that they do not interfere with the GPS receiver. The further the antenna is away from our electronics the less trouble we will have.

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

CONCLUSION

The anti-theft control system is a breakthrough in today's world where automobile theft has increased rapidly. Today, majority of the communication and its applications are used by using GSM. The combination of GSM in anti-theft control system ensures efficiency and security as is required by it. The GSM also ensures that the effectiveness of the system is not just restricted to local use but can be covered over a wide range .Our proposed project can prevent the vehicle from hotwiring and fraudulent theft.

Our Vehicle theft prevention project acts as communication medium between the owner and the embedded system. This project with low cost is very useful to general public. It works for low range vehicles also.This automatic car theft detection system will alert the user about unauthorized access and then help to locate the vehicle correctly. The system is versatile, extendable and totally adjustable to user needs.

FUTURE ENHANCEMENT

We can develop this project in future by adding fingerprint sensor and face detection sensor. Presently, only the message feature is available. For ease of operation, developments can be made to include the Call Feature. Microphone can also be interfaced to the GMS module so that during theft activity, voice call could be established with the owner.

In future, this security system can be improvised to function as an integrated-data-security system for car communication systems. It would ensure that all the data exchanged within the vehicle and outside the vehicle is protected.

PUBLICATION

This project is published in the following conference

Title of the paper: Real Time Vehicle Theft Control System Using Engine Temperature Measurement

Conference : International Conference on Smart Modernistic in Electronics and Communication (ICSMEC – 21)

Status : Accepted

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Aboveall, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **DR.B.HariKrishna**, **Head &Professor**, the Dept. Electronics And Communication for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our department project coordinator DR. A. Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mr. S. Santosh Singireddy, Assistant Professor,** Department of ECE and our class project coordinator **Mrs. A. Sowmya, Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

2.U.Nikitha(17K81A0455)

3.V.Jaya Surya(18K85A0401)

ABSTRACT

Recently, Siamese neural networks have been employed to build several high performance object trackers capable of operating in real time. To further improve the tracking performance, one can train one network on the tracking task and another network on the task of object classification. One can then use the feature representations of both networks to obtain a tracker which performs better than each network on its own. This approach, however, has the downside that two networks have to be evaluated instead of one, resulting in runtime degradation. We demonstrate that it is feasible to train one Siamese network on the tracking and the classifications tasks simultaneously. Specifically, we achieve a tracking performance similar to the performance of two networks trained on tracking and classification separately. Since our approach does not depend on two separate networks though, it allows one to improve the performance of a Siamese network tracker without any runtime penalty.

INTRODUCTION

1.1 Introduction To The Project:

Traffic data such as vehicle counts, speeds, and classification are important in traffic engineering applications, transportation planning, and Intelligent Transportation Systems (ITS). Collecting traffic data manually by direct observations of human observers has a number of drawbacks including high cost, extreme weather and difficulties imposed by staffing limitations While in-road technologies such as inductive loop detectors offer good accuracy for counts and presence detection, their installation and maintenance causes traffic disruption. Sensors that are placed on the pavements (magnetometers, road tubes) can be damaged by snow removal equipment or street sweepers. As mentioned in at times it is difficult to obtain accurate counts using intrusive technologies due to roadway geometry (e.g., geometry where there are significant lane changes or where vehicles do not follow a set path in making turns). Some of the non-intrusive roadside sensors might be prohibitive due to high cost (e.g., laser) or low precision (e.g., microwave).

Infrared sensors have an advantage of day/night operation and perform better than visible wavelength sensors in fog. However, in addition to the problem of unstable detection zones, for reliable operation at least one sen1 sor is required in each traffic lane (a notableexception is the TIRTL sensor Ultrasonic sensors exhibit difficulty in detecting snow- covered vehicles and are sensitive to changes in ambient temperature and humidity. In addition, the problem of detecting motorcycles remains elusive for the sensors described above.

The output of these sensors is a poor description of the traffic events. This is a serious limitation in case of a critical situation, where a human operator is required to make a decision based on the sensor data. In such cases, video sensors provide the information in the form of live video of the scene. In addition, a single video sensor placed at an appropriate position provides wide area coverage making it possible to detect incidents in multiple lanes simultaneously. The same is the case in calculating queue lengths. Another advantage of video is that it provides sufficient information for vehicle tracking to be feasible, which is useful for detecting events such as sudden lane changes, vehicles moving in the wrong direction, stalled vehicles etc.

There is a broad range of real world applications where it is necessary to track objects over several video frames. For example, in traffic surveillance scenarios it is crucial to track the movements of vehicles or pedestrians in order to estimate velocities or to detect traffic violations. When devising a tracking algorithm, one has to take into account the possibilities of out-of-plane rotations, illumination changes, occlusions and deformations of objects. While being flexible enough to handle these difficulties, the method should also have sufficient discriminant power in the sense that it should be capable of distinguishing one object from another in scenarios of many similar objects appearing close to each other. Furthermore, runtime aspects usually have to be taken into account. Since tracking algorithms are often used to process video streams, real-time performance is often a hard constraint**.**

With the rise of deep learning in various computer vision applications, it comes as no surprise that deep learning methods have also been employed in the domain of object tracking. One kind of deep learning tracking architecture are Siamese networks. These networks attempt to find a feature representation which is robust with respect to the before mentioned transformations. One can then use a similarity measure in feature space to locate an object in subsequent frames. Often, the performance of an artifical neural network can be improved by learning a feature representation which works well on another task simultaneously . For example, in the domain of object tracking proposed to train two separate networks: a classification network and a tracking network. The features of the classification network are used to improve the tracking performance. They statethat in their experiments jointly training one feature extractor on both the classification and the tracking task has a considerably worse tracking performance than separately training two networks. The separate training of two feature extractors has the downside that two networks have to be evaluated during tracking, leading to a worse runtime than when only one network has to be evaluated.

Our contributions can be summarized as follows: • We propose a Siamese tracking network architecture which has a single feature extractor. Unlike the feature extractor in other Siamese tracking networks, we train it such that the learned features are useful for the tracking as well as for the classification tasks. • We show experimentally that jointly training on both tasks can result in a tracker which performs similar to two separate networks, while only one feature extractor needs to be evaluated during inference.

1.2 INTRODUCTION TO IMAGE PROCESSING

IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1.2.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

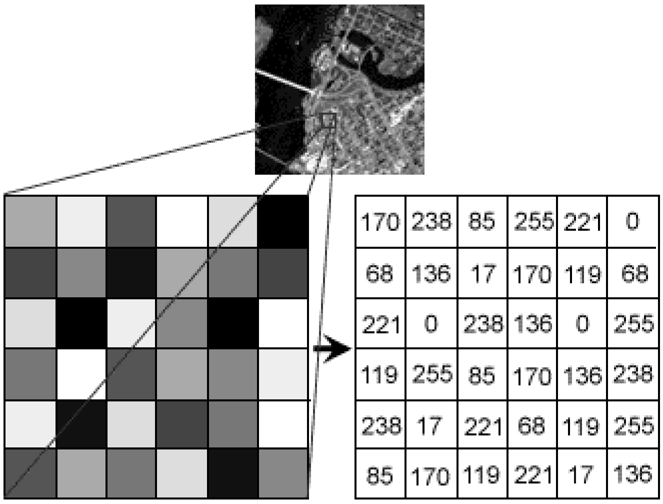

Fig 1.2.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

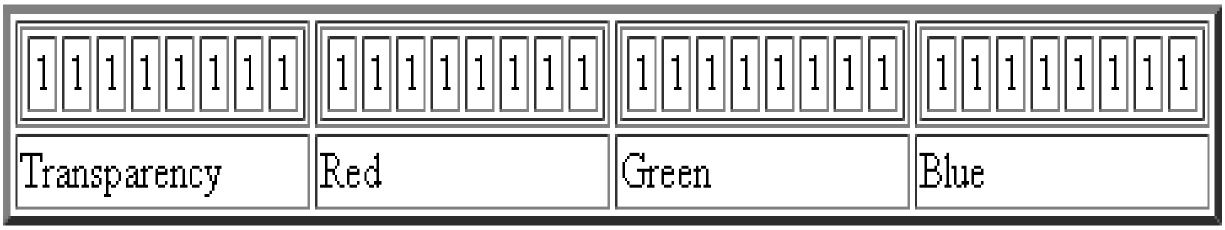

Fig 1.2.3 Transparency image

IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

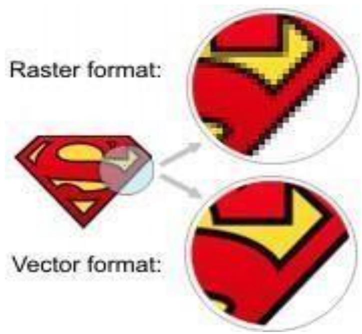

Fig 1.2.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own nativeformat.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

JPEG/JFIF:

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored ina lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

EXIF:

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

TIFF:

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

PNG:

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

GIF:

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

BMP:

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric descriptionwhich can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

CGM:

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical informationindependent from any particular application, system, platform, or device.

SVG:

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

1.3 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

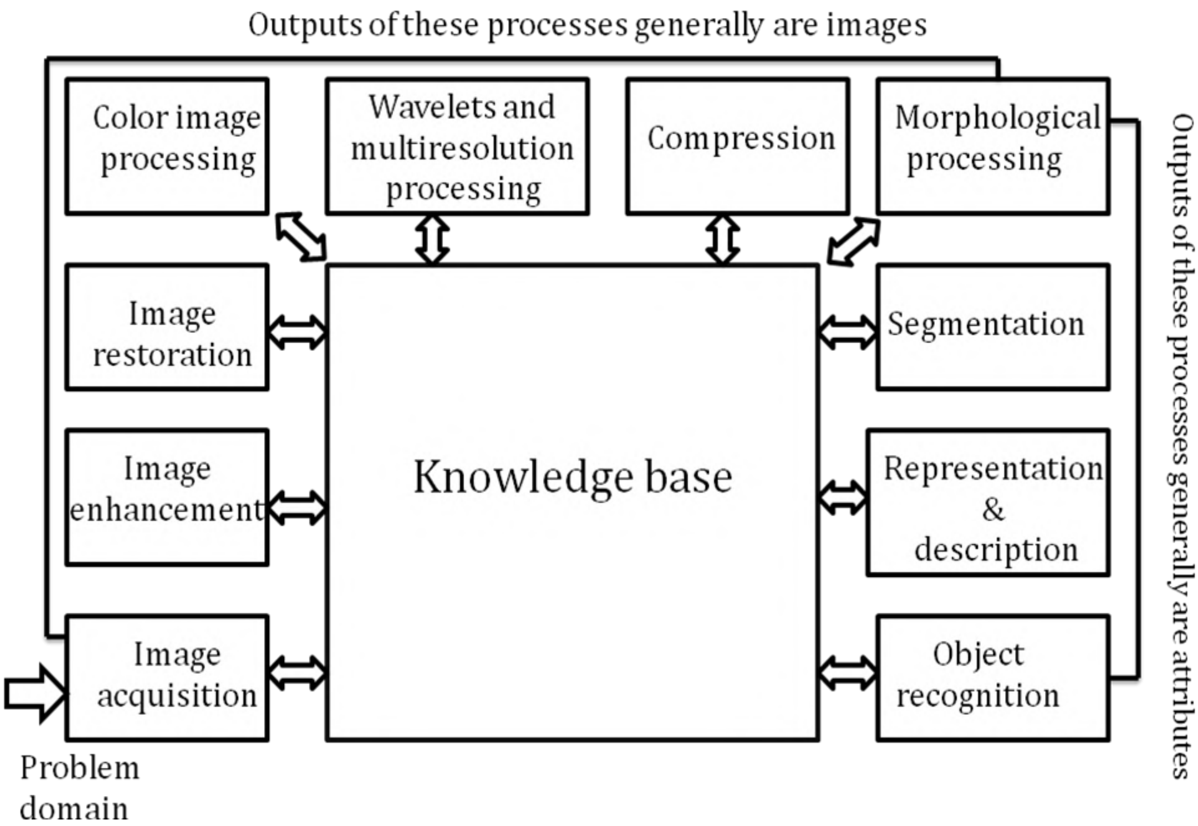

Fig 1.3.1 Image fundamental

Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.3.2 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.3.3 digital camera cell

Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjectivearea of image processing.

Fig 1.3.4 Image enhancement

Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.3.5 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.3.6 Color & Gray scale image

Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

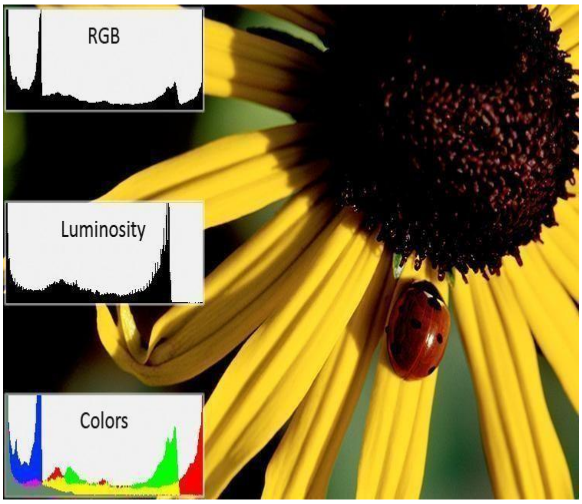

Fig 1.3.7 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called Multiresolution theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.3.8 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

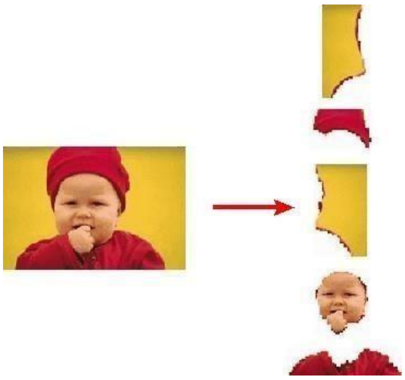

Fig 1.3.9 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.4 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached toequally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

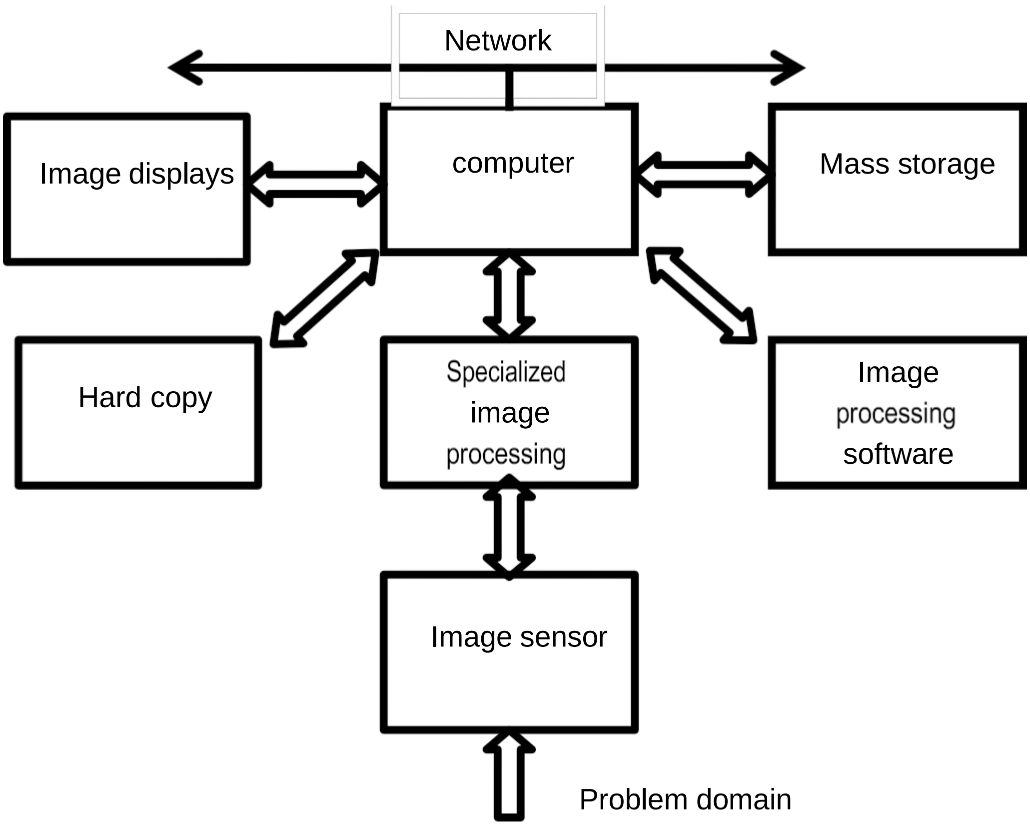

Fig 1.4.1 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

Image sensors:

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

Specialized image processing hardware:

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

Computer:

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

Image processing software:

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commandsfrom at least one computer language.

Mass storage:

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

Image displays:

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

Hardcopy:

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

Network:

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly usedto capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i, j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance 'd' apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance 'd' apart. This atproach can effectively represent color distribution in an image. However, correlogram features do notcapture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrixand the spatial distance 'd' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i,j) = \mathbf{Pr}((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i,j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM).MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of theweight-learning algorithms. In order to overcome these problems, researchers have triedto combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a

$3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculat ion. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for colorand intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM).

This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primaryHue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright- light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level whilefor higher saturation and intensity, the pixel color can be approximated by its hue. Forlow intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for eachpixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts.Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 \ \ if \ \ h \in [316,20] \\ 1 \ \ if \ \ h \in [21,40] \\ 2 \ \ if \ \ h \in [41,75] \\ 3 \ \ if \ \ h \in [76,155] \\ 4 \ \ if \ \ h \in [156,190] \\ 5 \ \ if \ \ h \in [191,270] \\ 6 \ \ if \ \ h \in [271,295] \\ 7 \ \ if \ \ h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \ \ if \ \ s \in [0,0.2) \\ 1 \ \ if \ \ s \in [0.2,0.7) \\ 2 \ \ if \ \ s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \ \ if \ \ v \in [0,0.2) \\ 1 \ \ if \ \ v \in [0.2,0.7) \\ 2 \ \ if \ \ v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national parkvisits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus onfeatures such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation ofa color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical

1.5 DIGITAL IMAGE PROCESSING

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low- level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves “Making sense” of an ensemble of recognized objects,as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] $\times$[0, b]I: [0, a] $\times$ [0, b] $\rightarrow$ [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0)   f(0,1) ....f(0,N-1)

f (1,0)   f(1,1) ....f(1,N-1)

f (xylem)= f (M-1,0)   f(M-1,1)..................f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f(1,2)............f(1,N)

f (2,1)   f(2,2) ....f (2,N)

f =   f (M,1)   f(M,2).......... f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is Imread ('filename')

Format name	**Description**	**Extensions**
TIFF	Tagged Image File Format	tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Table 1.1:File formats to read images.

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread ('8. jpg');

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name	Description
Double	Double _ precision, floating_ point numbers the Approximate.
Uint8	unsigned 8_bit integers in the range [0,255].
Uint16	unsigned 16_bit integers in the range [0, 65535].
Uint 32	unsigned 32_bit integers in therange [0, 4294967295]
Int8	signed 8_bit integers in the range [-128,127].
Int 16	signed 16_byte integers in the range [32768, 32767].
Int 32	Signed 32_byte integers in the range [-2147483648, 21474833647].
Single	single _precision floating _point numbers with values
Char	characters (2 bytes per elements).
Logical	values are 0 to 1 (1byte per element).

Table 1.2 Data Classes In Matlab

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines.Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 pointto the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as "stack" of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is $(2^b)^3$, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER 2

LITERATURE SURVEY

2.1 Literature survey:

To measure the similarity between two objects, it is often beneficial to transform the data into another feature space and then compute the distances between vectors in this space. This can be accomplished by training a Siamese network to learn an appropriate transformation. Early research in this direction was conducted by who devised a system based on Siamese networks where handwritten signatures are compared with each other to perform signature verification. The SiamFC tracker is the basis of a multitude of Siamese networks for object tracking. It uses a network architecture similar to AlexNet for feature extraction. showed that using deeper and wider network architectures yields better tracking performance, at the cost of an increase in inference time. introduced a triplet loss function for training Siamese tracking networks. They found that, compared to the more commonly used logistic loss, using this loss function results in a better performance in all network architectures they investigated. A significant increase in tracking performance was achieved with the introduction of SA-Siam. In the VOT2018 benchmark SA-Siam achieved the second place among all real-time trackers. The basic idea behind SA-Siam is to train one network on the object tracking task and another network on object classification. The first network learns a feature representation which models the appearance of an object while the latter network outputs sparse features with more semantic meaning. The outputs of both networks are used for tracking, leading to a performance superior toboth networks used on their own. The SiamBM tracker improves the tracking performance of SASiam by adding angle estimation, spatial masks and template updating.

2.2 Existing models:

ResNet

To train the network model in a more effective manner, we herein adopt the same strategy as that used for DSSD (the performance of the residual network is better than that of the VGG network). The goal is to improve accuracy. However, the first implemented for the modification was the replacement of the VGG network which is used in the original SSD with ResNet. We will also add a series of convolution feature layers at the end of the underlying network. These feature layers will gradually be reduced in size that allowed prediction of the detection results on multiple scales. When the input size is given as 300 and 320, although the ResNet–101 layer is deeper than the VGG–16 layer, it is experimentally known that it replaces the SSD's underlying convolution network with a residual network,and it does not improve its accuracy but rather decreases it.

R-CNN

To circumvent the problem of selecting a huge number of regions, Ross Girshick et al. proposed a method where we use the selective search for extract just 2000 regions from the image and he called them region proposals. Therefore, instead of trying to classify the huge number of regions, you can just work with 2000 regions. These 2000 region proposals are generated by using the selective search algorithm which is written below.

Selective Search:

1. Generate the initial sub-segmentation, we generate many candidate regions
2. Use the greedy algorithm to recursively combine similar regions into larger ones
3. Use generated regions to produce the final candidate region proposals

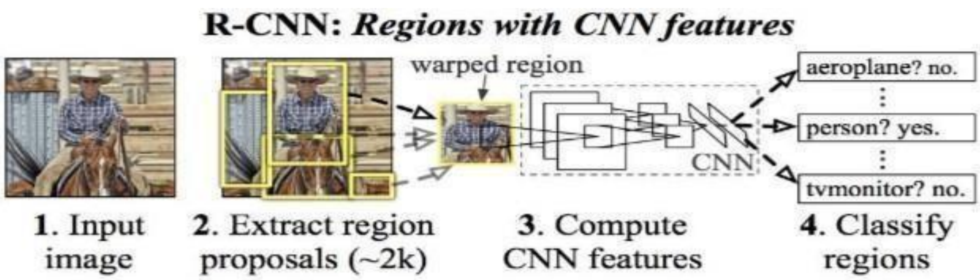

Fig. 2.1 R-CNN Architecture

These 2000 candidate regions which are proposals are warped into a square and fed into a convolutional neural network that produces a 4096-dimensional feature vector asoutput. The CNN plays a role of feature extractor and the output dense layer consists of the features extracted from the image and the extracted features are fed into an SVM for the classify the presence of the object within that candidate region proposal. In addition to predicting the presence of an object within the region proposals, the algorithm also predicts four values which are offset values for increasing the precision of the bounding box. For example, given the region proposal, the algorithm might have predicted the presence of a person but the face of that person within that region proposal could have been cut in half. Therefore, the offset values which is given help in adjusting the bounding box of the region proposal.

Fast R-CNN:

The same author of the previous paper(R-CNN) solved some of the drawbacks of R-CNN to build a faster object detection algorithm and it was called Fast R-CNN. The approach is similar to the R-CNN algorithm. But, instead of feeding the region proposals to the CNN, we feed the input image to the CNN to generate a convolutional feature map. From the convolutional feature map, we can identify the region of the proposals and warp them into the squares and by using an RoI pooling layer we reshape them into the fixed size so that it can be fed into a fully connected layer. From the RoI feature vector, we can use a soft max layerto predict the class of the proposed region and also the offset values for the bounding box.

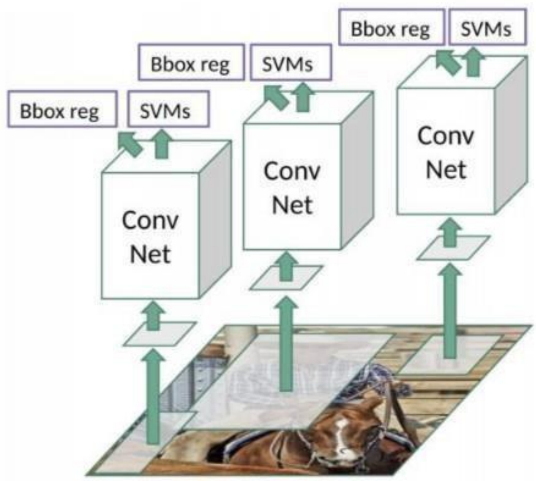

Fig. 2.2 Fast R-CNN Architecture

The reason “Fast R-CNN” is faster than R-CNN is because you don’t have to feed 2000 region proposals to the convolutional neural network every time. Instead, the convolution operation is always done only once per image and a feature map is generated from it.

Faster R-CNN:

Both of the above algorithms(R-CNN & Fast R-CNN) uses selective search to find out the region proposals. Selective search is the slow and time-consuming process which affect the performance of similar to Fast R-CNN, the image is provided as an input to a convolutional network which provides a convolutional feature map. Instead of using the selective search algorithm for the feature map to identify the region proposals, a separate network is used to predict the region proposals. The predicted he region which is proposals are then reshaped using an RoI pooling layer which is used to classify.

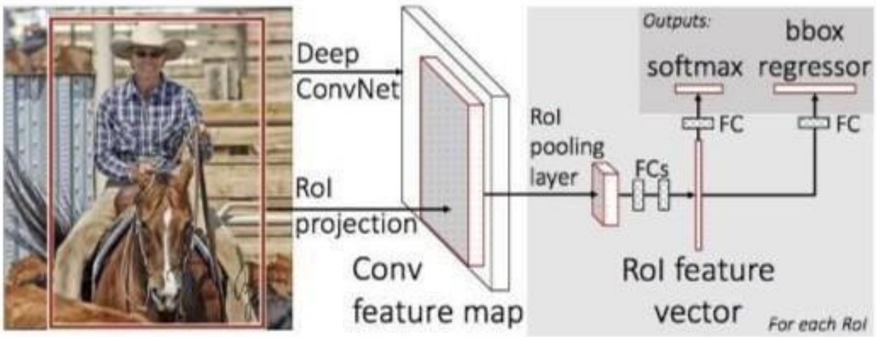

Fig. 2.3 Faster R-CNN Architecture

SDD:

The SSD object detection composes of 2 parts:

1. Extract feature maps, and

2.. Apply convolution filters to detect objects.

SSD uses VGG16 to extract feature maps. Then it detects objects using the Conv4_3 layer. For illustration, we draw the Conv4_3 to be 8 × 8 spatially (it should be 38 × 38). For each cell in the image(also called location), it makes 4 object predictions.

Each prediction composes of a boundary box and 21 scores for each class (one extra class for no object), and we pick the highest score as the class for the bounded object. Conv4_3 makes total of 38 × 38 × 4 predictions: four predictions per cell regardless of the depth of feature maps. A expected, many predictions contain no object. SSD reserves a class “0” to indicate

.

SSD does not use the delegated region proposal network. Instead, it resolves to a very simple method. It computes both the location and class scores using small convolution filters. After extraction the feature maps, SSD applies 3 × 3 convolution filters for each cell to make predictions. (These filters compute the results just like the regular CNN filters.) Each filter gives outputs as 25 channels: 21 scores for each class plus one boundary box.

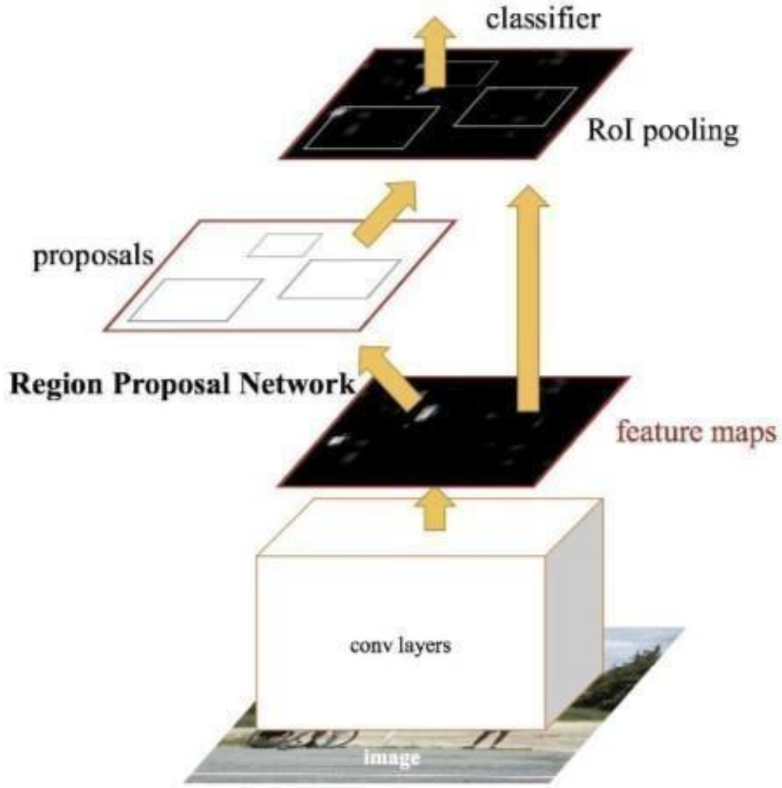

Fig. 2.4 SDD Architecture

Beginning, we describe the SSD detects objects from a single layer. Actually, it uses multiple layers (multi-scale feature maps) for the detecting objects independently. As CNN reduces the spatial dimension gradually, the resolution of the feature maps also decrease. SSD uses lower resolution layers for the detect larger-scale objects. For example, the 4× 4 feature maps are used for the larger-scale object.

MANet:

Target detection is fundamental challenging problem for long time and has been a hotspot in the area of computer vision for many years. The purpose and objective of target detection is, to determine if any instances of a specified category of objects exist in an image. If there is an object to be detected in a specific image, target detection return the spatial positions and the spatial extent of the instances of the objects (based on the use a bounding box, for example). As one of cornerstones of image understanding and computer visions, targets and object detection forms the basis for more complex and higher-level visual tasks, such as object tracking, image capture, instance segmentation, and others.Target detection is also widely used in areas such as artificial intelligence and information technology, including machine vision, automatic driving vehicles, and human–computer interaction. In recent times, the method automatic learning of represented features from data based on deep learning has effectively improved performance of target detection. Neural networks are foundation of deep learning. Therefore, design of better neural networks has become an key issue toward improvement of target detection algorithms and performance. Recently developed objectdetectors that has been based on convolutional neural networks (CNN) has been classified in two types:The first is two-stage detector type, such as Region-Based CNN (R–CNN), Region-Based Full Convolutional Networks (R–FCN), and Feature Pyramid Network (FPN), and the other is single-stage detector, such as the You Only Look Once (YOLO), Single-shot detector (SSD), and the RetinaNet. The former type generates an series of candidate frames as samples of data , and then classifies the samples based on a CNN; the latter type do not generate candidate frames but directly converts the object frame positioning problem into a regression processing problem.

To maintain realtime speeds without sacrificing precision in various object detectors described above, Liu et al proposed the SSD which is faster than YOLO and has a comparable accuracy to that of the most advanced region-based target detectors.SSD combines regression idea of YOLO with the anchor box mechanism of Faster R–CNN, predicts the object region based on the feature maps of the different convolution layers, and outputs discretised multi-scale and multi proportional default box coordinates. The convolution kernel predicts frame coordinates compensation of a series of candidate frames and the confidence of each category. The local feature maps of multi-scale area are used to obtain results for each position in the entire image. This maintains the fast characteristics of YOLO algorithm and also ensures that the frame positioning effect is similar to that is induced by the Faster R–CNN. However, SSD directly and independently uses two layers of the backbone VGG16 and four extra layers obtained by a convolution with stride 2 toconstruct feature pyramid but lacks strong contextual connections.

2.3 Proposed Model:

In recent years, the tracking model based on the Siamese Network has been widely used in the object tracking field to model the object tracking task as a similarity matching problem, which balances the tracking speed and accuracy. However, there are insufficient robustness, discriminative ability and generalisation ability for object deformation and complex background interference. In this paper, an improved Fully-convolutional Siamese Network is proposed. The Triplet Loss function is used as the model objective function instead of logistic loss, and the multi-channel attention mechanism is introduced to make the model pay more attention to the tracking related information and enhance the model discriminating ability. In the offline training phase, an effective data augmentation strategy is used to control the uneven distribution of sample categories and improve the generalisation ability of the model.

In the tracking phase, the Distractor-aware module is used to transfer the general feature representation domain to a specific object domain, thereby improving model discriminating ability. In experiments, the results on VOT2016 tracking benchmark shows that our model has a significant improvement over the SiamFC tracker in multiple evaluation indicators.

CHAPTER 3

BLOCK DIAGRAM

3.1 BLOCK DIAGRAM DESCRIPTION:

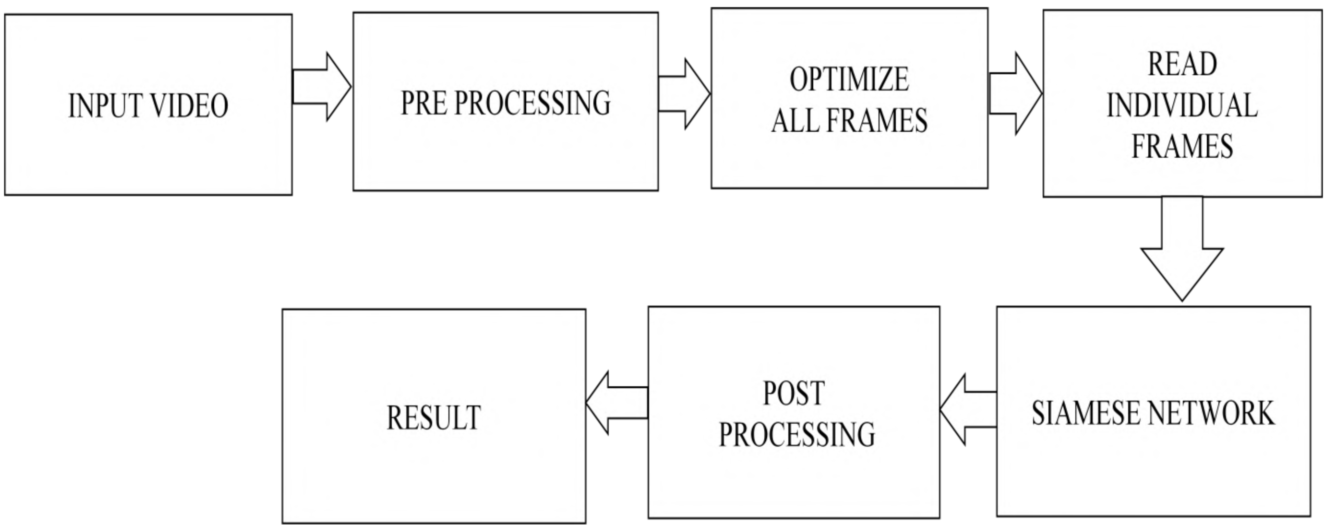

Fig 3.1 Block Diagram

Pre Processing:

We used a network architecture inspired by the SiamFC network. Specifically, as feature extractor we used a network similar to AlexNet. In order to support inputs of different sizes, our feature extractor is a fully-convolutional network. Let φ denote the function computed by the feature extractor. Then we train the network such that P i φ(z)iφ(z 0)ishould be large when z and z 0 are images of the same object and small otherwise. Given a templatez and a search image x, we can then compute φ(x) ? φ(z), where ? denotes the cross- correlation operator. The result should ideally be high

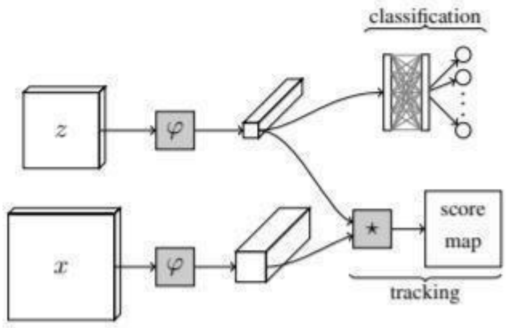

Fig.3.2 Architecture of our network

at the location where the object in z is located in image x and low everywhere else. Similar to the original AlexNet classification network, for the classification task we added fully-connected layers after the feature extractor. The output of this network head are classification labels. This network architecture forces the feature extractor to learn features which are helpful for the tracking task as well as for the classification task.

Siamese Network:

The cross-correlation of the output features should ideally yield a score map y with high values in the center and low values everywhere else. To formalize this requirement, let the score map be a function

$$y \ : \ \{0, \ldots, k\}^2 \to \mathbb{R}.$$

We define two thresholds a and b satisfying $a \leq b$. The grid of the domain of the score map can be partitioned into the sets

$$\begin{aligned} X &= (i,j)^T \in \{0, \ldots, k\}^2 : \|(i,j)^T - (\tfrac{k}{2}, \tfrac{k}{2})^T\| \leq a \\ Y &= (i,j)^T \in \{0, \ldots, k\}^2 : \|(i,j)^T - (\tfrac{k}{2}, \tfrac{k}{2})^T\| > b \\ Z &= \{0, \ldots, k\}^2 \setminus (X \cup Y). \end{aligned}$$

Then we want y(n) to be large for all $n \in X$ and to be small for all $n \in Y$. The scores y(n) for $n \in Z$ are disregarded. Usually, the logistic loss is used to train atracker:

$$l_L(y) = \frac{1}{|X|}\sum_{n\in X}\log(1+\exp(-y(n)))+$$
$$\frac{1}{|Y|}\sum_{m\in Y}\log(1+\exp(y(m)))$$

This loss function is small when the score map has a sharp peak in the center. During tracking, the maximum of the score map is used to update the position of the object. Thus, it is important that the differences between y(n), n ∈ X and y(n), n ∈ Y are large. To accomplish that, proposed to use the triplet loss

$$l_T(y) = \frac{1}{|X|\cdot|Y|}\sum_{\substack{n\in X\\ m\in Y}}\log(1+\exp(y(m)-y(n))).$$

The triplet loss has been used in several other computer vision applications, such as face recognition [11]. For the object classification task, we use the cross entropy loss lC . The loss function we try to minimize is then l(c, y) = lC (c) + μ · lT (y), (3) where c is the output of the classification head of our network.

Post Processing:

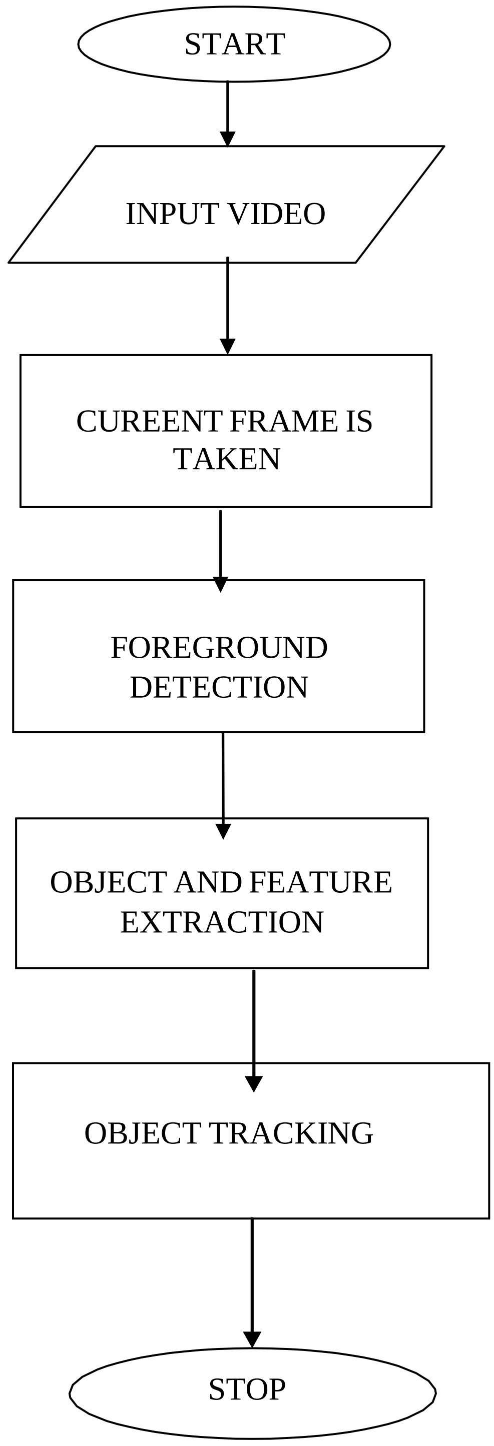
In the tracking problem, a tracker is provided with an initial image and a corresponding bounding box enclosing the object to be tracked. The task of the tracker is then to find the corresponding bounding boxes in the subsequent images. The na¨ıve way to solve this task with Siamese networks is to compute ϕ(z1) once, where z1 is a patch containing the target in the initial frame and use ϕ(z1) for all subsequent frames. showed experimentally that updating the template during tracking improves the performance of the tracker. Let zi be the target patch in frame i. Then the template ti for locating the target in frame i is defined as

$$t_2 = \varphi(z_1)$$
$$t_{i+1} = (1-\lambda)\cdot t_i + \lambda\cdot\varphi(z_i), \quad i>1$$

for some learning rate λ. We adopted this template updating scheme in our tracker.1 It is possible to devise other updating schemes. For example, proposed an updating scheme where $\phi(z1)$ is weighted higher than subsequent patches. Recently, proposed a more sophisticated updating scheme where the update function is learned by a neural network.

Result: Finally the tracking of the object will be shown during the run time of the code and tracking in the frames will be shown from one frame to another and classification of the objects in the each frame wil be shown parallel to the tracking of the object. This classification is shown in the top left of the screen.

3.2 FLOW CHART:



3.3 ALGORITHM:

Step 1: Start

Step 2: Upload the input video in the code and then the video will be splited into frames.

Step 3: The first frame is displayed and then the object which we want to track is to be bounded in a square box.

Step 4: The object to be tracked its feature are extracted and the background features are eliminated and then the centroid is located for the object.

Step 5: The centroid of the object is compared with frames there by the displacement is compared in all the frames of the object.

Step 6: The displacemet is shown according on the screen during thr run time from first frame to last frame.

Step 7: Stop.

Ki

CHAPTER 4

SOFTWARE IMPLEMENTATION

4.1. INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

4.2 THE MATLAB SYSTEM:

The MATLAB system consists of five main parts

Development Environment:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

The MATLAB Mathematical Function Library:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

The MATLAB Language:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

4.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M- functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

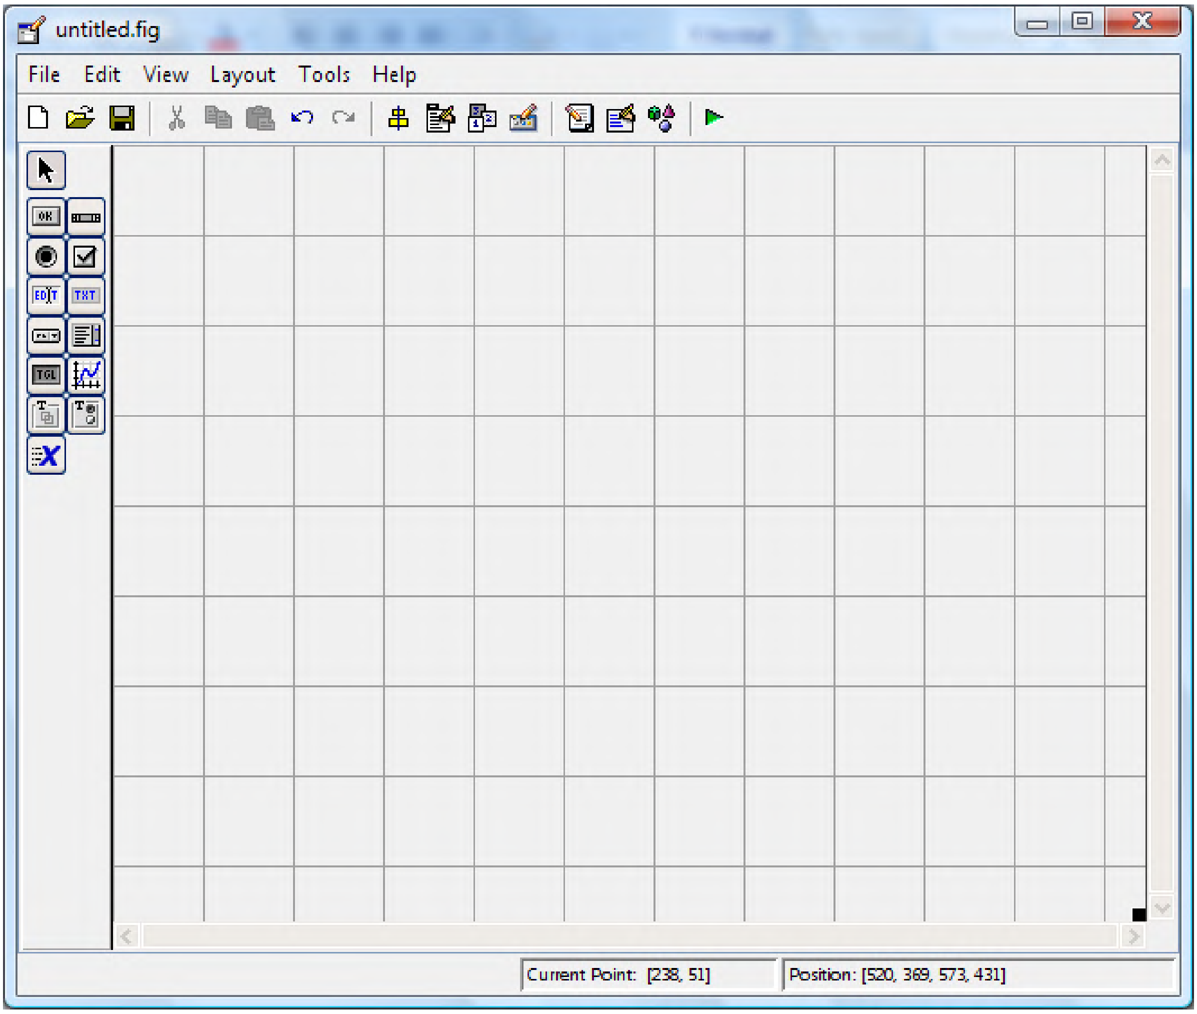


Fig 4.3.1 Blank Window

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

4.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

Introduction - describes the components of the MATLAB system.

Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

Manipulating Matrices - introduces how to use MATLAB to generate matrices andperform mathematical operations on matrices.

Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

4.5 DEVELOPMENT ENVIRONMENT

Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics underDevelopment Environment in the MATLAB documentation, which is available online as well as in print.

Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

Current Directory Browser
Workspace Browser
Array Editor

Editor/Debugger

Command Window

Command History

Launch Pad

Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace byusing functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace toa binary file called a MAT-file, which has a .mat extension. There are options for savingto different formats. To read in a MAT-file, select Import Data from the File menu, or usethe load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

4.6 MANIPULATING MATRICES

Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

Enter an explicit list of elements.
Load matrices from external data files.
Generate matrices using built-in functions.
Create matrices with your own functions in M-files.
Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

Separate the elements of a row with blanks or commas.
Use a semicolon, ; , to indicate the end of each row.
Surround the entire list of elements with square brackets, [ ].
To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

A =

16	3	2	13
5	10	11	8
9	6	7	12
4	15	14	1

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Table 4.1 List Of Arithmetic Operators

Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of theelementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of usefulconstants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Table 4.2 Functions And Its Values

4.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

GUI Development Environment

The process of implementing a GUI involves two basic task.

Laying out the GUI components

Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

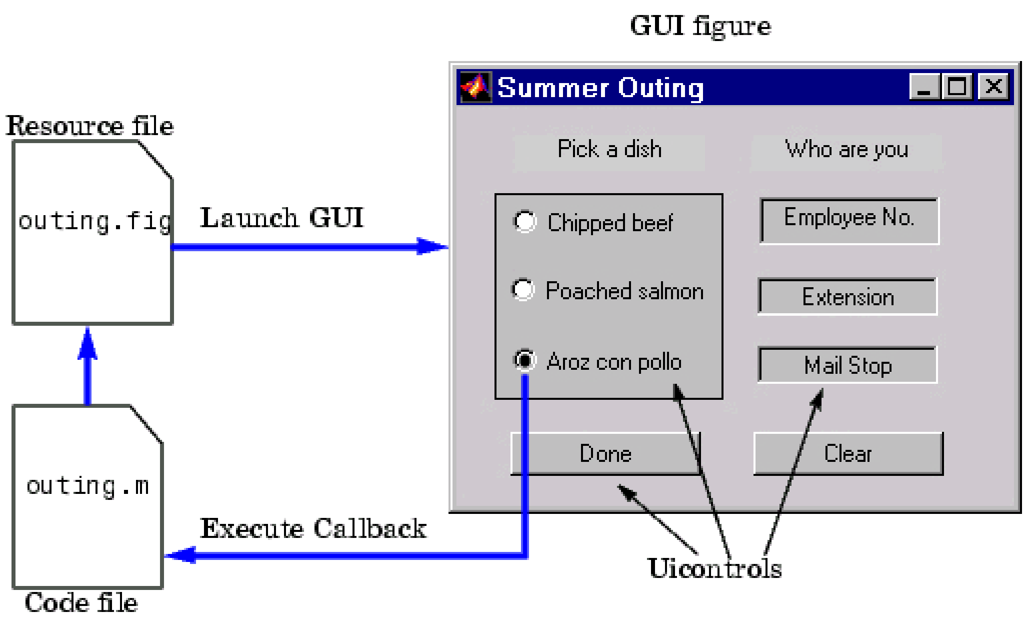

FIG 4.7.1 graphical user blocks

Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commandssuch as findobj, set, and get. If you issue another plotting command, the output is directedto the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and areprogrammable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed;

when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed and equal to the Min property when the toggle button is not depressed

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')
```

% toggle button is not pressed

End

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

  .

  .

  .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

    errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine toexecute. This behavior is consistent with the respective platform conventions. Clicking onother components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the indexcontained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

This callback checks the index of selected item and uses a switch statement to take action based on the value. If the contents of popup menu is fixed,you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val
```

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's

ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,axes(handles.axes1)

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 5

RESULT ANALYSIS

5.1 Results:

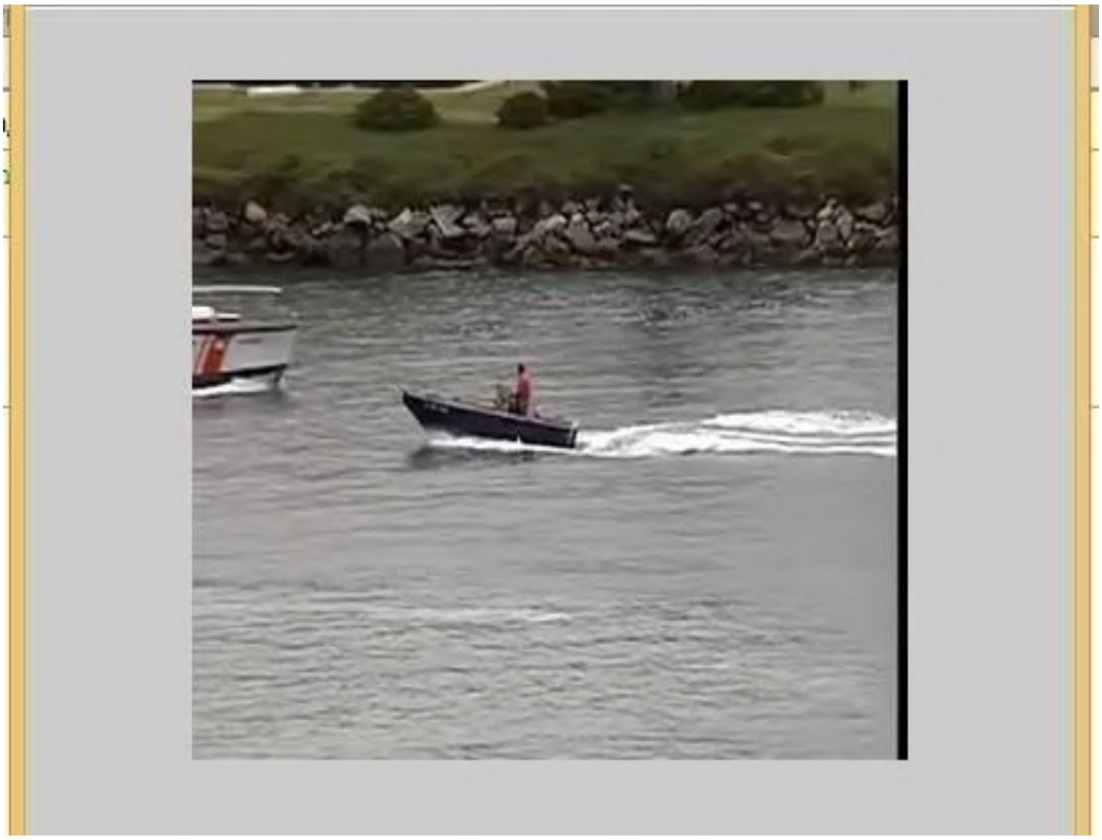

Fig 5.1 Output 1 of the system

In Fig 5.1, it shows the test frame display of the input video soon after we run the code.

Fig 5.2 Output 2 of the system

In the fig.2, we will select the object which has to be tracked and classified by dragging a box around the object

Fig 5.3 Output 3 of the system

In the fig.3, it shows the object is tracked up to 80 frames out of 191 frames, i.e till the point where the object is exactly visible.

CHAPTER 6

ADVANTAGES AND LIMITATIONS

6.1 Advantages:

- In object tracking you know to recognize same object in 2 different frames, helping you for example to count vehicles etc, because you know that exact objects showed and disappeared.
- In object tracking we use image measurements to estimate position of object, but also incorporate position predicted by dynamics.
- Object tracking is helpful in trying to detect articulated objects.
- An object tracking method will be more robust to changes in pose/viewpoint.
- Object tracking using Siamese network has High precision rate, High performance, Low misdetection rate and Less complexity.
- Object tracking with siamese networks require fewer data samples required and can work with highly imbalanced data.

6.2 Limitations:

- Difficulties in tracking objects can arise due to abrupt object motion, changing appearance patterns of both the object and the scene, nonrigid object structures, object-to-object and object-to-scene occlusions, and camera motion.
- Detecting of the object has following challenges: dual priorities, speed, multiple scales, limited data, and class imbalance.
- In this network, a large amount of training data because of so many pairs of classes.
- Not generalizable. A model trained for one task cannot be used for another task.
- Sensitive to some variations in the input.
- For object tracking single method cannot give good accuracy for different kind of videos with different situation like poor resolution, change in weather condition.
- It has non real time applications.
- It locates objects with horizontal bounding box.

6.3 Applications

Object tracking has an assortment of uses, some of which are

- Surveillance and security.
- Traffic checking.
- Video correspondence.
- Robot vision and activity.
- Defence systems.

CHAPTER 7

CONCLUSION AND FUTURE SCOPE

7.1 Conclusion:

We have shown that training a feature extractor on both the classification and the tracking task can be beneficial for building a tracker. One key advantage of building a tracker like this instead of using separate feature extractors is that it is faster during inference. The runtime aspect is crucial, given that many tracking systems run in real-time mention that their feature extractor trained on classification learns very sparse features while the other feature extractor trained on tracking learns dense features. It might be interesting to investigate the feature representation learned by our network, which trains on both tasks simultaneously. It might also be worthwhile to investigate if the converse is also true, i.e. if a classifier can be improved by training its feature extractor on the task of tracking. Furthermore, it might be possible to train the feature extractor of a tracker on computer vision tasks other than classification and see similar improvements in tracking performance.

7.2 Future scope:

Our future work may include:

1. The results of object detection and classification in this experiment are good, but the performance of object tracking is not ideal. Tracking objects by using data association may not be the best solution. In the future, LSTM can be employed to predict the trajectory of objects, thereby improves the accuracy of object tracking.
2. The types of anomalies monitored by the network are limited. In future, more data can be trained to implement the detection of more abnormal categories.
3. The network proposed in this experiment cannot tracking objects across cameras due to the similarity of the same target in different backgrounds predicted by SiamRPN is not accurate enough. Meanwhile, for the actual application of video surveillance, anomaly detection is usually multiple camera-based, for example, tracking the same suspicious target in different cameras. In the future, the algorithm can be optimized to achieve multi-target tracking by using these cameras.

Acceptance Letter for online oral presentation & journal publication

Online Mega international Conference "Smart Modernistic in Electronics and Communication" *(ICSMEC–21) on 02nd & 03rd July 2021*

Dear P.Sushma, U.Nikitha, V.Jaya Surya:

Title of the paper: A SHARED REPRESENTATION FOR OBJECT TRACKING AND CLASSIFICATION USING SIAMESE NETWORKS

Paper ID: ICSMEC21-0075

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in online mega International Conference on "Smart Modernistic in Electronics and Communication" ***(ICSMEC-21).***

ICSMEC-21 conference received over 400+ submissions from different parts of the world and regions so far, reviewed by international experts; the acceptance ratio is controlled below 20%. Your paper will be submitted for **Journal publications free of cost** in the appropriate given Journals after registration. **You will be given registration kit, International conference proceedings with ISBN (Soft copy), and international certificate of publication.**

You are now required to pay the conference registration fees (Faculty / Research Scholars: Rs.3500/-) as mentioned below A/C details on or before 5 working day after receiving this email else your paper will not be considered for presentation as well as publication in the Journal.

For NEFT/RTGS/IMPS

Account Details: (Current Account)

A/C Name: PRINCIPAL, St. Martin's Engineering College
Bank Name: SBI, Kukatpally, Hyderabad
Account No: 30667640268
IFSC code: SBIN0011664
Swift Code: SBININBB725 (Applicable for foreign author)

For PAYTM users

After payment, please send the registration form, payment proof and final paper in.doc/.docx format.

Your interest in *ICSMEC-21* is very much appreciated. Look forward to meeting you on the day of conference.

Yours sincerely,
ICSMEC- 21 Organizing Committees

DECLARATION

We declare that this project report titled "AUTOMATIC RAIN WATER SENSING UMBRELLA" submitted in partial fulfillment of the degree of B. Tech in Electronics and Communication Engineering record of original work carried out by us under the guidance and supervision of Mrs. G. Laxmi Priyanka, and has not formed the name basis for the award of any other degree or diploma, in this or any other Institution or University. In keeping with the ethical practice in reporting scientific information, due acknowledgements have been made wherever the findings of others have beencited.

P.vinay kumar	**Akshay sakre**	**Shaik Altaf**
17K81A0439	**17K81A0443**	**17K81A0447**

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

We extended our deep sense of gratitude to Principal, **Dr. P. SANTOSH KUMAR PATRA**, St. Martin's Engineering College, Dhulapally, for permitting us to undertake this project.

We are also thankful to **Dr.B.Hari Krishna** Head of the Department, Electronics And Communications, St. Martin's Engineering College, Dhulapally, for his support and guidance throughout our project and as well as our project coordinator **Dr.A.Anand**, Professor in Electronics And Communication Engineering, for his valuable support.

We would like to express our sincere gratitude and indebtedness to our project supervisor **Mrs.G. Laxmi Priyanka**, Assistant Professor, Electronics And Communications St. Martin's Engineering College, Dhulapally, for her support and guidance throughout our project.

We sincerely thank our project internal guide , **Ms G. Laxmi priyanka** , Assistant professor , Department of ECE and our class project coordinator **Ms A.Sowmya** Assistant professor, Department of ECE for guidance and encouragement in carrying out this project work

Finally we are highly grateful and obliged to our college coordinator **Dr Malayadri** professor of IT and **Dr Ravi Kumar** associate professor of ECE for their advice supervision and vital contribution as and when required during this research work and for their support and cooperation That is difficult to express in words.

We express thanks to all those who have helped us in successfully completing the project.

1. P.vinay kumar
2. Akshay sakre
3. Shaik Altaf

Abstract

During monsoon, sellers with an open shop, neighbours drying clothes outside and many similar situations cause inconveniences in our life. In case of street vegetable sellers, they need to protect the vegetables, fruits and customers from rains in monsoon season. Even the tarpaulins don't prove to be of any use during torrential rains accompanied by a thunderstorm. To overcome such problems and help us live with the inconvenience raining system. this auto rain-sensing umbrella smart system comes up with a solution. This smart rain sensing system can detect the rain and opens up the umbrella. In this smart system, we have a raindrop sensing system, which gives a reading proportional to the amount of rain pouring on it. The smart system consisting of a rack and pinion system, the rack is fixed to umbrella such that when a sensor senses the exceeding value of raindrops, it gives a signal to the pinion attached to a motor. Then the motor starts rotating and the umbrella opens.

CHAPTER 1

INTRODUCTION

Introduction:

Natural resource elements are associated with day-to-day activities such as rainfall and sun light which is having both positive as well as negative impact on our lives and property. The sun emits ultraviolet energy which is one of the sources for vitamin D, staggering the growth of oncogenes and also used by plants during photosynthesis which is indirectly source of food for all living creature. Rainfall also having its very negative impact and such as destruction and damage of nursery bed herbs or plants and various ornamental flowers, skin disorder in humans, fever and sickness, and increase in mortality of living stocks, structural and materialistic deformation of properties such as fabrics [1]. A larger number and various types of structural and control system have been proposed in the past for particularly management, regulation, controlling and moderation of weather element to the life and property, but the retractable roof is the most suitable form for moderating these weather elements (Rain and Sunlight). Unlike permanent structures for the same purpose, the self-adjustable system only acts when a threshold is attained [2, 3]. The problem identified in previous model was for the continuous power supply so our designed model can be installed anywhere. It could be possibly access to renewable source of energy like sunlight which is cheaper and cleaner source of energy. The problem associated with the proper design of the umbrella which can be possibly be made portable and easy to use is also there and other components with that which are to be protected from the extreme weather conditions. The design proposed for many systems uses retractable roof of wooden which can possibly be damaged by rain so proper material selection has to be done for longer life [4, 5]. Sunlight and rainfall Activated Retractable Illustrates through his paper that natural climatic elements like sunlight and rainfall have a very huge importance in our day-to-day life. These two weather elements have both positive and negative impacts in our life. These two weather elements have some positive consequences so they cannot be ignored completely [6, 7]. To avoid the complete isolation of sunlight and rainfall a system is developed which will economical and give space reuse whenever the threshold value exceeds then roof automatically gets open up. An Algorithm is developed by the author to facilitate the automatic working of the roof whenever the intensity of these two weather elements exceeds the present value. In this system author has used an LDR sensor to detect to intensity of sunlight and ultrasonic and rain sensor for detection of rainfall intensity and pressure which will be helping in smart decision making. This system has a programmable device Arduino which will help in controlling of stepper motor for opening and closing of roof and two switches aiding for better control in all direction. ‘Smart Automation System Using Arduino and Rain Drop Sensor’ illustrated in his project that during rainy season the crops gets affected due to unexpected rainfall or even with hailstorm sometime in order to eliminate such things he developed a system to protect it from heavy rainfall [8]. The basic idea behind this research is to protect or to save the crops along with the rain water harvesting system. The rain sensing device along with the soil moisture sensing device is used in this system which will help in opening and closing of the automated roof. Automatic Rain Water and Crop Saving System discuses in his paper that agriculture is one of the most important sectors as it employs more than 45% of working population.

Agriculture sector contributes a larger section in our country’s GDP so its really important to look what are the factors affecting it in some way. Due to heavy rainfall farmers across globe face a lot of problem which affect the total income and productivity of the farmer and field respectively as unexpected rainfall washes off the grains and cereals. So, if they have to protect the crop a system can be developed which will ultimately look after the fields or the harvested crop and protect them from extreme condition of weather and also helps in rain water harvesting [9]. The problem stated above which is faced by people in day-to-day life by the extreme condition of weather leads to immense amount of problem in our lives. These problems are not only associated with money value but it also with emotional wellbeing of the person as loss of essential can lead to emotional breakdown of person. Various technological cannot be made to eliminate these problems completely but at certain extent to minimize the total cost. The equipment which is to be developed should be economical and easy to use. So that implementation of it can be done on larger areas. The Purpose this research is chosen to improve the design of the pre-existing umbrellas. Often times when rainfalls a person must constantly adjust the head of the umbrella to block the rain as it falls at different angles due to the wind. Our idea intends design a smart umbrella to be an extension to current umbrellas that will automatically adjust the head of the umbrella to block the maximum amount of rain according to the wind direction and speed. The designed system which is proposed should be light in weight, cost effective, and easy to attach to existing products in the market still existing adhesion problems. The modelled describes about all the important components which in turn will be used for making of system.

CHAPTER 2

EMBEDDED SYSTEMS

2.1 Embedded System

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes. The applications software on such processors is sometimes referred to as firmware

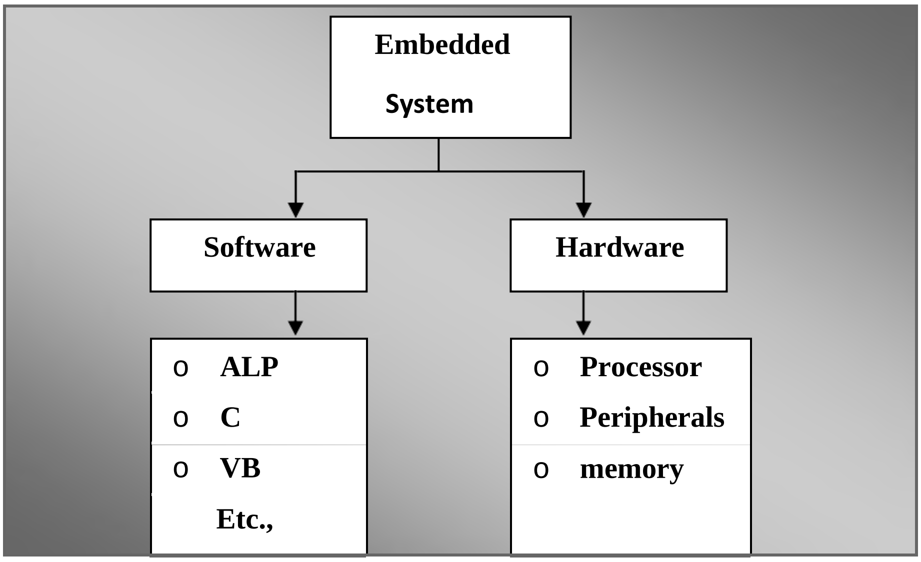

Figure 2.1 Block diagram of Embedded SystemNo table of figures entries found.

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory.

Memory: It is used to store data or address.

Peripherals: These are the external devices connected

Processor: It is an IC which is used to perform some task

Applications of embedded systems

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

Processors are classified into four types like:

- Micro Processor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Three basic characteristics differentiate microprocessors:

- **Instruction set**: The set of instructions that the microprocessor can execute.
- **Bandwidth :** The number of bits processed in a single instruction.
- **Clock speed :** Given in megahertz (MHz), the clock speed determines how many instructions per second the processor can execute.

In both cases, the higher the value, the more powerful the CPU. For example, a 32-bit microprocessor that runs at 50MHz is more powerful than a 16-bit microprocessor that runs at 25MHz. In addition to bandwidth and clock speed, microprocessors are classified as being either RISC (reduced instruction set computer) or CISC (complex instruction set computer).

A microprocessor has three basic elements, as shown above. The ALU performs all arithmetic computations, such as addition, subtraction and logic operations (AND, OR, etc). It is controlled by the Control Unit and receives its data from the Register Array. The Register Array is a set of registers used for storing data. These registers can be accessed by the ALU very quickly. Some registers have specific functions - we will deal with these later. The Control Unit controls the entire process. It provides the timing and a control signal for getting data into and out of the registers and the ALU and it synchronizes the execution of instructions (we will deal with instruction execution at a later date).

Three Basic Elements of a Microprocessor

Micro Controller (µc):

A microcontroller is a small computer on a single **integrated circuit** containing a processor core, memory, and programmable **input/output** peripherals. Program memory in the form of **NOR flash** or **OTP ROM** is also often included on chip, as well as a typically small amount of RAM. Microcontrollers are designed for embedded applications, in contrast to the **microprocessors** used in **personal computers** or other general purpose applications.

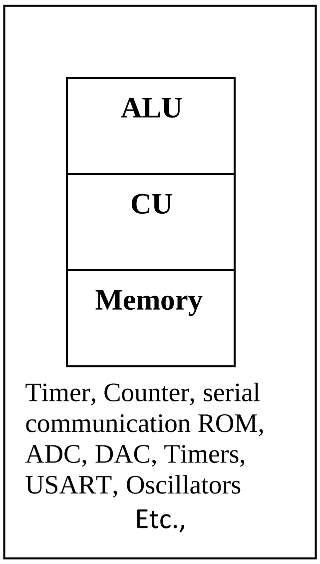

Figure 2.2 Block Diagram of Micro Controller (µc)

Digital Signal Processors (DSPs):

Digital Signal Processors is one which performs scientific and mathematical operation. Digital Signal Processor chips - specialized microprocessors with architectures designed specifically for the types of operations required in digital signal processing. Like a general-purpose microprocessor, a DSP is a programmable device, with its own native instruction code. DSP chips are capable of carrying out millions of floating point operations per second, and like their better-known general-purpose cousins, faster and more powerful versions are continually being introduced. DSPs can also be embedded within complex "system-on-chip" devices, often containing both analog and digital circuitry.

Application Specific Integrated Circuit (ASIC)

ASIC is a combination of digital and analog circuits packed into an IC to achieve the desired control/computation function

ASIC typically contains

- CPU cores for computation and control
- Peripherals to control timing critical functions
- Memories to store data and program
- Analog circuits to provide clocks and interface to the real world which is analog in nature
- I/Os to connect to external components like LEDs, memories, monitors etc.

2.2 Computer Instruction Set

There are two different types of computer instruction set there are:

1. RISC (Reduced Instruction Set Computer) and

2. CISC (Complex Instruction Set computer)

2.2.1 Reduced Instruction Set Computer (RISC)

A RISC (reduced instruction set computer) is a microprocessor that is designed to perform a smaller number of types of computer instruction so that it can operate at a higher speed (perform more million instructions per second, or millions of instructions per second). Since each instruction type that a computer must perform requires additional transistors and circuitry, a larger list or set of computer instructions tends to make the microprocessor more complicated and slower in operation.

Besides performance improvement, some advantages of RISC and related design improvements are:

- A new microprocessor can be developed and tested more quickly if one of its aims is to be less complicated.
- Operating system and application programmers who use the microprocessor's instructions will find it easier to develop code with a smaller instruction set.
- The simplicity of RISC allows more freedom to choose how to use the space on a microprocessor.

Higher-level language compilers produce more efficient code than formerly because they have always tended to use the smaller set of instructions to be found in a RISC computer.

2.2.2 RISC characteristics

- **Simple instruction set:**

In a RISC machine, the instruction set contains simple, basic instructions, from which more complex instructions can be composed.

- **Same length instructions.**

Each instruction is the same length, so that it may be fetched in a single operation.

- **1machine-cycleinstructions.**

Most instructions complete in one machine cycle, which allows the processor to handle several instructions at the same time. This pipelining is a key technique used to speed up RISC machines.

2.2.3 Complex Instruction Set Computer (CISC)

CISC, which stands for **Complex Instruction Set Computer,** is a philosophy for designing chips that are easy to program and which make efficient use of memory. Each instruction in a CISC instruction set might perform a series of operations inside the processor. This reduces the number of instructions required to implement a given program, and allows the programmer to learn a small but flexible set of instructions.

The advantages of CISC

At the time of their initial development, CISC machines used available technologies to optimize computer performance.

- Microprogramming is as easy as assembly language to implement, and much less expensive than hardwiring a control unit.
- The ease of micro-coding new instructions allowed designers to make CISC machines upwardly compatible: a new computer could run the same programs as earlier computers because the new computer would contain a superset of the instructions of the earlier computers.
- As each instruction became more capable, fewer instructions could be used to implement a given task. This made more efficient use of the relatively slow main memory.
- Because micro program instruction sets can be written to match the constructs of high-level languages, the compiler does not have to be as complicated.

The disadvantages of CISC

Still, designers soon realized that the CISC philosophy had its own problems, including:

- Earlier generations of a processor family generally were contained as a subset in every new version --- so instruction set & chip hardware become more complex with each generation of computers.
- So that as many instructions as possible could be stored in memory with the least possible wasted space, individual instructions could be of almost any length---this means that different instructions will take different amounts of clock time to execute, slowing down the overall performance of the machine.
- Many specialized instructions aren't used frequently enough to justify their existence --- approximately 20% of the available instructions are used in a typical program.
- CISC instructions typically set the condition codes as a side effect of the instruction. Not only does setting the condition codes take time, but programmers have to remember to examine the condition code bits before a subsequent instruction changes them.

2.3 Memory Architecture

There two different type's memory architectures there are:

- Harvard Architecture
- Von-Neumann Architecture

2.3.1 Harvard Architecture

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The **Harvard architecture** is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

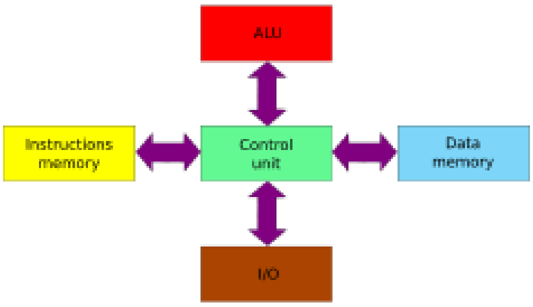

Figure 2.3 Harvard Architecture

Modern uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behavior must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction pre-fetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.3.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. The **von Neumann architecture** is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.A **stored-program** digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

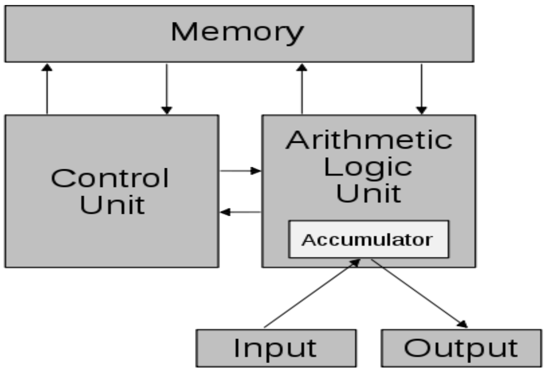

Figure 2.4 Schematic of the Von-Neumann Architecture.

Basic Difference between Harvard and Von-Neumann Architecture

- The primary difference between Harvard architecture and the Von Neumann architecture is in the Von Neumann architecture data and programs are stored in the same memory and managed by the same information handling system.
- Whereas the Harvard architecture stores data and programs in separate memory devices and they are handled by different subsystems.
- In a computer using the Von-Neumann architecture without cache; the central processing unit (CPU) can either be reading and instruction or writing/reading data to/from the memory. Both of these operations cannot occur simultaneously as the data and instructions use the same system bus.
- In a computer using the Harvard architecture the CPU can both read an instruction and access data memory at the same time without cache. This means that a computer with Harvard architecture can potentially be faster for a given circuit complexity because data access and instruction fetches do not contend for use of a single memory pathway.
- Today, the vast majority of computers are designed and built using the Von Neumann architecture template primarily because of the dynamic capabilities and efficiencies gained in designing, implementing, operating one memory system as opposed to two. Von Neumann architecture may be somewhat slower than the contrasting Harvard Architecture for certain specific tasks, but it is much more flexible and allows for many concepts unavailable to Harvard architecture such as self-programming, word processing and so on.

CHAPTER 3

POWER SUPPLY

3.1 Block Diagram

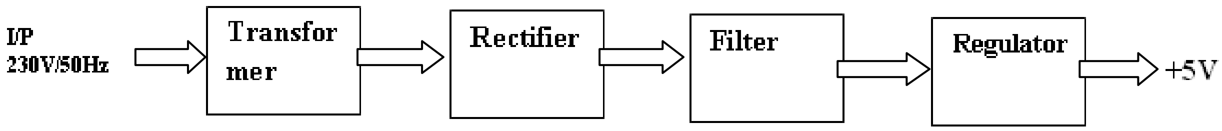

Figure 3.1 Power Supply

3.2 Circuit Diagram

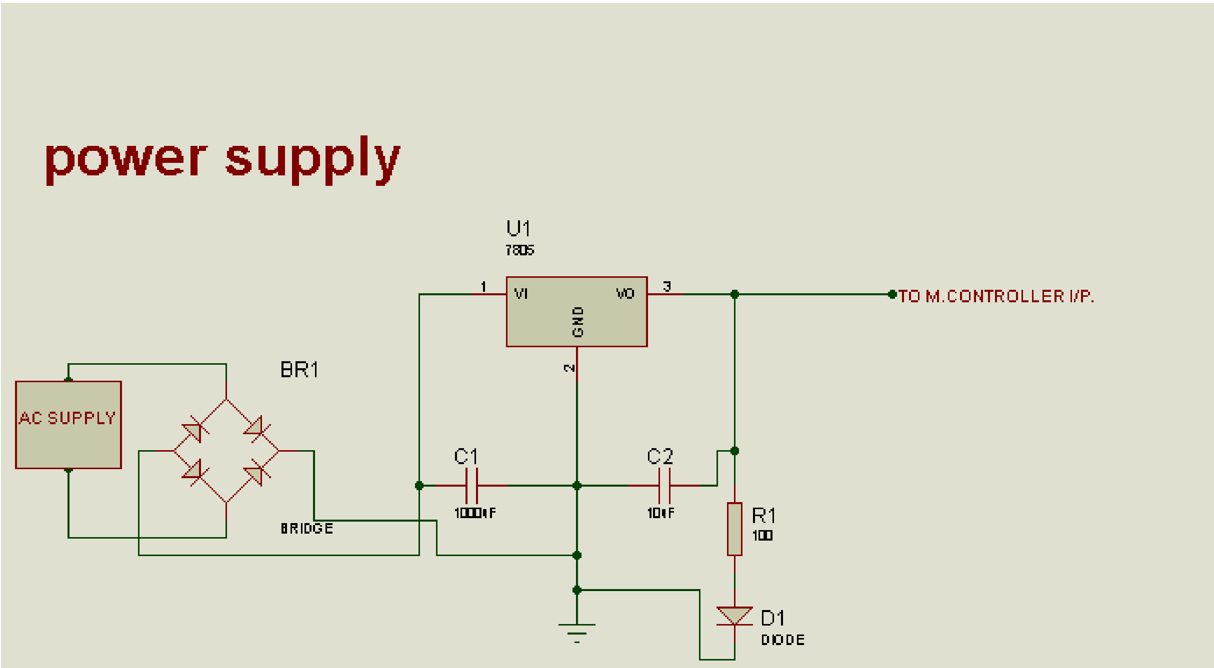

Figure 3.2 circuit diagram

Description

3.2.1 Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

Transformer is a device that converts the one form energy to another form of energy like a transducer.

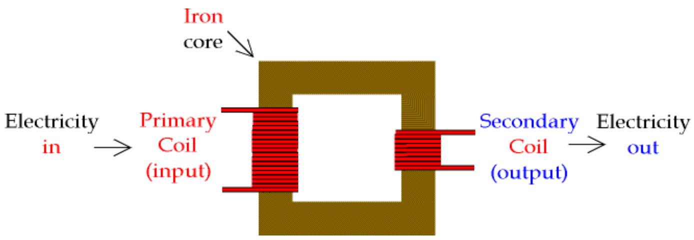

Figure 3.3 Transformer

Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

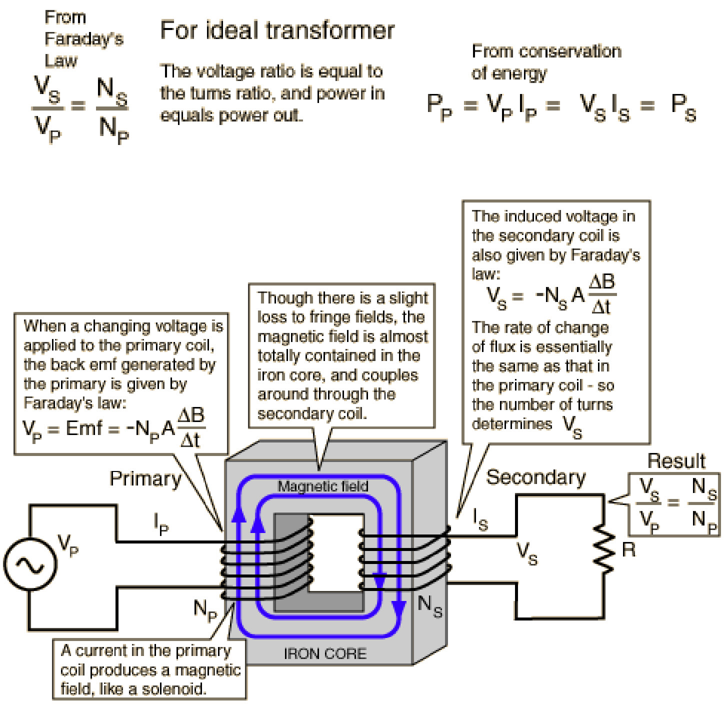

Figure: 3.4 Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

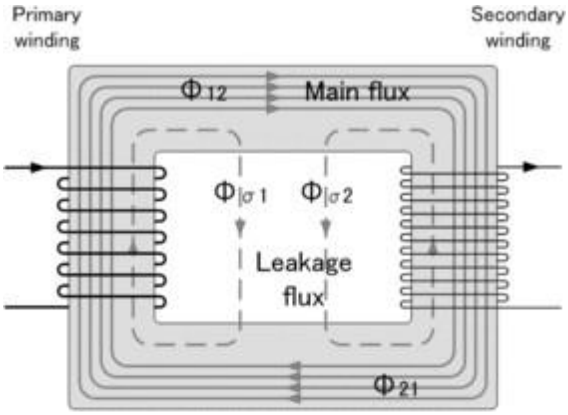

Figure: 3.5 Basic Transformers

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

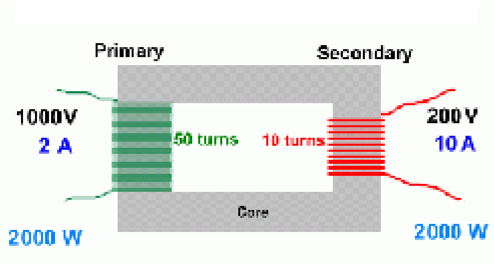

Figure: 3.6 Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

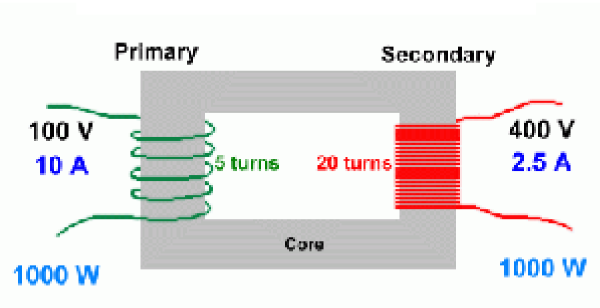

Figure: 3.7 Step-Up Transformer

Applications

Generally these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

3.2.2 Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

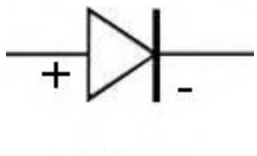

Figure 3.8 Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.2.3 Rectifier

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-wave Rectifier

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure .

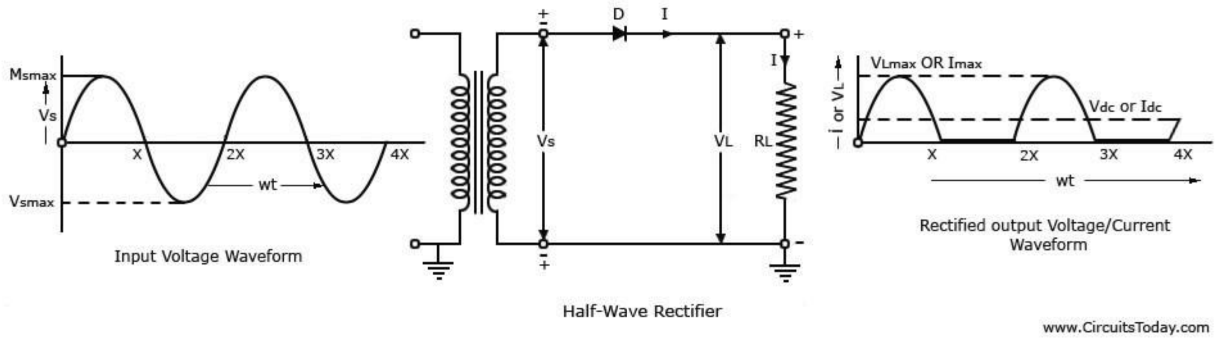

Figure 3.9 Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is 0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

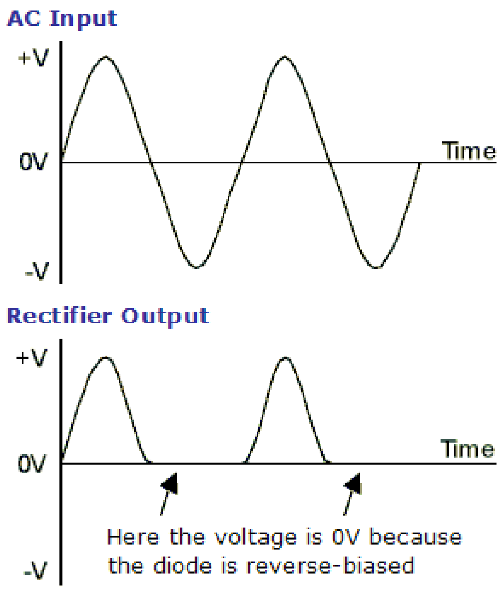

Figure 3.10 Half-Wave Rectification

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC. The resulting waveform is shown in figure 4.

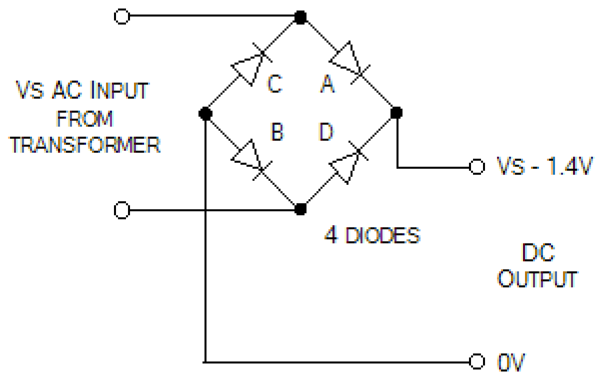

Figure 3.11 Full-Wave Rectifier

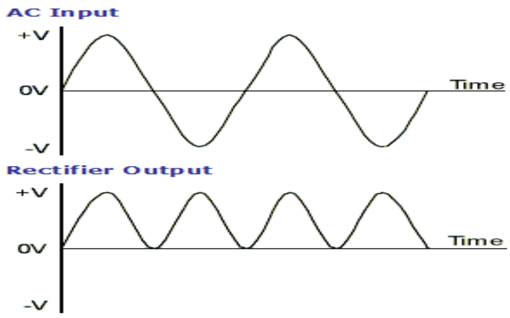

Figure 3.12 Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

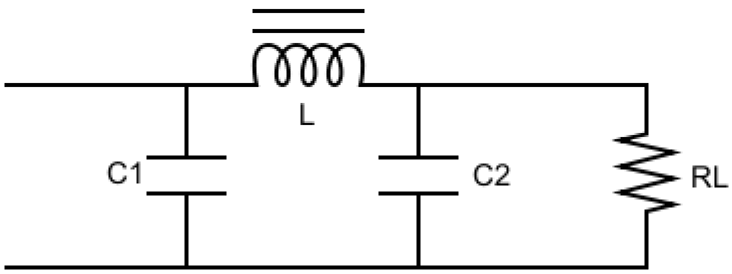

Figure:3.13 Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L

2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

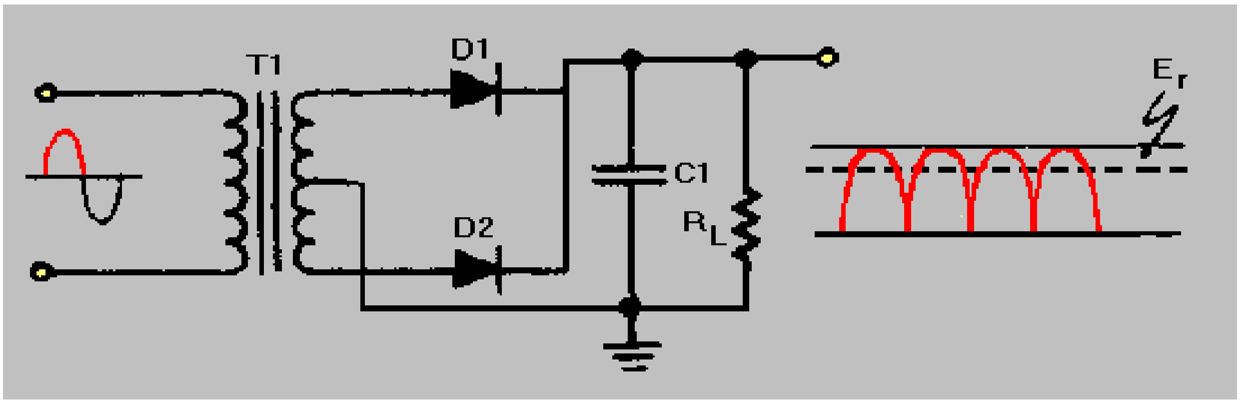

Figure: 3.14 Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.2.4 Voltage Regulator:

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

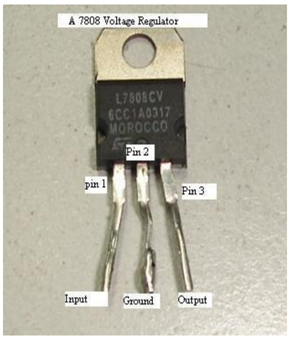

Figure 3.15 Regulator

CHAPTER 4

SOFTWARE

4.1 Proteus

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

4.1.1 About Proteus

It is a software suite containing schematic, simulation as well as PCB designing.

ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

4.1.2 Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

4.2 Starting New Design

Step 1: Open ISIS software and select New design in File menu

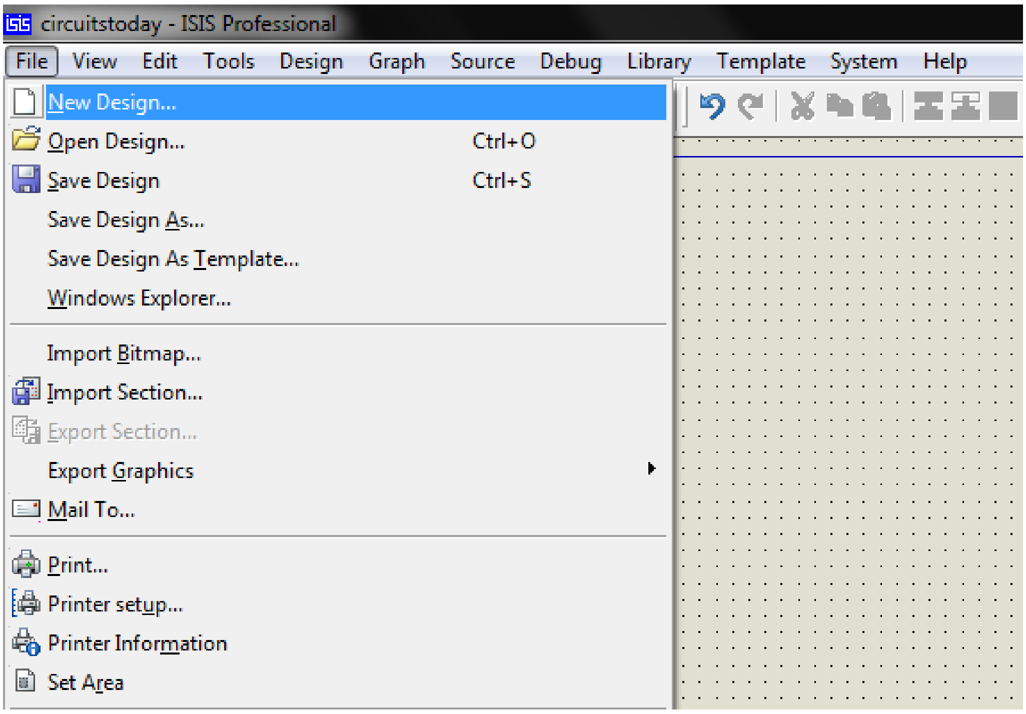

Figure 4.1 Proteus File Menus

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

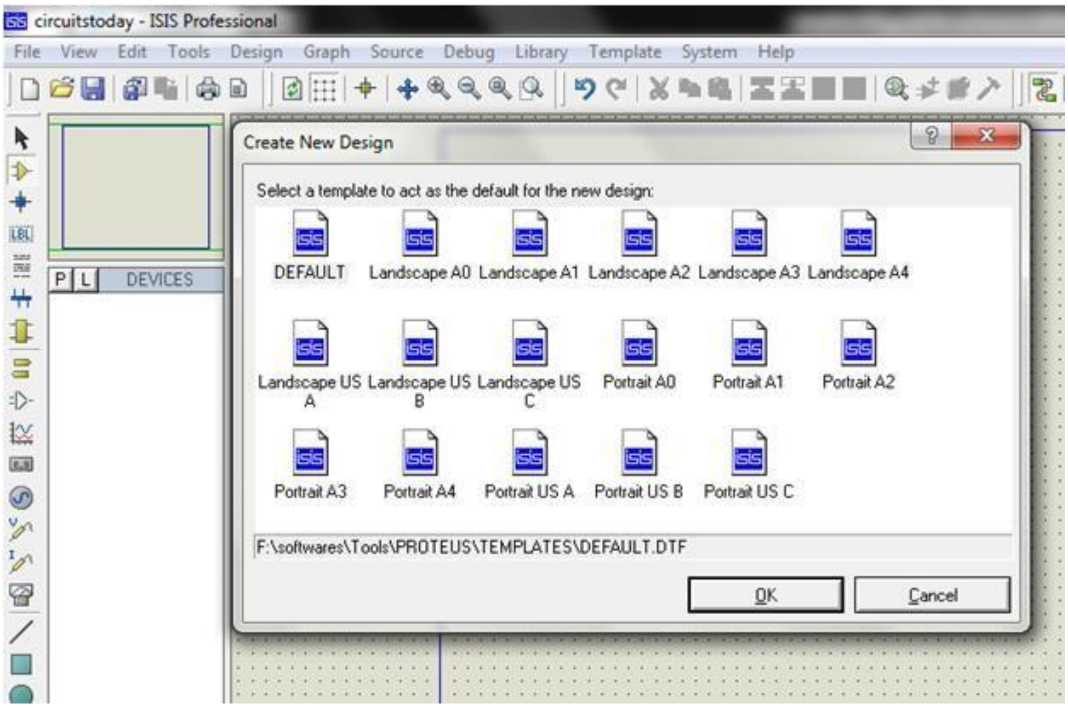

Figure 4.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

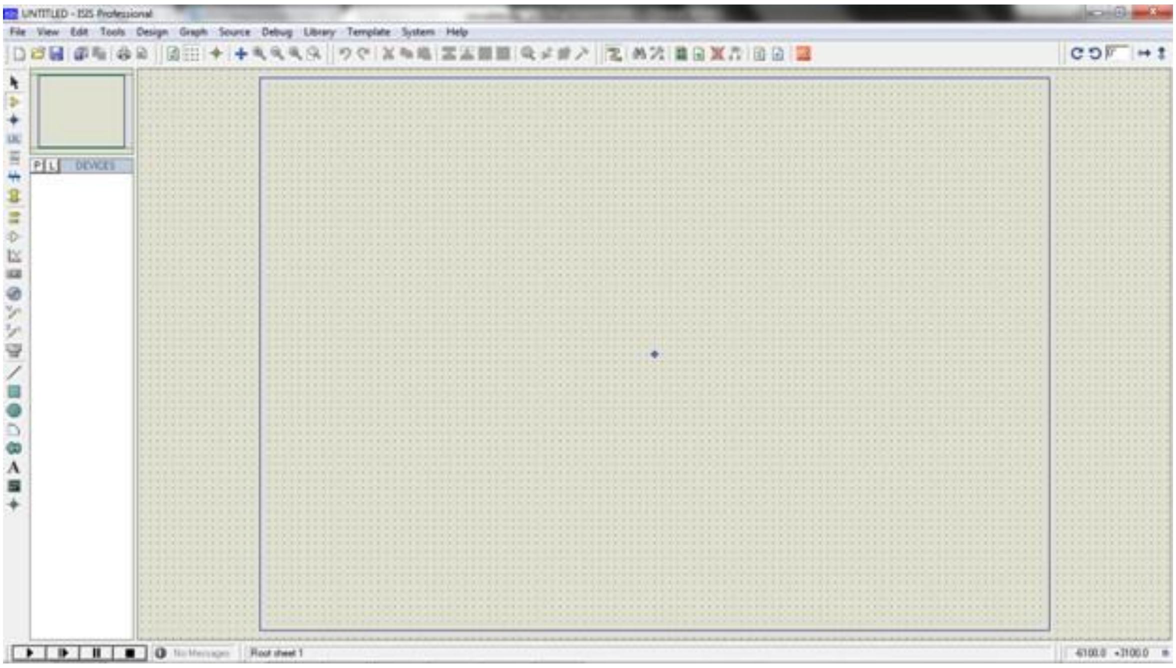

Figure 4.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

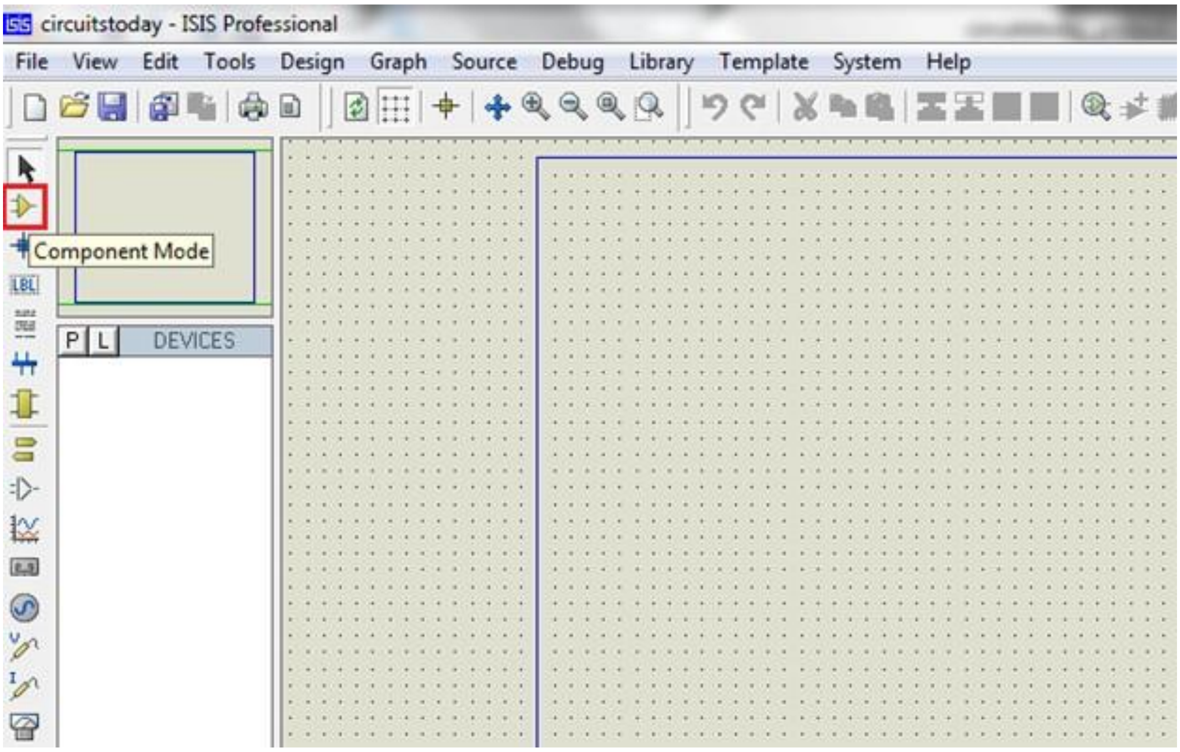

Figure 4.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

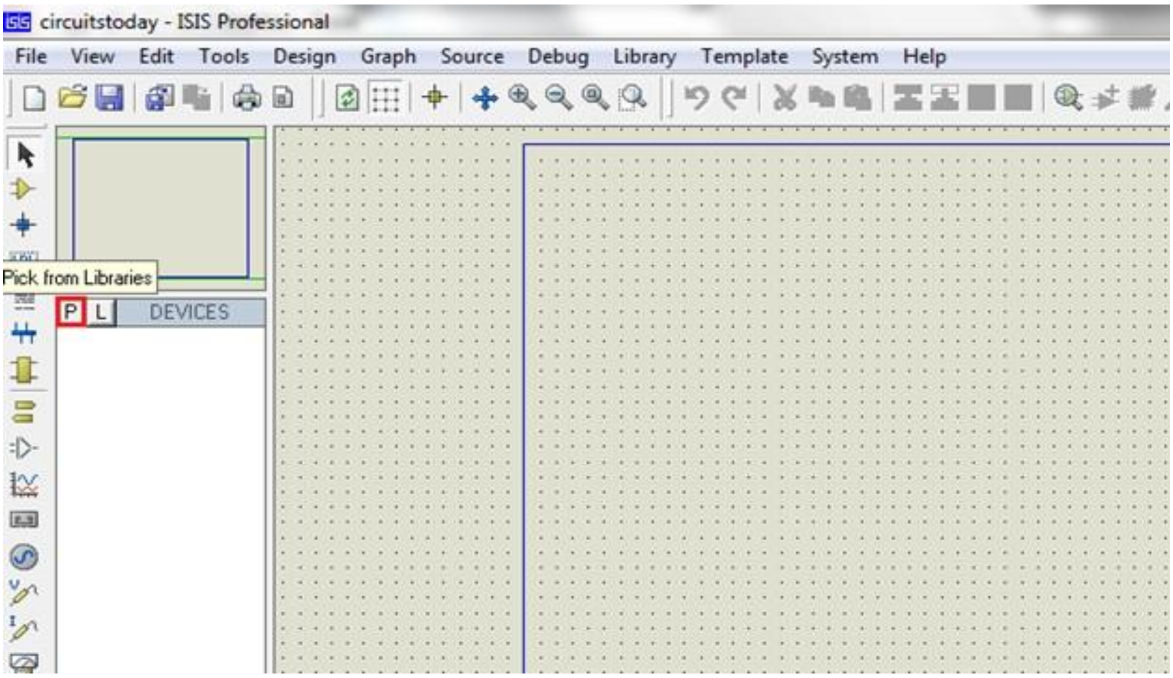

Figure 4.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

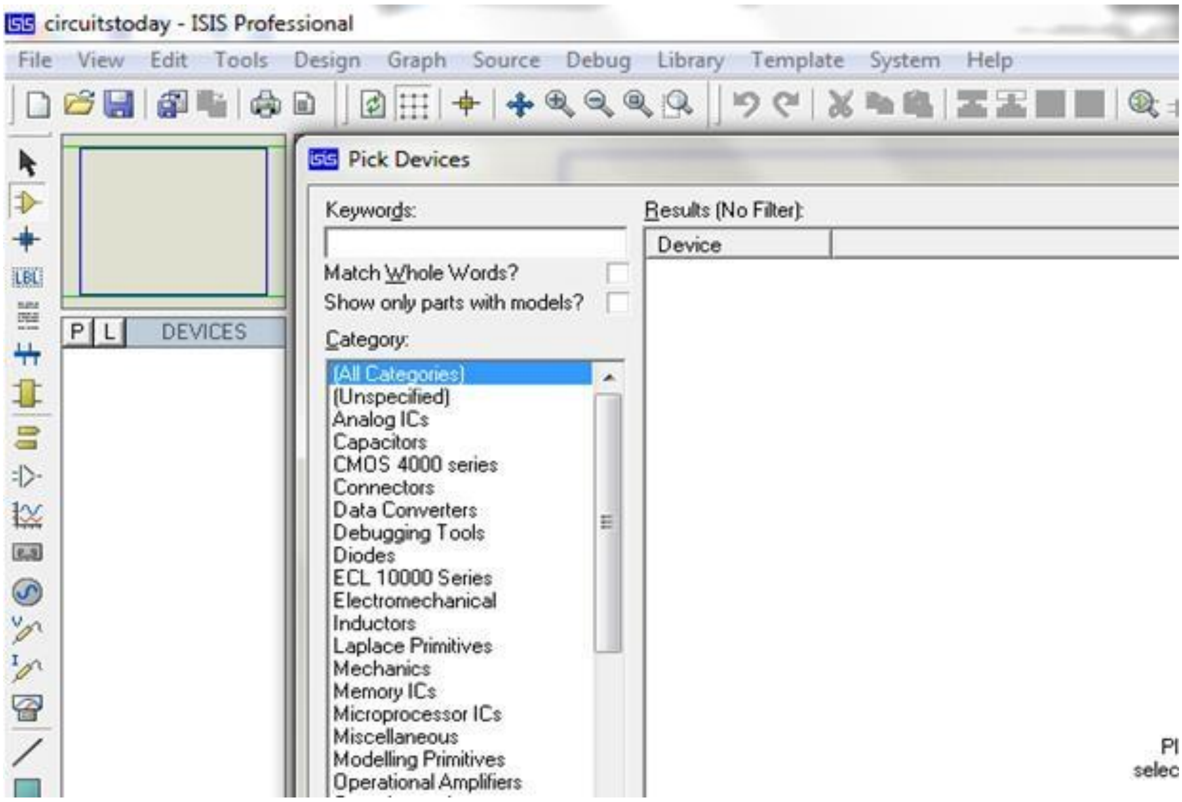

Figure 4.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

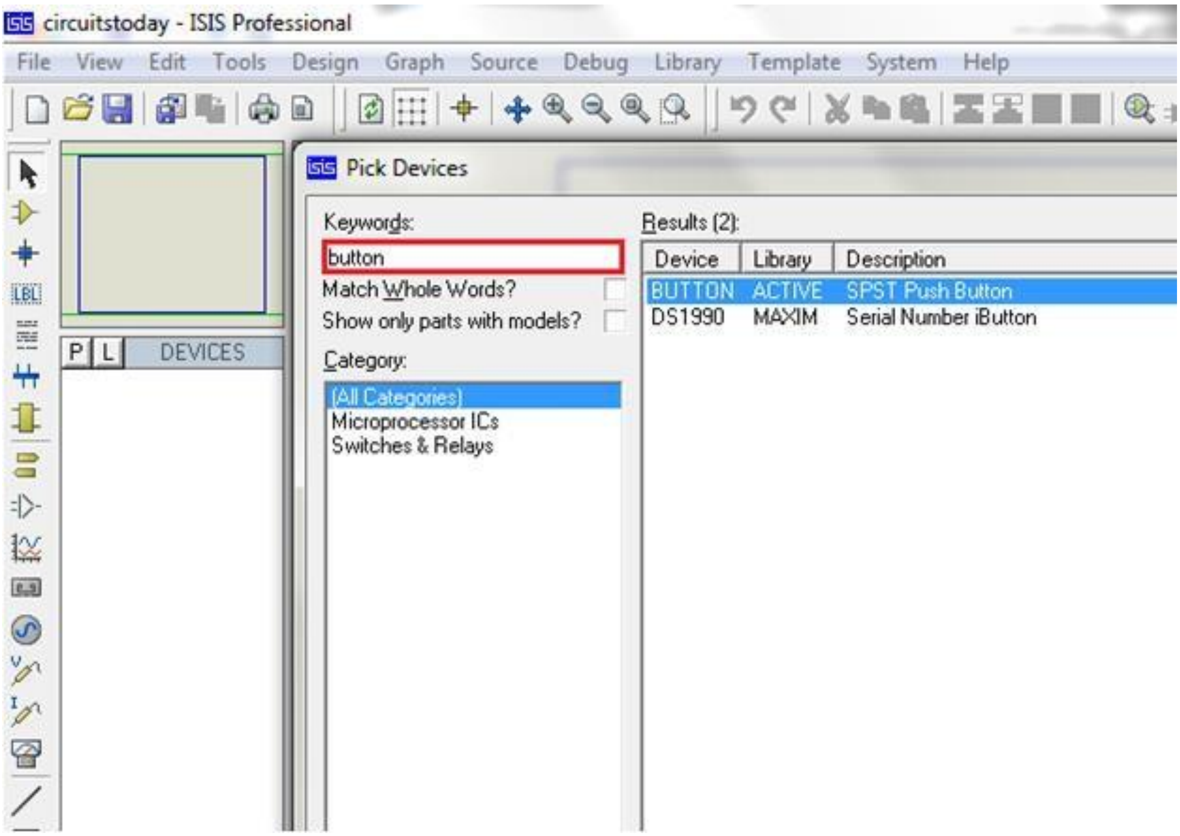

Figure 4.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

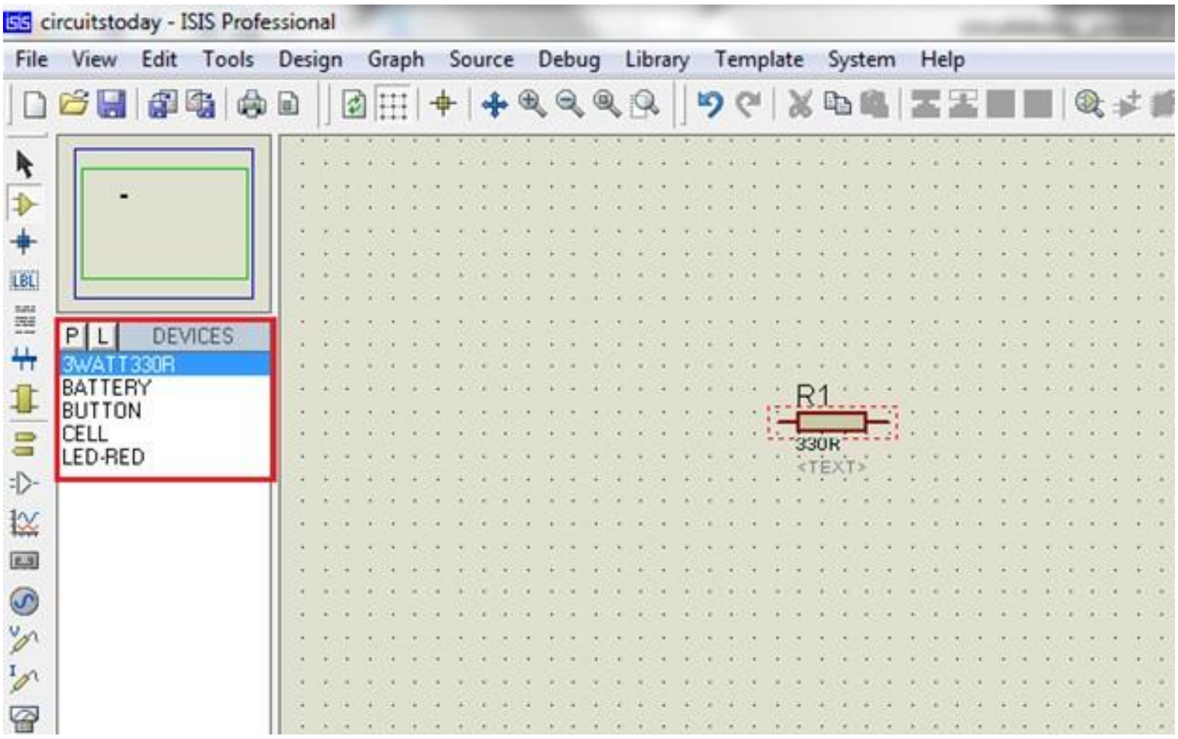

Figure 4.8 Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

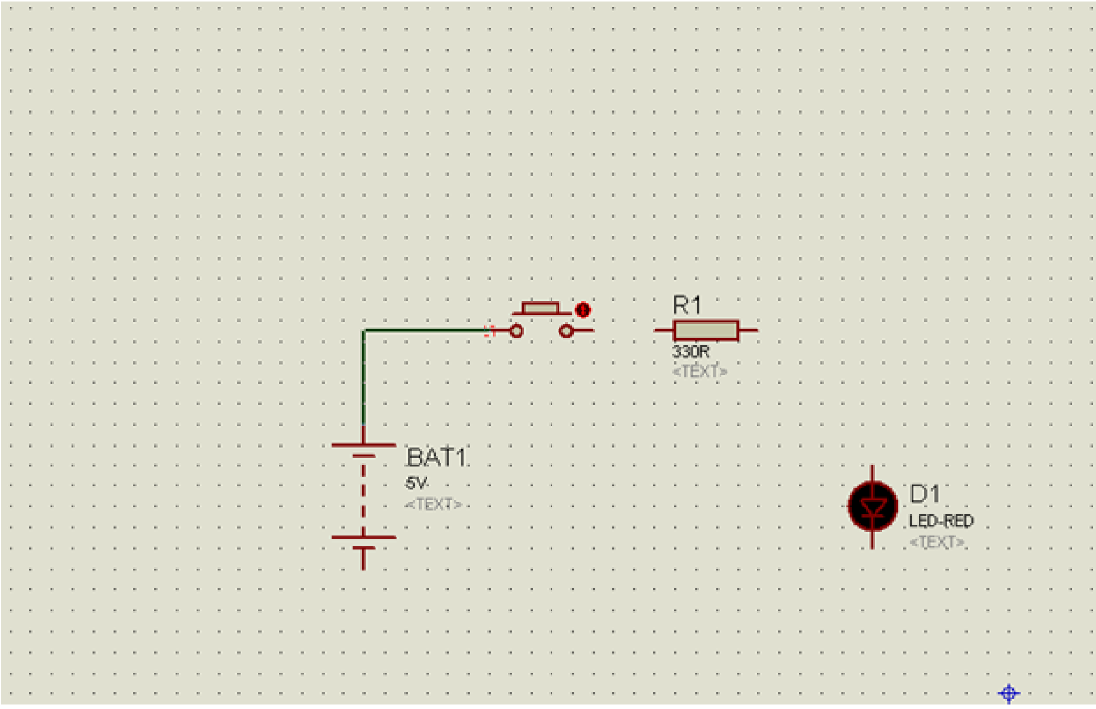

Figure 4.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

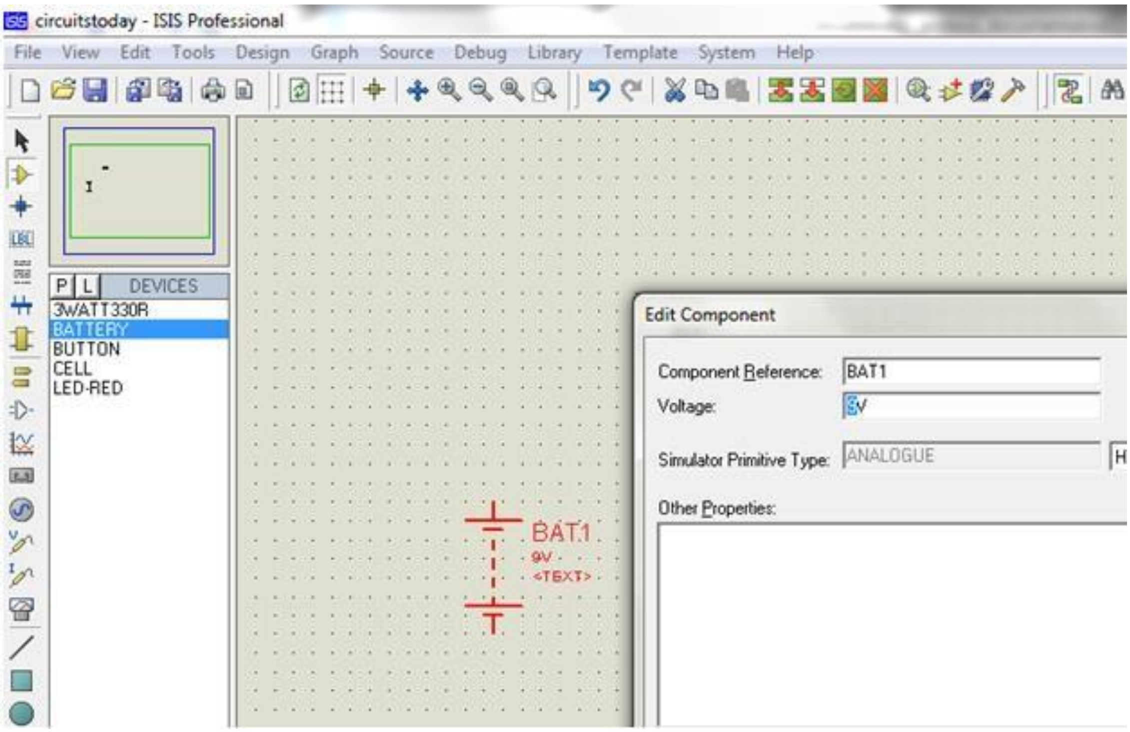

Figure 4.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

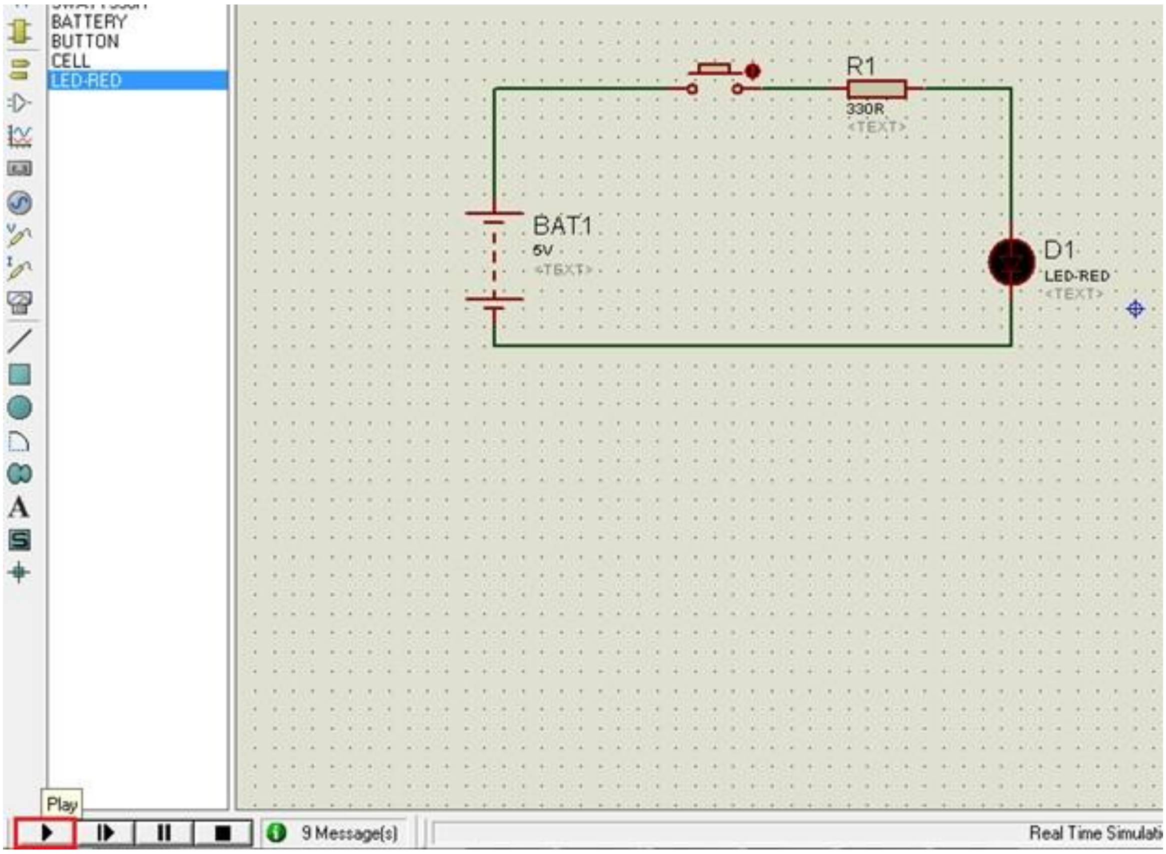

Figure 4.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

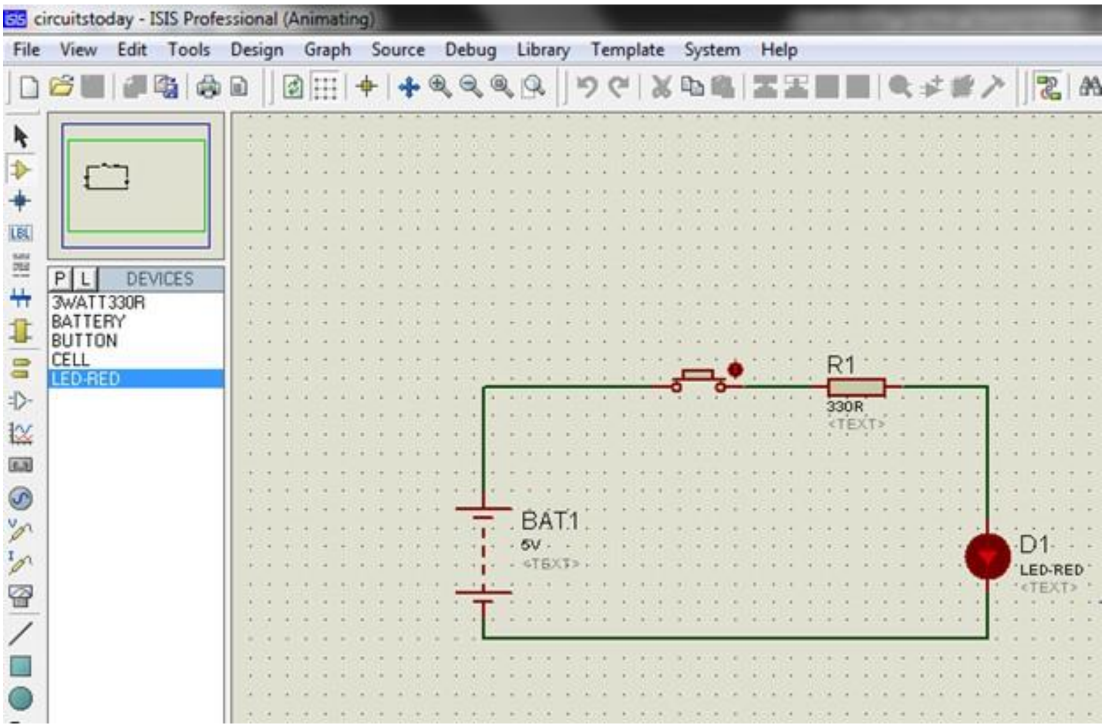

Figure 4.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

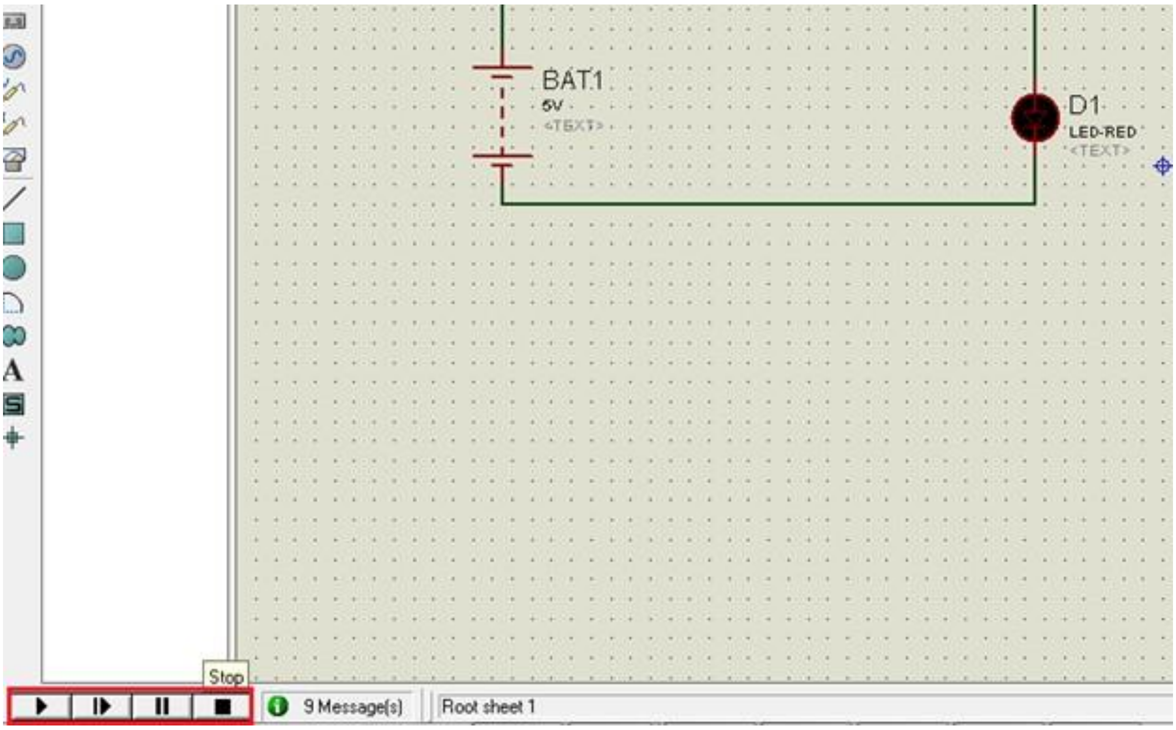

Figure 4.13 Simulation Step-Pause-Stop Buttons

4.3 Arduino IDE

The **Arduino Integrated Development Environment (IDE)** is a cross-platform application (for Windows, macOS, Linux) that is written in functions from C and C++. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards. The source code for the IDE is released under the GNU General Public License, version 2. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude* to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

Arduino Pro IDE

Table 4.1 Arduino Pro Ide

In October 2019 the Arduino organization began providing early access to a new Arduino Pro IDE with debugging and other advanced features. After learning about the main parts of the Arduino UNO board, we are ready to learn how to set up the Arduino IDE. Once we learn this, we will be ready to upload our program on the Arduino board.

4.3.1 Installation

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Figure 4.14 USB Cable

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Figure 4.15 USB Mini B Cable

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

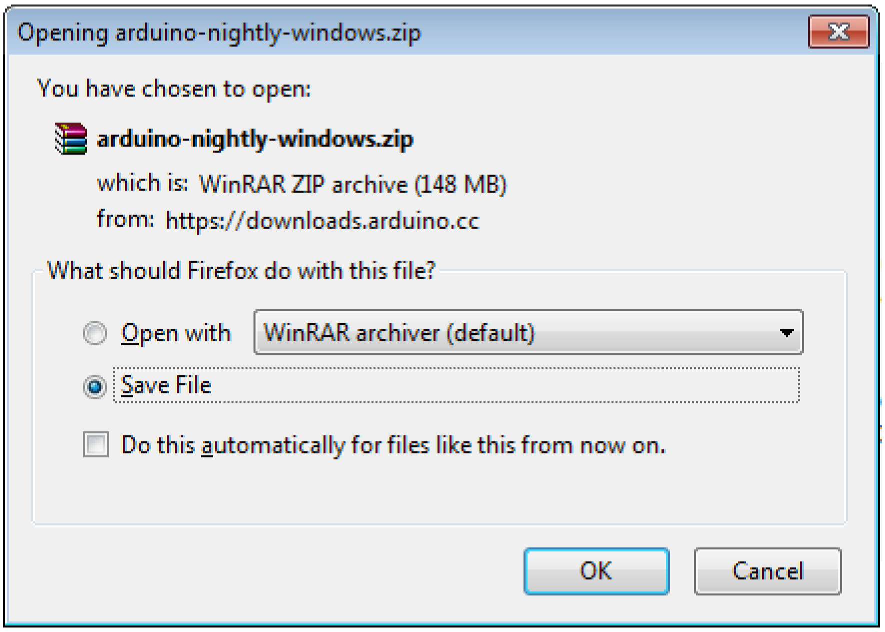

Figure 4.16 Arduino Window

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

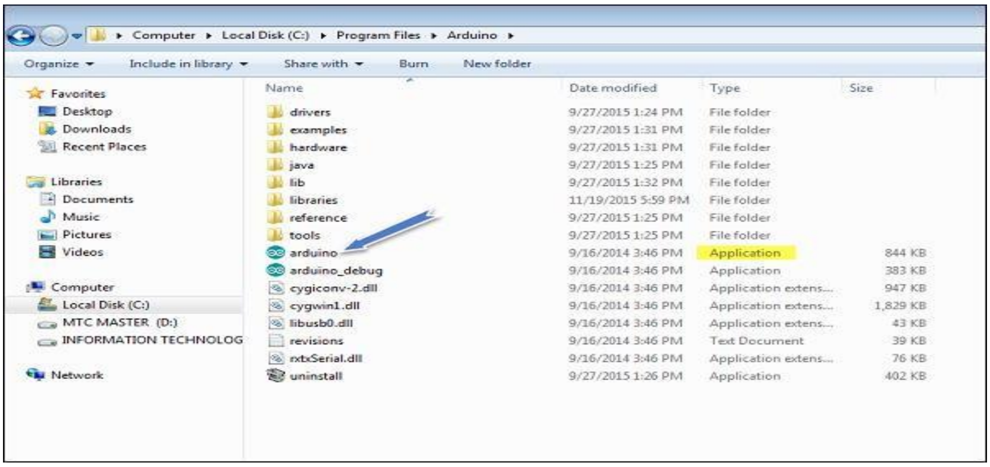

Figure 4.17 Local Disk

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.

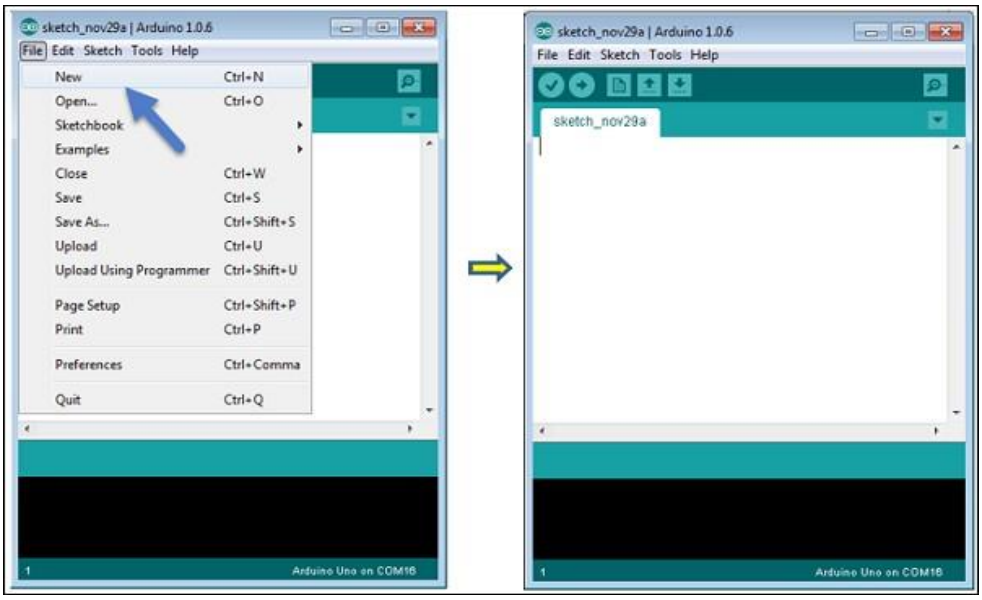

Figure 4.18 To create file

To open an existing project example, select File → Example → Basics → Blink.

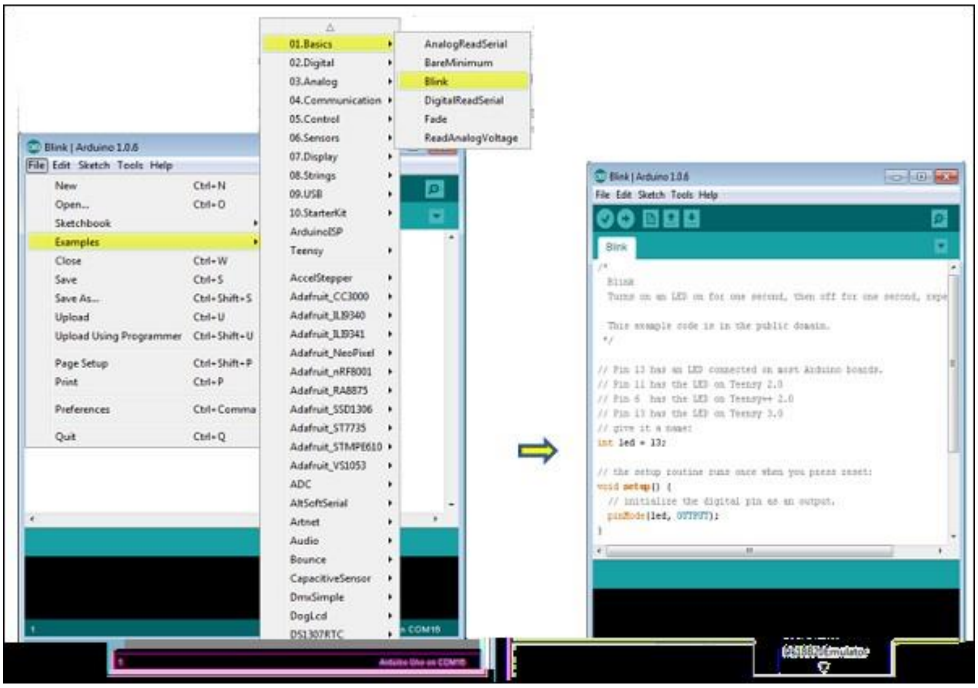

Figure 4.19 File Details

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

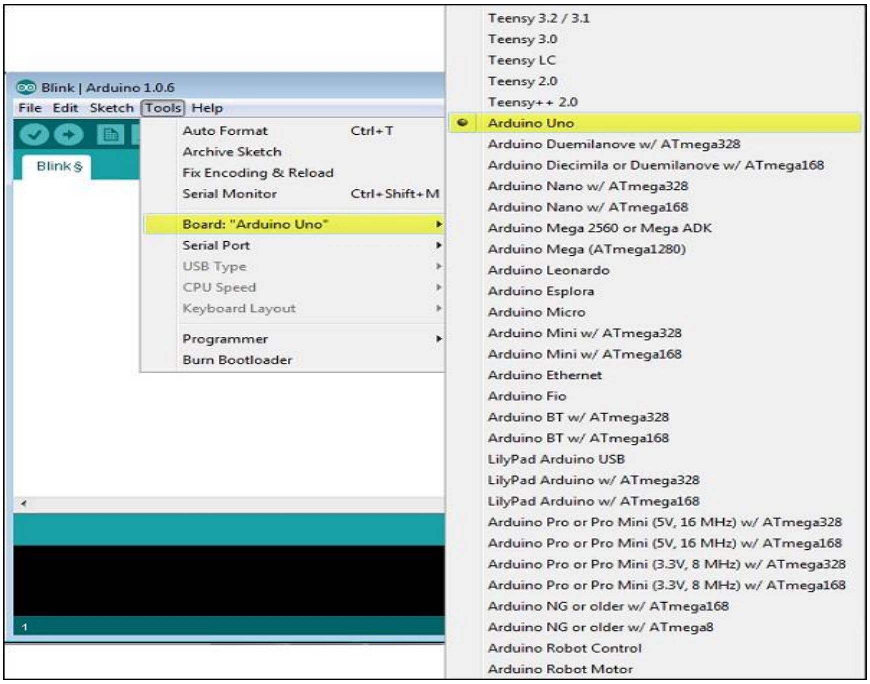

Figure 4.20 Select your arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

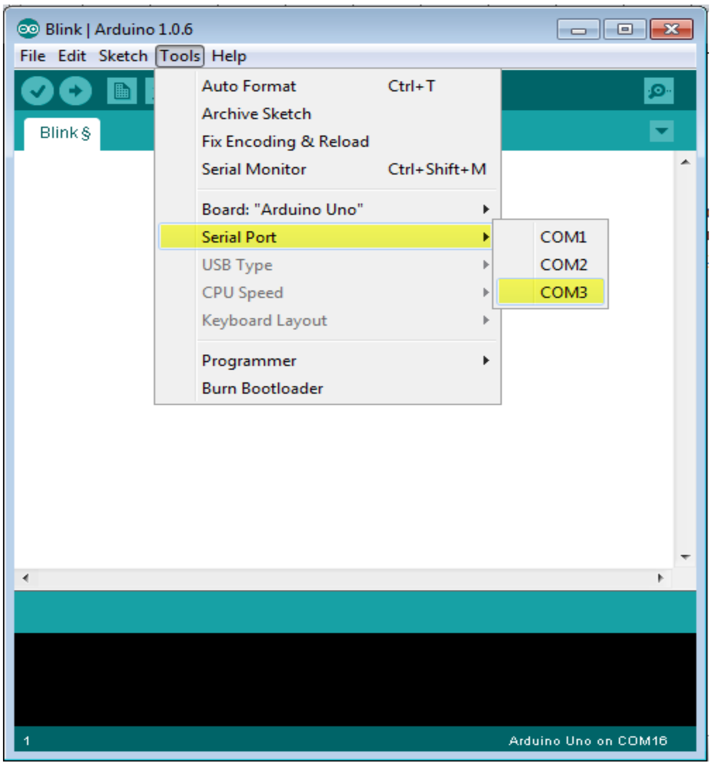

Figure 4.21 Select your serial port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

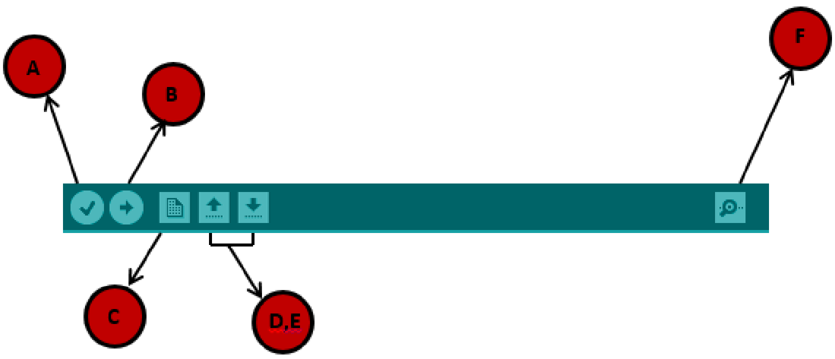

Figure 4.22 Upload the program

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

CHAPTER 5

HARDWARE

5.1 Arduino

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

5.1.1 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 5.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header

LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

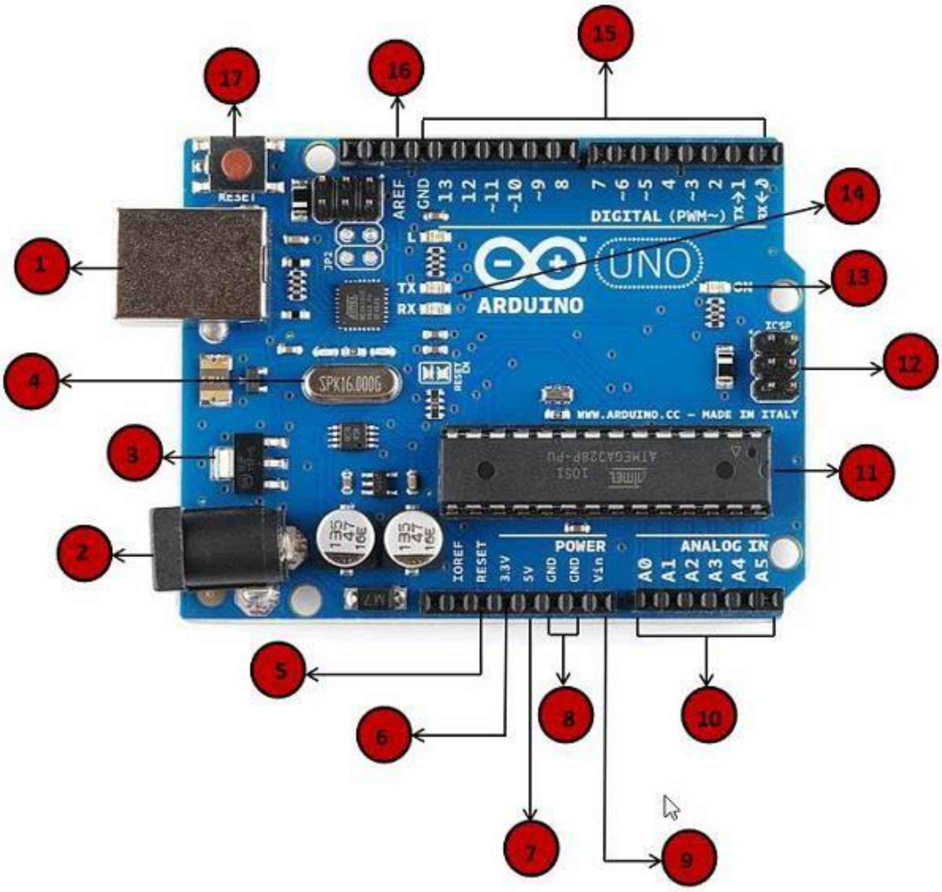

Figure 5.1 Arduino Board

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other

	elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.

12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

5.2 Liquid Cristal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Many microcontroller devices use 'smart LCD' displays to output visual information. LCD displays designed around LCD NT-C1611 module, are inexpensive, easy to use, and it is even possible to produce a readout using the 5X7 dots plus cursor of the display. They have a standard ASCII set of characters and mathematical symbols. For an 8-bit data bus, the display requires a +5V supply plus 10 I/O lines (RS RW D7 D6 D5 D4 D3 D2 D1 D0). For a 4-bit data bus it only requires the supply lines plus 6 extra lines(RS RW D7 D6 D5 D4). When the LCD display is not enabled, data lines are tri-state and they do not interfere with the operation of the microcontroller.

5.2.1 Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

Table 5.5 LCD Display Pins

5.3 FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure 5.2 Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8,16,20,24,32 and 40 characters are all standard, in one, two and four line versions.

Several different LC technologies exists. “supertwist” types, for example, offer Improved contrast and viewing angle over the older “twisted nematic” types. Some modules are available with back lighting, so that they can be viewed in dimly-lit conditions. The back lighting may be either “electro-luminescent”, requiring a high voltage inverter circuit, or simple LED illumination.

5.4 PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

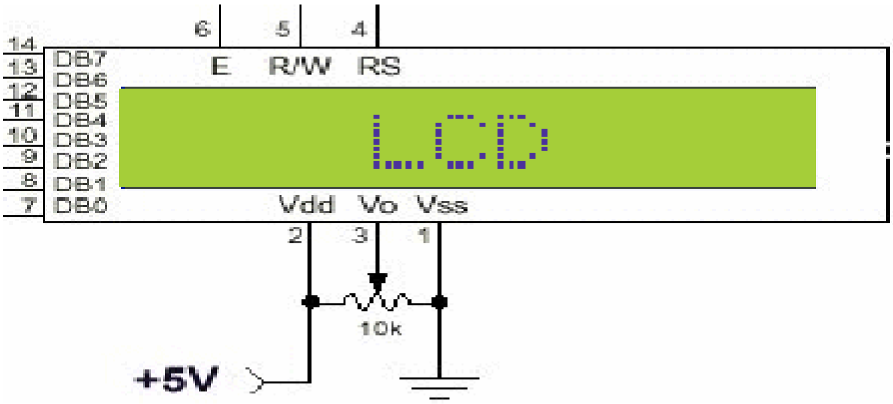

Figure 5.3 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Figure 5.4 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low. Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 5.6 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left
0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

Rain Drop Sensor

Raindrop Sensor is a tool used for sensing rain. It consists of two modules, a **rain board** that detects the rain and a **control module**, which compares the analog value, and converts it to a digital value. The raindrop sensors can be used in the automobile sector to control the windshield wipers automatically, in the agriculture sector to sense rain and it is also used in home automation systems.

Pin Configuration of Rain Sensor:

S.No:	Name	Function
1	VCC	Connects supply voltage- 5V
2	GND	Connected to ground
3	D0	Digital pin to get digital output
4	A0	Analog pin to get analog output

Raindrop Sensor Features:

- Working voltage 5V
- Output format: Digital switching output (0 and 1), and analog voltage output AO
- Potentiometer adjust the sensitivity
- Uses a wide voltage LM393 comparator
- Comparator output signal clean waveform is good, driving ability, over 15mA
- Anti-oxidation, anti-conductivity, with long use time
- With bolt holes for easy installation
- Small board PCB size: 3.2cm x 1.4cm

Note: The complete technical details can be found in the **Rain Sensor datasheet** given at the bottom of this page.

How to use Raindrop sensor:

Interfacing the raindrop sensor with a microcontroller like 8051, Arduino, or PIC is simple. The rain board module is connected with the control module of the raindrop sensor as shown in the below diagram.

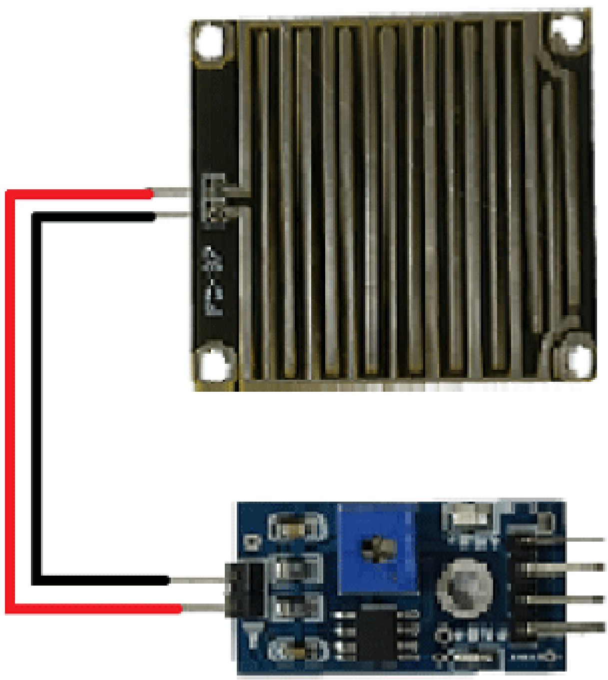

Figure 5.6 Raindrop Sensor

The control module of the raindrop sensor has 4 outputs. VCC is connected to a 5V supply. The GND pin of the module is connected to the ground. The D0 pin is connected to the digital pin of the microcontroller for digital output or the analog pin can be used. To use the analog output, the A0 pin can be connected to the ADC pin of a microcontroller. In the case of Arduino, it has 6 ADC pins, so we can use any of the 6 pins directly without using an ADC converter. The sensor module consists of a potentiometer, LN393 comparator, LEDs, capacitors and resistors. The pinout image above shows the components of the control module. The rain board module consists of copper tracks, which act as a **variable resistor**. Its resistance varies with respect to the wetness on the rain board. The below fig shows the rain board module.

Figure 5.7 raindrop sensor module

The circuit diagram of a raindrop sensor module is given below.

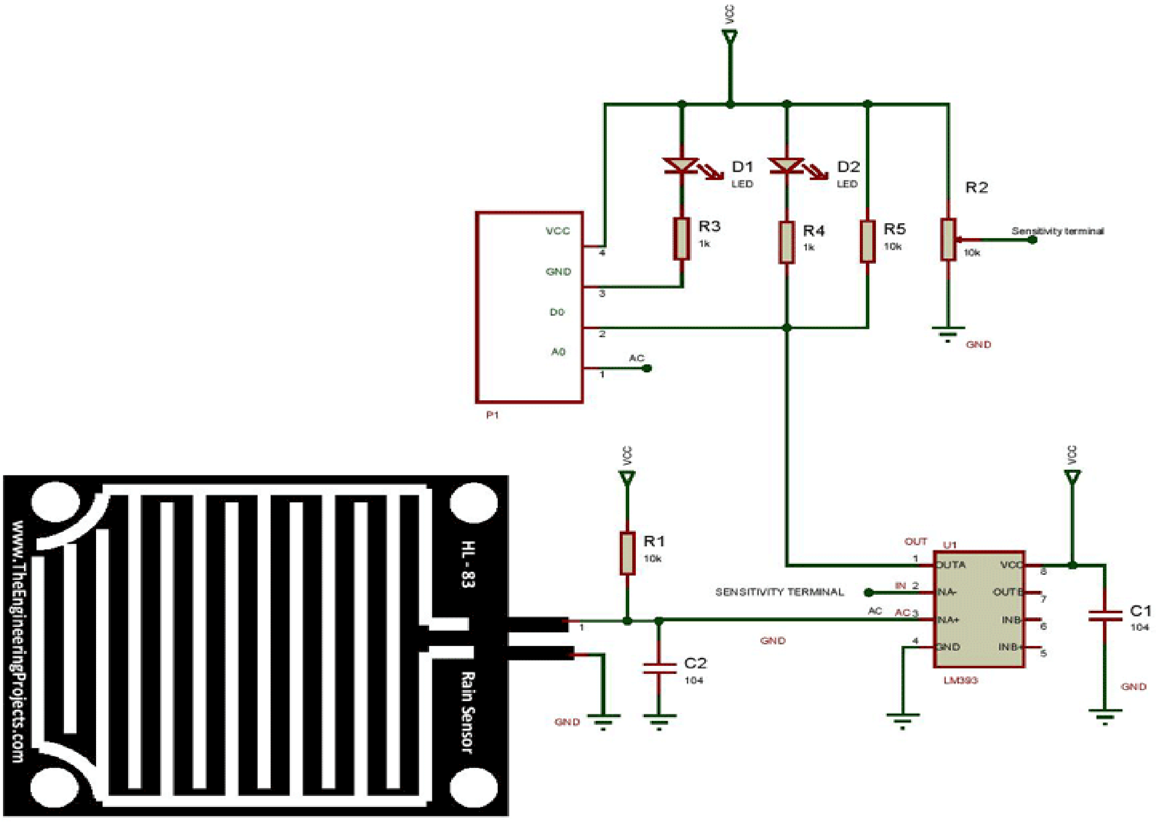

Figure 5.8 Raindrop sensor module circuit diagram

As shown in the above figure, the R1 resistor and the rain board module will act as a **voltage divider**. Capacitors C1 and C2 are used as a biasing element. The input for the Non-inverting terminal is taken from the connection point of the R1, and rain board module. Another point is taken from this connection and connected to the A0 terminal of the control module.The input to the inverting terminal of the LM393 is taken from the potentiometer (R2). The R2 resistor acts as a voltage divider, and by varying R2 we can vary the input voltage to the inverting terminal, which in turn affects the sensitivity of the control module. The connections are shown in the above fig. The resistors R3 and R4 will act as current limiting resistors, while resistor R5 will act as a pull-up resistor to keep the bus in a high state when not in use.

Working of Rain Sensor:

Case1: When the input of the inverting terminal is higher than the input of the non-inverting terminal.

Case2: If the input of the inverting terminal is lower than the input of the non-inverting terminal.

The input to the inverting terminal is set to a certain value by varying the potentiometer and the sensitivity is set. When the rain board module's surface is exposed to rainwater, the surface of the rain board module will be wet, and it offers minimum resistance to the supply voltage. Due to this, the minimum voltage will be appearing at the non-inverting terminal of LM393 Op-Amp. The comparator compares both inverting and non-inverting terminal voltages. If the condition falls under case (1), the output of the Op-Amp will be digital LOW. If the condition falls under case (2), the output of the Op-Amp will be digital HIGH. The below diagram shows the equivalent circuit of both the conditions.

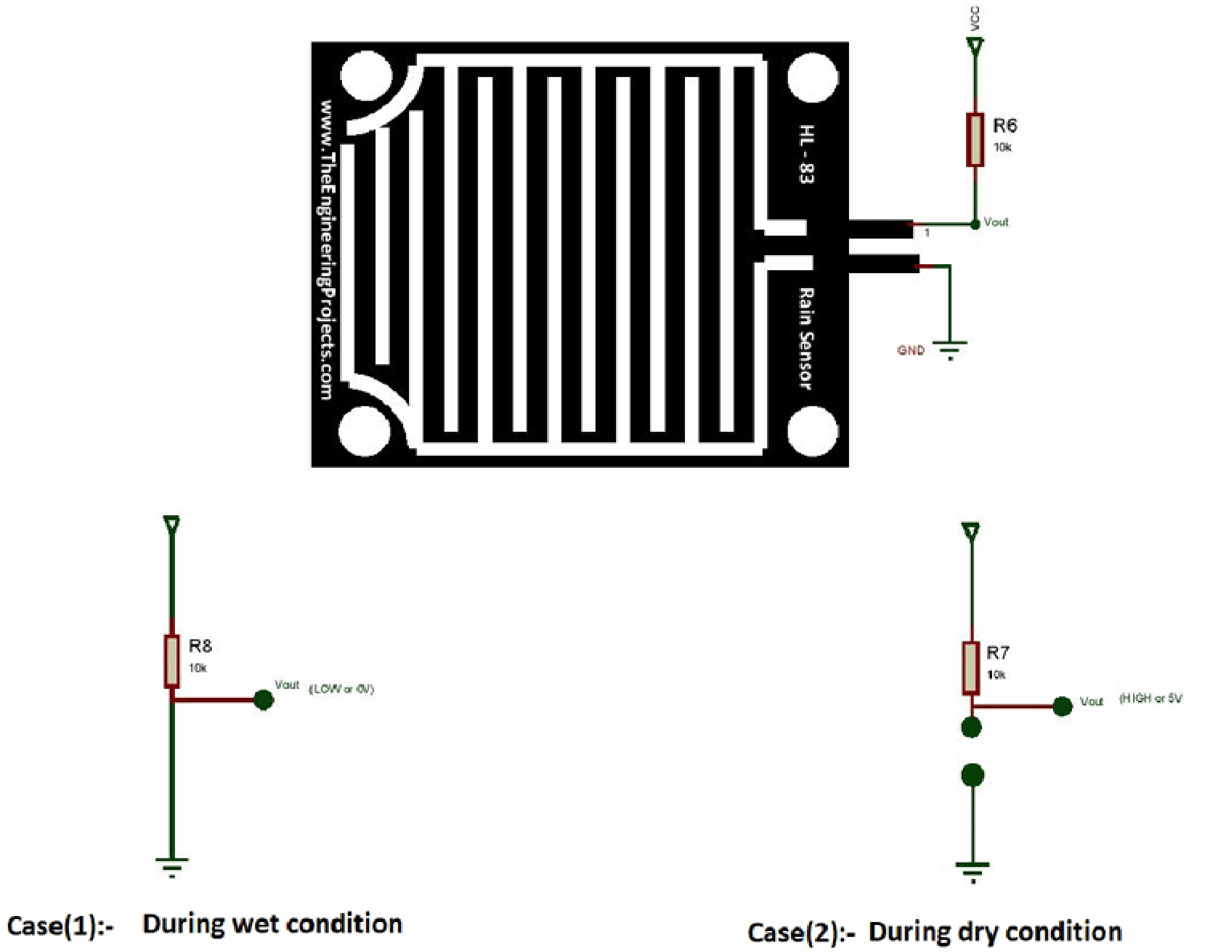

Figure 5.9 Sensor conditions

When the A0 pin is connected to the microcontroller, an additional analog to digital converter (ADC) circuit is used. In the case of Arduino, it consists of 6 ADC pins, which can be directly used for calculation purposes.

Applications of Rain sensor:

- Automatic windshield wipers
- Smart Agriculture

- Home-Automation

L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to builtin H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

Introduction to L293D

L293D is basically a motor driver or controller. It has two builtin H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large inpu voltage supply range, large output current high noise immunity input signals etc. Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

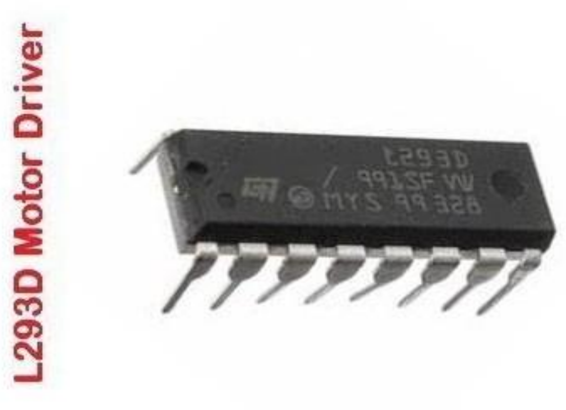

Figure 5.10 L293D Motor Driver

1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

Table 5.7 L293D Pins

3. L293D Pinout

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.
- L293D pinout diagram is shown in the figure given below.

Figure 5.11 L293D Pinout

DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjuntion with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher. Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparible AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

Easy to control torque

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.Simple, cheap drive designThe result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance tradeoffs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

Disadvantages

- Expensive to produce
- Can't reliably control at lowest speeds
- Physically larger
- High maintenance
- Dust

WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.

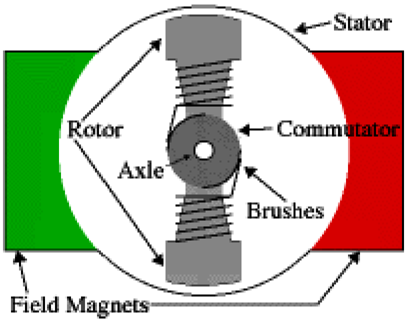

Figure 5.12 DC Motor

Principle

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously.When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) .

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator. You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).

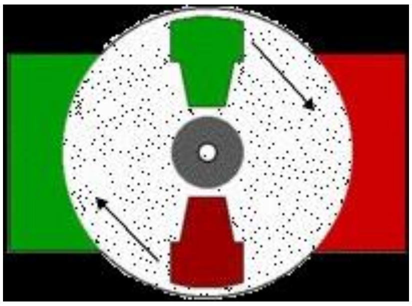

Figure 5.13 DC Motor Rotation

Construction and Working

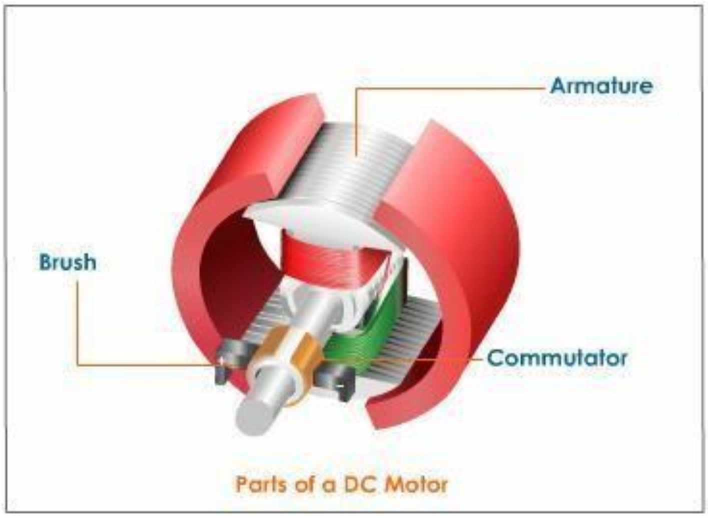

Figure 5.14 Working and construction

Parts of a DC Motor

Armature

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

Commutator

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.

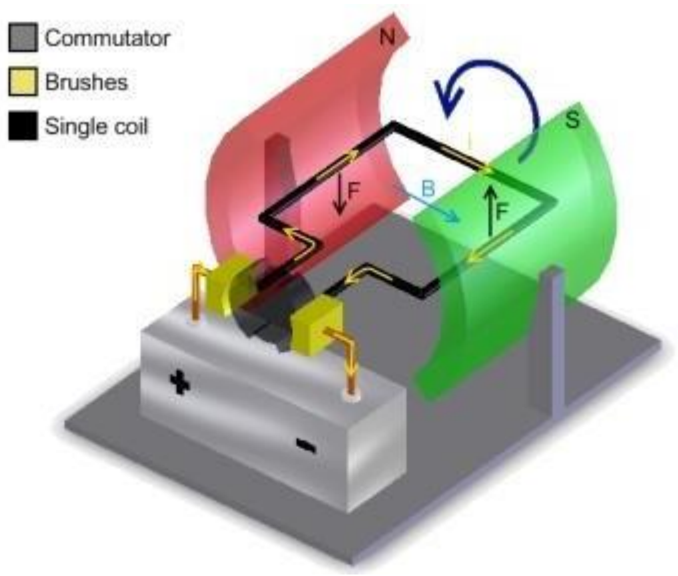

Figure 5.15 DC Motor parts

Brushes

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

Working of a DC Motor

When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.

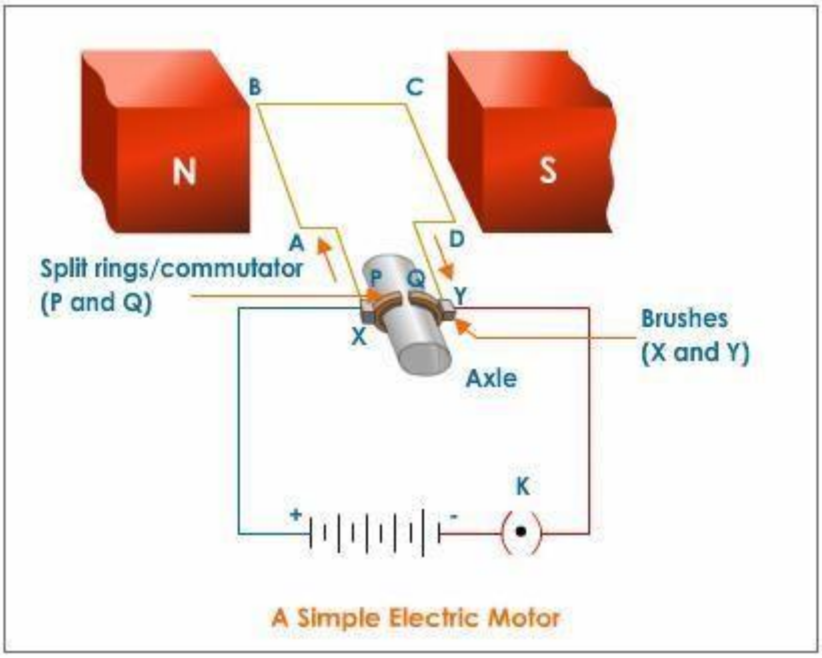

Figure 5.16 Working of a DC Motor

When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.

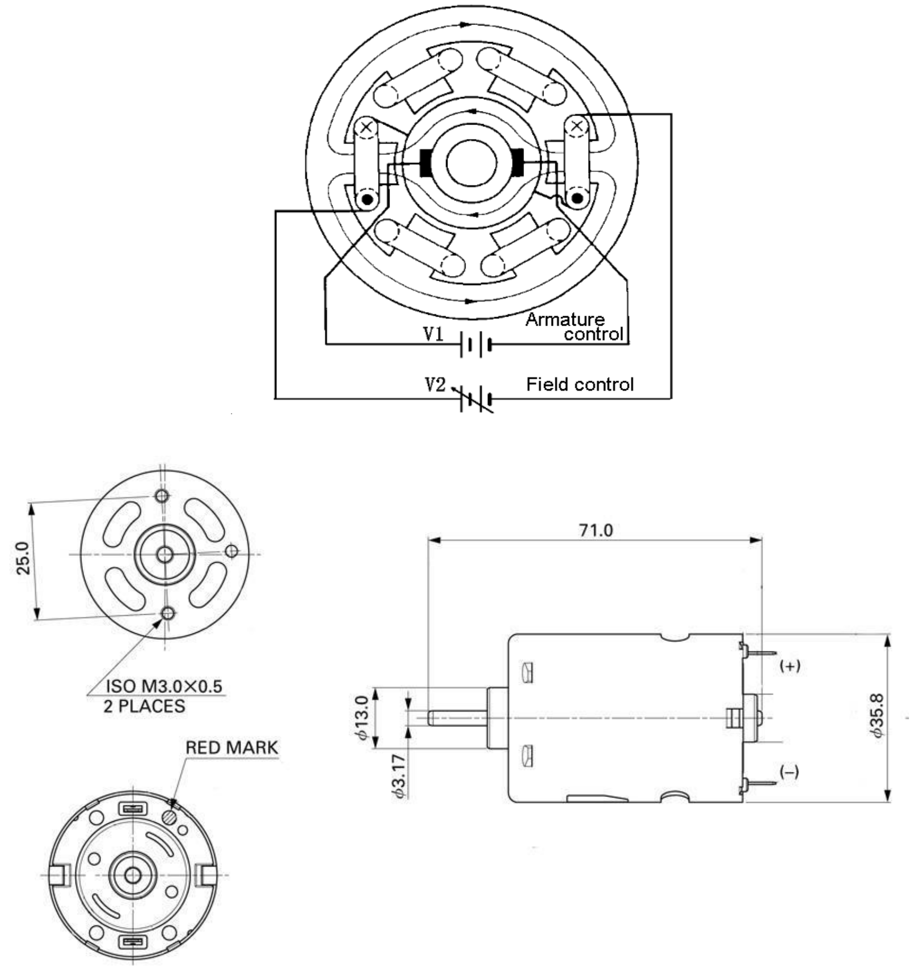

Figure 5.17 Rotation of Motor

PARAMETRS OF THE DC MOTRS

1. Direction of rotation
2. Motor Speed
3. Motor Torque
4. Motor Start and Stop

Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.

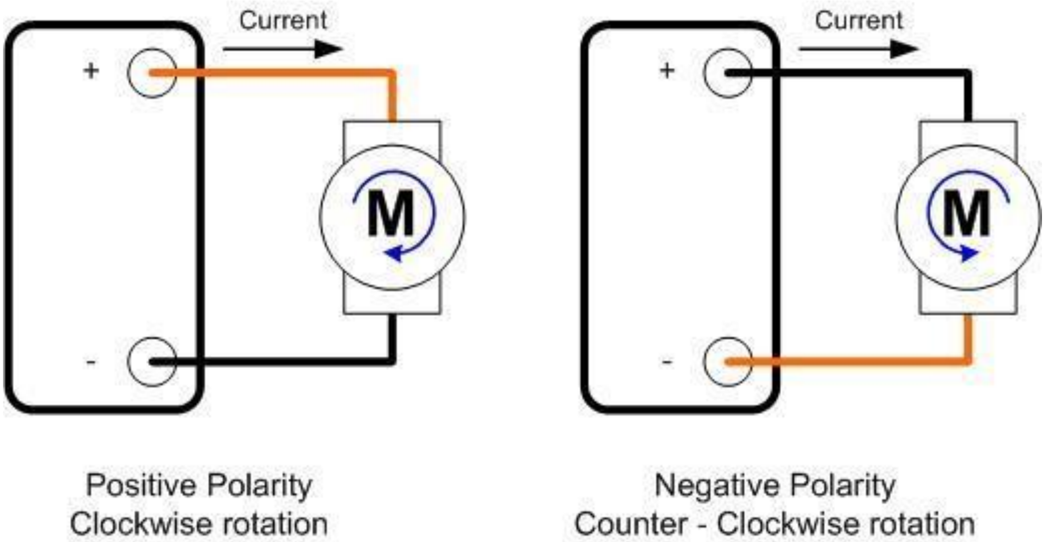

Figure 5.18 Polarity

DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.
- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

DC Motor Speed

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as atract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attaction will try to take place. As a result, motor speed is directly proportional to applied voltage.

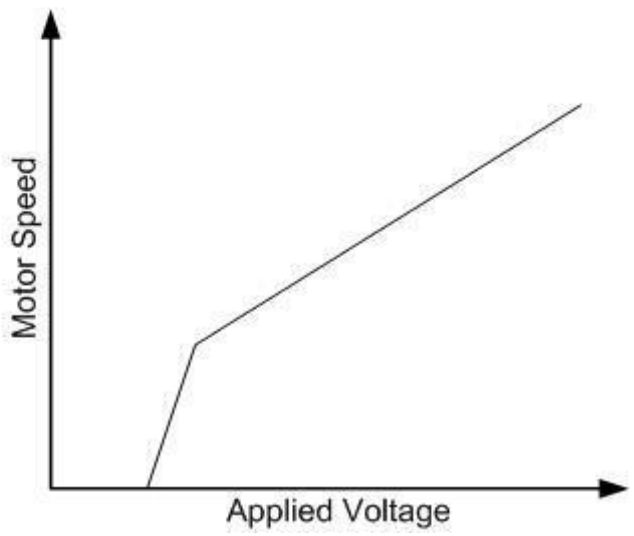

Figure 5.19 Motor speed

Motor Speed Curve

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will simply not move. This is because the magnetic field strength is not enough to overcome friction. Once friction is overcome, motor speed will start to increase as voltage increase.The following video shows the concept of speed control and offers some ideas on how this can be achieved.

Motor Torque

In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy can not be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

$$P = IV$$

Where P is power, I is motor current and V is motor voltage

Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current. As you increase load (or torque requirements) current must also increase.

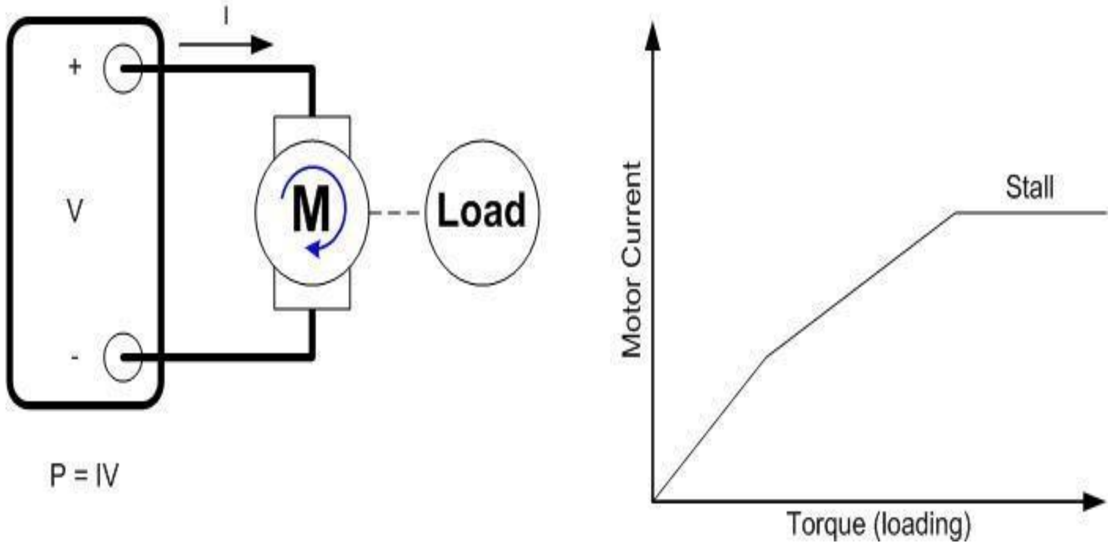

Figure 5.20 Motor curve

Motor Loading

One aspect about DC motors which we must not forget is that loading or increase of torque can not be infinite as there is a point in which the motor simply can not move. When this happens, we call this loading "Stalling Torque". At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

Motor Start and Stop

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current can not change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs. The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back As already said, H-bridge can be made with the help of transistors as well as MOSFETs, the only thing is the power handling capacity of the circuit. If motors are needed to run with high current then lot of dissipation is there. So, head sinks are needed to cool the circuit. Now you might be thinking in why i did not discuss the cases like High side left on and Low side left on or high side right on and low side right on. Clearly seen in the diagram, you don't want to burn your power supply by shorting them. So that is why those combinations are not discussed in the truth table.

CHAPTER 6

RESULTS

6.1 Results

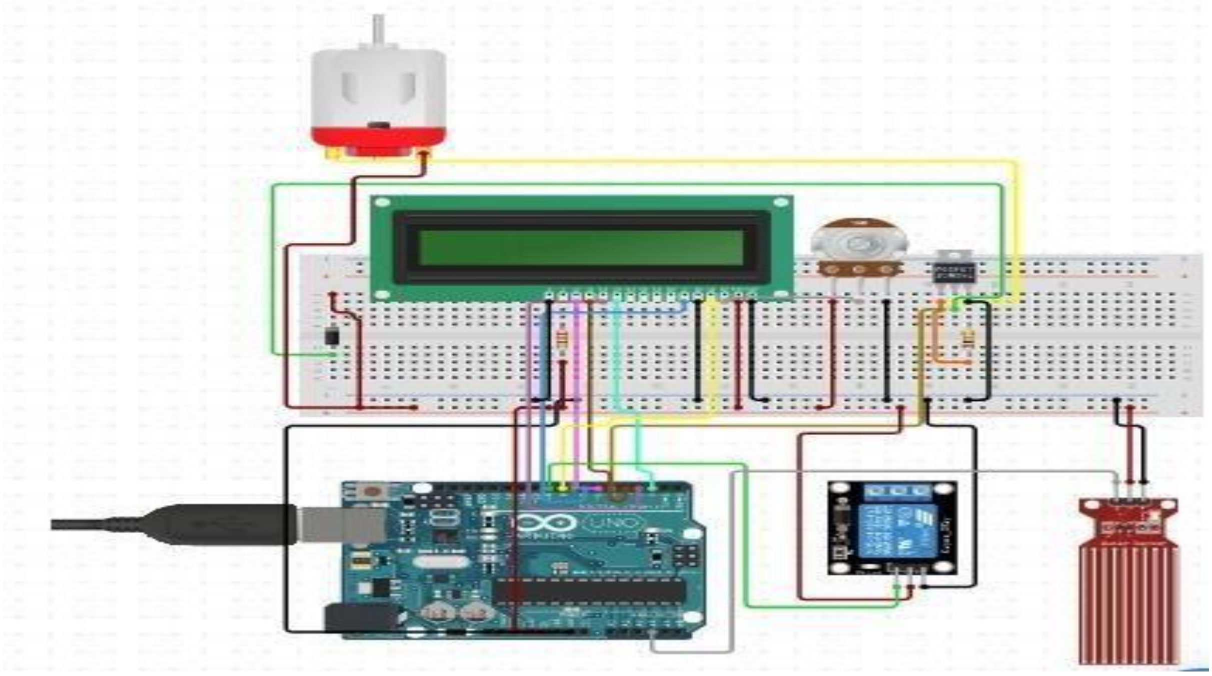

Figure 6.1 schematic diagram

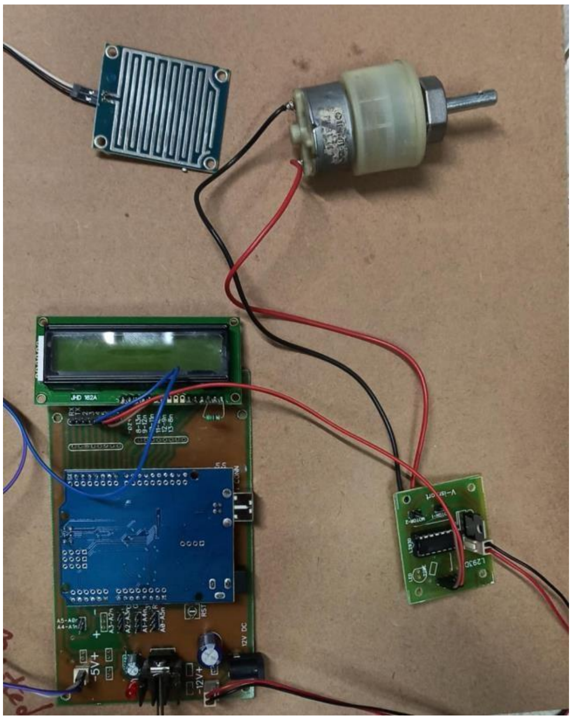

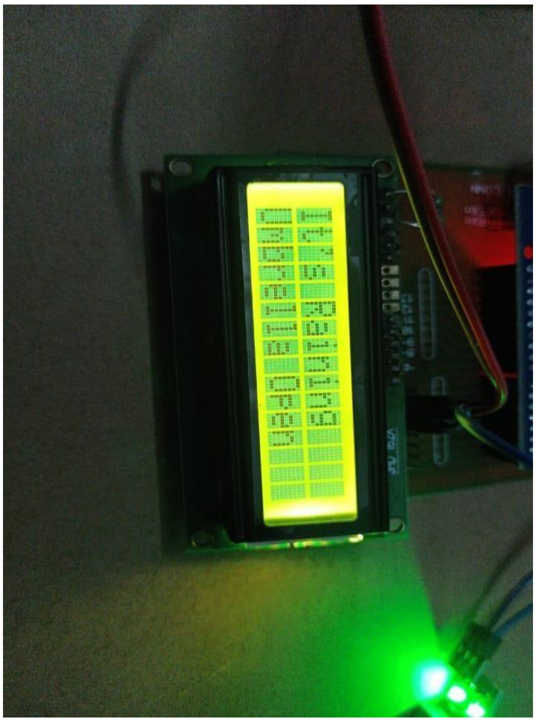

Figure 6.1 (a) setup components

Figure 6.1(b) result on LCD Display

The smart system consisting of a rack is fixed to umbrella such that when a sensor senses the exceeding value then the it will give some information to the arduino so that the arduino will take the information and makes some processing then send to the LCD display the LCD display will show the result of the sensor so that the paddle which is connected is start working by use of DC motor the DC motor will start rotating so the paddle will start opening so the rack which is fixed to the umbrella is start functioning. so the umbrella is opened

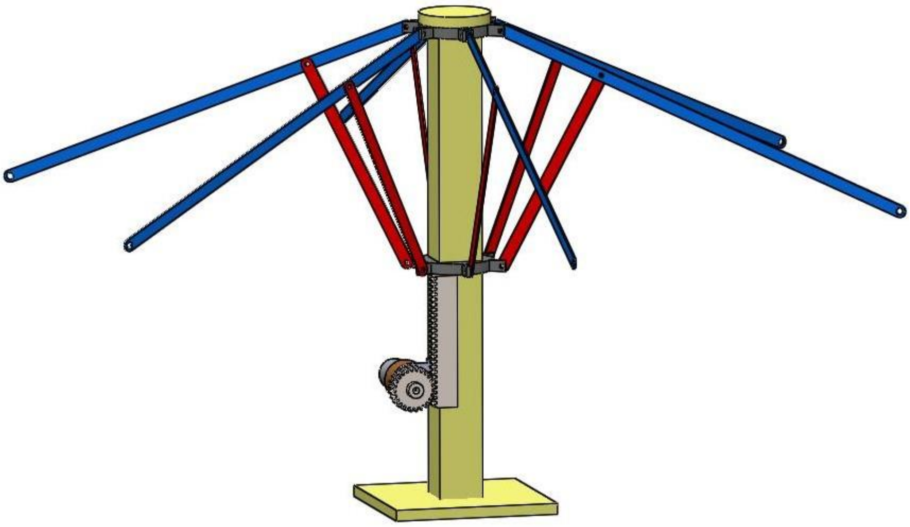

Figure 6.3 setup of automatic rainwater sensing umbrella

CHAPTER 7

CONCLUSION AND FUTURE SCOPE

7.1 Conclusion:

After completing the present work with all the process involved in designing the automated umbrella which can be of reasonable cost analysis and effective way to providing the shelter and safety to the object and goods with high intensity of power and this type of umbrella should be used in the various place in village to protect crops and the vehicles, etc. It can be applying at large scale area for reduced human work. It included the rack and pinion gear which changes the motion rotation into reciprocating. It also used in future after some of modification algorithm can be developed to coordinate Working system of rain to identify weather condition based on set value. The designed system prototype can be used along with the renewable source of energy. The designed model is not only smart but also intelligent as it will take decision about folding and unfolding of umbrella. The system can be control by Arduino and dc motor used for folding the roof with two or more switch fix along with the knowledge of next future direction.

7.2 Future Scope

The automatic rain water sensing umbrella can be implemented for the following

- Sheltering the houses
- Covering the farm lands in heavy rains

// ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head & Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our department project coordinator Dr.A.Anand kumar** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mrs.P.Kiranmayee, Assistant Professor**, Department of ECE and our class project coordinator **Mrs.A.Sowmya, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

The main purpose of this wireless black box project is to develop a vehicle black box system that can be installed into any vehicle all over the world. This paradigm is often designed with minimum range of circuits. Wireless black box is basically a device that will indicate all the parameters of a vehicle crash and will also store and display its parameters such as temperature, location, vibration, alcohol limit etc. At the time of accident, the message will be sent from the system built inside the car to the registered mobile numbers such as emergency numbers of police stations, hospitals, family members, owner etc. We have used various types of sensors like temperature sensor, which is used to measure temperature. Vibration sensor measures vibrations felt by the car during accident. Alcohol sensor is located on the steering wheel which will indicate whether the driver is drunk. Gyroscope sensor is used to indicate tilt during the accident. GSM module, GPS module are some of the devices used in this project which helps in accomplishing the output.

CHAPTER 1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

The main purpose of this wireless black box project is to develop a vehicle black box system that can be installed into any vehicle all over the world. This paradigm is often designed with minimum range of circuits. Wireless black box is basically a device that will indicate all the parameters of a vehicle crash and will also store and display its parameters such as temperature, location, vibration, alcohol limit etc. At the time of accident, the message will be sent from the system built inside the car to the registered mobile numbers such as emergency numbers of police stations, hospitals, family members, owner etc. We have used various types of sensors like temperature sensor, which is used to measure temperature. Vibration sensor measures vibrations felt by the car during accident. Alcohol sensor is located on the steering wheel which will indicate whether the driver is drunk. Gyroscope sensor is used to indicate tilt during the accident. GSM module, GPS module are some of the devices used in this project which helps in accomplishing the output. If any accident occurs, this wireless device will send a message from mobile phone and indicating the position of vehicle by tracking the location through GPS system to family member, emergency service so that they can provide ambulance and necessary treatment.

1.2 OBJECTIVES OF THE STUDY

The primary objective for doing our project was to introduce a blackbox system to alert the registered mobile numbers when an accident has occurred in an efficient and effective manner. To achieve this, the following objectives have to be completed.

- Studying the problem of providing help and medical aid to the victims when an accident has occurred at any location.
- Studying how fast the medical assistance is provided to the victims.
- Develop a solution to that problem.
- Studying the technologies that can solve the problem.
- Designing and developing a system for solving the problem.
- Testing and maintaining the implemented system

1.3 SCOPE OF THE STUDY

Road accidents are a human tragedy. Deaths are due to non timely availability of helps/medical aid after accidents.

If the person who has suffered the accident receives medical help in time he can survive the accident and many important lives can be saved. The system is easy to build and compact in size so that it can be easily installed in any vehicle.

Our project plays crucial role at the time of accident. The range of this system is extended to motorcycles and motorvehicles.

1.4 MATERIAL REQUIREMENT

1.4.1 HARDWARE REQUIREMENT

- Arduino Uno
- GPS Receiver
- GSM
- Temperature sensor LM35
- Accelerometer ADXL345
- Gas sensor MQ3
- Vibration sensor
- Motor driver L293D
- Motor

1.4.2 SOFTWARE REQUIREMENT

- Arduino IDE
- Circuito.io

1.5 PROCUMENT OF EQUIPMENT

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in circuito.io tool and understood working of every individual component.

Then, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

CHAPTER 2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA

The Black Box concept is derived from the aviation industry, a flight recorder, colloquially known as a black box; although it is now orange-colored for easy search, is an electronic recording device placed in an aircraft for the purpose of facilitating the investigation of aviation accidents and incidents.

Figure 2.1 Flight Recorder

A flight recorder is an electronic recording device placed in an aircraft for the purpose of facilitating the investigation of aviation accidents and incidents. Flight recorders are also known by the misnomer black box—they are, in fact, painted bright orange in color to aid in their recovery after accidents.

An FDR has historically been one of two types of "flight recorder" carried on aircraft, the other being a cockpit voice recorder. Where both types of recorder are fitted, they are now sometimes combined into a single unit (ICAO Definition: *Combination recorders*). Combination recorders need to meet the flight recorder equipage requirements as specifically detailed in ICAO Annex 6 - Operation of Aircraft.

In existing system most of people associate black box with airplanes but they are no longer just key tool in investigation airplane accident. Presently tracking system introduced in vehicle to avoid accident and save the peoples life. But this system still installed in some of high-end vehicles only because this system is too expensive for most of the vehicle user.

Presently tracking system introduced in vehicle to avoid accident and save the peoples life. But this system still installed in some of high end vehicles only because this system are too expensive for most of the vehicle user.

2.2 REVIEW ON RELATED LITERATURE

Existing system is a device installed to record vehicle crashes or accidents. Electronically sensed problems in the engine or a sudden change in wheel speed trigger's this device

It do not track the vehicle movement or the driver's action and do record several types of important data only few seconds before the collision, due to the existing system is designed to monitor activation of airbags

2.3 CONCLUSIONS ON REVIEWS

- Post-Accident Detection Systems: All the existing systems are in such a way that the family members of the accident victim will come to know about the incident after a long duration which leads to death of the victim.
- Lack of Intelligence in the detection systems: Due to the lack of intelligence the person life may get into risk

In our project we are introducing accident detection and alarm system which is expected to save peoples life by detecting the accidents occurred and provides help by tracing the location of the motorcycle riders with the help of GPS technology.

The purpose of the project is to find the accident location using GPS module and to send this location by means of sending a message using GSM module to the pre-coded number.

CHAPTER 3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

Four sensors that are temperature sensor LM35, vibration sensor, gas sensor MQ3, accelerometer ADXL345 are the primary inputs. LCD display, GPS6MV2, GSM SIM800L are the primary outputs. To indicate motion of car we are using a motor.

Initially the threshold detection level of sensors value is predefined. When the device is switched on, it displays “Wireless Blackbox”. Now the user is prompted to give an input such that it exceeds the threshold of the sensors. Once this happens the SMS is sent to registered mobile number with the location of the accident place.

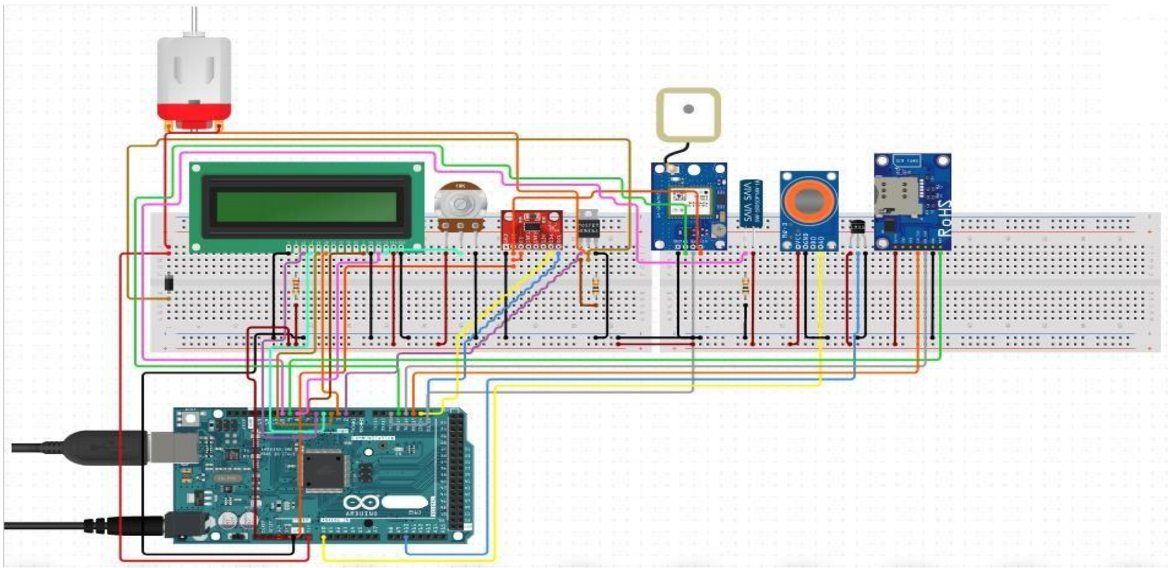

Figure 3.1: Overview of the design

3.2 EQUIPMENT ANALYSIS

3.2.1 Arduino Uno:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

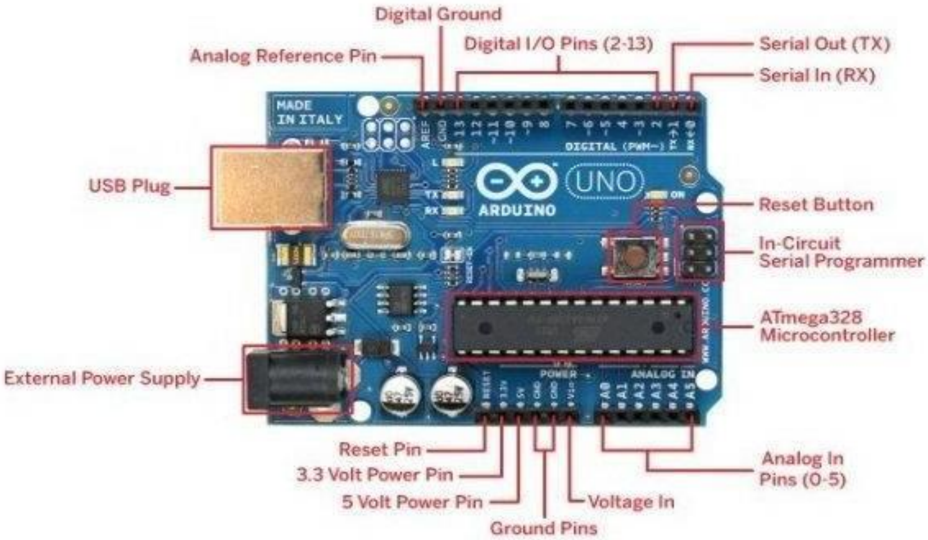

Figure 3.2: Arduino Board Description

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

Board Types :

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)**

	Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the

	brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF**

	AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

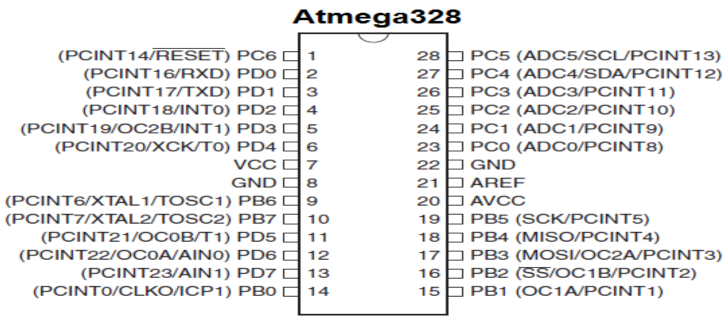

Figure 3.3: Pin description of Atmega 328

3.2.2 GPS Receiver:

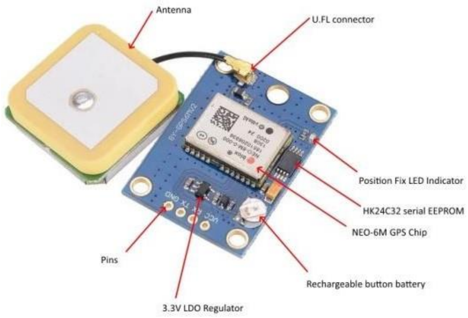

Figure 3.4: GPS6MV2 Receiver

The **NEO-6MV2** is a **GPS** (Global Positioning System) module and is used for navigation. The module simply checks its location on earth and provides output data which is longitude and latitude of its position.It is from a family of stand-alone GPS receivers featuring the high performance u-blox 6 positioning engine. These flexible and cost effective receivers offer numerous connectivity options in a miniature (16 x 12.2 x 2.4 mm) package. The compact architecture, power and memory options make **NEO-6 modules** ideal for **battery operated mobile devices** with very strict cost and space constraints. Its Innovative design gives **NEO-6MV2** excellent navigation performance even in the most challenging environments.

The module has four output pins and we will describe the function each pin of them below. The powering of module and communication interface is done through these four pins.

Pin Name	Description
VCC	Positive power pin
RX	UART receive pin
TX	UART transmit pin
GND	Ground

Features and Electrical Characteristics:

- Standalone GPS receiver
- Anti-jamming technology
- UART Interface at the output pins (Can use SPI ,I2C and USB)
- Under 1 second time-to-first-fix for hot and aided starts
- Receiver type: 50 Channels - GPS L1 frequency - SBAS (WAAS, EGNOS, MSAS)
- Time-To-First-fix: For Cold Start 32s, For Warm Start 23s, For Hot Start <1s
- Maximum navigation update rate: 5Hz
- Default baud rate: 9600bps
- EEPROM with battery backup
- Sensitivity: -160dBm
- Supply voltage: 3.6V
- Maximum DC current at any output: 10mA
- Operation limits: Gravity-4g, Altitude-50000m, Velocity-500m/s
- Operating temperature range: -40ºC TO 85°C

This module is one of popular GPS modules on the market and is also cheap to buy. The location data provided by it is accurate enough to satisfy most applications. And for it to be included in smart phones and tablets design points out its efficiency. This module is famous among hobbyist and engineers altogether who want to work on applications involving navigation.

3.2.3 GSM:

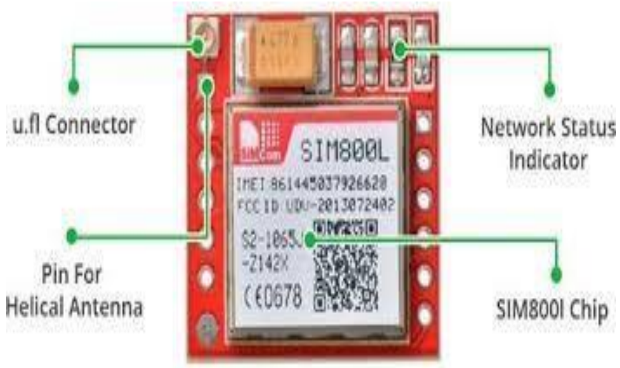

Figure 3.5: GSM SIM800L

At the heart of the module is a SIM800L GSM cellular chip from SimCom. The operating voltage of the chip is from 3.4V to 4.4V, which makes it an ideal candidate for direct LiPo battery supply. This makes it a good choice for embedding into projects without a lot of space.

All the necessary data pins of SIM800L GSM chip are broken out to a 0.1″ pitch headers. This includes pins required for communication with a microcontroller over UART. The module supports baud rate from 1200bps to 115200bps with Auto-Baud detection.

The module needs an external antenna to connect to a network. The module usually comes with a Helical Antenna and solders directly to NET pin on PCB. The board also has a U.FL connector facility in case you want to keep the antenna away from the board.

There's a SIM socket on the back! Any activated, 2G micro SIM card would work perfectly. Correct direction for inserting SIM card is normally engraved on the surface of the SIM socket.

This module measures only 1 inch² but packs a surprising amount of features into its little frame. Some of them are listed below:

- Supports Quad-band: GSM850, EGSM900, DCS1800 and PCS1900
- Connect onto any global GSM network with any 2G SIM
- Make and receive voice calls using an external 8Ω speaker & electret microphone
- Send and receive SMS messages

- Send and receive GPRS data (TCP/IP, HTTP, etc.)
- Scan and receive FM radio broadcasts
- Transmit Power:
    - Class 4 (2W) for GSM850
    - Class 1 (1W) for DCS1800
- Serial-based AT Command Set
- FL connectors for cell antennae
- Accepts Micro SIM Card

We cannot directly connect Rx pin on module to Arduino's digital pin as Arduino Uno uses 5V GPIO whereas the SIM800L module uses 3.3V level logic and is NOT 5V tolerant. This means the Tx signal coming from the Arduino Uno must be stepped down to 3.3V so as not to damage the SIM800L module. There are several ways to do this but the easiest way is to use a simple resistor divider.

3.2.4 Temperature sensor LM35:

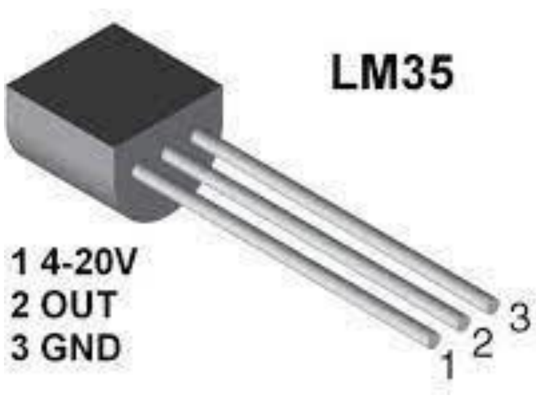

Figure 3.6: Temperature sensor LM35

Pin Configuration:

Pin Number	Pin Name	Description
1	Vcc	Input voltage is +5V for typical applications
2	Analog Out	There will be increase in 10mV for raise of every 1°C. Can range from -1V(-55°C) to 6V(150°C)
3	Ground	Connected to ground of circuit

LM35 Regulator Features:

- Minimum and Maximum Input Voltage is 35V and -2V respectively. Typically 5V.
- Can measure temperature ranging from -55°C to 150°C
- Output voltage is directly proportional (Linear) to temperature (i.e.)
- There will be a rise of 10mV (0.01V) for every 1°C rise in temperature.
- ±0.5°C Accuracy
- Drain current is less than 60uA
- Low cost temperature sensor
- Small and hence suitable for remote applications
- Available in TO-92, TO-220, TO-CAN and SOIC package

LM35 is a precession Integrated circuit Temperature sensor, whose output voltage varies, based on the temperature around it. It is a small and cheap IC which can be used to measure temperature anywhere between -55°C to 150°C. It can easily be interfaced with any Microcontroller that has ADC function or any development platform like Arduino.

The LM35 series are precision integrated-circuit temperature devices with an output voltage linearly proportional to the Centigrade temperature. The LM35 device does not require any external calibration or trimming to provide typical accuracies of ±¼°C at room temperature and ±¾°C over a full −55°C to 150°C temperature range.

3.2.5 Alcohol sensor MQ-3 :

Figure 3.7: Alcohol sensor MQ-3

Pin Name	Description
VCC	This pin powers the module, typically the operating voltage is +5V
GND	Used to connect the module to system ground
Digital Out (DO)	You can also use this sensor to get digital output from this pin, by setting a threshold value using the potentiometer
Analog Out (AO)	This pin outputs 0-5V analog voltage based on the intensity of the gas

Features of MQ-3 Alcohol Sensor:

- Sensor Type - Semiconductor
- Easy SIP header interface
- Compatible with most of the microcontrollers
- Low-power standby mode
- Requires heater voltage
- Good sensitivity to alcohol gas
- Fast response and High sensitivity
- Long life and low cost
- Requires simple Drive circuit

Specifications of MQ-3 Gas Sensor:

- Power requirements: 5 VDC @ ~165 mA (heater on) / ~60 mA (heater off)
- Current Consumption: 150mA
- DO output: TTL digital 0 and 1 (0.1 and 5V)

- AO output: 0.1- 0.3 V (relative to pollution)
- The maximum concentration of a voltage of about 4V
- Detecting Concentration: 0.05-10mg/L Alcohol
- Interface: 1 TTL compatible input (HSW), 1 TTL compatible output (ALR)
- Heater consumption: less than 750mW
- Operating temperature: 14 to 122 °F (-10 to 50°C)
- Load resistance: 200kΩ
- Sensitivity S: Rs(in air)/Rs(0.4mg/L Alcohol)≥5
- Sensing Resistance Rs: 2KΩ-20KΩ(in 0.4mg/l alcohol)
- Dimensions: 32 x 22 x 16 mm
- MQ-3 module is suitable for detecting Alcohol, Benzine, CH_4, Hexane, LPG, CO. Sensitive material of MQ-3 gas sensor is SnO_2, which with lower conductivity in clean air. When the target alcohol gas exist, the sensor's conductivity is more higher along with the gas concentration rising. MQ-3 gas sensor has high sensitity to Alcohol, and has good resistance to disturb of gasoline, smoke and vapor.
- This sensor provides an analog resistive output based on alcohol concentration. When the alcohol gas exist, the sensor's conductivity gets higher along with the gas concentration rising.

3.2.6 Accelerometer ADXL345 :

Figure 3.8: Accelerometer ADXL345

The **ADXL345** is a small, low power, complete 3-axis MEMS accelerometer modules with both I2C and SPI interfaces. The ADXL345 board feature on-board 3.3V voltage regulator and level shifter, which makes it simple to interface with 5V microcontrollers such as the Arduino.

ADXL345 Module Features & Specifications:

- 3V-6V DC Supply Voltage
- On-board LDO Voltage regulator
- Built-in Voltage level convertor (MOSFET based)
- It can be interface with 3.3V or 5V Microcontroller.
- Ultra-Low Power: 40uA in measurement mode, 0.1uA in standby@ 2.5V
- Tap/Double Tap Detection
- Free-Fall Detection
- SPI and I2C interfaces
- Measuring Range: ±16g
- Measuring Values (-16g to +16g):
- X: -235 to +270
- Y: -240 to +260
- Z: -240 to +270

This **ADXL345 Accelerometer module** consists of an ADXL345 Accelerometer IC, Voltage Regulator IC, Level Shifter IC, resistors, and capacitors in an integrated circuit. Different manufacturers use a different voltage regulator IC.

ADXL345 IC from Analog Devices is the brain of this module. The ADXL345 is a small, thin, low power, complete 3-axis accelerometer with signal conditioned voltage outputs. The product measures acceleration with a minimum full-scale range of ±16g.

ADXL345 Accelerometer module consists of 8 pins. Using the ADXL345 module with a microcontroller is very easy. Connect VCC and GND pins to 5V and GND pins of Microcontroller. Also, connect SCL and SDA pins to the SCL and SDA pins of Arduino.

The basic structure of the accelerometer consists of fixed plates and moving plates. When the acceleration is applied on an axis capacitance between fixed plates and moving plates is changed. This results in a sensor output voltage amplitude, which is proportional to the acceleration.

3.2.7 Vibration sensor :

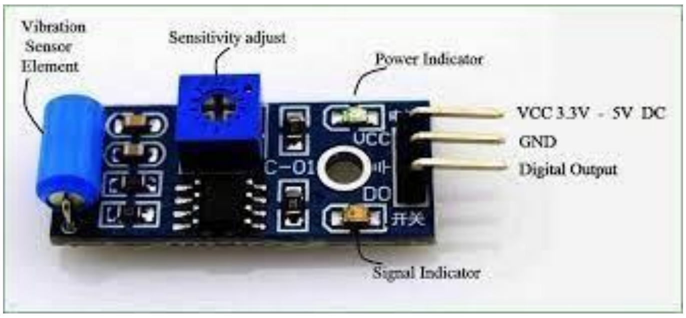

Figure 3.9: Vibration sensor

A vibration sensor is a device that measures the amount and frequency of vibration in a given system, machine, or piece of equipment. Those measurements can be used to detect imbalances or other issues in the asset and predict future breakdowns.

3.2.8 LCD 16X2 Display:

Figure 3.10: LCD display

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

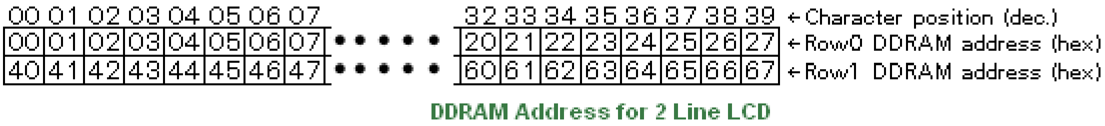

Figure 3.11: DDRAM addresses of 2 Line LCD

16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.9 Motor driver L293D :

Figure 3.12: Motor driver L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

L293D is basically a motor driver or controller. It has two built-in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g. stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc. Its common real-life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.
- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	V_{CC2}
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	V_{CC1}

Table 3.4: L293D Pin Functions

3.2.10 Motor:

Figure 3.13: Motor

Motor’s usually operates on this higher current. L-293D has to built-in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction.

3.2.11 Arduino IDE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing.

Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments.

All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers.

- The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-
This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Figure 3.14: Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Figure 3.15: Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

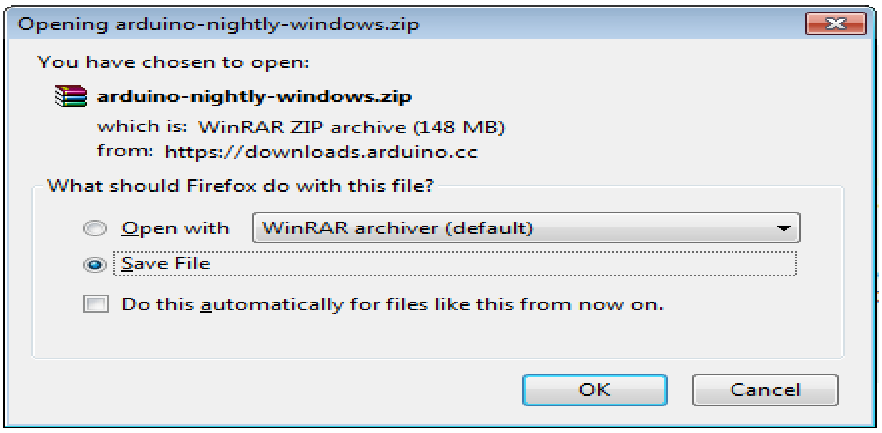

Figure 3.16: Download Arduino IDE Software

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

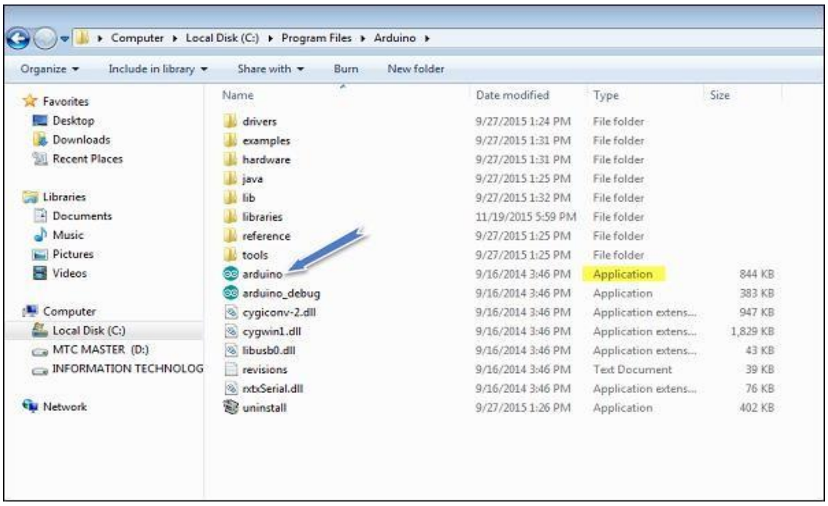

Figure 3.17: Launch Arduino IDE

Step 5 – Open your first project.

Once the software starts, you have two options –

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

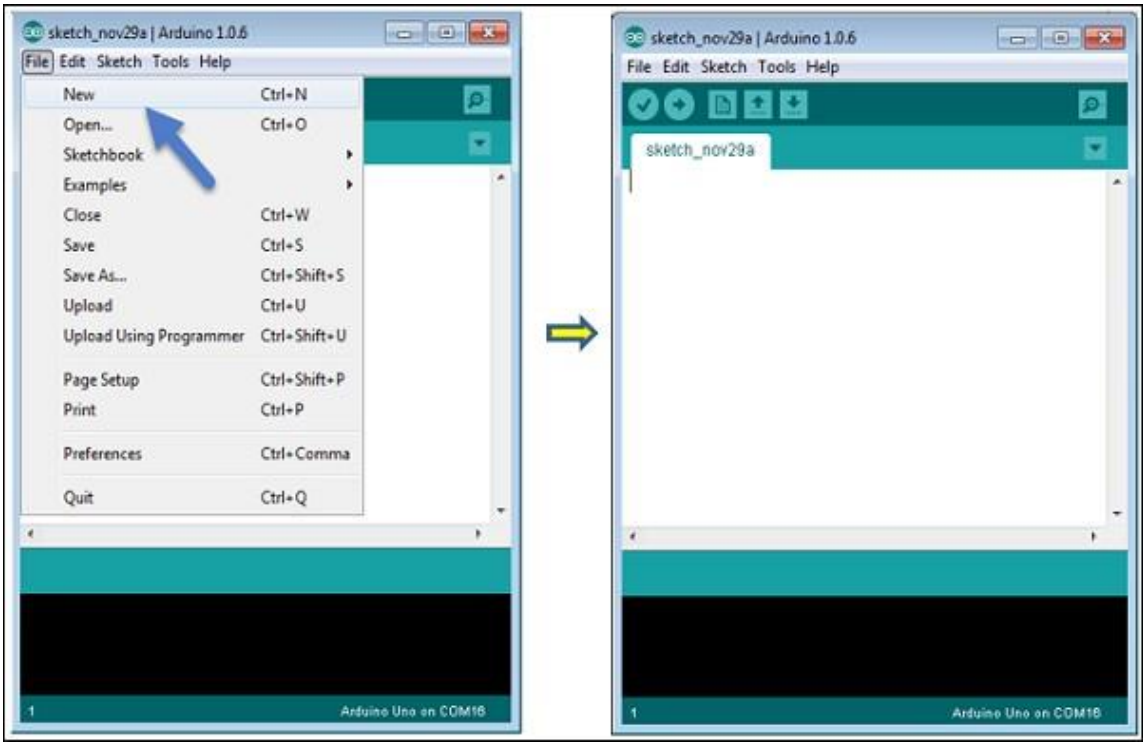

Figure 3.18: Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

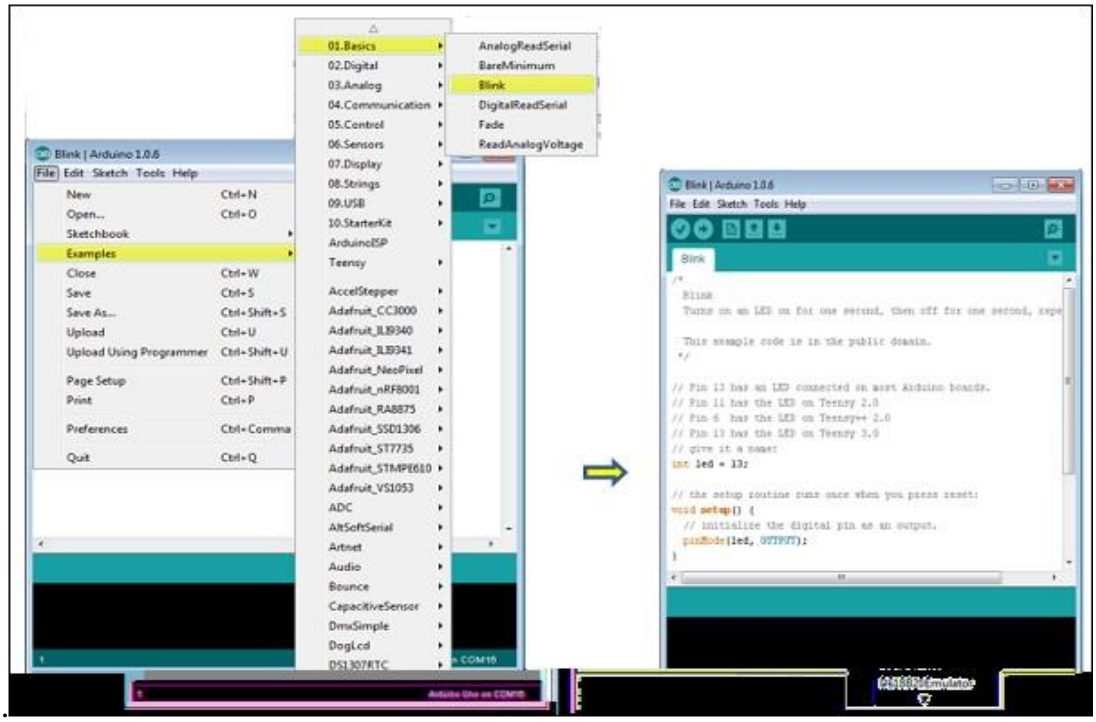

Figure 3.19: Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

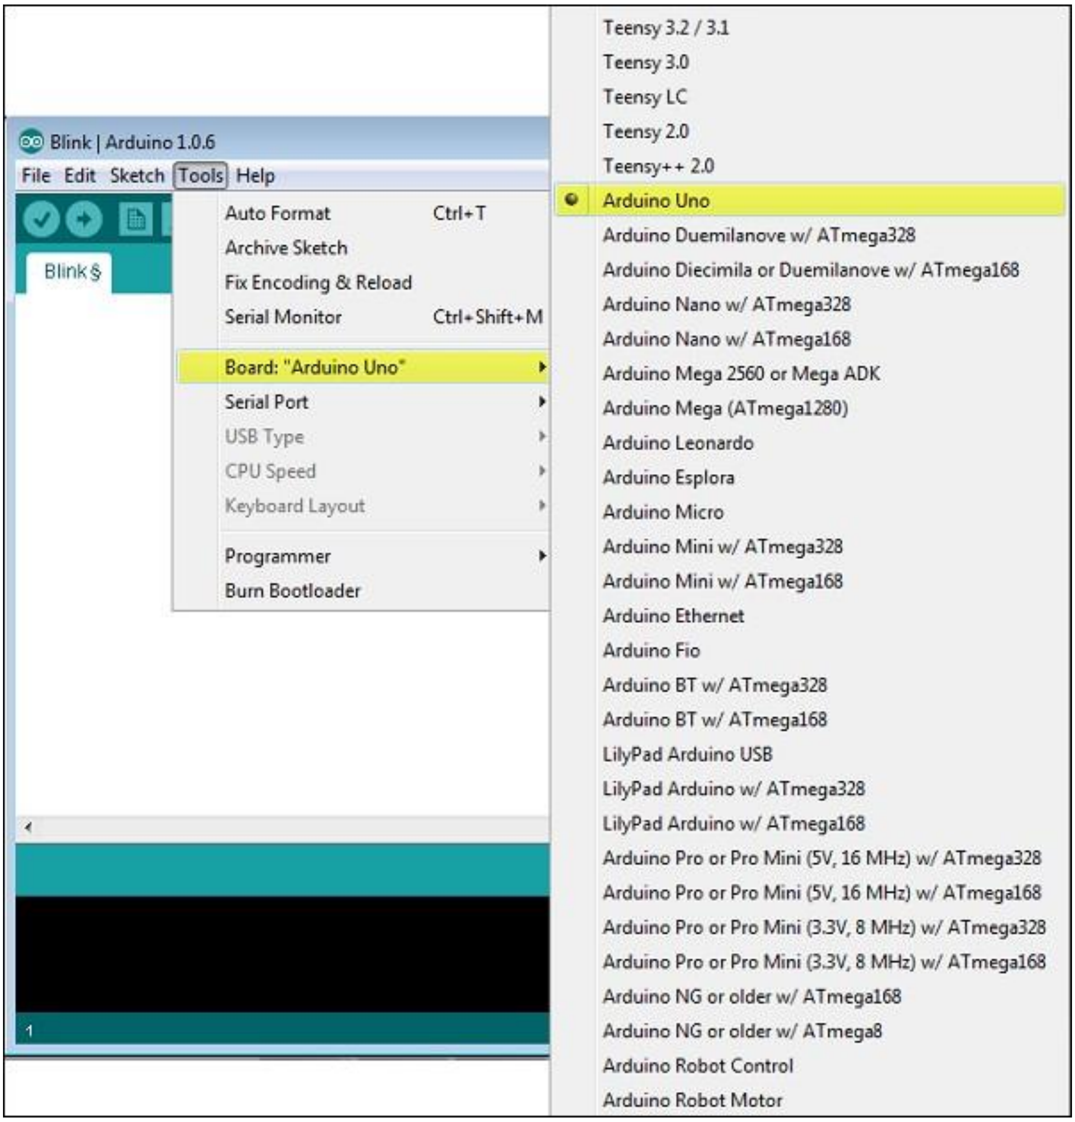

Figure 3.20: Select your Arduino board

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

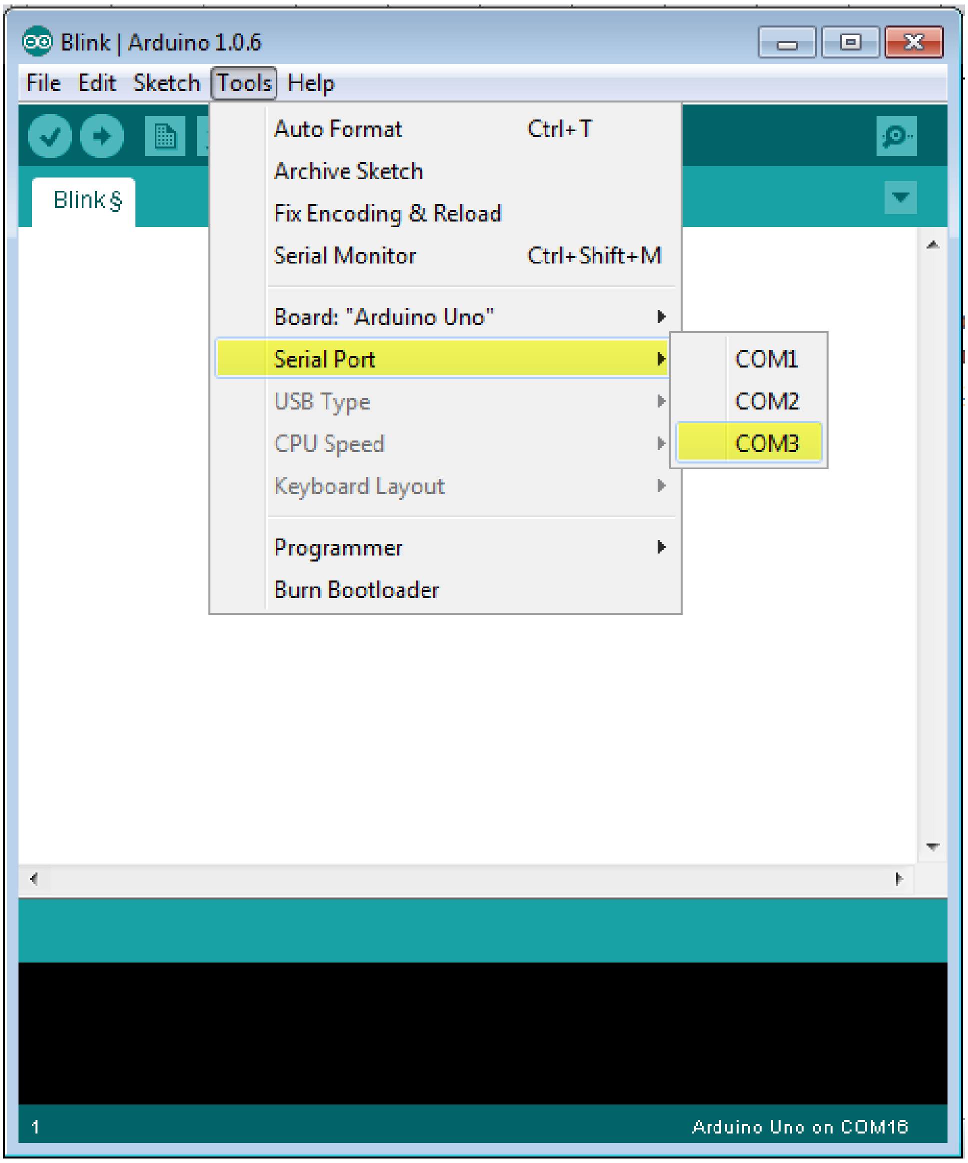

Figure 3.21: Select your serial port

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

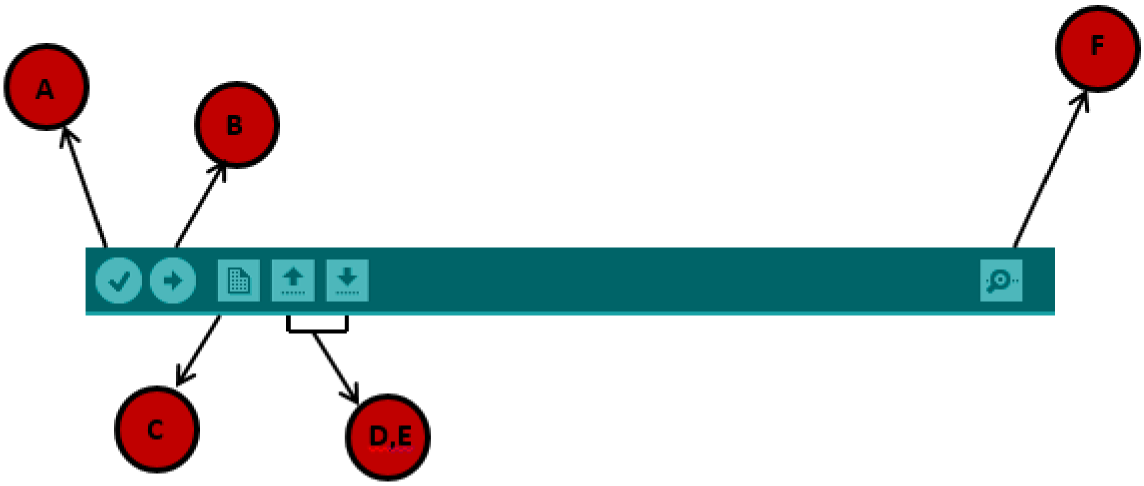

Figure 3.22: Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

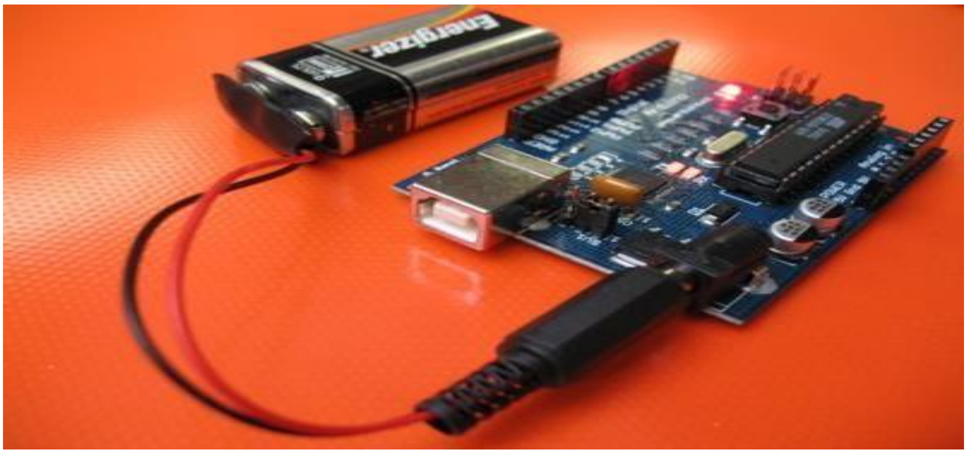

Figure 3.23: Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

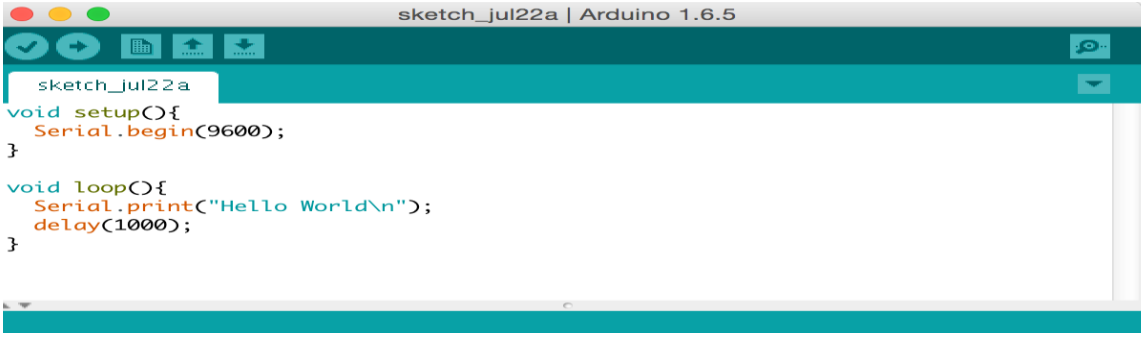

Figure 3.24: Example Program

3.2.12 Circuito.io:

Figure 3.25: circuito tool to design schematic diagram

Circuito.io is an online tool for designing complete electronic circuits. The Circuito app generates instant and accurate schematics and code for your electronic circuit. You select the major building blocks, and it computes all the electrical requirements for your selection.

It has a fantastic interface that allows you to drag and drop different parts together. It also has three different sections that one needs to work on before testing, and the first is the Bill of Materials (BoM) called DESIGN.

Here, you check out all the materials available and you then select your preferred options. You choose the components you want, or you think you need and move on to the next section. The next section being the wiring tool which will process, add all necessary additional items required and in return give a well-labeled wiring diagram.

Another exciting aspect about circuito.io is that it has an interface that allows you to step through each building component, guiding you through the creation of the circuit; This simply means that you are not working with a static diagram rather one that can move in different directions.

It does not end there though, and it only gets better with circuito.io. After building with the aid of the diagram, one can move on to the CODE module; this is a part of the platform that gives examples on how to program every piece used in the previous steps. The platform will solve the problem of hundreds of Arduino users, and it will be a lot easier to program your circuit after going through sample sketches for various pieces. It even acts as a tutorial method for beginners. So if you are stuck on what Arduino project to work on, circuito.io might just be the app for you.

3.3 DEFINE THE MODULES

3.3.1 GSM Module

Figure 3.26: SIM800L PINOUT

- NET is a pin where you can solder Helical Antenna provided along with the module.
- VCC supplies power for the module. This can be anywhere from 3.4V to 4.4 volts. Remember connecting it to 5V pin will likely destroy your module! It doesn't even run on 3.3 V! An external power source like Li-Po battery or DC-DC buck converters rated 3.7V 2A would work.
- RST (Reset) is a hard reset pin. If you absolutely got the module in a bad space, pull this pin low for 100ms to perform a hard reset.
- RxD (Receiver) pin is used for serial communication.
- TxD (Transmitter) pin is used for serial communication.
- GND is the Ground Pin and needs to be connected to GND pin on the Arduino.
- RING pin acts as a Ring Indicator. It is basically the 'interrupt' out pin from the module. It is by default high and will pulse low for 120ms when a call is received. It can also be configured to pulse when an SMS is received.
- DTR pin activates/deactivates sleep mode. Pulling it HIGH will put module in sleep mode, disabling serial communication. Pulling it LOW will wake the module up.
- MIC± is a differential microphone input. The two microphone pins can be connected directly to these pins.
- SPK± is a differential speaker interface. The two pins of a speaker can be tied directly to these two pins.

3.3.2 GPS Module

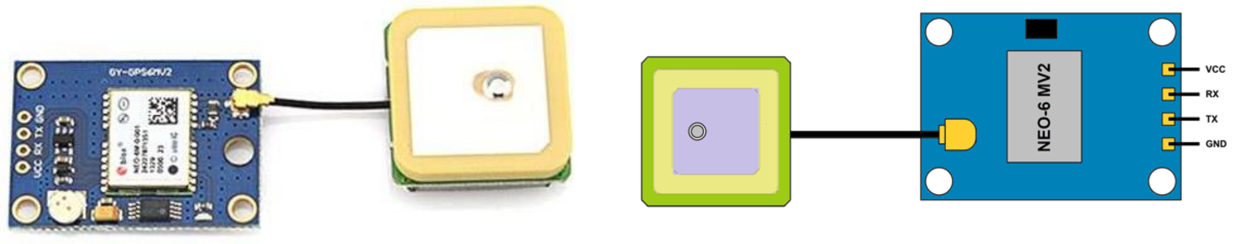

Figure 3.27: GPS6MV2 Receiver

The module has four output pins and we will describe the function each pin of them below. The powering of module and communication interface is done through these four pins.

Pin Name	**Description**
VCC	Positive power pin
RX	UART receive pin
TX	UART transmit pin
GND	Ground

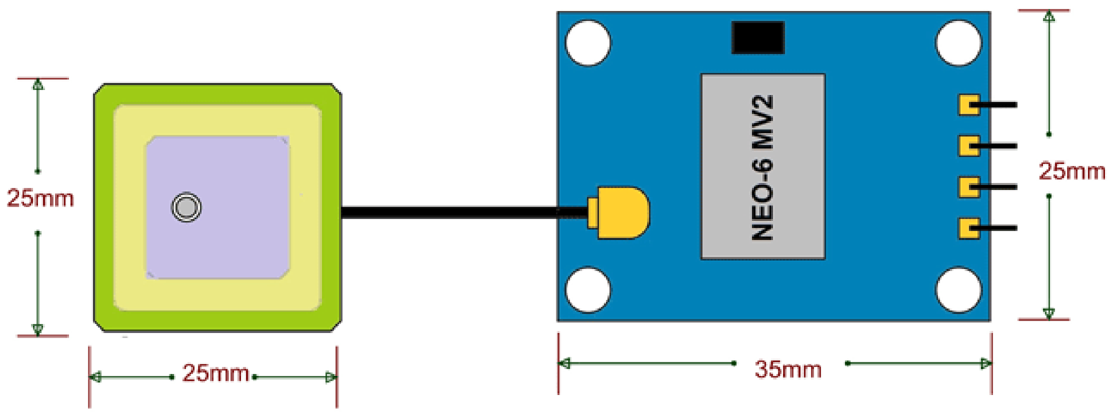

Figure 3.27: GPS6MV2 2-D model

3.4 MODULE FUNCTIONALITIES

3.4.1 GSM Functioning:

GSM is an open, digital cellular technology used for transmitting mobile voice and data services. GSM is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM and CDMA).

Computers use AT commands to control modems. Both GSM modems and dial-up modems support a common set of standard AT commands. GSM modem can be used just like a dialup modem. In addition to the standard AT commands, GSM modems support an extended set of AT commands. These extended AT commands are defined in the GSM standards. With the extended AT commands, various things can be done such as - Sending SMS messages, Monitoring the signal strength etc.

For sending AT commands and communicating with the SIM800L module, we will use the serial monitor. The sketch below will enable the Arduino to communicate with the SIM800L module on serial monitor. Before we proceed with detailed breakdown of code, connect your Arduino to PC, compile below code and upload it to the Arduino.

The sketch starts by including a SoftwareSerial.h library and initializing it with the Arduino pins to which Tx and Rx of SIM800L module is connected.

In setup function: we initialize a serial communication link between Arduino, Arduino IDE and SIM800L module at a baud rate of 9600.

Now that we have established a basic connection, we will try to communicate with the SIM800L module by sending AT commands.

- AT – It is the most basic AT command. It also initializes Auto-baud'er. If it works you should see the AT characters echo and then OK, telling you it's OK and it's understanding you correctly! You can then send some commands to query the module and get information about it such as

- AT+CSQ – Check the 'signal strength' – the first # is dB strength, it should be higher than around 5. Higher is better. Of course it depends on your antenna and location!

- AT+CCID – get the SIM card number – this tests that the SIM card is found OK and you can verify the number is written on the card.

- AT+CREG? Check that you're registered on the network. The second # should be 1 or 5. 1 indicates you are registered to home network and 5 indicates roaming network. Other than these two numbers indicate you are not registered to any network.

- ATI – Get the module name and revision

- AT+COPS? – Check that you're connected to the network, in this case BSNL

- AT+COPS=? – Return the list of operators present in the network.

- AT+CBC – will return the lipo battery state. The second number is the % full (in this case its 93%) and the third number is the actual voltage in mV (in this case, 3.877 V)

- AT+CMGF=1 – Selects SMS message format as text. Default format is protocol data unit (PDU).

- AT+CMGS=+ZZxxxxxxxxxx – Sends SMS to the phone number specified. The text message entered followed by a 'Ctrl+z' character is treated as SMS. 'Ctrl+z' is actually a 26^{th} non-printing character described as 'substitute' in ASCII table. So, we need to send 26_{DEC} ($1A_{HEX}$) once we send a message.

- AT+CMGF=1 – Selects SMS message format as text. Default format is Protocol Data Unit (PDU)

- AT+CNMI=1,2,0,0,0 – specifies how newly arrived SMS messages should be handled. This way you can tell the SIM800L module either to forward newly arrived SMS messages directly to the PC, or to save them in message storage and then notify the PC about their locations in message storage.

3.4.2 GPS Functioning:

The Global Positioning System satellites transmit signals to equipment on the ground. GPS receivers passively receive satellite signals; they do not transmit. GPS receivers require an unobstructed view of the sky, so they are used only outdoors and they often do not perform well within forested areas or near tall buildings. GPS operations depend on a very accurate time reference, which is provided by atomic clocks on board. Each GPS satellite transmits data that indicates its location and the current time.

All GPS satellites synchronize operations so that these repeating signals are transmitted at the same instant. The signals, moving at the speed of light, arrive at a GPS receiver at slightly different times because some satellites are further away than others. The distance to the GPS satellites can be determined by estimating the amount of time it takes for their signals to reach the receiver. When the receiver estimates the distance to at least four GPS satellites, it can calculate its position in three dimensions.

There are at least 24 operational GPS satellites at all times plus a number of spares. The satellites, operated by the U.S. Department of Defence, orbit with a period of 12 hours (two orbits per day) at a height of about 11,500 miles travelling at near 2,000mph. Ground stations are used to precisely track each satellite's orbit.

Start by connecting the patch antenna to the U.FL connector. Remember to thread the U.FL cable through one of the mounting holes for robust connection. The module usually comes with header pins unsoldered. So, you'll need to solder them.

Now, connect Tx and Rx pin on module to digital pin#2 and #3 respectively on Arduino; as we'll be using software serial to talk to the module. Next, connect VCC pin to the 5V pin on the arduino and GND to ground.

$	Every NMEA sentence starts with $ character.
GPRMC	Global Positioning Recommended Minimum Coordinates
123519	Current time in UTC – 12:35:19
A	Status A=active or V=Void.
4807.038,N	Latitude 48 deg 07.038′ N
01131.000,E	Longitude 11 deg 31.000′ E
022.4	Speed over the ground in knots
084.4	Track angle in degrees True
003.1,W	Magnetic Variation
*6A	The checksum data, always begins with *

- gps.speed.value() function returns current ground speed in 100ths of a knot.
- gps.course.value() function returns current ground course in 100ths of a degree.
- gps.satellites.value() function returns the number of visible, participating satellites.

- gps.hdop.value() function returns horizontal diminution of precision.

3.4.3 Project Code:

```
#include <Wire.h>

CHAPTER 4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM

The Black Box concept is derived from the aviation industry, a flight recorder, colloquially known as a black box. With the advancement in technology and cost coming down, in our project we attempt to build similar device for our car which can send the location to pre-coded number when an accident occurs

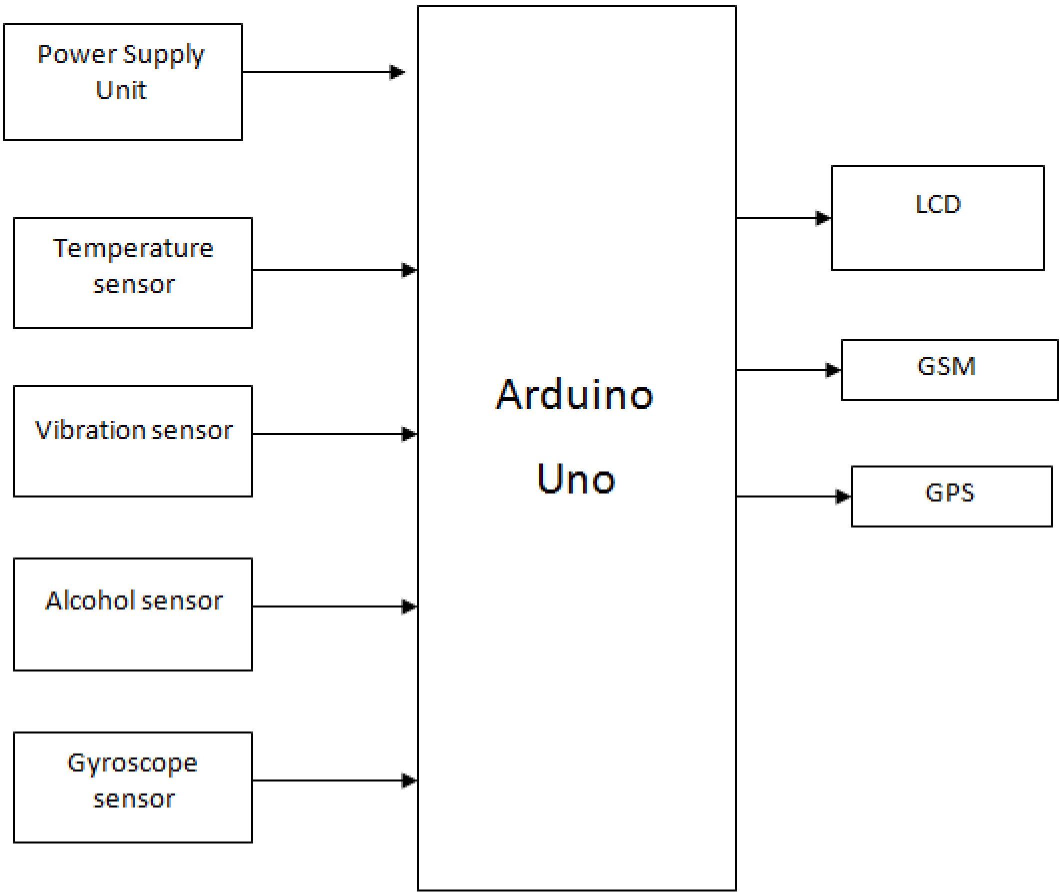

Figure 4.1: Block diagram of the blackbox

Four sensors that are temperature sensor LM35, vibration sensor, gas sensor MQ3, accelerometer ADXL345 are the primary inputs. LCD display, GPS6MV2, GSM SIM800L are the primary outputs. To indicate motion of car we are using a motor.

4.2 FLOW CHART

.

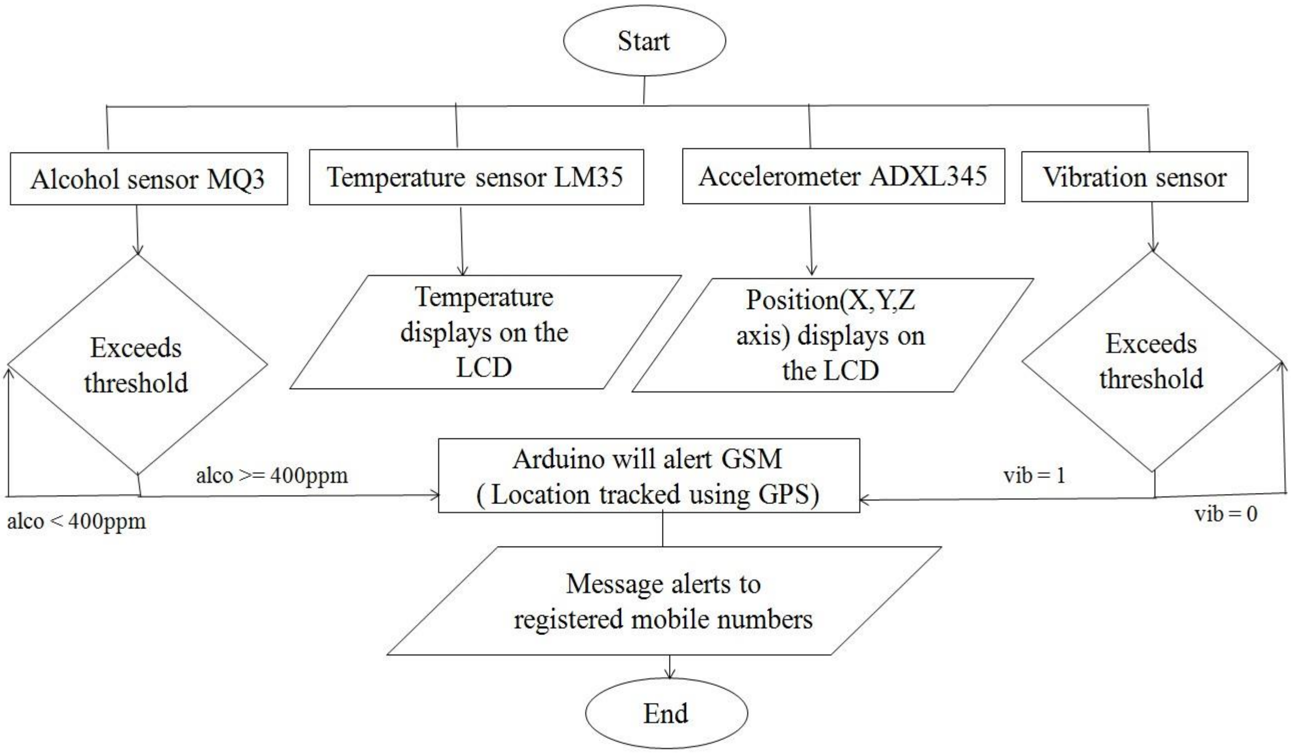

Figure 4.2: Flow chart of the system

This flow chart gives a brief idea as to how the project “Wireless Blackbox for cars using sensors and gps module” works.

Initially the threshold detection level of sensors value is predefined. When the device is switched on, it displays “Wireless Blackbox”. Now the user is prompted to give an input such that it exceeds the threshold of the sensors. Once this happens the SMS is sent to registered mobile number with the location of the accident place.

The GPS receiver helps to collect the location of the place. The GSM module sends the SMS.

4.3 HARDWARE SETUP

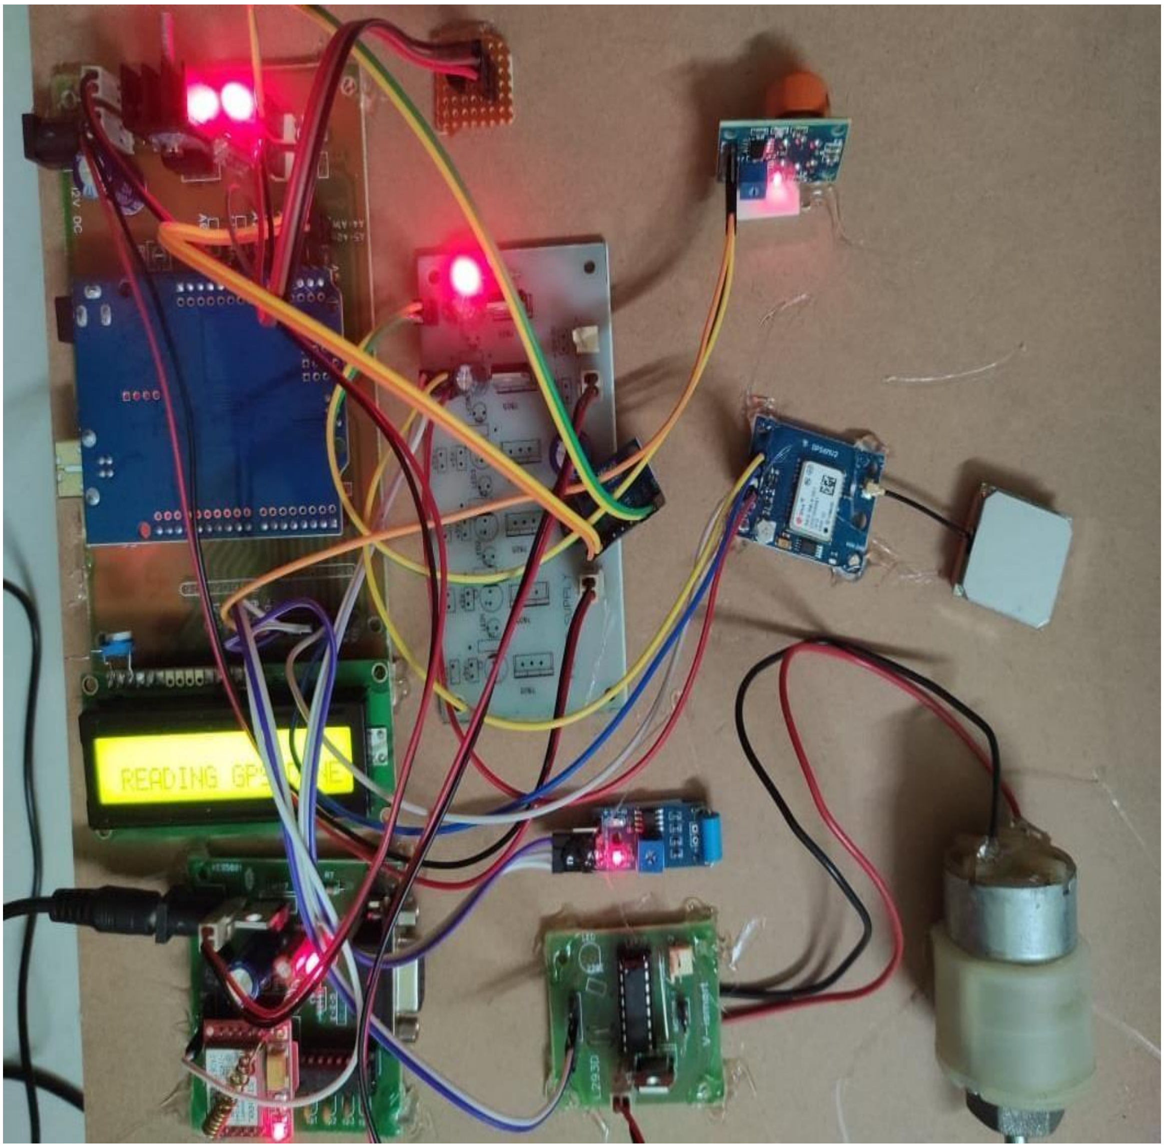

Figure 4.3: Hardware Setup

This hardware setup gives a brief idea as to how the components of the project “Wireless Blackbox for cars using sensors and gps module” were connected.

4.4 RESULT

After successfully developing and implementing the project, whenever the threshold limit of the alcohol sensor MQ3 exceeded or vibration is detected by the vibration sensor the following results (alert messages) were obtained.

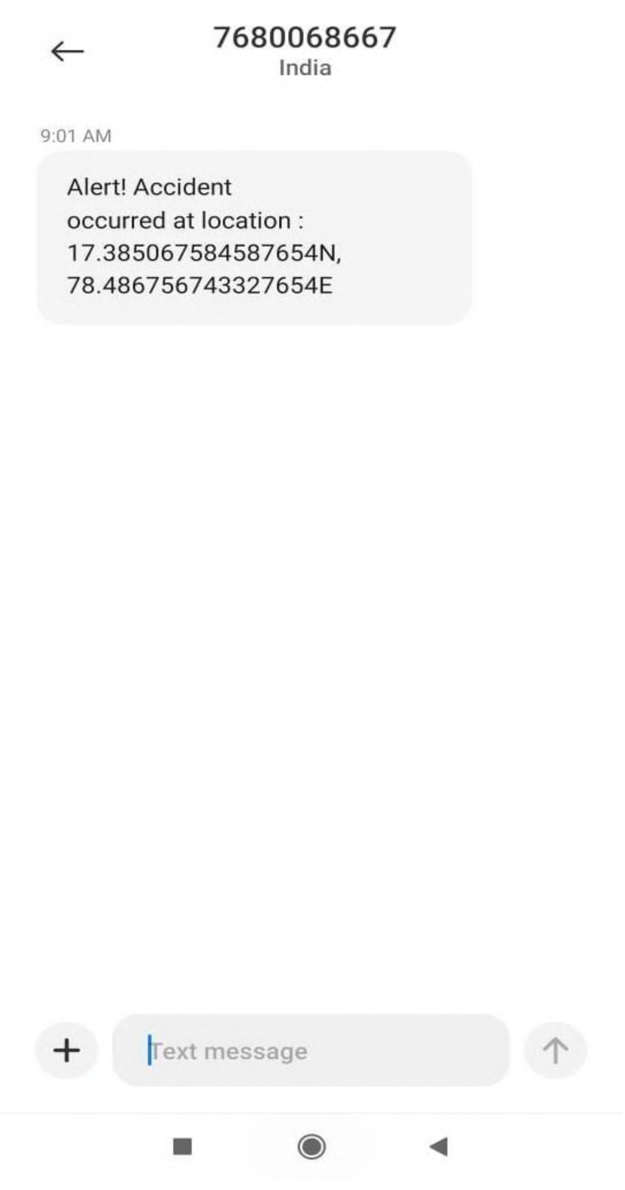

Figure 4.4: Alert message received when alcohol limit exceeded

Figure 4.5 Alert message received when accident occurred

CHAPTER 5

PROJECT TESTING

Input	Output
LM35 senses temperature	Temperature displayed on LCD
MQ3 detects alcohol & alcohol concentration exceeds 400pm	Sends alert message
Vibration sensor detects vibrations	Sends alert message
ADXL345 detects tilt	X,Y,Z co-ordinates(position) are displayed on the LCD

Table 5.0: Analyzing experimental data

- Initially the threshold detection level of sensors value is predefined.
- When the device is switched on, it displays “Wireless Blackbox”.
- Now the user is prompted to give an input such that it exceeds the threshold of the sensors.
- Once this happens the SMS is sent to registered mobile number with the location of the accident place.

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION:

The sole purpose of this project was to develop a blackbox system for car accidental monitoring and alerting. The system has successfully overcome the drawbacks of the existing system by introducing alert messages.

Finally, We conclude that system wireless black box using sensors, GSM and GPS tracking has been developed for car accidental monitoring and alerting which gives an intelligent solution to the problem.

6.2 FUTURE ENHANCEMENT:

In future, by applying ultrasonic sensors features we can detect the distance of a vehicles moving nearby our vehicles. This system can be interfaced with vehicle airbag system that prevents vehicle occupants from striking interior objects such as steering wheel or window.

This can also be developed by interconnecting a camera to the controller module that takes the photograph of the accident spot that makes tracking easier.

PUBLICATION

We have published a paper on our project titled “Wireless Blackbox for cars using sensors and gps module” at Online Mega International Conference on “Smart Modernistic in Electronics and Communication” **(ICSMEC-21)** organized by Department of Electronics & Communication Engineering, St. Martin’s Engineering College **(ID :** ICSMEC21-0070)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B. Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our **Department Project Coordinator Dr. A. Anand Kumar** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our class project coordinator and our project internal guide **Mrs.A.Soumya,** Assistant Professor, Department of ECE for guidance and encouragement in carrying out this project work.

2. R.Sai Spurthy (17K81A0441)
3. S.Manvitha (17K81A0446)

ABSTRACT

Blind stick is an innovative stick designed for visually disabled people for improved navigation. We here propose an advanced blind stick that allows visually challenged people to navigate with ease using advanced technology. The blind stick is integrated with ultrasonic sensor along with light and water sensing. Our proposed project first uses ultrasonic sensors to detect obstacles ahead using ultrasonic waves. On sensing obstacles the sensor passes this data to the microcontroller. The microcontroller then processes this data and calculates if the obstacle is close enough. If the obstacle is not that close the circuit does nothing. If the obstacle is close the microcontroller sends a signal to sound a buzzer. It also detects and sounds a different buzzer if it where detects water and alerts the blind. One more feature is that it allows the blind to detect if there is light or darkness in the room. The system has one more advanced feature integrated to help the blind find their stick if they forget they kept it. A wireless RF based remote is used for this purpose. Pressing the remote button sounds a buzzer on the stick which helps the blind person to find their stick. Thus this system allows for obstacle detection as well as finding stick if misplaced by visually disabled people.

LIST OF FIGURES

CHAPTER I

INTRODUCTION

1.0 Overview of the project:

Blindness is a condition of lacking the visual perception due to physiological or neurological factors partially or fully. The main concept of the paper is to provide an electronic aid as guidance to overcome the lacking of their visualization power by proposing a simple, efficient, configurable electronic guidance system for blind and visually impaired pedestrians. Ultrasonic Sensor is the proposed electronic aid which senses the obstacles in its path by continuously transmitting the ultrasonic waves.

When an obstacle appears in its vicinity then the ultrasonic waves get reflected to the system immediately. And then ultrasonic receiver senses these ultrasonic waves. This method supports the microcontroller to obtain the information from ultrasonic waves and then it alerts the blind pedestrians through voice message.

The advantage of our proposed system is its voice-based announcement for easy navigation which can assist a blind pedestrian to pass through a busy road. Moreover, this system is an auditory guidance system for the visually impaired pedestrians using ultrasonic-to-audio signal transformation

In this project, the system is designed in such a way that it gathers data about the environment via ultrasonic sensors and extracts the visual information from that data. This visual information is then transformed into an audio signal immediately and the blind pedestrian can recognize the environmental information through binaural sound generated by the system.

The whole operation of the project can be described by using block diagram which is a graphical method for explaining the concept of the system without the presence of the individual components within the project. Figure 1 represents the basic block diagram of the whole system of project.

1.1 Objectives of the Study:

The main objective is to help visually challenged people to navigate with ease using advance technology. In this technology controlled world, where people strive to live independently, this project proposes an ultrasonic stick for blind people to help them gain personal independence. Since this is economical and not bulky, one can make use of it easily.

1.2 Scope of the Study:

The system can be supplemented with ultrasonic sensor which can be used in detecting obstacles and we can also provide a buzzer for alerting a person.We can also add speakers to store voice notes and play accordingly.

1.3 Material Requirement:

Component	Specification	Quantity
Ultrasonic Sensor	HC -SR04	1
Arduino	UNO	1
Buzzer	5-Volt	1
LCD	16 x 2	1
Battery	9 Volt	1

Table 1 : Materials Required for the project

1.4 Procument of Equipment:

This project is developed in such a way that it is efficient and affordable in a simple way. So,all the components required to implement the system is available in the market in low prize. Firstly,we made a list of the components and looked for the places and prioritized the places with good quality and of low cost.Next we ordered all the required things . After receiving all the equipments, we started the implementation of the project.

1.5 Organization of Chapters:

1.5.0 Introduction:

Visually impaired persons have difficulty to interact and feel their environment. They have little contact with surroundings.

Physical movement is a challenge for visually impaired persons, because it can become tricky to distinguish obstacles appearing in front of them, and they are not able to move from one place to another. They depend on their families for mobility and financial support. Their mobility opposes them from interacting with people and social activities.

In the past, different systems are designed with limitations without a solid understanding of the

nonvisual perception. Researchers have spent the decades to develop an intelligent and smart stick to assist and alert visually impaired persons from obstacles .Over the last decades, research has been conducted for new devices to design a good and reliable system for visually impaired persons to detect obstacles and warn them at danger places.

Smart walking stick is specially designed to detect obstacles which may help the blind to navigate care-free. The audio messages will keep the user alert and considerably reduce accidents. A voice enabled automatic switching is also incorporated to help them in private space as well. This system presents a concept to provide a smart electronic aid for blind people, both in public and private space The proposed system detects the obstacle images which are present in outdoor and indoor with the help of a sensor. The Stick measures the distance between the objects and smart walking stick by using an ultrasonic sensor. When any objects or obstacles come in range of an ultrasonic sensor then the buzzer beeps. The smart walking stick is a simple and purely mechanical device to detect the obstacles on the ground. This device is light in weight and portable. But its range is limited due to its own size. It provides the best travel aid for the person. The blind person can move from one place to another independently without the others help. The main aim of the system is to provide a efficient navigation aid for the blind persons which gives a sense of vision by providing the information about their surroundings and objects around them.

1.5.1 Literature Survey:

Nowadays, the wearable health monitoring system is the main application of Internet of things Likewise lots of wearable devices are designed for visually impaired people. Few systems are discussed here. In sensor assisted stick for the blind people describes about a wearable equipment which consists of a light weight blind stick.

the obstacle detection circuit based on a sensor. It is mainly developed to help the blind person to move alone safely from one place to another and to avoid any obstacles that may be encountered. The device detects the fixed as well as moving objects and thus it may help to avoid accidents. The main component for the working of this system is the infrared sensor which is used to scan a predetermined area around the blind person by emitting-reflecting waves. The reflected signals are received from the objects are used as inputs to the microcontroller and then used for determining the direction and distance of the objects around the blind person.

The main objective of this is to provide an application for blind people to detect the obstacles in various directions, detecting pits and manholes on the ground to make free to walk.

An innovative stick is designed for the visually disabled people for their easy navigation. The blind stick is able to detect the water by integrating with ultrasonic sensor. In this system, the ultrasonic sensors are used to detect obstacles by using ultrasonic waves. By sensing the obstacles the sensor passes the received data to the microcontroller. The microcontroller processes the data and calculates if the obstacle is close enough to the person. If the obstacle is not close to the microcontroller, the circuit does not do anything. If the obstacle is close enough to the microcontroller, it sends a signal to buzzer. The system also detects water and provides different sounds and alerts the blind person.

Multitasking stick is designed to indicate safe path to visually disable people. The micro-controller based automated hardware allows a blind person to detect obstacles in front of them. The hardware part consists of a micro-controller which was incorporated with an ultrasonic sensor, voice play back module and additional equipment. The ultrasonic waves are used to detect the obstacles. The temperature sensors are provided to detect the fire or high temperature area. The presence of water is detected using the current sensing principle. The acknowledgement from the sensing obstacle is received through the voice play back module. The system is provided with RF module to find the misplaced stick. These features allow the blind people to move from one place to another independently and easily.

1.5.2 Project Design:

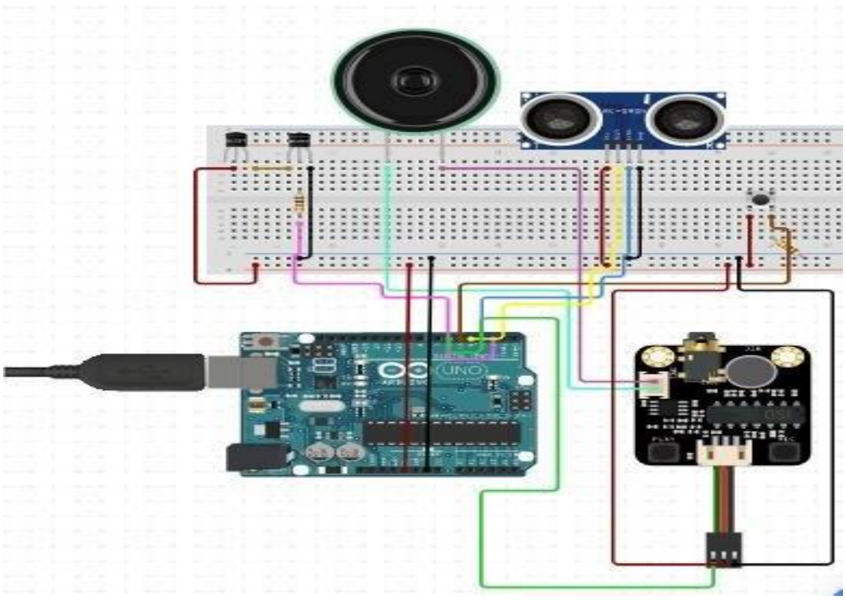

Figure 1.0 : Schematic design of the Project

1.5.3 Project Implementation:

The proposed system provides improvements to the existing system design. It tries to make the existing system more efficient, convenient and user- friendly. The implementation of the proposed design of the stick requires following hardware components:

1. Ultrasonic sensor
2. Arduino
3. Buzzer
4. APR9600

1.5.4 Project Testing:

The purpose of the testing phase is to evaluate and test declared requirements, features, and expectations regarding the project prior to its delivery in order to ensure the project matches initial requirements stated in specification documents.

1.5.5 Conclusion and Future Enhancement:

The smart walking stick, constructed with at most accuracy, will help the blind people to move from one place to another without others help. This could also be considered a crude way of giving the blind a sense of vision. This stick reduces the dependency of visually impaired people on other family members, friends and guide dogs while walking around. The smart stick detects objects or obstacles in front of users and feeds warning back, in the form of beep. The advantage of the system lies in the fact that it can prove to be a low cost solution to millions of blind person worldwide.Hence, we can conclude that there are a number of techniques for making a ultrasonic blind walking stick for blind people. The advantage of the system lies in the fact that it can prove to be a very low cost solution to millions of blind person worldwide. Our prototype can detect the obstacles of 3 metres range.The system can be supplemented with actual GPS module used in cars and we can provide a vibrator for the partially deaf person. This makes the system further more compact. A wall following function can also be added so that the user can walk straight along a corridor in an indoor environment.

CHAPTER II

CHAPTER II
LITERATURE SURVEY

2.0 Literature Review on Research Area:

The authors Ashraf Anwar and Sultan Aljahdali in their paper used ultrasonic sensor for detecting the obstacle coming in the path of the blind person, also they have used heat and moisture sensor for giving more details to the person with the stick about the road or path. For alarming the blind person they are using different buzzers and sensors that will tell the person that something is there in front of him/her. The only disadvantage of this system is that GPS is not included in this system.

In the paper named 'Implementation and Design of Smart Blind Stick for Obstacle Detection and Navigation System' whose authors are K.S.Manikanta, T. S. S. Phani , A. Pravin used Buzzers and speakers in their model which helped the visually impaired person to stay alert on the roads without the help of others. As moisture sensor is not included in the model so it cannot detect water present in the path of the person using that stick.

2.1 Review on Related Literature:

This section describes appropriate related works on the development of smart canes intended for visually-impaired people. According to [1], technology can help in reducing manybarriers that people with disabilities face. These kinds of technologies are referred to as assistive technology (AT). There are many types of disabilities, including physical disabilities, hearing-impaired, and visually-impaired. A T has been utilized in assisting them [4, 5, 6, 9]. However,developing an AT is expensive [3], making their selling price high.

The GuideCane [9] is designed to help the visually-impaired users navigate safely and quickly. and other hazards. GuideCane is used like the widely used white cane, where the user holds the GuideCane in front of the user while walking. The GuideCane is considerably heavier than the white cane, because it uses a s ervo motor. The wheels are equipped with encoders to determine the relative motion. The servo motor, controlled by the built-in computer, can steer the wheels left and right relative to the cane. To detect obstacles, the GuideCane is equipped with ten ultrasonic mini joystick located at the handle allows the user to specify a desired direction of motion. GuideCane is far heavier than the ordinary white cane and also it is hard to keep because it cannot be folded.

2.2 Conclusions on Reviews:

So,There by we conclude that after going through all the previously published papers ,we decided to implement an efficient and affordable smart stick in a simplest way.

For this,we'll add a sensor to detect the obstacle and also a buzzer so that it can alert the person using the kit and we can also supplement it with APR9600,so that he can add some voice notes.

CHAPTER III

CHAPTER III
PROJECT DESIGN

3.0 Overview of the Design:

The aim of this project is to investigate the development of a navigation aid for blind and visually impaired People. It is based on a microcontroller with synthetic speech output. This aid is portable and gives information to the user about urban walking routes to point out what decisions to make. On the other hand, and in order to reduce navigation difficulties of the blind, an obstacle detection system using ultrasounds added to this device. Blind stick is an innovative stick designed for visually disabled people for improved navigation. We here propose an advanced blind stick that allows visually challenged people to navigate with ease using advanced technology. The blind stick is integrated with ultrasonic sensor and a buzzing system. The brain of the circuit is Arduino Uno MCU board (Board1). Ultrasonic sensor "HC-SR04" is used for obstacle detection using ultrasonic waves. This sensor require a power supply of 3.3V each to operate up to a distance of 3 m and can detect obstacles within an average angle of 25 degrees in the sphere.

POWER SUPPLY

3.1 Block Diagram

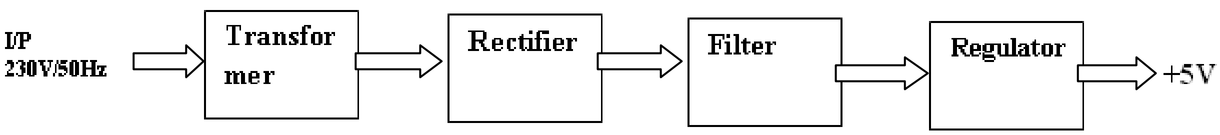

Figure 3.1 Power Supply

Circuit Diagram

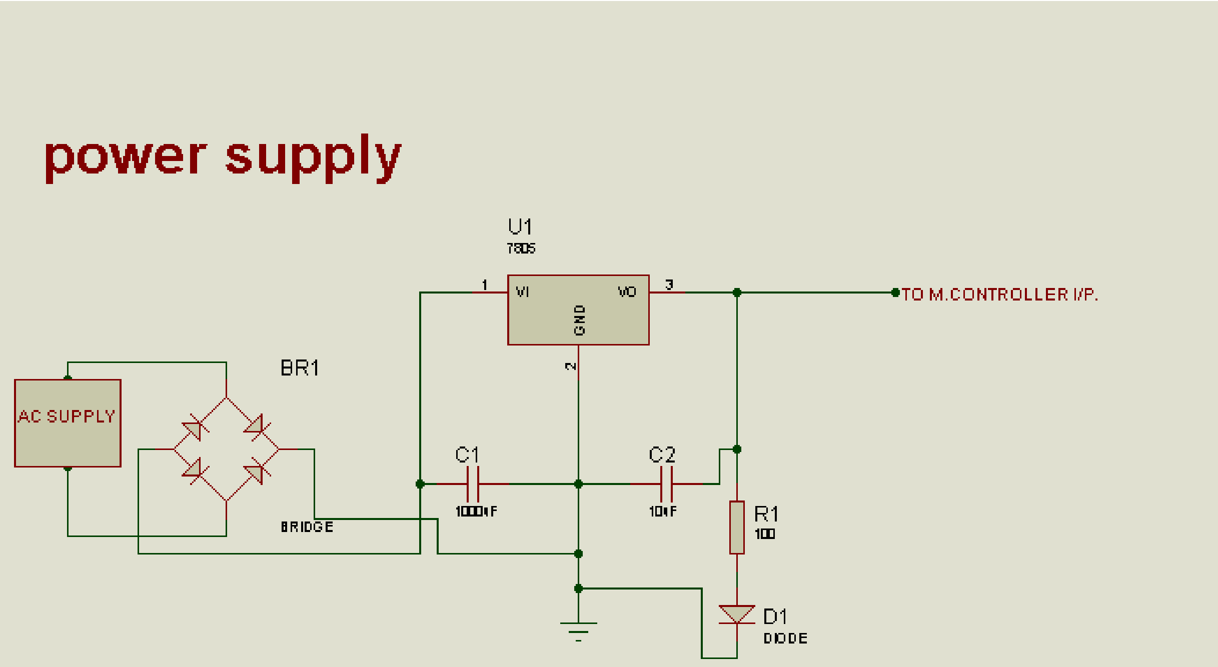

Figure 3.2 Circuit Diagram

Description

3.2.1 Transformer

A **transformer** is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

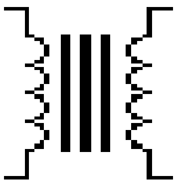

Figure: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

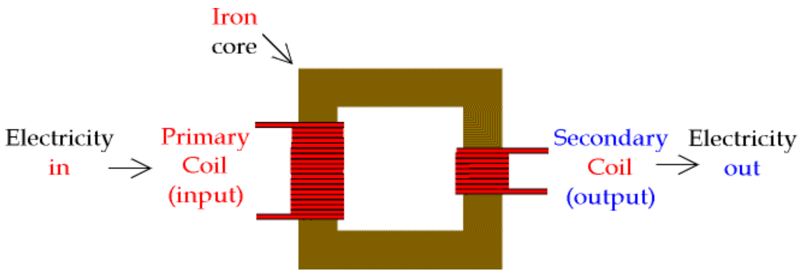

Figure : Transformer

Basic Principle:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

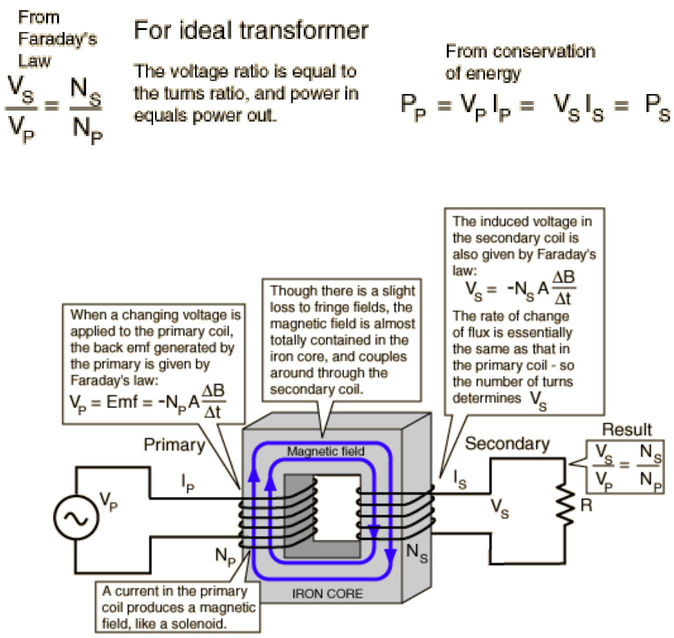

Figure: Basic Principle

Transformer Working

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

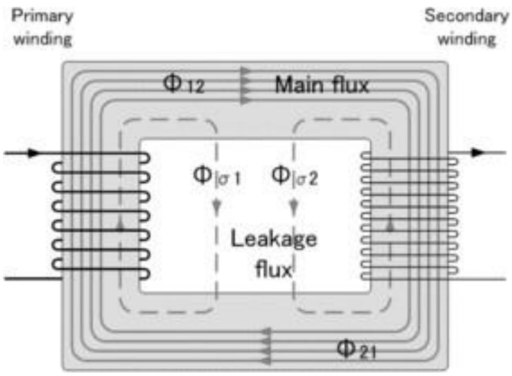

Figure: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

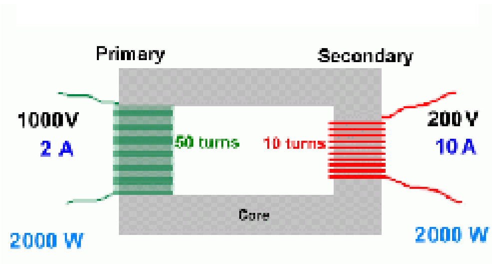

Figure: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant.

Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single-phase step-down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase step up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step-up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply.

A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

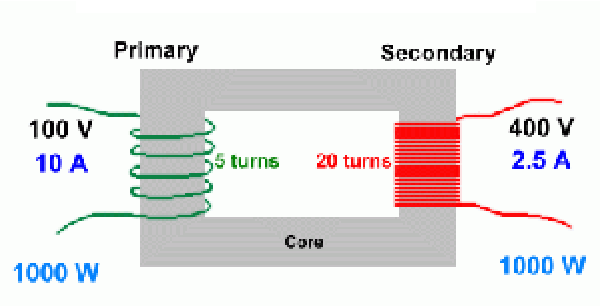

Figure: Step-Up Transformer

Applications

Generally, these **Step-Up Transformers** are used in industries applications only.

Turns Ratio and Voltage

The ratio of the number of turns on the primary and secondary coils determines the ratio of the voltages...

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

...where V_p is the primary (input) voltage, V_s is the secondary (output) voltage, N_p is the number of turns on the primary coil, and N_s is the number of turns on the secondary coil.

3.2.2 Diodes

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

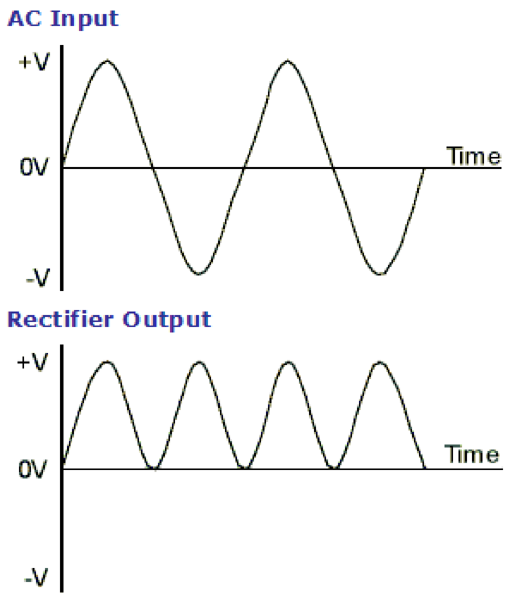

Figure Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased.

While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

Capacitor Filter

The **capacitor-input filter**, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

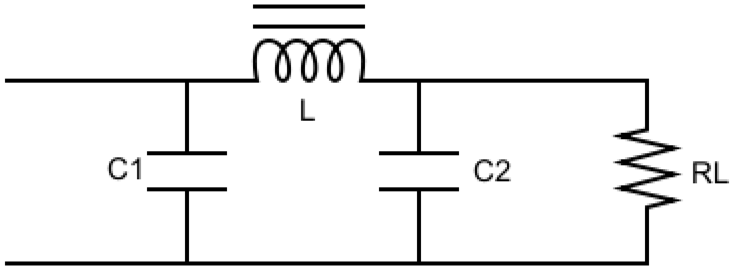

Figure: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result the DC component flows through the inductor while the AC component is blocked.

1. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result only the DC component appears across the load RL.

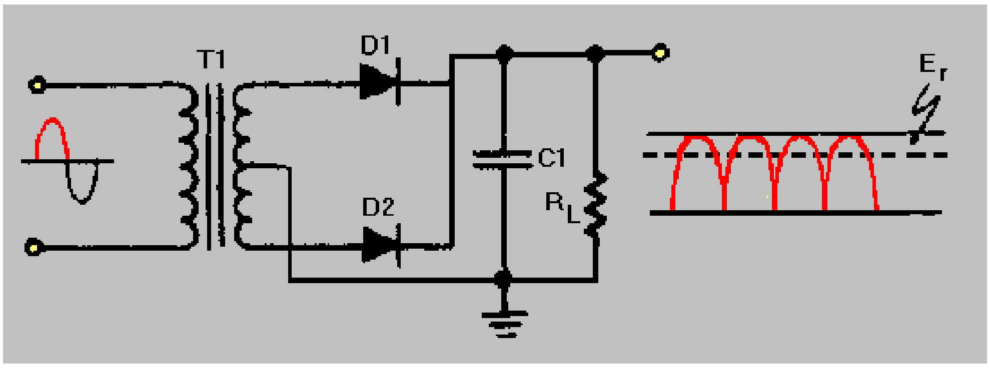

Figure: Centered Tapped Full-Wave Rectifier with a Capacitor Filter

Voltage Regulator:

A **voltage regulator** is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components.

Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the p ositive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consists the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

Arduino Uno:

Arduino/Genuino **Uno** is a microcontroller board based on the ATmega328P (datasheet). It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button.

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.

Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

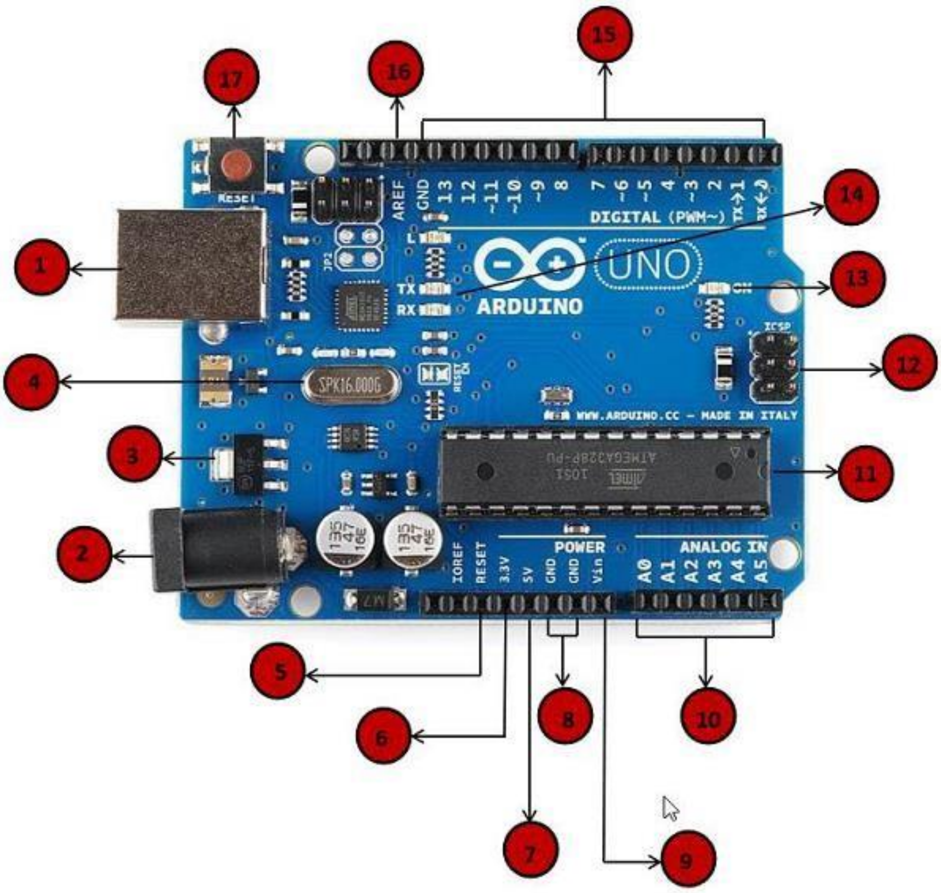

Figure : Arduino

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.

4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an

	"expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Ultrasonic Sensor:

An **ultrasonic sensor** is an electronic device that measures the distance of a target object by emitting **ultrasonic** sound waves, and converts the reflected sound into an electrical signal. **Ultrasonic** waves travel faster than the speed of audible sound (i.e. the sound that humans can hear).

Buzzer:

A buzzer or beeper is an audio signalling device, which may be mechanical, electromechanical, or piezoelectric. Typical uses of buzzers and beepers include alarm devices,timers,and confirmation of user input such as a mouse click or keystroke.

APR9600:

APR9600 is a low-cost high performance sound record/replay IC incorporating flash analogue storage technique. .... Total sound recording time can be varied from 32 seconds to 60 seconds by changing the value of a single resistor.

3.3 Module Functionalities:

Arduino Uno:

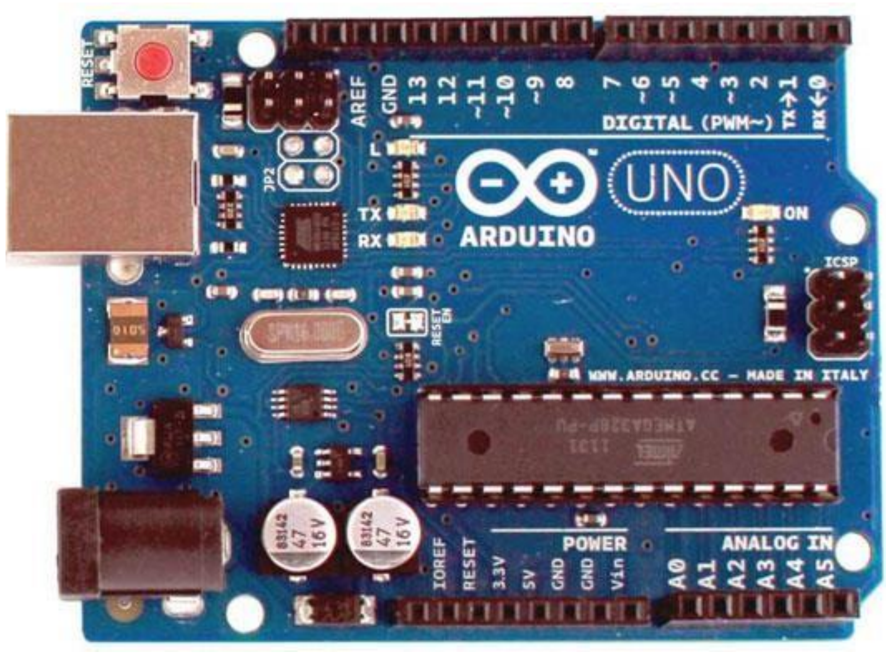

FIGURE 3.3 : Arduino

The Uno is a microcontroller board based on the ATmega328P. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button.

It contains everything needed to support the microcontroller. Page to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started.. You can tinker with your UNO without worrying too much about doing something wrong, worst case scenario you can replace the chip for a few dollars and start over again.

The Arduino Uno is programmed using the Arduino Software(IDE), our Integrated Development Environment common to all our boards and running both online and offline.

Ultrasonic Sensor:

Figure : 3.4

An ultrasonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal. Ultrasonic waves travel faster than the speed of audible sound (i.e. the sound that humans can hear). Ultrasonic sensors have two main components: the transmitter (which emits the sound using piezoelectric crystals) and the receiver (which encounters the sound after it has travelled to and from the target).

Ultrasonic Sensor Pin Configuration

Pin Number	**Pin Name**	**Description**
1	Vcc	The Vcc pin powers the sensor, typically with +5V
2	Trigger	Trigger pin is an Input pin. This pin has to be kept high for 10us to initialize measurement by sending US wave.
3	Echo	Echo pin is an Output pin. This pin goes high for a period of time which will be equal to the time taken for the US wave to return back to the sensor.
4	Ground	This pin is connected to the Ground of the system.

HC-SR04 Sensor Features

- Operating voltage: +5V
- Theoretical Measuring Distance: 2cm to 450cm
- Practical Measuring Distance: 2cm to 80cm
- Accuracy: 3mm
- Measuring angle covered: <15°
- Operating Current: <15mA
- Operating Frequency: 40Hz

Equivalent distance measuring Sensors

US transmitter Receiver pair, IR sensor module, IR sensor pair, IR Analog distance sensor,

HC-SR04 Ultrasonic Sensor - Working

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4 pin module, whose pin names are Vcc, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver. The sensor works with the simple high school formula that

Distance = Speed × Time

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

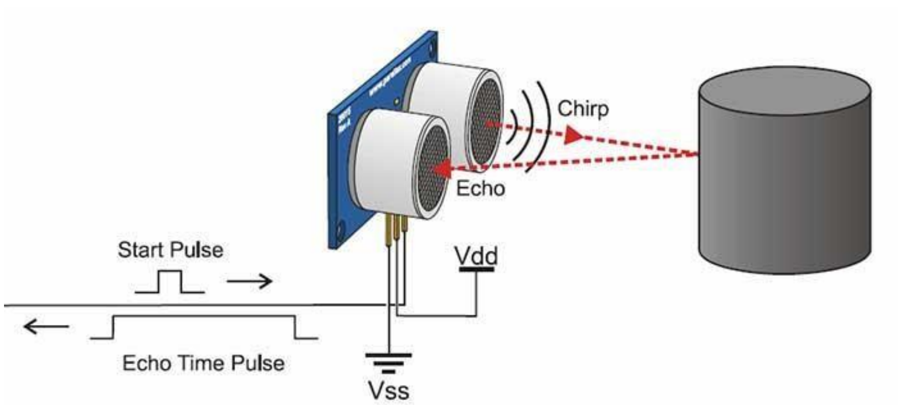

Figure : 3.5

Ultrasonic sensors work by sending out a sound wave at a frequency above the range of human hearing. The transducer of the sensor acts as a microphone to receive and send the ultrasonic sound. Our ultrasonic sensors, like many others, use a single transducer to send a pulse and to receive the echo. The sensor determines the distance to a target by measuring time lapses between the sending and receiving of the ultrasonic pulse.

The working principle of this module is simple. It sends an ultrasonic pulse out at 40kHz which travels through the air and if there is an obstacle or object, it will bounce back to the sensor. By calculating the travel time and the speed of sound, the distance can be calculated.

Ultrasonic sensors are a great solution for the detection of clear objects. For liquid level measurement, applications that use infrared sensors, for instance, struggle with this particular use case because of target translucence.

For presence detection, ultrasonic sensors detect objects regardless of the color, surface, or material (unless the material is very soft like wool, as it would absorb sound.)

To detect transparent and other items where optical technologies may fail, ultrasonic sensors are a reliable choice.

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

How to use the HC-SR04 Ultrasonic Sensor

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

Power the Sensor using a regulated +5V through the Vcc ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to be made high for 10uS and then turned off

This action will trigger an ultrasonic wave at frequency of 40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information the distance is measured as explained in the above heading.

Applications

- Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot, path finding robot etc.
- Used to measure the distance within a wide range of 2cm to 400cm
- Can be used to map the objects surrounding the sensor by rotating it
- Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water

Buzzer

1. Magnetic Transducer

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

2. Magnetic Buzzer (Sounder)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side.

The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency.

This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

Specifications:

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.
Direct Current Resistance: The direct current resistance is measured by ammeter directly.
Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.
Operating Temp: Keep working well between -30℃ and +70℃.
Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.
Dimension: Dimension affects frequency, small size result in high frequency.
Voltage: Depend on V o-p (1/2 square waves)
Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.
Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

How to choose a buzzer

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self drive type to choose. Because of the internal set drive circuit, the self drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

Figure 3.6 Buzzer

APR9600 voice features :

- ✓ Single-chip, high quality voice recording & playback solution
- o No external Ics required
- o Minimum external component

- o Random access of multiple fixed duration messages
- o Sequential access of multiple variable duration messages
- ✓ User friendly, easy to use operation
- o Programming & development systems not required
- o Level activated recording & edge activated playback switches
- ✓ Low power consumption
- o Operating current: 25mA typically
- o Standby current: 1uA typically
- o Automatic power down
- ✓ Chip enable pin for simple message expansion

General Description:

The APR9600 device offers true single chip voice recording, non volatile storage, and playback capability for 40 to 60 seconds.

The device supports both random and sequential access of multiple messages. Sample rates are user selectable, allowing designers to customize their design for unqiue quality and storage time needs. Integrated output amplifier, microphone amplifier, and AGC circuits greatly simplify system design. The device is ideal for use in portable voicce recorders, toys, and many other consumer and industrial applications.

APLUS integrated achieves these high levels of storage capability by using its proprietary analog/multilevel storage technology enables the APR9600 device to reproduce voice signals in their natural form. It eliminates the need for encoding and compression, which often introduce distortion.

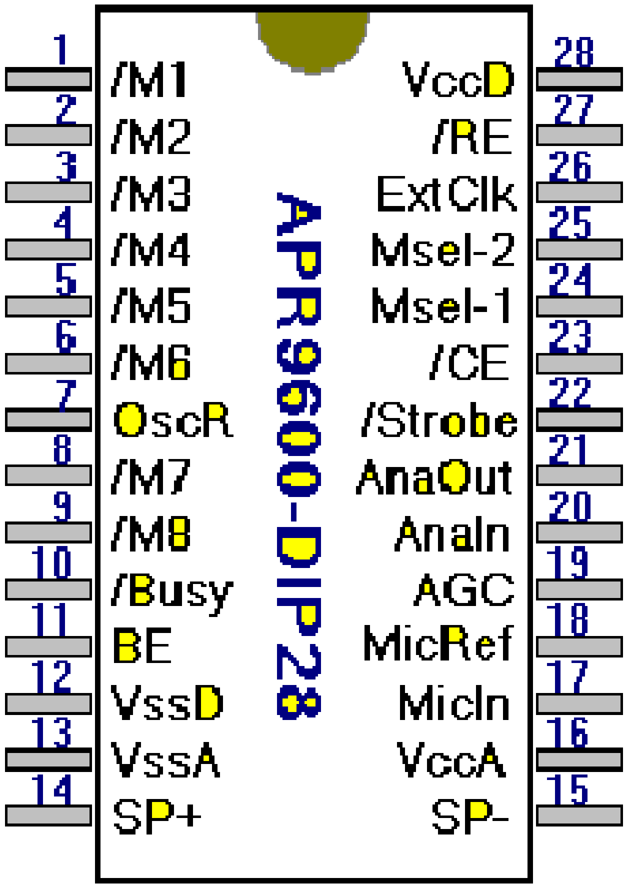

Figure : 3.7 The APR9600 DIP

Functional Description:

APR9600 block diagram is included in order to describe the device's internal architure. At the left hand side of the diagram are the analog inputs. A differntial microphone amplifier, including integrated AGC, is included on-chip for applications requiring use. The amplified microphone signals fed into the device by connecting the ANA_OUT pin to the ANA_IN pin through an external DC blocking capacitor. Recording can be fed directly into the ANA_IN pin through a DC blocking capacitor, however, the connection between ANA_IN and ANA_OUT is still required for playback. The next block encountered by the input signal is the internal anti alising filter.

The filter automatically adjust its response according to the sampling frequency selected so Shannon;s Sampling Theorem is satisfied. After anti aliasing filtering is accomplished the signal is ready to be clocked into the memory arry. This storage is accomplished through a combination of the sample and hold circuit and the analog write/read circuit. These circuits are clocked by either the internal oscillator or an external clock source. When playback is desired the previously stored recording is retrived from memory, low pass filtered, and amplified as shown on the right hand side of the diagram. The signal can be heard by connecting a speaker to the SP+ and SP- pins.

Chip wide management is accomplished through the device control block shown in the upper right hand corner. Message management is provided through the message control block represented in the lower center of the block diagram.

APR9600 Block Diagram:

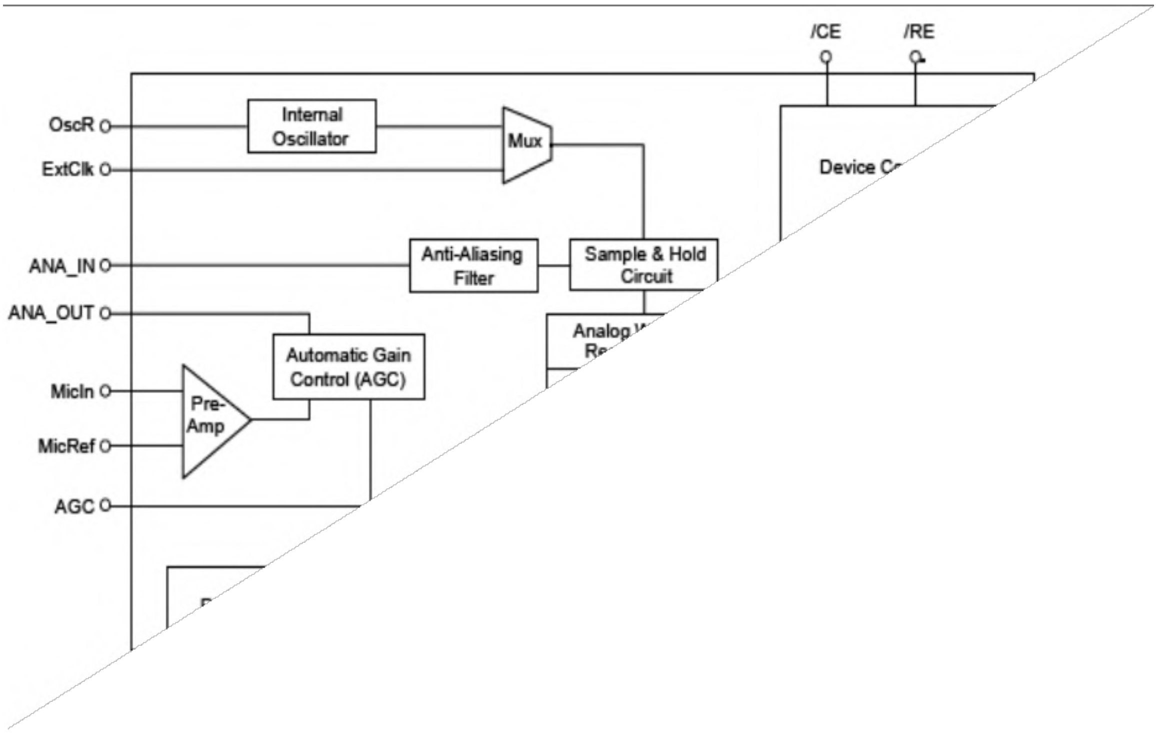

Figure :3.8

Message Management:

Message Management General Description:

Playback and record operations are managed by on-chip circuitry. These are several avaliable messaging modes depending upon desired operation. These message modes determine message management style, message length, and external parts count. Therefore, the designer must select the appropriate operating mode before behining the design.

Operating modes do not affect voice quality for information on factors affecting quality refer to the sampling rate & voice quality section. The device supports five message management modes (defined by the MSEL1, MSEL2 and /M8_OPTION pins).

Random access mode with 2, 4, or 8 fixed duration messages tape mode, with multiple variable duration messages, provides two options:

- Auto rewind
- Normal

Table 3.3 Modes

Mode	MSEL1	MSEL2	/M8_OPTION
Random access 2 fixed duration messages	0	1	Pull this pin to Vcc through 100k resistor
Random access 4 fixed duration messages	1	0	Pull this pin to Vcc through 100k resistor
Random access 8 fixed duration messages	1	1	The /M8 message trigger becomes input pin
Tape mode, Auto rewind operation	0	0	0
Tape mode, Normal operation	0	0	1

Modes cannot be mixed. Switching of modes after the device has recorded an intial message is not recommended. If modes are switched after an intial recording has been made some unpredictable message fragments from the previous mode may remain present, and be audible on playback, in the new mode. These fragments will disappear after a record operation in the newly selected mode. Table1 defines the recording necessary to choose the desired mode.

An important feature of the APR9600 message management capabilities is the ability prompt the user to change in the device's status through the use of "beeps" superimposed on the device's output. This feature is enabled by asserting a logic high level on the BE pin.

Random Access Mode:

Random access mode supports 2, 4, or 8 message segments of fixed duration. As suggested recording or playback can be made randomly in any of the selected messages. The length of each message segment is the total recording length available (as defined by the selected sampling rate) divided by the total number of segments enabled (as decoded in table1). Random access mode provides easy indexing to message segments.

Functional Description of Recording in Random Access Mode:

On power up, the deviceis ready to record or playback in amy of the enabled message segments. To record, /CE must be set low to enble the device and /RE must be set low to enable recording. You intiate recording by applying a low level on the message trigger pin that represents the message segment you intend to use. The message trigger pins are labeled /M1_MESSAGE - /M8_OPTION on pins 1-9 (excluding pin 7) for message segments 1-8 respectively.

Note: Message trigger pins of M1_MESSAGE, /M2_NEXT, /M7_END, and /M8_OPTION, have expanded names to represent the different functionality that these pins assume in the other pins with the same functinality as /M3, /M4, /M5, and /M6. For a more through explanationtable that appears. When actual recording begins the device responds with a single beep (if the BE pin is high to enable the beep tone) at the speaker outputs to indicate that it has started recording. Recording continues as long as the message pin stays low. The rising edge of the same message trigger pin during record stops the recording operation (indicated with a single beep). If the message trigger pin is held low beyond the end of the maximum allocated duration, recording stops automatically (indicated with two beeps), regardless of the state of the message trigger pin. The chip then enters low power mode until the message trigger pin returns high. After the message trigger pin returns to high, the chip enters standby mode. Any subsequent high to low transition on the same message trigger pin will intiate recording from the beginning of the same message segment. The entire previous message is then overwritten by the new message, regardless of the duration of the new message. Transition on any other message trigger pin orthe /RE pin during the record operation are ignored until after the device enters standby mode.

Functional Description of Playback Random Access Mode:

On power up, the device is ready to record or playback, in any of the enabled message segments. To playback, /CE must be set low to enable thye device and /RE must be set high to disable recording & enable playback. You intiate playback by applying a high to low edge on the message trigger pin that represents the message segment you intended to playback. Playback will continue until the end of the message is reached. If a high to low edge occurs on the same message trigger pin during playback, playback of the current message stops immediately. If a different message trigger pin pulses during playbck, playback of the current message stops immediately (indicated by one beep) and playback of the new message segment begins.

A delay equal to 8,400 cycles of the sample clock will be encountered before the device staqrts playing the new meesage. If a message trigger pin is held low, the selected message is playback repeatedly as long as the trigger pin stays low. A period of silence, of a duration equal to 8,400 cycles of the sampling clock, will be inserted during looping as an indicator to the user of the transition between the end and the beginning of the message.

Tape Mode:

Tape mode manages messages sequentially much like traditional cassette tape recorders. Within tape mode two options exist, auto rewind and normal. Auto rewind mode configures the device to automatically rewind or playback of the message. In tape mode, using either option, messages must be recorded or playback sequentially, much like a traditional cassette tape recorder.

Function Description of Recording in Tape Mode using the Auto Rewind Option:

On power up, the device is ready to record or playback, starting at the first address in the memory arry. To record, /CE must be set low to enable the device and /RE must be set low to enable recording. A falling edge of the /M1_MESSAGE pin initiates voice recording (indicated by one beep).A subsequent rising edge of the /M1_MESSAGE pin during recording stops the recording (also indicated by one beep). If the M1_MESSAGE pin is held low beyond the end of the available memory, recording will stop automatically (indicated by two beeps). The device will then assert a logic low on the /M7_END pin until the /M1 Message pin is released.

The device returns to standby mode when the /M1_MESSAGE pin goes high again.After recording is finished the device will automatically rewind to the beginning of the most recently recorded message and wait for the next user input. The auto rewind function is convenient because it allows the user to immediately playback and review the message without the need to rewind. However, caution must be practiced because a subsequent record operation will overwrite the last recorded message unless the user remembers to pulse the /M2_Next pin in order to increment the device past the current message. A subsequent falling edge on the /M1_Message pin starts a new record operation, overwriting the previously existing message. You can preserve the previously recorded message by using the /M2_Next input to advance to the next available message segment. To perform this function, the /M2_NEXT pin must be pulled low for at least 400 cycles of the sample clock.The auto rewind mode allows the user to record over the just recorded message simply by initiating a record sequence without first toggling the /M2_NEXT pin.

To record over any other message however requires a different sequence. You must pulse the /CE pin low once to rewind the device to the beginning of the voice memory.

The /M2_NEXT pin must then be pulsed low for the specified number of times to move to the start of the message you wish to overwrite. Upon arriving at the desired message a record sequence can be initiated to overwrite the previously recorded material.After you overwrite the message it becomes the last available message and all previously recorded messages following this message become inaccessible.

If during a record operation all of the available memory is used, the device will stop recording automatically,(double beep) and set the /M7_END pin low for a duration equal to 1600 cycles of the sample clock.Playback can be initiated on this last message, but pulsing the /M2_Next pin will put the device into an "overflow state".Once the device enters an overflow state any subsequent pulsing of /M1_MESSAGE or /M2_NEXT will only result in a double beep and setting of the /M7_END pin low for a duration equal to 400 cycles of the sample clock. To proceed from this state the user must rewind the device to the beginning of the memory array. This can be accomplished by toggling the /CE pin low or cycling power. All inputs, except the /CE pin,are ignored during recording.

Function Description of playback in Tape Mode using Auto Rewind Option:

On power-up, the device is ready to record or playback,starting at the first address in the memory array.Before you can begin playback, the /CE input must be set to low to enable the device and /RE must be set to high to disable recording and enable playback. The first high to low going pulse of the /M1_MESSAGE pin initiates playback from the beginning of the current message; on power up the first message is the current message. When the /M1_MESSAGE pin pulses low the second time, playback of the current Message stops immediately. When the /M1_MESSAGE pin pulses low a third time, playback of the current message starts again from its beginning. If you hold the /M1_MESSAGE pin low continuously the same message will play continuously in a looping fashion. A 1,540ms period of silence is inserted during looping as an indicator to the user of the transition between the beginning and end of the message.Note that in auto rewind mode the device always rewinds to the beginning of the current message. To listen to a subsequent message the device must be fast forwarded past the current message to the next message. This function is accomplished by toggling the /M2_NEXT pin from high to low. The pulse must be low for least 400 cycles of the sampling clock.

After the device is incremented to the desired message the user can initiate playback of the message with the playback sequence described above.

A special case exists when the /M2_NEXT pin goes low during playback. Playback of the current message will stop, the device will beep,advance to the next message and initiate playback of the next message. (Note that if /M2 Next goes low when not in playback mode, the device will prepare to play the next message, but will not actually initiate playback).

If the /CE pin goes high during playback, playback of the current message will stop, the device will beep,reset to the beginning of the first message, and wait for a subsequent playback command.When you reach the end of the memory array, any subsequent pulsing of /M1_MESSAGE or /M2_NEXT will only result in a double beep. To proceed from this state the user must rewind the device to the beginning of the memory array. This can be accomplished by toggling the /CE pin low or cycling power.

Functional Description of Recording in Tape Mode using the Normal Option:

On power-up, the device is ready to record or playback,starting at the first address in the memory array.Before you can begin recording, the /CE input must be set to low to enable the device and /RE must be set to low to enable recording. On a falling edge of the /M1_MESSAGE pin the device will beep once and initiate recording. A subsequent rising edge on the /M1 Message pin will stop recording and insert a single beep. If the M1_MESSAGE pin is held low beyond the end of the available memory, recording Stops automatically, and two beeps are inserted; regardless of the state of the /M1_MESSAGE pin. The device returns to the standby mode when the /M1_MESSAGE pin is returned high.A subsequent falling edge on the /M1_MESSAGE pin starts a new record operation in the memory array immediately fol- lowing the last recorded message, thus preserving the last recorded message.To record over all previous messages you must pulse the /CE pin low once to reset the device to the beginning of the first message. You
can then initiate a record sequence, as described above, to record a new message. The most recently recorded message will become the last recorded message and all previously recorded messages following this message will become inaccessible.

If you wish to preserve any current messages it is recommend that the Auto Rewind option be used instead of the Normal option. If the Normal option is necessary the following sequence can be used. To preserve current messages you must fast forward past the messages you want to keep before you can record a new message.

To fast forward when using the Normal option you must switch to play mode and listen to messages sequentially until you arrive at the beginning of the
message you wish to overwrite.

At this stage you should switch back to record mode and overwrite the desired message.The most recently recorded message will become the last recorded message and all previously recorded messages following this message will become inaccessible. All inputs, except /CE, are ignored during recording.

Functional Description of Playback in Tape Mode using the Normal Option:

On power-up, or after a low to high transition on /RE the device is ready to record or playback starting at the first address in the memory array. Before you can begin playback ofmessages, the /CE input must be set to low to enable the device and /RE must be set to high to enable playback.

The first high to low going pulse of the /M1_MESSAGE pin initiates playback from the beginning of the current message. When the /M1_MESSAGE pin pulses from high to low a second time, playback of the current message stops immediately. When the /M1_MESSAGE pin pulses from high to low a third time, playback of the next message starts again from the beginning. If you hold the /M1_MESSAGE pin low continuously, the current message and subsequent messages play until the one of the following conditions is met: the end of the memory array is reached, the last message is reached,the /M1_message pin is released. If the last recorded message has already played, any further transitions on the /M1_MESSAGE pin will initiate a double beep for warning and the /M7_END pin will go low. To exit this state you must pulse the /CE pin high and then low once during standby to reset the pointer to the beginning of the first message.

CHAPTER IV

CHAPTER IV

PROJECT IMPLEMENTATION

To complete the project successfully, the process has to done in a disciplined way step by step. Different steps involved in the implementing the project are

- Project Initiation.
- Project Planning.
- Project Execution.
- Project Monitoring and Controlling.
- Project Closing.

Stages in Detail

- **Project Initiation** : This step involves initializing the project i.e **Project initiation** is the first phase of the project management life cycle and in this stage, companies decide if the project is needed and how beneficial it will be for them. The two metrics that are used to judge a proposed project and determine the expectations from it are the business case and feasibility study.

- **Project Planning:** Project planning is a discipline for stating how to complete a project within a certain timeframe, usually with defined stages, and with designated resources. One view of project

- Planning divides the activity into: Setting objectives (these should be measurable) **Planning** the **schedule**. Making supporting plans.

- **Project Execution: Project execution** is the stage of the **project** where everything your team has planned is put into action.

- **Project Monitoring and Controlling:**The **Monitoring and Controlling** process oversees all the tasks and metrics necessary to ensure that the approved and authorized **project** is within scope, on time, and on budget so that the **project** proceeds with minimal risk. **Monitoring and Controlling** process is continuously performed throughout the life of the **project.**

- **Project Closing**: This is the last step in implementing stages. In this phase results are obtained if all above stages are implemented perfectly.

Results

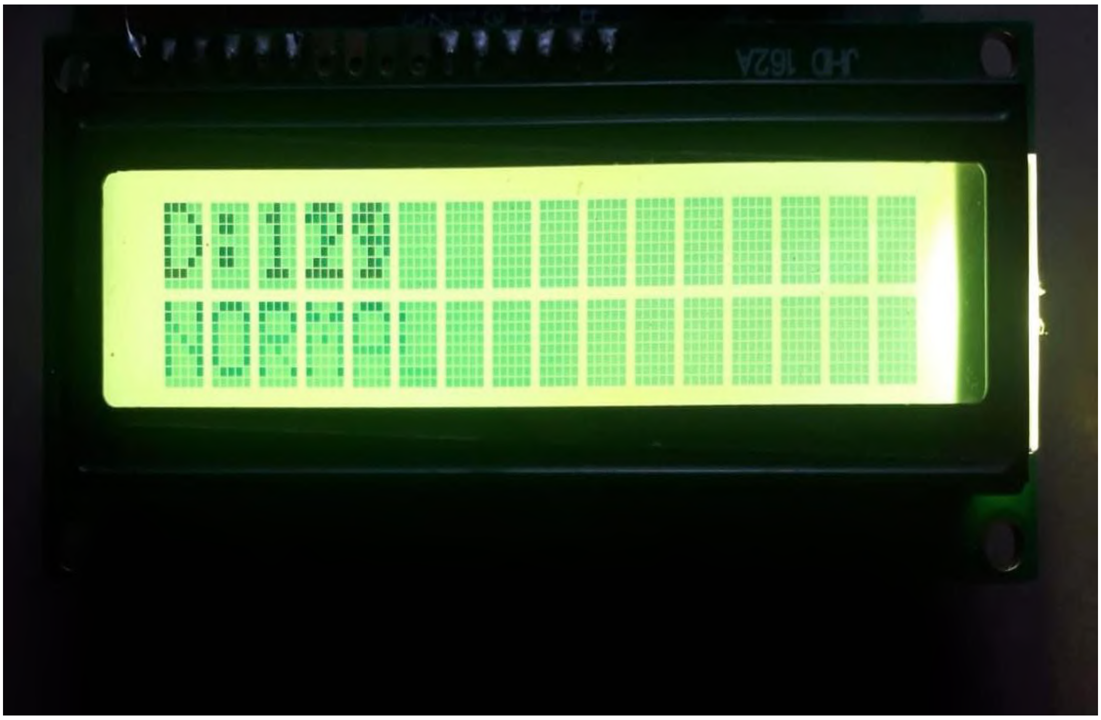

Figure 4.2.2 : When obstacle is not detected

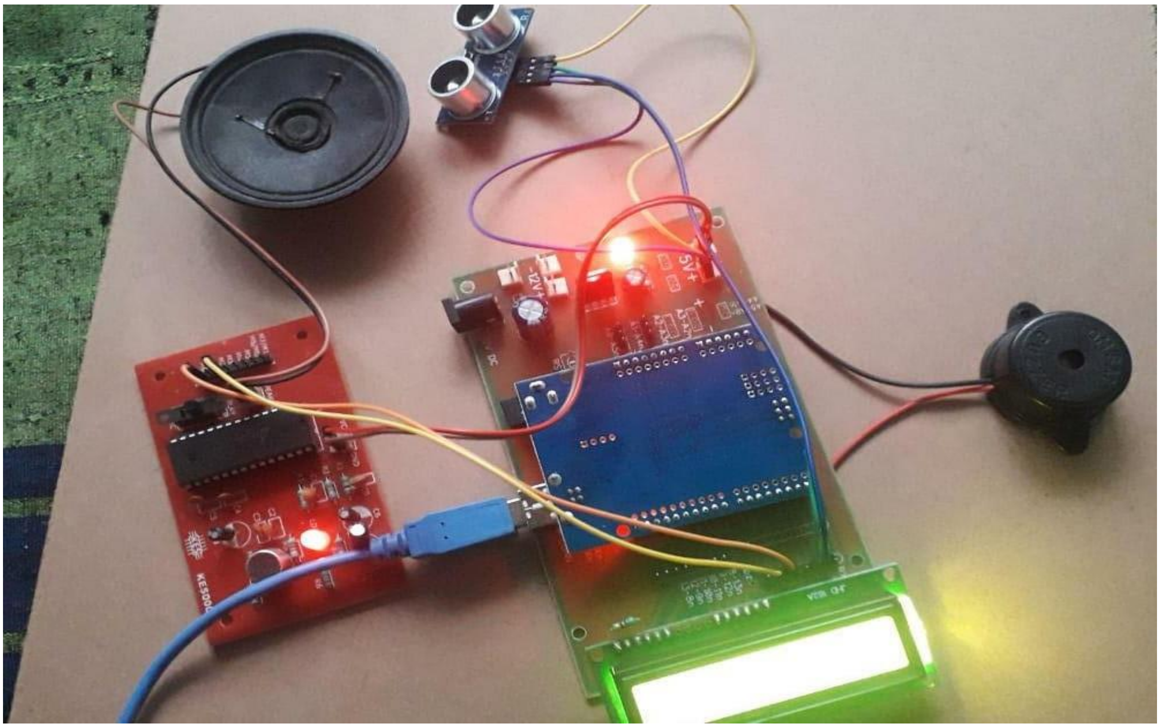

Figure 4.2.3 : Overall Output of the Project

CHAPTER V

CHAPTER V
PROJECT TESTING

5.0 Overview of Testing Methods

- It is observed that the performance difference between the estimated and the actual performance is very minute.
- It worked better for all the inputs provided.
- Estimated result is obtained.
- No Errors Occurred during the functioning of the kit.
- The person using the kit was able to know the presence of obstacles infront of him by using the stick.
- Not only the blind person but also person who is both blind and deaf can use this kit as we are having buzzer which vibrats when the obstacle is found.

DECLARATION

We, the student of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: 2017 – 2021, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "QUADRIPLEGICS WHEELCHAIR CONTROL BY HEAD MOTION USING ACCELOROMETER" is the outcome of our own bona fide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Mr. S. Shivakumar Reddy(17K81A0449)

Mr. S. Satish Kumar Reddy(17K810450)

Ms. S. Rajitha(17K81A0451)

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to our **College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr. P. Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr. B. HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We proud to record that had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr. A. ANAND, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we highly grateful and obliged to our project guide **Mr. Joel Josephson, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

The problems faced by paralyzed and handicapped people are many among which the move any of their body parts except head. This robotic wheelchair project aims at designing a wheelchair that will work crucial one is independent mobility. They need external help from other people to execute and perform their daily activities. Electric and advanced wheelchairs are manufactured and designed with an aim to aid paraplegics. But such electric wheelchairs cannot by patients having high range of impairment like persons who cannot on the basis of head movement of the patient. For normal movement of wheelchair we use hand force.

Traditional Wheelchairs though have certain limitations with the flexibility, heavy weight of the chair and limited functions. Tremendous developments have been made in the field of wheelchair technology. Be that as it may, even these noteworthy advancements couldn't help the quadriplegics to explore wheelchair freely. Medical gadgets intended to support the Paraplegic and Quadriplegic patients are exceptionally muddled, once in a while accessible and costly. We go for planning a straightforward financially effective programmed wheelchair utilizing MEMS technology for quadriplegics with head and neck versatility. The control system interprets the situation of the user's head into speed and directional control of the wheelchair. The system is divided into two main units: MEMS Sensor and programmed Arduino Micro Controller. The MEMS sensor senses the change in direction of head and likewise the signal is given to microcontroller. Depending on the direction of the Acceleration, microcontroller controls the wheel chair directions like LEFT, RIGHT, FRONT, and BACK with the aid of DC motors.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Introduction:

Now a days, many elderly and physically disabled people need wheelchairs to make their personal mobility easy so for them wheelchair is a suitable device. By using wheelchair they can move from one place to another effortlessly. By using standard wheelchairs, it requires another person's help or by self-propelling. These problems can be overcome by using electric wheelchairs or joystick controlled wheelchair. Generally, Electric Wheelchairs cost ranges from 50000 and more [1]. This Head-motion controlled Wheelchair is way cheaper than Electric or Joystick controlled wheelchair available in market. The Head-motion Controlled Wheelchair is far better than conventional Wheelchairs. The conventional joystick wheelchair requires hand motion for controlling which are not suitable for physically handicapped peoples. But Head motion controlled wheelchair is suitable for those whose hands or fingers are paralyzed as it requires head motion. Rather than these, the head-motion controlled wheelchair is far cheaper than joystick wheelchairs. This paper investigates the research work of Head-motion controlled wheelchair for the user interaction. Gesture type, interface, technology used, user types, issues, problems, advantages and final result have been listed and described to give background of Wheel Chair based technology development.

Quadriplegics are people who can't utilize any of the furthest points. The purposes behind such diminished movement prospects can be unique: stroke, joint pain, hypertension, degenerative sicknesses of bones and joints and instances of loss of motion and birth abandons. Likewise, quadriplegia shows up as a result of mishaps or age. The patients with such serious incapacities can't play out their ordinary activities, for example, taking care of, and development through space. Contingent upon the seriousness of the in capacity, a patient can hold opportunity of development to a specific level by utilizing diverse clinical gadgets. Versatility has gotten significant for a decent personal satisfaction.

Arranging a system with free versatility for such debilitated people is our point in this endeavour. We target planning a straightforward savvy wheelchair constrained by head level-opponent which additionally incorporates patient monitoring framework and obstacle detection framework. This wheelchair incorporates ADXL335 sensor, battery, dc motor, and Arduino uno microcontroller. ADXL335 which is used for perceiving the tilt. This sensor finds the tilt and alters the Course of the wheel chair relying upon tilt.

1.2 OBJECTIVES OF THE STUDY:

The main objective of the project is to design a wheelchair tilt communicator system that could operate the wheelchair of the handicapped person with the help of tilt of head movements. This system could be used by physically disabled persons who cannot move their hands or legs but make head and eye motions. This wheelchair could be operated in any direction using head tilt movements by the handicapped person. Design and development of Head motion controlled wheelchair has been achieved using tilt sensors and wireless modules. The system is implemented practically and works well with a person sitting on it. This wheelchair is aimed to be designed at a lower cost as compared to the other versions available in the market. The head motion controlled wheelchair designed using tilt communicator system turns out to be a great use for quadriplegic patients and disabled people having more than 45% or more disability as this could be operated easily through head gestures.

1.3 SCOPE OF THE STUDY:

- In the race of man versus machine head motion controlled system comes as an example companionship of man and machine.

- To avoid physical hardship an accelerometer is used due to which the slight movement of head turns the wheelchair into the desired direction. It is designed to be characterized by low price and higher reliability.

- Quadriplegics are persons who are not able to use any of the extremities. The reasons for such decreased motion possibilities can be different: stroke, arthritis, high blood pressure, degenerative diseases of bones and joints and cases of paralysis and birth defects. Also, quadriplegia appears as a consequence of accidents or age. The patients with such severe disabilities are not able to perform their everyday actions, such as: feeding, toilette usage and movement through space.

- Depending on the severity of the disability, a patient can retain freedom of movement to a certain level by using different medical devices.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- ARDUINO UNO
- ACCELOROMETER (ADXL335)
- DC MOTORS
- MOTOR DRIVER(L293D)
- LCD (16*2)
- BATTERY

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the toll booth system with better efficiency, with less time delay and the results were also satisfactory and we successfully got the output in mobile telnet app and LCD screen. We would like to improve the project in future for further developments.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

When an unfortunate event affects the motor capacity of a person, it is necessary to use devices like wheelchairs that offer a means of displacement for patients with motors problems of the lower limbs. Tremendous leaps have been made in the field of wheelchair technology However, even these significant advances haven't been able to help quadriplegics field of wheelchair technology. However, even these significant advances haven't been able to help quadriplegics navigate wheelchair unassisted. Some patients that cannot manipulate the wheelchair with their arms due to a lack of force

2.2 REVIEW ON RELATED LITERATURE:

According to research paper, "HAND GESTURE RECOGNITION: A LITERATURE REVIEW"[2], it focuses on human computer interaction. It is a survey of recent hand gesture recognition systems. Key issues of hand gesture recognition system are presented with challenges of gesture system. Review methods of recent postures and gestures recognition system presented as well. Orientation histogram method applied in this have some problems which are; similar gestures might have different orientation histograms and different gestures could have similar orientation histograms, besides that, the proposed method achieved well for any objects that dominate the image even if it is not the hand gesture.

- According to research paper, titled "IR Sensor-Based Gesture Control Wheelchair" [3] published in IEEE, it works on the principle of gesture recognition by using Infrared sensors. In this method, IR sensors are used for identifying the simple gestures to control the powered wheelchair to move in any direction. In the proposed prototype system, a gesture pad that includes IR sensors, MCU and power management circuit is designed for gesture recognition and identification and a controller for driving motors is implemented. The main problem that comes with IR is during daylight, its sensitivity is reduced, and hence causing problem for processing the further programs. And it is difficult to recognize exact gestures using IR sensors
- In research paper published, entitled, "Electric Powered Wheelchairs",[4] its aim was to review the concepts and previous work on velocity control, traction control, suspension control, stability control, stair-climbing wheelchairs, and wheelchair navigation. The information gathered in this study is

intended to promote awareness of the status of contemporary powered wheelchair control technology and increase the functional mobility of people who use EPWs. But, it has a major disadvantage of cost efficiency. It's quite expensive as compared to normal wheelchair.

• In an article [5], from Int. Journal of Engineering Research and Applications, aims at gesture control wheelchair using hand movements. According to this article, with hand movements, wheelchair's direction can be changed. But it has disadvantage over paralyzed patients, who cannot move their hands.

• We are using accelerometer, mounted to the earpiece, so that with movement in head, or say, by moving

2.3 CONCLUSION ON REVIEWS:

The existing systems include hand gesture based, accelerometer and voice controlled systems etc. The hand gesture based system used the transfer of hand gesture information commands to move the wheel chair. The accelerometer and voice controlled system used voice recognition kit and MEMS motion sensor to drive the wheel chair.

The issues with the existing system are:

1) Unable to adapt to external conditions.

2) Less identification accuracy.

3) Classification techniques employed are complex.

4) Time consuming and costly.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

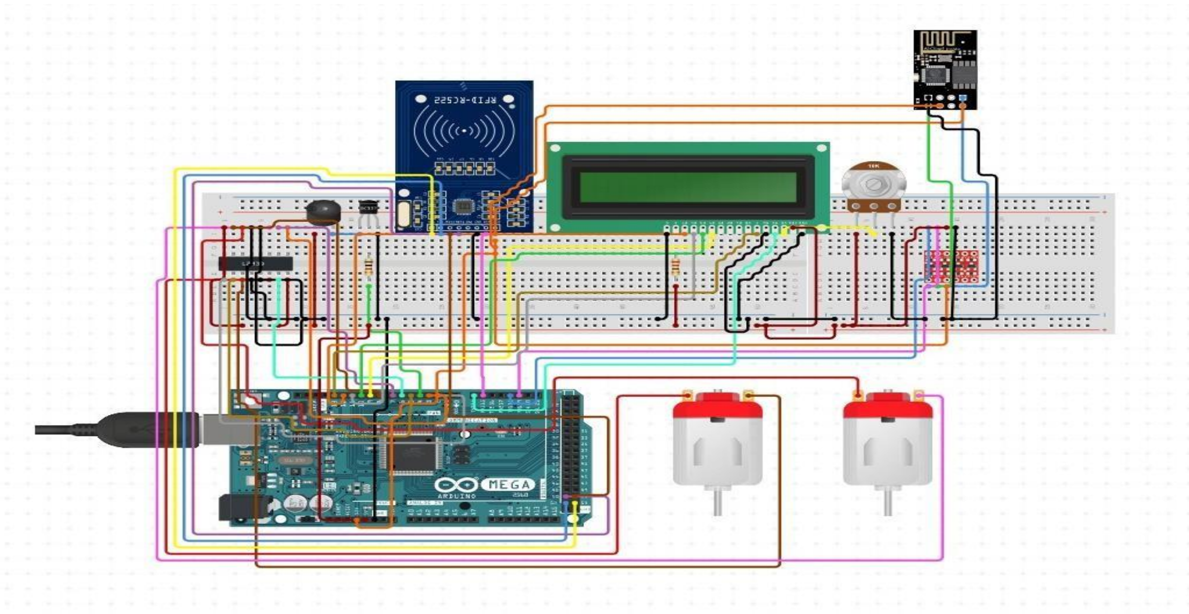

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

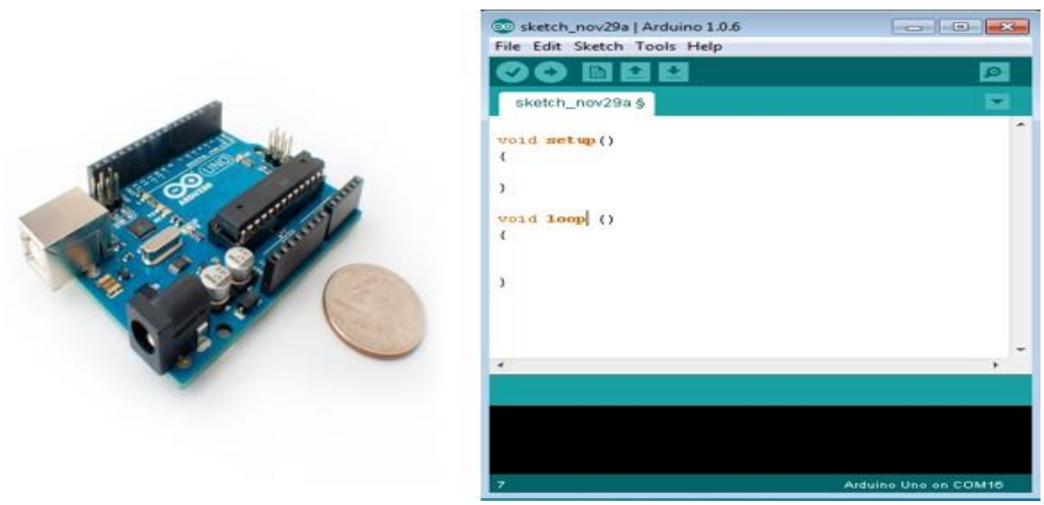

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

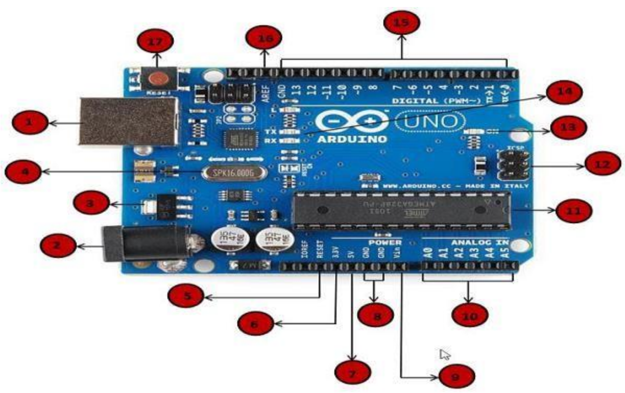

Fig.3.2.1.3 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC

	your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.4: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

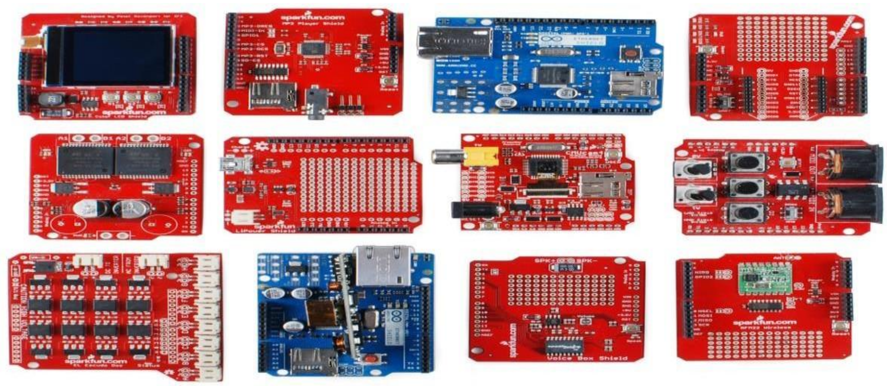

Fig.3.2.1.5: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

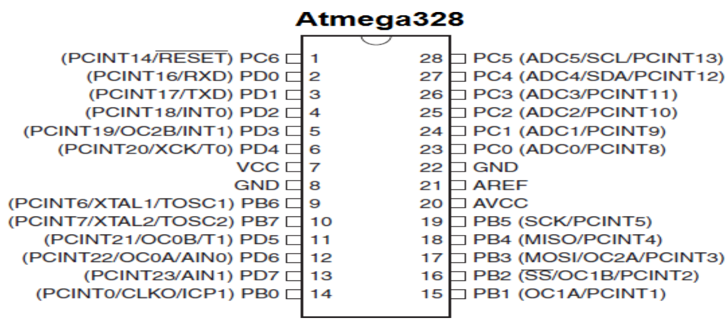

Fig.3.2.1.6 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

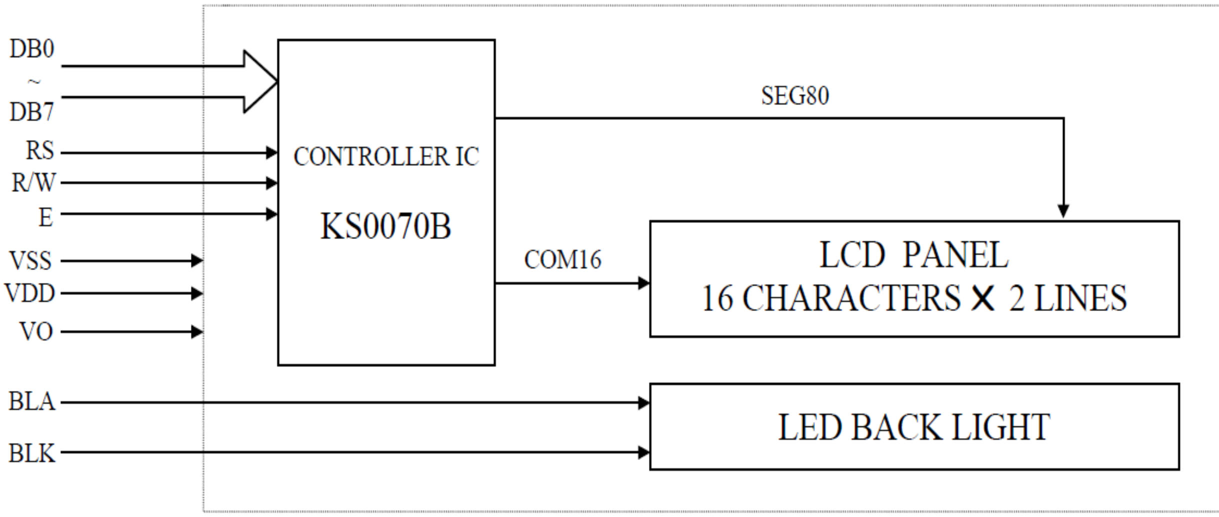

fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

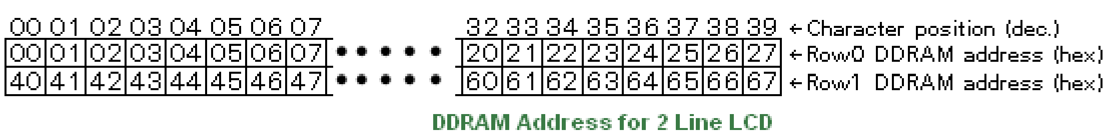

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible

- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 L293D

3.2.3.1 INTRODUCTION

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output

L293D is basically a motor driver or controller. It has two built-in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g. stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc. Its common real-life applications include stepping motor drivers, relay drivers, DC motor drivers etc.

L-293D motor driver/controller is shown in the figure given below.

Fig. 3.2.3.1 L293D Motor Driver

3.2.3.2 L293D PINS:

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

3.2.3.3 L293D PIN FUNCTIONS:

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

Table 3.2.3.3 L293D Pin Functions

3.2.3.4 L293D PINOUT:

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.

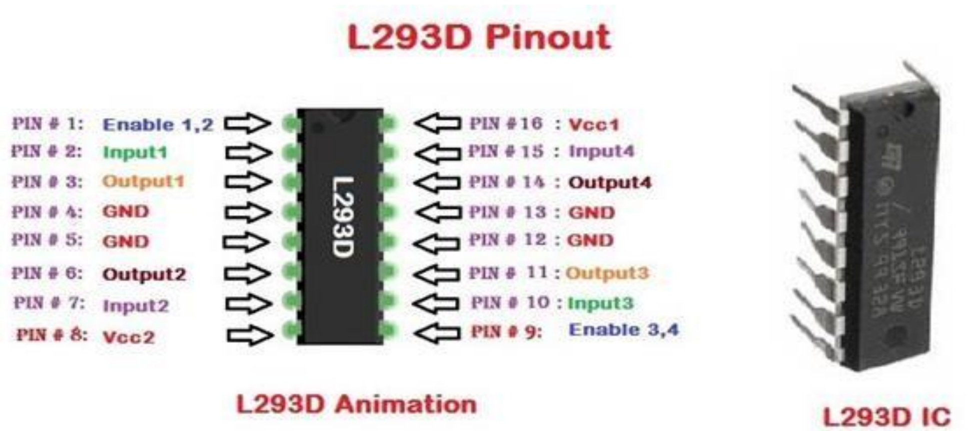

Fig. 3.2.3.4 L293D Pinout

3.2.4 MOTOR

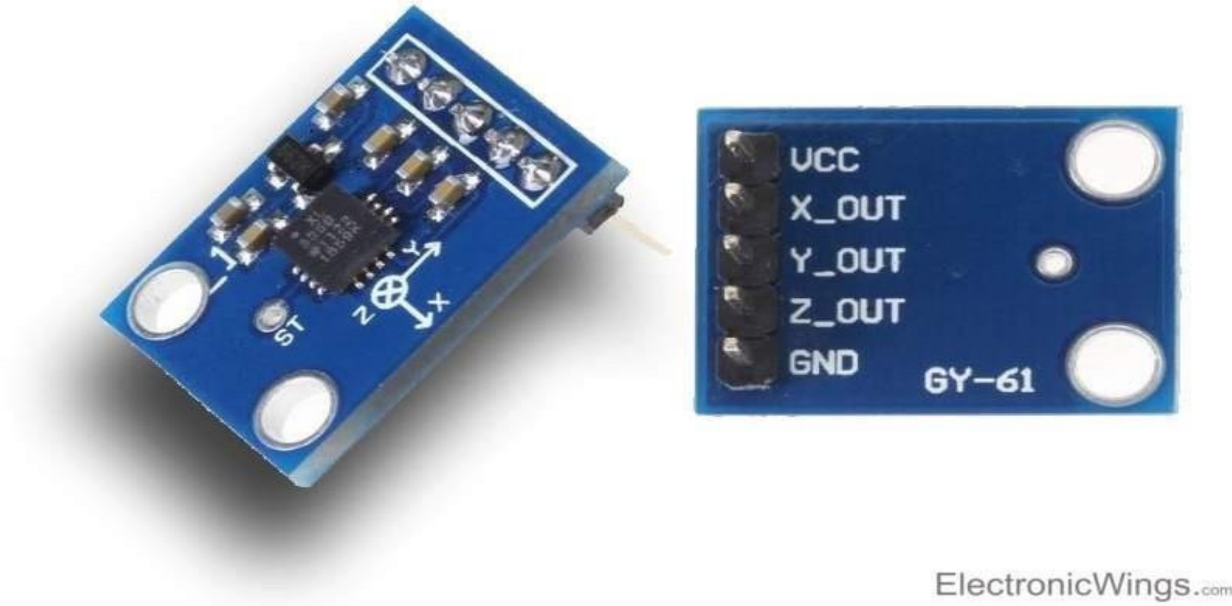
Motors usually operates on this higher current. L-293D has to built-in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g. relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

3.2.5 ACCELOROMETER:

3.2.5.1 INTRODUCTION:

An accelerometer is a device that measures the vibration, or acceleration of motion of a structure. The force caused by vibration or a change in motion (acceleration) causes the mass to "squeeze" the piezoelectric material which produces an electrical charge that is proportional to the force exerted upon it. Since the charge is proportional to the force, and the mass is a constant, then the charge is also proportional to the acceleration. These sensors are used in a variety of ways from space stations to handheld devices, and there's a good chance you already own a device with an accelerometer in it. For example, almost all smartphones today house an accelerometer. They help the phone know whether it undergoes acceleration in any direction, and it’s the reason why your phone’s display switches on when you flip it. In an industry setting, accelerometers help engineers understand a machine's stability and enable them to monitor for any unwanted forces/vibrations
An accelerometer is a **transducer** that is used to measure the physical or measurable acceleration that is made by an object. Co-ordinate acceleration cannot be measured using this device.

An accelerometer is an electro-mechanical device that is used to measure the specific force of an object, a force obtained due to the phenomenon of weight exerted by an object that is kept in the frame of reference of the accelerometer. In the case of static acceleration, the device is mainly used to find the degrees at which an object is tilted with respect to the ground. In dynamic acceleration, the movement of the object can be foreseen.



.32

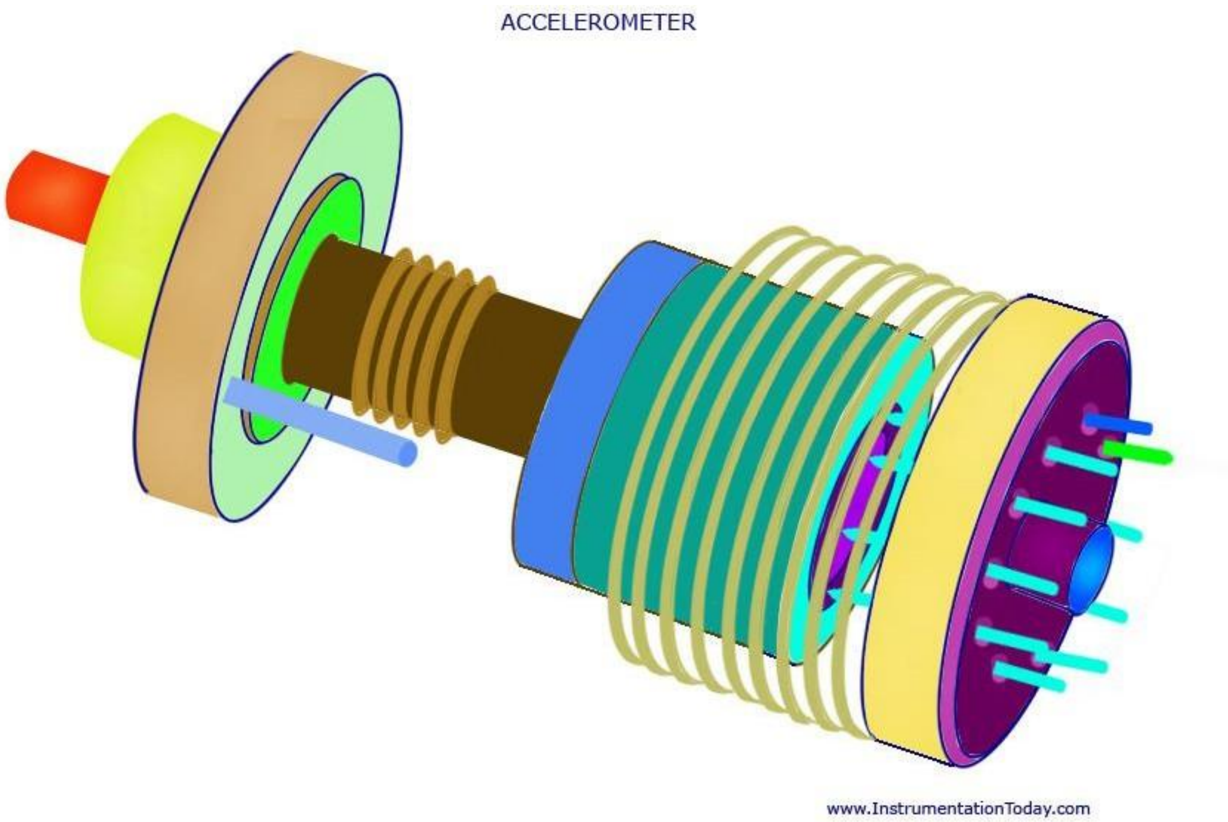


Fig.3.2.5.1: Accelorometer

3.2.5.2. Working

The most commonly used device is the piezoelectric accelerometer. As the name suggests, it uses the principle of piezoelectric effect. The device consists of a piezoelectric quartz crystal on which an accelerative force, whose value is to be measured, is applied.

Due to the special self-generating property, the crystal produces a voltage that is proportional to the accelerative force. The working and the basic arrangement is shown in the figure below.

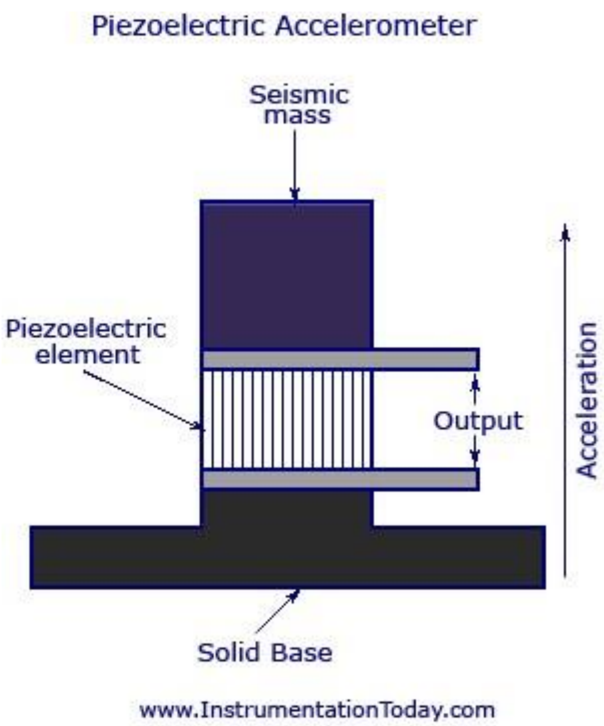

Fig 3.2.5.2. Piezoelectric Accelerometer

As the device finds its application as a highly accurate vibration measuring device, it is also called a vibrating sensor. Vibration sensors are used for the measurement of vibration in bearings of heavy equipment and pressure lines. The piezoelectric accelerometer can be classified into two. They are high impedance output accelerometer and low impedance accelerometer.

In the case of high impedance device, the output voltage generated in proportion to the acceleration is given as the input to other measuring instruments. The instrumentation process and signal conditioning of the output is considered high and thus a low impedance device cannot be of any use for this application. This device is used at temperatures greater than 120 degree Celsius.

The low impedance accelerometer produces a current due to the output voltage generated and this charge is given to a FET transistor so as to convert the charge into a low impedance output. This type of accelerometers is most commonly used in industrial applications.

3.2.5.3. Types

In industrial applications, the most commonly used components to convert the mechanical action into its corresponding electrical output signal are piezoelectric, piezoresistive and capacitive in nature. Piezoelectric devices are more preferred in cases where it is to be used in very high temperatures, easy mounting and also high frequency rang e up to 100 kilohertz. Piezoresistive devices are used in sudden and extreme vibrating applications. Capacitive accelerometers are preferred in applications such as a silicon-micro machined sensor material and can operate in frequencies up to 1 kilohertz. All these devices are known to have very high stability and linearity. Nowadays, a new type of accelerometer called the **Micro Electro-Mechanical System (MEMS) Accelerometer** is being used as it is simple, reliable and highly cost effective. It consists of a cantilever beam along with a seismic mass which deflects due to an applied acceleration. This deflection is measured using analog or digital techniques and will be a measure of the acceleration applied.

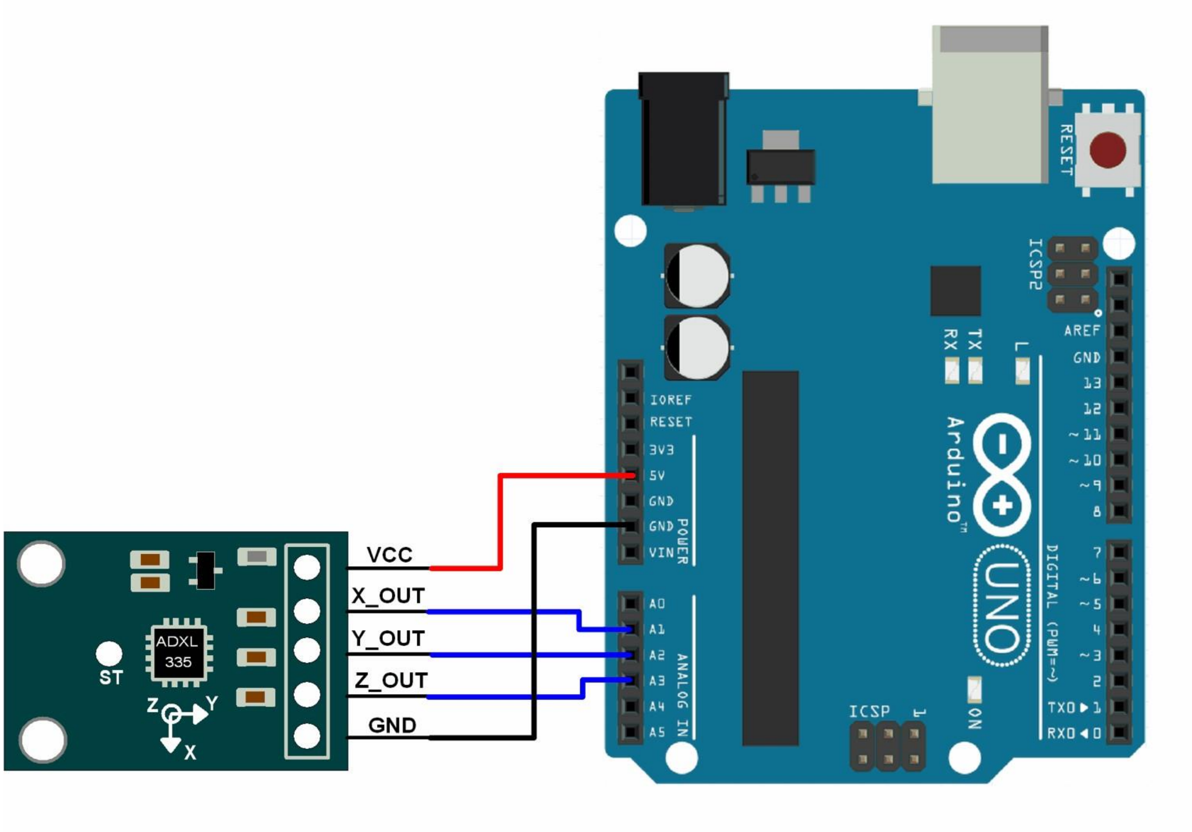

Fig 3.2.5.3. Interfacing accelerometer with Arduino uno

3.2.5.4. Accelerometer Specifications

Frequency Response – This parameter can be found out by analyzing the properties of the quartz crystal used and also the resonance frequency of the device.

1. Accelerometer Grounding – Grounding can be in two modes. One is called the Case Grounded Accelerometer which has the low side of the signal connected to their core. This device is susceptible to ground noise. Ground Isolation Accelerometer refers to the electrical device kept away from the case. Such a device is prone to ground produced noise.

2. Resonant Frequency – It should be noted that the resonant frequency should be always higher the the frequency response.

3. Temperature of Operation – An accelerometer has a temperature range between -50 degree Celsius to 120 degree Celsius. This range can be obtained only by accurate installment of the device.

4. Sensitivity – The device must be designed in such a way that it has higher sensitivity. That is, even for a small accelerative force, the electrical output signal should be very high. Thus a high signal can be measured easily and is sure to be accurate.
5. Axis – Most of the industrial applications requires only a 2-axis accelerometer. But if you want to go for 3D positioning, a 3-axis accelerometer will be needed.
6. Analog/Digital Output – You must take special care in choosing the type of output for the device. Analog output will be in the form of small changing voltages and digital output will be in PWM mode.

3.2.5.5. Device Selection

Selection of the device depends on the following factors.

1. Selection depends on the range of frequency you need.
2. Depends on the size and shape of the object whose acceleration is to be measured.
3. Whether the measurement environment is dirty or clean.
4. Depends on the range of vibration that is to be measured.
5. Depends on the range of temperature in which the device will have to work.
6. Depends on whether the device is to be case grounded or grounded isolated.

3.2.5.6. Applications

1. Machine monitoring.
2. Used to measure earthquake activity and aftershocks.
3. Used in measuring the depth of CPR chest compression.
4. Used in Internal Navigation System (INS). That is, measuring the position, orientation, and velocity of an object in motion without the use of any external reference.
5. Used in airbag shooting in cars and vehicle stability control

6. Used in video games like PlayStation 3, so as to make the steering more controlled, natural and real.

7. Used in camcorder to make images stable.

3.2.6 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.6.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are

completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handy board, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and

wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other micro controller plat forms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++

libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

- Open source and extensible hardware - The plans of the Arduino boards are published under

a Creative Commons license, so experienced circuit designers c an make their own version
Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-
This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.
When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

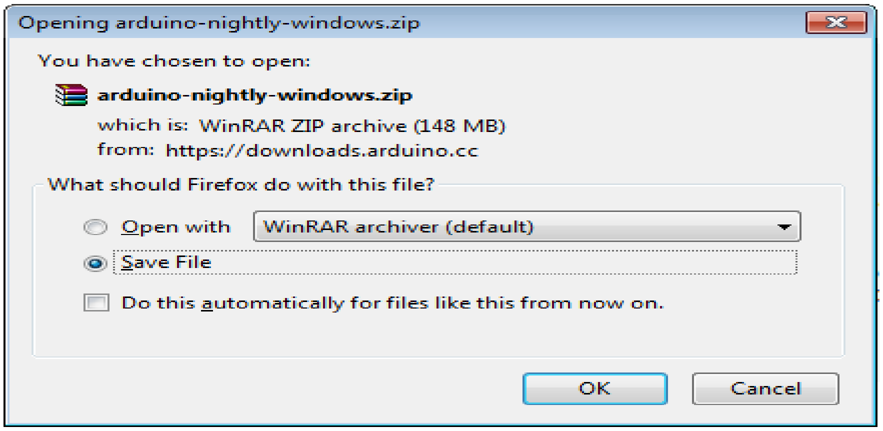

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

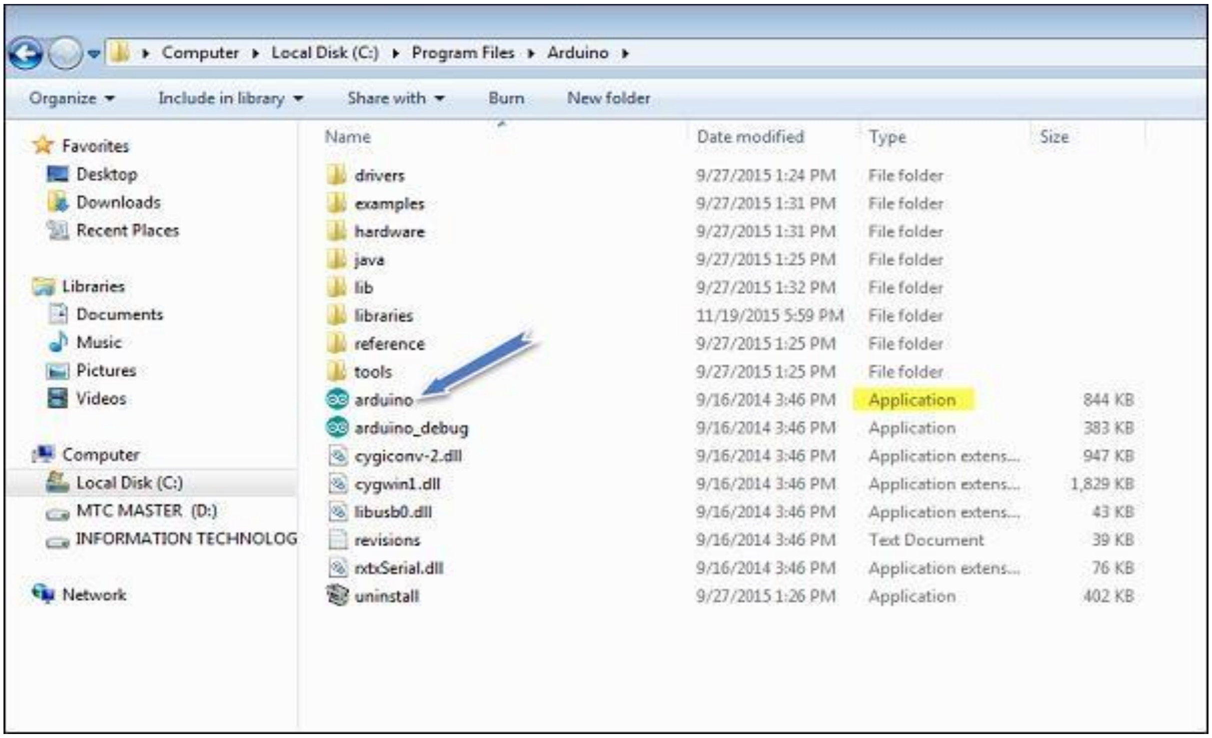

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

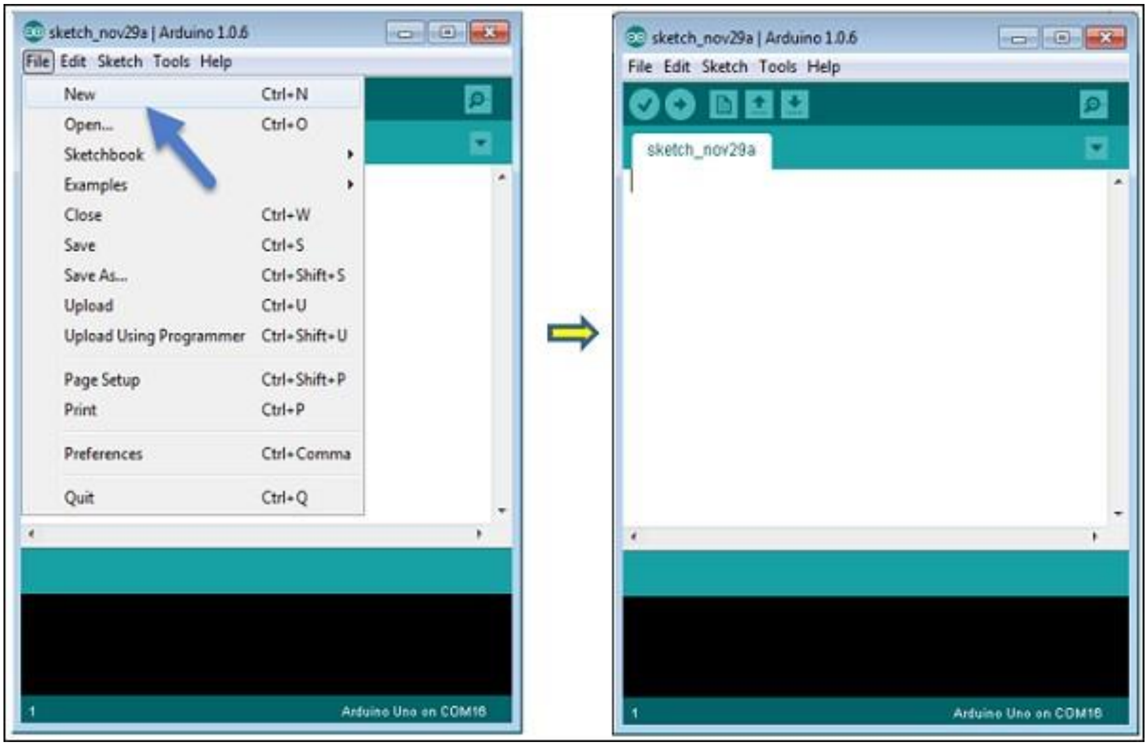

Fig. 3.2.6.4.5 Open your first project.

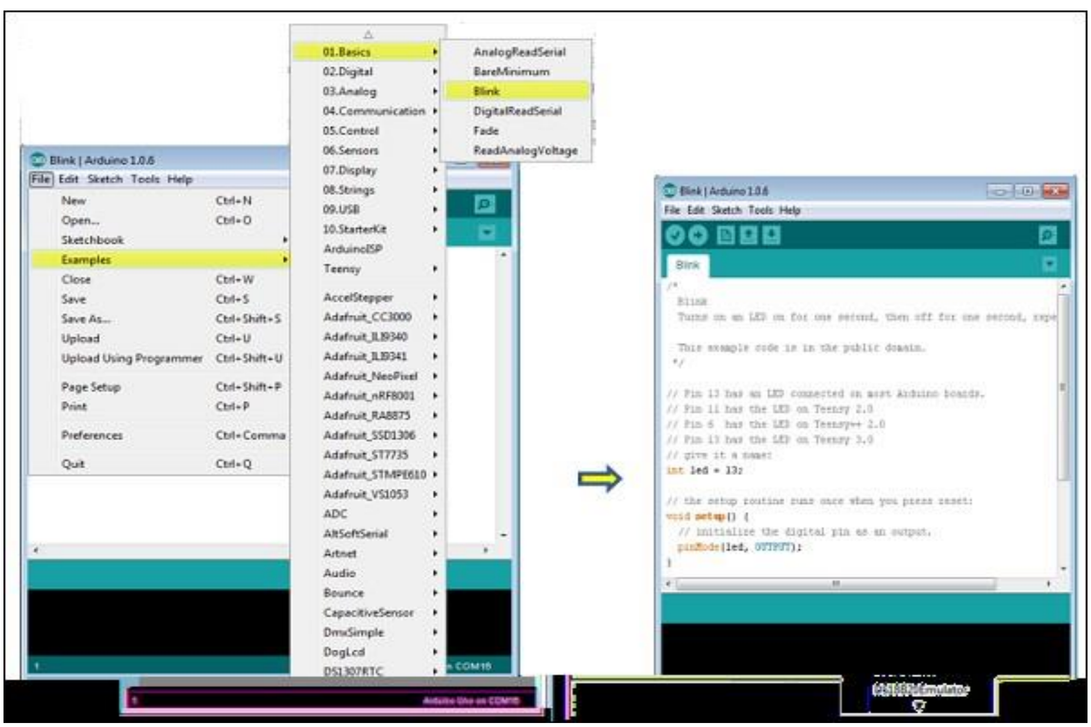
To open an existing project example, select File → Example → Basics → Blink.



.

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

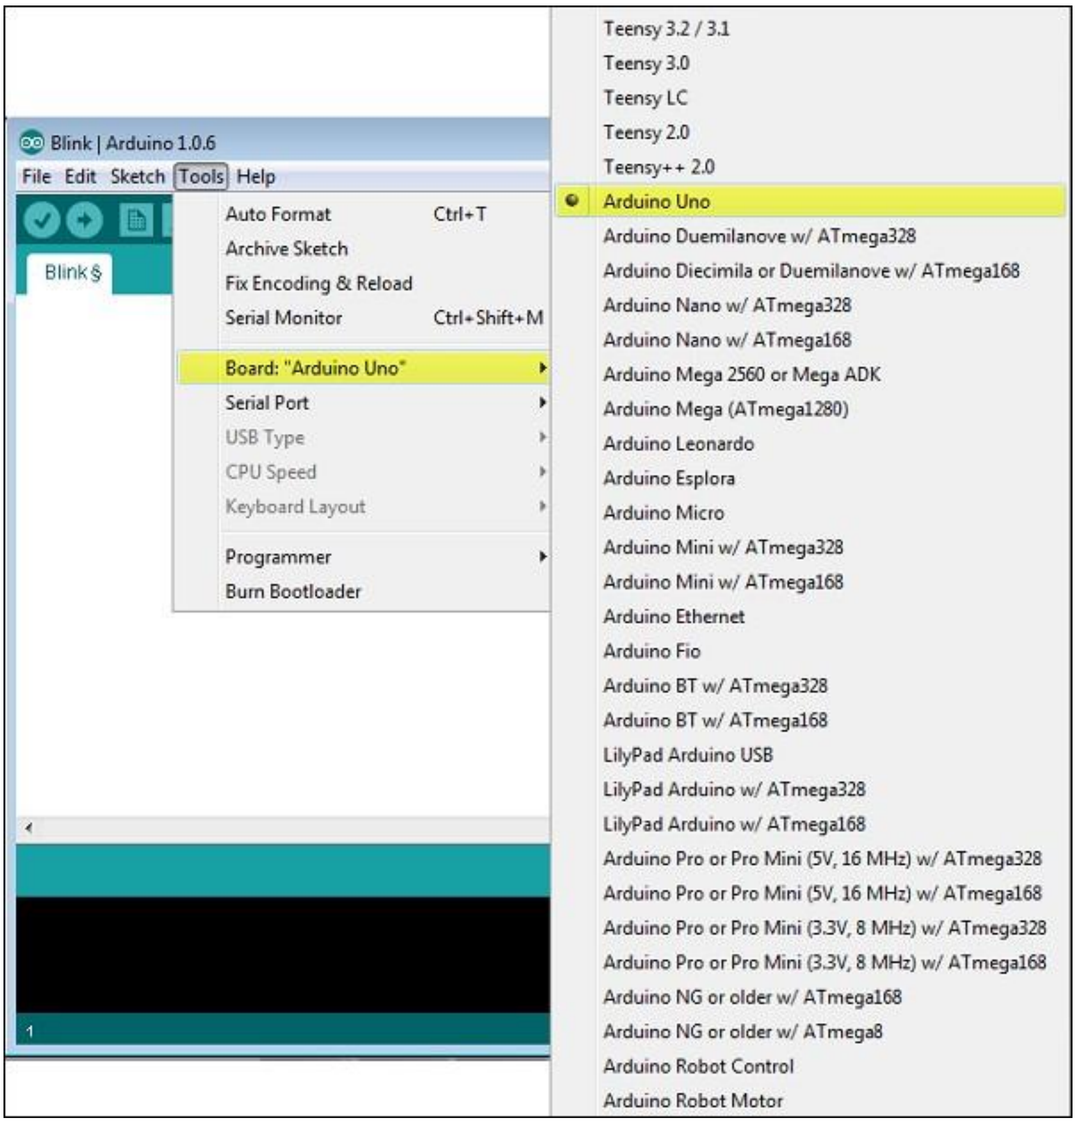


Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

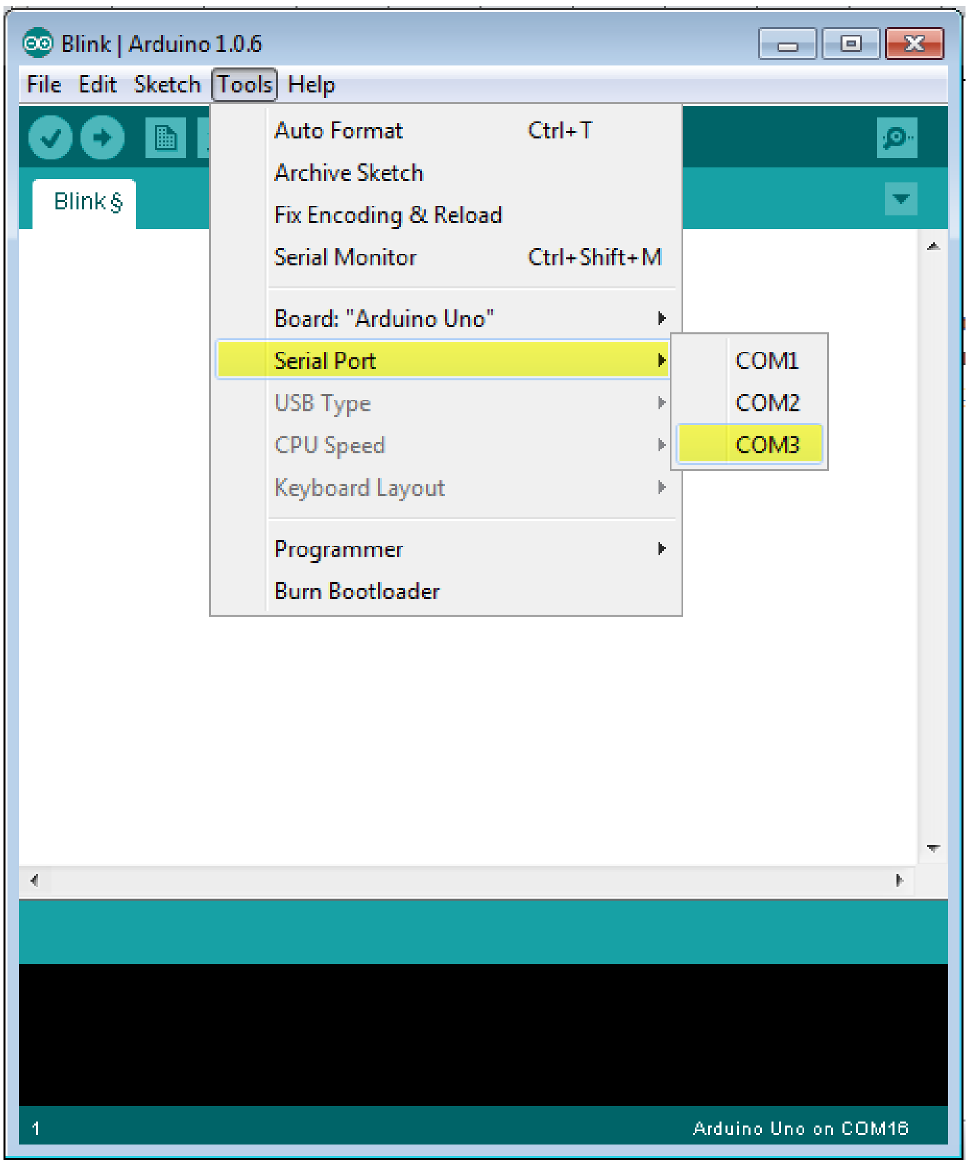

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

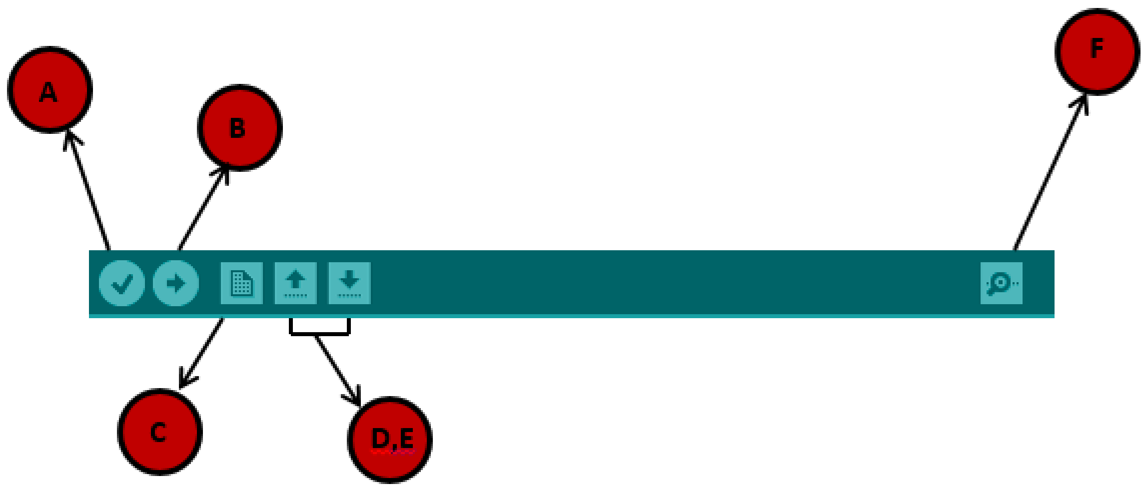

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

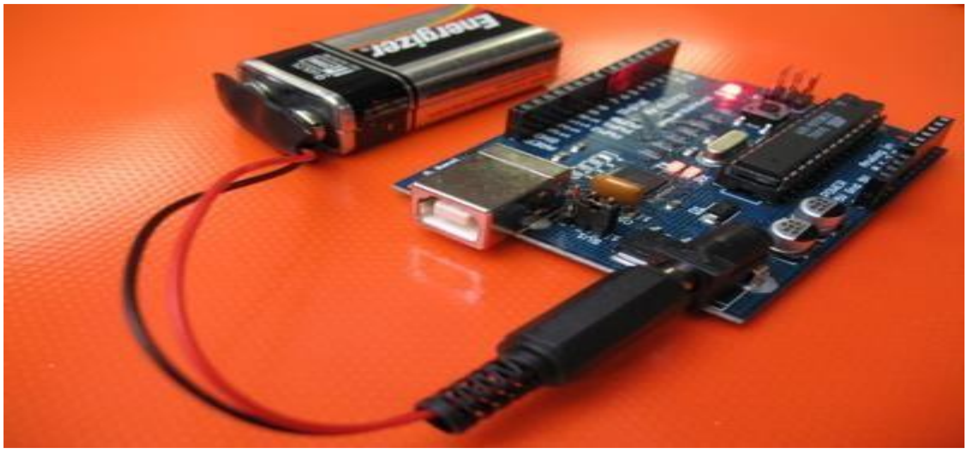

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

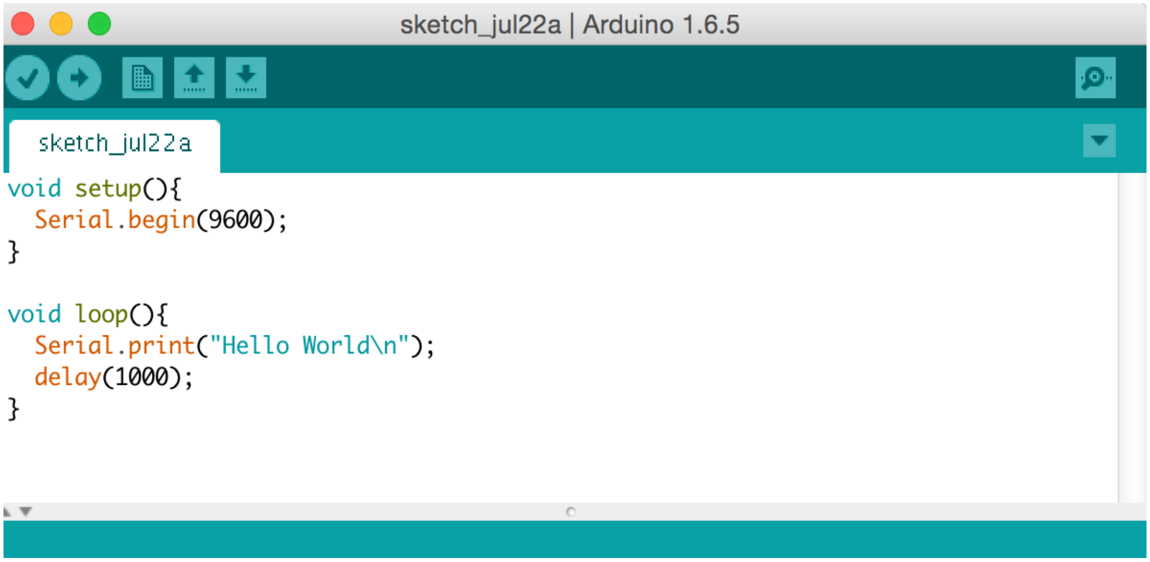

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages.

It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

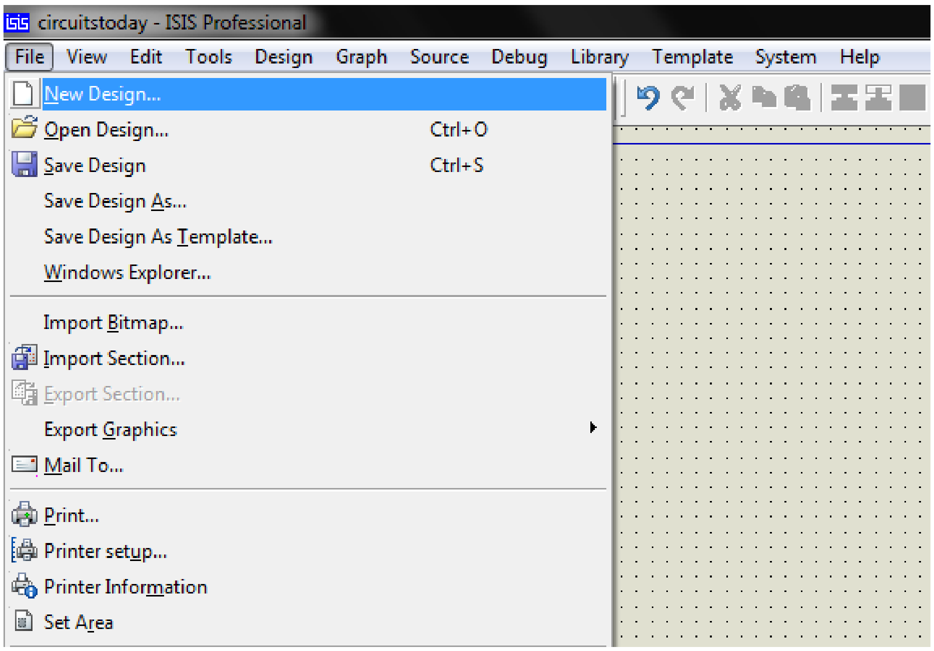

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

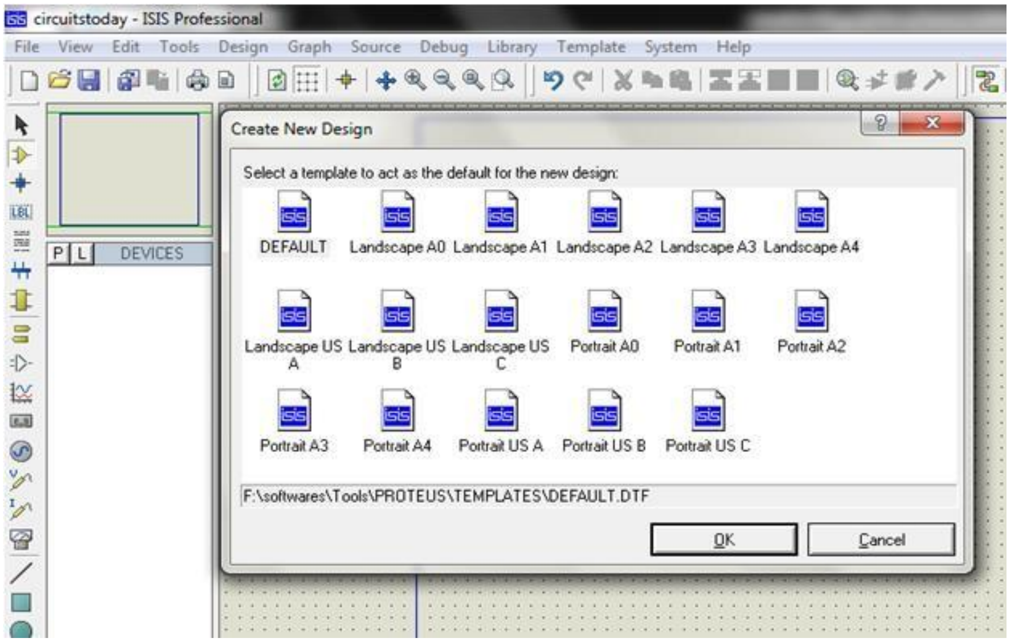

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

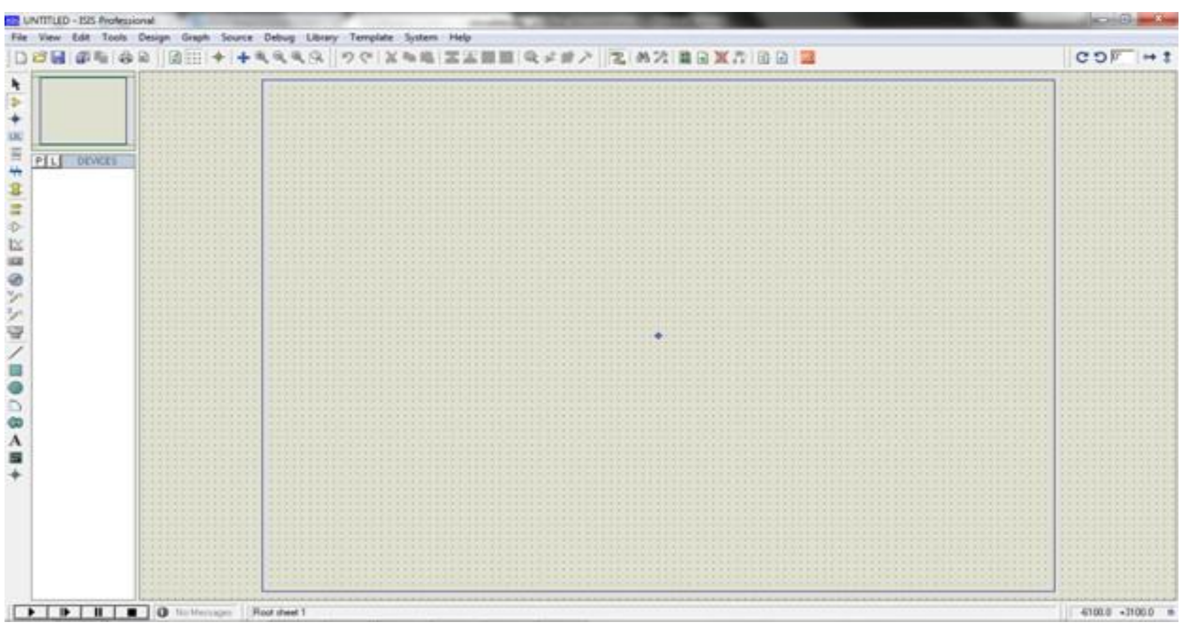

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

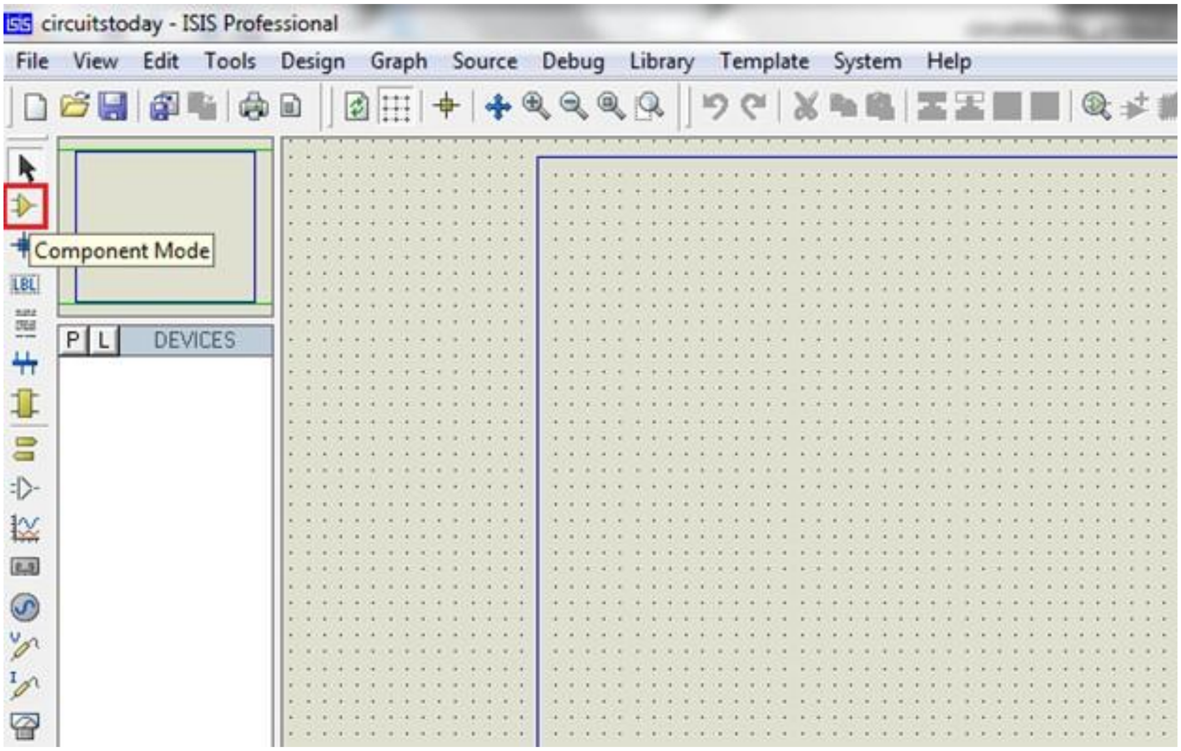

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

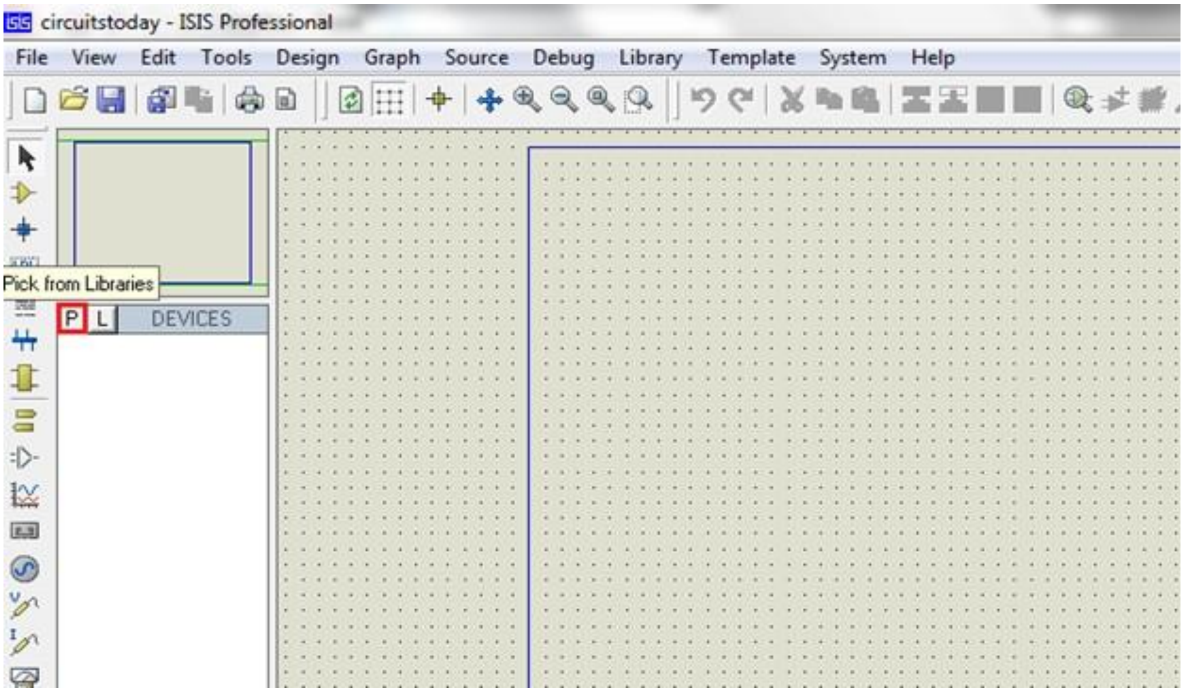

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

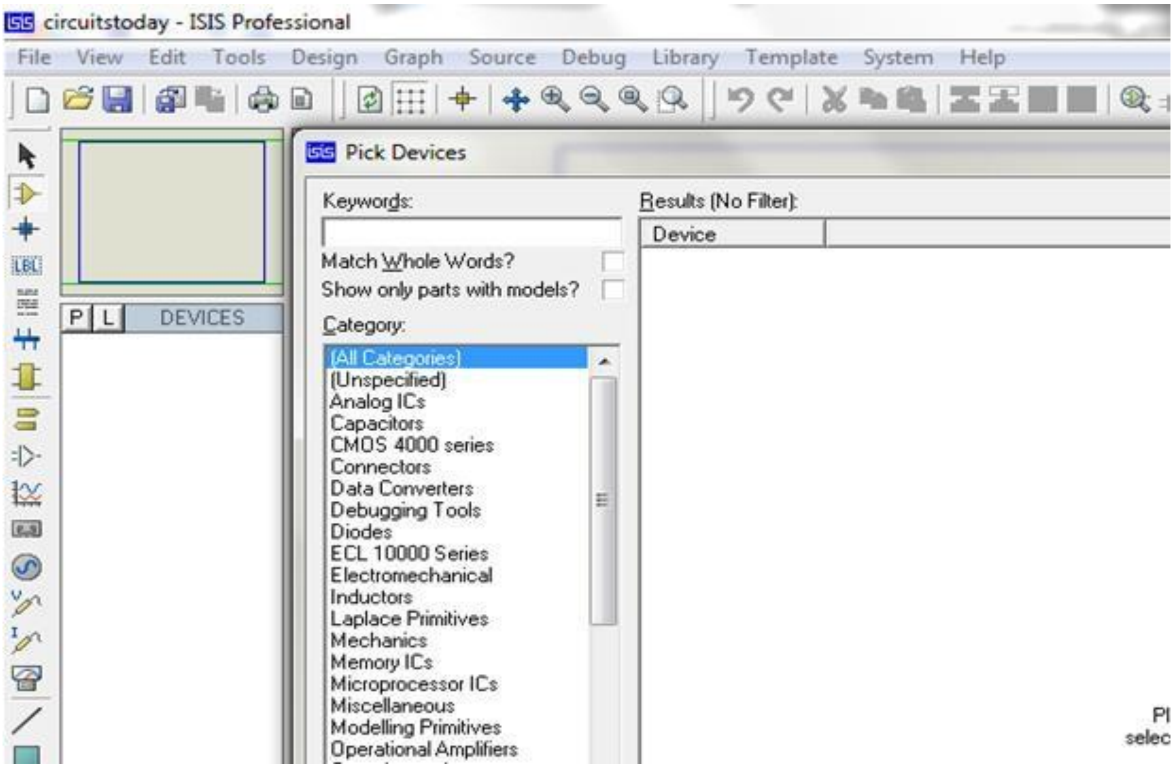

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

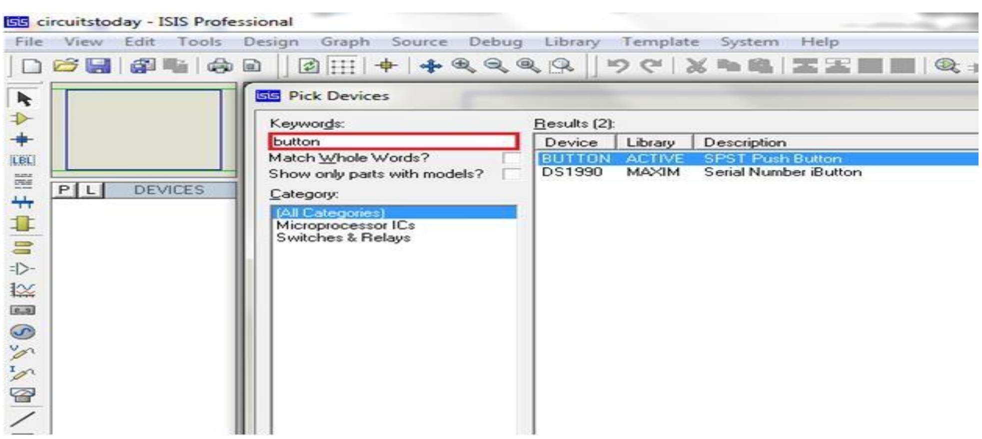

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

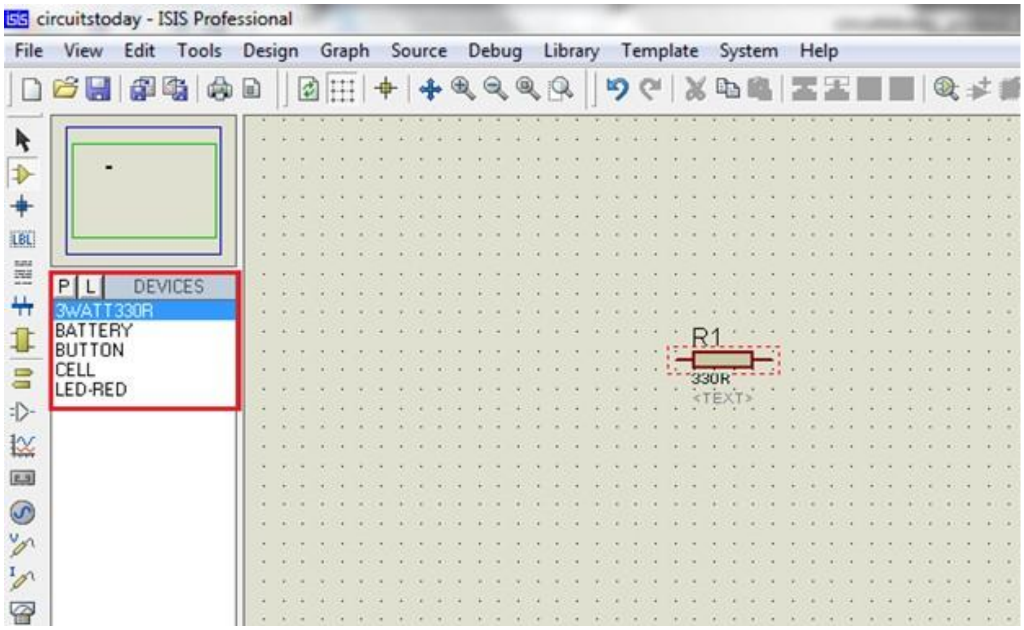

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

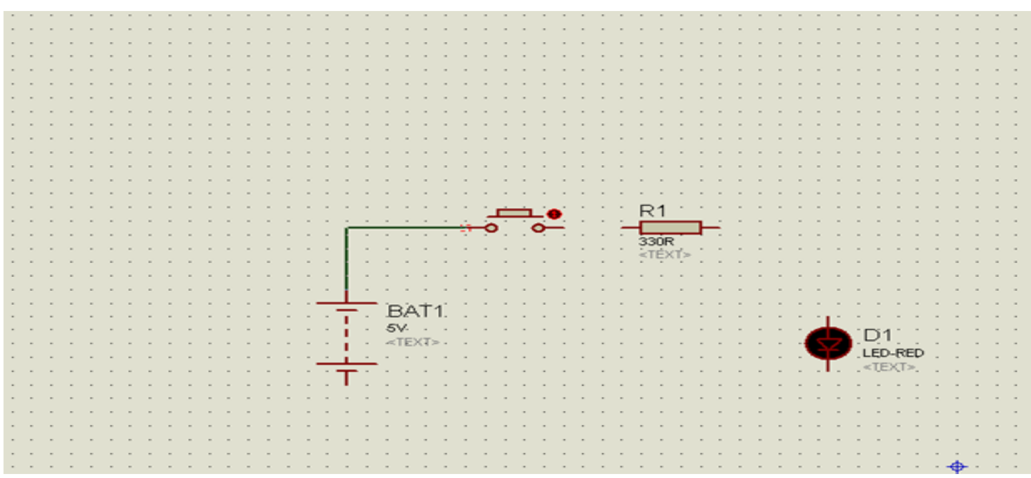

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

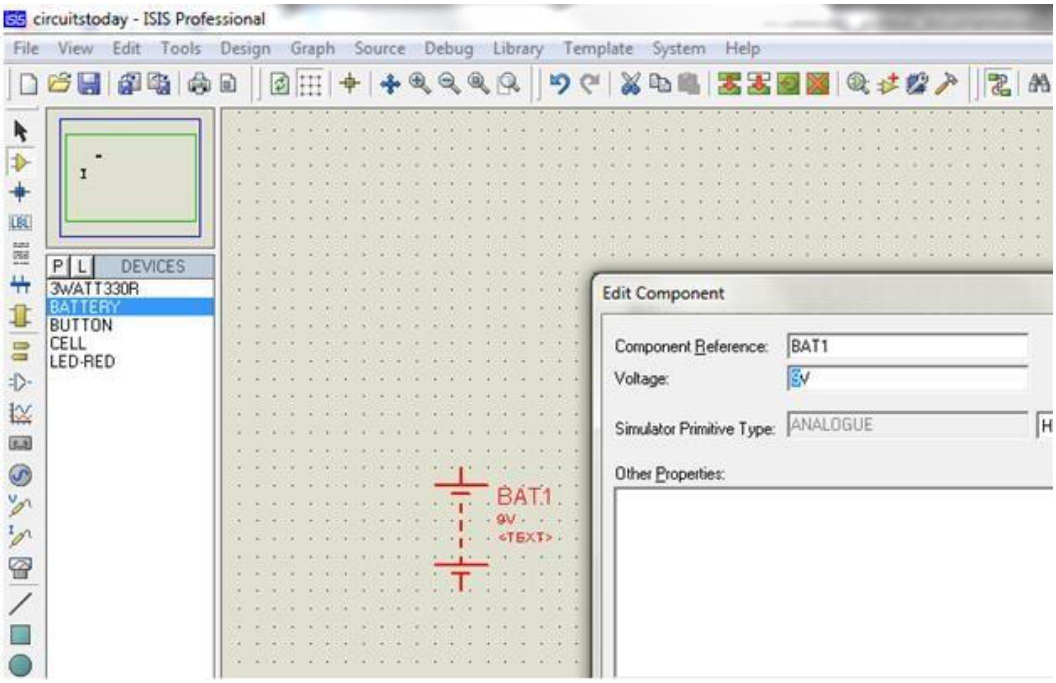

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

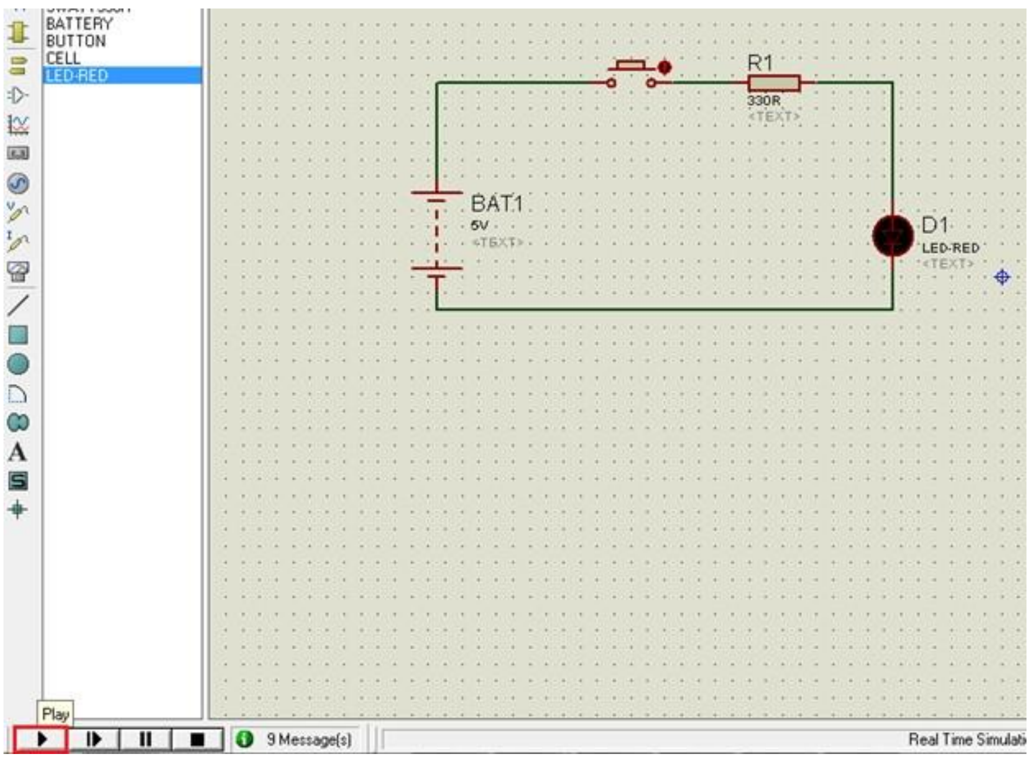

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

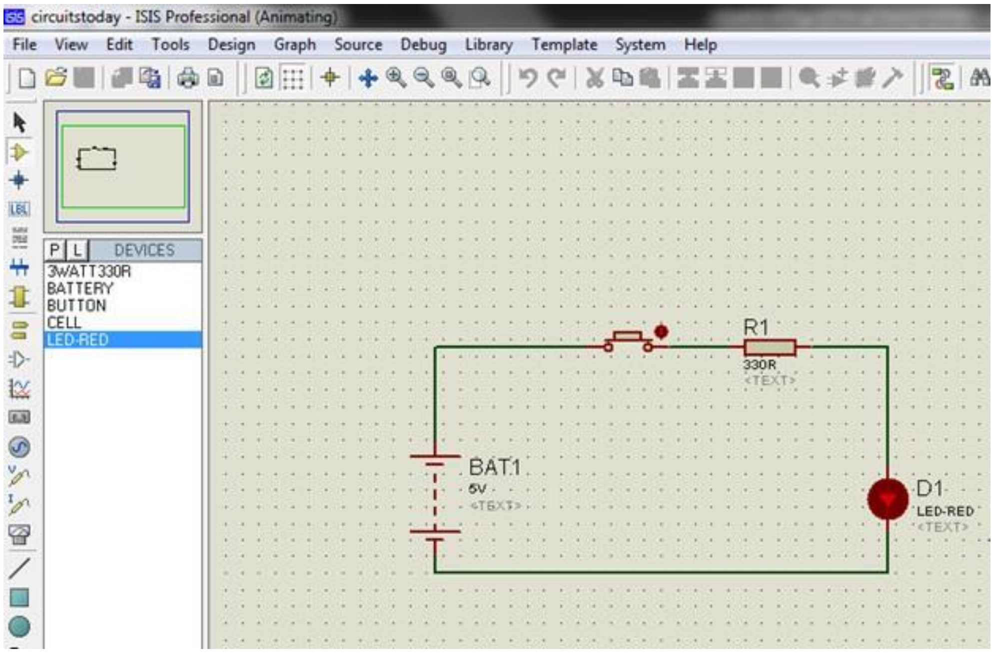

Fig . 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

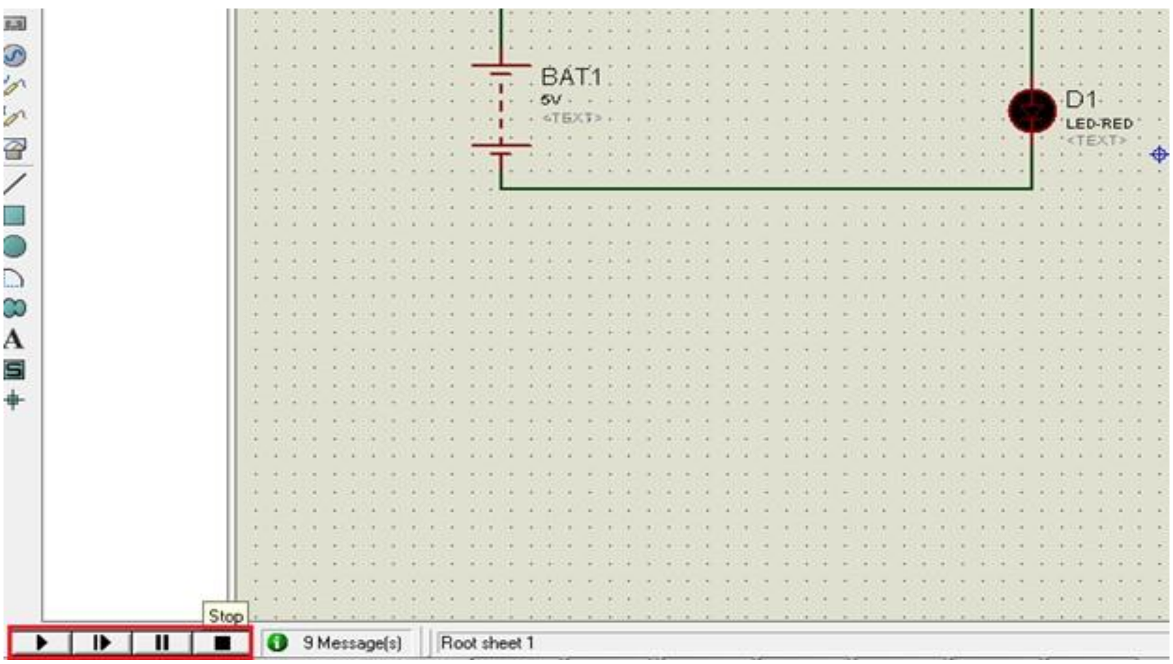

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

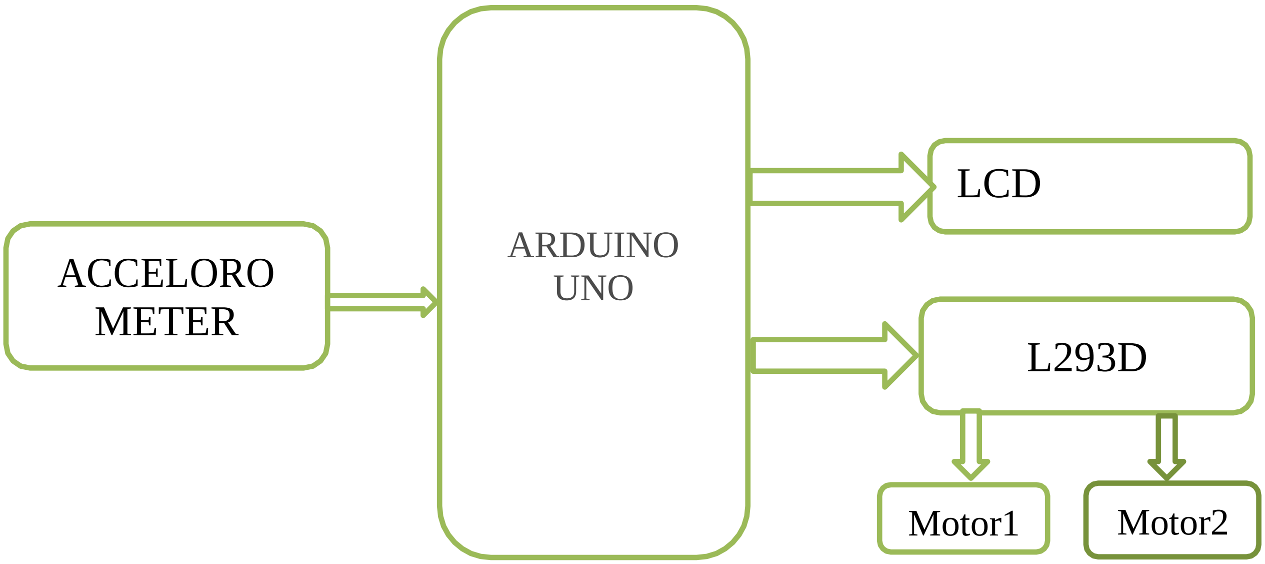

Fig.4.1: Block diagram of the project

4.2 FLOW CHART

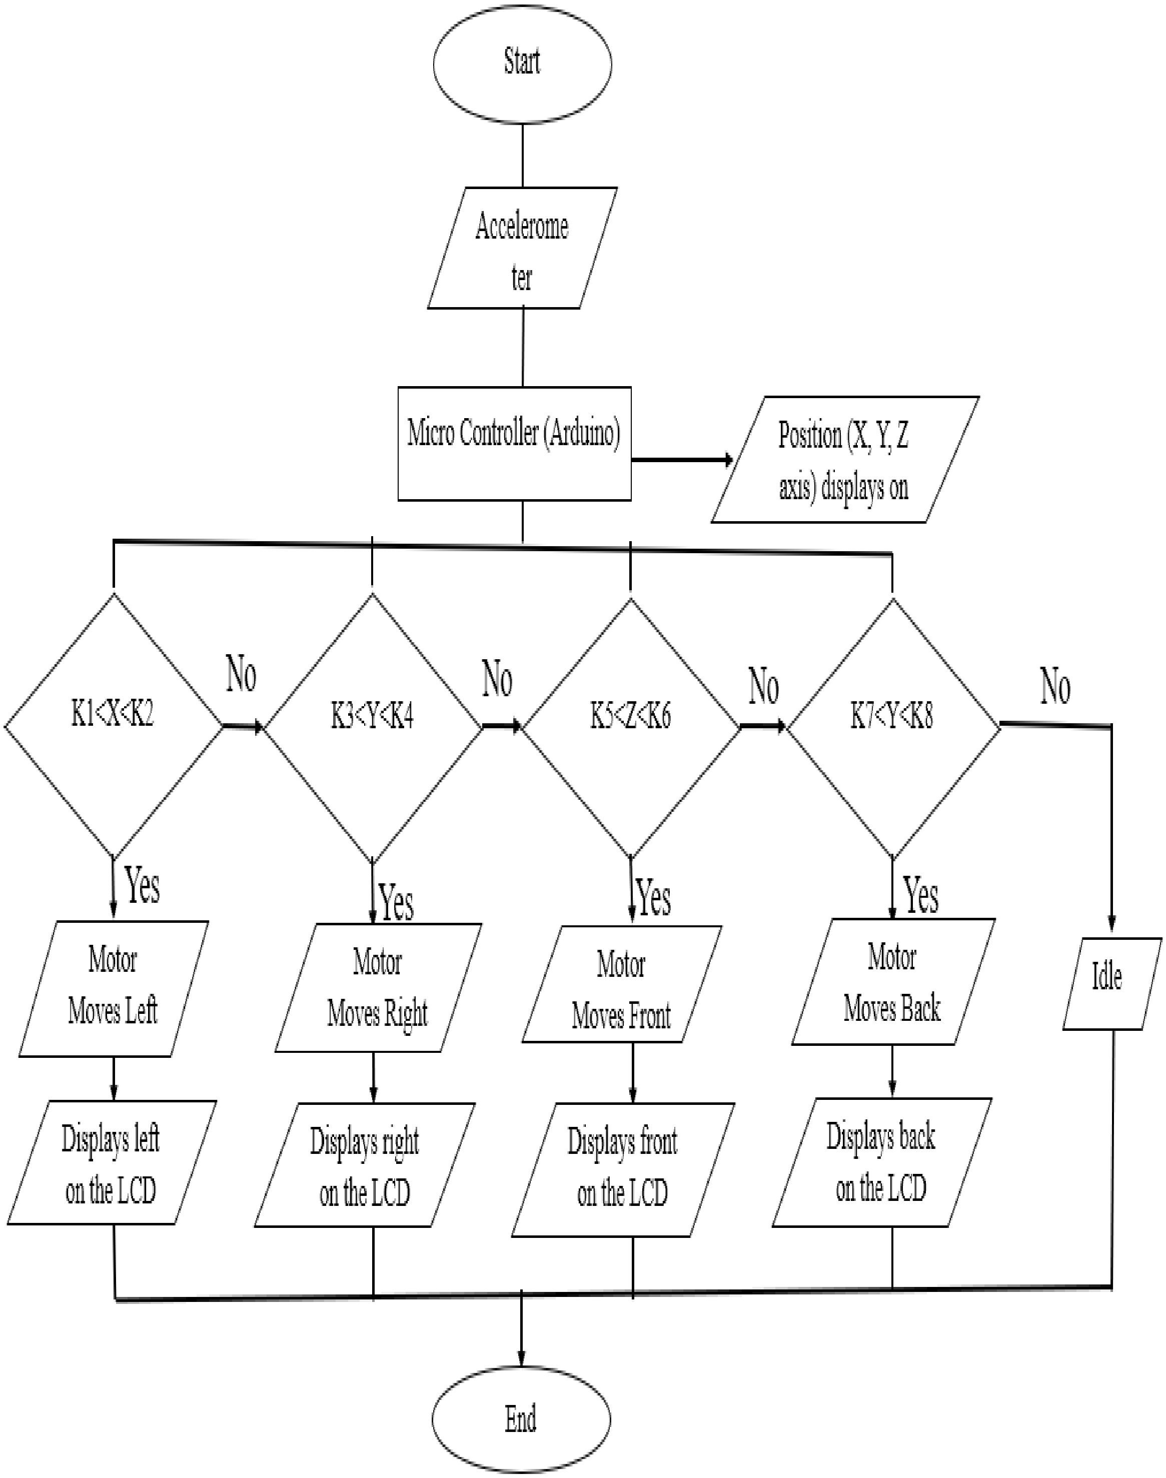

Fig.4.2 Flow Chart

4.3 IMPLEMENTATION STAGES

Stepwise implementation of Quadriplegics wheelchair Control by Head Motion using Accelorometer is given as follows

Step1: Switch on power supply

Step2: Place Accelorometer on head of the disabled person and if any tilt occurs then accelerometer will takes corresponding x, y, z values and sends to Arduino uno.

Step3: Micro controller will compares the x, y, z values with original values and then sends a message to LCD that contains x, y, z values**.**

Step4: At the same time the micro controller will sends the commands to dc motors ,then dc motors will acts correspondingly.

Step5: Then with the help of dc motors the chair will move left, right, front or back

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

5.1 SOFTWARE TESTING

Software Testing is a process of executing the application with intent to find any software bugs. It is used to check whether the application met its expectations and all the functionalities of the application is working.

The final goal of testing is to check whether the application is behaving in the way it is supposed to under specified conditions. All aspects of the code are examined to check the quality of application. The primary purpose of testing is to detect software failures so that defects may be uncovered and corrected. The test cases are designed in such way that scope of finding the bugs is maximum.

5.2 TESTING LEVELS:

There are various testing levels based on the specificity of test.

• **Unit testing:** Unit testing refers to tests conducted on a section of code in order to verify the functionality of that piece of code. This is done at the function level.

• **Integration Testing:** Integration testing is any type of software testing that seeks to verify the interfaces between components against a software design. Its primary purpose is to expose the defects associated with the interfacing of modules.

• **System Testing**: System testing tests a completely integrated system to verify that the system meets its requirements.

• **Acceptance testing**: Acceptance testing tests the readiness of application, satisfying all requirements.

• **Performance testing:** Performance testing is the process of determining the speed or effectiveness of a computer, network, software program or device such as response time or millions of instructions per second etc. 62

5.3 SYSTEM TEST CASES

A test case is a set of test data, preconditions, expected results and post conditions, developed for a test scenario to verify compliance against a specific requirement. We have designed and executed a few test cases to check if the project meets the functional requirements.

5.4 CODE IMPLEMENTATION

```

delay(2000);
}
}
```

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

The proposed framework is expected to make a financially savvy wheelchair to assist quadriplegic with peopling who think that it's hard to move freely. The structure uses head advancement to control the wheelchair. The tilt focuses made are distinguished and voltages are created by accelerometer. These voltages are taken by microcontroller which in this way controls the course of wheelchair.

This venture work was carried on to satisfy the prerequisite of older and impair individuals, giving the autonomous route utilizing head movement-controlled wheelchair. It causes them to move effectively as like ordinary people do.+

The circuit works appropriately to the order given by the user and the wheelchair is moved in understanding to the head signal given by the individual. Head movement-controlled wheelchair incorporates obstacle detection, which assists with distinguish in g the hindrance and stops the wheelchair. Monitoring of the patient's wellbeing condition is possible with the assistance of patient monitoring framework.

6.2 FUTURE ENHANCEMENT

- We can make a wheelchair which can be worked by a remote. Output of device are often applied to wireless transmitter circuit and might received at chair circuit by receiver electronic equipment. So wireless operation can reduce wiring arrangements
- Instead of using MEMS we can use eye retina using optical sensor to move wheelchair in different direction. Using tissue layer movement we'd be ready to drive a chair.
- Researchers are going on improvement of handicap wheelchair using nervous system of human..
- The structured wheelchair can be broadened utilizing sun powered boards which is increasingly productive. Sun powered board itself stimulates the wheelchair. But solely the downside is setup of panel and conjointly weight of chair will increase.

- Voice monitoring helps the disabled person to determine the obstacle by acknowledging with alarm signals. That can act as motor kill switch.

APPENDICES

This survey is the accomplishment of the task where gesture controlled user interface for elderly and disable people has been. From this survey it has been identified that elderly and disable needs more technology support using their nature behaviour, considering their limitations. We can use affordable technology for daily activities. The wheelchair is fully capable of carrying the load up to 110Kg, and moving in accordance to the head gesture given by the person who is using the wheel chair. Certain improvisation and improvement can be done to make the wheelchair more reachable to those whose whole body is paralyzed. Certain eyes gesture or brain signals reader can be imparted on the wheelchair system so as to make it better. For now, it works for all kind of disabled or elderly person, and even for those patients whose whole body is paralyzed but still head movement is possible.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head & Professor**, the Dept. of electronics and communication engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. Project Coordinator Dr.A.Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **T.Sowmya, Assistant Professor**, department of ECE and our class project coordinator **A. Soumya, Assistant professor**, department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Deep learning approaches in image processing predominantly resort to supervised learning. A majority of methods for image denoising are no exception to this rule and hence demand pairs of noisy and corresponding clean images. Only recently has there been the emergence of methods such as Noise2Void, where a deep neural network learns to denoise solely from noisy images. However, when clean images that do not directly correspond to any of the noisy images are actually available, there is room for improvement as these clean images contain useful information that fully unsupervised methods do not exploit. In this paper, we propose a method for image denoising in this setting. First, we use a flow-based generative model to learn a prior from clean images. We then use it to train a denoising network without the need for any clean targets. We demonstrate the efficacy of our method through extensive experiments and comparison.

CHAPTER 1

INTRODUCTION

1.0 OVERVIEW OF THE PROJECT

First, we use a flow-based generative model to learn a prior from clean images. We then use it to train a denoising network without the need for any clean targets. We demonstrate the efficacy of our method through extensive experiments and comparisons.

1.1 OBJECTIVES OF THE STUDY

Each method has its own advantages and disadvantages. In this project, we summarize some important objective in the field of image denoising. First, we give the formulation of the image denoising problem, and then we present several image denoising techniques. In addition, we discuss the characteristics of these techniques. Finally, we provide several promising directions for future research.

1.2 SCOPE OF THE STUDY

With the explosion in the number of digital images taken every day, the demand for more accurate and visually pleasing images is increasing. However, the images captured by modern cameras are inevitably degraded by noise, which leads to deteriorated visual image quality. Therefore, work is required to reduce noise without losing image features (edges, corners, and other sharp structures).

Image de noising is a classical yet still active topic in low level vision since it is an indispensable step in many practical applications. The goal of image denoising is to recover a clean image x from a noisy observation y which follows an image degradation model y = x + v. One common assumption is that v is additive white Gaussian noise (AWGN) with standard deviation σ. From a Bayesian viewpoint, when the likelihood is known, the image prior modeling will play a central role in image denoising. Over the past few decades, various models have been exploited for modeling image priors, including nonlocal self-similarity (NSS) models sparse models, gradient models and Markov Noise corrupts virtually any image captured through a camera. The degradation due to noise is typically captured in the equation: Y = X + N where X is a clean image, N is noise and Y is the corresponding noisy version of X. Image denoising methods attempt to recover the clean image from its noisy version. Traditional methods such as BM3D, NSCR, WNNM rely on the self-similarity of image patches to denoise solely from noisy images. Methods such as that use deep learning have been proposed for image denoising. Although they achieve state-of-the-art performance along with excellent test times, they are all discriminative models. As a result, they require pairs of noisy images and their corresponding clean images. Recently, deep learning methods like Noise2Noise and Noise2Void have been proposed that use statistical properties of noisy image patches to eliminate noise. While these methods do not need any clean images, in situations where they are available, they cannot utilize the valuable information available in the clean images.

Despite their high denoising quality, most of the image prior-based methods typically suffer from two major drawbacks. First, those methods generally involve a complex optimization problem in the testing stage, making the de noising process time – consuming. Thus, most of the prior based methods can hardly achieve high performance without sacrificing computational efficiency. Second, the models in general are non-convex and involve several manually chosen parameters, providing some leeway to boost denoising performance.

To overcome the limitations of prior-based approaches, several discriminative learning methods have been recently developed to learn image prior models in the context of truncated inference procedure. The resulting models are able to get rid of the iterative optimization procedure in the test phase. Schmidt and Roth proposed a cascade of shrinkage fields (CSF) method that unifies the random field-based model and the unrolled half-quadratic optimization algorithm into a single learning framework. Chen et al. proposed a trainable nonlinear reaction diffusion (TNRD) model which learns a modified fields of experts [12] image prior by unfolding a fixed number of gradient descent inference steps. Some of the other related work can be found .Although CSF and TNRD have shown promising results toward bridging the gap between computational efficiency and denoising quality, their performance are inherently restricted to the specified forms of prior. To be specific, the priors adopted in CSF and TNRD are based on the analysis model, which is limited in capturing the full characteristics of image structures. In addition, the parameters are learned by stage-wise greedy training plus joint fine-tuning among all stages, and many handcrafted parameters are involved. Another no negligible drawback is that they train a specific model for a certain noise level, and are limited in blind image de noising.

Deep learning methods have been successfully applied in various computer vision tasks, including image classification and object detection and have dramatically improved the performance of these systems, setting the new state-of-the-art. Recently, very promising results have also been reported for image processing applications such as image restoration super-resolution and optical flow. The significant boost in performance achieved by deep networks can be mainly attributed to their advanced modeling capabilities, thanks to their deep structure and the presence of non-linearities that are combined with discriminative learning on large training datasets. However, most of the current deep learning methods developed for image restoration tasks are based on general network architectures that do not fully exploit problem-specific knowledge. It is thus reasonable to expect that incorporating such information could lead to further improvements in performance. Only very recently, Schmidt and Roth [34] and Chen and Pock [6] introduced deep networks whose architecture is specifically tailored to certain image restoration problems. However, even in these cases, the resulting models are local ones and do not take into account the inherent non-local self-similarity property of natural images. On the other hand, conventional methods that have exploited this property have been shown to gain significant improvements compared to standard local approaches. A notable example is the Block Matching and 3D Collaborative Filtering (BM3D) method which is a very efficient and highly engineered approach that held the state-of-the-art record in image denoising for almost a decade.

CHAPTER 2

LITERATURE REVIEW

Recently, deep learning methods like Noise 2 Noise and Noise 2 Void have been proposed that use statistical properties of noisy image patches to eliminate noise. While these methods do not need any clean images, in situations where they are available, they cannot utilize the valuable information available in the clean images. Corresponding author, email id: priyathamkat@smail.iitm.ac.in Ground truth Noisy input Our output Fig. 1: Sample result from our method. Observe that the fine details in the tree are restored without any noticeable blur even when the noise level in the input is high ($\sigma = 35$). Image taken from BSD68. Another important class of methods are prior based. Priors are crucial for obtaining a reasonable answer out of all the possible solutions for an ill-posed problem such as image denoising. With handcrafted priors, these methods can be used when clean images are not available. However, these priors have been criticized as they are often chosen for their computational or analytical convenience rather than accuracy. Deep learning has allowed for constructing more accurate priors. Deep image prior claims that the architecture of a convolutional neural network alone can act as a prior for natural images. Though the results are good, it is surprising as there is no mathematical justification for why this prior works. Going further, Chen et al have used a GAN to explicitly construct a prior for realistic noise which they use for denoising. In this paper, we propose an approach for denoising using another class of generative models, called flow-based generative models .These models learn an invertible transformation from a complex distribution like images to a simple one like the Gaussian distribution. They have been successfully used to generate realistic images. An example of this is the work by King ma et al., where in they use flow based models to generate photorealistic face images using the Celeb A HQ dataset.

CHAPTER 3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

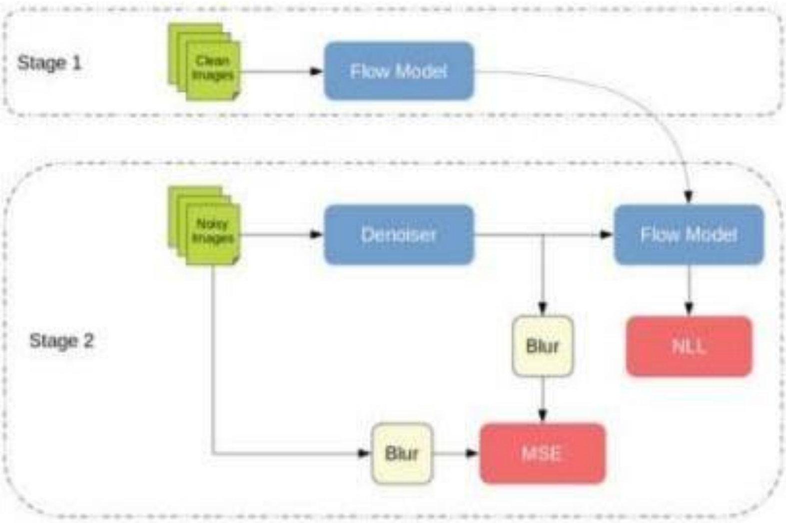

Fig 3.1 Proposed method.

Above figure. An illustration of our method. In the first stage, we train a flow-based model to learn a prior distribution on clean images. Next, we use this prior along with weak supervision train a denoising network. In this section we describe our two-stage approach to using the log-likelihood as a prior for image denoising.

Stage 1: Training the Flow model First, we train a flow-based model based on clean images to learn a transformation from clean images to the standard multivariate Gaussian random variable. Due to structure of the flow-based model as described in (2) and the tractable probability density of a Gaussian random variable, we can evaluate (6) for any given image and obtain the likelihood that the image is clean. Concretely, we train a flow-based model h to minimize the following objective:

$$-\log P(\boldsymbol{X}) = -\log P(\boldsymbol{Z}) + \sum_{i=1}^{n} \log \left| \frac{\mathrm{d}\boldsymbol{Z_i}}{\mathrm{d}\boldsymbol{Z_{i-1}}} \right| \quad (10)$$

$$= \frac{1}{2}\|\boldsymbol{Z}\|_2^2 + \sum_{i=1}^{n} \log \left| \frac{\mathrm{d}\boldsymbol{Z_i}}{\mathrm{d}\boldsymbol{Z_{i-1}}} \right| + C \quad (11)$$

where C is a constant that normalizes the Gaussian distribution. It has no bearing on the training and hence can be eliminated. Note that once the training in Stage 1 is complete, h is fixed during Stage 2.

Stage 2: Training the Denoiser Given a noisy image Y , the posterior distribution for the corresponding clean image X is

$$P(\boldsymbol{X} \mid \boldsymbol{Y}) = \frac{P(\boldsymbol{Y} \mid \boldsymbol{X})P(\boldsymbol{X})}{P(\boldsymbol{Y})} \qquad (12)$$

To obtain the maximum a posteriori (MAP) estimate of the clean image, the denominator can be ignored and the numerator or equivalently its log value is maximized.

$$\arg\max_{\boldsymbol{X}} \log P(\boldsymbol{X} \mid \boldsymbol{Y}) = \arg\max_{\boldsymbol{X}} \log P(\boldsymbol{Y} \mid \boldsymbol{X}) + \log P(\boldsymbol{X}) \qquad (13)$$

Assuming additive white Gaussian noise, log P(Y |X) is simply the negative of the squared error between Y and X. Using the flow model h trained in Stage 1, we can also compute the prior log-likelihood of X. Based on (13), we can formulate a loss function (note the change of signs as by convention, we want to minimize this loss) for the denoiser d as follows:

$$(Y - X)\ 2 - \lambda \log P(X) \qquad (14)$$

where λ is a hyper parameter that controls the relative importance of the conditional and the prior probability distributions. To be mathematically precise, λ depends on the noise level in the image. From our experiments, we also find that the performance of the denoiser is very sensitive to the choice of λ. This poses a challenge as we want to train a single denoiser for a range of noise levels. To reduce the dependency of λ on the noise level, we modify the first term in (14) to instead measure the squared error between blurred versions of X and Y. Intuitively speaking, we are training d to copy only the low frequency information from the input Y while adding details that make the output X to look cleaner. The flow model h dictates what details are added to Y. The final form of the loss function we use for the denoiser d is (B(Y) − B(X))2 − λ log P(X) (15) Here B is a local mean filter, the size of which is chosen to be 3 × 3, as that gave the best performance on the validation set.

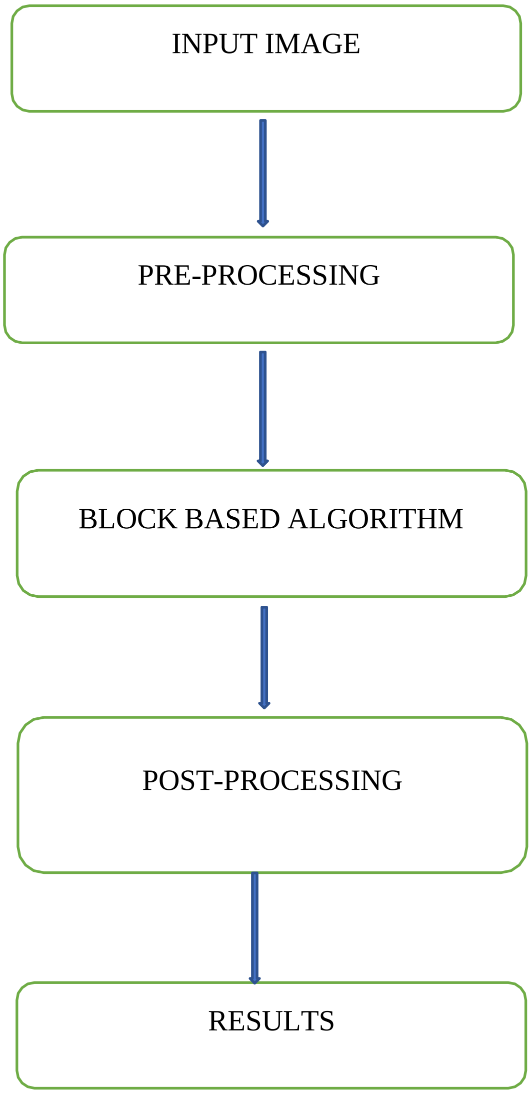

Fig 3.2 Block diagram

3.3 FLOW CHART

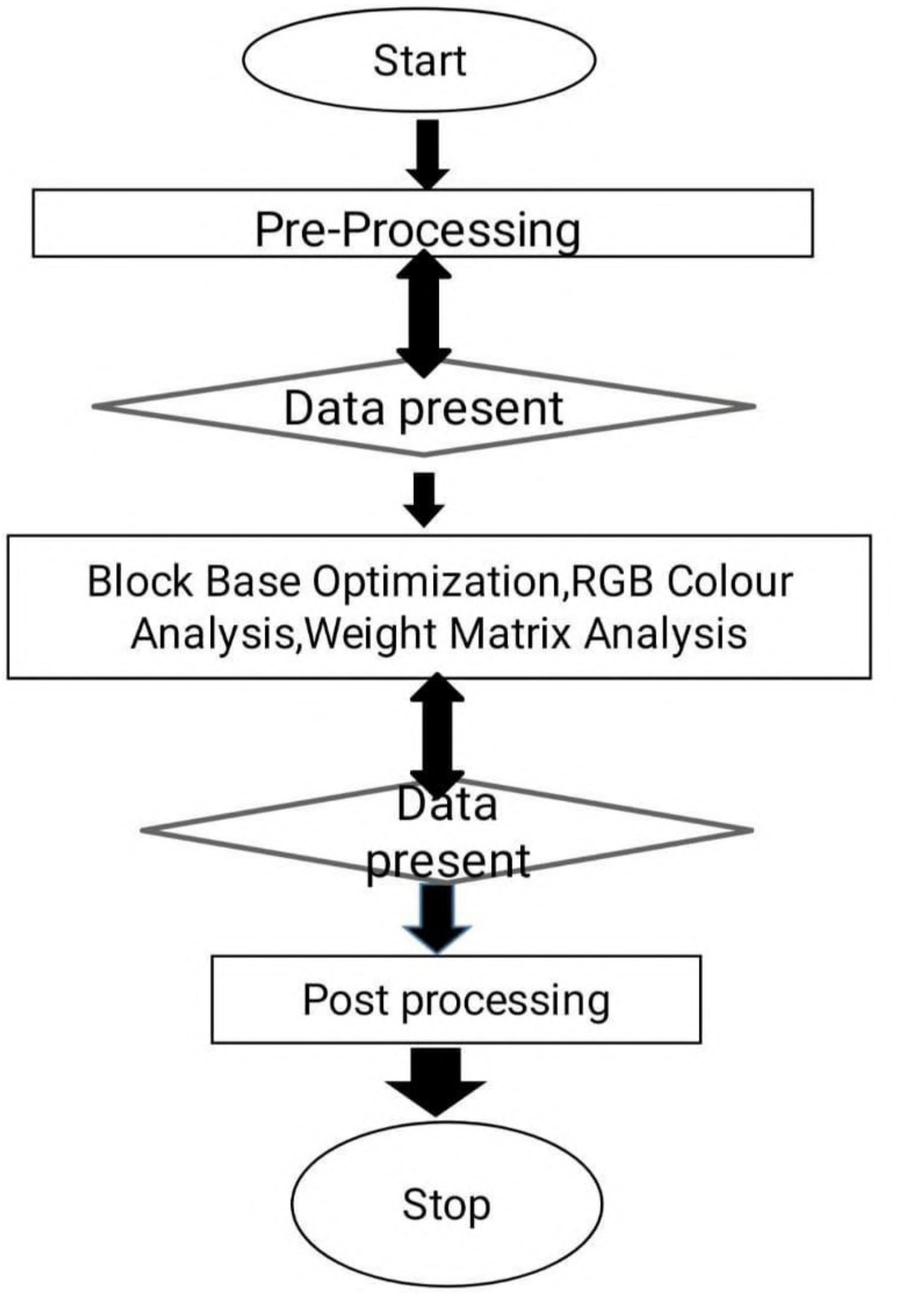

Fig 3.3 Flow chart

3.4 FLOW-BASED GENERATIVE MODELS:

Flow-based generative models [13, 14] learn the bijective transformation from a high-dimensional, complicated random variable X to a latent random variable Z. Typically, X represents images in a dataset while Z is assumed to be a standard normal random vector

$$\boldsymbol{Z} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I}) \qquad (1)$$

$$\boldsymbol{X} = h(\boldsymbol{Z}) \qquad (2)$$

To learn the transformation h, the following unbiased estimate of the negative log-likelihood of X is minimized:

$$\frac{1}{N}\sum_{i=1}^{N} - \log P(\boldsymbol{x_i}) \qquad (3)$$

Here, xi are samples from the dataset. Using the standard rules of random variable transformation, log P(X) can be written as

$$\log P(\boldsymbol{X}) = \log P(\boldsymbol{Z}) - \log \left| \frac{\mathrm{d}h}{\mathrm{d}\boldsymbol{x}} \right| \qquad (4)$$

where dh dx is the determinant of the Jacobian of h. This term can be further decomposed when h is a composition of several other functions as is typical in a deep neural network.

$$\boldsymbol{X} = \boldsymbol{Z_0} \xrightarrow{h_1} \boldsymbol{Z_1} \xrightarrow{h_2} \boldsymbol{Z_2} \dots \xrightarrow{h_n} \boldsymbol{Z_n} = \boldsymbol{Z} \qquad (5)$$

$$\log P(\boldsymbol{X}) = \log P(\boldsymbol{Z}) - \sum_{i=1}^{n} \log \left| \frac{\mathrm{d}\boldsymbol{Z_i}}{\mathrm{d}\boldsymbol{Z_{i-1}}} \right| \qquad (6)$$

To make the computation of the right hand side of (6) tractable, flow-based models restrict the class of transformations to those for which the Jacobian is a triangular (or even a diagonal) matrix. A simple example is the following additive coupling layer

$$\boldsymbol{y_{p_1}} = \boldsymbol{x_{p_1}} \qquad (7)$$

$$\boldsymbol{y_{p_2}} = \boldsymbol{x_{p_2}} + m(\boldsymbol{x_{p_1}}) \qquad (8)$$

where x, y are the inputs and outputs of the layer respectively; p1, p2 is a partition of the features along the channel dimension and m is an arbitrary transformation. For this layer, it is easy to see that the Jacobian is

$$\begin{bmatrix} \boldsymbol{I_{p_1}} & 0 \\ \frac{\mathrm{d}m(\boldsymbol{x_{p_1}})}{\mathrm{d}\boldsymbol{x_{p_1}}} & \boldsymbol{I_{p_2}} \end{bmatrix} \tag{9}$$

where Ip1 , Ip2 are identity matrices that are of the same size as the partitions p1, p2. Conveniently, the determinant of the matrix in (9) is simply 1 and hence it is ideal for use in a flow-based model. Unlike in we do not require invertible transformations as there is no need for sampling when we are only learning a prior. Nevertheless, in our work we use the layers and formulation of flow-based models proposed .

CHAPTER 4

INTRODUCTION TO IMAGE PROCESSING

4.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 4.1 General image.

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

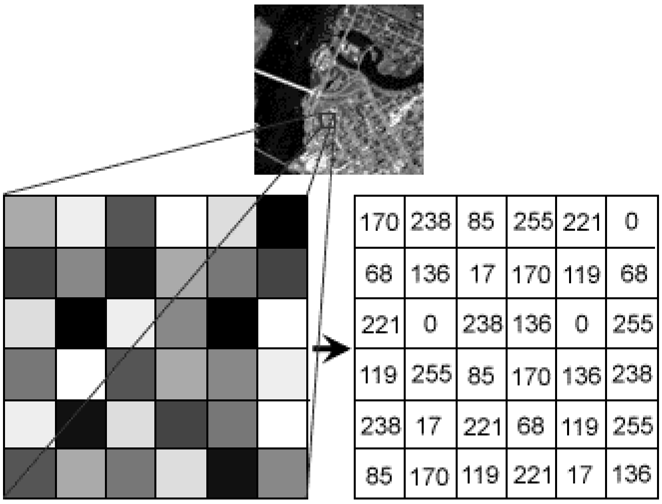

Fig 4.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

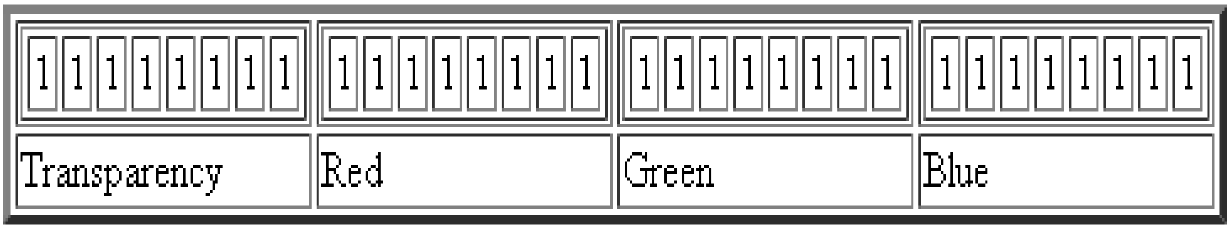

Fig 4.3. Transparency image

4.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

4.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

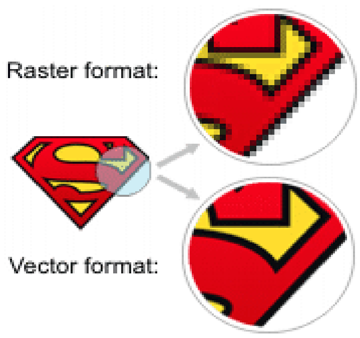

Fig4.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

4.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pix maps).

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image meta data between digital cameras and editing and viewing software. The meta data are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

4.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

4.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

4.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

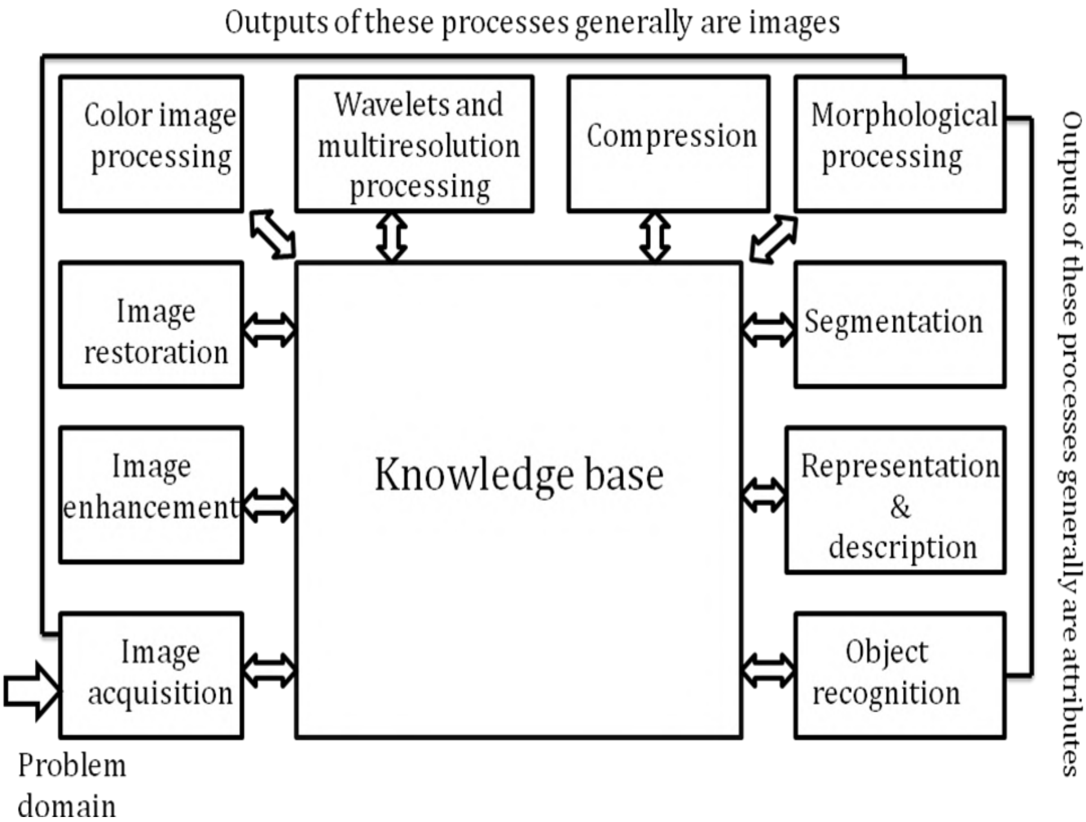

Fig 4.5 Image fundamental

4.5.1 IMAGE ACQUISITION:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 4.5.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 4.5.2 digital camera cell

4.5.2 IMAGE ENHANCEMENT:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 4.5.3 Image enhancement

4.5.3 IMAGE RESTORATION:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 4.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where removal of image blur by applying a deblurring function is considered a restoration technique.

4.5.4 COLOR IMAGE PROCESSING:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 4.5.5 Color & Gray scale image

4.5.5 WAVELETS AND MULTIRESTORATION PROCESSING:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

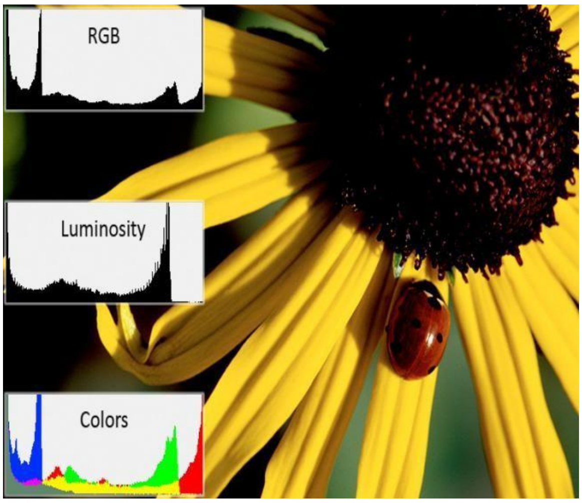

Fig 4.5.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

4.5.6 COMPRESSION:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

4.5.7 MORPHOLOGICAL PROCESSING:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 4.5.7 blur to de blur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x, y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

4.5.8 SEGMENTATION:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

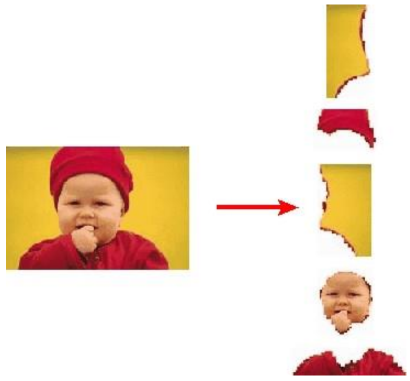

Fig 4.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

4.5.9 REPRESENTATION AND DESCRIPTION:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

4.5.10 OBJECT RECOGNITION:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

4.5.11 KNOWLEDGEBASE:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

4.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

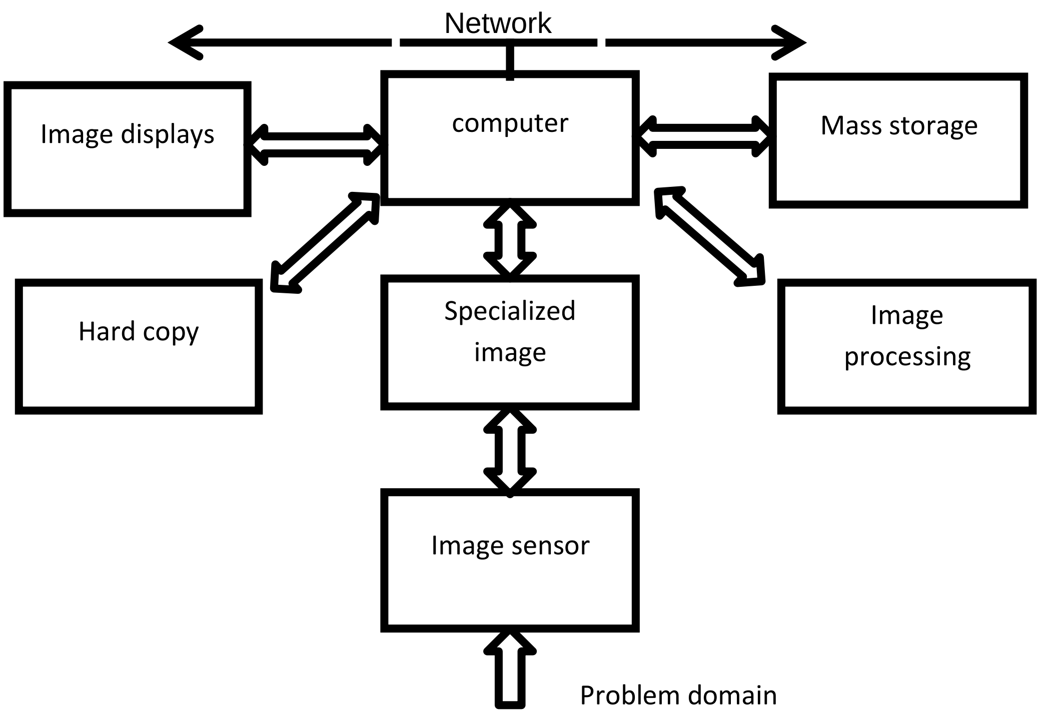

Fig 4.6 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image Sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized Image Processing Hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit

(ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image Processing Software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage for image processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), G bytes (meaning giga, or one billion, bytes), and T bytes (meaning tera, or one trillion, bytes).

  One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image Displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl ∈{0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \mathrm{Pr}((\mathrm{gl}\ \ \mathrm{gl}$$

GCM(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation. Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL}-1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD; CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

Proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi- channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcm UV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application.

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Ternary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the ternary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue (H), saturation (S) and value (V).

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 & \text{if } h \in [316,20] \\ 1 & \text{if } h \in [21,40] \\ 2 & \text{if } h \in [41,75] \\ 3 & \text{if } h \in [76,155] \\ 4 & \text{if } h \in [156,190] \\ 5 & \text{if } h \in [191,270] \\ 6 & \text{if } h \in [271,295] \\ 7 & \text{if } h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 & \text{if } s \in [0,0.2) \\ 1 & \text{if } s \in [0.2,0.7) \\ 2 & \text{if } s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 & \text{if } v \in [0,0.2) \\ 1 & \text{if } v \in [0.2,0.7) \\ 2 & \text{if } v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

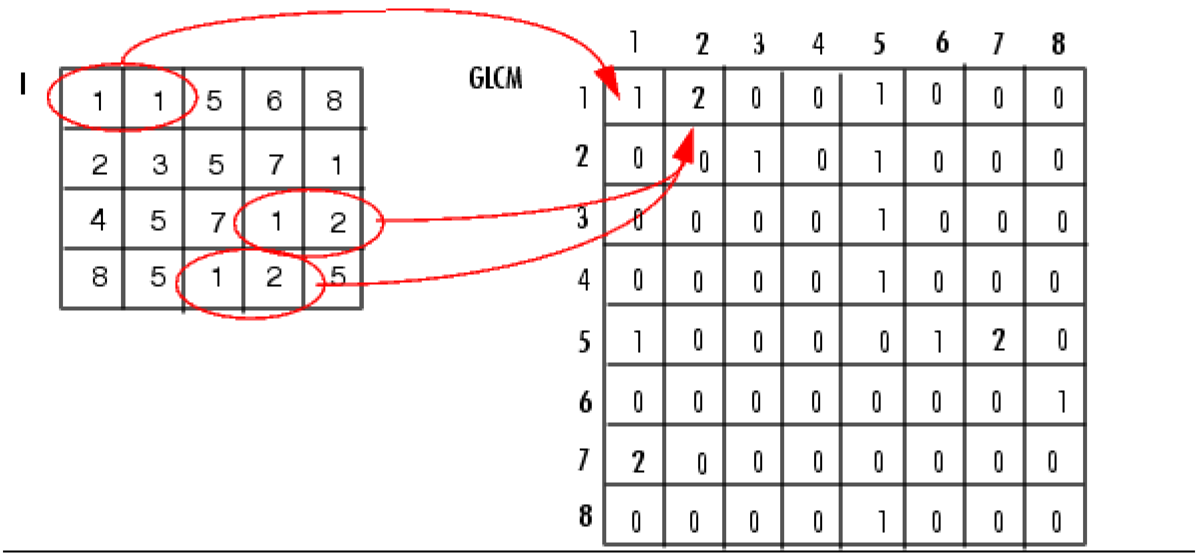
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures.

Based on the Textures the images can be segmented. To differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



4.7 Overview of Texture

CHAPTER-5

DIGITAL IMAGE PROCESSING

Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude off at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane I(x, y) is the intensity of the image at the point (x, y) on the image plane. I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate’s values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates. In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0) f(0,1)… ....f(0,N-1)

f(1,0) f(1,1) ....f(1,N-1)

f(xylem) = f (M-1,0) f(M-1,1)… .... f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.A digital image can be represented naturally as a MATLAB matrix:

f(1,1) f(1,2) ……. f(1,N)

f(2,1) f(2,2) ....f(2,N)

. . .

f = f (M,1) f(M,2).......... f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions.

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Table 5.1 Format Names

Format Name	**Description**	**Recognized Extension**
TIFF	Tagged Image File Format	.tif, .tiff

JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line >> f = I m read ('8. jpg');

Reads the JPEG (above table) image chest Xray into image array f. Note the use of single quotes (') to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many IPT functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Table 5.2 Data Classes

Name	Description
Double	double precision, floating-point numbers the Approximate
Unit 8	unsigned 8_bit integers in the range[0,255] (1 byte per element)
Unit 16	unsigned 16_bit integers in the range[0,65535] (2 bytes per element)
Unit 32	unsigned 32_bit integers in the range[0,4294967295] (4 byte per element)
Int 8	signed 8_bit integers in the range[-128,127] (1 byte per element)
Int 16	unsigned 16_bit integers in the range[32768,32767] (2 byte per element)
Int 32	unsigned 32_bit integers in the range[-2147483648,21474833647] (one byte per element)
Single	single precision floating-point numbers with values in the approximate range (4 byte per element)
Char	Character(2 bytes per elements)
Logical	Values are 0 to 1(1 bytes per element)

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images

2. Binary images

3. Indexed images

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.Using relational and logical operators also creates logical arrays. To test if an array is logical we use the I logical function is logical(c). If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses "direct mapping" of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors**.**

CHAPTER 6

SOFTWARE INTRODUCTION

6.1. INTRODUCTION TO MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include:

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M

– files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

6.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files. Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

6.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files. A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed. To launch GUIDE from the MATLAB command window, type guide filename**.** Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

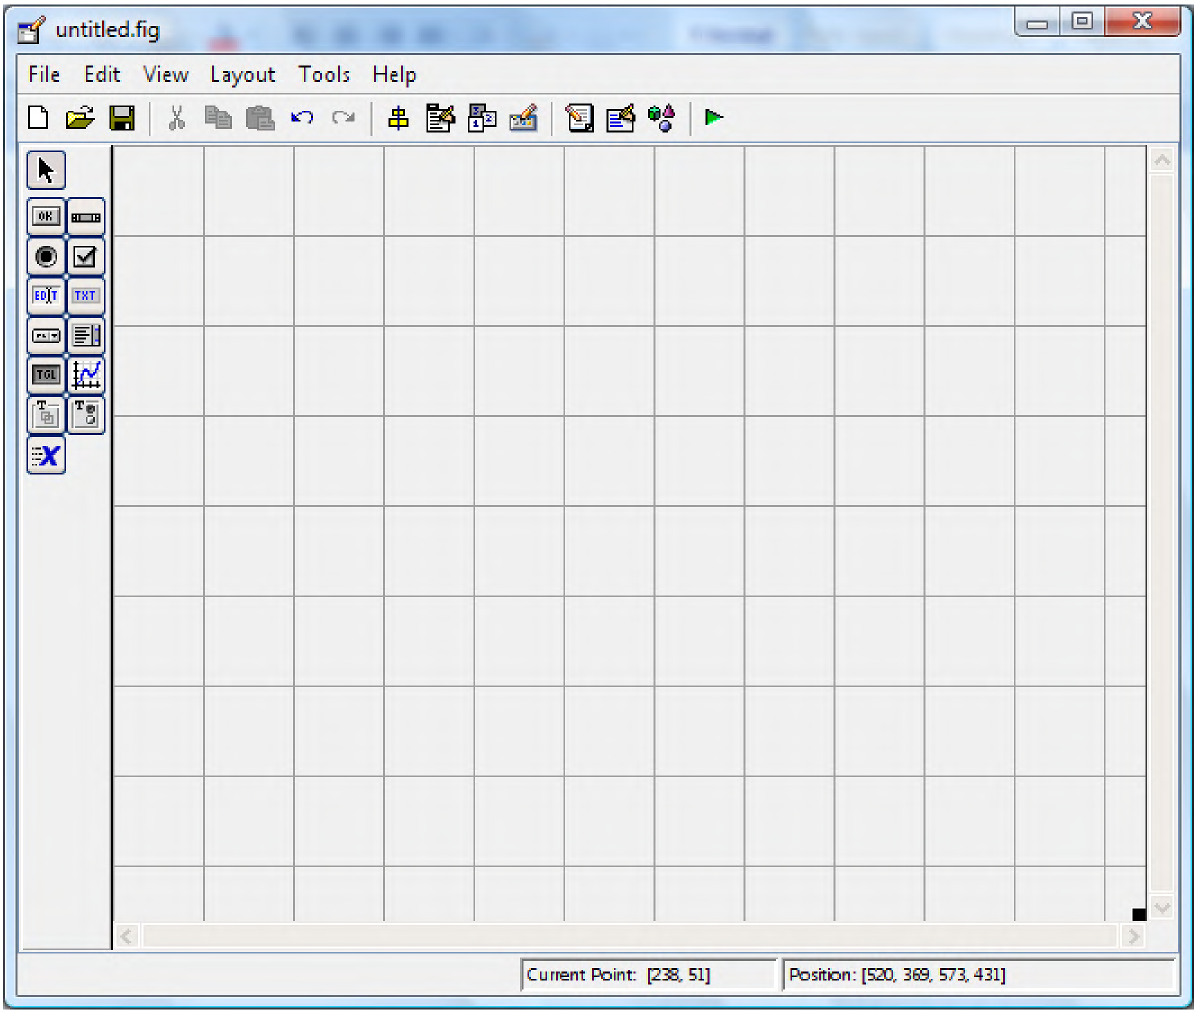


Figure 6.3 GUI

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

6.4 Getting Started:

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator,

and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos. At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

6.4.1 Introduction - describes the components of the MATLAB system.

6.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

6.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

6.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

6.5 DEVELOPMENT ENVIRONMENT

6.5.1 INTRODUCTION

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

6.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop. You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

6.5.3 QUITTING MATLAB:

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

6.5.4 MATLAB DESKTOP:

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries. You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts. You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

6.5.5 DESKTOP TOOLS:

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser
-

Command Window:

Use the Command Window to enter variables and run functions and M-files.

Command History:

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs:

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad:

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator:

Use to Help Navigator to find information. It includes:

Product filter -Set the filter to show documentation only for the products you specify.

Contents tab -View the titles and tables of contents of documentation for your products.

Index tab -Find specific index entries (selected keywords) in the Math Works documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane:

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser:

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path:

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser:

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces. To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor:

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger:

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint. If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

6.6 MANIPULATING MATRICES

6.6.1 ENTERING MATRICES

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example. You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

  Start by entering Durer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon; to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

  To enter Durer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

   16    3    2   13

    5   10   11    8

    9    6    7   12

    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

5.6.2 EXPRESSIONS

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables:

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example, num_students = 25 Creates a 1-by-1 matrix named num students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers:

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

6.6.3 OPERATORS

Expressions use familiar arithmetic operators and precedence rules.

Table 6.6.3 Operators

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

6.6.4 FUNCTIONS

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun,   For a list of more advanced mathematical and matrix functions, type help specfun help elmat. Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Table 6.6.4 Functions

Pi	3.14159265...
I	Imaginary unit, √-1
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

6.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

6.7.1 CREATING GUIs WITH GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

6.7.2 GUI DEVELOPMENT ENVIRONMENT

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI:

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file -contains a complete description of the GUI figure and all of its children (UI controls and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the call backs, which are defined as sub functions. This M-file is referred to as the application M-file in this documentation. Note that the application M-file does not contain the code that lays out the UI controls; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

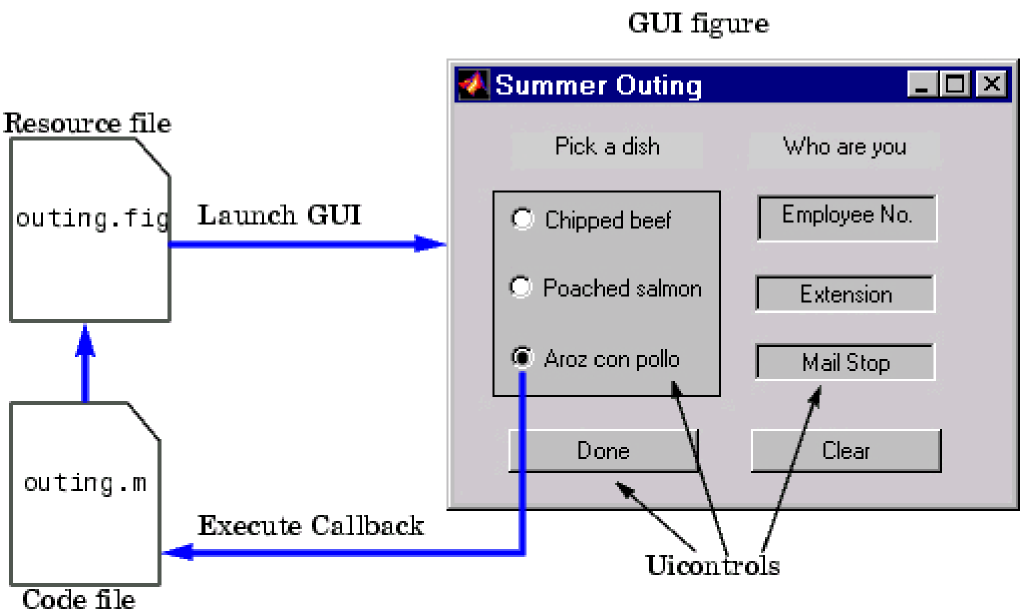

Figure 6.7.2 graphical user blocks

6.7.3 FEATURES OF THE GUIDE-GENERATED APPLICATION M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information). The automatically inserted sub function prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no control creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

6.7.4 BEGINNING THE IMPLEMENTATION PROCESS

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility:

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as find object, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

6.7.5 USER INTERFACE CONTROL

The Layout Editor Component palette contains the user interface controls that you can use in your GUI. These components are MATLAB UI control objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons

- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons:

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set:

String - set this property to the character string you want displayed on the push button.

Tag-GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback:

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons:

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback:

The call back routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File:

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

    % toggle button is pressed

elseif button_state == get(h,'Min')

    % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button:

Assign the C Data property an m-by-n-by-3 array of RGB values that define a true color image. For example, the array defines 16-by-128 true color image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'C Data',a)
```

Radio Buttons:

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive with in a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior:

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following sub function, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles:

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback.
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes:

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes). The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text:

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user. To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component:

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (is nan) and displays an error dialog (error dlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

    errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution:

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text:

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it.

Frames:

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only UI controls can appear within frames (axes cannot).

Placing Components on Top of Frames:

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes:

List boxes display a list of items and enable users to select one or more items. The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1. The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty. The List box Top property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. List box Top is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non integer values are fixed to the next lowest integer

Single or Multiple Selection:

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type:

List boxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution:

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a done button (push button) and program its callback routine to query the list box Value property (and possibly the figure Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback sub function from the application M-file. Leave the callback sub function stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus:

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu:

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item. This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls:

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

On-The control is operational

Off-The control is disabled and its label (set by the string property) is grayed out. Inactive-The control is disabled, but its label is not grayed out. When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure Window Button Down FCN callback executes. Then the control's Button Down FCN callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes:

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks:

Axes are not UI control objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button Down FCN property to define the callback.

6.7.6 PLOTTING TO AXES IN GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes:

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example, axes (handles.axes1) makes the axes whose Tag property axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for example that uses two axes.

Figure:

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 7

RESULTS

Figure 7.1 Input Color Image

We evaluate our method on the BSD68 dataset for different noise levels and compare it with BM3D, Noise2Void, deep image prior.

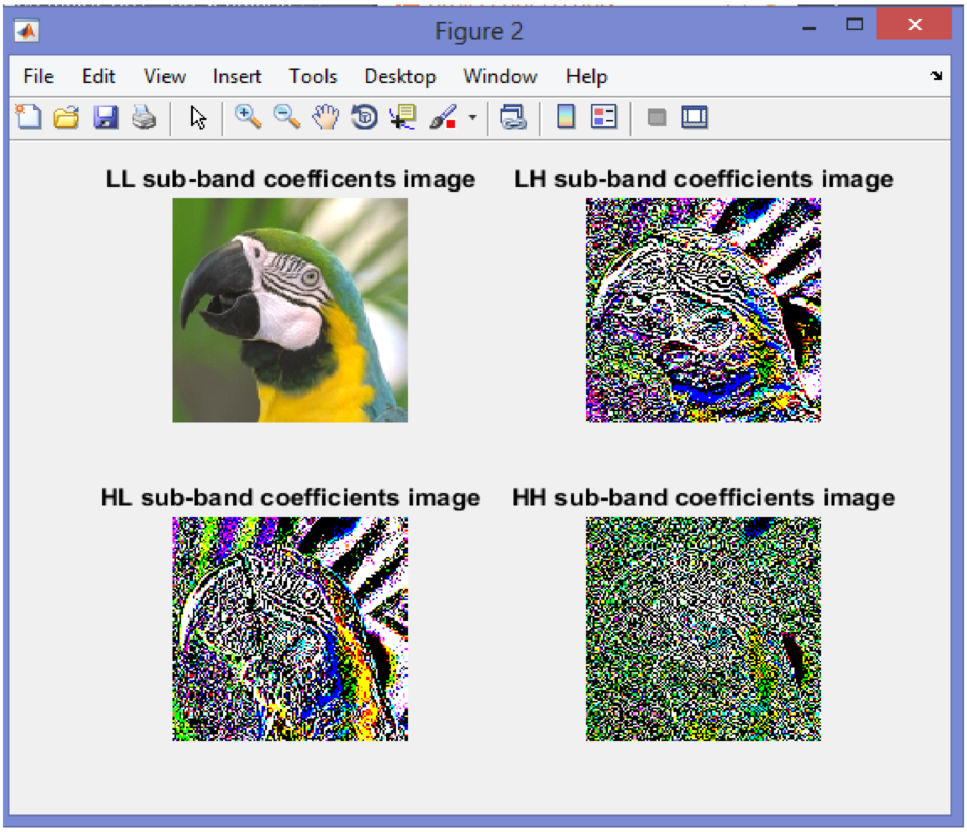

Figure 7.2 Image Coefficients

All comparisons are made using either results reported in the respective papers or those obtained from running the code that the authors have generously shared. average PSNR values of different methods for images from BSD68.

Figure 7.3 Reconstructed Image

Although PSNR is not an accurate metric for perceptual quality, our method performs competitively with Noise2Void and is better than Deep image prior.

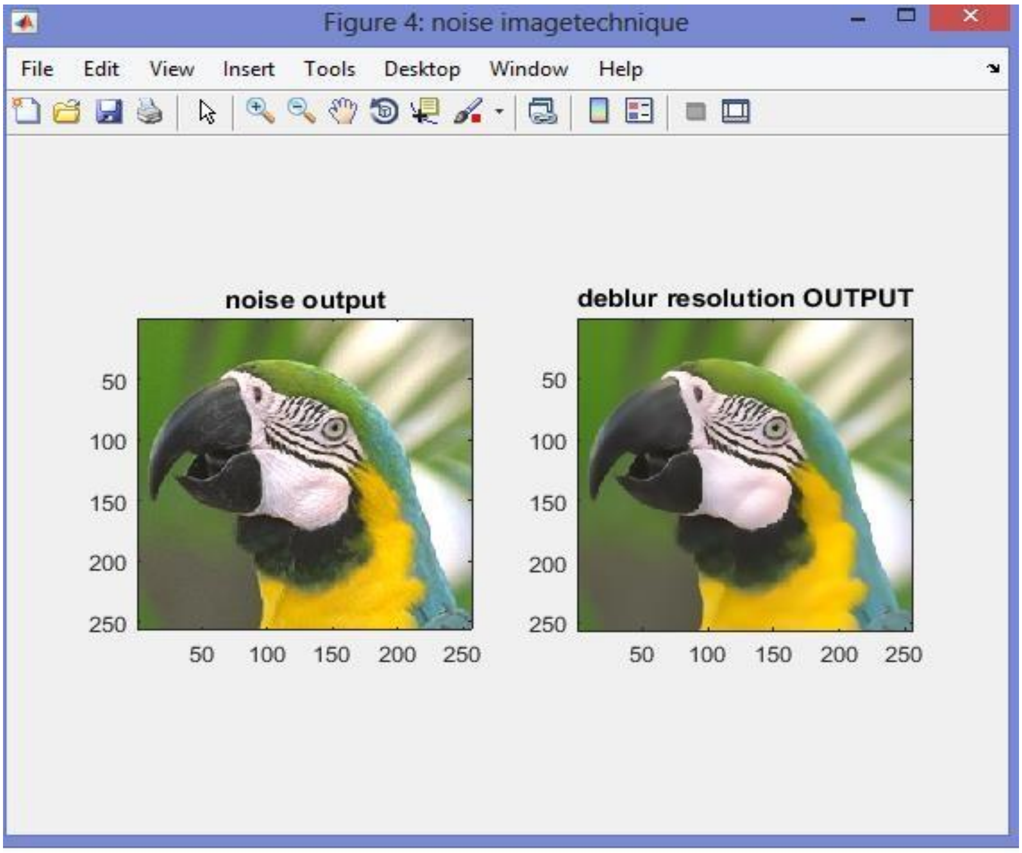

Figure 7.4 Noise output and DeBlur Resolution Output Image

Our method is able to remove noise effectively without blurring any textures, details or sharp edges (this is obvious in the sky in the first set of images). Deep image prior produces outputs that still have visible noise.

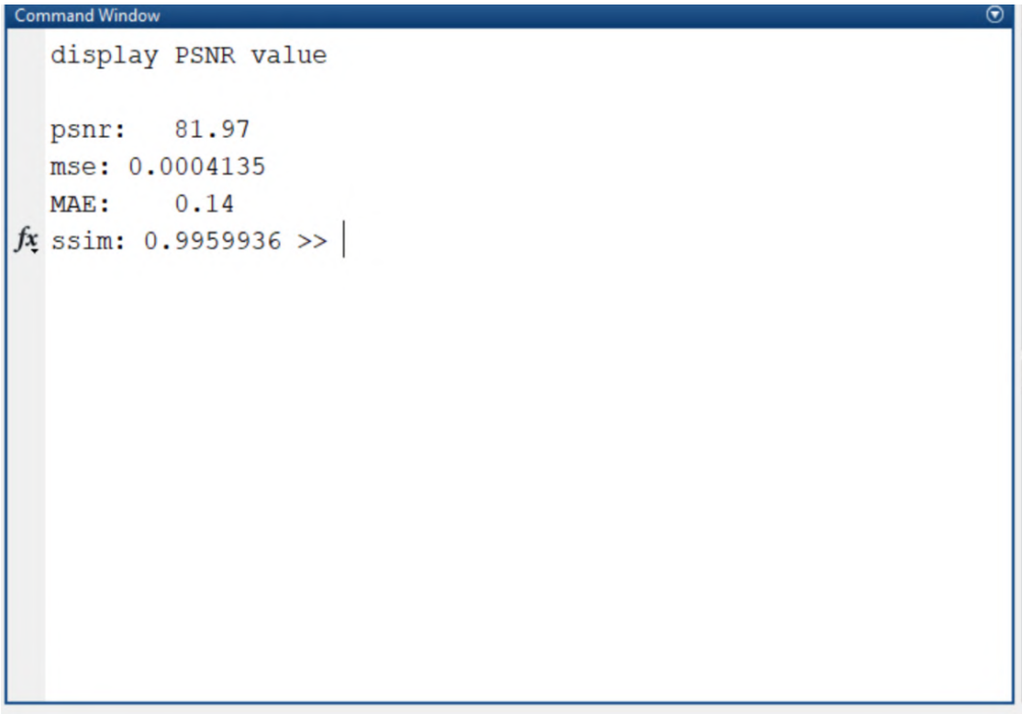

Figure 7.5 PSNR Values.

In the Command Window we will be having the niose values and PSNR values of our output image.

CHAPTER 8

CONCLUSION AND FUTURE SCOPE

CONCLUSION

We have proposed the use of flow-based model as a mathematically justifiable and realistic prior for image denoising. We have conducted qualitative and quantitative experiments on the BSD68 dataset that reveals the competitive performance of our method. Motivated by our success, we conjecture that using a flow based model prior should be effective for solving other image restoration tasks such as image deblurring and super resolution in an unsupervised fashion.

FUTURE SCOPE

With the explosion in the number of digital images taken every day, the demand for more accurate and visually pleasing images is increasing. However, the images captured by modern cameras are inevitably degraded by noise, which leads to deteriorated visual image quality. Therefore, work is required to reduce noise without losing image features (edges, corners, and other sharp structures.

DECLARATION

We, the student of "**BACHELOR OF TECHNOLOGY IN DEPARTMENT OF ELECTRONICS AND COMMUNICATION ENGINEERING"**, session: (2017 – 2021), St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled '**Deep Learning Underwater Image Color Correction And Contrast Enhancement Based On Hue Preservation'** is the outcome of our bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted to any university for the award of any degree.

K. Kiran Kalyan	**Rishabh Singh**
(17K81A0427)	**(17K81A0442)**

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P. Santosh Kumar Patra,** our beloved **Principal**, **St. Martin's Engineering College** for his invaluable encouragement, suggestions, and support from an early stage of this research and for providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr. B Hari Krishna**, **Head &Professor**, the Dept. of Information Technology for his/her advice, supervision, and vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our dept. **Project coordinator Dr. A. Anand** for his/her involvement with originality has triggered and nourished the intellectual maturity that will help me for a long time to come.

We sincerely thank our **Class Project Coordinator, Mrs. A. Soumya,** Department of ECE and our project **Internal guide, Mr. K. Naga Venkateshwara Rao, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college-level Project Coordinators **Dr.Maalyadri, Professor in IT, and Dr.R.Santhosh Kumar, Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1. K. Kiran Kalyan
2. Rishabh Singh

ABSTRACT

Underwater Image suffers from serious color distortion and low contrast problems because of complex light propagation in the ocean. Given the computing constraints of underwater vehicles, we propose a high-efficiency deep-learning framework based on hue preservation. The framework contains three convolutional neural networks for underwater image color restoration. At first, we use the first CNN to convert the input underwater image into the grayscale image. Next, we enhance the grayscale underwater image with the second CNN. And then, we perform the color correction to the input underwater image by the third CNN. At last, we can obtain the color-corrected image by integrating the outputs of three CNNs based on hue preservation. In our framework, that CNN's specialize in each work can be able to simplify each architecture and improve the regression quality to achieve low computing cost and high efficiency. However, the problem with the underwater CNNs is that the underwater training data is too few and without the corresponding ground truth. Thus, we use the unsupervised learning method CycleGAN to train the underwater CNNs. We design a training method as the combination of three CycleGANs that can train the three CNNs at the same time to share the regression status. This training method may let the three CNNs of our proposed framework support each other to avoid the training overfitting and without constraint. By the proposed framework and training method, our method can process the underwater images with high quality and low computing cost. The experimental results have demonstrated the correct colors and high image quality of the proposed method's results, compared with other related approaches.

LIST OF FIGURES

CHAPTER 1: INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

- Underwater Image suffers from serious color distortion and low contrast problems because of complex light propagation in the ocean.
- We propose a high-efficiency deep-learning framework based on hue preservation.
- The framework contains three convolutional neural networks for underwater image color restoration.
- We can obtain the color-corrected image by integrating the outputs of three CNNs based on the hue preservation.
- Thus, we use the unsupervised learning method Cycle-GAN to train the underwater CNNs. Our method can process the underwater images with high quality and low computing cost.

1.2 OBJECTIVES OF THE STUDY

The main objective of the project is to perform the following four stages

- The underwater image grayscale stage
- The grayscale underwater image details enhancement stage
- The underwater image color restoration stage
- The generation stage

1.3 SCOPE OF STUDY

- MATLAB Software
- Operating System – Windows 10
- 64bit (Intel or AMD) Processor

- GPU Acceleration using parallel computing toolbox

1.4 INTRODUCTION OF PROJECT

The earth is the associate aquatic planet and the maximum amount as eightieth of its surface is roofed by water. Moreover, there is a strong interest in knowing what lies underwater. In present days, an image of deep waters has scope to large investigation to explore the underwater for seafloor expedition and navigation. The enthusiasm of underwater imaging includes the inspection of plants, seabed exploration, the search for wrecks up, and the exploration of natural resources. There were several issues faced by the human underwater if he dives deep into the ocean and stays there for a long time to perform experimentation. [1]. Due to the above reasons, unmanned remote vehicles are used for seafloor exploration.

A. Historical Development

Underwater image quality improvement approaches present a path to magnify the object recognition in the underwater surrounding. A heap of research started for the up-gradation of image visual quality, but a little amount of work has been carried out in this area. In the deep waters, image quality is degraded due to poor illumination conditions and the light properties differ in water compared to air.[2]. Several parameters decrease the quality of an image in underground waters. So to remove all these effects

several techniques have been implemented and practiced.

B. Need for Preprocess

Initially, the processing is necessary for deep water images due to their poor quality during acquisition. A necessity for pre-processing of deepwater images are discussed below:

(i) Quality of images taken from deep water is deteriorated due to light ray attributes like scattering and absorption of light.
(ii) Specificity of surroundings such as lighting inequalities, water torridness, and blue complexion is more or less influential when vehicles move.

(iii) Video or image captured from deep waters like unknown rigid scene, and the depth of the scene and low light sensitivity due to Marine snow, etc.

Figure 1.1 Example of Underwater Image

1.5 INTRODUCTION TO IMAGE ENHANCEMENT AND RESTORATION

The goal of underwater image processing is to enhance visibility and rectify the color deviation. In general, underwater image processing techniques can be divided into two categories, namely, underwater image enhancement and restoration. The underwater image enhancement methods, such as histogram equalization, white balance, pixel stretching, retinex-based methods, and fusion-based methods, generally improve image visual effect by modifying image pixels without concerning the physical degradation mechanism of underwater images. These enhancement-based methods do not exploit physical imaging models and consequently, they are often inadequate for restoring original scene features, especially color features.

On the other hand, underwater image restoration methods aim to recover clear images by exploiting the optical imaging model. The most important task for restoration is to estimate two key model parameters, i.e., transmission and ambient light, which are usually estimated either by prior-based approaches or by learning-based approaches. The prior-based approaches heavily depend on the reliability of certain prior information, such as dark channel prior, red channel prior haze-line prior, and so on. However, priors generally have their respective limitations, and may not adapt to some conditions. Thus, a mismatch between the adopted prior and the target scene may incur significant estimation error, and consequently, recover distorted results.

By contrast, the learning-based approaches aim to obtain more robust and accurate estimation by exploring the relations between the underwater images and the corresponding parameters in a data-driven manner, such as. To this end, it is essential to have a suitable training dataset and an efficient neural network that can be trained to learn such relations. Unfortunately, the existing networks are not capable of estimating the parameters accurately enough and the resulting restored images often suffer from various artifacts; it is also difficult to create a dataset capturing complex and varying underwater environments. Based on the well-known model for underwater physical imaging, we propose a deep convolutional neural network (CNN) model with two parallel branches for underwater image restoration, accompanied by a training dataset in this paper. By exploring the inherent relations between the degraded underwater images and the associated blue channel transmission map as well as global ambient light in a data-driven manner, the proposed CNN can perform more accurate and robust parameter estimation; as a consequence, the restored images exhibit better visibility and more natural color compared to those produced by the state-of-the-art methods.

The contributions of this work are summarized as follows:

(1) We propose a new end-to-end underwater image restoration algorithm using a deep CNN model to improve the contrast and color cast of the recovered images. The whole network consists of two paralleled branches: a transmission estimation sub-network (T-network) and a global ambient light estimation sub-network (A-network), by which the transmission map and the ambient light can be estimated simultaneously. Since in our case no prior information is used to estimate the transmission and ambient light, it avoids the aforementioned mismatch issue commonly encountered in the prior-based methods and helps to improve the accuracy and universality of the estimation method.

1.6 RELATED WORK

Numerous methods have been proposed to enhance underwater degraded images in the past decade. Roughly speaking, these methods can be classified into two categories, namely, enhancement-based methods and restoration-based methods. Enhancement-based methods improve the image quality in a specific sense by using an image enhancement technique designed for that purpose. This type of method can effectively improve the visual effect of the images.

However, because the physical degradation principle is not considered and the relationship between degradation degree and scene depth is neglected, the enhancement results can not reflect the true color features of the scene correctly. On the contrary, the restoration-based methods use the constructed underwater imaging model to reverse the degradation process, for which it is necessary to estimate the unknown parameters: transmission and ambient light. If the model is properly constructed and the parameter estimation is accurate, the restored image will be close to the real scene. Depending on how parameter estimation is performed, they can be further divided into prior-based restoration methods and deep-learning-based restoration methods. In the following subsections, we mainly review the related works belonging to these two kinds of restoration methods.

1.6.1 Prior-Based Restoration Methods

Several techniques are used very frequently for processing the image to improve the visual quality. Some of them are as follows:

(i) Contrast Stretching

(ii) Adaptive Histogram Equalization

1.6.1.1 Contrast stretching

The contrast stretching is a method to transform the high intense region of an image into a brighter and less intense region into darker by using a predefined transformation function T(r) [2]. Generally, the underwater images will have fewer grey values. There are 256 grey values. ‘0’ indicates black and ‘255’ indicates white. In this method, the current grey value of the image is stretched towards 255 i.e., from black to white, pixel by pixel. That means the contrast of the image is stretched so that the quality of the image is improved for better vision.

For example:

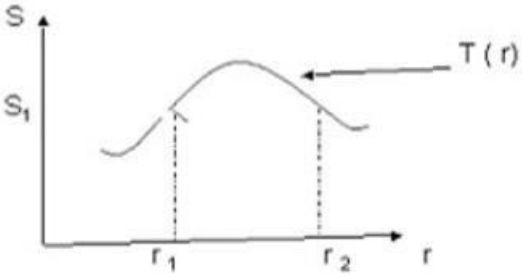

Figure 1.2 Two different gray levels look the same

Here two different thresholds are considered for the entire image and the values between them are stretched to the maximum extent so that the contrast increases. And more over by this method the entire global image contrast is enhanced.

Figure 1.3 Raw image

Figure 1.4 Enhanced image

1.6.1.2 Adaptive histogram equalization

Adaptive histogram equalization is a PC-based image processing technique that is used to improve the quality of image properties like the contrast. It is similar to the contrast stretching method but with a slight difference. It computes several intensities of a specific gray value, each corresponding to a distinct portion of an image, and with the help of them, intensities are rearranged by applying a suitable transformation function. For example, a simple transformation function such as each pixel transformed based on the histogram of a square surrounding the pixel [3]. Existing values will be mapped to new values keeping an actual number of intensities in the resulting image equal or less than the original number of intensities. The transformation function applied on the histogram is proportional to the cumulative distributive function (CDF) of pixel values in the neighborhood. Therefore it suits for enhancing the local details and enhancing the edge information of each region of an image.

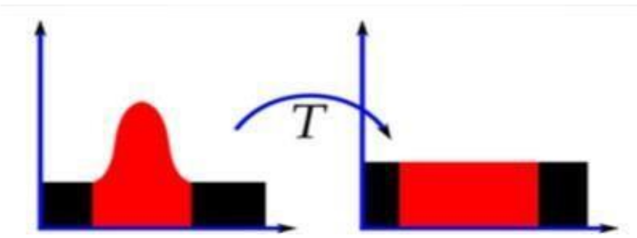

Figure 1.5 Histograms of an image before and after histogram equalization

Histogram equalization is a technique for changing the overall pixel intensities based on the transformation function and contrast of an image. Histogram equalization is an effective technique that will benefit the images with extreme contrast values. The limitation of this technique highlights the unwanted noise present in the background of an image and leads to a loss in the information signal. It results in undesired effects in the resultant images.

Figure 1.6 Raw image

Figure 1.7 Enhanced image

The ocean has a large storage of resources, but the riches of the sea have yet to be developed. The main problem is that the underwater environment is hostile to humans. Thus, automatic technology plays a major role in underwater engineering. The automatic technology includes automatic inspection, process control, and robot guidance. These applications are all based on machine vision to provide imaging-based inspection and analysis. However, machine vision is not effective enough in an underwater environment. Due to the complex light propagation in an underwater environment, the acquired images suffer from serious color distortion and poor visual quality. It would reduce the accuracy and efficiency of machine vision. Therefore, researchers have attempted restoring the underwater image to the correct color and high image quality. In this paper, we focus on underwater image color restoration from a single image.

1.7 DEEP-LEARNING-BASED RESTORATION METHODS

Deep learning techniques have gained increasing popularity in image processing, and have been used for image transmission map estimation in particular. Deep-learning-based methods rely on neural networks, trained by a large amount of data, to learn the relationship between an image and its associated transmission map. They can avoid, to a certain extent, the estimation errors incurred by invalid priors as seen in the prior-based methods. However, the neural networks that have been proposed so far are all for single-channel transmission estimation, with the implicit assumption that three color channels have the same transmission map. As such, they are only able to correct blurring and low contrast caused by scattering, but not color deviation induced by the discrepancies between the transmission maps of three channels commonly seen in underwater images.

Inspired by DehazeNet, Shin et al. proposed an underwater restoration method based on deep learning, which estimates global ambient light and local transmission of underwater images using the same network, and then leverages the estimates to restore the clear image via the optical model. This method uses synthetic data for training. Specifically, the underwater image patches are simulated by adding different color deviations to the clear image patches, and the training label of each image patch is the corresponding transmission value or the ambient light value. Although this method achieves promising results, there are several aspects to be improved. In particular, since local image patches are used as the training data (which lack global information) and that the discrepancies between the transmission maps of three channels are ignored in recovery, this method is often not able to estimate the parameters with sufficient accuracy and the restored images tend to suffer from color distortion and low clarify. A similar method was developed by Barbosa et al, which estimates the transmission map and the ambient light respectively using a retrained DehazeNet and a prior proposed by Drews et al. It is well known that the performances of deep-learning-based methods depend critically on the quality of the training data. The training datasets used to consist of haze images with no color deviation. The work by Shin et al uses a large number of training image patches with color deviation not specific to underwater environments, which are known to be mostly blue/green. For transmission estimation, Barbosa et al. rendered two 3D scenes and obtained a large set of images by positioning the camera in different locations, which are nevertheless still not sufficient to simulate diverse underwater environments. The lack of suitable training datasets has become a roadblock for the deep-learning-based approach to underwater image restoration.

1.8 INTRODUCTION TO IMAGE PROCESSING

1.8.1 Image

An image is a two-dimensional picture, which has a similar appearance to some subject, usually a physical object or a person.

Image is two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Figure 1.8 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

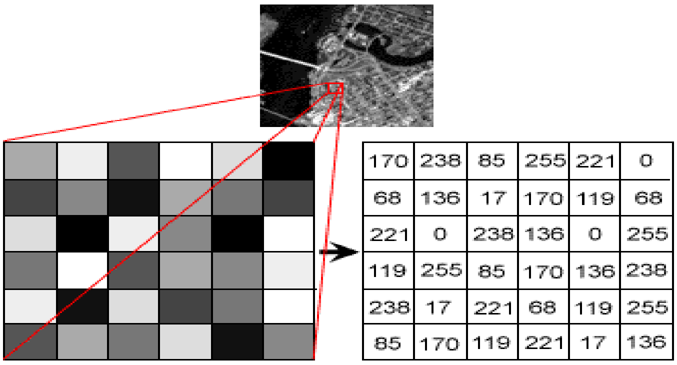

Figure 1.9 image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

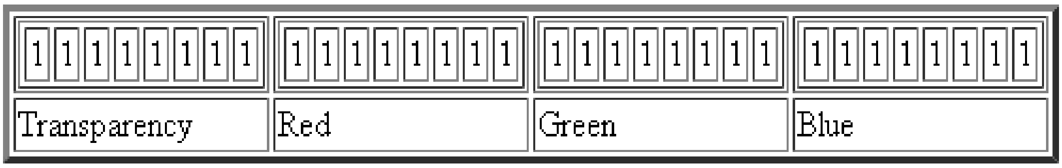

Figure 1.10 Transparency image

1.8.2 Image file sizes

The image file size is expressed as the number of bytes that increase with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High-resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.8.3 Image file formats

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

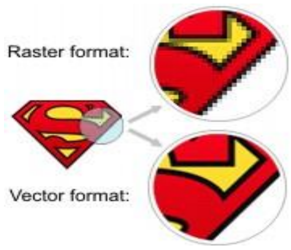

Figure 1.11 Resolution image

In addition to straight image formats, Metafile formats are portable formats that can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their native format.

1.8.4 Raster formats

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is a lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata is recorded for individual images and includes such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of the camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos, and cartoon-style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

1.8.5 Vector formats

As opposed to the raster image formats above (where the data describes the characteristics of each pixel), vector image formats contain a geometric description that can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows, and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable, and all-purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.8.6 Image processing

Digital image processing, the manipulation of images by computer, is a relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of image with varying degrees of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields suffers from myths, dis-connect ions, misunderstandings, and misinformation. It is the vast umbrella under which fall diverse aspects of optics, electronics, mathematics, photography graphics, and computer technology. It is a truly multidisciplinary endeavor plowed with imprecise jargon.

Several factors combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low-cost microprocessors, and the use of charge-coupled devices (CCDs) for digitizing, storage during processing and display, and large low cost of image storage arrays.

1.8.7 Fundamental steps in digital image processing

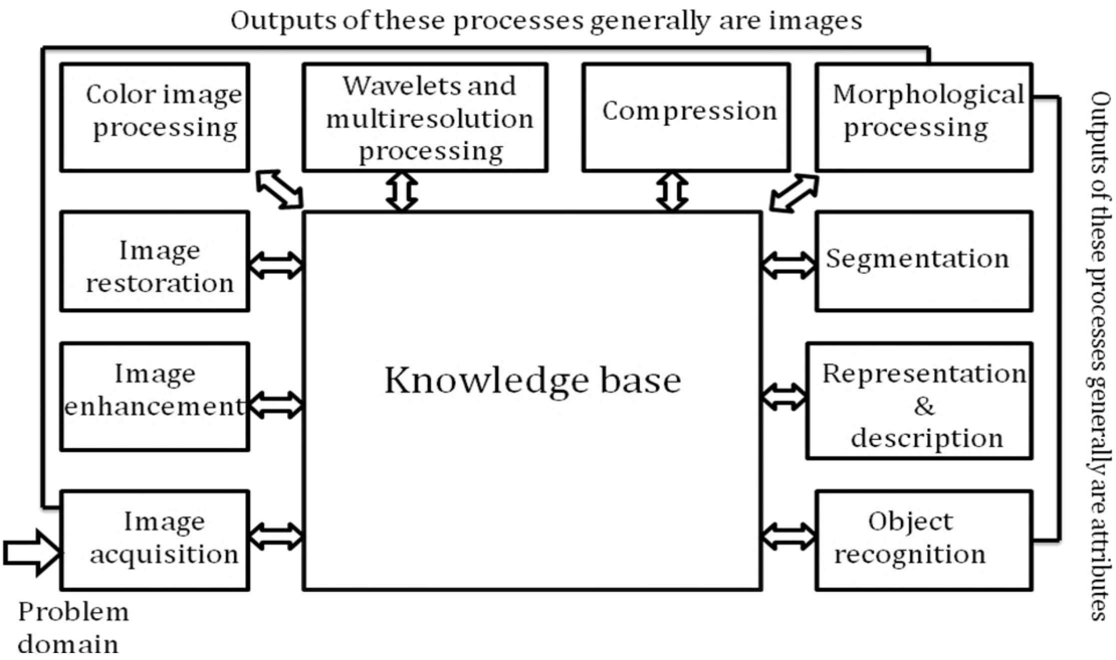

Figure 1.12 Image fundamental

1.8.8 Image Acquisition

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Figure 1.13 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Figure 1.14 Digital camera cells

1.8.9 Image Enhancement

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of an interesting image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Figure 1.15 Image enhancement

1.8.10 Image restoration

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Figure 1.16 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

1.8.11 Color image processing

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Figure 1.17 Color & grayscale image

1.8.12 Wavelets and multiresolution processing

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950’s, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

Figure 1.18 RGB histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called Multiresolution theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.8.13 Compression

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

1.8.14 Morphological processing

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Figure 1.19 Blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.8.15 Segmentation

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

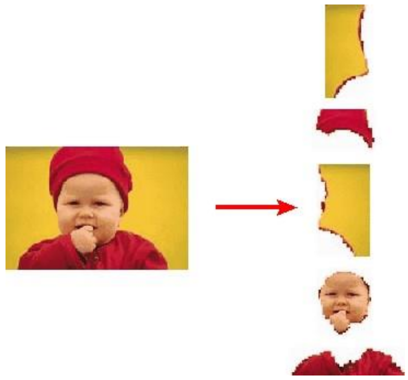

Figure 1.20 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

1.8.16 Representation and description

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

1.8.17 Object recognition

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

1.8.18 Knowledgebase

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.8.19 Components of an image processing system

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

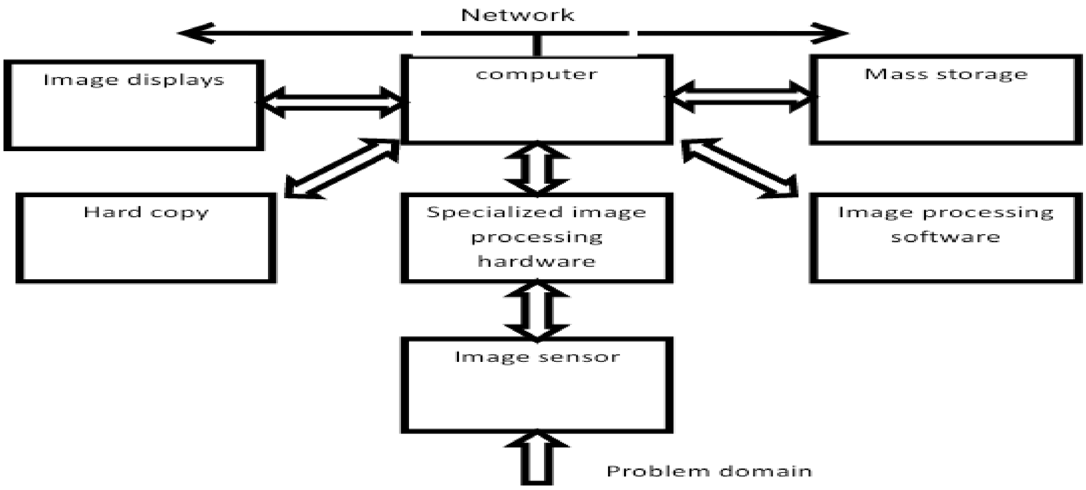

Figure 1.21 Components of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

Equation 1 Each component of GCM

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where

$$\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$$

Equation 2 Hue values set

then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \mathrm{Pr}((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Equation 3 Each component of CCM

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pairwise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(i; j) = Pr((up; vNp) = (i; j))$$

$$mcmLU(i; j) = Pr((lp; uNp) = (i; j))$$

$$mcmLV(i; j) = Pr((lp; vNp) = (i; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i,

j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the

properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

1.8.20 Integrated color and intensity co-occurrence matrix

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

1.8.21 HSV color space

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

1.8.22 Properties of the HSV color space

Sensing light from an image in the layers of the human retina is a complex process with rod cells contributing to the scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing, or transmission of color information in images. Out of these, HSV is one of the models that separate the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when the incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree to which a pure color is diluted by white light. For light with low illumination, the corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3, and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacore with a value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the purest form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated and are visually perceived as the true colors represented by their hues. Low saturation implies the presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree to which a pixel contributes to color perception and gray level perception.

One possible way of capturing the color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such hard thresholding does not properly capture color perception near the threshold values. This is because there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

1.8.23 Non interval quantization

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify the HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according to the human color perception has been applied on H, S, V components.

Based on the color model of substantial analysis, we divide the color into eight parts. Saturation and intensity are divided into three parts separately following the human eyes to distinguish. Per the different colors and subjective color perception quantification, quantified hue(H), saturation(S), and value(V)

Following the quantization level above, the H, S, V three-dimensional feature vector for different values with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

In this way three-component vector of the HSV from a one-dimensional vector, which quantizes the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of a one-dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

1.8.24 Image retrieval

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords, or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time-consuming, expensive, and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002]

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential.

More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

1.8.25 Overview of texture

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them. We can reproduce Textures by producing the descriptions.

1.9 ORGANIZATION OF CHAPTERS

1.9.1 Introduction

This section provides information about the project such as overview, objective and scope of the project. Along with that, this chapter also includes information about the techniques that have been used or considered while working on the project.

1.9.2 Literature Survey

This section provides the information about the existing methods on 'underwater image color correction and contrast enhancement' with the help of which this project was modified.

1.9.3 Project Design

This section provides the information about the methodology that is applied in this project i.e., the design is discussed and also the software used to implement it.

1.9.4 Project Implementation

This section provides the information about how the project is implemented. It also contains the results of the project.

1.9.5 Conclusion and Future Enhancement

This section concludes the project along with the applications of it. This project can be enhanced further for better results and wide utility and the future enhancement chances are mentioned here.

CHAPTER 2: LITERATURE SURVEY

Single image underwater image restoration is an ill-posed problem. To restore the information of underwater image, the underwater image transmission model need to be estimated. The image processing theories are the traditional method to solve this estimation problem. C. Li et al. [1] proposed a restoration method by blue-green channels dehazing and red channel color correction. It restores the red channel of underwater image with the Gray-World assumption theory. Blue and green channels are processed with the modification of Dark Channel. To prevent the result become too dark or too bright, the restored image would be adjusted by the adaptive exposure map at last. D. Berman et al. [2] proposed a underwater image color restoration method that consider wavelength-dependent attenuation and take into account various water types. In this method, the underwater image transmission are estimated by the attenuation ratios of the blue-red and blue-green color channels. The value of attenuation ratios are defined by each water type. The underwater image would evaluate the all possible water types and the one that matches the Gray-World assumption best is chosen as the result. Besides the image processing method, the deep learning is also the popular method for image restoration. However, the underwater datasets are scarce and without corresponding ground truth. The common deep supervised learning needs pairs of training data for training, so the unsupervised learning is used to generate the fake underwater image pairs as the training dataset. J. Li et al. [3] proposed an unsupervised pipeline called WaterGAN. WaterGAN is based on generative adversarial network(GAN) [4] to generate realistic underwater image by the in-air image and corresponding depth map.

2.1 CONCLUSION ON REVIEWS

The disadvantage of the existing methods is that the transformation function is not unique. Depending on the application the suitable transformation function is chosen. Also the noise in relatively homogeneous regions of the image is amplified which results in poor SNR. Only the local objects of the image are enhanced and the background is left unenhanced.

So, this paper proposed an end-to-end convolutional neural network for underwater image color restoration. This convolutional neural network architecture contains two stage. The first stage is relative depth estimation for the underwater image. The estimated depth map and underwater image are the input of the second stage to restore the correct color. The dataset that generated by WaterGAN is used to train this endto-end network to restore the underwater image

CHAPTER 3: PROJECT DESIGN

3.1 FRAMEWORK OF PROPOSED UNDERWATER IMAGE ENHANCEMENT

the proposed deep learning-based underwater image restoration framework consists of the four stages: (1) the underwater image grayscale stage relying on CNN to convert the underwater image to the best gray-channel image; (2) the grayscale underwater image details enhancement stage also relying on CNN to remove the noise and enhance the image quality; (3) the underwater image color restoration stage via end-to-end CNN; and (4) the generation stage of the final high image quality and correct color underwater image by integrating the outputs of the other three stages. The details of the four stage is in the following four subsection, respectively.

3.1.1 Underwater Image Grayscale Transformer

Based on hue preservation enhancement method, the first stage is converting the input underwater image to the grayscale image. Different from the in-air image, the red channel and the green channel of underwater image is attenuated by light propagation. We have to analysis the degree of light attenuation to evaluate the best ratio among three channels. To accelerate the algorithm computing, we use the convolutional neural network to predict the ratios. As shown in Fig. 2, the proposed underwater image grayscale transform CNN aims at transforming an input underwater RGB image to the three coefficients that are used to combine RGB three channel to the corresponding grayscale image. The CNN consists of four convolutional layers (denoted by Conv in Fig. 2). In the network architecture, the concatenation layer (denoted by Concat in Fig. 2) is used to stack the outputs from two convolutional layers with different filter size. It would be useful to condense multi-scale features to learn the prediction method. The activation functions of all convolutional layer in this architecture are the rectified linear unit (ReLU) [5]. ReLU is mainly utilized for nonlinearity, which has been shown to allow for faster and more correct regression than other non-linear separators. We obtains the coefficients from the mean of all elements in each feature map from the output of the final convolutional layer. This network architecture benefits the advantages that enable to extract multi-scale image feature, which would be helpful for grayscale ratio prediction.

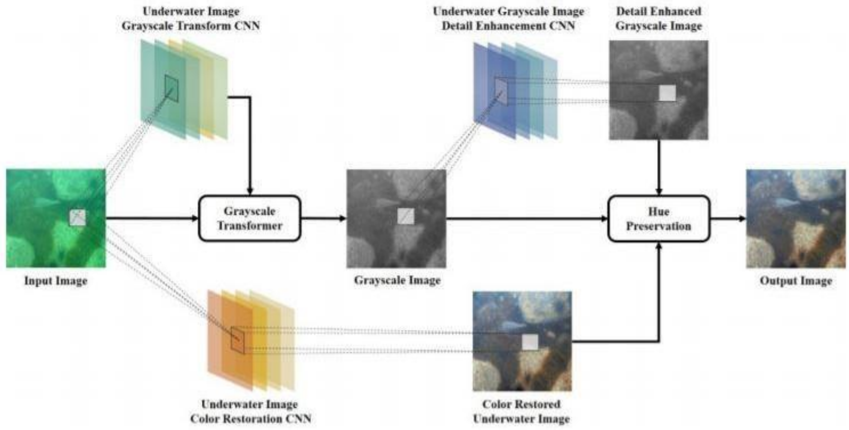

Figure 3.1 The diagram of the proposed deep learning-based underwater image color restoration framework

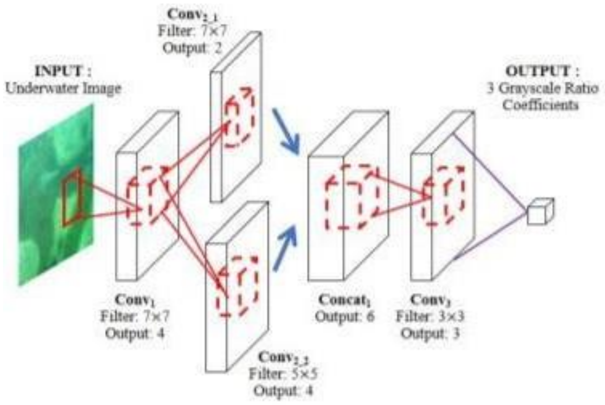

Figure 3.2 The proposed underwater image transform convolutional neural network architecture for gray ratio prediction

As a result, the grayscale image is obtained from the input underwater image and the three coefficients from underwater image grayscale transform CNN as:

$$I_{Gray} = \frac{p_R}{p_R+p_G+p_B} I_R + \frac{p_G}{p_R+p_G+p_B} I_G + \frac{p_B}{p_R+p_G+p_B} I_B, \quad (1)$$

where I_R , I_G , I_B ,denote the R, G, B channel of the input underwater image and P_R ,P_G , P_B are the gray channel ratio coefficients predicted by underwater image grayscale transform CNN. By this method, we can obtain the underwater grayscale image with the most image complexity and information.

3.1.2 Underwater Grayscale Image Detail Enhancement

The end-to-end convolutional neural network method is a great way to solve the image processing problems with low computing cost and high quality. However, the deep learning methods still contain some problems. Because of slight deviation in image regression, the processed image may contains noise and blurry. Otherwise, the convolutional neural network with the light architecture cannot burden to do the underwater image color correction and the underwater image denoise at the same time. Thus, based on hue preservation, we proposed the underwater grayscale image detail enhancement CNN for the underwater image denoise and CNN processed image detail correction. Inspired by the Google Inception V3 Net, the architecture of underwater grayscale image detail enhancement CNN is shown in Fig. 3. This CNN aims at transforming an input underwater grayscale image to the enhancement transmission map. The architecture consists of seven convolutional layers. In this architecture, we choose Parametric Rectified Linear Unit (PReLU) as the activation function. PReLU is better than ReLU at learning the transmission map about image texture modification and enhancement. At last, the enhanced underwater grayscale image is obtained by adding the enhancement transmission map to the input grayscale image.

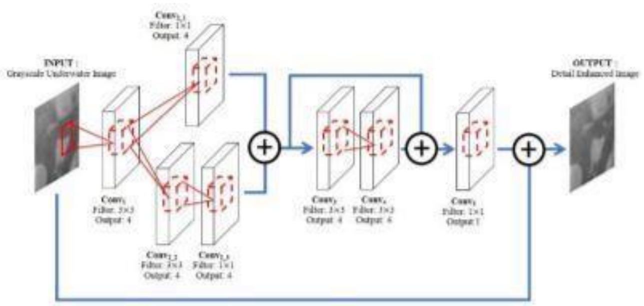

Figure 3.3 The proposed underwater grayscale image detail enhancement convolutional neural network architecture

3.1.3 Underwater Image Color Restoration

The underwater image color restoration is the main stage of the framework. We use the end-to-end convolutional neural network to correct the color loss in underwater image. Underwater color correction is a complex problem. A high image quality in-air images have to contain high color saturation, right color balance and appropriate image contrast. Thus, we design a loss function which restricts many conditions for the underwater image color restoration CNN regression. The content details of the loss function present in Sec. III.

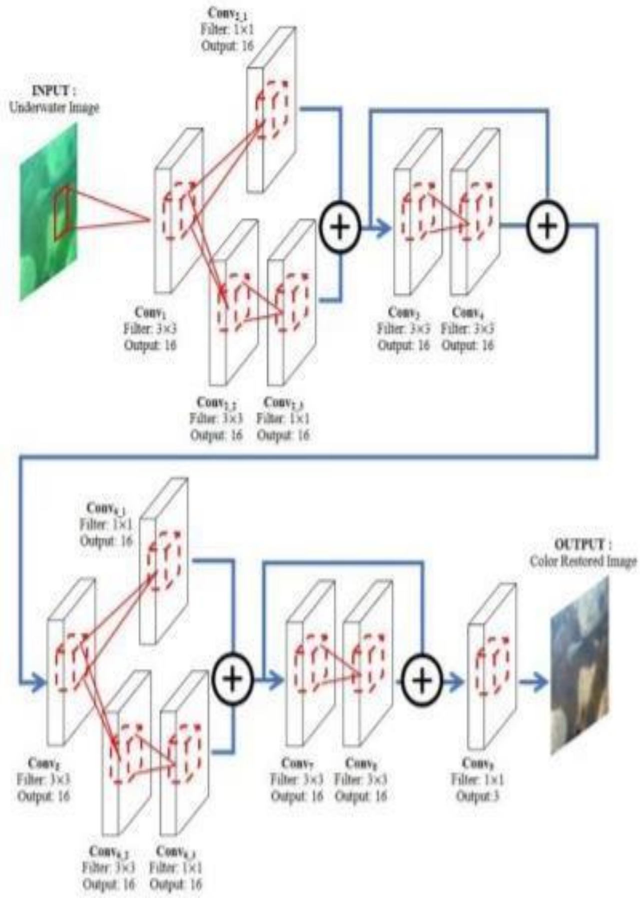

Figure 3.4 The proposed underwater image color restoration convolutional neural network architecture

3.1.4 Hue Preservation Enhancement

Hue preservation is necessary for color image enhancement. In this stage, we use the hue preservation enhancement method from Tian et al. [8]. Tian et al. proposed a global contrast adaptive enhancement method based on hue preservation enhancement. It is a great method to integrate the results of color correction and detail enhancement. The output image $I_R(x)$ is generated by integrating the outputsf other three stages as:

$$I_R(x) = \begin{cases} \frac{I_{GE}(x)}{I_G(x)} I_C(x), & if\ \frac{I_{GE}(x)}{I_G(x)} \leq 1 \\ \frac{255-G_E(x)}{255-G(x)} (I_C(x) - I_G(x)) + I_{GE}(x), & if\ \frac{I_{GE}(x)}{I_G(x)} > 1 \end{cases} \quad (2)$$

Where $I_C(x)$ represents the hue preservation enhanced color image, $I_G(x)$ is the grayscale image of the input underwater image generated by the underwater image grayscale transformer stage, $I_{GE}(x)$ is the output of the grayscale image detail enhancement stage, Hence it's the color restored underwater image from the underwater image color restoration stage and x denotes the positions of pixels on the image.

3.1.5 Proposed Unsupervised Training Method

The main problem for deep learning-based underwater image restoration method is the lack of dataset. The underwater image datasets are rare and have no ground truth. To solve this problem, we use the unsupervised learning to train the proposed convolutional neural networks. GAN is the popular unsupervised learning method which have achieved many impressive results in image generation and image editing. Based on the algorithm of GAN, CycleGAN is proposed. As shown in Fig. 5, the architecture contains backpropagation to restore the images that generate by another generator. Using the cycle consistency loss and adversary loss, It can also guide the generator network to perform better in reconstructing image

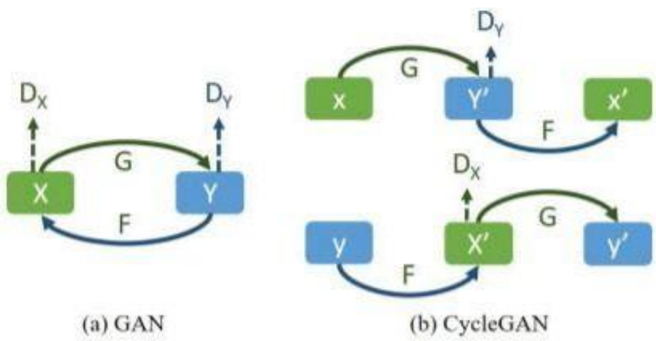

Figure 3.5 The architecture of GAN and CycleGAN

We combine three CycleGANs as our training method to train the three CNNs of the proposed framework at the same time. We distinguish these three CycleGANs by their generators. In the first part, we train the underwater grayscale image detail enhancement CNN as the generator. The two domains of the input training data are the gray underwater images and the gray in-air underwater image. The underwater image color restoration CNN are trained as the generator of the second part. The second CycleGAN learning the mapping between the color underwater image and the color in-air image. The generator of the last part is the whole framework. The training data of the last CycleGAN is same as the second ones. With these three parts, we can training all CNNs in the whole framework at the same time. However, CycleGAN alone cannot perfectly train the underwater image restoration framework. Overfitting and falling into a cycle of greedy optimization are the problems of CycleGAN that would affect the training results. Thus, we additional set some conditions in loss function to restrict the CNN regression. These conditions also share the training information from other CNNs to make the CNNs learn the mapping more comprehensively.

3.2 DEFINE THE MODULES

3.2.1 Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modelling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non-interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In the industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available to include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2.2 The MATLAB system

The MATLAB system consists of five main parts

- **Development Environment:**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigenvalues, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using the IMAGE PROCESSING toolbox.

3.2.3 Graphical User Interface (GUI)

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG file contains binary data that does not need to be parsed when the associated GUI-based M function is executed.

● A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited and callback functions that are executed when a user interacts with GUI objects for example when a button is pushed.

To launch GUIDE from the MATLAB command window, type :

guide filename

Where filename is the name of an existing FIG-file on the current path. If the filename is omitted,

GUIDE opens a new (i.e., blank) window.

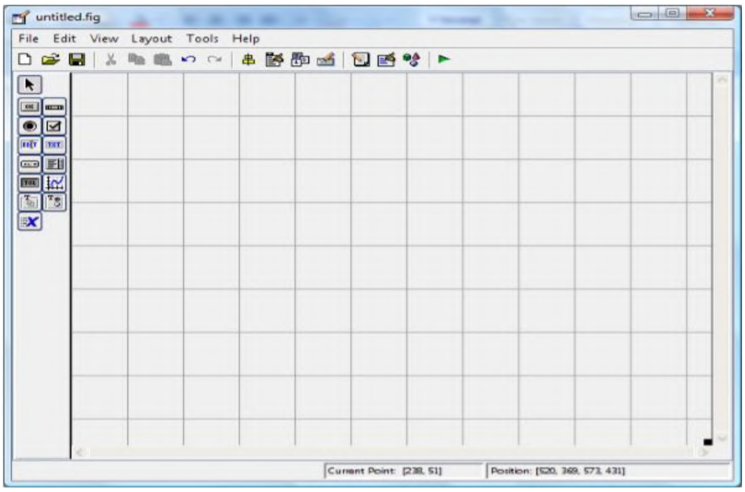

Figure 3.6 MATLAB procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, pushbuttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.2.4 Getting Started to Matlab

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.2.5 Introduction.

Describes the components of the MATLAB system.

3.2.6 Development environment

Introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.2.7 Manipulating matrices

Introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.2.8 Graphics

Introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images. 2.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.2.9 Development Environment

- **Introduction**

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

- **Starting MATLAB**

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type MATLAB

At the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup and reduce startup time in some situations.

- **Quitting MATLAB**

To end your MATLAB session, select Exit MATLAB from the File menu on the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

- **MATLAB Desktop**

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

- **Desktop Tools**

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the Help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favourite tab - View a list of documents you previously designated as favourites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term on the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces. To view the workspace and information about each variable, use the Workspace browser, or use the functions who and who's. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT file, which has a .mat extension. There are options for saving to different formats. To read in a MAT file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop.

3.2.10 Digital image processing background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem.

An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

3.2.11 What is Digital Image Processing

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital images by means of a digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensors, so it is not surprising that images play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting & somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

3.2.12 What is an image:

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

3.2.13 Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ·[0, b]I: [0, a] · [0, b] → [0, info)

3.2.14 Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

3.2.15 Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

3.2.16 Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

$$
f\,(xylem) = \begin{array}{cccc}
f\,(0,0) & f(0,1) & \ldots\ldots\ldots.. & f(0,N-1) \\
f\,(1,0) & f(1,1) & \ldots\ldots\ldots\ldots & f(1,N-1) \\
. & . & & . \\
f\,(M-1,0) & f(M-1,1) & \ldots\ldots\ldots\ldots\ldots & f(M-1,N-1)
\end{array}
$$

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

$$f = \begin{matrix} f(1,1) & f(1,2)\ldots\ldots\ldots\ldots f(1,N) \\ f(2,1) & f(2,2)\ldots\ldots\ldots\ldots f(2,N) \\ . & . \qquad\qquad . \\ . & . \qquad\qquad . \\ f(M,1) & f(M,2)\ldots\ldots\ldots f(M,N) \end{matrix}$$

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

3.2.17 Reading Images:

Images are read into the MATLAB environment using function imread whose syntax " Imread ('filename

Table 3.1 Different Formats Of Images

FORMAT NAME	DESCRIPTION	RECOGNIZED EXTENSION
TIFF	Tagged Image File Format	.tif, .tiff

JPEG	Joint Photographic Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread ('8. jpg')

Table 3.2 DataTypes

NAME	DESCRIPTION
DOUBLE	Double_precision, floating_point numbers the approximate
uint8	unsigned 8_bit integers in the range [0,255] (1byte per element).
unit16	unsigned 16_bit integers in the range [0, 65535] (2byte per element).
unit32	unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element).
int8	signed 8_bit integers in the range [-128,127] 1 byte per element).

int16	signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
int32	Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).
Single	single _precision floating _point numbers with values in the approximate range (4 bytes per element).
Char	characters (2 bytes per element).
Logical	values are 0 to 1 (1byte per element).

Reads the JPEG (above table) image chest x ray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

3.2.18 Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

Images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logic or by using relational operators.

3.2.19 Image Types:
The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB color images.

3.2.20 Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

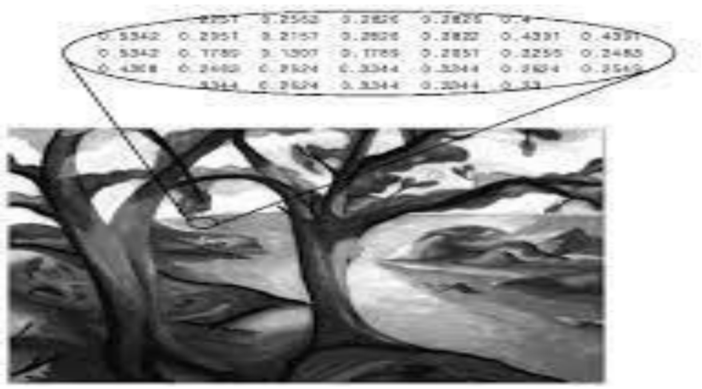

Figure 3.7 Intensity image example

3.2.21 Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB. A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays. To test if an array is logical, we use the I logical function: is logical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

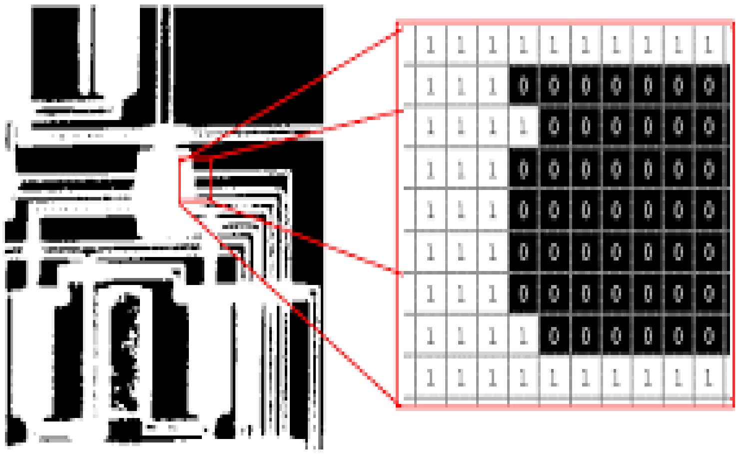

Figure 3.8 Binary image example

3.2.22 Indexed Images:

An indexed image has two components: 1. A data matrix integer, x 2. A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

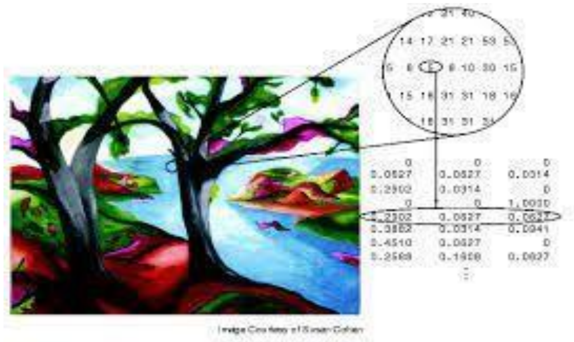

Figure 3.9 Indexed image example

3.2.23 RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep. Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors.

Figure 3.10 RGB image example

CHAPTER 4: PROJECT IMPLEMENTATION

4.1 IMPLEMENTATION STAGES

4.1.1 Block Diagram:

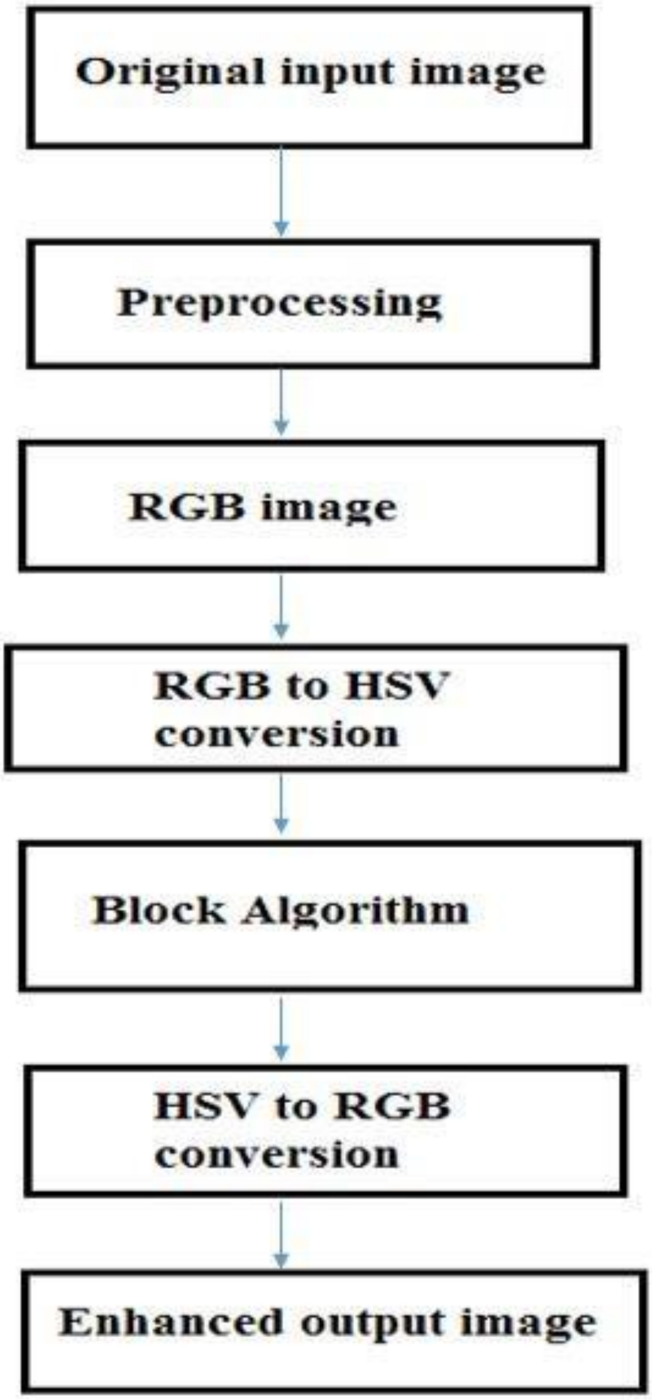

Figure 4.1 Block Diagram

a) **ORIGINAL IMAGE:** In the initial stage we give an original image as an input image, the input image is generally in a distorted condition

b) **PRE-PROCESSING:** This block is responsible for the pre-processes i.e., converting an RGB image into a Grayscale image for easier and effective results and also to make sure that all the images are of the same dimensions.

c) **RGB TO HSV CONVERSION:** Usually, objects in images have distinct colors (hues) and luminosities, so that these features can be used to separate different areas of the image. In the RGB representation the hue and the luminosity are expressed as a linear combination of the R, G, B channels, whereas they correspond to single channels of the HSV image (the Hue and the Value channels).

d) **RGB IMAGE:** An RGB image, sometimes referred to as a true color image, is stored in MATLAB as an m-by-n-by-3 data array that defines red, green, and blue colour components for each individual pixel. RGB images do not use a palette.

e) **BLOCK ALGORITHM:** Application of block algorithm is nothing but dividing the image into required number of blocks (or frames) for effective search.

f) **HSV TO RGB CONVERSION:** RGB = hsv2rgb(HSV) converts the hue, saturation, and value (HSV) values of an HSV image to red, green, and blue values of an RGB image. Rgb map = hsv2rgb(hsv map) converts an HSV colormap to an RGB colormap.

g) **ENHANCED OUTPUT IMAGE:** The final output Image we get is a completely enhanced image

4.1.2 Flow of Program:

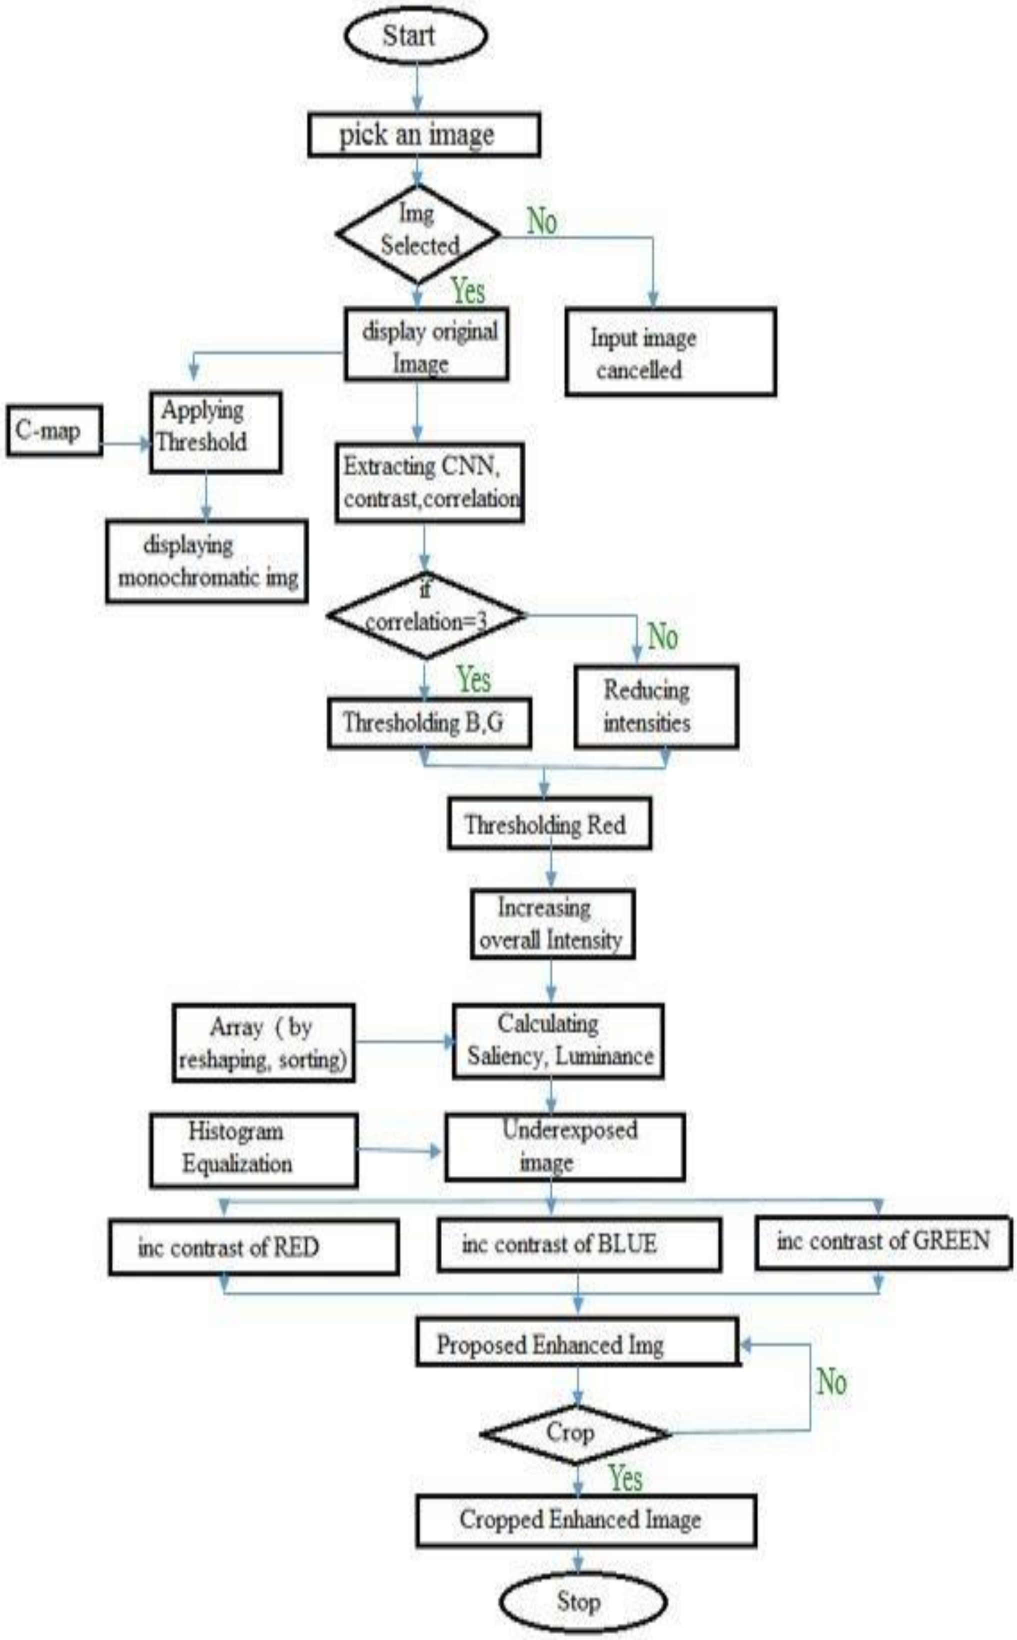

Figure 4.2 Flow Chart

Step1:

Pick an underwater image from the directory. As we have given the condition that, if the filename equal to 0 then no image is taken and it redirects a “help dialogue box” stating “Image input canceled”. If the filename is not equal to 0 then the image is read and stored in the variable.

Step2:

Applying a threshold to show a monochromatic image where monochromatic is nothing but ‘RGB differentiated colors’ where red, blue, green components of the image are separated.

Step3:

Extracting several components from the original image and applying a threshold to only blue and green channels of the image as these channels have higher intensities.

Step4:

Thresholding low-intensity components i.e, red channel of the original image

Step5:

After successfully limiting all the components, we will increase the overall intensity of the original image to get the perfect saliency and luminance values.

Step6:

Calculation of saliency and luminance values to obtain underexposed images.

Step7:

Increasing the contrast of each color using a function called adaptive histogram equalization.

Step8:

Concatenation of all the three enhanced contrast parts to get the “Proposed enhanced underwater image”.

Step9:

By cropping the particular part of the image to be enhanced, we get the "Proposed enhanced cropped underwater image"

4.2 RESULTS

- **Original Underwater frame:**

  When we run the code in MATLAB software it'll ask us to select a certain file that need to be enhanced from the file directory which is basically an underwater image as shown below in figure 4.3

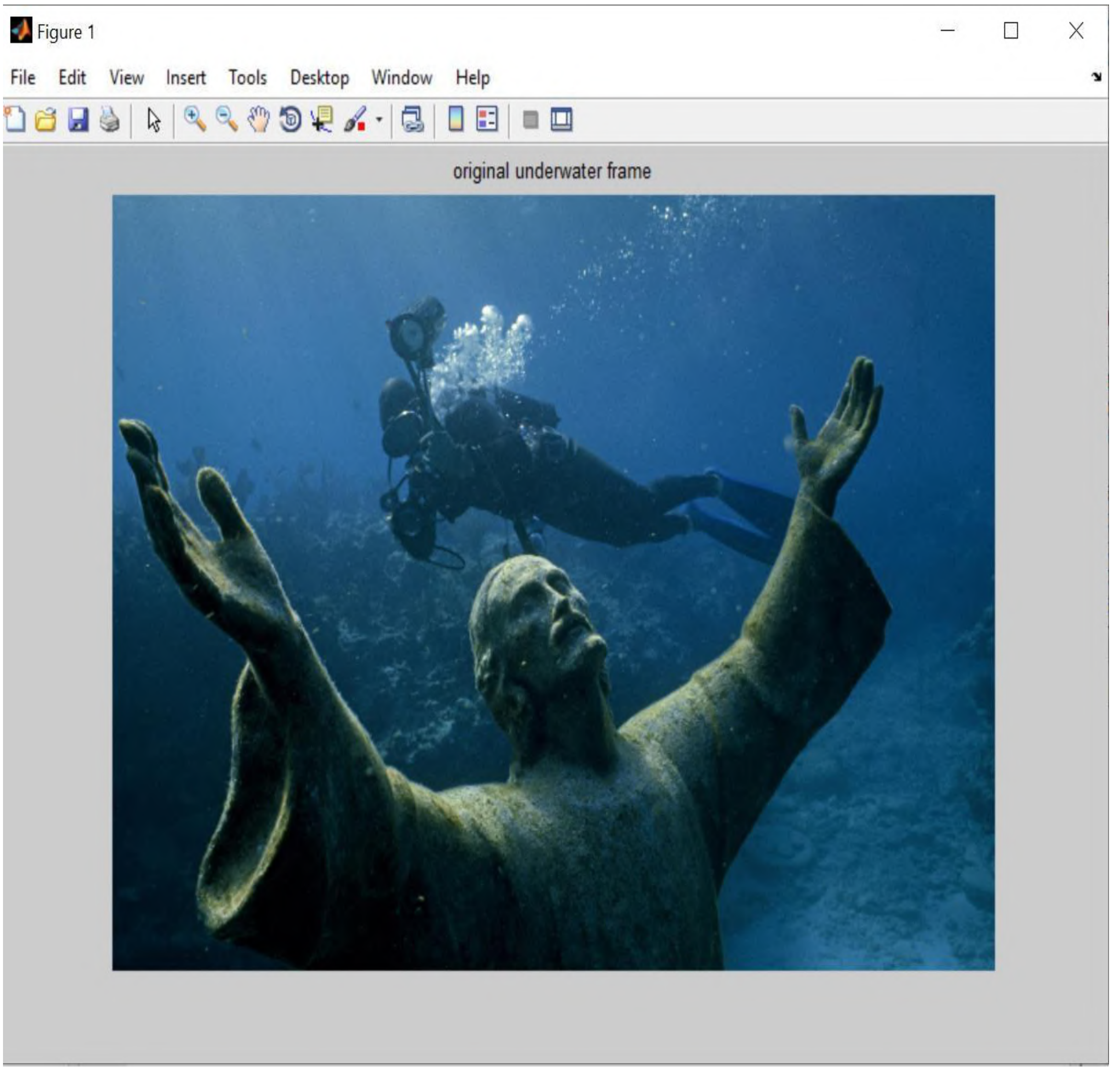

Figure 4.3 Input Underwater Image

- **Channelizing original image using CNN:**

  After applying a threshold to all the 3 channels that's (RED, GREEN, BLUE) of the image and using colormap(c map) we obtain a monochromatic image also known as RGB differentiated colors. The output of this process is shown below

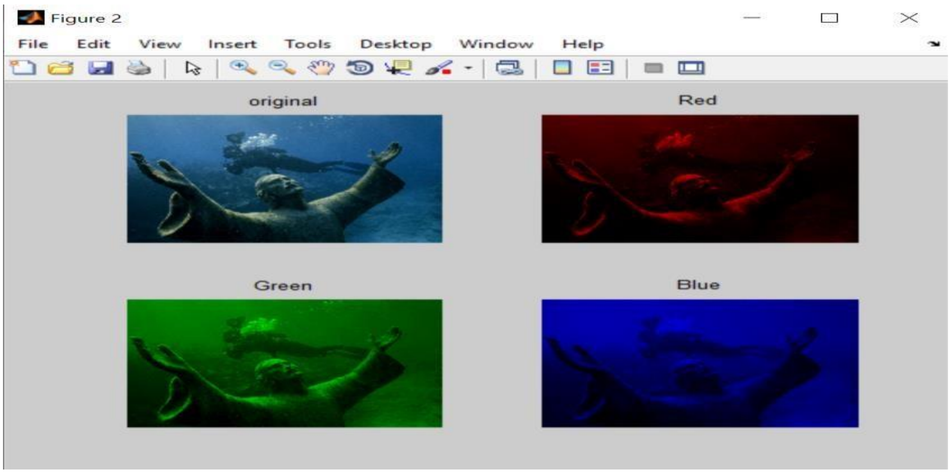

Figure 4.4 Channelized Underwater Image

- **Underexposed Image Enhancement:**

  Figure 4.5 below shows the enhanced underexposed image which is obtained by calculating the saliency and luminance values for the channelized underwater image

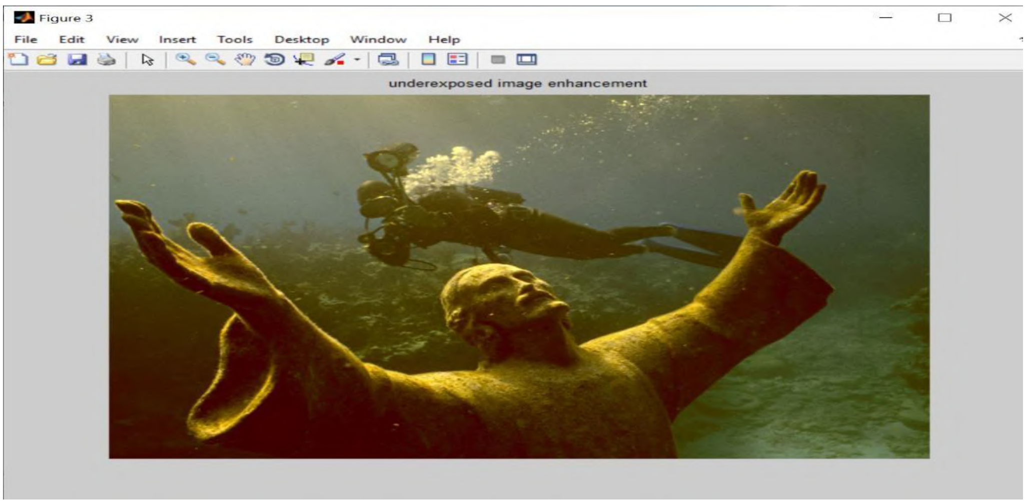

Figure 4.5 Underexposed Image Enhancement

- **Proposed Enhanced Image:** After Increasing the contrast of all the 3 channels using Histogram Equalization and by the concatenation of all the 3 channels, we obtain the figure below

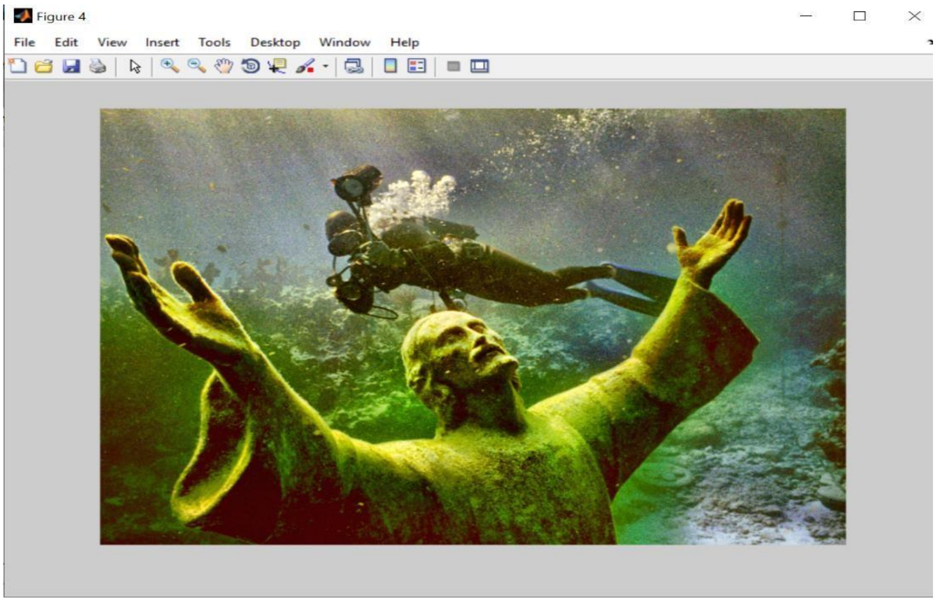

Figure 4.6 Proposed Enhanced Image

- **Particular Part of an Image:** In addition to this proposed method, we have an additional feature where we can crop a desired part of the image and we'll get an enhanced version of that cropped out part as shown in the above figure

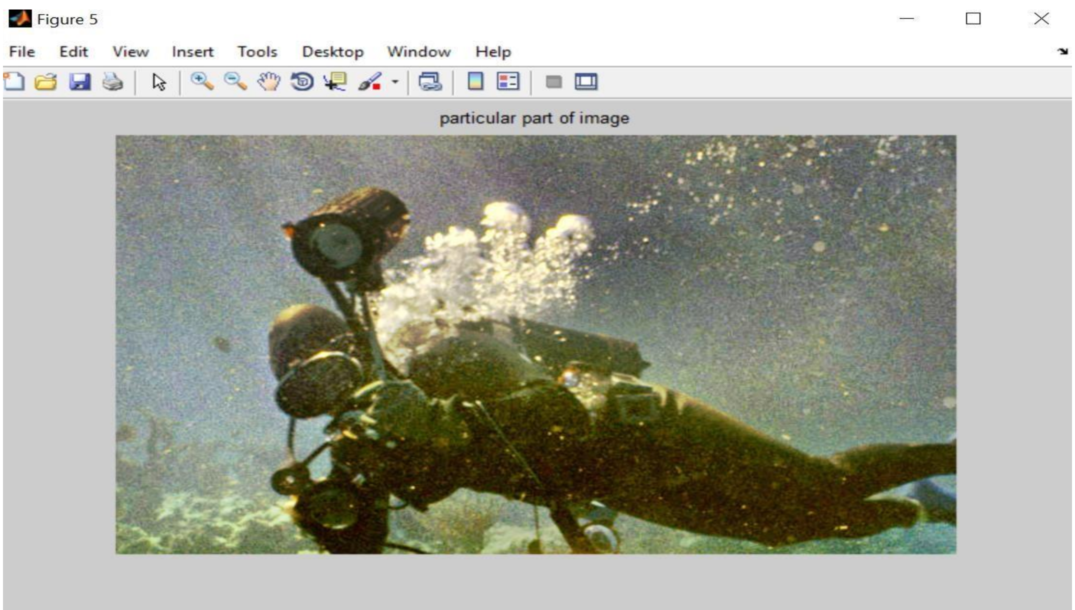

Figure 4.7 Particular Part of an Image

CHAPTER 5: CONCLUSION AND FUTURE SCOPE

5.1 CONCLUSION

In this paper, we propose a CNN framework for underwater image color restoration. Our method converts an input underwater image to the grayscale image by using CNN to estimate the grayscale coefficients. We also use CNN to restore the color of the input underwater image. To remove the noise in the underwater environment and reserve the detail that may affect by CNN, we propose a grayscale detail enhancement CNN. At last, we integrate all works by the hue preservation enhancement. Our experimental results show that the proposed method achieves better underwater image restoration performance than other methods.

5.1.1 APPLICATIONS:

- This technology can be used to verify the authenticity of an image. It can be used in situations where images are legal evidence and also can be used in forensic investigations.
- It's used extensively in medical imaging, astronomical imaging, and forensic science
- It's ergonomically used in Underwater imaging especially in conditions where the visibility level is low and the water is denser

5.2 FUTURE SCOPE

- ➢ It also may concentrate on recognizing profoundly compounded pictures. This method can further be developed for recognizing phony videos for investigation
- ➢ Better and robust algorithms which are camera independent.
- ➢ These algorithms, when incorporated into these robots will not only aid in procuring better enhanced underwater exploration images but also in bringing down the cost of these robots significantly.

PUBLICATION

to me

Mon, May 24, 3:43 PM

Dear Author(s),

Warm Greetings from St.Martins Engineering College.

With heartiest congratulations we are pleased to inform you that based on the recommendations of the expert reviewers, your paper has been accepted for journal publication and oral presentation in the online mega International Conference on "Smart Modernistic in Electronics and Communication" (ICSMEC-21).

Paper ID:ICSMEC21-0013

Paper Title: Deep Learning Underwater Image Colour Correction and Contrast Enhancement Based on Hue Preservation

Paper Accepted.

We have converted our project into paper with the title "**Deep learning underwater Image Colour Correction and Contrast Enhancement Based on Hue Preservation**" in the online mega International on "**Smart Modernistic in Electronics and Communication"(ICSMEC-21)** and it has been accepted with reference number ICSMEC21-0013

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our Dept. Project coordinator Dr.A.Anand** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Ms. B. Shiny Sucharitha, Assistant Professor**, Department of Electronics and Communication Engineering and our class project coordinator **Mrs. A. Soumya,** Department of ECE for guidance and encouragement in carrying out the project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

In times of COVID we have special Covid 19 Quarantine centres setup in order to treat covid patients. Since covid is highly infectious it is very important to quarantine covid patients but at the same time doctors need to monitor health of covid patients too. With the increasing number of cases, it is becoming difficult to keep a track on the health conditions of s many quarantined patients.

The problems here are:

• Doctors need to regularly monitor patient health.

• There is increasing number of patients for the doctors to monitor.

• The doctors are at risk of infection just for monitoring purpose.

To solve this issue, we here design a remote IOT based health monitor system that allows for remotely monitoring of multiple covid patients over the internet. The system monitors patient heartbeat, temperature and blood pressure using a heartbeat sensor, temperature sensor respectively.

The system then transmits this data over the internet using wi-fi transmission by connecting to Wi-Fi internet connection. The data is transmitted and received over IOT-by-IOT Gecko platform to display data of patient remotely. The entire system is run by a microcontroller-based circuitry. If any anomaly is detected in patient health pr if the patient presses the emergency help button on IOT device, an alert is sent over IOT remotely.

This System allows:

• Doctors to monitor patients remotely without risk of infection

• A single doctor over 500 patients at a time.

• Doctor gets instant alert in case of health fluctuations of emergency.

The system is mounted at patient bedside and constantly transmits patient health data over the internet so that doctors can monitor multiple patients remotely and attend the desired patient urgently when needed.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

GLOSSARY OF COMMONLY USED TERMS

IOT: The Internet of Things (IoT) describes the network of physical objects—"things"—that are embedded with sensors, software, and other technologies for the purpose of connecting and exchanging data with other devices and systems over the internet. These devices range from ordinary household objects to sophisticated industrial tools.

Covid-19: Coronavirus disease (COVID-19) is an infectious disease caused by a newly discovered coronavirus.Most people infected with the COVID-19 virus will experience mild to moderate respiratory illness and recover without requiring special treatment. Older people, and those with underlying medical problems like cardiovascular disease, diabetes, chronic respiratory disease, and cancer are more likely to develop serious illness.

Sensors: A sensor is a device that detects the change in the environment and responds to some output on the other system. A sensor converts a physical phenomenon into a measurable analog voltage (or sometimes a digital signal) converted into a human-readable display or transmitted for reading or further processing.

Wi-Fi Module: The ESP8266 Wi-Fi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

Health is always a major concern in every growth the human race is advancing in terms of technology. Like the recent corona virus attack that has ruined the economy of China to an extent is an example how health care has become of major importance. In such areas where the epidemic is spread, it is always a better idea to monitor these patients using remote health monitoring technology. So, Internet of Things (IoT) based health monitoring system is the current solution for it [1]. Remote Patient Monitoring arrangement empowers observation of patients outside of customary clinical settings (e.g., at home), which expands access to human services offices at bring down expenses [2].

The core objective of this project is the design and implementation of a smart patient health tracking system that uses Sensors to track patient health and uses internet to inform their loved ones in case of any issues. The objective of developing monitoring systems is to reduce health care costs by reducingSMS based patient flourishing viewing and IOT based patient checking framework. In IOT based framework, subtle parts of the patient flourishing can be seen by different clients [4]. The explanation behind this is the information should be checked by passing by a site or URL.

While, in GSM based patient viewing, the flourishing parameters are sent utilizing GSM by strategies for SMS. In most of the rural areas, the medical facility would not be in a hand reach distance for the natives [5]. So normally the peoplephysician office visits, hospitalizations, and diagnostic testing procedure [3]. Each of our bodies utilizes temperature and also pulse acknowledging perusing understanding wellbeing. The sensors are linked to a microcontroller to track the status which is thus interfaced to an LCD screen and additionally remote association with have the capacity to exchange alarms.

If framework finds any sudden changes in understanding heart beat or body temperature, the framework consequently alarms the client about the patient's status over IOT and furthermore indicates subtle elements of pulse and temperature of patient live in the web. In this manner IOT set up tolerant wellbeing following framework viably utilizes web to screen quiet wellbeing measurements and spare persists time. There is a significant capability betweenneglect any kind of minor health issues which is shown in early stages by variation of vital elements like body temperature, heartbeat rate etc.

1.2 OBJECTIVES OF THE STUDY

The main objective of the this project is to design and implement an efficient monitoring system through which the required parameters are monitored remotely using internet and the data gathered from the sensors are stored in the cloud and to project the estimated trend on the web browser. Monitoring and control of infection diseases, including Covid-19, have attracted the researchers, to adopt many solutions to control different types of infections such as using health monitoring mobile applications. A mobile based android system for infectious diseases, the system is limited but do not cover the cough system detection and temperature, although the device is not wearable. A PCB Board has been used to enable portable, reconfigurable, multichannel amperometry data acquisition to measure the current-input signals from biosensor. The electronic read-out circuit can provide constant biasing voltages to the amperometry sensor. However, there is no scope for data analysis or data storing. The work has focused on finding, analysing the geographic location of the patients without providing health information system. The paper in is good proposal to send infection index information for analysis, but again, no hardware part application. Mobile phone enabled social community extraction for controlling of disease propagation in healthcare is designed and tested to follow the disease, in other hand, the project is mainly focus on following the propagation pattern only through mobiles and without giving any health data analysis. Modelling and evaluation of disease propagation factors has been studied theoretically on, but still there is no real time implementation. In addition to the previous discussion, countries have been implemented drones, Mobile phones, and thermal cameras to follow infections; however, this can be used only for on sport checking. That is representing a temporary solution as they had no physical contact. Recently a wearable IOT design framework has been suggested on which can be considered as a good technical background for the proposed system implementations if it it’s implemented on its modified version.

1.3 SCOPE OF THE STUDY

In recent years, the healthcare industry has shown rapid growth and has been a major contributor to revenue and employment .A few years ago, the diagnosis of diseases and abnormality in the human body was only being possible after having a physical analysis in the hospital. Most of the patients had to stay in the hospital throughout their treatment period. This resulted in an increased healthcare cost and also strained the healthcare facility at rural and remote locations. The technological advancement that has been achieved through these years has now allowed the diagnosis of various diseases and health monitoring using miniaturized devices like smartwatches. Moreover, technology has transformed a hospital-centric healthcare system into a patient-centric system .For example, several clinical analyses (such as measuring blood pressure, blood glucose level, pO2, level, and so on) can be performed at home without the help of a healthcare professional. Further, the clinical data can be communicated to healthcare centers from remote areas with the help of advanced telecommunication services. The use of such communication services in conjunction with the rapidly growing technologies (e.g., machine learning, big data analysis, Internet of things (IoT), wireless sensing, mobile computing, and cloud computing) has improved the accessibility of the healthcare facilities.

1.4 MATERIAL REQUIREMENT

1.4.1 HARDWARE REQUIREMENT:

1. Arduino UNO
2. Lcd
3. Power Supply Unit
4. LM35
5. Heart beat Sensor
6. Wi-Fi Module
7. UV Lights
8. Slide Switch

1. Arduino UNO

Arduino is open source software. Arduino Uno is a microcontroller, ATmega328Pcontain in it. It has 14 digital i/o pins and 6 analog input pin, a 16 MHz quartz crystal, a USB connection, a power jack and a reset button. Simply connect to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. Embedded C program is used for coding.

2. LCD

The LCD is used to display whenever there is a gas leakage or fire detected in the area. Whenever there is a gas leakage the Arduino that is connected to the sensor and LCD sends a message to LCD to display ‘Gas leakage’. When there is fire outbreak the Arduino again sends a message to LCD to display ‘Fire Detected’ notifying us if there is a gas leakage or fire detected in the vicinity.

3. Power Supply Unit

Every electrical and electronic device that we use in our day-to-day life will require a power supply. In general, we use an AC supply of 230V 50Hz, but this power has to be changed into the required form with required values or voltage range for providing power supply to different types of devices. There are various types of power electronic converters such as step-down converter, step-up converter, voltage 31 stabilizer, AC to DC converter, DC 25 to DC converter, DC to AC converter, and so on. For example, consider the microcontrollers that are used frequently for developing many embedded systems based projects and kits used in real-time applications. These microcontrollers require a 5V DC supply.

4. LM35

LM35 is a precession Integrated circuit Temperature sensor, whose output voltage varies, based on the temperature around it. It is a small and cheap IC which can be used to measure temperature anywhere between -55°C to 150°C. There will be rise of 0.01V (10mV) for every degree Celsius rise in temperature.

5. Heart beat Sensor

An optical heart rate sensor measures pulse waves, which are changes in the volume of a blood vessel that occur when the heart pumps blood. Pulse waves are detected by measuring the change in volume using an optical sensor and green LED.

6. ESP-01 (Wi-Fi Module)

The ESP8266 Wi-Fi Module is a self contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your Wi-Fi network. The ESP8266 is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much Wi-Fi-ability as a Wi-Fi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely costeffective board with a huge, and ever growing, community

7. UV Lights

UV light (ultraviolet light) is having a wavelength between 10 and 400 nm. UV light is used as disinfection i.e., kills virus and bacteria.

8. Slide switch

Slide switches as the name suggest are mechanical devices which have a slider on the top of switch which slides from one position to another. These switches have a slider that moves (slides) from one position to another. Based on the actuator type, the handle can be either flush or raised.

1.4.2 SOFTWARE REQUIREMENT:

1. **ARDUINO IDE**: Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs.

2.**PROTEUS SOFTWARE:** Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.It is a proprietry software tool suite used primarily for electronic design engineers and technicians to create schematics and electronic prints for manufacturing printed circuit boards.

1.5 PROCUMENT OF EQUIPMENT

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual sensors to Arduino in Proteus Software and understood working of every individual sensor in Proteus Software. Now, we assembled all sensors and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware sensors in Arduino IDE, we understood the working of all sensors in a practical way. We measured al the heartbeat and temperature values of patient and all the information is sent to the online server.

.

CHAPTER-2

LITERATRE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

There is considerable work in the literature regarding the use of the Internet of Things (IoT) to deliver health services. Usak et al. conducted a systematic literature review of the use of IoT in health care systems. That work also included a discussion of the main challenges of using IoT to deliver health services, and a classification of the reviewed work in the literature. Wu et al. proposed a hybrid IoT safety and health monitoring system. The goal was to improve outdoor safety. The system consists of two layers: one is used to collect user data, and the other to aggregate the collected data over the Internet. Wearable devices were used to collect safety indicators from the surrounding environment, and health signs from the user. Hamidi studied authentication of IoT smart health data to ensure privacy and security of health information. The work proposed a biometric-based authentication technology. Rath and Pattanayak proposed a smart healthcare hospital in urban areas using IoT devices, inspired by the literature. Issues such as safety, security and timely treatment of patients in VANET zone were discussed. Evaluation of the proposed system was conducted using simulators such as NS2 and Net Sim. Darwish et al. proposed a Cloud IoT-Health paradigm, which integrates cloud computing with IoT in the health area, based on the relevant literature. The paper presented the challenges of integration, as well as new trends in Cloud IoT-Health. These challenges are classified at three levels: technology, communication and networking, and intelligence.Zhong and Li studied the monitoring of college students during their physical activities. The paper focused on a Physical Activity Recognition and Monitoring (PARM) model, which involves data pre-processing. Several classifiers, such as decision tree, neural networks, and SVM, were tested and discussed. Din and Paul proposed an IoT-based smart health monitoring and management architecture. The architecture is composed of three layers: (1) data generation from battery-operated medical sensors and processing, (2) Hadoop processing, and (3) application layers. Because of the limited capacity of batteries to power the sensors, the work employed an energy-harvesting approach using piezoelectric devices attached to the human body. Otoom et al. developed an IoT-based prototype for real-time blood sugar control. ARIMA and Markov-based statistical models were used to determine the appropriate insulin dose. Alshraideh et al. proposed an

IoT-based system for Cardiovascular Disease detection. Several machine learning algorithms were used for CVD detection.

Nguyen presented a survey of Artificial intelligence (AI) methods being used in the research of COVID-19. This work classified these methods into several categories, including the use of IoT. Maghdid proposed the use of sensors available on smartphones to collect health data, such as temperature. Rao and Vazquez proposed the use of machine learning algorithms to identify possible COVID-19 cases. The learning is done on collected data from the user through web survey accessed from smartphones. Allam and Jones discussed the need to develop standard protocols to share information between smart cities in pandemics, motivated by the outbreak of COVID-19. For instance, AI methods can be applied to data collected from thermal cameras installed in smart cities, to identify possible COVID-19 cases. Fatima et al. proposed an IoT-based approach to identify coronavirus cases. The approach is based on a fuzzy inference system. Peeri et al. conducted a comparison between MERS, SARS, and COVID-19, using the available literature. They suggested the use of IoT in mapping the spread of the infection.To our knowledge, no one has developed a complete framework for using IoT technology for the identification and monitoring of COVID-19.

2.2 REVIEW ON RELATED LITERATURE:

On December 31, 2019, the China Health Authority alerted the World Health Organization (WHO) to several cases of pneumonia of unknown aetiology in Wuhan City in Hubei Province in central China. The cases had been reported since December 8, 2019, and many patients worked at or lived around the local Huanan Seafood Wholesale Market although other early cases had no exposure to this market . On January 7, a novel coronavirus, originally abbreviated as 2019-nCoV by WHO, was identified from the throat swab sample of a patient . This pathogen was later renamed as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) by the Coronavirus Study Group [3] and the diseasewas named coronavirus disease 2019 (COVID-19) by theWHO. As of January 30, 7736 confirmed and 12,167 suspected cases had been reported in China and 82 confirmed cases had been detected in 18 other countries . In the same day, WHO declared the SARS-CoV-2 outbreak as a Public Health Emergency of International Concern (PHEIC)According to the National Health Commission of China, the mortality rate among confirmed cased in China was 2.1% as of February 4 and the mortality rate was 0.2% among cases outside China . Among patients admitted to hospitals, the mortality rate ranged between 11% and 15% . COVID-19 is moderately infectious with a relatively high mortality rate, but the information available in public reports and published literature is rapidly increasing. The aim of this review is to summarize the current understanding of COVID-19 including causative agent, pathogenesis of the disease, diagnosis and treatment of the cases, as well as control and prevention strategies.

2.3 CONCLUSION ON REVIEWS:

Hence as the technology is advancing day by day and we have to follow the new technologies so in the proposed system we used internet of things for makings things smarter. Here in the proposed system it consists of two units – in the first unit , we connect all the sensors to the Arduino Uno that the sensors sense the heartbeat and temperature of patient and sends to Arduino Uno. In the second unit, this transmitted information is displayed on the lcd and simultaneously sends to the online server. Later UV LIGHT is switched “ON” to kill the viruses.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

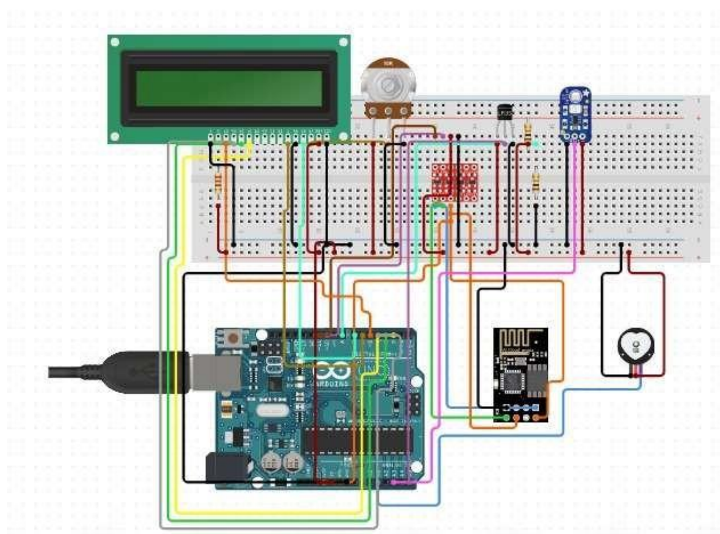

Fig 3.1 Overview of the Design

Arduino UNO has 6 analog pins from A0 to A6 which are generally input pins. It also has 14 digital pins from 0-13 which are the output pins. The analog pin A4 is connected to the temperature sensor, heartbeat sensor at pin 4 and buzzer at pin 7. The digital pins 8-13 are connected to the LCD to display the output values. Here pin 2 and 3 is used for serial communication. These pins are used for the esp8266 wi-fi module to transmit the information to the online server.

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION

It is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

- The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.
- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

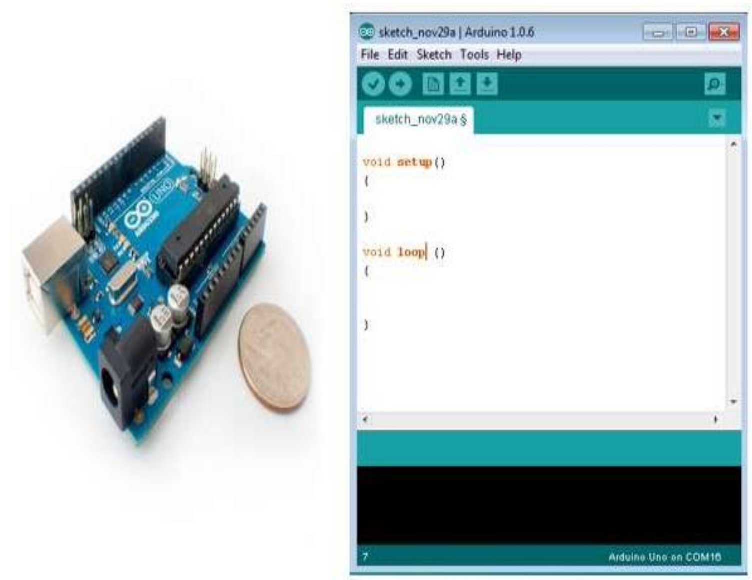

Fig.3.2 Arduino UNO

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE. The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V. Here is a list of different Arduino boards available.

Table 3.1 Arduino Boards based on ATMEGA328 Microcontroller

Board Name	Operating Volt	lock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming nterface

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3.5 Arduino Boards based on AT91SAM3X8E microcontroller

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit.

	• Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.

15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.3 Board Description

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most of them remain the same.

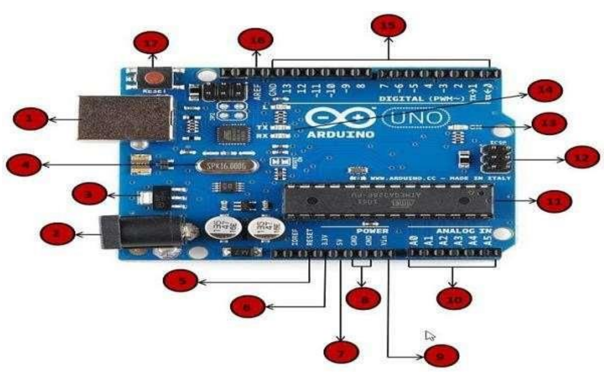

Fig.3.3 Arduino UNO Pin Description

Table 3.6 Arduino UNO Pin Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5,17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6,7 8,9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.

13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.3.2 Liquid Crystal Display

A liquid crystal display (LCD) is a thin, flat display device made up of any number of color or monochrome pixels arrayed in front of a light source or reflector. Each pixel consists of a column of liquid crystal molecules suspended between two transparent electrodes, and two polarizing filters, the axes of polarity of which are perpendicular to each other. Without the liquid crystals between them, light passing through one would be blocked by the other. The liquid crystal twists the polarization of light entering one filter to allow it to pass through the other.

A program must interact with the outside world using input and output devices that communicate directly with a human being. One of the most common devices attached to an controller is an LCD display. Some of the most common LCDs connected to the contollers are 16X1, 16x2 and 20x2 displays. This means 16 characters per line by 1 line 16 characters per line by 2 lines and 20 characters per line by 2 lines, respectively.

Description Of 16x2:

This is the first interfacing example for the Parallel Port. We will start with something simple. This example doesn't use the Bi-directional feature found on newer ports, thus it should work with most, if no all-Parallel Ports. It however doesn't show the use of the Status Port as an input. So what are we interfacing? A 16 Character x 2 Line LCD Module to the Parallel Port. These LCD Modules are very common these days, and are quite simple to work with, as all the logic required to run them is on board.

Schematic Diagram

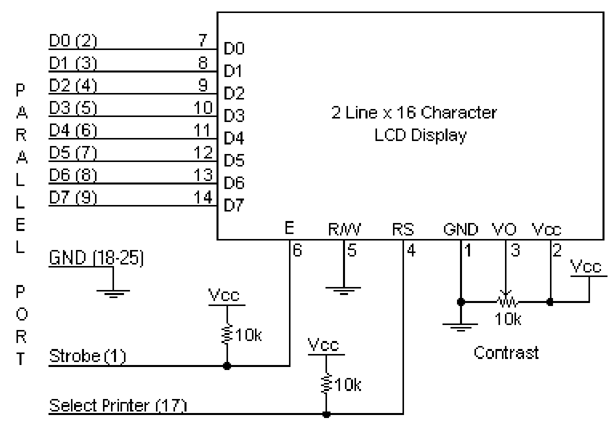

Fig: 3.4 Schematic Diagram

- Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.
- We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.
- The 10k Potentiometer controls the contrast of the LCD panel. Nothing fancy here. As with all the examples, I've left the power supply out. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.

16 x 2 Alphanumeric LCD Module Features:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

Table: 3.7 16 x 2 Alphanumeric LCD Module Specifications:

Pin	Symbol	Level	Function
1	V_{SS}	-	Power, GND
2	V_{DD}	-	Power, 5V
3	Vo	-	Power, for LCD Drive
4	RS	H/L	Register Select Signal H: Data Input L: Instruction Input
5	R/W	H/L	H: Data Read (LCD->MPU) L: Data Write (MPU->LCD)
6	E	H,H->L	Enable
7-14	DB0-DB7	H/L	Data Bus; Software selectable 4- or 8-bit mode
15	NC	-	**NOT CONNECTED**
16	NC	-	**NOT CONNECTED**

FEATURES:

• 5 x 8 dots with cursor

• Built-in controller (KS 0066 or Equivalent)

• + 5V power supply (Also available for + 3V)

• 1/16 duty cycle

• B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)

• N.V. optional for + 3V power supply

Data can be placed at any location on the LCD. For 16×1 LCD, the address locations are:

POSITION		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
ADDRESS	LINE1	00	01	02	03	04	05	06	07	40	41	42	43	44	45	46	47

Figure Address locations for a 1x16 line LCD

Even limited to character based modules, there is still a wide variety of shapes and sizes available. Line lengths of 8, 16,20,24,32 and 40 characters are all standard, in one, two and four line versions..

PIN DESCRIPTION:

Most LCDs with 1 controller has 14 Pins and LCDs with 2 controller has 16 Pins (two pins are extra in both for back-light LED connections).

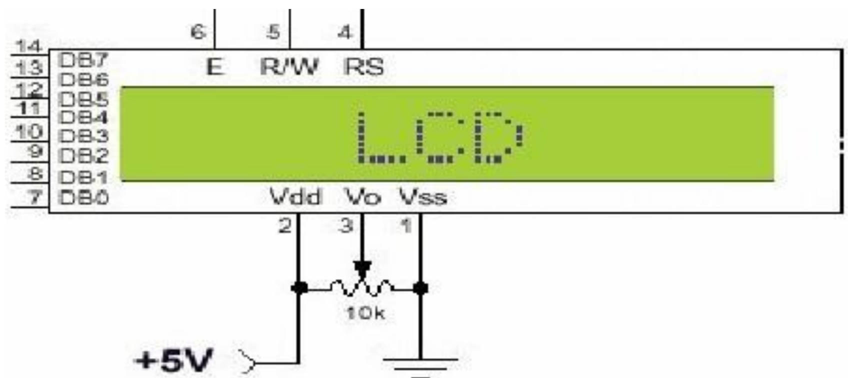

Figure 3.5 Pin diagram of 1x16 lines LCD

PIN	SYMBOL	FUNCTION
1	Vss	Power Supply(GND)
2	Vdd	Power Supply(+5V)
3	Vo	Contrast Adjust
4	RS	Instruction/Data Register Select
5	R/W	Data Bus Line
6	E	Enable Signal
7-14	DB0-DB7	Data Bus Line
15	A	Power Supply for LED B/L(+)
16	K	Power Supply for LED B/L(-)

Table 3.8 Pin specifications

CONTROL LINES:

EN: Line is called "Enable." This control line is used to tell the LCD that you are sending it data. To send data to the LCD, your program should make sure this line is low (0) and then set the other two control lines and/or put data on the data bus. When the other lines are completely ready, bring EN high (1) and wait for the minimum amount of time required by the LCD datasheet (this varies from LCD to LCD), and end by bringing it low (0) again.

RS: Line is the "Register Select" line. When RS is low (0), the data is to be treated as a command or special instruction (such as clear screen, position cursor, etc.). When RS is high (1), the data being sent is text data which should be displayed on the screen. For example, to display the letter "T" on the screen you would set RS high.

RW: Line is the "Read/Write" control line. When RW is low (0), the information on the data bus is being written to the LCD. When RW is high (1), the program is effectively querying (or reading) the LCD. Only one instruction ("Get LCD status") is a read command. All others are write commands, so RW will almost always be low.Finally, the data bus consists of 4 or 8 lines (depending on the mode of operation selected by the user). In the case of an 8-bit data bus, the lines are referred to as DB0, DB1, DB2, DB3, DB4, DB5, DB6, and DB7.

Logic status on control lines:

• E - 0 Access to LCD disabled

- 1 Access to LCD enabled

• R/W - 0 Writing data to LCD

- 1 Reading data from LCD

• RS - 0 Instructions

- 1 Character

Writing data to the LCD:

1) Set R/W bit to low

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Read data from data lines (if it is reading) on LCD:

1) Set R/W bit to high

2) Set RS bit to logic 0 or 1 (instruction or character)

3) Set data to data lines (if it is writing)

4) Set E line to high

5) Set E line to low

Entering Text:

First, a little tip: it is manually a lot easier to enter characters and commands in hexadecimal rather than binary (although, of course, you will need to translate commands from binary couple of sub-miniature hexadecimal rotary switches is a simple matter, although a little bit into hex so that you know which bits you are setting). Replacing the d.i.l. switch pack with a of re-wiring is necessary.

LCD Commands:

There are some present commands instructions in LCD, which we need to send to LCD through some microcontroller. Some important command instructions are given below:

Table 3.9 Commands

Hex Code	Command to LCD Instruction Register
0F	LCD ON, cursor ON
01	Clear display screen
02	Return home
04	Decrement cursor (shift cursor to left)
06	Increment cursor (shift cursor to right)
05	Shift display right
07	Shift display left

0E	Display ON, cursor blinking
80	Force cursor to beginning of first line
C0	Force cursor to beginning of second line
38	2 lines and 5×7 matrix
83	Cursor line 1 position 3
3C	Activate second line
08	Display OFF, cursor OFF
C1	Jump to second line, position 1
OC	Display ON, cursor OFF
C1	Jump to second line, position 1
C2	Jump to second line, position 2

3.3.3 TEMPERATURE SENSOR (LM35)

General Description:

The LM35 series are precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius (Centigrade) temperature. The LM35 thus has an advantage over linear temperature sensors calibrated in °Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1/4°C at room temperature and ±3/4°Cover a full −55 to +150°C temperature range. Low cost is assured by trimming and calibration at the wafer level. The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 µA from its supply, it has very low self-heating, less than 0.1°C in still air. The LM35 is rated to operate over a −55° to +150°C temperature range, while the LM35C is rated for a −40° to +110°C range (−10° with improved accuracy). The LM35 series is available packaged in hermetic TO-46 transistor packages, while the LM35C, LM35CA, and LM35D are also available in the plastic TO-92 transistor package. The LM35D is also available in an 8-lead surface mount small outline package and a plastic TO-220 package (Fig 3.2.1).
