The coverage area is increased, and the outage probability decreased in comparison to an MFN, due to increased received signal strength averaged over all sub-carriers.

Although the guard interval only contains redundant data, which means that it reduces the capacity, some OFDM-based systems, such as some of the broadcasting systems, deliberately use a long guard interval in order to allow the transmitters to be spaced farther apart in an SFN, and longer guard intervals allow larger SFN cell-sizes.

A rule of thumb for the maximum distance between transmitters in an SFN is equal to the distance a signal travels during the guard interval — for instance, a guard interval of 200 microseconds would allow transmitters to be spaced 60 km apart.

A single frequency network is a form of transmitter macro diversity. The concept can be further utilized in dynamic single-frequency networks (DSFN), where the SFN grouping is changed from timeslot to timeslot.

OFDM may be combined with other forms of space diversity, for example antenna arrays and MIMO channels. This is done in the IEEE802.11nWireless LAN standard.

Linear transmitter power amplifier:

An OFDM signal exhibits a high peak-to-average power ratio (PAPR) because the independent phases of the sub-carriers mean that they will often combine constructively. Handling this high PAPR requires:

- a high-resolution digital-to-analogue converter (DAC) in the transmitter
- a high-resolution analogue-to-digital converter (ADC) in the receiver
- A linear signal chain.

Any non-linearity in the signal chain will cause inter modulation distortion that

- raises the noise floor
- may cause inter-carrier interference
- Generates out-of-band spurious radiation.

The linearity requirement is demanding, especially for transmitter RF output circuitry where amplifiers are often designed to be non-linear to minimize power consumption.

In practical OFDM systems a small amount of peak clipping is allowed to limit the PAPR in a judicious trade-off against the above consequences. However, the transmitter output filter which is required to reduce out-of-band spurs to legal levels has the effect of restoring peak levels that were clipped, so clipping is not an effective way to reduce PAPR.

Although the spectral efficiency of OFDM is attractive for terrestrial and space communications, the high PAPR requirements have so far limited OFDM applications to terrestrial system

Idealized System:

This section describes a simple idealized OFDM system model suitable for a time-invariant AWGN channel.

TRANSMITTER:

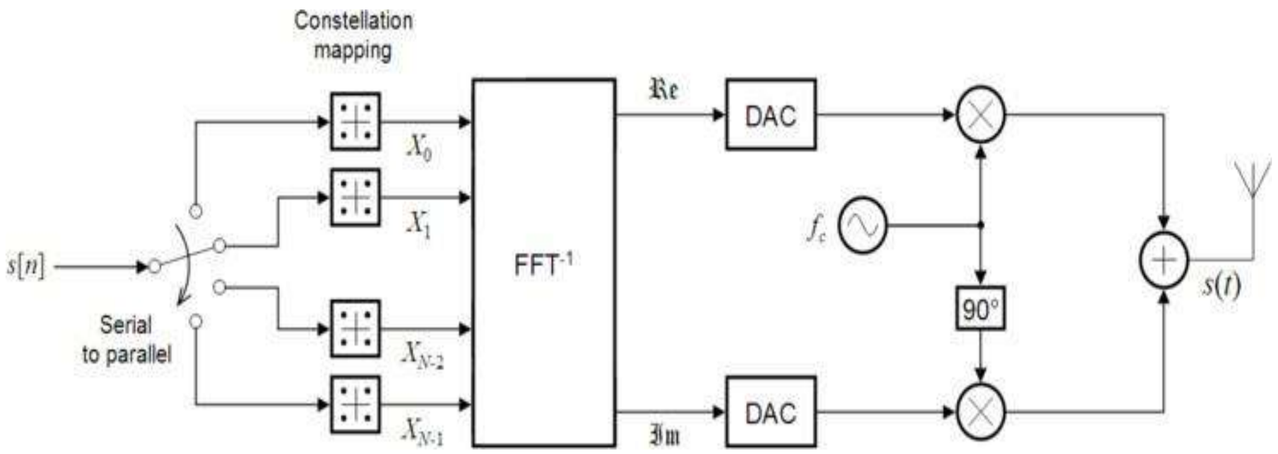

Fig.1.6

An OFDM carrier signal is the sum of a number of orthogonal sub-carriers, with baseband data on each sub-carrier being independently modulated commonly using some type of quadrature amplitude modulation (QAM) or phase-shift keying (PSK). This composite baseband signal is typically used to modulate a main RF carrier. $s[n]$ is a serial stream of binary digits. By inverse multiplexing, these are first de-multiplexed into N parallel streams, and each one mapped to a (possibly complex) symbol stream using some modulation constellation (QAM, PSK, etc.). Note that the constellations may be different, so some streams may carry a higher bit-rate than others.

An inverse FFT is computed on each set of symbols, giving a set of complex time-domain samples. These samples are then quadrature-mixed to passband in the standard way. The real and imaginary components are first converted to the analogue domain using digital-to-analogue converters (DACs); the analogue signals are then used to modulate cosine and sine waves at the carrier frequency, f_c respectively. These signals are then summed to give the transmission signal, $s(t)$.

RECEIVER:

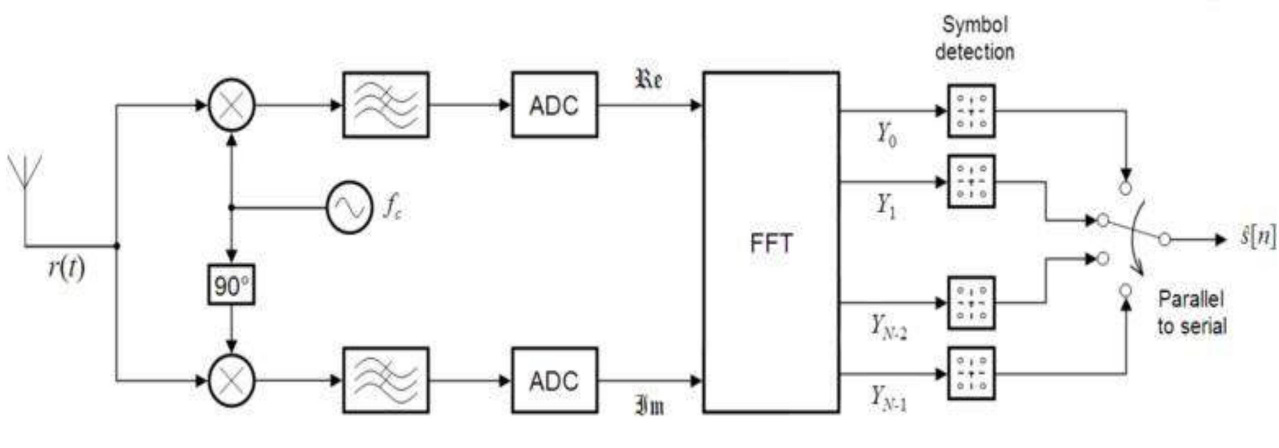

Fig.1.7

The receiver picks up the signal $r(t)$, which is then quadrature-mixed down to baseband using cosine and sine waves at the carrier frequency. This also creates signals centered on $2f_c$, so low-pass filters are used to reject these. The baseband signals are then sampled and digitized using analogue-to-digital converters (ADCs), and a forward FFT is used to convert back to the frequency domain.

This returns N parallel streams, each of which is converted to a binary stream using an appropriate symbol detector. These streams are then re-combined into a serial stream, $\hat{s}[n]$, which is an estimate of the original binary stream at the transmitter.

Mathematical description:

If N sub-carriers are used, and each sub-carrier is modulated using M alternative symbols, the OFDM symbol alphabet consists of M^N combined symbols.

The low-pass equivalent OFDM signal is expressed as:

$$\nu(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi kt/T}, \quad 0 \le t < T,$$

Where $\{X_k\}$ are the data symbols, N is the number of sub-carriers, and T is the OFDM symbol time. The sub-carrier spacing of $\frac{1}{T}$ makes them orthogonal over each symbol period; this property is expressed as:

$$\frac{1}{T}\int_0^T \left(e^{j2\pi k_1 t/T}\right)^* \left(e^{j2\pi k_2 t/T}\right) dt$$
$$= \frac{1}{T}\int_0^T e^{j2\pi(k_2-k_1)t/T} dt = \delta_{k_1 k_2}$$

where $(\cdot)^*$ denotes the complex conjugate operator and δ is the Kronecker delta.

To avoid inter symbol interference in multipath fading channels, a guard interval of length T_g is inserted prior to the OFDM block. During this interval, a cyclic prefix is transmitted such that the signal in the interval $-T_g \le t < 0$ equals the signal in the interval $(T-T_g) \le t < T$. The OFDM signal with cyclic prefix is thus:

$$\nu(t) = \sum_{k=0}^{N-1} X_k e^{j2\pi kt/T}, \quad -T_g \le t < T$$

The low-pass signal above can be either real or complex-valued. Real-valued low-pass equivalent signals are typically transmitted at baseband wireline applications such as DSL use this approach. For wireless applications, the low-pass signal is typically complex-valued; in which case, the transmitted signal is up-converted to a carrier frequency f_c. In general, the transmitted signal can be represented as:

$$s(t) = \Re\left\{\nu(t)e^{j2\pi f_c t}\right\}$$
$$= \sum_{k=0}^{N-1} |X_k| \cos\left(2\pi[f_c + k/T]t + \arg[X_k]\right)$$

Chapter 2

LITERATURE SURVEY

In the study of signal processing, we define the Nyquist rate as the rate which is twice the bandwidth of a band limited signal or a channel. It can be conceptually studied relating the Nyquist rate in accordance with signaling and sampling as two different approaches. From the sampling point of view, it is defined that in order to have no aliasing effect, the minimum sampling rate should be equal to or greater than double the highest frequency component contained within the signal. This means that sampling rate must be higher than the Nyquist rate. Sampling process involves the discretization of the continuous time signals. These samples are to be taken in a manner that it represents the original signal significantly. The number of samples taken defines the signal rate for specific signal bandwidth.

Nyquist signaling or Nyquist pulse shaping criteria highlights the necessary and sufficient condition so as to achieve zero ISI scenario. In the Nyquist paper [22], it is described about the number of pulses that could be transmitted and received over a band limited channel and also the rate of transmission. In the paper, the Nyquist signaling rate is defined as the maximum possible pulses that could be transmitted through a given bandwidth limited channel. This gives an idea about the Nyquist signaling, which provides platform for the design of the modern communication systems.

Nyquist rate clarifies the concept defining the rate as lower bound for the sample rate and upper bound for the symbol rate in a bandwidth constrained baseband channel without ISI. The upper limit for the number of bits per signal change is defined by the channel characteristics which is also known as the Shannon limit [23]. In short, the sampling frequency greater than twice the bandwidth is the condition where no aliasing effect occurs indicating the fulfillment of the Nyquist criteria. This means that for the continuous function $x(t)$ sampled at fixed sampling rate, the function that is band limited to $1/2fs$ only satisfies the Nyquist condition, i.e., its Fourier transform

$X(f) = 0$ for all $|f| \geq 1/2fs$.

For $B \leq 1/2fs$, $2B$ and $1/2fs$ are the expressions defining Nyquist rate and frequency respectively, where the symbol $T = 1/fs$ represents the sample period, or the sampling interval and B is the bandwidth.

Necessary and sufficient conditions for Nyquist criteria:

In a wireless communication, when the linearly modulated symbols are transmitted, the channel impulse response or the frequency response spreads the transmitted signal 18 in time domain. Such consecutive symbol transmission can create aliasing effect as previously transmitted signal may overlap over the other later signal. Nyquist criterion indicates the condition which when fulfilled, provides the zero ISI during such transmission.

As seen from the derivation in section 2.3, we can define the Nyquist ISI criteria as, for the discrete signals, x[n] = x(nT s) and the channel impulse response h(t) = h(nT s), the necessary and sufficient Nyquist condition for zero ISI or pulse shaping criteria stipulate that for a given pulse h[n], it has to satisfy [2]

$$h[n] = \begin{cases} 1 & n = 0 \\ 0 & n \neq 0 \end{cases}$$

and its Fourier transform satisfy 1

$$\frac{1}{T_s} \sum_{k=-\infty}^{\infty} H(f + k/T_s) = 1$$

which means that the frequency shifted versions of H(f), the Fourier transform of h(t), is summed up to 1.

The relation gives information that the Nyquist criterion is the condition of a wireless channel threshold for designing transceiver structures to attain an ISI free transmission. Nyquist first criterion [24] explains that the contributions at the sampling instant (T, 2T, 3T...) of the received waveform must be zero. Equations (3.2) and (3.3) indicate the fact that the sum of delayed pulse spectra by k/T should sum up to T or a constant. Raised cosine pulses are such commonly used practical pulses that meet the Nyquist ISI criterion. This is discussed later in section

2.1 Pulse shaping filters:

Considering a situation for increasing data rate or transmission rate for a system with given (fixed) bandwidth without accuracy degradation, we see the bandwidth constraint to be constant. One possible way is to modify the pulses effectively such that it requires less bandwidth than the contemporary means. The pulse shape is desired to be smooth. The distorted shape may deteriorate the condition requiring larger bandwidth since such shapes contains the energy spectrum including lower frequency harmonic components. It is required that, at the perfect scenario, transmitted pulse do not interfere each other at the receiver with the successive symbols being received. The error occurred during this procedure is termed as ISI. So it is somewhat like a tradeoff between the gain and complexity. In order to have smooth shape for spectral efficiency, pulse shaping filter is selected such that it can transform the given waveform into the desired form.

The transmitted signals are the result of the data pulse passed through a pulse shaping filter which is responsible for defining the transmitter spectrum. They have a role of allocating the prescribed signal in a defined bandwidth minimizing the spectral leakage and also to maintain the high transmission rate and low error rate for a signal. In a system with band limited channels, during the increased modulation rate of a transmitted signal, it is highly probable to have distortion or the ISI due to bandwidth limitation. So, it requires fixing the transmitted waveform into the shape such that signal remains 19 in the prescribed bandwidth. Ideal filters undergo a proper sampling procedure to ensure the minimum ISI and high stop band attenuation to reduce the inter channel interference (ICI) [25].

Usually, a rectangular ideal pulse is desired over an interval [0, T] but the pulses having different functional forms for, e.g., Sinc pulses have the spectrum with side lobes decreasing with frequency. This causes an unintentional overlapping of the symbols from the adjacent channels or the signals. Ideally, we expect the pulse with peak at $t = 0$ and zero at other sampling instants $t = T, 2T, 3T$. In time domain it must satisfy that its impulse response has periodic zero and zeros must occur at other sampling times, i.e., $h[nT] = 0$, where T is the data sample period. Pulses bearing such characteristics are referred as Nyquist pulses and the corresponding filters bearing such impulse responses are called Nyquist filters [26]. The pulse shaping filters are designed to satisfy the Nyquist ISI criterion.

When the band pass filtering is done prior to matched filtering, these filters reduce the cost of hardware designs as well. Pulse shaping filters implemented in frequency domain make it easy to recover the information embedded in the carrier signal by exploiting the frequency diversity at the receiver end using the signal decomposition or recombination [27].

For optimal filter design, the delta function $\delta(t)$ with pulse information is sent from the transmitter end. The full signal recovery ideal output then should be $\delta(1 + \sigma)$, where σ is the time delay of the causal system. Consequently, at the receiver end, there should be ideal output $\delta(t)$ [28].

Usually, these pulse shaping filters at the transmitter is used in reference to the corresponding matched filter at the receiver unit for optimal performance. Many pulse shaping filters like Sinc shaped filter, rectangular pulse filter, Raised-cosine filter, Gaussian filter are in practice.

Here, in the thesis work, raised cosine filters are used for its best suitability satisfying Nyquist criteria and the spectral efficiency.

2.2 Roll-off factor:

Roll-off factor gives the measure of the excess bandwidth occupied by any digital filter as compared to that of theoretical minimum Nyquist bandwidth. Bandwidth utilization is very important in wireless communication. In real time communication, the signals usually tend to occupy the bandwidth more than specified by Nyquist bandwidth. This excess value is referred as the roll-off factor. For, e.g., any digital filter with 100 MHz Nyquist bandwidth if occupies 130 MHz, is said to have roll-off factor 0.3 which means the filter excess bandwidth is 0.3 times the Nyquist bandwidth. It can also be defined as the steepness measure in the transition between the stop band and pass band of the filters. It directly relates to the bandwidth saving strategy.

Bandwidth saving between two spectral roll-off factors can be calculated as [29]

Bandwidth saving (%) = 100 − (($\beta 1/\beta 2$) × 100).

Here, $\beta 1$ is referred from the lower value between the two roll-off factors. Mathematically roll-off factor can be related as, for the Nyquist bandwidth of 1/2T, if the excess bandwidth as compared to this Nyquist bandwidth be Δf, then the roll-off fac- 20 tor (β) is given by

$\beta = \Delta f\ 1/2T = \Delta f\ Rs/2 = 2T\ \Delta f$,

where 1/T is the symbol rate. The value of β lies between 0 and 1. It is an important modulation parameter to determine the signal bandwidth and spectral efficiency.

Variation in the values of roll-off factor causes a change in the characteristics of modulated signal which directly affects the impact of the transmission signal. Higher roll-off means low ISI, since it reduces the change rate of the amplitude of output pulse at zero crossings. But it makes the signal bandwidth wider consequently consuming larger spectrum. On the other hand, lower the value of roll-off factors designed, higher is the spectral efficiency achieved. However, the rate of signal decay is slowest in the time domain. This makes the baseband signal more complex. In short, comparative lower roll-off values means a corresponding decrease in bandwidth usage and increase in symbol rate and overall throughput. This highlights that the proper selection of roll-off factor plays an important role on the performance of the system designed. The maximum symbol rate Rs attainable as studied in [30] can be related from rolloff factor for the given bandwidth as

$Rs = B(1 + \beta)$,

where B is the bandwidth of the system and β be the roll-off factor.

Raised cosine pulse:

Raised cosine (RC) filters are known for their ability to reduce the inter symbol interference of the signal. In communication systems, they are used as pulse shaping filters to shape the pulses. Basically, the name raised cosine stands for non-zero portion of the frequency spectrum with roll-off factor equal to 1 which defines the cosine function raised above the horizontal axis. It is the representation of pulse spectrum. For the channel with bandwidth B, if T > 1/2B then the pulse spectrum for this condition is called the raised cosine spectrum where 1/T is the sampling rate of the signal.

Raised cosine pulse shaping modulation is bandwidth efficient, i.e., more bits/sec/Hz and also power efficient, i.e., it requires comparatively low Eb/N0 for same bit error rate. These pulses stand as a balance between the rectangular pulse and the Sinc pulses. Rectangular pulses have sharp edges in the time domain indicating the large bandwidth in the frequency domain. So it requires infinite bandwidth. On the other hand, Sinc pulses have an infinite length of time domain sequence. Raised cosine pulses are therefore preferred as they exhibit the balanced nature between these two pulses. These pulses do not show such infinite long nature in both the time and frequency domains. When the passband frequency of these filters is half the data rate, it satisfies the Nyquist criterion such that T = NTs [31], where T is the data period and N is any integer. 21 Frequency response characteristic of a raised cosine function is given by [2] Xrc(f) =

$$X_{rc}(f) = \begin{cases} T & for \quad 0 \leq |f| \leq \frac{1-\beta}{2T} \\ \frac{T}{2}\{1 + \cos(\pi T/\beta(|f| - \frac{1-\beta}{2T}))\} & for \quad \frac{1-\beta}{2T} \leq |f| \leq \frac{1+\beta}{2T} \\ 0 & for \quad |f| > \frac{1+\beta}{2T}. \end{cases}$$

β is the roll-off factor and T is the reciprocal of symbol rate. Impulse response of the spectrum for raised cosine function is given by [2]

$$\begin{aligned} x(t) &= \frac{sin(\pi t/T)}{\pi t/T} \frac{cos(\pi\beta t/T)}{1 - 4\beta^2 t^2/T^2} \\ &= Sinc(\pi t/T) \frac{cos(\pi\beta t/T)}{1 - 4\beta^2 t^2/T^2}. \end{aligned}$$

the raised cosine pulse takes the form of a Since pulse shapes. The bandwidth of the pulse and the rate of decay are determined by the value of roll-off factor (β). Lower the value of β, sharper the spectrum. With roll-off value 1, it gives the pure raised cosine spectrum removing the flat portion. The tails of the signal x(t) is decayed as 1/t3 for roll-off factor greater than zero. This is the reason behind the formation of ISI which is formed when the timing mismatch occurs during sampling. Since the impulse response of RC filters has indefinite structure, it needs to be truncated for practical applications. In frequency domain, this truncation yields a non-zero side lobe. However, since pulse response delay is proportional to 1/t3 , the result might vary from that of theoretical approach [26].

Ideal response of a raised cosine filter has a unity gain in the region of low frequency and total attenuation at the high frequency. In the middle of these two frequencies, responses have a raised cosine function, size of which is determined by the roll-off factor. So, they are also called low pass filters. This raised cosine function meets the requirement of a pulse shaping filter, i.e., low pass response in frequency domain, zero ISI case and finite extent in time domain [26].

For an ideal channel,

Xrc(f) = Gt(f)Gr(f),

Where Gt(f) and Gr(f) are the frequency responses of the transmitter filter and receiver filter respectively [2]. These filters are used to analyze the overall desired frequency response.

For the matched condition of transmitter and receiver filter, Gt(f) = G∗ r (f) which yields,

$$G_t(f) = \sqrt{|X_{rc}(f)|}e^{-j2\pi f t_0}$$

Here, t0 is the nominal delay that is introduced to ensure the physical realizability of the filter [2].

2.3 Matched Filters:

Matched filters are the optimum linear filters used for enhancing the signal power or SNR. Basically, these filters are implemented using a known signal as a reference signal and comparing the unknown signal with the known referenced signal. This is done by taking the convolution of unknown signal with the time reversed form of referenced known signal. It can also be referred as convolution of unknown signal with conjugated time reversed version of known signal. The pulse compression where impulse response is matched to input signals, radar signaling are the examples of matched filtering. They are the linear time invariant filters that increases the SNR and decreases the error probability.

Since the main principles for matched filter were developed by Dwight North in 1943, reproduced in 1963 by Lamont Blake, it is also known as the North filter or conjugate filter [37]. Matched filter has its unique feature that it gives maximum possible instantaneous SNR at the output for the input of signal plus additive white noise.

The received signal consists of the transmitted pulses distorted by an additive channel noise. These noises are usually considered as additive Gaussian white noise. These received noisy signals are to be filtered out to receive the original transmitted pulse without noise components. Minimizing the noise effect out of the received signal is done in an optimum manner. Output signal power is desired to be considerably higher than the instantaneous noise power which is defined as maximizing the signal to noise power ratio. These filters give sharp peak response to the desired pulse at its input. This peak helps to determine the location t0 and the amplitude of the pulse from received signal. The general matched filter representation is shown in Figure.

For a transmitted signal x(t) and noise n(t), 26 Signal x(t) Noise n(t) Received signal s(t) Matched Filter H(w) Output y(t)

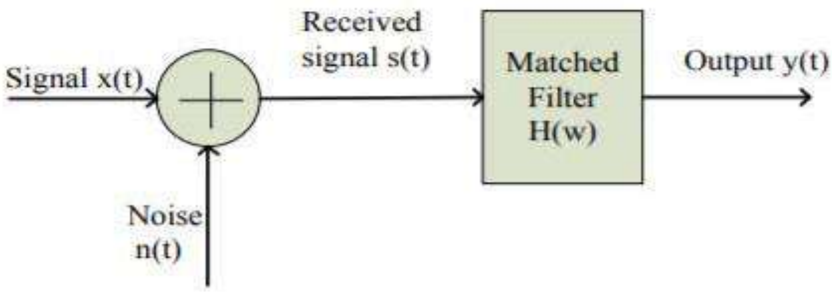

Fig.2.1 Basic representation of a matched filter.

$$s(t) = x(t) + n(t)$$

filter output, $$y(t) = s(t) * h(t).$$

Since the filter is linear, output can be written as,

$$y(t) = x(t) * h(t) + n(t) * h(t) = x0(t) + n0(t).$$

Now the matched filter is the linear filter h(t) or equivalently H(ω) that maximizes the SNR. Let the input signal for matched filter be represented by

$$x(t) = Csi(t - t1) + ni(t),$$

where t1 is the unknown time delay, ni(t) is the input white noise and C is any constant value. Now for the white input noise, its autocorrelation and power spectral density (PSD) functions can be written as

$$Rni(t) = N0\ 2\ \delta(t)\ Sni(\omega) = N0/2,$$

where N0 is a constant value. Output can then be written as, [38]

$$y(t) = Cso(t - t1) + no(t)$$

$$so(t) = si(t) * h(t)\ no(t) = ni(t) * h(t).$$

Here h(t) is the impulse response and * denotes convolution operation.

SNR of the matched filter depends on the ratio of signal energy to the PSD of the white noise at filter output. The signal component with maximum energy occurs at the sampling instant t = T. In matched filter, output is proportional to the shifted version of the auto correlation function of input signal [39].

Matched filters are used considering the noise as white noise. However, if the noise is colored, the problem is solved by using the filter, known as whitening filter, which filters the input signal noise to make it white.

Matched filters are the optimal equalizers used to maximize the SNR at each beam former output beam when the impulse response is known and the noise is additive white noise. Since each different signal requires different filters, it is called matched filtering as it has to match all the waveforms. These filters, however, do not play role in minimizing ISI. Since the optimization procedure in matched filter assumes only one signal transmitted over a channel, it does not focus much with ISI [40]. It enhances the SNR by improving the received signal and not the noise.

2.4 Whitening filters:

In any communication systems, noise is always an unavoidable parameter, which is present in the received signal that deteriorates the quality of signal power. Since it degrades the throughput of the system, it needs to be minimized. White noises are the ones with flat power spectrum having constant power at all the frequencies, i.e., they are random signal with constant power spectral density. They can also be considered as a sequence of serially uncorrelated random variables having zero mean and constant variance. Unlike this, colored noise is the one with varying power spectrum. Such noises increase inefficiency of the system. So it is imperative to whiten the colored noise. The filters that implement this process of whitening the noises are called whitening filters.

Whitening transformation is basically inferred as the decorrelation transformation of random variables with known covariance matrix into new set of random variables with identity matrix as its new covariance. This transforms the noise vector into a white noise vector, hence the name whitening filter. They are uncorrelated and have the variance equal to unity. Whitening filters can help minimize the interference due to other users in spread spectrum communication systems. The process is also known as digital whitening. During whitening, first the interfering signals are estimated and then the coefficients to be used in transversal filter are computed which is then followed by the filtering procedures for the received signal. In Figure, r(t) is the received signal

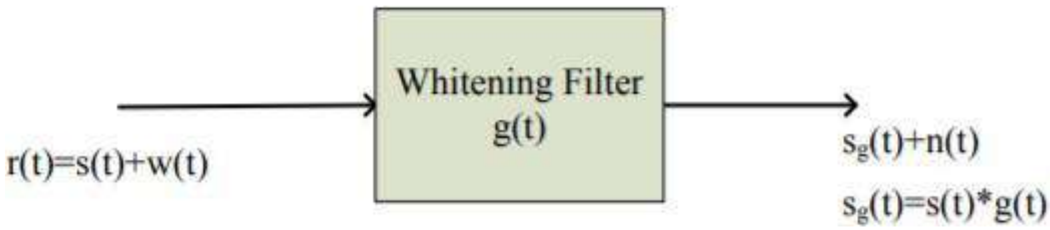

Fig.2.2 Basic flow for Whitening Filter.

comprising of signal s(t) with colored noise w(t), is passed through a whitening filter to get the whitened output signal. The term g(t) indicates the whitening filter and n(t) is the white noise having unit spectral density.

These filters can also be considered as an inverse of the system that distorts it. If the frequency response of the system is H(Z), then the white filter response is 1/H(Z). In 28 whitened matched filter model, noise whitening filter is introduced after the sampled matched filter. To be useful in practice, the whitening filter should be stable and causal as well. If the filter g(t) is used to whiten the noise in order to produce the output noise having power spectral density S 0 n (f) = N0/2 , then the filter should have [41]

$$S_n(f)|G(f)|^2 = N_0/2$$
$$i.e. \qquad |G(f)|^2 = N_0/2 \cdot 1/S_n(f)$$

where g(t) is the impulse response of filter, G(f) is its transfer function which change the power spectral density Sn(f) of the Gaussian noise process with noise N(t).

2.5 Equalizers:

Wireless communications is very likely to face different frequency dependant phase and amplitude distortions due to multipath signal transmissions and fading. In signal transmission, the received pulses come in a distorted form than the original transmitted pulse. The transmission characteristics of a band limited channel or channel noise gives rise to an ISI which is the cause for the distortion of the signals. Design of the inverse filter to counterfeit the channel impulse response so as to compensate the error and retain the signals as a replica of original signal is the main task of an equalizer.

Usually the signals are given a pattern through a pulse shaping filter. Proper sampling of the signals with no addition of the noise yields no ISI scenario. However, if it is not sampled at the sampling interval or against the Nyquist condition, the signal reconstruction is not exact. Moreover, the addition of channel noise causes a distortion in signal regenerating process at the receiver. To overcome this situation, the distorted signal is passed through a filter which is basically a multiplicative inverse in spectral domain of the frequency response of a channel. This is called equalization. Thus the equalized output is considered as reliable output.

Generally for short range transmissions, preset equalizers are used since in such case channel characteristics is not an important factor that needs to be considered. This is because the channel parameters are more or less time invariant. For the long range communications, the equalizers must be adaptive such that equalizers adapt to the time varying characteristics of the channel. The equalizer adjustment algorithms are mainly based on either peak distortion criteria or mean square distortion criteria [42].

In a communication system, considered linear time invariant, output signal can be modeled

as

$$x[n] = X\infty\ k=-\infty\ h[k]s(n-k) + v(n),$$

where s[n] is the transmitted symbol, h[k] the impulse response and v[n] is additive white gaussian noise (AWGN). Now equation can be simplified as,

$$x[n] = h[0] + s[n] + X\infty\ k=-\infty,k6=0\ h[k]s(n-k) + v(n).$$

In equation the second part of the equation refers to the delayed version of the transmitted symbols, which are known as inter symbol interferences. The equalizer is focused to eliminate this ISI to the minimum level possible. Various equalization methods are implemented as demanded by the situation of signal transmitting and receiving procedures. In the thesis work, MMSE equalization method is effectuated.

2.6 MMSE equalization

In digital communications, equalizers come along with matched filters where equalizers are responsible to minimize ISI and the matched filters reduce the channel noise. Equalizers can be classified based on their structure, algorithms used to adapt the coefficients or their optimization criteria. MMSE algorithm makes use of the joint minimization of noise and ISI parameters.

MMSE equalization is considered as a measure of estimator quality. It is based on MMSE filtering. The linear filter which is designed to minimize the error between the transmitted signal and the received output such that original signal can be estimated out of it are the MMSE filters. The error consists of an ISI in addition to the noise. The MMSE criterion ensures an optimum tradeoff between the residual ISI in the received signal and noise enhancement. In such equalization, since the minimization of mean square error (MSE) is done, the noise amplification is reduced. This is why it outperforms the zero forcing equalizers.

The main objective of the MMSE equalizer is to minimize the variance of the error signal or the the mean square value of the error. The error signal is calculated by the help of estimated signals. It is the difference of transmitted signal and the estimate of the received signal. At low to moderate SNR values, these equalizers give remarkably lower bit errors as compared to zero forcing equalizers

$$el = sl - Gl,l\hat{R}\ l$$

$$Jl = E|e|\ \hat{}2$$

In the relation (3.23), Jl is mean square error, Gl,l is equalizer coefficient, sl is the transmitted signal, $\hat{R}$ l the estimate of received signal and el is the error. Minimizing the mean square error can be done using the orthogonality principle which states that mean square error Jl is minimum if the equalizer coefficient Gl,l is selected in a way that received signal Rl and error el are orthogonal to each other [43]

$$E[elR* \ l\ ] = 0.$$

Now the equalizer coefficient for the MMSE equalization is calculated by the equation

$$Gl,l = H*l,l\ |Hl,l|\ 2 + \sigma\ 2$$

where H represents the channel matrix with the diagonal components Hl,l and σ 2 represents the noise variance. Equation infers that MMSE computation needs the value of noise variance (σ 2), which is determined during the system design that helps MMSE equalizer give the optimal performance.

CHAPTER 3

SOFTWARE INTRODUCTION:

3.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 The MATLAB system:

The MATLAB system consists of five main parts.

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.) and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension. fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type, guide filename, Where filename is the name of an existing FIG-file on the current path. If filename is omitted,
GUIDE opens a new (i.e., blank) window.

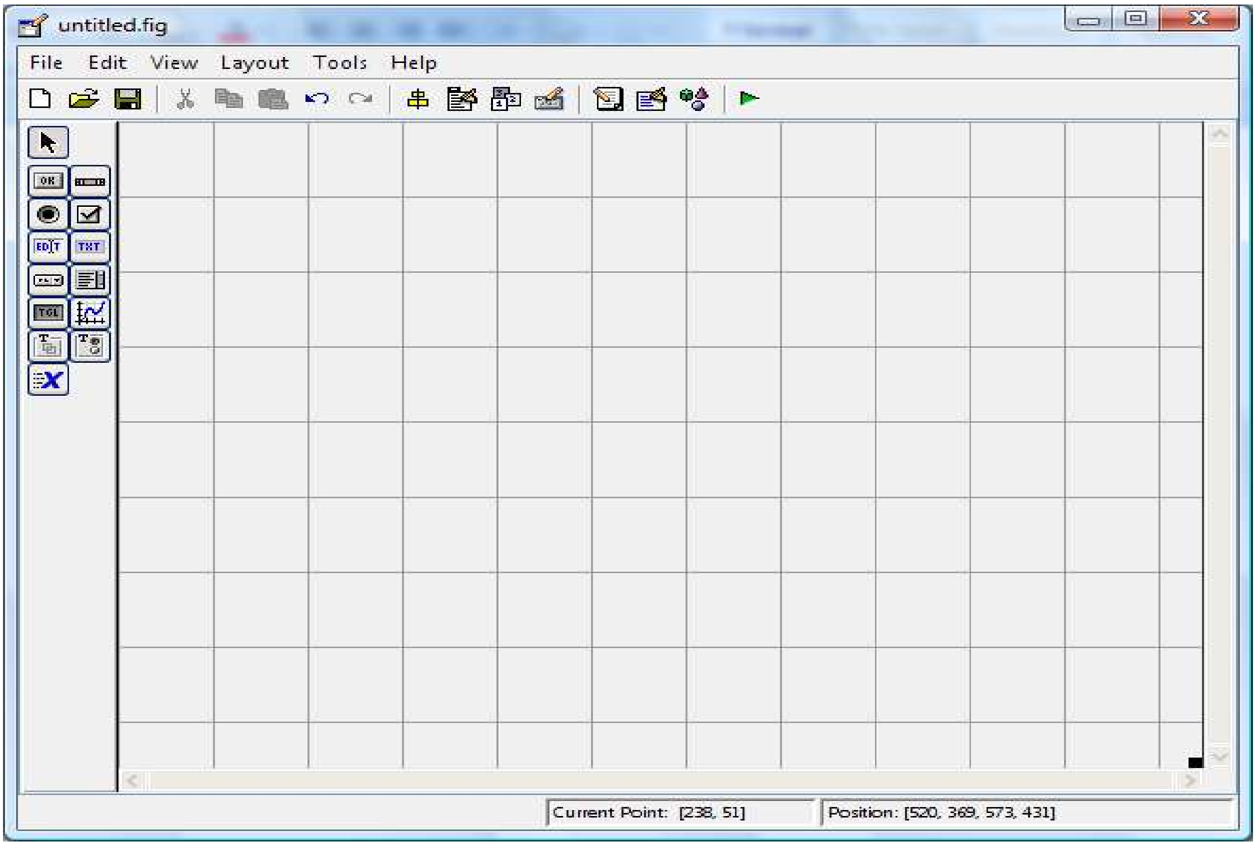

Fig.3.1

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.4.1 Introduction - describes the components of the MATLAB system.

3.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

3.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.5 DEVELOPMENT ENVIRONMENT

3.5.1 Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type MATLAB at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish. M script.

3.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example, maces magic's invokes an editor called emacs for a file named magic's. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whose.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a. mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to run MATLAB functions. The Editor/Debugger provides a graphical user interface for basic textediting, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type of function.

3.6 MANIPULATING MATRICES

3.6.1 Entering Matrices.

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Durer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Durer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =
   16    3    2   13
    5   10   11    8
    9    6    7   12
    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

3.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables

- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)

^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

3.6.4 Functions

MATLAB provides many standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfin For a list of more advanced mathematical and matrix functions, type help spec fun help elm at

Some of the functions, like sqrt and sin, are built in. They are part of the MATLAB core, so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sin, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realm in	Smallest floating-point number, 2^{-1022}
Realm ax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NAN	Not-a-number

3.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

3.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of UI controlled objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (UI controls and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

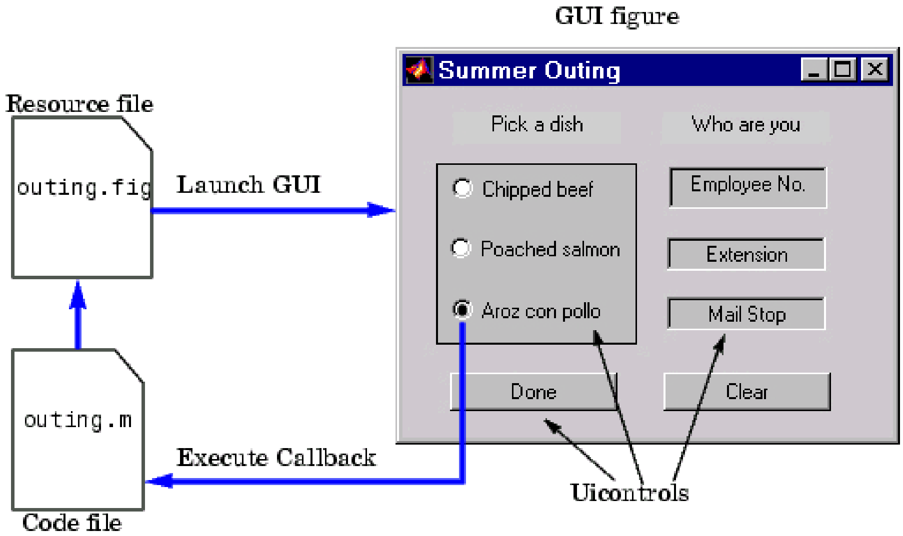

FIG 3.2 graphical user blocks

3.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no UI control creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

3.7.4 Beginning the Implementation Process:

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB UI control objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- List boxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h, event data, handles, varargin)
button_state = get(h,'Value');
if button_state == get(h,'Max')
   % toggle button is pressed
elseif button_state == get(h,'Min')
   % toggle button is not pressed
end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a true color image. For example, the array a defines 16-by-128 true color image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)
set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)
off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
mutual_exclude(off)
% Continue with callback
 .
 .
 .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with several independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
errordlg('You must enter a numeric value','BadInput','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menu bar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menu bar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only UI controls can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The List box Top property defines which string in the list displays as the topmost item when the list box is not large enough to display all list entries. List box Top is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Non integer values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

List boxes differentiate between single and double clicks on an item and set the figure Selection Type property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections.In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure Selection Type property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure Window Button Down Fcn callback executes. Then the control's Button Down Fcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not UIcontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button Down Fcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)

Chapter 4

PROJECT IMPLIMENTATION

PROPOSED FTN-BASED HYBRID SIGNALING

In this section, we present the proposed hybrid signaling scheme employing the FTN signaling for the data transmission and the OFDM signaling for the ICI-free pilot transmission. Key features of the proposed scheme are as follows:

• A slot, the unit of data scheduling in time domain, is generated by the time division multiplexing (TDM) of OFDM and FTN symbols (see Fig. 3).

• Control and pilot signals are transmitted by the OFDM signaling to guarantee the accurate channel estimation quality. Whereas, data transmission is served by the FTN signaling for better spectral efficiency.

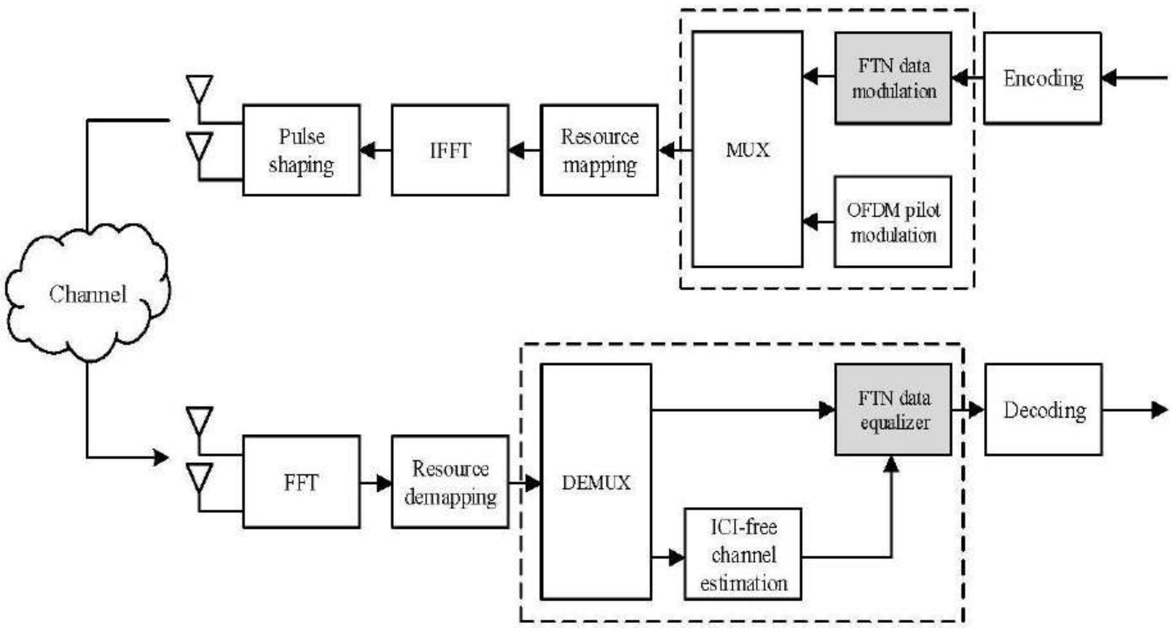

Fig. 4.1 Proposed Block Diagram

4.1 Proposed Slot Structure

In 4G LTE or 5G NR systems, user data is transmitted on resource units [12], [13].4 In the proposed scheme, we set the duration of OFDM and FTN symbols to be the same (i.e., TOFDM = TFTN), which simplifies the scheduling operation in the basestation as well as the buffering operation at the user terminal. Similarly, alignment of resource block (RB)

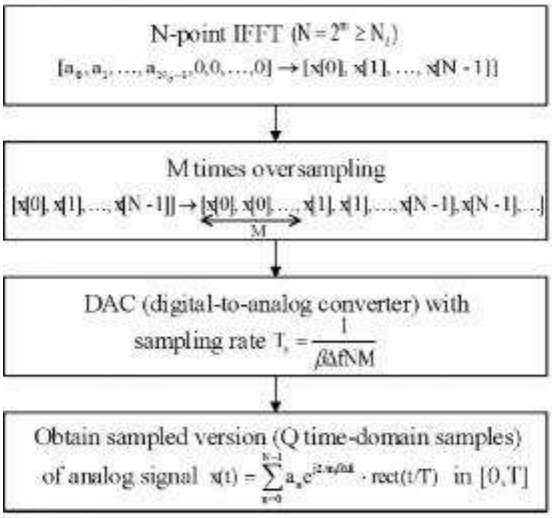

Fig: Multi-carrier signal generation procedure.

between OFDM and FTN symbols can also simplify the system operation by enabling the transceiver processing per RB. Towards this end, the squeezing factor β should be chosen such that the number of subcarriers for FTN and OFDM in one RB satisfies NRB,OFDM = βNRB,FTN(NRB,FTN ∈ N), given that ΔfFTN = βΔfOFDM.

Fig shows the case where each RB consists of 12 sub-carriers (for the OFDM signaling) and 15 and 20 subcarriers (for the FTN signaling). In general, downlink slot consists of control channel, pilot signal, and data. In case each slot consists of 14 symbols as in 5G NR system [1], two symbols are used for the control channel, one symbol is used for the pilot signaling, and the rest of 11 symbols are used for the data transmission. When compared to the OFDM systems, the proposed FTN transmission scheme can achieve up to 20% spectral efficiency gain for β = 0.8. In case the downlink slot consists only of pilot signals and data, the spectral efficiency gain is increased up to 23%.

Practical Consideration on the Proposed Hybrid Signaling

In this subsection, we discuss the sampling rate alignment between OFDM and FTN symbols used to facilitate the implementation of the proposed FTN-based hybrid signaling. By the alignment of the sampling rate, complicated timing switch between OFDM and FTN signaling can be prevented. Fig. depicts the multi-carrier signal generation procedure at the transmitter. Without loss of generality, the IFFT size is set to be larger than or equal to the number of data subcarriers Nd (i.e., N = 2m ≥ Nd (m ∈ Z)). After the IFFT operation, oversampling (with factor of M) and digital-to-analog conversion (DAC) with the sampling rate Ts are performed. Finally, under given symbol duration T, pulse shaping (e.g., square-root raised cosine) is applied to obtain the time-domain samples in the analog domain.

Two factors determining the alignment of the sampling rate Ts between OFDM and FTN symbols are the IFFT size N and oversampling factor M (see Fig. 4). First, in order to avoid the change of the IFFT size in the same slot, the IFFT size of the OFDM signaling should be set such that N ≥ Nd,FTN (Nd,FTN>Nd,OFDM) where Nd,FTN and Nd,OFDM are the

TABLE.4.1 Number of subcarriers for the system bandwidth supported by the 5G system(β = 0.8).

		Bandwidth [MHz]					
	SCS [kHz]	5	10	15	20	25	40
OFDM	15	300	624	948	1272	1596	2592
	30	132	288	456	612	780	1272
	60	N/A	132	216	288	372	612
FTN	12	375	780	1185	1590	1995	3240
	24	165	360	570	765	975	1590
	48	N/A	165	270	360	465	765

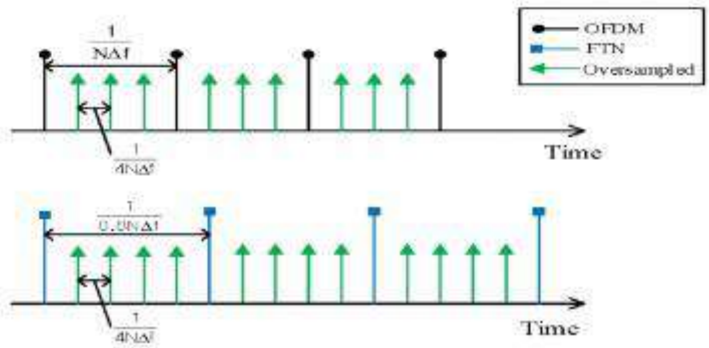

Fig.4.2

Time domain samples of OFDM and FTN signaling when β = 0.8.number of data subcarriers supported by the FTN and OFDM signaling, respectively. For example, as observed from Table I, when the system bandwidth is 15 MHz and Δf = 15 kHz, OFDM can use 1024 IFFT size for Nd,OFDM = 948, but FTN uses 2048 IFFT size for Nd,FTN = 1185. By choosing the IFFT size N = 2048, we can employ the same IFFT size in the transmission time interval.

We next investigate the oversampling factor M with the same IFFT size N for both OFDM and FTN signaling. Note that the sampling rates of the OFDM and FTN symbols are expressed as Ts,OFDM =1/ΔfNMOFDM and Ts,FTN =1/βΔfNMFTN, respectively. In order to avoid the switching of the sampling rate in the same slot, we need to choose the oversampling factor such that βMFTN = MOFDM. As shown in Fig. 5, by choosing the oversampling factors MOFDM = 4 and MFTN = 5 when β = 0.8, we can satisfy the alignment condition βMFTN = MOFDM.

In summary, two conditions to align the sampling timing of OFDM and FTN symbols are as follows:

• The IFFT size N for both OFDM and FTN signaling should satisfy N ≥ Nd,FTN.

• The oversampling factors for OFDM and FTN should satisfy βMFTN = MOFDM.

4.2 PAPR Analysis

In this subsection, we investigate the peak to average power ratio (PAPR) of the proposed FTN-based hybrid signaling scheme. Note that the PAPR is an important metric in the waveform design since the high PAPR brings on the signal distortion in the nonlinear region of the high power amplifier [14]. The PAPR of continuous-time signal x(t) is defined as

$$PAPR = \frac{\max |x(t)|^2}{E[|x(t)|^2]},$$

,

where max |x(t)|^2 is the peak power of the signal x(t) and E[|x(t)|^2] is the average power. The discrete version of PAPR can be expressed as

$$PAPR = \frac{\max_{k\in\{0,\ldots,Q-1\}} |x[k]|^2}{E[|x[k]|^2]}$$

where Q is the number of time-domain samples at a given symbol duration T (see (3)). When the number of subcarriers is sufficiently large, the distribution of x[k] approaches to the complex Gaussian and thus |x[k]|^2 can be readily approximated to χ 2-random variable with 2 degrees of freedom. Thus, the PDF is given by pX(x) = 1 2σ2 e –x 2σ2 and the PDF of Y = |x0[k]|^2 =|x[k]|^2 E[|x[k]| 2] =X 2σ2 is pY (y) = 2σ 2pX(2σ 2y) = e−y Since the CDF of Y is given by Pr(Y ≤ y) = R Y0pY (y) =1 − e−γ, the CDF of PAPR in (8) is

$$\begin{aligned} Pr(PAPR \le \gamma) &= Pr\left(\bigcap_{i=0}^{Q-1} \left(|x_0[k]|^2 \le \gamma\right)\right) \\ &= \prod_{i=0}^{Q-1} Pr\left(\left(|x_0[k]|^2 \le \gamma\right)\right) = \prod_{i=0}^{Q-1} (1 - e^{-\gamma}) \end{aligned}$$

and hence the complementary CDF of the PAPR is

$$Pr(PAPR > \gamma) = 1 - \prod_{i=0}^{Q-1} (1 - e^{-\gamma}) = 1 - \left(1 - e^{-\gamma}\right)^Q$$

When the IFFT sizes of OFDM and FTN symbols are the same and the oversampling factors satisfy βMF T N = MOFDM, the number of time domain samples Q in the same symbol duration T equals for both OFDM and FTN symbols. It is not hard to convince from this discussion that when the OFDM and FTN symbols have the same number of time domain samples Q, similar PAPR performance can be achieved for both OFDM and FTN symbols.

.

4.3 Transmission Capacity

In this subsection, we compare the capacity of the conventional OFDM signaling and FTN-based signaling schemes. The achievable capacity for the OFDM signaling and FTN-based signaling under SISO AWGN channel can be expressed as

$$C_{OFDM} \approx W \log2(1 + PS/PN),$$
$$C_{FTN} \approx W/\beta \log2(1 + PS/PN + PICI),$$

where W is the signal bandwidth, PS is the signal power, PN is the noise power, and PICI is the ICI power. One can easily see that the maximum achievable capacity of the FTN-based signaling is higher than that of the OFDM signaling when ICI is controlled properly. When we set β = 0.8, performance gap of the proposed scheme over the OFDM signaling with perfect channel state information is negligible [4]. In Fig, we observe that the capacity gain of the FTN-based signaling over the OFDM signaling is about 23%, which is close to the maximum achievable capacity gain (i.e., 25%) for β = 0.8.

Chapter 5

PROJECT TESTING AND RESULTS

5.1 OVERVIEW OF TESTING METHODS:

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

5.2 RESULTS:

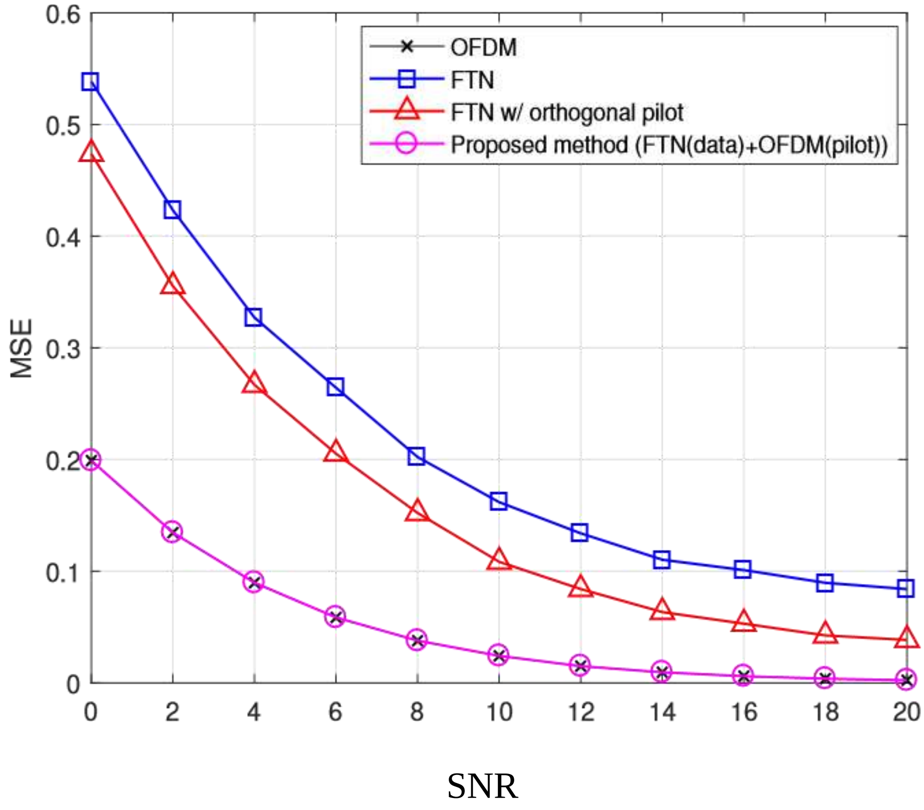

Fig. 5.2 MSE performance for hybrid FTN and OFDM

Chapter 6

CONCLUSION AND FUTURE ENHANCEMENT

In this paper, we proposed the FTN signaling scheme suitable for the MIMO transmission. Our work was motivated by the observation that the FTN-based pilot transmission degrades the channel estimation quality severely. Key features of the proposed scheme are 1) channel estimation using the OFDM signaling and 2) data reception using the FTN signaling. We observed from numerical evaluations that the proposed hybrid scheme achieves a substantial gain in the spectral efficiency over the OFDM and FTN systems. One future direction is to improve the channel estimation quality of the proposed FTN signaling by recycling the detected symbols as pilots.

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.SANTOSH KUMAR PATRA**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr.A.ANAND, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our project guide **Mr.P.JOEL JOSEPHSON, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1.MILALIYAN SAMANTARY (17K81A04M8)
2.GURRAM RAKESH (17K81A04K9)
3.PREETHI ROSHAN (17K81A04N8)

ABSTRACT

The soldier Health and Position Tracking System allows military to track the current GPS position of soldier and checks the health status including body temperature and heartbeats of soldier. The System also consists extra feature with the help of that soldier can ask for help manually or send a distress signal to military if he is in need. The GPS modem sends the latitude and longitude position with link pattern with the help of that military can track the current position of the soldier. The system is very helpful for getting health status information of soldier and providing them instant help.

CHAPTER 1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

The nation's security is monitored and kept by army, navy, and air-force. The important and vital role is of soldiers who sacrifice their life for their country. There are many concerns regarding the safety of the soldier. Soldiers entering the enemy lines often lose their lives due to lack of connectivity, it is very vital for the army base station to know the location as well as health status of all soldiers. India has already lost so many soldiers in war-fields as there was no proper health backup and connectivity between the soldiers on the war-fields and the officials at the army base stations. Recently on 29 September 2016, a military confrontation between India and Pakistan began, Indian soldiers conducted a surgical strike against militant launch pads across the line of control in Pakistani-administered Azad Kashmir and inflicted "significant casualties". Indian soldiers are mainly known for their courage, despite scarce ammunitions and safety measures, they have many triumphs to their credits. All must be really concerned about the safety of the soldiers, so we have decided to build a project which will efficiently keep a check on the health status of the soldier, and his precise location to equip him with necessary medical treatments as soon as possible. Soldier's tracking is done using GPS and GSM is used to provide wireless communication system. For monitoring the health parameters of soldiers, we are using biomedical sensors such as temperature sensors and heartbeat sensors.

An oxygen level sensor is used to monitor atmospheric oxygen so if there are any climatic changes the soldiers will be equipped accordingly.
The infantry soldier of tomorrow promises to be one of the most technologically advanced modern warfare has ever seen. Around the world, various research programs are currently being conducted, such as the United States' Future Force Warrior (FFW) and the United Kingdom's Future Infantry Soldier Technology (FIST), with the aim of creating fully integrated combat systems .Alongside vast improvements in protective and weaponry subsystems, another major aspect of this technology will be the ability to provide information superiority at the operational edge of military networks by equipping the dismounted soldier with advanced visual, voice, and data communications.

Helmet mounted visors, capable of displaying maps and real-time video from other squad members, ranges of physiological sensors display the heartbeat, body temperature, atmosphere pressure, surrounding oxygen level etc. These devices will improve awareness for collateral military personnel as well as who will exchange information using wireless networks along with hosts. The challenge was to integrate these piecemeal components into a lightweight package that could achieve the desired result without being too bulky and cumbersome or requiring too much power. Communicating with the base (control room) station become the fundamental challenges in military operations. The proper navigation between soldier's organizations plays an important role for careful planning and coordination.

1.2 OBJECTIVES OF THE STUDY

So, this project focuses on tracking the location of soldiers from GPS, which is useful for control room stations to know the exact location of soldiers and accordingly they will guide them. Also High-speed, short-range, soldier-to-soldier wireless communications to relay information on situational awareness, such as Biomedical sensors, GPS navigation, Wireless communication.

1.3 SCOPE OF THE STUDY

- Soldier health and position tracking system is such a type of a system that provides the health and position status of a soldier fast with the help of gps and gsm modules.

- Soldiers are important assets of our country. They workday and night to protect our country. Sometimes even they sacrifice their life for the country.

- And soldiers at borders often lose their lives defending the country.

- To overcome this situation this system helps us to track the position of the soldiers and even information regarding health is produced by this system. And will efficiently keep a check on the health status of the soldier, and his precise location to equip him with necessary medical treatments as soon as possible.

- Here we have proposed a system that is called Soldier health and position tracking system, which is so much efficient, reliable, and friendly to use. In this system soldier's tracking is done using GPS and GSM is used to provide wireless communication systems. For monitoring the health parameters of soldiers, we are using biomedical sensors such as temperature sensors and heartbeat sensors.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- 12V Battery
- Temperature Sensor
- Heartbeat sensor
- Push Button
- LCD
- GSM
- GPS
- Buzzer

1.4.2 SOFTWARE REQUIREMENT

- Proteus Software
- Arduino Software

1.5 PROCUMENT OF EQUIPMENT

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the health and position of soldiers better than before we successfully got the output in mobile and LCD screen. We would like to improve the project in future for further developments.

CHAPTER 2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA

Nowadays all nations keep its security at high priority. Wars are being fought for land, water and acquiring the position of most powerful nation. A country's arm forces consist of three professional uniformed services: the army, the navy, and the air force. Soldiers being the backbone of any armed force usually lose their lives due to lack of medical help when in emergency, also soldiers who are involved in missions or in special operations get straggled on war fields and lose contact with the authorities. To overcome these concerns, we had built this project which, using wireless body area sensor network (WBANS) such as temperature sensor, heartbeat sensor etc. will monitor the health status of the soldier whenever required. Also using GPS, we can track the soldier's exact location whenever required. Using oxygen level sensor, we can also monitor the environmental condition, so authorities can provide essential aids. The communication is established between the soldiers and authorities via GSM. Any abnormalities in the readings of wireless body area sensor network (WBASNs) are considered as a trigger for GSM to establish the connection between the soldier and base unit and send current location and health status to the receiver. By using all this equipment's, we had tried to implement the basic guarding system for the soldier in low cost, light weighted, portable and precise device.

In enemy territory soldiers not only have to deal with the physical threat, but also with stress and fatigue caused by protracted operations or lack of sleep. So, for the security purpose we need a tool for remote soldier performance and health monitoring. So, in this project a tool is implemented using biosensors for health monitoring purpose. Also, a GPS system is used to track the location of soldier. Additionally, a GSM modem is also used to make the system wirelessly compatible.

In today's world, warfare is an important factor in any nation's security. One of the important and vital roles is played by the army soldiers. There are many concerns regarding the safety of soldiers. So, for their security purpose, many instruments are mounted on them to view their health status as well as their real time location. Bio-sensor systems comprise various types of small physiological sensors, transmission modules and processing capabilities, and can thus facilitate low-cost wearable unobtrusive solutions for health monitoring. This paper gives an ability to track the location and monitor health of the soldiers in real time who become lost and get injured in the battlefield.

2.2 REVIEW ON RELATED LITERATURE

In [1], the author has worked on the safety of the soldier by tracking his health condition during the war which provides the control room to plan the war strategies and tracks the location if by chance the soldier is lost. When the control room notices the soldier is lost in the battlefield then they guide the soldier in the right path. The soldier's health information is transmitted to the control room and keeps track of the injured soldier and take necessary action to save the life. This system mainly focuses on the soldier who have involved in the warfare and tracking the health of the injured soldier. In [2], the author has focused to improve the communication of the soldier with the control room people and control plane operation continuously. He has also focused to track and guide the position, direction, and the surrounding temperature of the soldier by using the wristwatch mountaineers and by providing headphones to guide the soldier to the right path. He has also used the technology like the Radio collar strapped to ankles, so the movement of the soldier can be tracked and displays the current location at the base station. Microcontroller is used to record the body parameters of the soldier's and transmitted to the base station. In [3], the author has focused to provide the embedded wireless system for the soldier and to minimize the time to track the location of the soldier, rescue and search operation and their health status using GPS module and wireless body sensors, the data are collected from the GPS and sensors are transmitted using the ZigBee technology to the base station/control room. It also allows the soldier to communicate with the other fellow soldiers within the wireless transmission range, they can also request help from the control room. In [4], the author has worked on the location tracking system using GPS with the Google Maps based monitoring for vehicle. This system provides tracking irrespective of weather condition. It gives the shortest route to track. This idea is deployed in the proposed system to track the current location and movement of the soldier along with the shortest path to him, which is need for the rescue operation. In [5], here the author focus is on monitoring the ill patient, continuously and reports the changes spontaneously to the concerned person using the GPS, 4 Chaitra R L, Mamatha V which helps in protecting the life of the individual. In this paper only, the ill patient is considered for monitoring. Once the patient is discharged from the hospital, the body sensor is mounted on them to monitor their health condition and take necessary action in case of emergency by reporting to the guardian. In [6], the author has worked to track the location of the soldier and monitor the health status using an Arduino board. For the transmitting of data to control room he has used GPS module for connectivity. In [7], the author focus is to provide a good connectivity between the control room and the soldier by using Arduino and GSM module.

2.3 CONCLUSION ON REVIEWS

From the above implementation we have concluded that the communication hurdles between the soldiers and authorities at the base unit is overcome using GSM, the precise location and health parameters are known using GPS and wireless body area sensor network (WBASNs) respectively and with the GSM modem all information is send to the base station so that field commander will take necessary action. Base station gets location of soldier from GPS. The base station can access the status of the soldier which is displayed on the phone with the help of GSM and hence appropriate actions can be found.

CHAPTER 3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

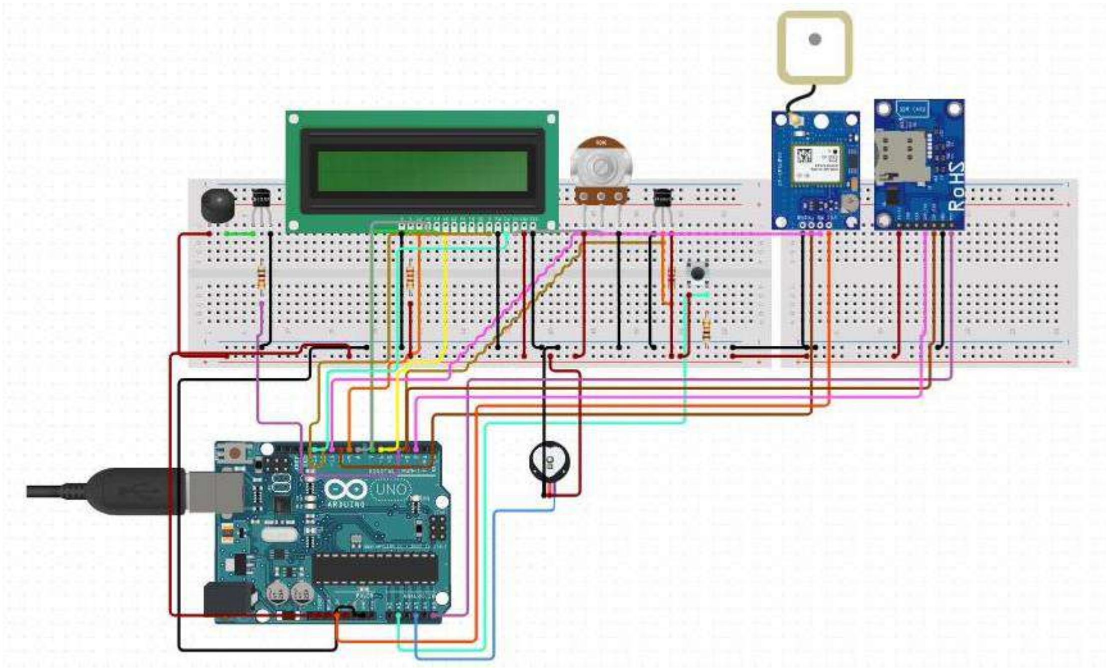

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS

3.2.1 ARDUINO

3.2.1.1 INTRODUCTION

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).

- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

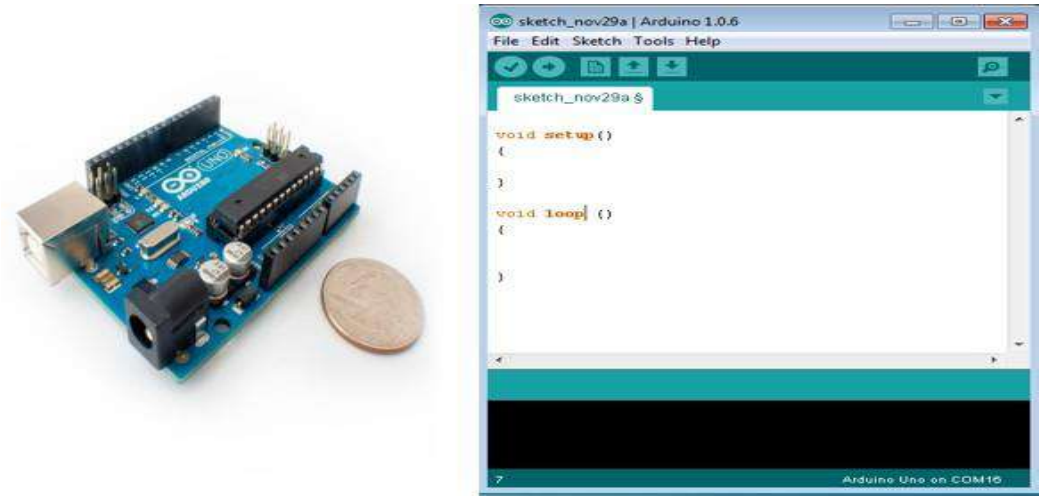

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini-05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini-3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Lilypad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati
Lilypad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3.2.1.2.4 Arduino boards based on AT91SAM3X8E microcontroller

3.2.1.3 BOARD DESCRIPTION

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

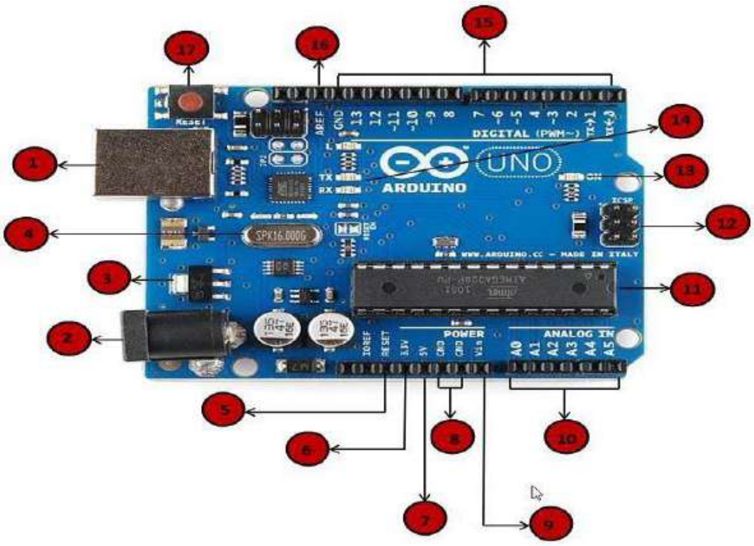

Fig.3.2.1.3 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).

6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in

	two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 3.2.1.3 Board description of Arduino UNO

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you are not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

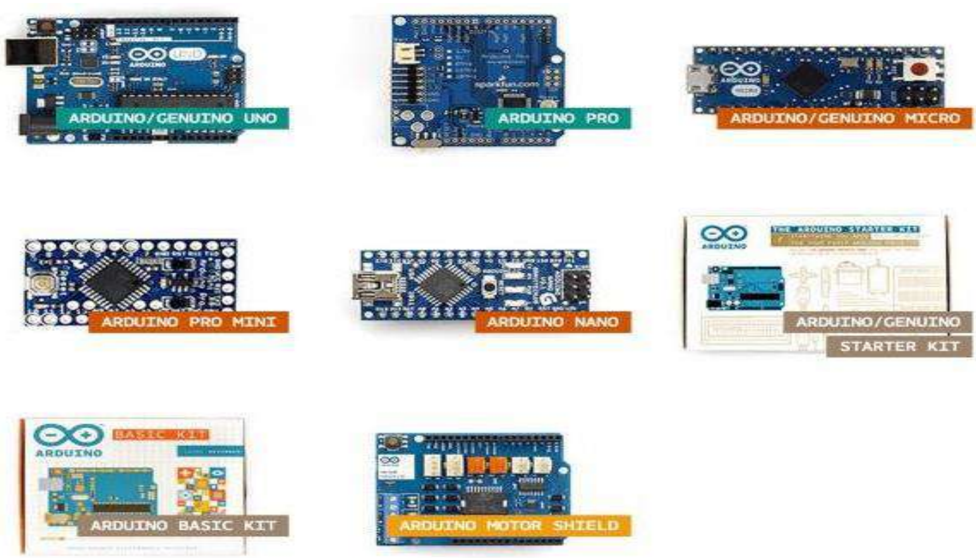

Fig.3.2.1.4 Arduino Family

3.2.1.5 SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.5 Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328

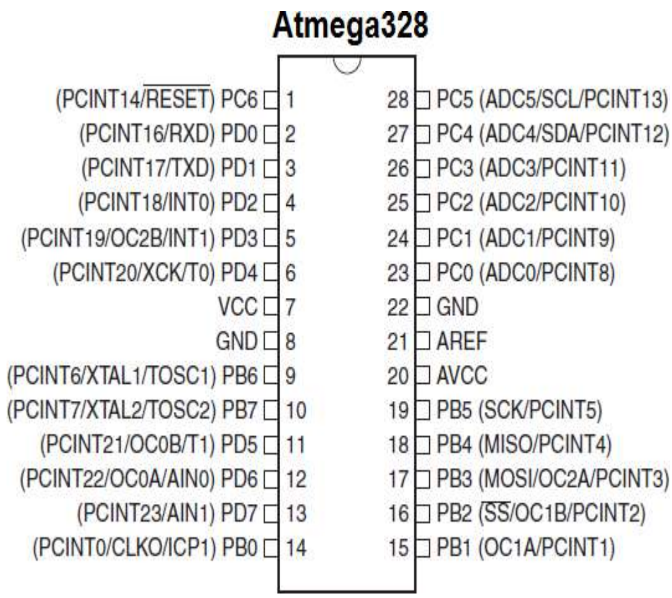

Fig.3.2.1.6 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

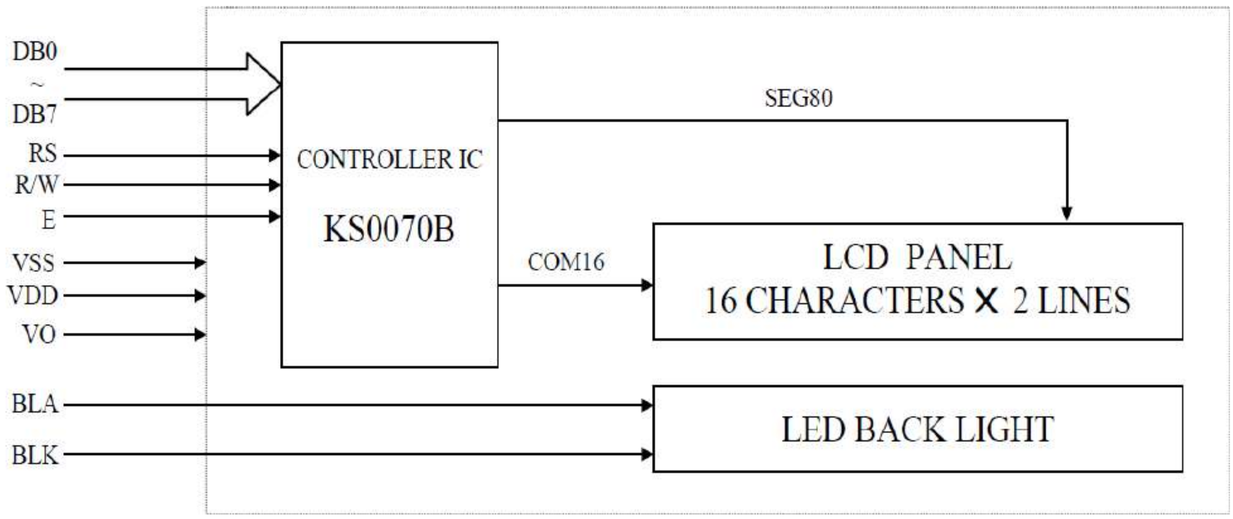

Fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

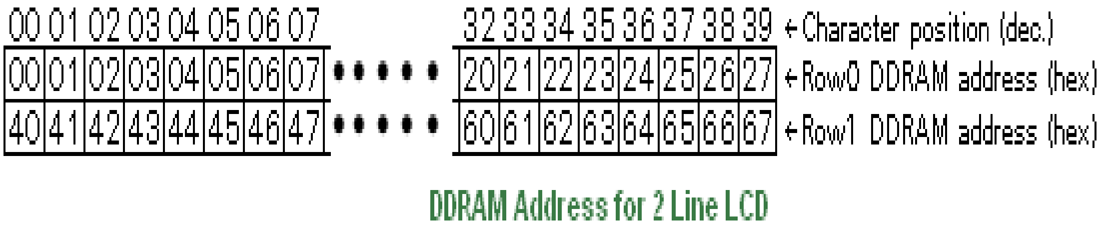

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 HOW TO CHOOSE A BUZZER

There are many kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic_buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound if connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.1 INTRODUCTION OF PIEZO BUZZER

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

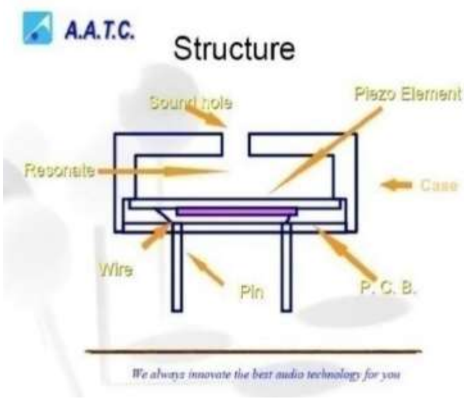

Fig.3.2.3.1 piezo buzzer

3.2.3.2 SPECIFICATIONS

Rated Voltage: A piezo buzzer is driven by square waves (Vp-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

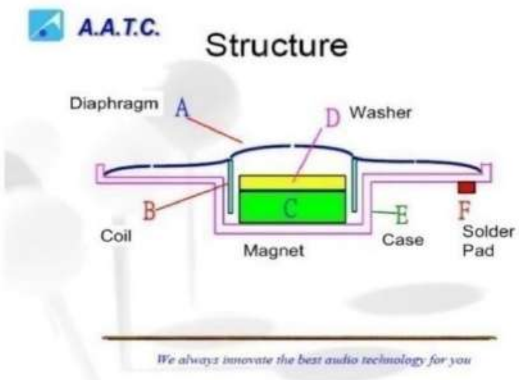

Fig. 3.2.3.2 structure of piezo buzzer

Sound Output: The sound output is measured by decibel meter.
Applying rated voltage and square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest

and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

3.2.4 TEMPERATURE SENSOR

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°Cover a full −55 to +150°C temperature range.

Features

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60 µA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

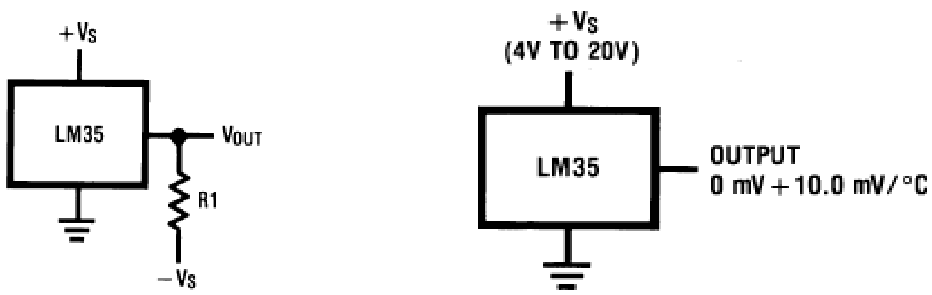

Figure. 3.2.4 Temperature Sensor

3.2.4.1 TEMPERATURE SENSING CIRCUIT

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact. In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

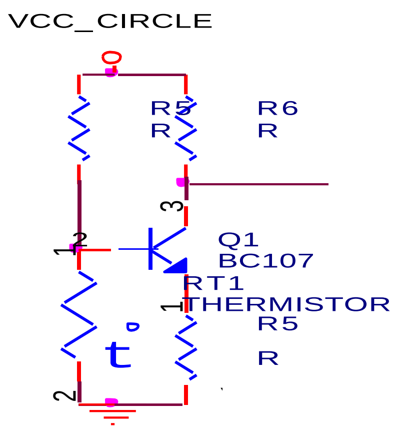

Figure. 3.2.4.1 Temperature Sensing Circuit

3.2.5 BATTERY

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place. When the material in the cathode or anode is consumed or no longer able to be used in the reaction, the battery is unable to produce electricity. At that point, your battery is "dead."

Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Fig.3.2.5.1 Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

Fig.3.2.5.2 Batteries come in a variety of shapes, sizes, and chemistries

3.2.5.1 THE TERM BATTERY

Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Fig.3.2.5.1 The term battery

3.2.6 SOFTWARE EXPLANATION

- Arduino software
- Proteus simulation
-

3.2.6.1 ARDUINO SOFTWARE

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards can read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for

beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE)

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

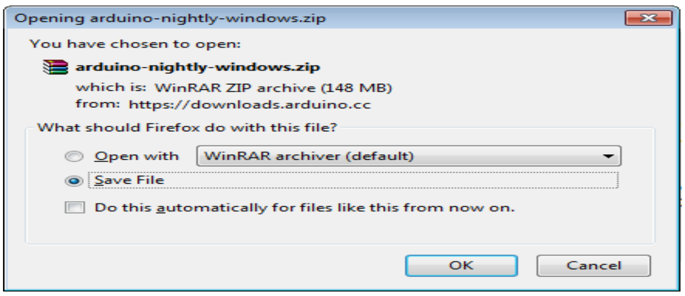

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

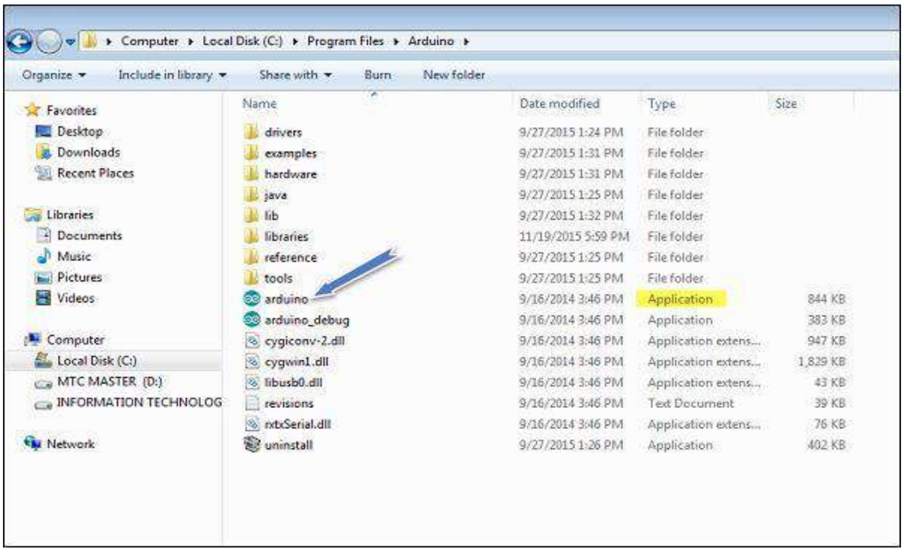

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

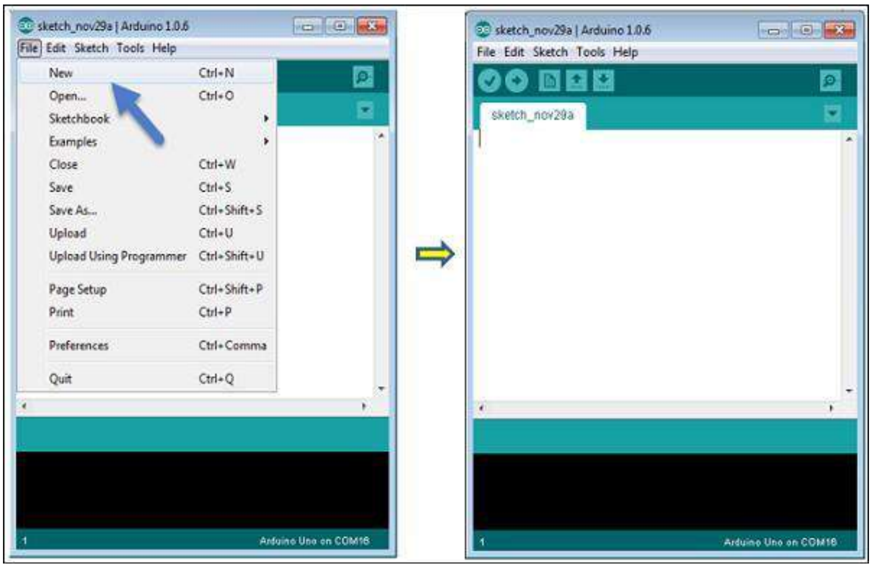

Fig. 3.2.6.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

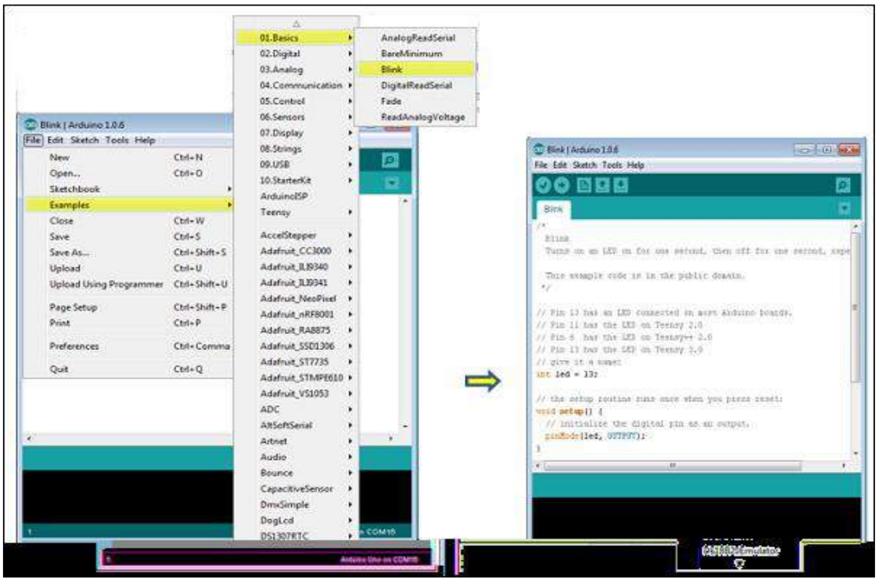

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

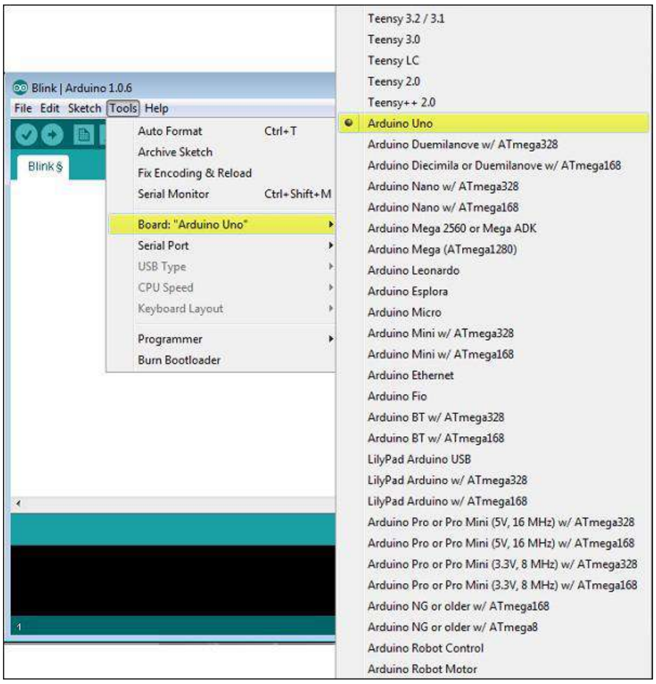

Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

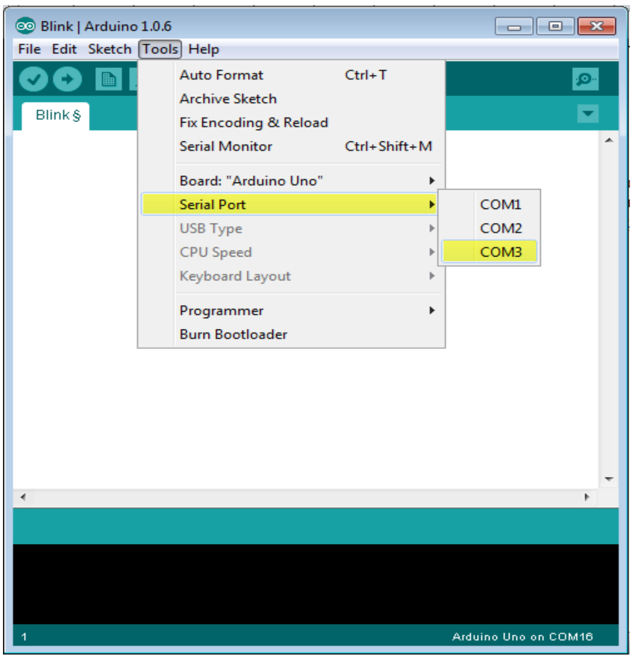

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

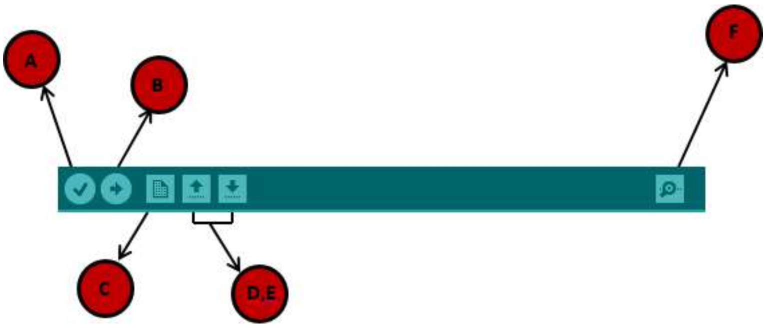

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

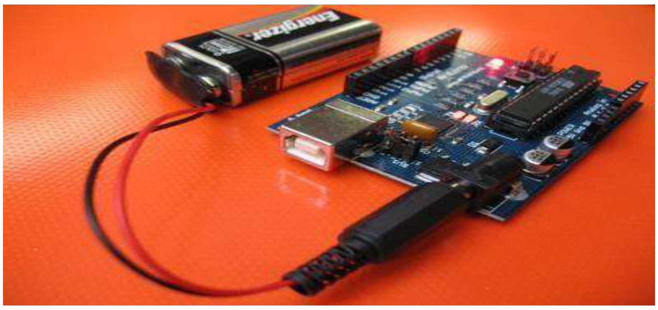

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

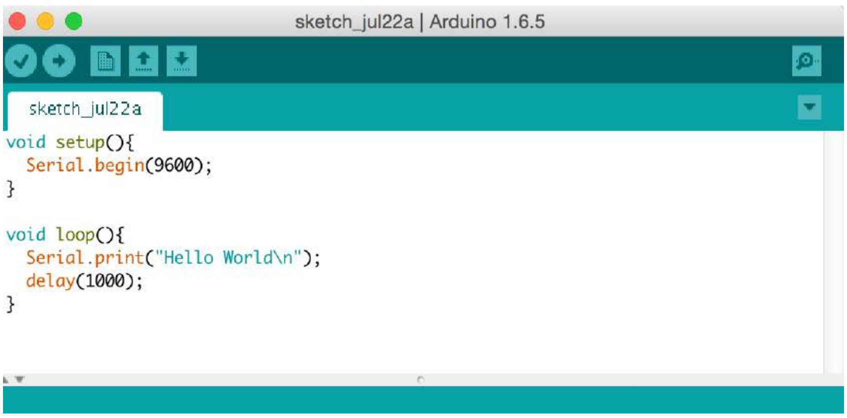

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS

PROTEUS

Proteus is a simulation and design software tool developed by Lab center Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the footprints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select new design in File menu

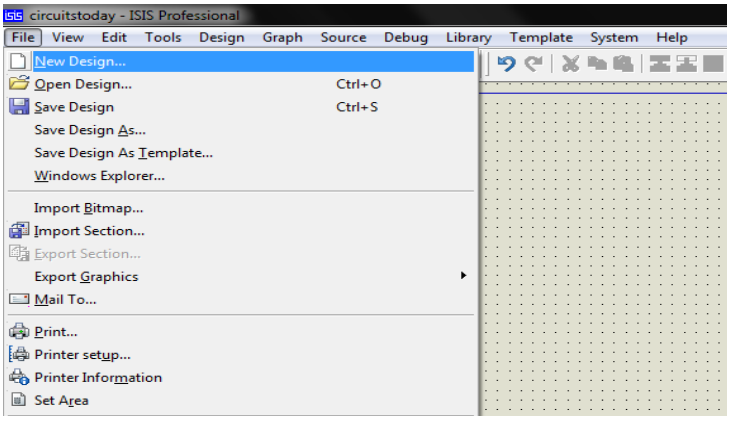

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

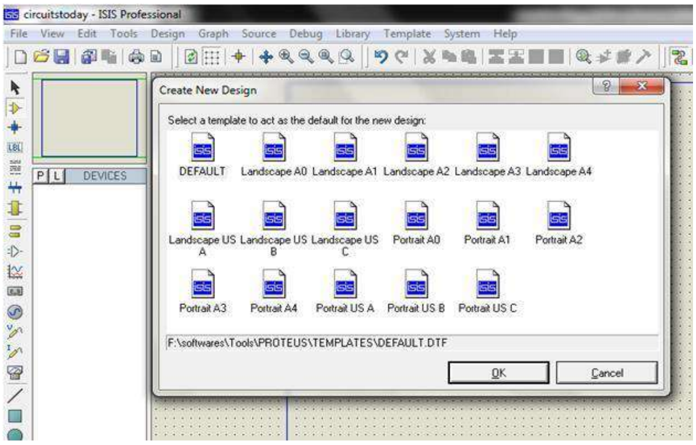

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

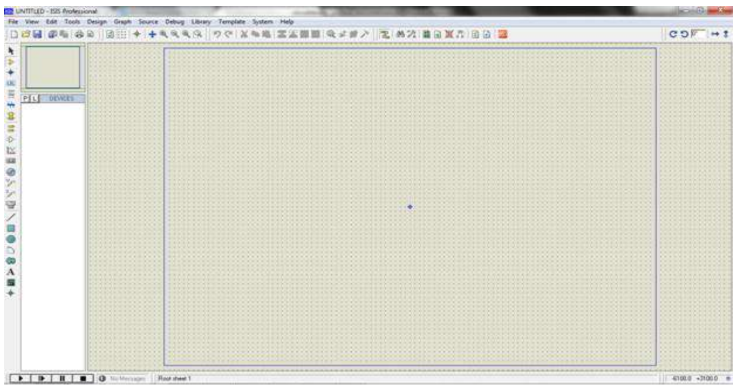

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

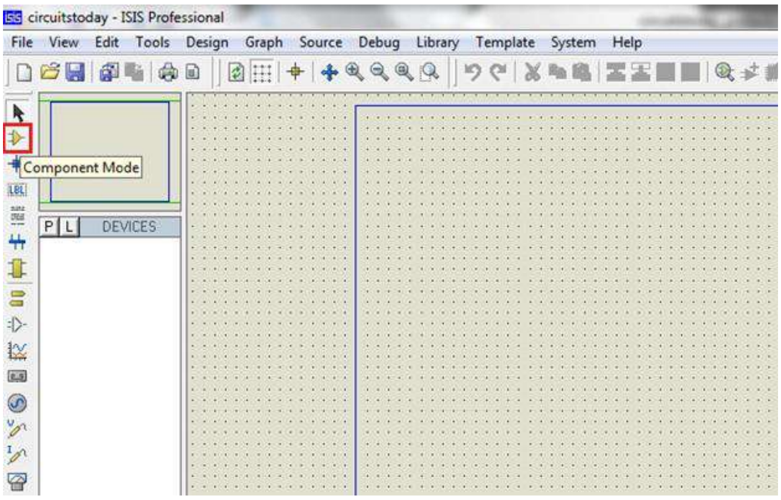

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

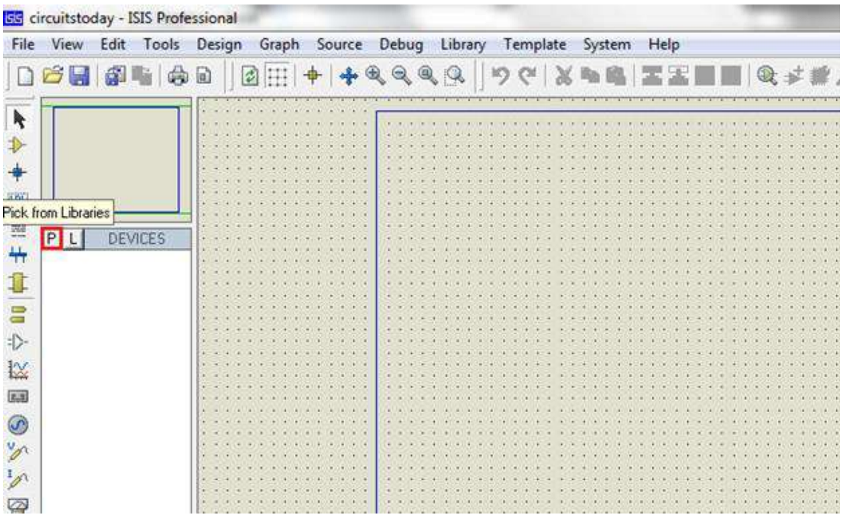

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

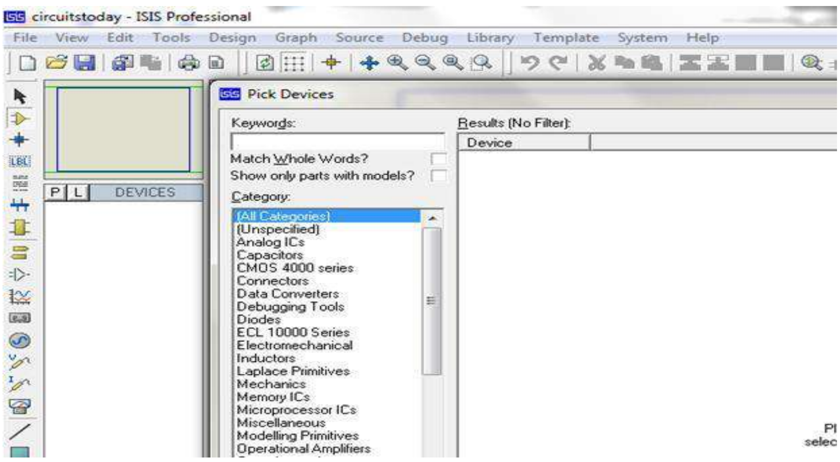

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

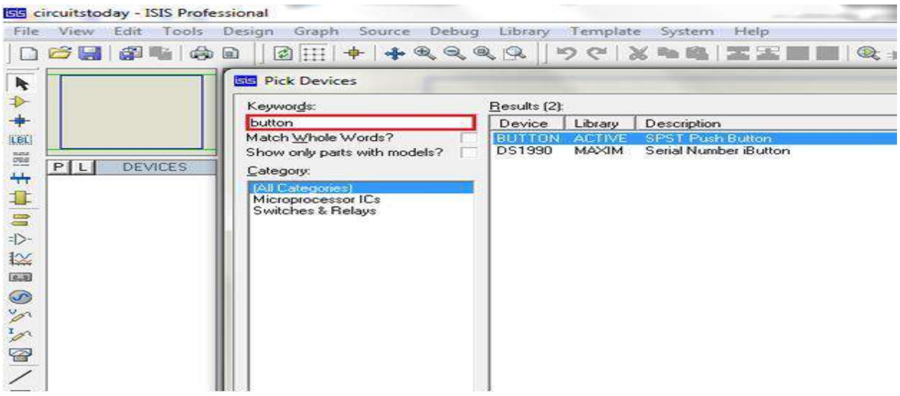

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

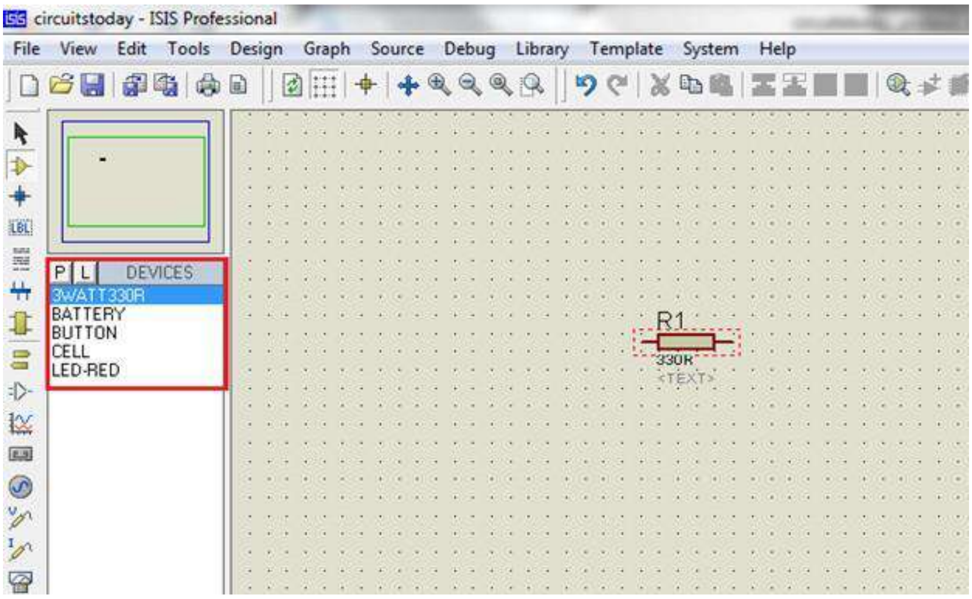

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

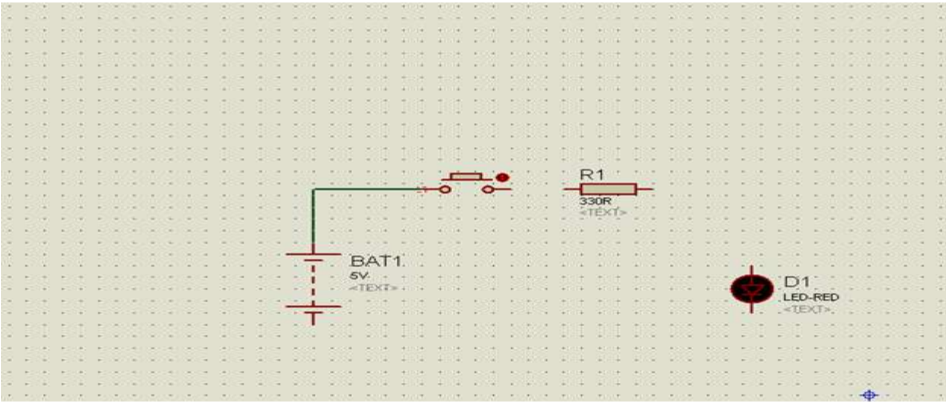

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

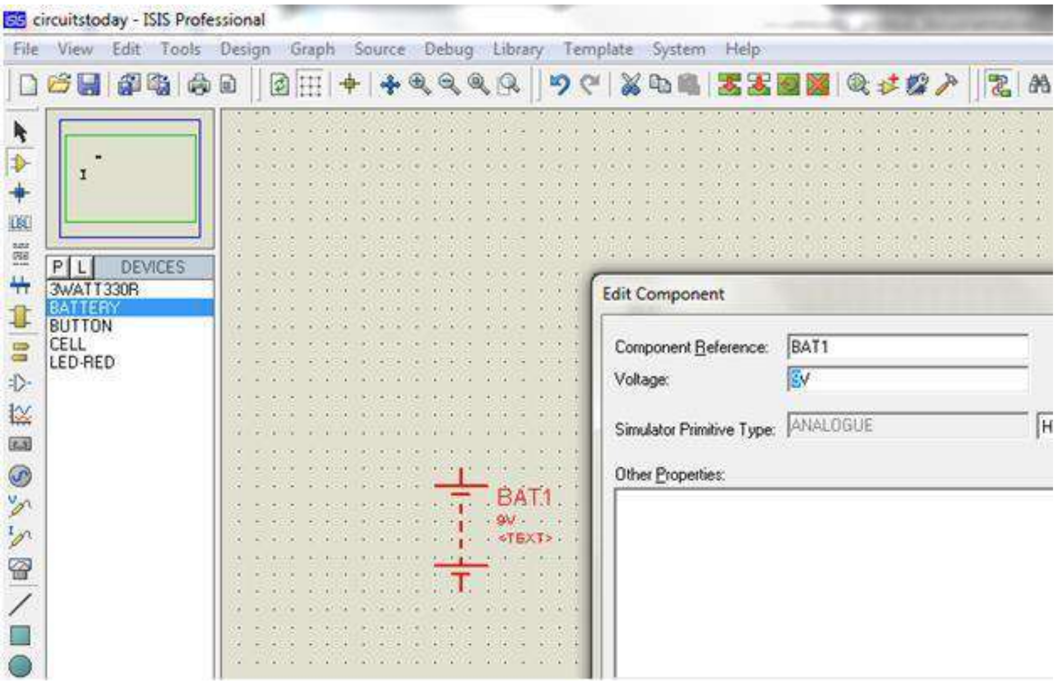

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

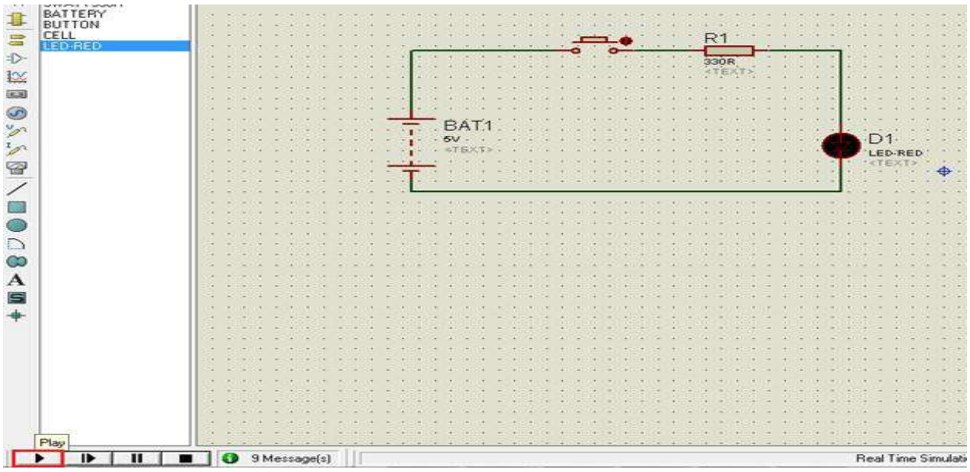

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

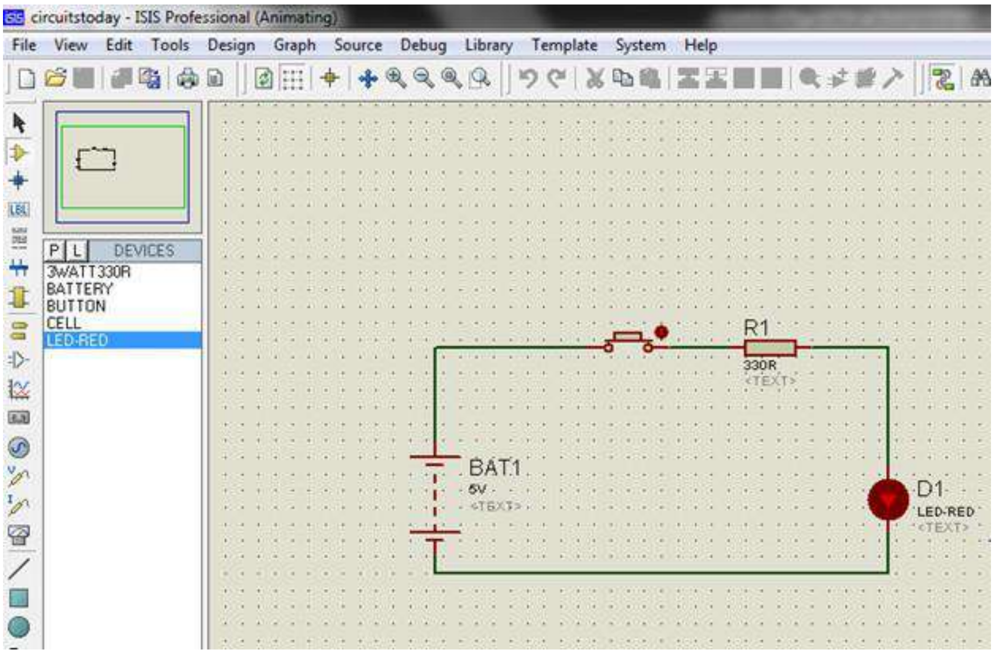

Fig. 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

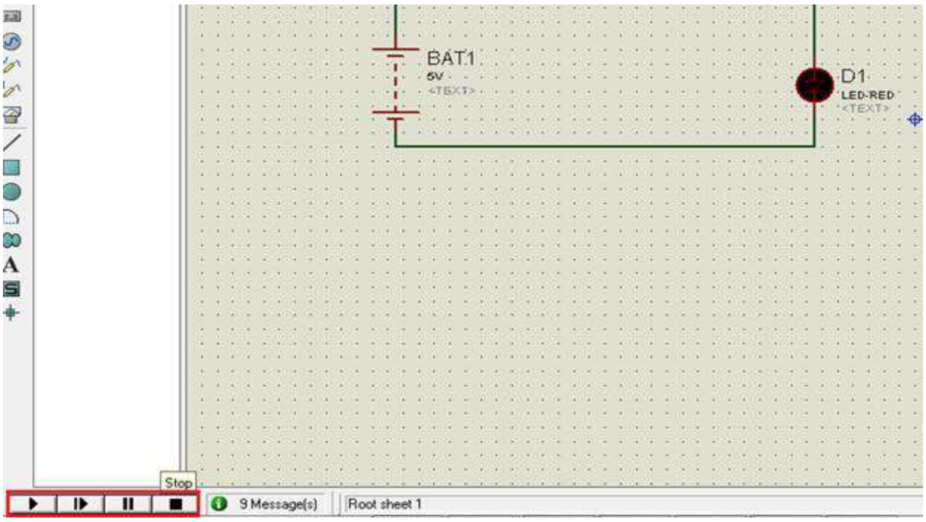

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by IOT Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works. [citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' MATLAB documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.3 DEFINE THE MODULES

3.3.1 GLOBAL SYSTEM FOR MOBILE COMMUNICATION (GSM)

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services. GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. It supports voice calls and data transfer speeds of up to 9.6 kbit/s, together with the transmission of SMS (Short Message Service).

3.3.1.1 INTRODUCTION TO GSM

The **GSM** (*Global System for Mobile communications*) network is at the start of the 21^{st} century, the most used mobile telephony standard in Europe. It is called as Second Generation

(2G) standard because communications occur in an entirely digital mode, unlike the first generation of portable telephones. When it was first standardized in 1982, it was called as **Group Special Mobile** and later, it became an international standard called **"Global System for Mobile communications"** in 1991.

In Europe, the GSM standard uses the 900 MHz and 1800 MHz frequency bands. In the United States, however, the frequency band used is the 1900 MHz band. For this reason, portable telephones that can operate in both Europe and the United States are called **tri-band** while those that operate only in Europe are called **bi-band**.

The GSM standard allows a maximum throughput of 9.6 kbps which allows transmission of voice and low-volume digital data like text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*).

3.3.1.2 GSM STANDARDS

GSM uses narrowband TDMA, which allows eight simultaneous calls on the same radio frequency. There are three basic principles in multiple access, FDMA (Frequency Division Multiple Access), TDMA (Time Division Multiple Access), and CDMA (Code Division Multiple Access). All three principles allow multiple users to share the same physical channel. But the two competing technologies differ in the way user sharing the common resource.

TDMA allows the users to share the same frequency channel by dividing the signal into different time slots. Each user takes turn in a round robin fashion for transmitting and receiving over the channel. Here, users can only transmit in their respective time slot.

CDMA uses a spread spectrum technology that is it spreads the information contained in a particular signal of interest over a much greater bandwidth than the original signal. Unlike TDMA, in CDMA several users can transmit over the channel at the same time.

3.3.1.3 TDMA IN BRIEF

In late1980's, as a search to convert the existing analog network to digital to improve capacity, the cellular telecommunications industry association chose TDMA over FDMA. Time Division Multiple Access is a type of multiplexing where two or more channels of information are transmitted over the same link by allocating a different time interval for the transmission of each channel. The most complex implementation using TDMA principle is of GSM's (Global System for Mobile communication). To reduce the effect of co-channel interference, fading and multipath, the GSM technology can use frequency hopping, where a call jumps from one channel to another channel in a short interval.

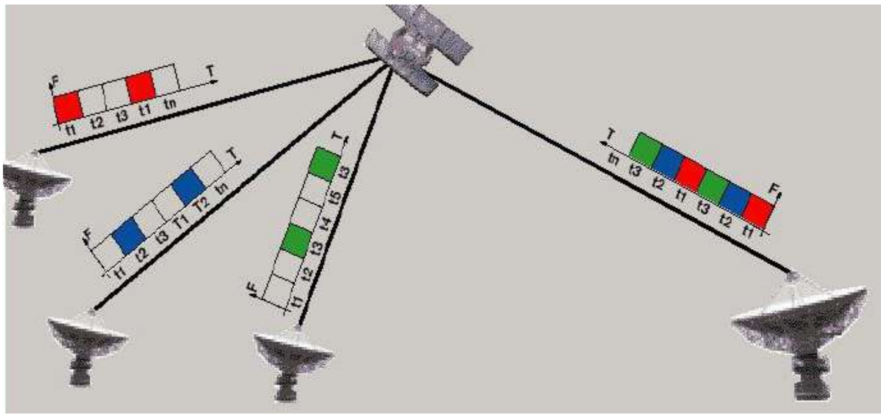

Fig.3.3.1.3 Time Division Multiplexing Access

TDMA systems still rely on switch to determine when to perform a handoff. Handoff occurs when a call is switched from one cell site to another while travelling. The TDMA handset constantly monitors the signals coming from other sites and reports it to the switch without caller's awareness. The switch then uses this information for making better choices for handoff at appropriate times. TDMA handset performs hard handoff, i.e., whenever the user moves from one site to another, it breaks the connection and then provides a new connection with the new site.

3.3.1.4 THE CONCEPT OF CELLULAR NETWORK

Mobile telephone networks are based on the concept of **cells**, circular zones that overlap to cover a geographical area.

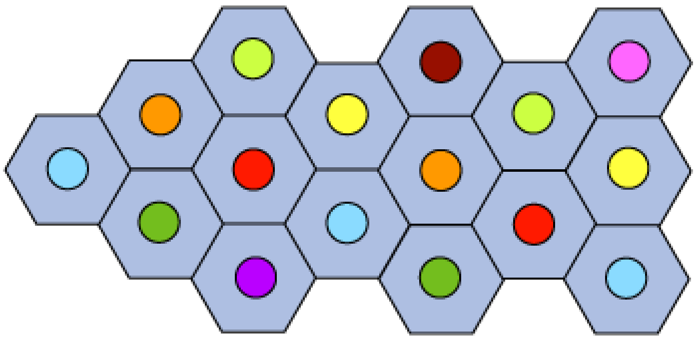

Fig.3.3.1.4 The Concept of cellular network

Cellular networks are based on the use of a central transmitter-receiver in each cell, called a "**base station**" (or *Base Transceiver Station*, written **BTS**). The smaller the radius of a cell, the higher is the available bandwidth. So, in highly populated urban areas, there are cells with a radius of a few hundred meters, while huge cells of up to 30 kilometers provide coverage in rural areas.

In a cellular network, each cell is surrounded by 6 neighboring cells (thus a cell is generally drawn as a hexagon). To avoid interference, adjacent cells cannot use the same frequency. In practice, two cells using the same frequency range must be separated by two to three times the diameter of the cell.

3.3.1.5 GSM MODEM

A GSM modem is a wireless modem that works with a GSM wireless network. A wireless modem behaves like a dial-up modem. The main difference between them is that a dial-up modem sends and receives data through a fixed telephone line while a wireless modem sends and receives data through radio waves.

Fig.3.3.1.5.1 GSM/GPRS Modem

A GSM modem can be an external device or a PC Card / PCMCIA Card. Typically, an external GSM modem is connected to a computer through a serial cable or a USB cable. A GSM modem in the form of a PC Card / PCMCIA Card is designed for use with a laptop computer. It should be inserted into one of the PC Card / PCMCIA Card slots of a laptop computer. Like a GSM mobile phone, a GSM modem requires a SIM card from a wireless carrier in order to operate.

A SIM card contains the following information:

- Subscriber telephone number (MSISDN)
- International subscriber number (**IMSI, International Mobile Subscriber Identity)**
- State of the SIM card
- Service code (operator)
- Authentication key
- PIN (***Personal Identification Code***)
- PUK (***Personal Unlock Code***)

Computers use AT commands to control modems. Both GSM modems and dial-up modems support a common set of standard AT commands. In addition to the standard AT commands, GSM modems support an extended set of AT commands. These extended AT commands are defined in the GSM standards. With the extended AT commands, the following operations can be performed:

- Reading, writing, and deleting SMS messages.
- Sending SMS messages.
- Monitoring the signal strength.
- Monitoring the charging status and charge level of the battery.
- Reading, writing, and searching phone book entries.

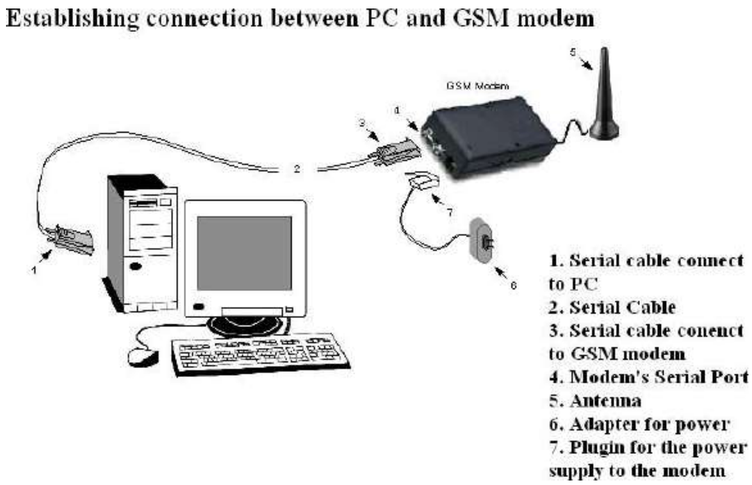

Fig.3.3.1.5.2 Establishing connection between PC and GSM modem

The number of SMS messages that can be processed by a GSM modem per minute is very low i.e., about 6 to 10 SMS messages per minute.

3.3.1.6 INRODUCTION TO AT COMMANDS

AT commands are instructions used to control a modem. AT is the abbreviation of Attention. Every command line starts with "AT" or "at". That is the reason, modem commands are called AT commands. Many of the commands that are used to control wired dial-up modems, such as ATD (Dial), ATA (Answer), ATH (Hook control) and ATO (Return to online data state) are also supported by GSM modems and mobile phones.

Besides this common AT command set, GSM modems and mobile phones support an AT command set that is specific to the GSM technology, which includes SMS-related commands like AT+CMGS (Send SMS message), AT+CMSS (Send SMS message from storage), AT+CMGL (List SMS messages) and AT+CMGR (Read SMS messages).

It should be noted that the starting "AT" is the prefix that informs the modem about the start of a command line. It is not part of the AT command name. For example, D is the actual AT command name in ATD and +CMGS is the actual AT command name in AT+CMGS.

Some of the tasks that can be done using AT commands with a GSM modem or mobile phone are listed below:

Get basic information about the mobile phone or GSM modem. For example, name of manufacturer (AT+CGMI), model number (AT+CGMM), IMEI number (International Mobile Equipment Identity) (AT+CGSN) and software version (AT+CGMR).

Get basic information about the subscriber. For example, MSISDN (AT+CNUM) and IMSI number (International Mobile Subscriber Identity) (AT+CIMI).

Get the status of the mobile phone or GSM/GPRS modem. For example, mobile phone activity status (AT+CPAS), mobile network registration status (AT+CREG), radio signal strength (AT+CSQ), battery charge level and battery charging status (AT+CBC).

Establish a data connection or voice connection to a remote modem (ATD, ATA, etc.).

Send and receive fax (ATD, ATA, AT+F*).

Send (AT+CMGS, AT+CMSS), read (AT+CMGR, AT+CMGL), write (AT+CMGW) or delete (AT+CMGD) SMS messages and obtain notifications of newly received SMS messages (AT+CNMI).

Read (AT+CPBR), write (AT+CPBW) or search (AT+CPBF) phonebook entries.

Perform security-related tasks, such as opening or closing facility locks (AT+CLCK), checking whether a facility is locked (AT+CLCK) and changing passwords (AT+CPWD). (Facility lock examples: SIM lock [a password must be given to the SIM card every time the mobile phone is switched on] and PH-SIM lock [a certain SIM card is associated with the mobile phone. To use other SIM cards with the mobile phone, a password must be entered.])

Control the presentation of result codes / error messages of AT commands. For example, the user can control whether to enable certain error messages (AT+CMEE) and whether error messages should be displayed in numeric format or verbose format (AT+CMEE=1 or AT+CMEE=2).

Get or change the configurations of the mobile phone or GSM/GPRS modem. For example, change the GSM network (AT+COPS), bearer service type (AT+CBST), radio link protocol parameters (AT+CRLP), SMS center address (AT+CSCA) and storage of SMS messages (AT+CPMS).

Save and restore configurations of the mobile phone or GSM/GPRS modem. For example, save (AT+CSAS) and restore (AT+CRES) settings related to SMS messaging such as the SMS center address.

It should be noted that the mobile phone manufacturers usually do not implement all AT commands, command parameters and parameter values in their mobile phones. Also, the behavior of the implemented AT commands may be different from that defined in the standard. In general, GSM modems, designed for wireless applications, have better support of AT commands than ordinary mobile phones.

3.3.2 GLOBAL POSITIONING SYSTEM

3.3.2.1 INTRODUCYION TO GPS

Fig 3.3.2.1 Interface ublox NEO-6M GPS Module with Arduino

Give your next Arduino project ability to sense locations with NEO-6M GPS Module that can track up to 22 satellites and identifies locations anywhere in the world. It may serve as a great launch pad for anyone looking to get into the world of GPS.

They are low power (suitable for battery powered devices), inexpensive, easy to interface with and are insanely popular among hobbyists.

3.3.2.2 HARDWARE OVERVIEW OF NEO-6M GPS MODULE

NEO-6M GPS Chip

At the heart of the module is a NEO-6M GPS chip from u-blox. The chip measures less than the size of a postage stamp but packs a surprising number of features into its little frame.

Fig.3.3.2.2 Overview of NEO-6M GPS Module

It can track up to 22 satellites on 50 channels and achieves the industry's highest level of sensitivity i.e., -161 dB tracking, while consuming only 45mA supply current.

Unlike other GPS modules, it can do up to 5 location updates a second with 2.5m Horizontal position accuracy. The u-blox 6 positioning engine also boasts a Time-To-First Fix (TTFF) of under 1 second.

One of the best features the chip provides is Power Save Mode (PSM). It allows a reduction in system power consumption by selectively switching parts of the receiver ON and OFF. This dramatically reduces power consumption of the module to just 11mA making it suitable for power sensitive applications like GPS wristwatch.

3.3.2.3 POSITION FIX LED INDICATOR

The necessary data pins of NEO-6M GPS chip are broken out to 0.1″ pitch headers. This includes pins required for communication with a microcontroller over UART. The module supports baud rate from 4800bps to 230400bps with default baud of 9600.

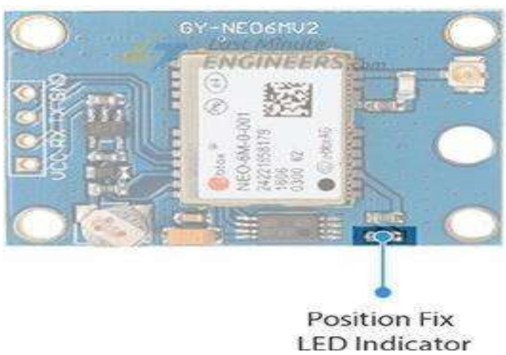

Fig.3.3.2.3 Position Fix LED Indicator

There is an LED on the NEO-6M GPS Module which indicates the status of Position Fix. It will blink at various rates depending on what state it's in:

- No Blinking – It is searching for satellites.
- Blink every 1s – Position Fix is found (The module can see enough satellites).

3.3.2.4 3.3V LDO REGULATOR

Fig.3.3.2.4 3.3V LDO Regulator

The operating voltage of the NEO-6M chip is from 2.7 to 3.6V. But the good news is that the module comes with MIC5205 ultra-low dropout 3V3 regulator from MICREL.

The logic pins are also 5-volt tolerant, so we can easily connect it to an Arduino or any 5V logic microcontroller without using any logic level converter.

3.3.2.5 BATTERY & EEPROM

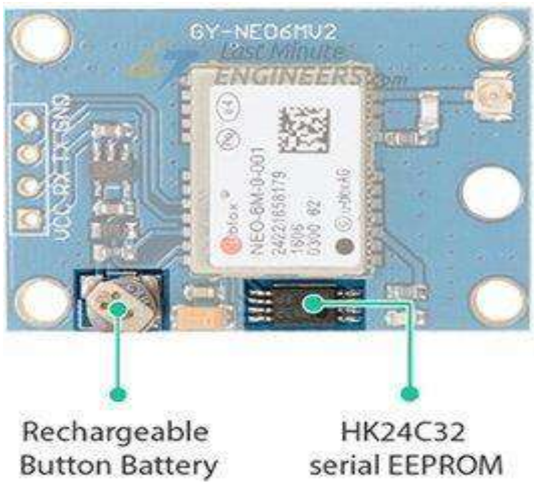

Fig. 3.3.2.5 Battery & EEPROM

The module is equipped with an HK24C32 two wire serial EEPROM. It is 4KB in size and connected to the NEO-6M chip via I2C.

The module also contains a rechargeable button battery which acts as a super-capacitor.

An EEPROM together with battery helps retain the battery backed RAM (BBR). The BBR contains clock data, latest position data (GNSS orbit data) and module configuration. But it’s not meant for permanent data storage.

As the battery retains clock and last position, time to first fix (TTFF) significantly reduces to 1s. This allows much faster position locks.

Without the battery the GPS always cold start so the initial GPS lock takes more time.

The battery is automatically charged when power is applied and maintains data for up to two weeks without power.

3.3.2.6 ANTENNA

An antenna is required to use the module for any kind of communication. So, the module comes with a patch antenna having -161 dBm sensitivity.

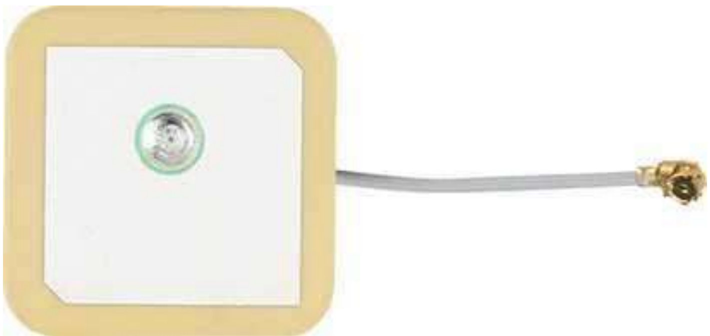

Fig. 3.3.2.6 Antenna

3.3.2.7 UFL CONNECTOR

You can snap-fit this antenna to small U.FL connector located on the module.

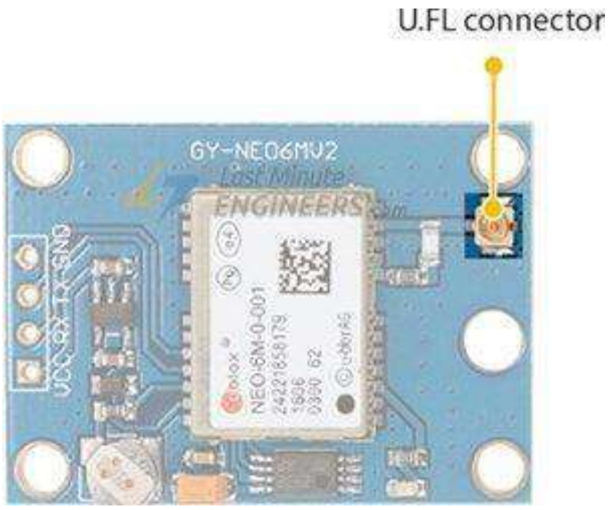

Fig.3.3.2.7 UFL Connector

Patch antenna is great for most projects. But if you want to achieve more sensitivity or put your module inside a metal case, you can also snap on any 3V active GPS antenna via the U.FL connector.

3.3.2.8 NEO-6M GPS MODULE PINOUT

The NEO-6M GPS module has total 4 pins that interface it to the outside world. The connections are as follows:

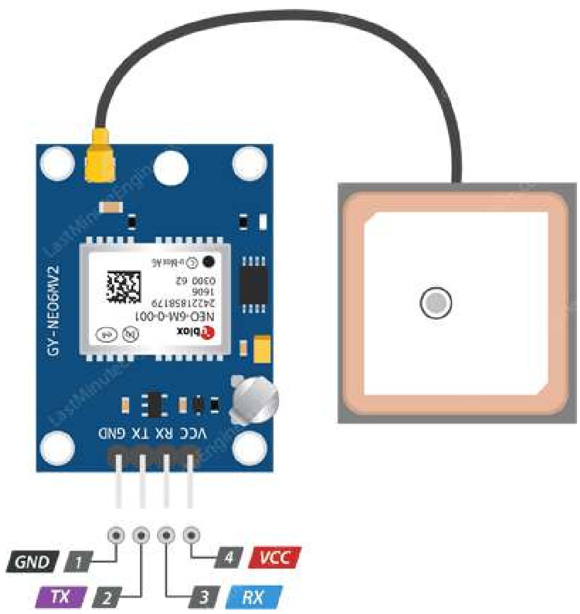

Fig.3.3.2.8 NEO-6M GPS MODULE PINOUT

GND is the Ground Pin and needs to be connected to GND pin on the Arduino.

TxD (Transmitter) pin is used for serial communication.

RxD (Receiver) pin is used for serial communication.

VCC supplies power for the module. You can directly connect it to the 5V pin on the Aíduino.

Wiring NEO-6M GPS module with Arduino UNO

Now that we know everything about the module, we can begin hooking it up to our Arduino!

Start by connecting the patch antenna to the U.FL connector. Remember to thread the U.FL cable through one of the mounting holes for robust connection.

The module usually comes with header pins unsoldered. So, you'll need to solder them.

Now, connect Tx and Rx pin on module to digital pin#2 and #3 respectively on Arduino; as we'll be using software serial to talk to the module.

Next, connect VCC pin to the 5V pin on the Arduino and GND to ground.

4.5 RESULTS

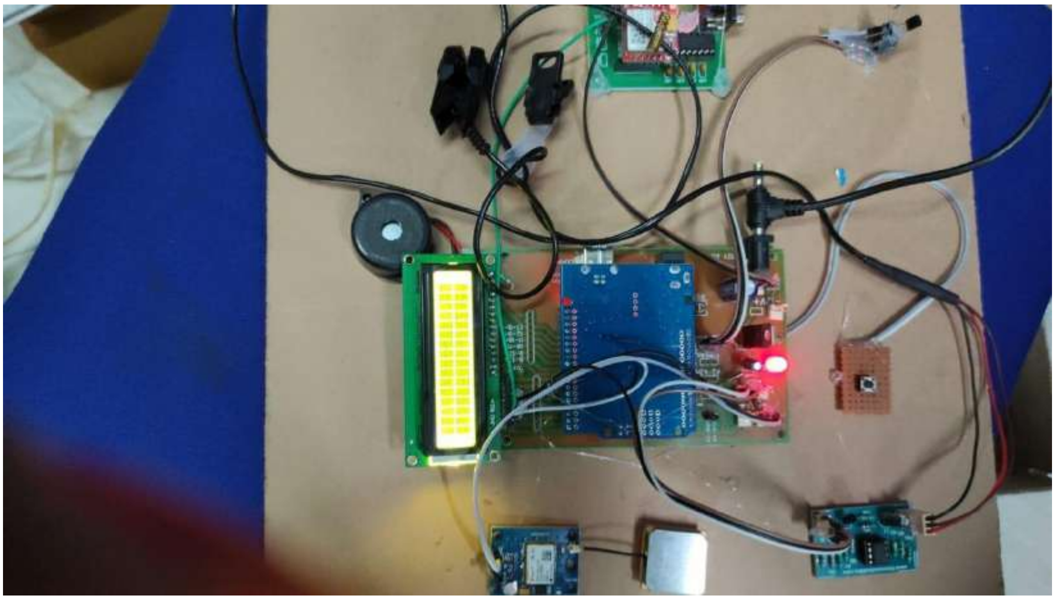

Fig 4.5 Final Output

CHAPTER 5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

The soldier Health and Position Tracking System allows the military to track the current GPS position of a soldier and checks the health status including body temperature and heartbeats of the soldier. The System also consists of extra features with the help that a soldier can ask for help manually or send a distress signal to the military if he is in need. The GPS modem sends the latitude and longitude position with a link pattern with the help of that the military can track the current position of the soldier. The system is very helpful for getting health status information of soldiers and providing them instant help. Here are some techniques used to track current position and health condition. In today's era enemy warfare is a very important factor in any nation's security. The national security mainly depends on the defense force. In this system we have come up with an idea of tracking soldiers as well as giving their status of their health condition and location during the war.

So, in implementation of the project, we encountered few problems such as the entire project depends on the wireless communication i.e., it depends on GSM module and signals. So, there are few problems we encountered and solved them.

- Signal problem in hill regions.
- Temperature differences in body that take place due to climatic changes.
- Rise of heartbeat in hill region when climbing.

1. Signal Problem:

   So, to overcome signal problem initially we had used helical antenna which perform well in open area and where there are no obstacles between antenna and signal towers which has many disadvantages, so it was replaced with another antenna which work works well in any environment and has proper bandwidth than helical antenna which is called as 3dBi.
   The 3dBi GSM antenna along with a U. FL to SMA adapter which can be obtained online for less than $3. You can snap-fit this antenna to small u.fl connector located on the top-left corner of the module. This type of antenna has a better performance and allows putting your module inside a metal case – as long the antenna is outside.

2. Temperature differences in body that take place due to climatic changes.

   Here we can change the value in program with respect to climate in outdoors which makes it flexible to any kind of climates can change the threshold values according to region of the soldier's mission.

3. Rise of heartbeat in hill region when climbing.

   Here depending on region in which mission is given to soldier's the threshold value can be varied.

CHAPTER-6

CONCLUSION AND FUTURESCOPE

6.1 CONCLUSION

- Above system, when completed, would make it easy to help in determining the health status of soldiers with measures of heart beats and body temperature.
- It would also help in tracking his position by using GPS modem and with GSM modem it can send all information to the base station so that further necessary action could be taken.

6.2 FUTURE SCOPE

- We can add a graphical display section to this project which helps to display a digital map which shows the position of all soldiers in the unit as they surround a block of buildings and launch their attacks.
- Welling to make live tracking possible.
- Helmet attached screens, accomplished by presenting information from maps and video using varieties of physiological sensors.

PUBLICATION

Submitted Paper in the Conference ICISECT - 21 with Paper ID (ICISECT21-0003) and got Acceptance for the Paper.

APPENDICES

The project shows that the health monitoring and tracking system for soldiers. The proposed system can be mounted on the soldier's body to track their health status and current location using GPS. This information will be transmitted to the control room through IoT. The proposed system comprises of tiny wearable physiological equipment's, sensors, transmission modules. Hence, with the use of the proposed equipment, it is possible to implement a low-cost mechanism to protect the valuable human life on the battlefield.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "SOLDIER HEALTH AND POSITION TRACKING SYSTEM" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

MILALIYAN SAMANTARAY GURRAM RAKESH PREETHI ROSHAN
(17K81A04M8) (17K81A04K9) (17K81A04N8)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.SANTOSH KUMAR PATRA**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr.A.ANAND, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

Finally, we are highly grateful and obliged to our project guide **Mr.P.JOEL JOSEPHSON, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1.MILALIYAN SAMANTARY (17K81A04M8)
2.GURRAM RAKESH (17K81A04K9)
3.PREETHI ROSHAN (17K81A04N8)

ABSTRACT

The soldier Health and Position Tracking System allows military to track the current GPS position of soldier and checks the health status including body temperature and heartbeats of soldier. The System also consists extra feature with the help of that soldier can ask for help manually or send a distress signal to military if he is in need. The GPS modem sends the latitude and longitude position with link pattern with the help of that military can track the current position of the soldier. The system is very helpful for getting health status information of soldier and providing them instant help.

CHAPTER 1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT

The nation's security is monitored and kept by army, navy, and air-force. The important and vital role is of soldiers who sacrifice their life for their country. There are many concerns regarding the safety of the soldier. Soldiers entering the enemy lines often lose their lives due to lack of connectivity, it is very vital for the army base station to know the location as well as health status of all soldiers. India has already lost so many soldiers in war-fields as there was no proper health backup and connectivity between the soldiers on the war-fields and the officials at the army base stations. Recently on 29 September 2016, a military confrontation between India and Pakistan began, Indian soldiers conducted a surgical strike against militant launch pads across the line of control in Pakistani-administered Azad Kashmir and inflicted "significant casualties". Indian soldiers are mainly known for their courage, despite scarce ammunitions and safety measures, they have many triumphs to their credits. All must be really concerned about the safety of the soldiers, so we have decided to build a project which will efficiently keep a check on the health status of the soldier, and his precise location to equip him with necessary medical treatments as soon as possible. Soldier's tracking is done using GPS and GSM is used to provide wireless communication system. For monitoring the health parameters of soldiers, we are using biomedical sensors such as temperature sensors and heartbeat sensors.

An oxygen level sensor is used to monitor atmospheric oxygen so if there are any climatic changes the soldiers will be equipped accordingly.
The infantry soldier of tomorrow promises to be one of the most technologically advanced modern warfare has ever seen. Around the world, various research programs are currently being conducted, such as the United States' Future Force Warrior (FFW) and the United Kingdom's Future Infantry Soldier Technology (FIST), with the aim of creating fully integrated combat systems .Alongside vast improvements in protective and weaponry subsystems, another major aspect of this technology will be the ability to provide information superiority at the operational edge of military networks by equipping the dismounted soldier with advanced visual, voice, and data communications.

Helmet mounted visors, capable of displaying maps and real-time video from other squad members, ranges of physiological sensors display the heartbeat, body temperature, atmosphere pressure, surrounding oxygen level etc. These devices will improve awareness for collateral military personnel as well as who will exchange information using wireless networks along with hosts. The challenge was to integrate these piecemeal components into a lightweight package that could achieve the desired result without being too bulky and cumbersome or requiring too much power. Communicating with the base (control room) station become the fundamental challenges in military operations. The proper navigation between soldier's organizations plays an important role for careful planning and coordination.

1.2 OBJECTIVES OF THE STUDY

So, this project focuses on tracking the location of soldiers from GPS, which is useful for control room stations to know the exact location of soldiers and accordingly they will guide them. Also High-speed, short-range, soldier-to-soldier wireless communications to relay information on situational awareness, such as Biomedical sensors, GPS navigation, Wireless communication.

1.3 SCOPE OF THE STUDY

- Soldier health and position tracking system is such a type of a system that provides the health and position status of a soldier fast with the help of gps and gsm modules.

- Soldiers are important assets of our country. They workday and night to protect our country. Sometimes even they sacrifice their life for the country.

- And soldiers at borders often lose their lives defending the country.

- To overcome this situation this system helps us to track the position of the soldiers and even information regarding health is produced by this system. And will efficiently keep a check on the health status of the soldier, and his precise location to equip him with necessary medical treatments as soon as possible.

- Here we have proposed a system that is called Soldier health and position tracking system, which is so much efficient, reliable, and friendly to use. In this system soldier's tracking is done using GPS and GSM is used to provide wireless communication systems. For monitoring the health parameters of soldiers, we are using biomedical sensors such as temperature sensors and heartbeat sensors.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- 12V Battery
- Temperature Sensor
- Heartbeat sensor
- Push Button
- LCD
- GSM
- GPS
- Buzzer

1.4.2 SOFTWARE REQUIREMENT

- Proteus Software
- Arduino Software

1.5 PROCUMENT OF EQUIPMENT

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the health and position of soldiers better than before we successfully got the output in mobile and LCD screen. We would like to improve the project in future for further developments.

CHAPTER 2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA

Nowadays all nations keep its security at high priority. Wars are being fought for land, water and acquiring the position of most powerful nation. A country's arm forces consist of three professional uniformed services: the army, the navy, and the air force. Soldiers being the backbone of any armed force usually lose their lives due to lack of medical help when in emergency, also soldiers who are involved in missions or in special operations get straggled on war fields and lose contact with the authorities. To overcome these concerns, we had built this project which, using wireless body area sensor network (WBANS) such as temperature sensor, heartbeat sensor etc. will monitor the health status of the soldier whenever required. Also using GPS, we can track the soldier's exact location whenever required. Using oxygen level sensor, we can also monitor the environmental condition, so authorities can provide essential aids. The communication is established between the soldiers and authorities via GSM. Any abnormalities in the readings of wireless body area sensor network (WBASNs) are considered as a trigger for GSM to establish the connection between the soldier and base unit and send current location and health status to the receiver. By using all this equipment's, we had tried to implement the basic guarding system for the soldier in low cost, light weighted, portable and precise device.

In enemy territory soldiers not only have to deal with the physical threat, but also with stress and fatigue caused by protracted operations or lack of sleep. So, for the security purpose we need a tool for remote soldier performance and health monitoring. So, in this project a tool is implemented using biosensors for health monitoring purpose. Also, a GPS system is used to track the location of soldier. Additionally, a GSM modem is also used to make the system wirelessly compatible.

In today's world, warfare is an important factor in any nation's security. One of the important and vital roles is played by the army soldiers. There are many concerns regarding the safety of soldiers. So, for their security purpose, many instruments are mounted on them to view their health status as well as their real time location. Bio-sensor systems comprise various types of small physiological sensors, transmission modules and processing capabilities, and can thus facilitate low-cost wearable unobtrusive solutions for health monitoring. This paper gives an ability to track the location and monitor health of the soldiers in real time who become lost and get injured in the battlefield.

2.2 REVIEW ON RELATED LITERATURE

In [1], the author has worked on the safety of the soldier by tracking his health condition during the war which provides the control room to plan the war strategies and tracks the location if by chance the soldier is lost. When the control room notices the soldier is lost in the battlefield then they guide the soldier in the right path. The soldier's health information is transmitted to the control room and keeps track of the injured soldier and take necessary action to save the life. This system mainly focuses on the soldier who have involved in the warfare and tracking the health of the injured soldier. In [2], the author has focused to improve the communication of the soldier with the control room people and control plane operation continuously. He has also focused to track and guide the position, direction, and the surrounding temperature of the soldier by using the wristwatch mountaineers and by providing headphones to guide the soldier to the right path. He has also used the technology like the Radio collar strapped to ankles, so the movement of the soldier can be tracked and displays the current location at the base station. Microcontroller is used to record the body parameters of the soldier's and transmitted to the base station. In [3], the author has focused to provide the embedded wireless system for the soldier and to minimize the time to track the location of the soldier, rescue and search operation and their health status using GPS module and wireless body sensors, the data are collected from the GPS and sensors are transmitted using the ZigBee technology to the base station/control room. It also allows the soldier to communicate with the other fellow soldiers within the wireless transmission range, they can also request help from the control room. In [4], the author has worked on the location tracking system using GPS with the Google Maps based monitoring for vehicle. This system provides tracking irrespective of weather condition. It gives the shortest route to track. This idea is deployed in the proposed system to track the current location and movement of the soldier along with the shortest path to him, which is need for the rescue operation. In [5], here the author focus is on monitoring the ill patient, continuously and reports the changes spontaneously to the concerned person using the GPS, 4 Chaitra R L, Mamatha V which helps in protecting the life of the individual. In this paper only, the ill patient is considered for monitoring. Once the patient is discharged from the hospital, the body sensor is mounted on them to monitor their health condition and take necessary action in case of emergency by reporting to the guardian. In [6], the author has worked to track the location of the soldier and monitor the health status using an Arduino board. For the transmitting of data to control room he has used GPS module for connectivity. In [7], the author focus is to provide a good connectivity between the control room and the soldier by using Arduino and GSM module.

2.3 CONCLUSION ON REVIEWS

From the above implementation we have concluded that the communication hurdles between the soldiers and authorities at the base unit is overcome using GSM, the precise location and health parameters are known using GPS and wireless body area sensor network (WBASNs) respectively and with the GSM modem all information is send to the base station so that field commander will take necessary action. Base station gets location of soldier from GPS. The base station can access the status of the soldier which is displayed on the phone with the help of GSM and hence appropriate actions can be found.

CHAPTER 3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN

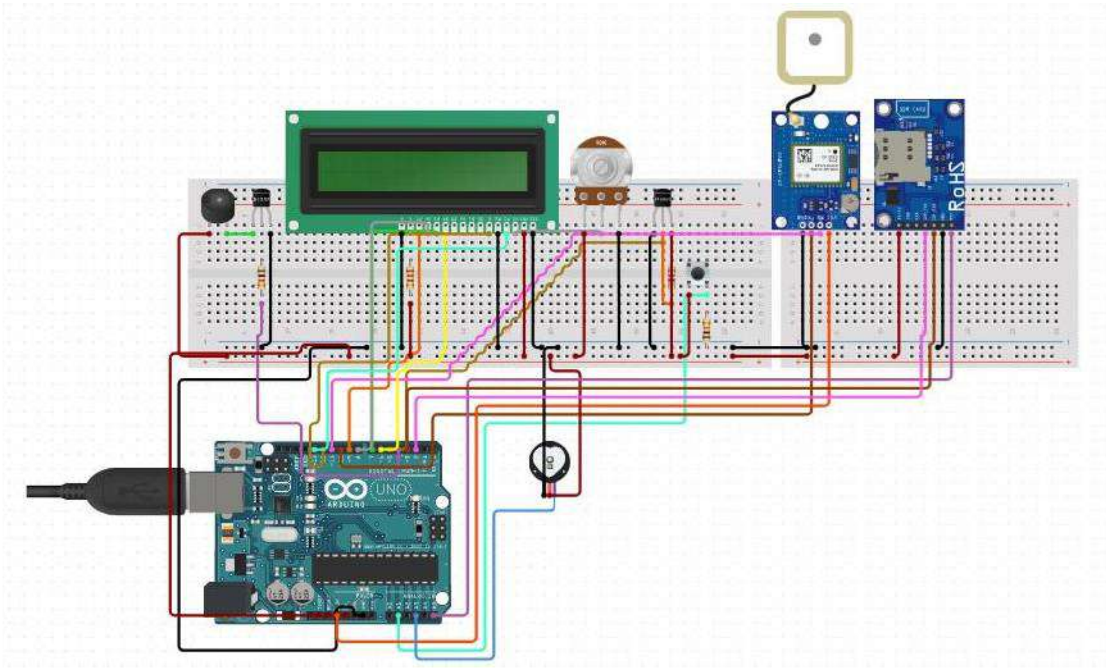

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS

3.2.1 ARDUINO

3.2.1.1 INTRODUCTION

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).

- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

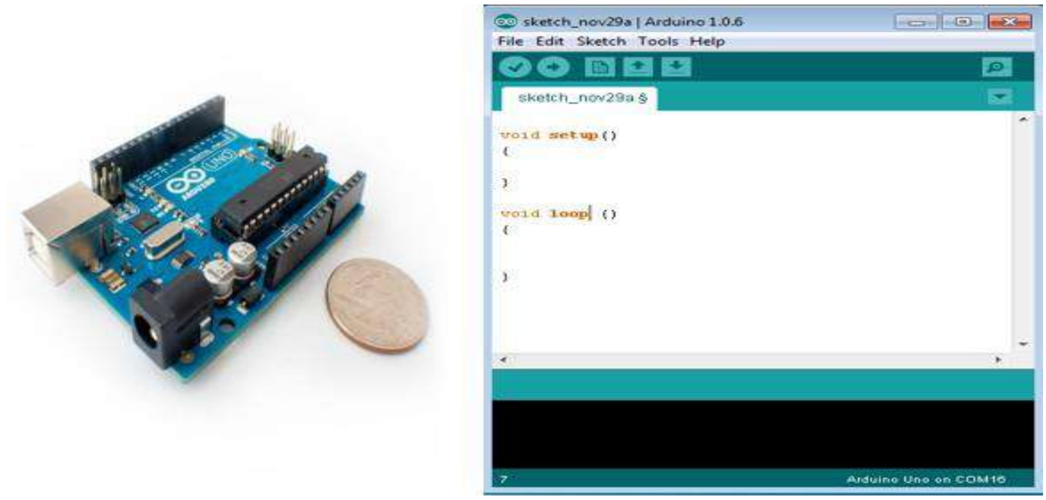

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini-05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini-3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Lilypad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compati
Lilypad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

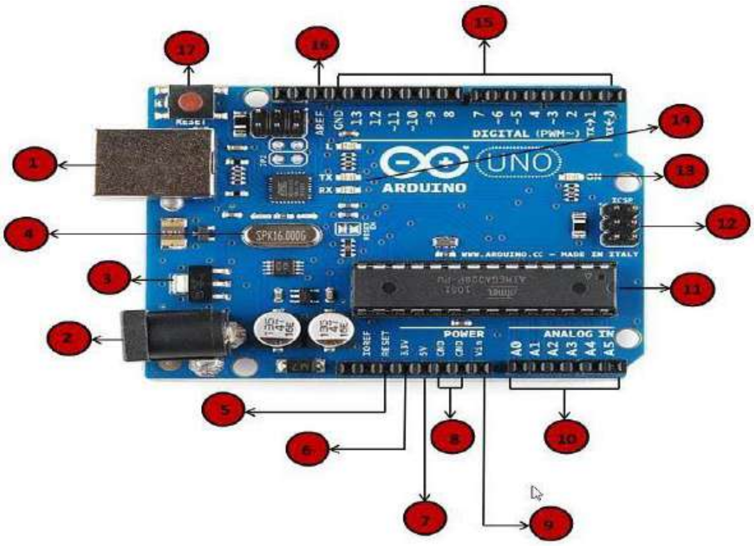

Fig.3.2.1.3 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).

6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volts. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in

	two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

Table 3.2.1.3 Board description of Arduino UNO

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you are not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.4 Arduino Family

3.2.1.5 SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.5 Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328

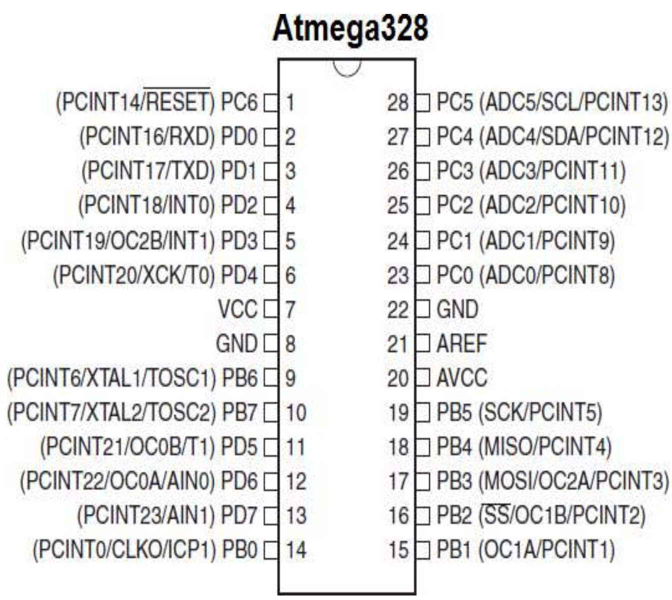

Fig.3.2.1.6 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

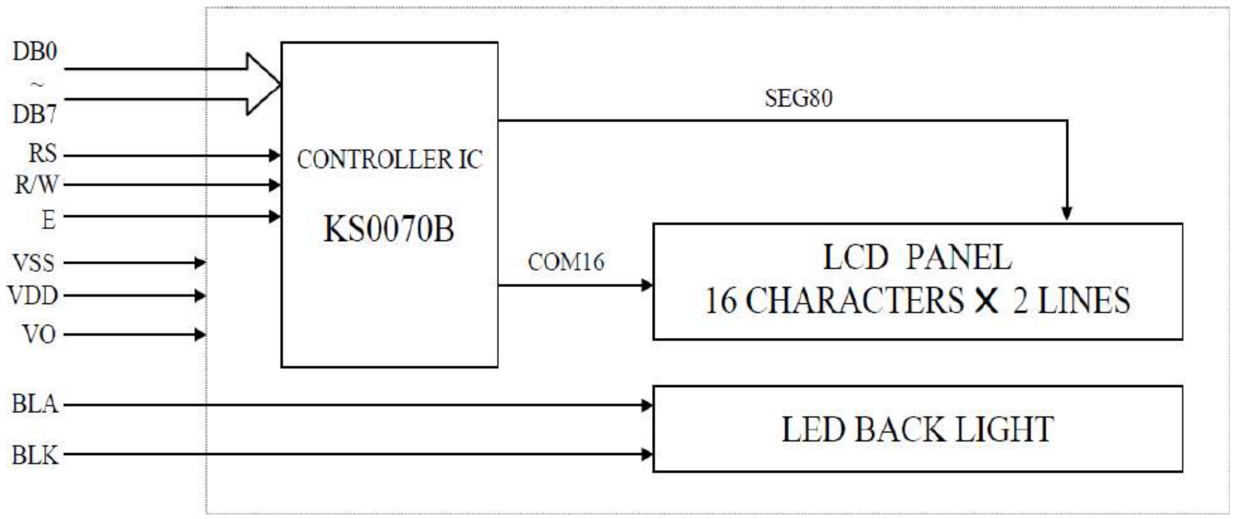

Fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

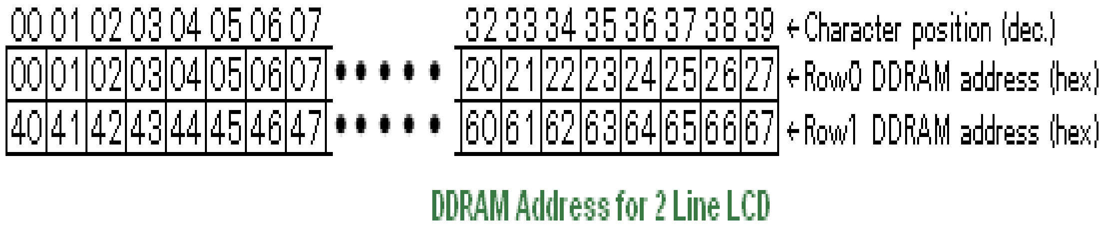

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.

Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore, by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore, we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result, we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly. The 2-line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 HOW TO CHOOSE A BUZZER

There are many kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic_buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self-drive type to choose. Because of the internal set drive circuit, the self-drive buzzer can emit sound if connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.1 INTRODUCTION OF PIEZO BUZZER

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

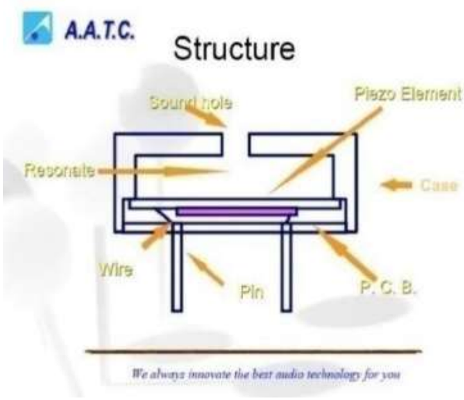

Fig.3.2.3.1 piezo buzzer

3.2.3.2 SPECIFICATIONS

Rated Voltage: A piezo buzzer is driven by square waves (Vp-p).
Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.
Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

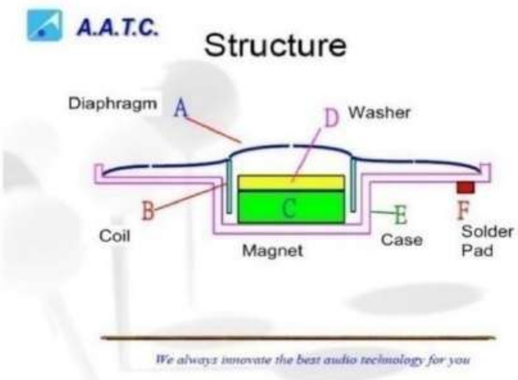

Fig. 3.2.3.2 structure of piezo buzzer

Sound Output: The sound output is measured by decibel meter.
Applying rated voltage and square waves, and the distance of 10 cm.
Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest

and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

3.2.4 TEMPERATURE SENSOR

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°Cover a full −55 to +150°C temperature range.

Features

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications
- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60 µA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

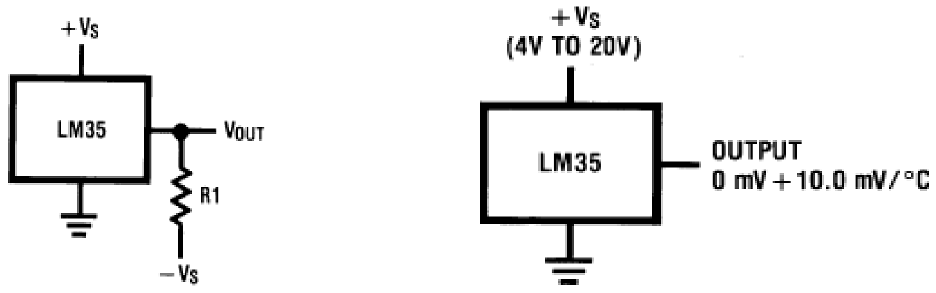

Figure. 3.2.4 Temperature Sensor

3.2.4.1 TEMPERATURE SENSING CIRCUIT

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact. In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

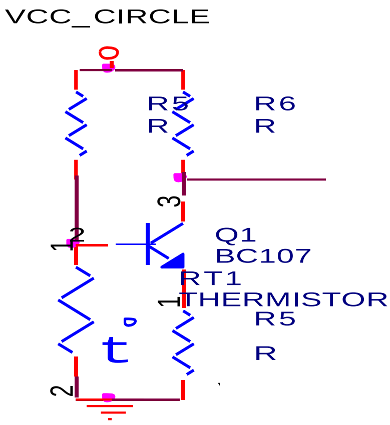

Figure. 3.2.4.1 Temperature Sensing Circuit

3.2.5 BATTERY

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place. When the material in the cathode or anode is consumed or no longer able to be used in the reaction, the battery is unable to produce electricity. At that point, your battery is "dead."

Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Fig.3.2.5.1 Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

Fig.3.2.5.2 Batteries come in a variety of shapes, sizes, and chemistries

3.2.5.1 THE TERM BATTERY

Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Fig.3.2.5.1 The term battery

Battery of Leyden Jar "capacitors" linked together (Image courtesy of Alvinrune of Wikimedia Commons)

3.2.6 SOFTWARE EXPLANATION

- Arduino software
- Proteus simulation
-

3.2.6.1 ARDUINO SOFTWARE

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards can read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low-cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for

beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open-source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE)

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

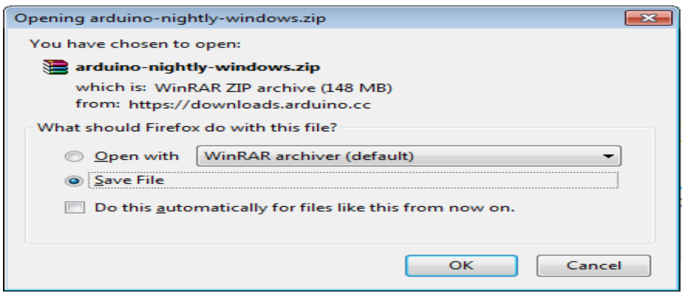

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

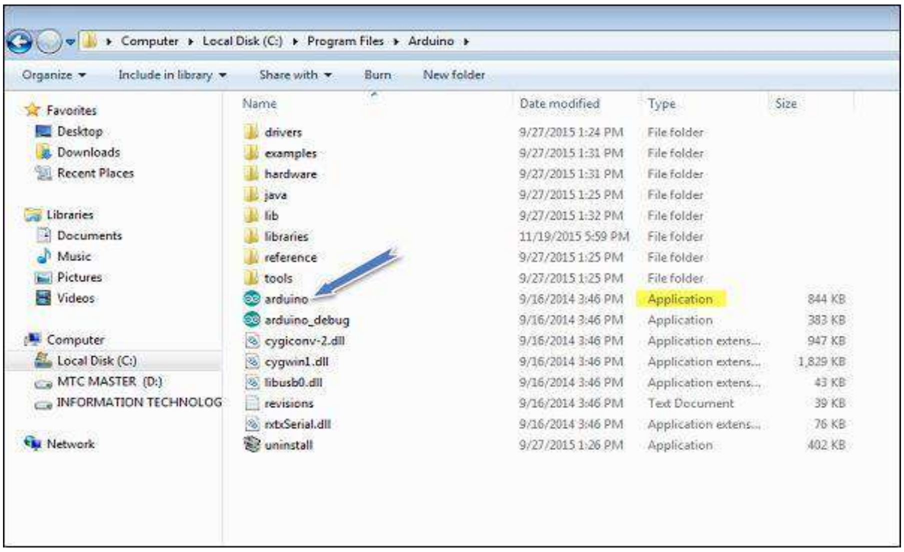

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

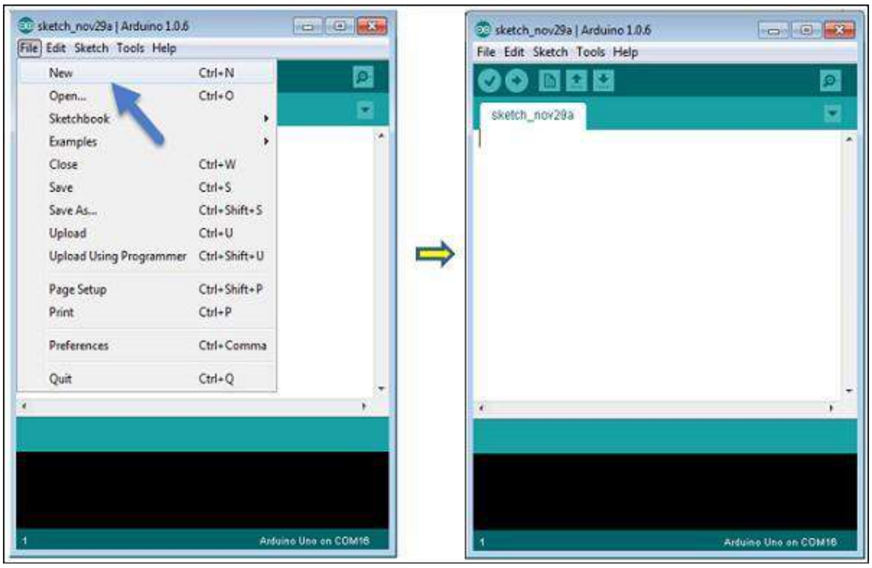

Fig. 3.2.6.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

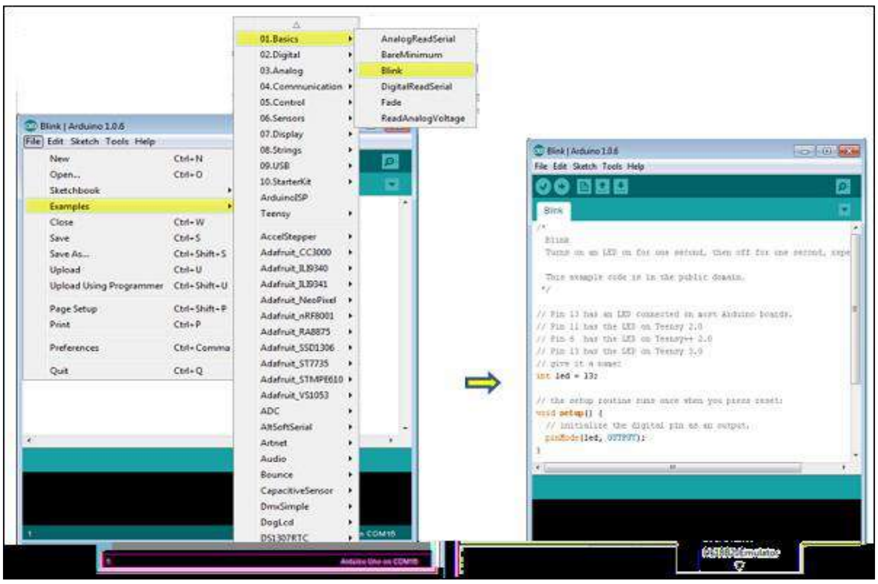

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

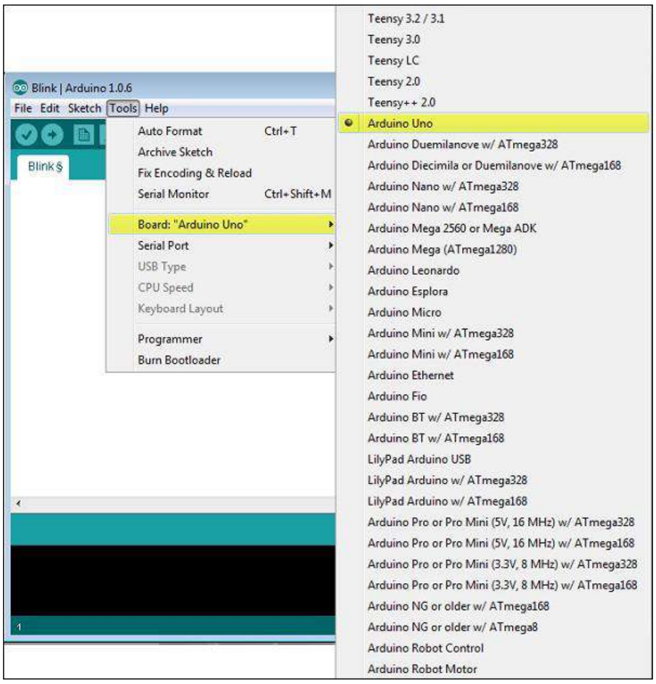

Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

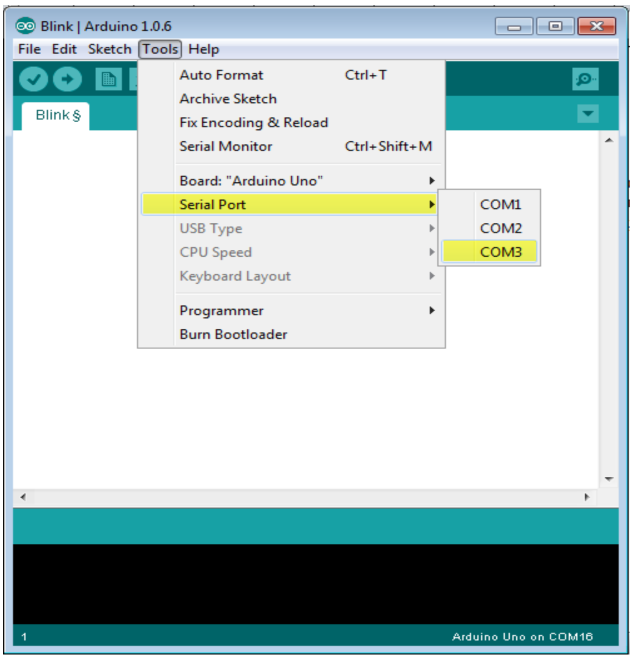

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

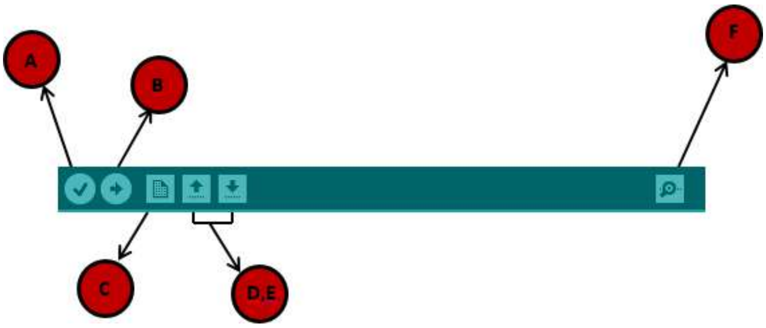

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketches.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

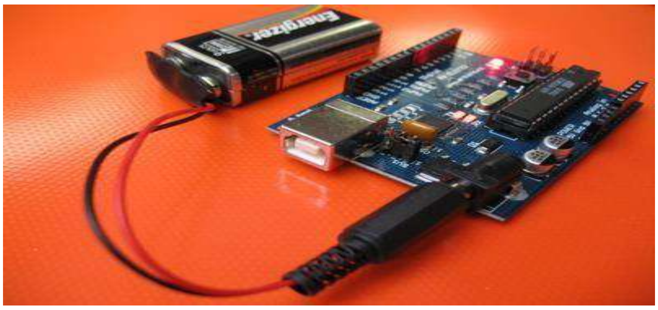

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

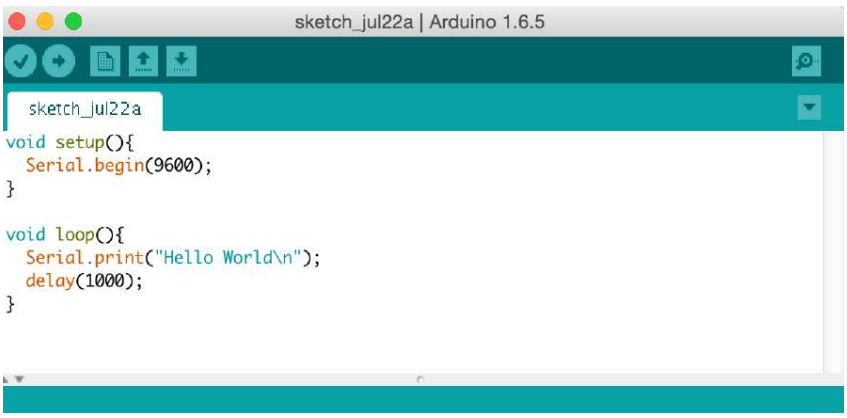

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS

PROTEUS

Proteus is a simulation and design software tool developed by Lab center Electronics for Electrical and Electronic circuit design. It also possesses 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the footprints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select new design in File menu

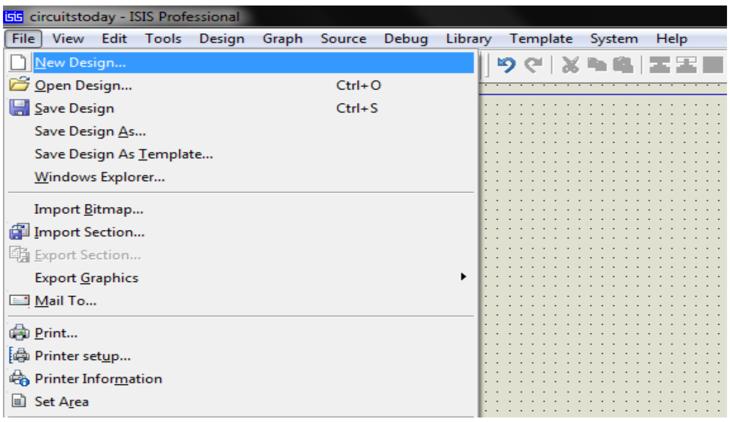

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

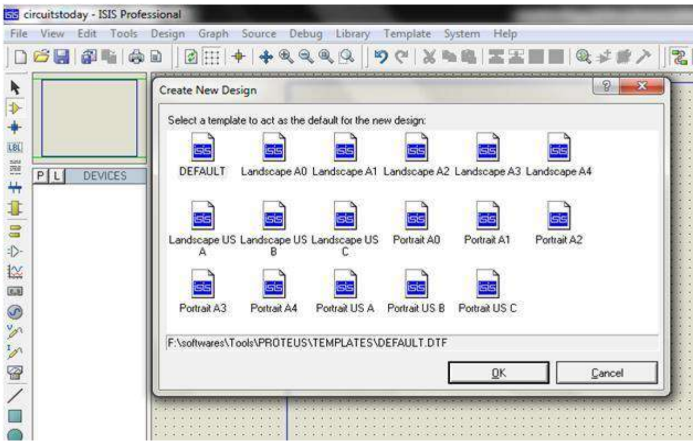

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

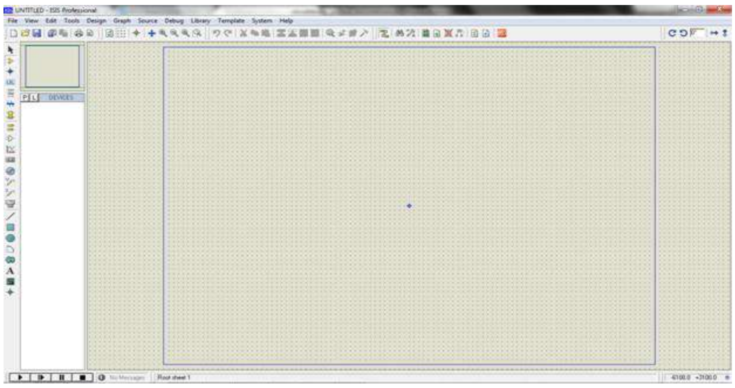

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

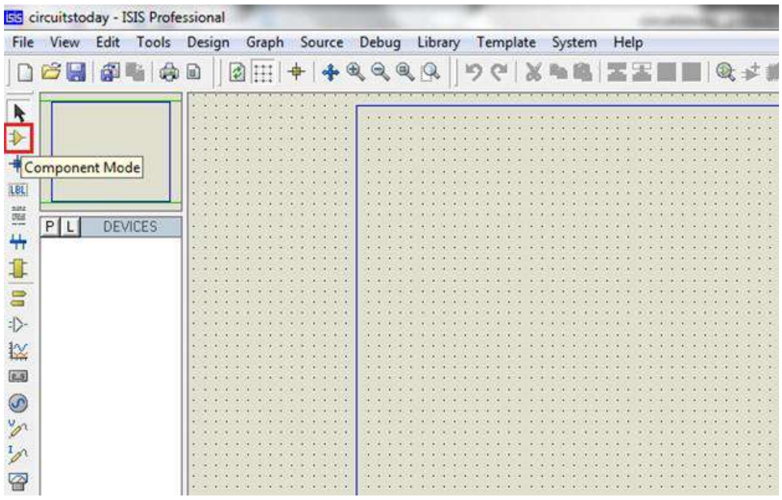

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

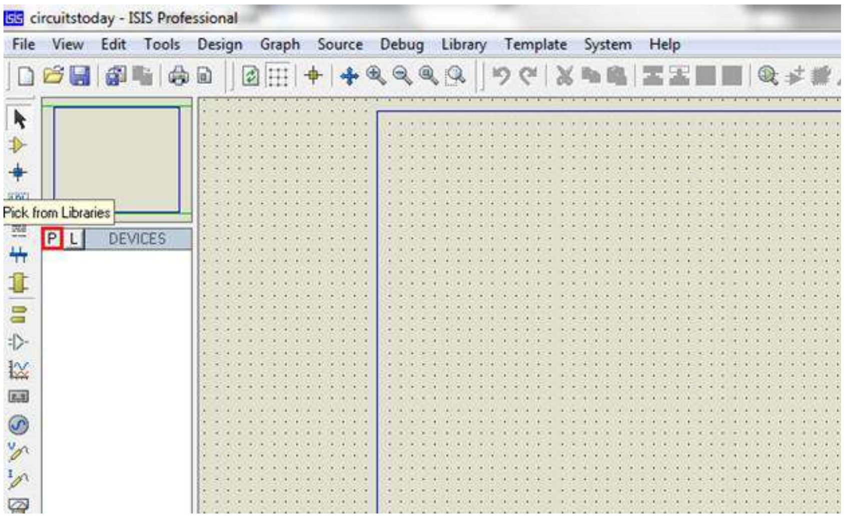

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keyword's text box.

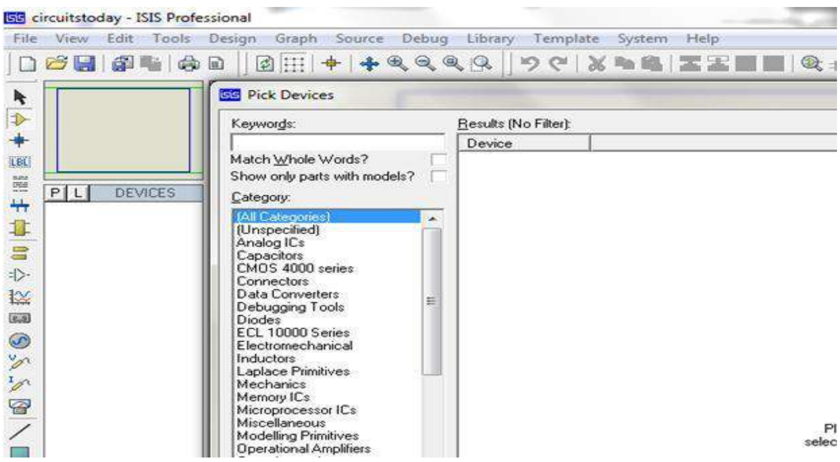

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

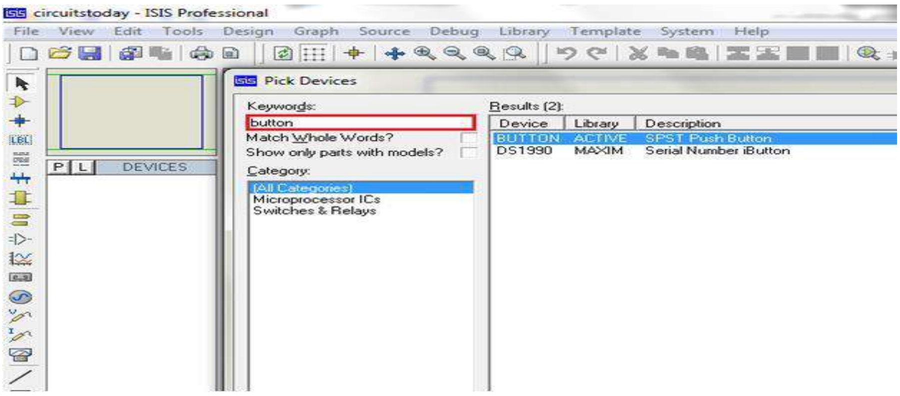

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

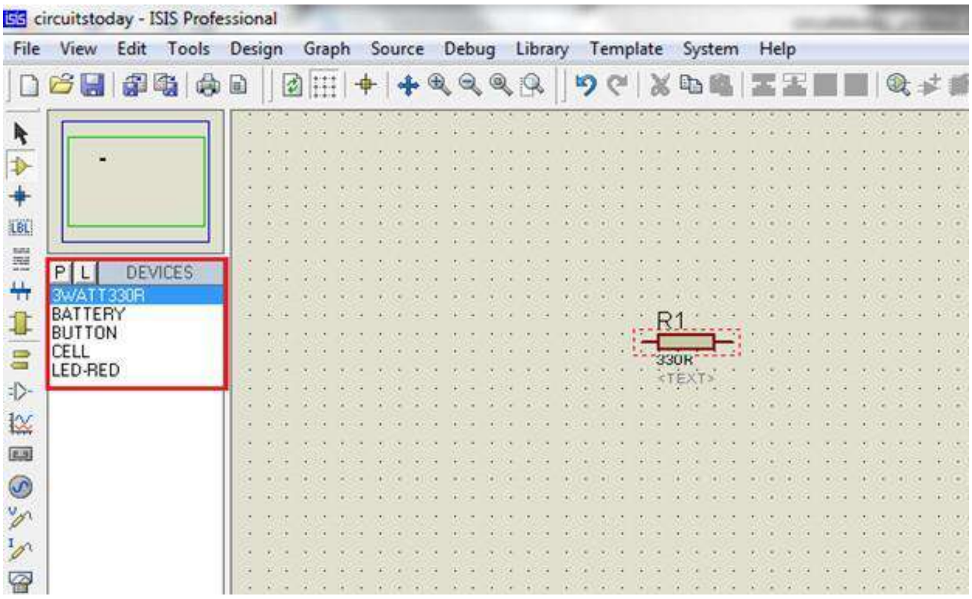

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

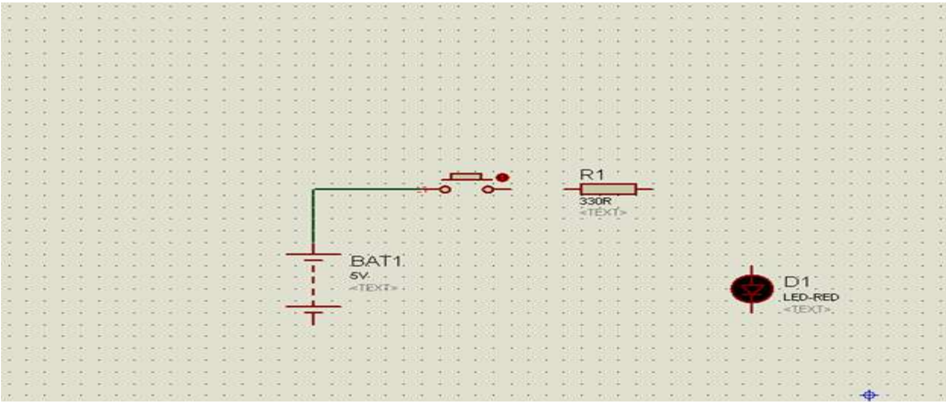

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

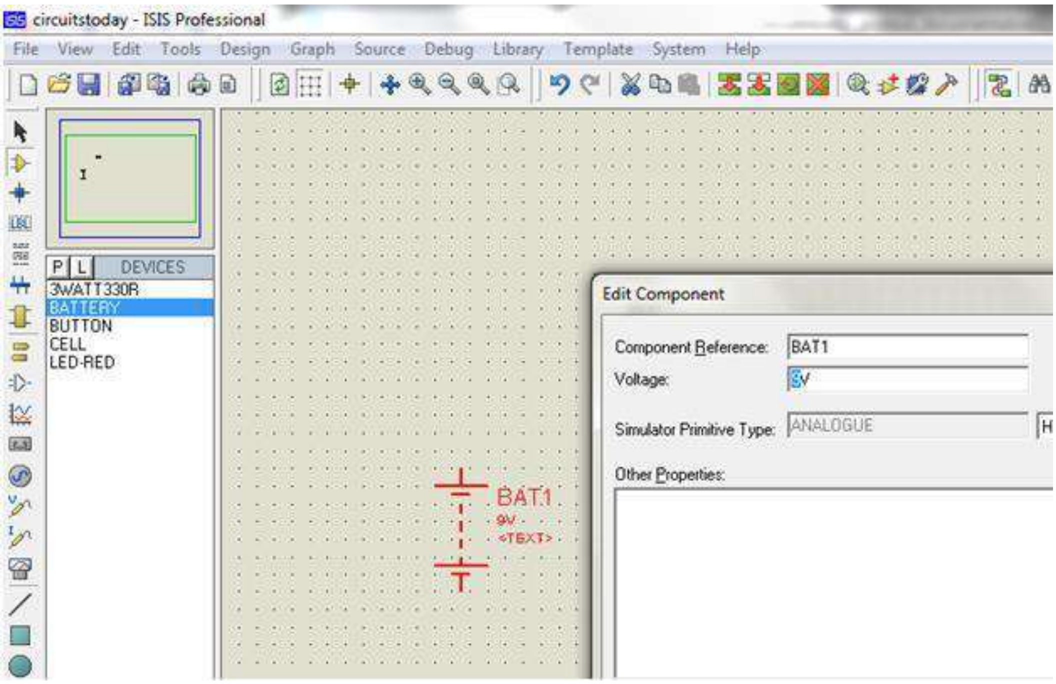

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

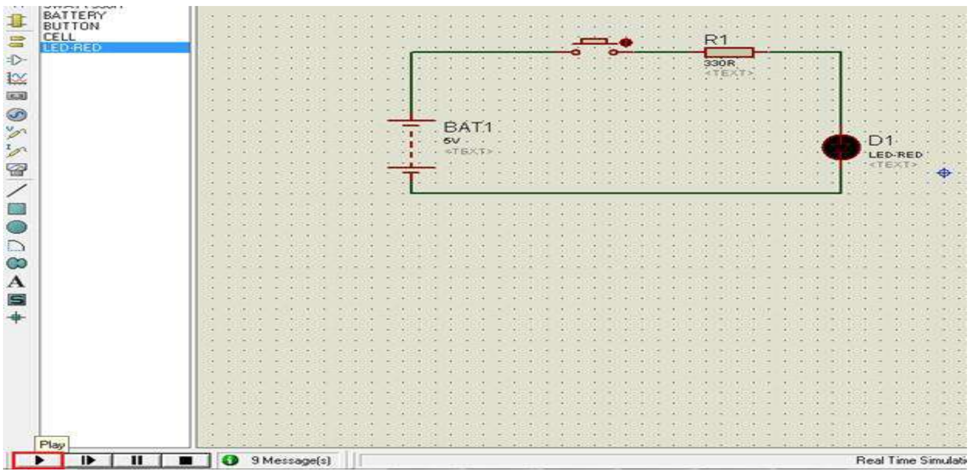

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

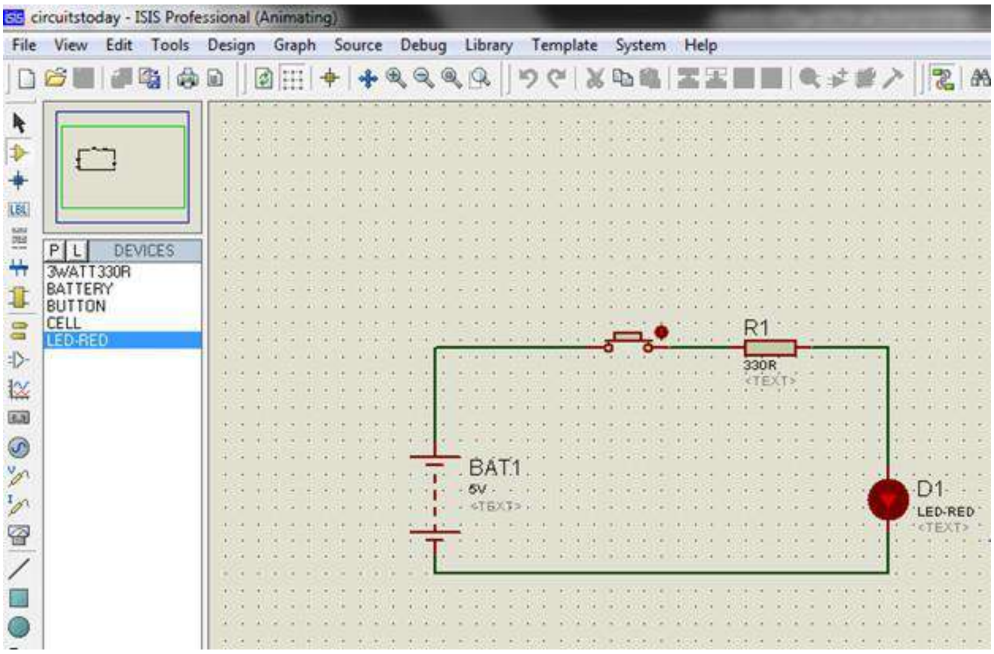

Fig. 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

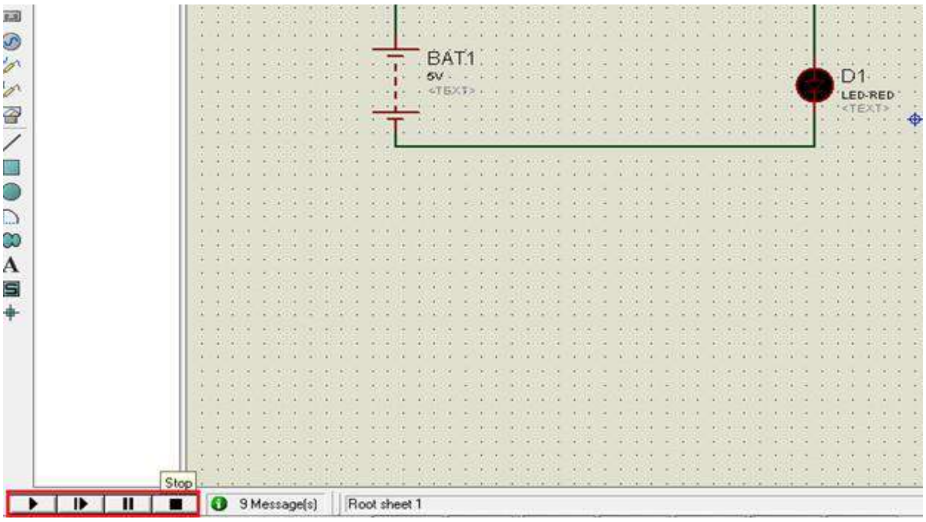

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by IOT Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works. [citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' MATLAB documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.3 DEFINE THE MODULES

3.3.1 GLOBAL SYSTEM FOR MOBILE COMMUNICATION (GSM)

GSM (Global System for Mobile communications) is an open, digital cellular technology used for transmitting mobile voice and data services. GSM (Global System for Mobile communication) is a digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot. It operates at either the 900 MHz or 1,800 MHz frequency band. It supports voice calls and data transfer speeds of up to 9.6 kbit/s, together with the transmission of SMS (Short Message Service).

3.3.1.1 INTRODUCTION TO GSM

The **GSM** (*Global System for Mobile communications*) network is at the start of the 21st century, the most used mobile telephony standard in Europe. It is called as Second Generation

(2G) standard because communications occur in an entirely digital mode, unlike the first generation of portable telephones. When it was first standardized in 1982, it was called as **Group Special Mobile** and later, it became an international standard called **"Global System for Mobile communications"** in 1991.

In Europe, the GSM standard uses the 900 MHz and 1800 MHz frequency bands. In the United States, however, the frequency band used is the 1900 MHz band. For this reason, portable telephones that can operate in both Europe and the United States are called **tri-band** while those that operate only in Europe are called **bi-band**.

The GSM standard allows a maximum throughput of 9.6 kbps which allows transmission of voice and low-volume digital data like text messages (**SMS**, for *Short Message Service*) or multimedia messages (**MMS**, for *Multimedia Message Service*).

3.3.1.2 GSM STANDARDS

GSM uses narrowband TDMA, which allows eight simultaneous calls on the same radio frequency. There are three basic principles in multiple access, FDMA (Frequency Division Multiple Access), TDMA (Time Division Multiple Access), and CDMA (Code Division Multiple Access). All three principles allow multiple users to share the same physical channel. But the two competing technologies differ in the way user sharing the common resource.

TDMA allows the users to share the same frequency channel by dividing the signal into different time slots. Each user takes turn in a round robin fashion for transmitting and receiving over the channel. Here, users can only transmit in their respective time slot.

CDMA uses a spread spectrum technology that is it spreads the information contained in a particular signal of interest over a much greater bandwidth than the original signal. Unlike TDMA, in CDMA several users can transmit over the channel at the same time.

3.3.1.3 TDMA IN BRIEF

In late1980's, as a search to convert the existing analog network to digital to improve capacity, the cellular telecommunications industry association chose TDMA over FDMA. Time Division Multiple Access is a type of multiplexing where two or more channels of information are transmitted over the same link by allocating a different time interval for the transmission of each channel. The most complex implementation using TDMA principle is of GSM's (Global System for Mobile communication). To reduce the effect of co-channel interference, fading and multipath, the GSM technology can use frequency hopping, where a call jumps from one channel to another channel in a short interval.

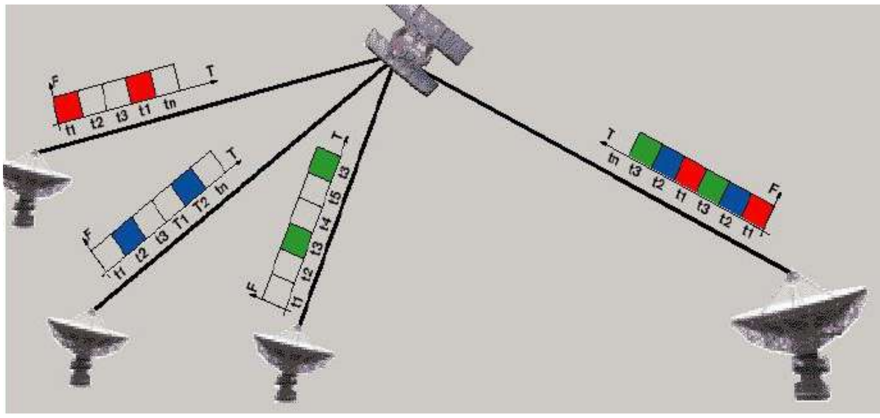

Fig.3.3.1.3 Time Division Multiplexing Access

TDMA systems still rely on switch to determine when to perform a handoff. Handoff occurs when a call is switched from one cell site to another while travelling. The TDMA handset constantly monitors the signals coming from other sites and reports it to the switch without caller's awareness. The switch then uses this information for making better choices for handoff at appropriate times. TDMA handset performs hard handoff, i.e., whenever the user moves from one site to another, it breaks the connection and then provides a new connection with the new site.

3.3.1.4 THE CONCEPT OF CELLULAR NETWORK

Mobile telephone networks are based on the concept of **cells**, circular zones that overlap to cover a geographical area.

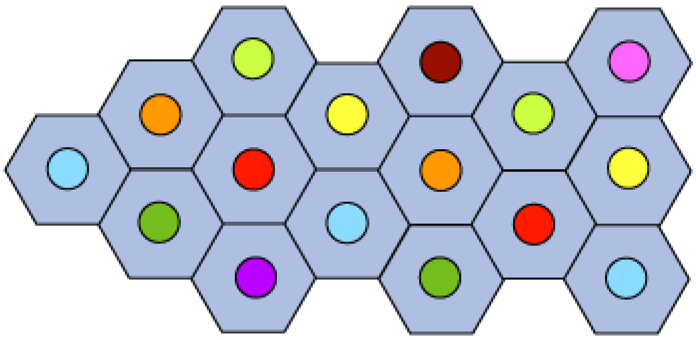

Fig.3.3.1.4 The Concept of cellular network

Cellular networks are based on the use of a central transmitter-receiver in each cell, called a "**base station**" (or *Base Transceiver Station*, written **BTS**). The smaller the radius of a cell, the higher is the available bandwidth. So, in highly populated urban areas, there are cells with a radius of a few hundred meters, while huge cells of up to 30 kilometers provide coverage in rural areas.

In a cellular network, each cell is surrounded by 6 neighboring cells (thus a cell is generally drawn as a hexagon). To avoid interference, adjacent cells cannot use the same frequency. In practice, two cells using the same frequency range must be separated by two to three times the diameter of the cell.

3.3.1.5 GSM MODEM

A GSM modem is a wireless modem that works with a GSM wireless network. A wireless modem behaves like a dial-up modem. The main difference between them is that a dial-up modem sends and receives data through a fixed telephone line while a wireless modem sends and receives data through radio waves.

Fig.3.3.1.5.1 GSM/GPRS Modem

A GSM modem can be an external device or a PC Card / PCMCIA Card. Typically, an external GSM modem is connected to a computer through a serial cable or a USB cable. A GSM modem in the form of a PC Card / PCMCIA Card is designed for use with a laptop computer. It should be inserted into one of the PC Card / PCMCIA Card slots of a laptop computer. Like a GSM mobile phone, a GSM modem requires a SIM card from a wireless carrier in order to operate.

A SIM card contains the following information:

- Subscriber telephone number (MSISDN)
- International subscriber number (**IMSI, International Mobile Subscriber Identity)**
- State of the SIM card
- Service code (operator)
- Authentication key
- PIN (***Personal Identification Code***)
- PUK (***Personal Unlock Code***)

Computers use AT commands to control modems. Both GSM modems and dial-up modems support a common set of standard AT commands. In addition to the standard AT commands, GSM modems support an extended set of AT commands. These extended AT commands are defined in the GSM standards. With the extended AT commands, the following operations can be performed:

- Reading, writing, and deleting SMS messages.
- Sending SMS messages.
- Monitoring the signal strength.
- Monitoring the charging status and charge level of the battery.
- Reading, writing, and searching phone book entries.

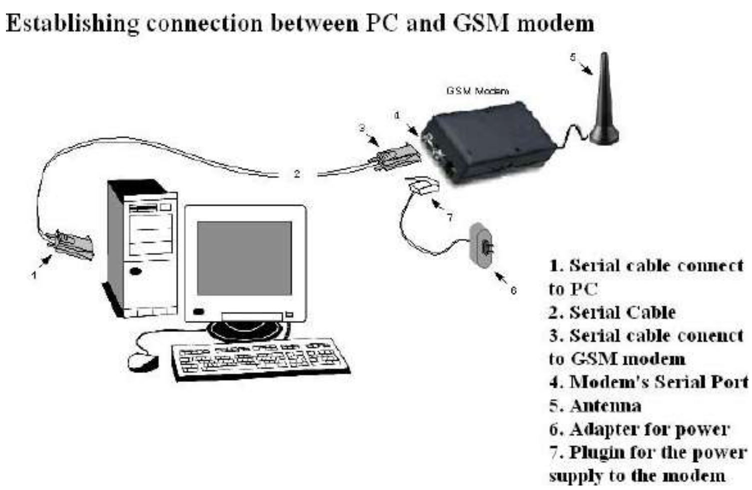

Fig.3.3.1.5.2 Establishing connection between PC and GSM modem

The number of SMS messages that can be processed by a GSM modem per minute is very low i.e., about 6 to 10 SMS messages per minute.

3.3.1.6 INRODUCTION TO AT COMMANDS

AT commands are instructions used to control a modem. AT is the abbreviation of Attention. Every command line starts with "AT" or "at". That is the reason, modem commands are called AT commands. Many of the commands that are used to control wired dial-up modems, such as ATD (Dial), ATA (Answer), ATH (Hook control) and ATO (Return to online data state) are also supported by GSM modems and mobile phones.

Besides this common AT command set, GSM modems and mobile phones support an AT command set that is specific to the GSM technology, which includes SMS-related commands like AT+CMGS (Send SMS message), AT+CMSS (Send SMS message from storage), AT+CMGL (List SMS messages) and AT+CMGR (Read SMS messages).

It should be noted that the starting "AT" is the prefix that informs the modem about the start of a command line. It is not part of the AT command name. For example, D is the actual AT command name in ATD and +CMGS is the actual AT command name in AT+CMGS.

Some of the tasks that can be done using AT commands with a GSM modem or mobile phone are listed below:

Get basic information about the mobile phone or GSM modem. For example, name of manufacturer (AT+CGMI), model number (AT+CGMM), IMEI number (International Mobile Equipment Identity) (AT+CGSN) and software version (AT+CGMR).

Get basic information about the subscriber. For example, MSISDN (AT+CNUM) and IMSI number (International Mobile Subscriber Identity) (AT+CIMI).

Get the status of the mobile phone or GSM/GPRS modem. For example, mobile phone activity status (AT+CPAS), mobile network registration status (AT+CREG), radio signal strength (AT+CSQ), battery charge level and battery charging status (AT+CBC).

Establish a data connection or voice connection to a remote modem (ATD, ATA, etc.).

Send and receive fax (ATD, ATA, AT+F*).

Send (AT+CMGS, AT+CMSS), read (AT+CMGR, AT+CMGL), write (AT+CMGW) or delete (AT+CMGD) SMS messages and obtain notifications of newly received SMS messages (AT+CNMI).

Read (AT+CPBR), write (AT+CPBW) or search (AT+CPBF) phonebook entries.

Perform security-related tasks, such as opening or closing facility locks (AT+CLCK), checking whether a facility is locked (AT+CLCK) and changing passwords (AT+CPWD). (Facility lock examples: SIM lock [a password must be given to the SIM card every time the mobile phone is switched on] and PH-SIM lock [a certain SIM card is associated with the mobile phone. To use other SIM cards with the mobile phone, a password must be entered.])

Control the presentation of result codes / error messages of AT commands. For example, the user can control whether to enable certain error messages (AT+CMEE) and whether error messages should be displayed in numeric format or verbose format (AT+CMEE=1 or AT+CMEE=2).

Get or change the configurations of the mobile phone or GSM/GPRS modem. For example, change the GSM network (AT+COPS), bearer service type (AT+CBST), radio link protocol parameters (AT+CRLP), SMS center address (AT+CSCA) and storage of SMS messages (AT+CPMS).

Save and restore configurations of the mobile phone or GSM/GPRS modem. For example, save (AT+CSAS) and restore (AT+CRES) settings related to SMS messaging such as the SMS center address.

It should be noted that the mobile phone manufacturers usually do not implement all AT commands, command parameters and parameter values in their mobile phones. Also, the behavior of the implemented AT commands may be different from that defined in the standard. In general, GSM modems, designed for wireless applications, have better support of AT commands than ordinary mobile phones.

3.3.2 GLOBAL POSITIONING SYSTEM

3.3.2.1 INTRODUCYION TO GPS

Fig 3.3.2.1 Interface ublox NEO-6M GPS Module with Arduino

Give your next Arduino project ability to sense locations with NEO-6M GPS Module that can track up to 22 satellites and identifies locations anywhere in the world. It may serve as a great launch pad for anyone looking to get into the world of GPS.

They are low power (suitable for battery powered devices), inexpensive, easy to interface with and are insanely popular among hobbyists.

3.3.2.2 HARDWARE OVERVIEW OF NEO-6M GPS MODULE

NEO-6M GPS Chip

At the heart of the module is a NEO-6M GPS chip from u-blox. The chip measures less than the size of a postage stamp but packs a surprising number of features into its little frame.

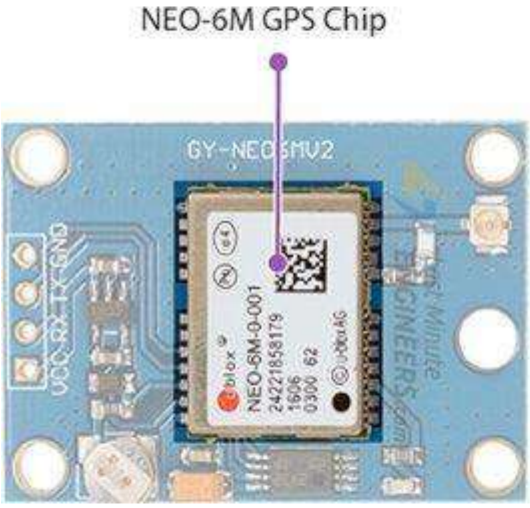

Fig.3.3.2.2 Overview of NEO-6M GPS Module

It can track up to 22 satellites on 50 channels and achieves the industry’s highest level of sensitivity i.e., -161 dB tracking, while consuming only 45mA supply current.

Unlike other GPS modules, it can do up to 5 location updates a second with 2.5m Horizontal position accuracy. The u-blox 6 positioning engine also boasts a Time-To-First Fix (TTFF) of under 1 second.

One of the best features the chip provides is Power Save Mode (PSM). It allows a reduction in system power consumption by selectively switching parts of the receiver ON and OFF. This dramatically reduces power consumption of the module to just 11mA making it suitable for power sensitive applications like GPS wristwatch.

3.3.2.3 POSITION FIX LED INDICATOR

The necessary data pins of NEO-6M GPS chip are broken out to 0.1″ pitch headers. This includes pins required for communication with a microcontroller over UART. The module supports baud rate from 4800bps to 230400bps with default baud of 9600.

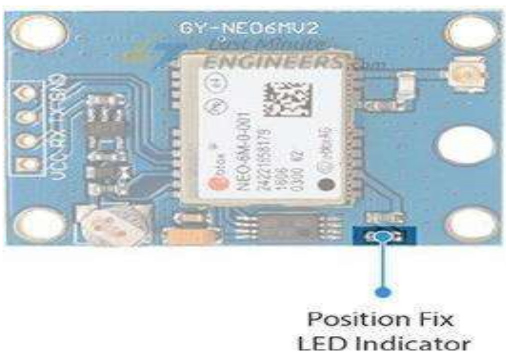

Fig.3.3.2.3 Position Fix LED Indicator

There is an LED on the NEO-6M GPS Module which indicates the status of Position Fix. It will blink at various rates depending on what state it’s in:

- No Blinking – It is searching for satellites.
- Blink every 1s – Position Fix is found (The module can see enough satellites).

3.3.2.4 3.3V LDO REGULATOR

Fig.3.3.2.4 3.3V LDO Regulator

The operating voltage of the NEO-6M chip is from 2.7 to 3.6V. But the good news is that the module comes with MIC5205 ultra-low dropout 3V3 regulator from MICREL.

The logic pins are also 5-volt tolerant, so we can easily connect it to an Arduino or any 5V logic microcontroller without using any logic level converter.

3.3.2.5 BATTERY & EEPROM

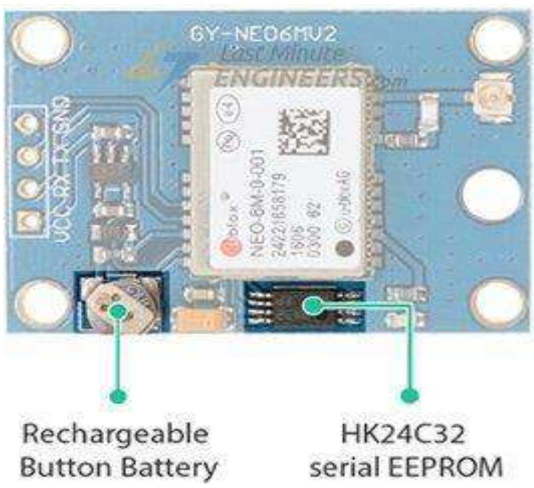

Fig. 3.3.2.5 Battery & EEPROM

The module is equipped with an HK24C32 two wire serial EEPROM. It is 4KB in size and connected to the NEO-6M chip via I2C.

The module also contains a rechargeable button battery which acts as a super-capacitor.

An EEPROM together with battery helps retain the battery backed RAM (BBR). The BBR contains clock data, latest position data (GNSS orbit data) and module configuration. But it's not meant for permanent data storage.

As the battery retains clock and last position, time to first fix (TTFF) significantly reduces to 1s. This allows much faster position locks.

Without the battery the GPS always cold start so the initial GPS lock takes more time.

The battery is automatically charged when power is applied and maintains data for up to two weeks without power.

3.3.2.6 ANTENNA

An antenna is required to use the module for any kind of communication. So, the module comes with a patch antenna having -161 dBm sensitivity.

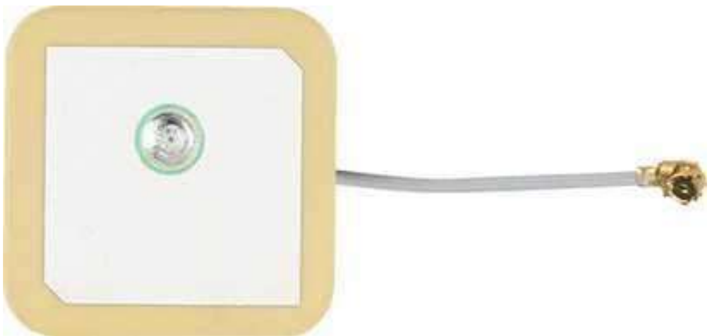

Fig. 3.3.2.6 Antenna

3.3.2.7 UFL CONNECTOR

You can snap-fit this antenna to small U.FL connector located on the module.

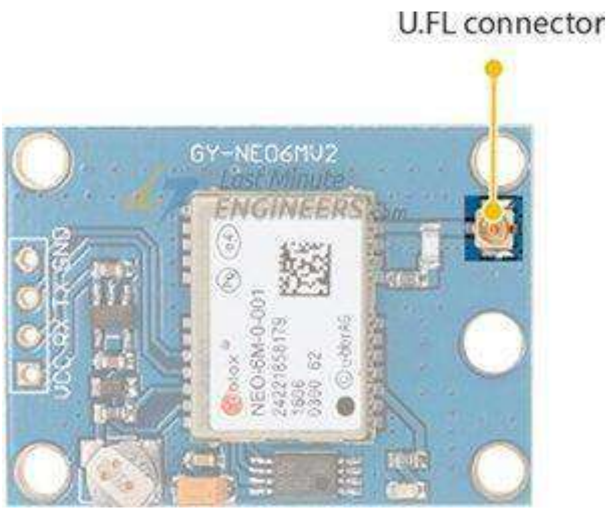

Fig.3.3.2.7 UFL Connector

Patch antenna is great for most projects. But if you want to achieve more sensitivity or put your module inside a metal case, you can also snap on any 3V active GPS antenna via the U.FL connector.

3.3.2.8 NEO-6M GPS MODULE PINOUT

The NEO-6M GPS module has total 4 pins that interface it to the outside world. The connections are as follows:

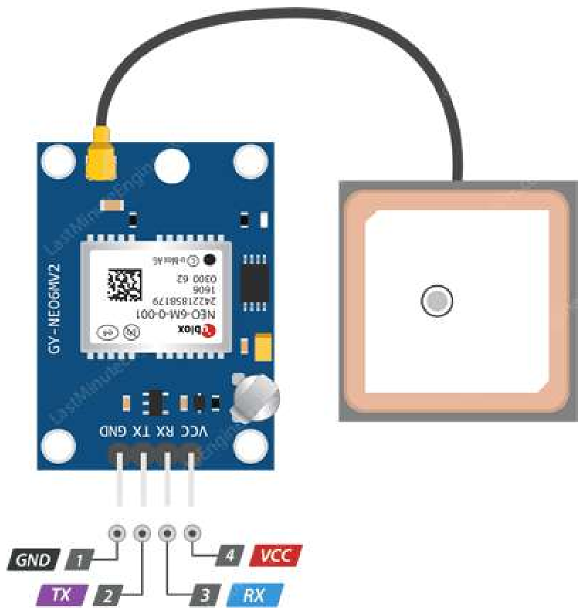

Fig.3.3.2.8 NEO-6M GPS MODULE PINOUT

GND is the Ground Pin and needs to be connected to GND pin on the Arduino.

TxD (Transmitter) pin is used for serial communication.

RxD (Receiver) pin is used for serial communication.

VCC supplies power for the module. You can directly connect it to the 5V pin on the Aíduino.

Wiring NEO-6M GPS module with Arduino UNO

Now that we know everything about the module, we can begin hooking it up to our Arduino!

Start by connecting the patch antenna to the U.FL connector. Remember to thread the U.FL cable through one of the mounting holes for robust connection.

The module usually comes with header pins unsoldered. So, you'll need to solder them.

Now, connect Tx and Rx pin on module to digital pin#2 and #3 respectively on Arduino; as we'll be using software serial to talk to the module.

Next, connect VCC pin to the 5V pin on the Arduino and GND to ground.

```

4.5 RESULTS

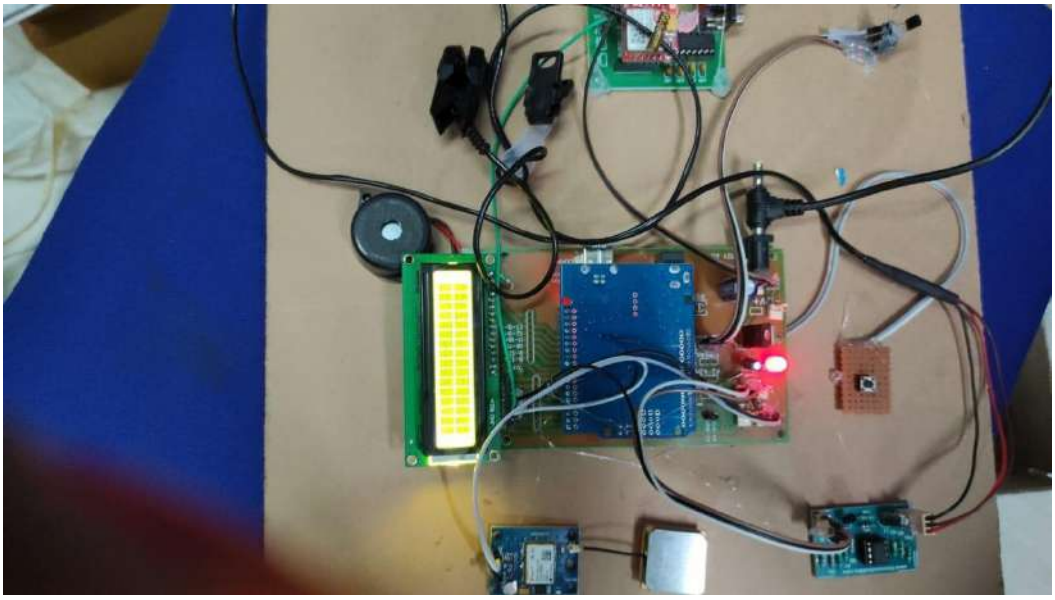

Fig 4.5 Final Output

CHAPTER 5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

The soldier Health and Position Tracking System allows the military to track the current GPS position of a soldier and checks the health status including body temperature and heartbeats of the soldier. The System also consists of extra features with the help that a soldier can ask for help manually or send a distress signal to the military if he is in need. The GPS modem sends the latitude and longitude position with a link pattern with the help of that the military can track the current position of the soldier. The system is very helpful for getting health status information of soldiers and providing them instant help. Here are some techniques used to track current position and health condition. In today's era enemy warfare is a very important factor in any nation’s security. The national security mainly depends on the defense force. In this system we have come up with an idea of tracking soldiers as well as giving their status of their health condition and location during the war.

So, in implementation of the project, we encountered few problems such as the entire project depends on the wireless communication i.e., it depends on GSM module and signals. So, there are few problems we encountered and solved them.

- Signal problem in hill regions.
- Temperature differences in body that take place due to climatic changes.
- Rise of heartbeat in hill region when climbing.

1. Signal Problem:

   So, to overcome signal problem initially we had used helical antenna which perform well in open area and where there are no obstacles between antenna and signal towers which has many disadvantages, so it was replaced with another antenna which work works well in any environment and has proper bandwidth than helical antenna which is called as 3dBi.
   The 3dBi GSM antenna along with a U. FL to SMA adapter which can be obtained online for less than $3. You can snap-fit this antenna to small u.fl connector located on the top-left corner of the module. This type of antenna has a better performance and allows putting your module inside a metal case – as long the antenna is outside.

2. Temperature differences in body that take place due to climatic changes.

   Here we can change the value in program with respect to climate in outdoors which makes it flexible to any kind of climates can change the threshold values according to region of the soldier’s mission.

3. Rise of heartbeat in hill region when climbing.

   Here depending on region in which mission is given to soldier’s the threshold value can be varied.

CHAPTER-6

CONCLUSION AND FUTURESCOPE

6.1 CONCLUSION

- Above system, when completed, would make it easy to help in determining the health status of soldiers with measures of heart beats and body temperature.
- It would also help in tracking his position by using GPS modem and with GSM modem it can send all information to the base station so that further necessary action could be taken.

6.2 FUTURE SCOPE

- We can add a graphical display section to this project which helps to display a digital map which shows the position of all soldiers in the unit as they surround a block of buildings and launch their attacks.
- Welling to make live tracking possible.
- Helmet attached screens, accomplished by presenting information from maps and video using varieties of physiological sensors.

PUBLICATION

Submitted Paper in the Conference ICISECT - 21 with Paper ID (ICISECT21-0003) and got Acceptance for the Paper.

APPENDICES

The project shows that the health monitoring and tracking system for soldiers. The proposed system can be mounted on the soldier's body to track their health status and current location using GPS. This information will be transmitted to the control room through IoT. The proposed system comprises of tiny wearable physiological equipment's, sensors, transmission modules. Hence, with the use of the proposed equipment, it is possible to implement a low-cost mechanism to protect the valuable human life on the battlefield.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to our College Management for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, our beloved **Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, the Dept. of Electronics and Communications Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our dept. Project Coordinator **Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide, **Mrs.K.Divya Vani, Assistant Professor,** Department of ECE and our class Project Coordinator **Ms.P.Pushpa, Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project Coordinators **Dr.Maalyadri**, **Professor in IT And Dr.R.Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Multiple input and multiple output orthogonal frequency division multiplexing (MIMO-OFDM) is used to improve the performance and capacity of wireless communication system. OFDM is an efficient and promising modulation technique or wireless transmission due to its high spectral efficiency and robustness to frequency selective adding channels. However, it has high peak to average ratio (PAPR) which is a main disadvantage. Partial transmit sequence (PTS) is one o the most widely used technique that gives a better performance in PAPR reduction or MIMO-OFDM system. However the computational complexity of traditional PTS method is tremendous. In this paper, A Low-Complexity Hybrid Subblock Segmentation PTS Scheme or PAPR Reduction in MIMO-OFDM System is proposed. For analytic purposes, we derive computational complexity expressions or the proposed segmentation method and analyze the computational complexity o the proposed segmentation method compared with that o the random segmentation method which has the best Peak to Average Power Ratio (PAPR) reduction perormance. The simulation results show that the PAPR reduction performance is degraded only slightly compared with random segmentation method.

LIST OF FIGURES

GLOSSARY OF COMMONLY USED TERM:

JPEG/JFIF-JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format.

EXIF-The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras.

TIFF-The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension.

PNG-The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas.

GIF-GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images.

BMP-The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

Chapter 1

INTRODUCTION

Based on a survey in 2010, skin diseases had the fourth leading cause of nonfatal disease burden in the world, and three of the world‘s most common diseases were skin diseases . Skin diseases have caused enormous economic burdens both in high-income and low-income countries. For each individual, skin problems can have adverse effects on all aspects of life, including interpersonal relationships, work, social functioning, physical activity and mental health.

1.0 OVERVIEW OF THE PROJECT

Usually, skin diseases cause skin lesions, scales, plaques, pigmentation and other symptoms on the patient‘s skin . These symptoms result in long-term pain and disfigurement. Such damage not only injures physical health but also contribute to serious mental problems, especially when such damage occurs on face. Studies showed that patients with primary skin diseases (such as psoriasis, alopecia areata and vitiligo) have a higher potential for mental problems, such as anxiety and depression. In addition, some skin disease treatments also have the possibility of inducing mental illness (such as isotretinoin, an acne medication, may induce suicidal depression).

1.1 OBJECTIVES OF THE STUDY

Facial skin is exposed to the air almost all the time, so it has a higher risk of being damaged than other areas. Moreover, facial skin is the most important part of the body for people‘s appearance, so people are more concerned about their facial skin health than skin health anywhere else. Along with the availability of massive amounts data brought by the Internet [9] and the improvement of computing power brought by advanced hardware, deep learning algorithms have achieved human-level performance in many fields. For example, convolutional neural networks (CNNs) have made many breakthroughs in the field of medical image processing, especially for pathological, CT and MRI images, which have rigid features and high resolution. However, research on clinical images is relatively insufficient. For these reasons, clinical images always contain a very complex context, and it is hard to control the conditions of acquiring the image. These circumstances make image processing tasks difficult.

1.2 SCOPE OF THE STUDY

Furthermore, datasets of a certain part of the body, especially the face, re relatively scarce. At present, most of the available datasets are not clearly labeled with information on the body parts; for some datasets that provide this information, the proportion of facial images is always small . All of these conditions make research difficult. Therefore, this paper first constructed a skin image dataset based on 6 common facial skin diseases (seborrheic keratosis (SK), actinic keratosis (AK), rosacea (ROS), lupus erythematosus (LE), basal cell carcinoma (BCC), and squamous cell carcinoma (SCC)). It includes 2,656 facial images for a total of 4,394 images. We focus on these diseases for the following reasons: 1) LE, ROS, BCC and SCC frequently occur on the face; 2) AK and SK usually transition from benign to malignant without timely treatment.

Based on the dataset, experiments were carried out on 5 different CNN structures to verify whether these methods can effectively diagnose facial skin diseases using clinical images. In the test set consisting entirely of facial images, the structure named Inception-ResNet-v2 achieved the highest average precision (77.0%).

1.3 MATERIAL REQUIREMENT

- Math and computation
- Algorithm development

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

1.4 PROCUMENT OF EQUIPMENT

1.4.1 THE MATLAB SYSTEM

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

  This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

  This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both ―programming in the small‖ to rapidly create quick and dirty throw-away programs, and ―programming in the large‖ to create large and complex application programs.

- **Graphics:**

  MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

  This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

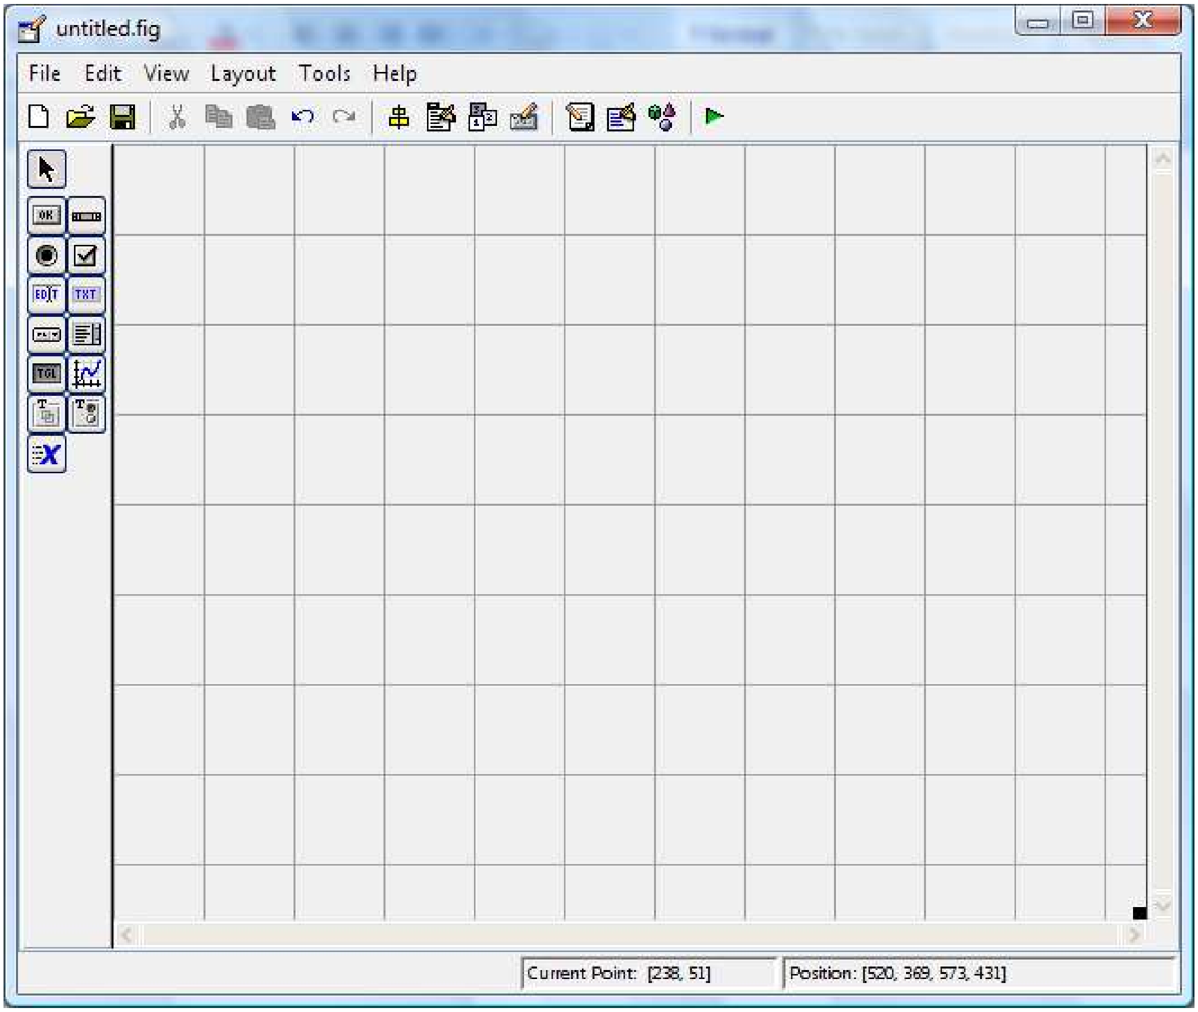

Fig:1.4.1 Matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

Chapter 2

LITERATURE REVIEW

2.0 LITERATURE REVIEW ON RESEARCH AREA:

Many studies have applied deep learning algorithms to skin diseases . For example, the performance in the task of classifying skin tumors using the Inception-v3 network has reached the level of professional dermatologists; for nine classes of tumors, a computer achieved an accuracy of 55.4%, and two dermatologists achieved accuracies of 53.3% and 55.0% . Using the same network structure, achieved an accuracy of 87.25 ± 2.24% on the dermoscopic images for four common skin diseases, including SK, BCC, psoriasis and melanocytic nevus. These studies show that current deep learning methods have the potential to be applied to dermatoses.

At the same time, the application of deep learning to facerelated diseases is also promising. Reference designed a deep learning algorithm called DeepGestalt and trained their model on more than 17,000 real facial images of genetic syndromes, and this model can identify more than 200 genetic syndromes using facial images with relatively high precision. Reference investigated using CNNs to classify acne into different severity grades ranging from clear to severe, and their results show that the accuracy of their method outperformed expert physicians. Initially, we investigated the proportion of facial images in the most commonly used public datasets for skin disease, which include AtlasDerm , DermlS , the ISIC Archive , Derm101 and Dermnet . Most of these datasets did not provide information about body parts. In [19], which does provide body parts information, there were only 195 facial images. It is difficult to perform further research on facial skin diseases using such limited data. As a result, building a specialized dataset for face images is extremely necessary for our research.

2.1 REVIEW ON RELATED LITERATURE

A neural network is a mathematical model inspired by the transfer process of biological neuron information, and its purpose is to learn a mapping from input to output. By using a loss function as a constraint and backpropagation to optimize the parameters, this method can automatically learn complex tasks for different fields. This method has reduced the need for human labor, such as manual feature extraction and data reconstruction for classification. A CNN is a type of neural network. It generally consists of an input layer, many hidden convolutional layers, and an output layer. Using this structure, the model can include a large number of parameters and obtain some usable properties, such as equivariance, for image-related tasks.

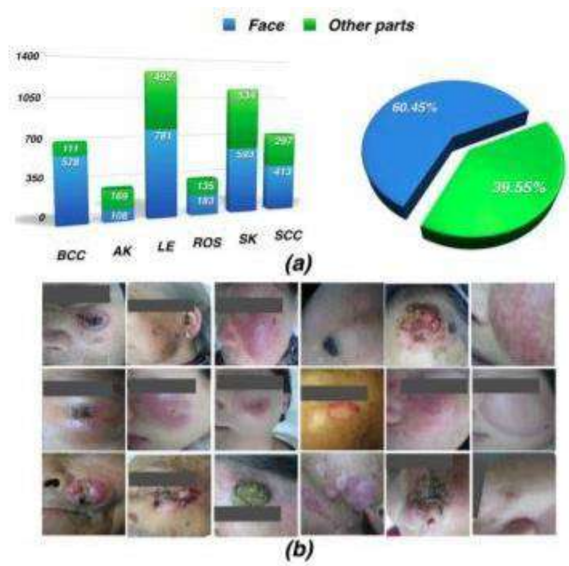

Fig:2.1 Diseases in the dataset

FIGURE 1. The stacked cylinder diagram ((a) left) and the pie chart ((a) right) show the distribution of the images of face and other body parts for different diseases in the dataset; (b) shows some examples of the dataset.

TABLE 1. Summary of dataset.

	IMAGE QTY	Face image	Train image	Test image
BCC	689	578	623	66
AK	277	108	219	58
LE	1273	781	1188	85
ROS	318	183	263	55
SK	1127	593	1075	52
SCC	710	413	638	72
Total	4394	2656	4006	388

Fig:2.1.1 Summary of dataset

we used five mainstream CNN algorithms that have been pretrained on ImageNet [9]. These five structures include ResNet-50, Inception-v3, DenseNet121, Xception and Inception-ResNet-v2. We used same pre-process for these images, including random reverse and crop. And to address the problem of data imbalance, we used different weights in the cost function for different diseases.

ResNet adds connections between the shallow and deep layers of the network. Such connections directly transmit the information of the shallow layer to the deep layer. On the other hand, the propagation of the gradient to the shallow layer during backpropagation greatly increases the number of network layers .

The basic module of the Inception structure is the inception block. There are different kernels in a block, and each type of kernel has a different shape; the output of the block is combines the output from different kernels. This improves the diversity of the network in terms of width and the diversity of the scale of the receptive field. Therefore, the model improved its recognition performance for objects with different sizes.

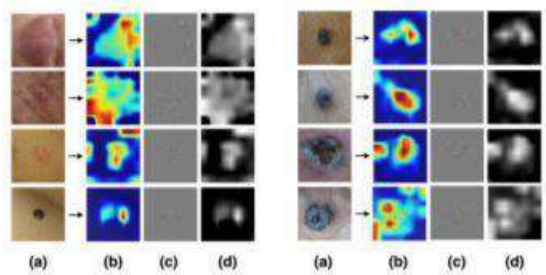

Fig:2.1.2 image heatmap

FIGURE 2. (a) is the input images, (b) is the heatmap for the combination of input images and the corresponding output of grad-CAM(d). (c) is the output of guided propagation.

DenseNet adds connections between each two layers; that is, the output feature maps of each layer will be used as the input for all subsequent layers. Using these dense connections, the network reuses features, thereby improving performance with fewer parameters, which makes the calculation more efficient .

Xception is an updated version of the Inception structure. Xception improves the Inception module with a depthwise separable convolution. This change decouples spatial correlations and cross-channel correlations. It can obtain a better performance than Inception-v3 with the same parameters . To some extent, Inception-ResNet is a combination of Inception and ResNet structures. By adding a residual connection to the Inception network, it can train deeper networks while maintaining the scale diversity of the network, thereby enhancing the performance .

we used the same 300∗300 input images for each network and did not change the basic structure from that in their origin paper. We replaced the first fully connected layer behind the last convolutional layer with global average pooling and a 1∗1 convolution to reduce the number of parameters and maintain spatial information. Finally, we used a 1024-d fully connected layer in each network and then used a softmax or logistic regression classifier to obtain 6 confidence outputs for six facial skin diseases. More details about the model structures are shown in Table 2, where inception block, dense block, transition layer,andinception resnet blockare modules that are the same as those from the origin papers.

2.2 CONCLUSION ON REVIEW:

This paper performed experiments using five mainstream CNN structures for the clinical image diagnosis of six common facial skin diseases and constructed a data set consisting mainly of facial skin disease images. The results demonstrate that CNNs have the ability to recognize facial skin diseases. Based on our experiments, we determined that different models to diagnose diseases on different body parts should be used. Furthermore, our experiments also showed that a more reasonable network structure could improve the performance of the model. The performance of the current network structure has been satisfactory in some diseases, but the overall performance has yet to be improved. As a result, if we want that people to actually use this technique to check their face skin health in their daily life, specialized improvements should be developed.

In our opinion, the application of artificial intelligence techniques in the medical field is not sufficient, and the datasets from this field should be improved both in quantity and quality. With the increasing amount of facial image data of various skin diseases and the continuous improvement of the network structure, CNN-based facial skin disease diagnosis algorithms will continue to improve in performance. We believe that, in the future, patients will use convenient CNN-based applications to keep their face skin healthy.

CHAPTER-3

PROJECT DESIGN

3.0 OVERVIEW OF THE PROJECT:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

3.1 EQUIPMENT ANALYSIS:

- Math AND Computation
- Algorithm Development
- Modeling, stimulation And Prototyping
- Data Analysis, Exploration And Visualization
- Application Development, including Graphical User Interface Building

3.2 DEFINE THE MODULES:

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves –Making sense‖ of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of _f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

3.3 MODULE FUNCTIONALITIES:

Gray scale image:

A grayscale image is a function I (xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem) takes non-negative values assume the image is bounded by a rectangle [0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem) for red, G (xylem) for green *and* B (xylem) for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate's values is called sampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

$$\text{f (xylem)=} \begin{matrix} f(0,0) & f(0,1) & \ldots\ldots\ldots.. & f(0,N-1) \\ f(1,0) & f(1,1) & \ldots\ldots\ldots\ldots & f(1,N-1) \\ . & . & & . \\ . & . & & . \end{matrix}$$

f (M-1,0)   f(M-1,1).................f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements. A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f(1,2)........... f(1,N)

f (2,1)   f(2,2)........... f (2,N)

.   .   .

f =   .   .   .

f (M,1)   f(M,2).......... f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (_filename‘)

Format name	Description	recognized extension
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	Portable Network Graphics	.png
XWD	X Window Dump	.xwd

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

```
>> f = imread (_8. jpg‘);
```

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (_) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name **Description**

Double Double _ precision, floating_ point numbers the Approximate.

Uint8 unsigned 8_bit integers in the range [0,255] (1byte per Element).

Uint16 unsigned 16_bit integers in the range [0, 65535] (2byte per element).

Uint 32 unsigned 32_bit integers in the range [0, 4294967295](4 bytes per element). Int8 signed 8_bit integers in the range [-128,127] 1 byte per element)

Int 16 signed 16_byte integers in the range [32768, 32767] (2 bytes per element).

Int 32 Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses ―direct mapping‖ of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as –stack‖ of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

3.4 IMAGE

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 3.4 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

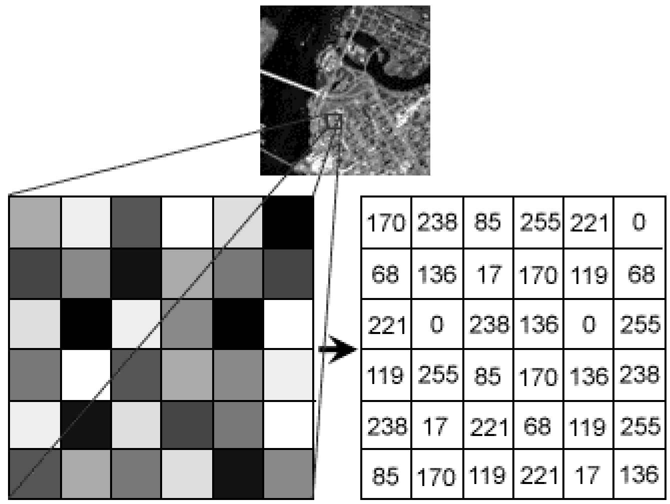

Fig 3.5 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

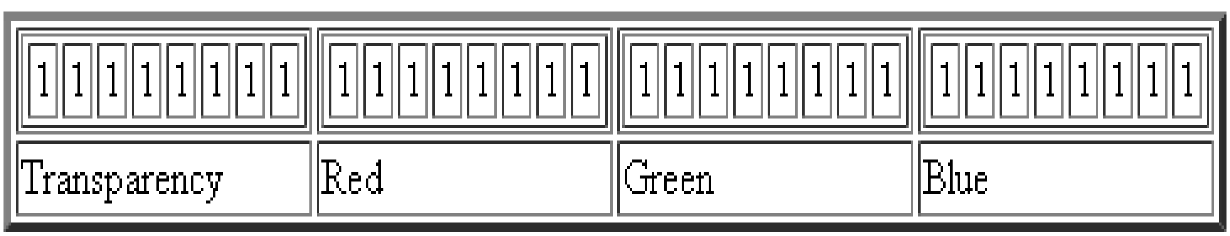

Fig 3.6 Transparency image

3.5 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

3.6 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

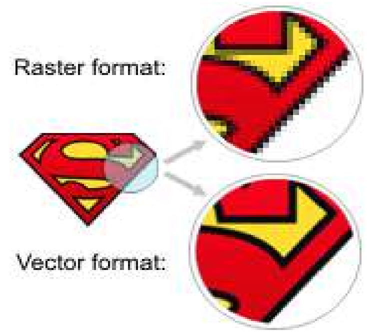

Fig3.7 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

3.6.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

3.6.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

3.7 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man‘s ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

3.8 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

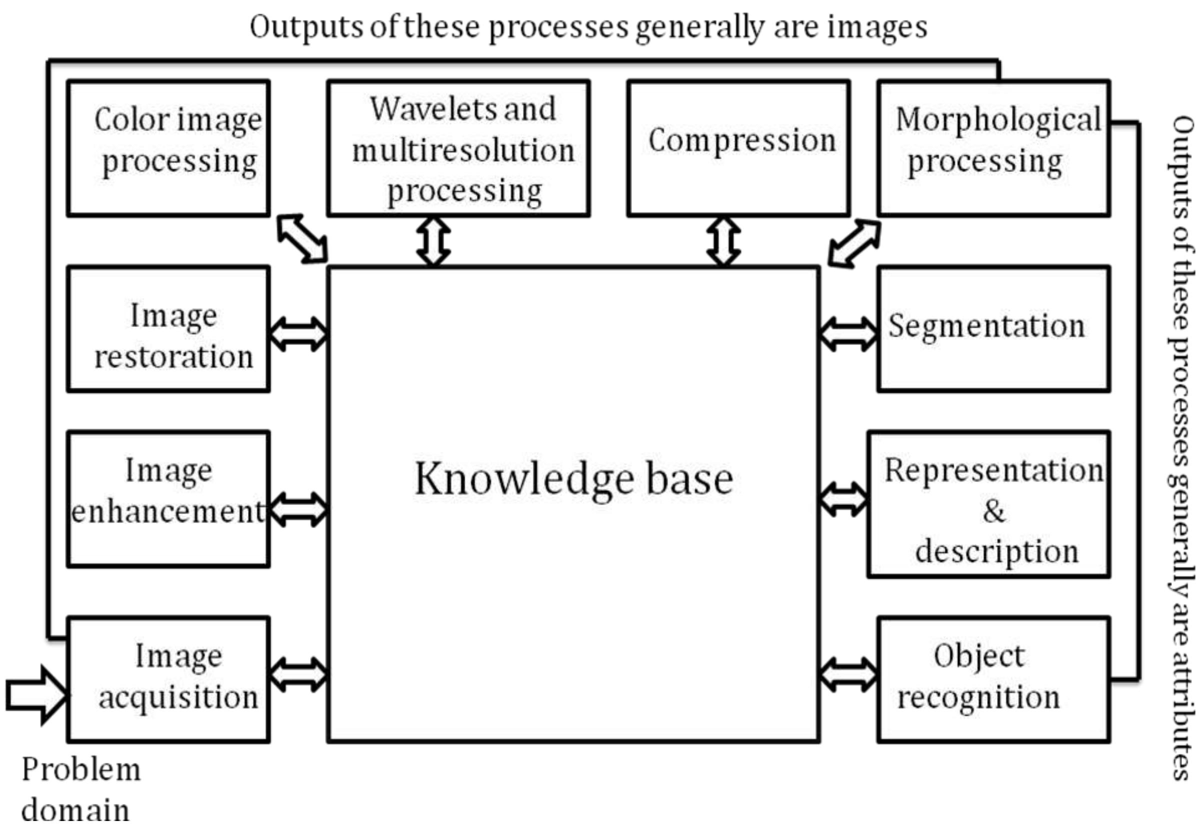

Fig 3.8 Image fundamental

3.8.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 3.8.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 3.8.2 digital camera cell

3.8.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because –it looks better.‖ It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 3.8.3 Image enhancement

3.8.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 3.8.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a –good‖ enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

3.8.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 3.8.5 Color & Gray scale image

3.8.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

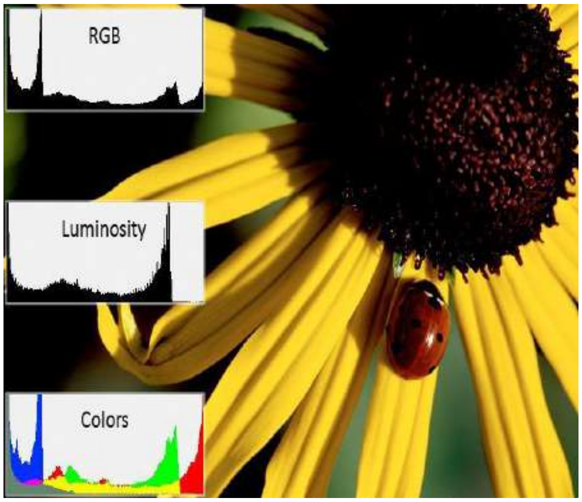

Fig 3.8.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

3.8.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

3.8.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 3.8.7 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

3.8.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

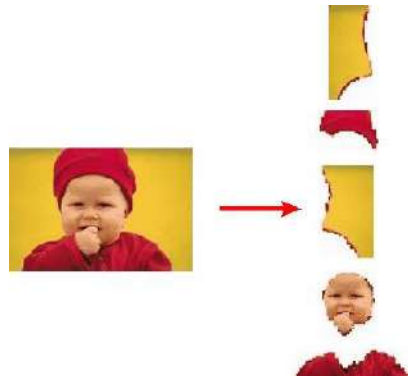

Fig 3.8.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

3.8.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

3.9 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

3.9.1 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

3.10 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

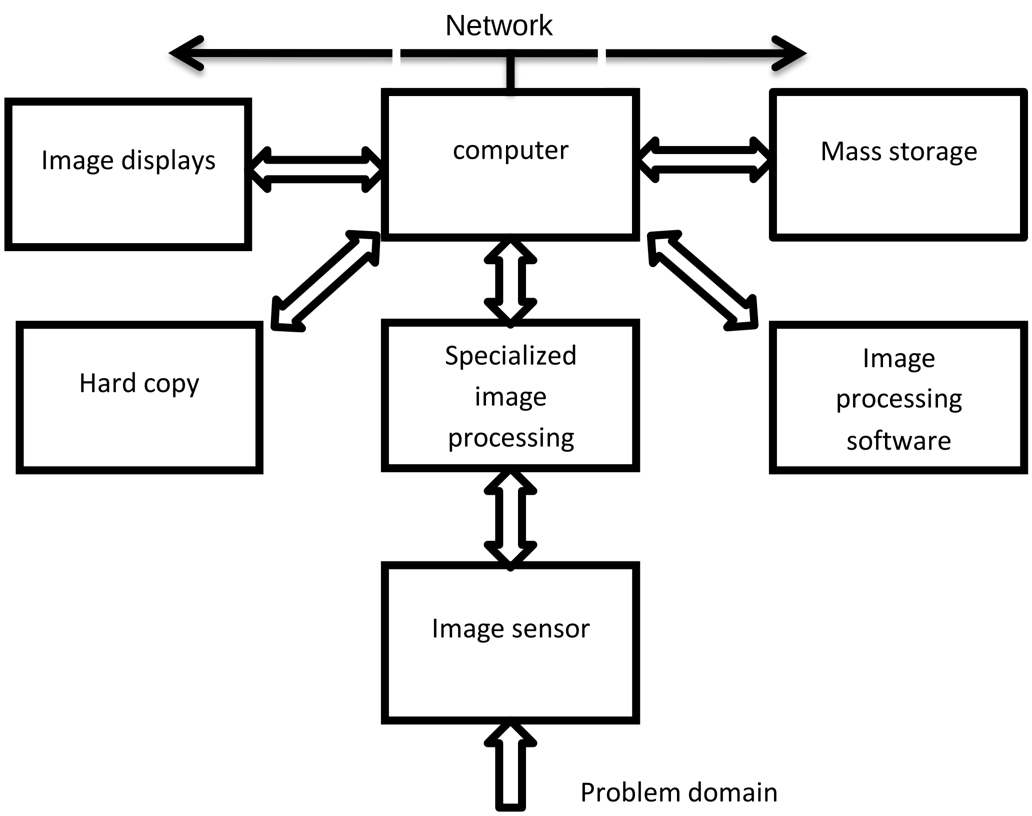

Fig 3.10 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

  Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in ―jukeboxes‖ are the usual media for archival applications.

- **Image displays:**

Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in \{0, . . ., GL - 1\}$, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i, j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‗d' apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‗d' apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‗d' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL}-1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(i; j) = Pr((up; vNp) = (i; j))$$

$$mcmLU(i; j) = Pr((lp; uNp) = (i; j))$$

$$mcmLV(i; j) = Pr((lp; vNp) = (i; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a $3 \cdot 3$ filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 \ \ if \ \ h \in [316,20] \\ 1 \ \ if \ \ h \in [21,40] \\ 2 \ \ if \ \ h \in [41,75] \\ 3 \ \ if \ \ h \in [76,155] \\ 4 \ \ if \ \ h \in [156,190] \\ 5 \ \ if \ \ h \in [191,270] \\ 6 \ \ if \ \ h \in [271,295] \\ 7 \ \ if \ \ h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \ \ if \ \ s \in [0,0.2) \\ 1 \ \ if \ \ s \in [0.2,0.7) \\ 2 \ \ if \ \ s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \ \ if \ \ v \in [0,0.2) \\ 1 \ \ if \ \ v \in [0.2,0.7) \\ 2 \ \ if \ \ v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

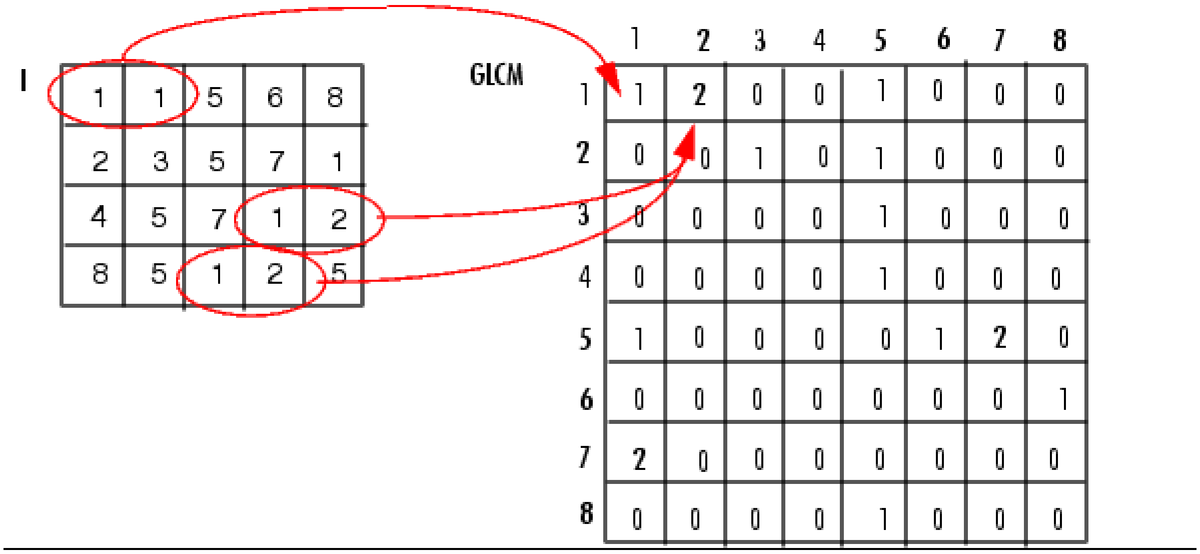
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google‘s Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



I
1 1 5 6 8
2 3 5 7 1
4 5 7 1 2
8 5 1 2 5
GLCM
1 2 3 4 5 6 7 8
1 1 2 0 0 1 0 0 0
2 0 0 1 0 1 0 0 0
3 0 0 0 0 1 0 0 0
4 0 0 0 0 1 0 0 0
5 1 0 0 0 0 1 2 0
6 0 0 0 0 0 0 0 1
7 2 0 0 0 0 0 0 0
8 0 0 0 0 1 0 0 0

Fig 3.11.1

CHAPTER 4

PROJECT IMPLEMENTATION:

4.0 IMPLEMNTATION STAGES:

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

```
A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]
```

MATLAB displays the matrix you just entered.

```
A =

   16    3    2   13

    5   10   11    8
```

9	6	7	12
4	15	14	1

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

4.0.1 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

4.0.2 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

Fig:4.0.2 Operators and precedence rules

4.0.3 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

Fig:4.0.3 Several special function

4.1 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

4.1.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

4.1.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

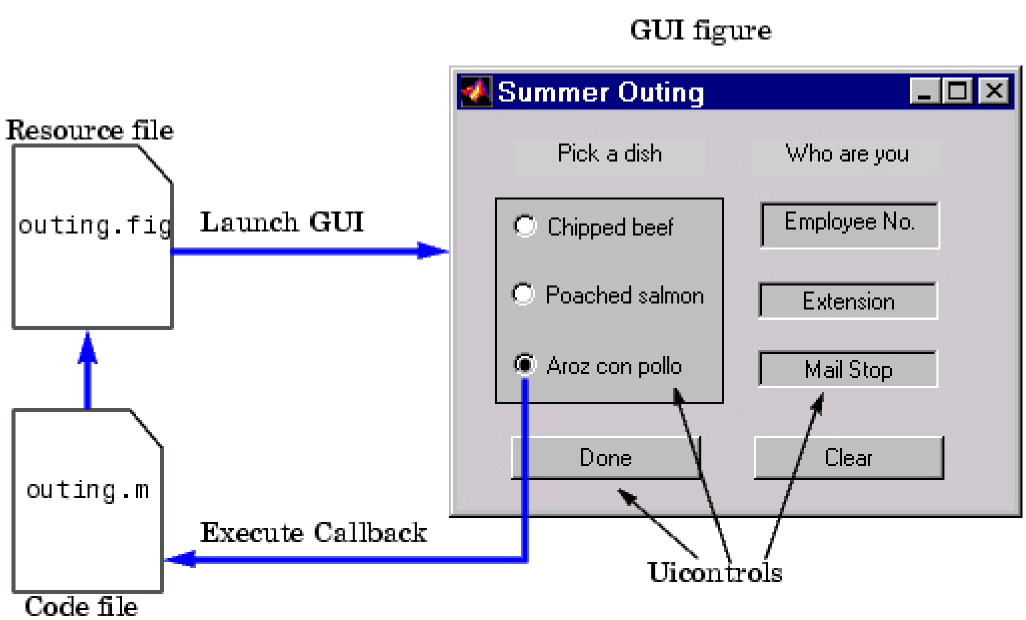


FIG 4.1.2 graphical user blocks

4.1.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

4.1.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

4.1.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');
```

```
if button_state == get(h,'Max')
   % toggle button is pressed
elseif button_state == get(h,'Min')
   % toggle button is not pressed
end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

   .

   .

   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

   % then checkbox is checked-take approriate action

else

   % checkbox is not checked-take approriate action

end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

   errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

4.1.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control

4.2 PROJECT CODE

```
%Studies on Different CNN Algorithms for Face Skin Disease
Classification Based on
%Clinical Images
close all
clear all

input_image = imread('p.png');
% Customerlized Mask
m = zeros(size(input_image,1),size(input_image,2));
m(20:120,20:120) = 1;
seg = CNN_Algorithms(input_image,m,500,0.1,'chan'); %
CNN_Algorithms
% Built-in Mask
seg = CNN_Algorithms(input_image,'medium',400,0.02,'chan'); %
ability on gray image
%-- End

%P = imread('p.png');
% Imnoise the original input
% input_image = P;
%I(:,:,1) = imnoise(I(:,:,1),'speckle');
%I(:,:,2) = imnoise(I(:,:,2),'salt & pepper');
figure(),subplot(1,2,1),imshow(input_image),title('original
image');
subplot(1,2,2),imshow(input_image),title('original image with
two components adding noise')

% Normal Chan & Vese cannot work
seg = CNN_Algorithms(input_image,'large',300,0.02,'chan');

% Chan & Vese for vector image works here
seg = CNN_Algorithms(input_image,'large',300,0.02,'vector');
% Using built-in mask = 'whole' leads faster and better
segmentation
seg = CNN_Algorithms(input_image,'whole',800,0.02,'vector');
% input_image = imread('p.png');
seg = CNN_Algorithms(input_image,'whole',100,0.1,'multiphase');

seg = CNN_Algorithms(input_image,'whole',400,0.2,'multiphase');
%-- End
```

PROJECT TESTING

5.0 OVERVIEW OF TESTING METHODS

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

5.0.1 Introduction - describes the components of the MATLAB system.

5.0.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

5.0.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

5.0.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5.0.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

5.1 DEVELOPMENT

ENVIRONMENT5.1.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

5.1.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

5.1.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

5.1.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

5.1.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

Chapter 6

CONCLUSION AND FUTURE ENCHANCEMENT

6.0 CONCLUSION:

- This paper performed experiments using five mainstream CNN structures for the clinical image diagnosis of six common facial skin diseases and constructed a data set consisting mainly of facial skin disease images.
- The results demonstrate that CNNs have the ability to recognize facial skin diseases. Based on our experiments, we determined that different models to diagnose diseases on different body parts should be used.
- Furthermore, our experiments also showed that a more reasonable network structure could improve the performance of the model. The performance of the current network structure has been satisfactory in some diseases, but the overall performance has yet to be improved.
- As a result, if we want that people to actually use this technique to check their face skin health in their daily life, specialized improvements should be developed.

6.1 FUTURE ENCHANCEMENT:

- In our opinion, the application of artificial intelligence techniques in the medical field is not sufficient, and the datasets from this field should be improved both in quantity and quality.
- With the increasing amount of facial image data of various skin diseases and the continuous improvement of the network structure, CNN-based facial skin disease diagnosis algorithms will continue to improve in performance.
- We believe that, in the future, patients will use convenient CNN-based applications to keep their face skin healthy.

PUBLICATION

Submitted Paper Conference ICISECT-21 with Paper ID (ICISECT21-0032) and got Acceptance for the Paper.

DECLARATION

We, the students of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **"IMAGE CONTRAST ENHANCEMENT IN AUTOMATIC MODE BY NONLINEAR STRETCHING"** is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for awardof any degree.

1) B.Shireesha(17K81A04J6)

2) K.Aruna(17K81A04L9)

3) Satish Kumar Nirala(17K81A04P3)

ACKNOWLEDGEMENT

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time to come.

We sincerely thank our project internal guide, **Dr.A.Anand**, **professor**, Department Of ECE and our class project coordinator **Ms. P. Pushpa, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our project guide **DR.A.ANAND, Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

1. B.Shireesha
2. K.Aruna
3. Satish Kumar Nirala

ABSTRACT

The problem of image enhancement in automatic mode is considered. A new method of contrast enhancement by adaptive nonlinear stretching using piecewise linear transformation of the brightness scale is proposed at which the average value of the brightness of transformed image is closest to the middle of the brightness range. The research of the effectiveness of the proposed and known methods of nonlinear stretching of monochrome images using the known no-reference metrics of integral contrast of image is carried out. Image enhancement is one of the most interesting and visually appealing areas of image processing. It involves operations such as enhancing contrast, reducing noise for improving the quality of the image. This paper presents an analysis of the mathematical morphological approach with comparison to various other state-of-art techniques for addressing the problems of low contrast in images. Histogram equalization (HE) is one of the common methods used for improving contrast in digital images.

LIST OF FIGURES

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Image enhancement is a preprocessing step in many image processing applications. The aim of image enhancement is to improve the interpretability or perception of information in images for human viewers, or to provide better input for other automated image processing techniques. There are various reasons for poor quality of an image such as distortion being introduced by the imaging systems, lack of expertise of the operator or the adverse external conditions at the time ofimage acquisition.

Mainly, Image enhancement includes intensity and contrast manipulation, noise reduction, edges sharpening and filtering, etc. Contrast Enhancement is focused on the problem of improving the contrast in an image to make various features more easily perceived. Contrast of an image is determined by its dynamic range, which is defined as the difference between lowest and highest intensity level. Contrast enhancement techniques have various application areas for enhancing the visual quality of low contrast images. Many contrast enhancement algorithms have been developed over the years. Contrast enhancement algorithms can broadly be divided into two categories: spatial domain techniques and frequency domain techniques.

In spatial domain techniques, the image enhancement is basedon direct manipulation of the pixels in an image. Frequency domain processing techniques are based on modifying the Fourier transform of an image. In frequency domain methods, the image is first transferred in to frequency domain. It means that, the Fourier Transform of the image is computed first. Allthe enhancement operations are then performed on the Fouriertransform of the image and then the Inverse Fourier transform is performed to get the resultant image.

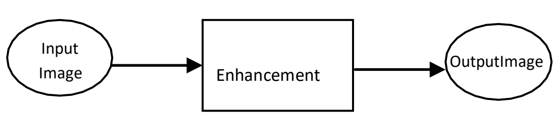

Fig 1.1: Image Enhancement

The problem of image enhancement in automatic mode is considered. A new method of contrast enhancement by adaptive nonlinear stretching using piecewise linear transformation of the brightness scale is proposed at which the average value of the brightness of transformed image is closest to the middle of the brightness range. The research of the effectiveness of the proposed and known methods of nonlinear stretching of monochrome images using the known no-reference metrics of integral contrast of image is carried out.

1.2 OBJECTIVES OF THE STUDY:

This project had been implemented by Adaptive non-linear stretching using piecewise transformation. It will enhance the image low to high contrast.

Contrast enhancement is one of the important research issues of image enhancement. There are many contrast enhancement methods which have been proposed in the literature. A very popular technique for image enhancement is histogramequalization (HE).But this technique is not much efficient to enhance small parts of an image so we are using adaptive non linear stretching. Some researchers havealso focused on improvement of histogram equalization based contrast enhancement such as adaptive non linear stretching which helps to enhance the contrast locally . Mathematical morphology is a relatively new approach to image processing and analysis.

(a) (b)

Fig 1.2 : Contrast Enhancement (a) A Low Contrast image (b) A High Contrast Image

Figure 2(b) shows the results of enhancing the contrast of the given image .

1.3 SCOPE OF THE STUDY:

The future of image processing will involve scanning the heavens for other intelligent life out in space. Also new intelligent, digital species created entirely by research scientists in various nations of the world will include advances in image processing applications.

Due to advances in image processing and related technologies there will be millions and millions of robots in the world in a few decades time, transforming the way the world is managed.

Advances in image processing and artificial intelligence6 will involve spoken commands, anticipating the information requirements of governments, translating languages, recognizing and tracking people and things, diagnosing medical conditions, performing surgery, reprogramming defects in human DNA, and automatic driving all forms of transport.

With increasing power and sophistication of modern computing, the concept of computation can go beyond the present limits and in future, image processing technology will advance and the visual system of man can be replicated.

The future trend in remote sensing will be towards improved sensors that record the same scene in many spectral channels. Graphics data is becoming increasingly important in image processing app1ications. The future image processing applications of satellite based imaging ranges from planetary exploration to surveillance applications.

Using large scale homogeneous cellular arrays of simple circuits to perform image processing tasks and to demonstrate pattern-forming phenomena is an emerging topic.

The cellular neural network is an implementable alternative to fully connected neural networks and has evolved into a paradigm for future imaging techniques. The usefulness of this technique has applications in the areas of silicon retina, pattern formation, etc.

1.4 MATERIAL REQUIREMENTS:

1.4.1 SOFTWARE REQUIREMENTS:

- Personal computer
- MATLAB Software

Matlab is a programming platform designed specifically for engineers and scientists to analyze and design systems and products that transform our world. The heart of MATLAB is the MATLAB language, a matrix-based language allowing the most natural expression of computational mathematics.

What Can I Do With MATLAB?

- Analyze data
- Develop algorithms
- Create models and applications

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

Image Processing is among rapidly growing technologies today, with its applications in various aspects of a business. Image processing is a method to convert an image into digital form and perform some operations on it, in order to get an enhanced image or to extract some useful information from it. It forms core research area within engineering and computer science disciplines too. In addition to applications in medicineand the space program, digital image processing techniques now are used in a broad range of applications. Computerprocedures are used to enhance the contrast or other features of the image for easier interpretation of x-rays and other images used in industry, medicine and the biological sciences .

Image enhancement is one of the most interesting and visuallyappealing areas of image processing. The basic idea behind image processing techniques is to make details more obvious or to simply highlight certain features of interest in an image. There are many aspects of images that are ambiguous and uncertain. Image enhancement operation improves the qualities of an image in terms of contrast, brightness characteristics, reduction of noise contents etc. Sometimes an image may be too dark containing blurredness and therefore it is difficult to recognize the different objects or scenery contained in the image. This type of image requires enhancement. A large number of image enhancement techniques exist for reducing image noise, highlighting edges, or displaying digital images. It is difficult to judge the effectiveness of these techniques due to various reasons such as the outcome depends on the exact application. An enhancement technique performing well in enhancing biomedical images may not be identically efficient in enhancing satellite images. Thus, the objective of image enhancement is dependent on the application context.

2.2 REVIEW ON RELATED LITERATURE:

M. Shakeri proposed a contrast enhancement algorithm based on local histogram equalization which was used to calculate the total sub-histograms automatically and their division based on their density. The algorithm worked in three stages. Initially, the estimation of the number of clusters for image brightness levels is done using histogram equalization. In the next stage, the image bright-ness levels are clustered and finally include the contrast enhancement for each individual cluster separately. The algorithm is com-pared with other methods based on quality and quantity measurement.

Lalit Maurya proposed a social spider optimization algorithm which produces two quality images one with better contrast, in-creased entropy and the second image with increased peak signal to noise ratio. Both the images are combined to get an effective image later. Comparisons were done with HE, Linear contrast stretching.

Standard Particle Swarm Optimization. Results show that the pro-posed method achieves better Peak signal to noise ratio, preserves brightness, enhances the contrast of any given image resulting a quality visual. Se EunKim worked upon wavelet domain using entropy for contrast enhancement. Initially it uses a local entropy scaling in the wavelet domain to obtain the desired contrast .mathematical works were used and then a color enhancing method in the HSI color space was developed. The algorithm worked in two steps: Modification of the low frequencies in the wavelet domain and scaling HIS color space by enhancing the intensity component such that low light images will get detailed color information without any post processing. Anil Singh Parihar proposes an entropy-based dynamic sub-histogram equalization algorithm for contrast enhancement with better intensity levels over the entire dynamic range. Parameters were not used. Results were compared with conventional contrast enhancement algorithms. Jeyong Shin proposed HBLPCE,an optimization problem to preserve the localities of the histogram for performing contrast enhancement. By this method the shape of the enhanced image re-mains the same as the original image. HBLPCE was quite successfull on all images with different statistical properties. Huang Lidong proposed an image enhancement method CLAHE-DWT which combines both CLAHE and DWT. The algorithm works in three stage.

2.3 CONCLUSION ON REVIEWS:

Image enhancement techniques change images to provide a better representation of the information encapsulated in the image. In this paper is presented a review for various fields of image enhancement. For every purpose like underwater imaging or medical images, there are different algorithms and techniques suitable for image enhancement. As we can see from this review paper, and also from other review papers, there is no universal image enhancement technique, the most important reason for that is the fact that there are a lot of different factors, for example, fogg in images and videos, or the fact that medical images are mostly grayscale images.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

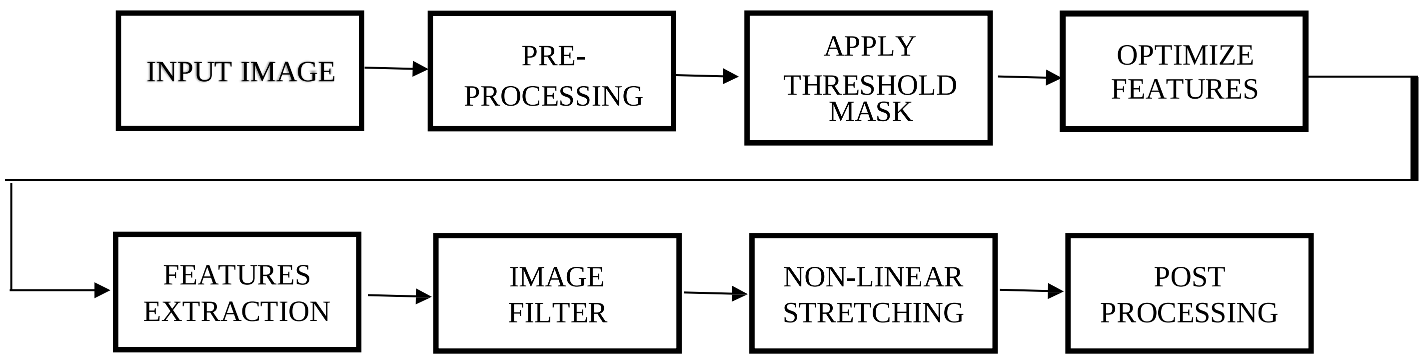

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 INTRODUCTION TO MATLAB:

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping

- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.3 THE MATLAB SYSTEM:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using image processing toolbox.

3.3.1 GRAPHICAL USER INTERFACE (GUI):

MATLAB’s Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

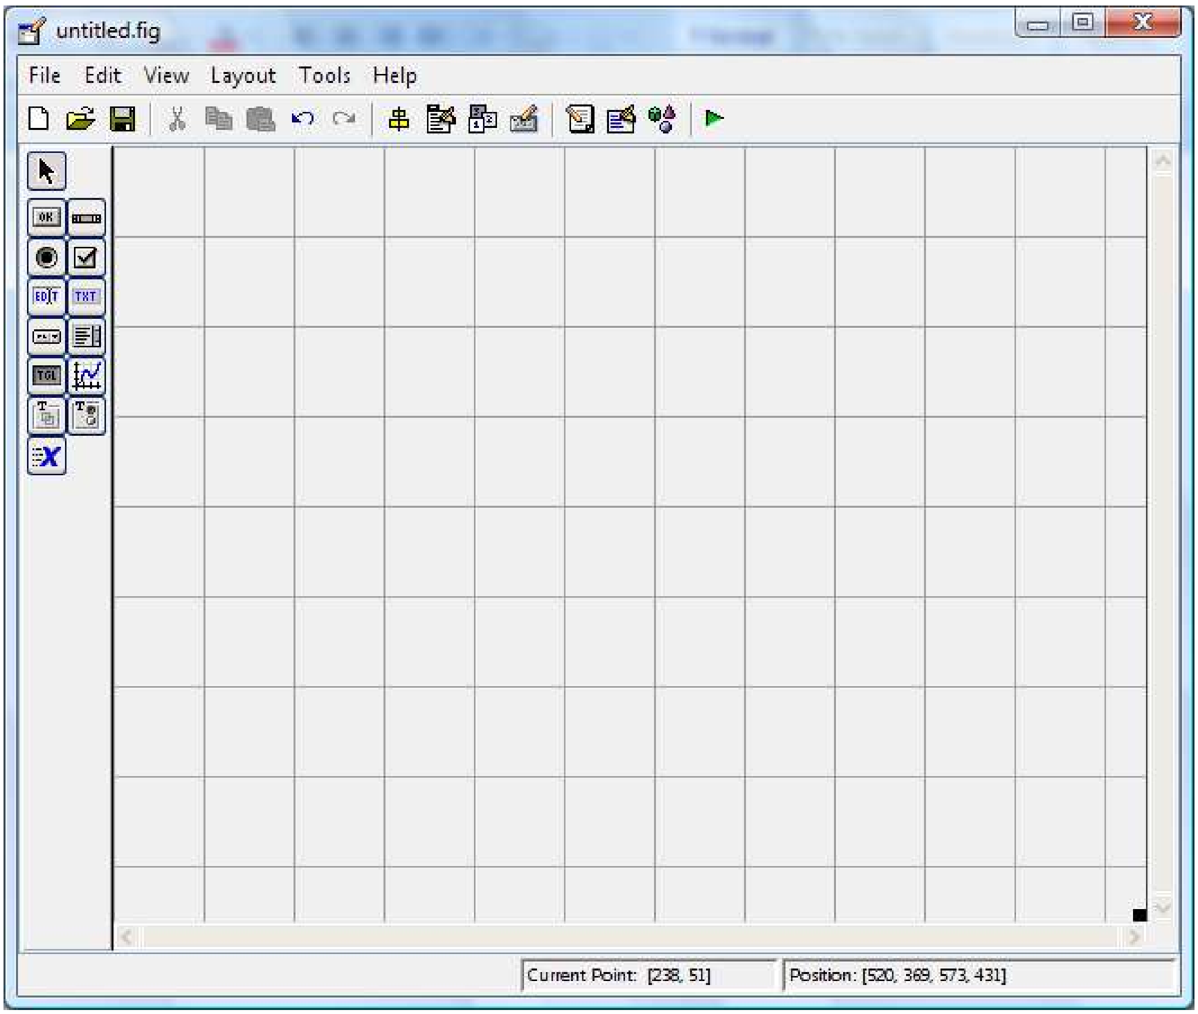
- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function’s GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 GETTING STARTED

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.4.1 Introduction - describes the components of the MATLAB system.

3.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

3.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.5 DEVELOPMENT ENVIRONMENT

3.5.1 Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command

History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator- Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

3.6 MANIPULATING MATRICES

3.6.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =
   16    3    2   13
    5   10   11    8
    9    6    7   12
    4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

3.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard.

Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

3.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}

Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

3.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

3.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

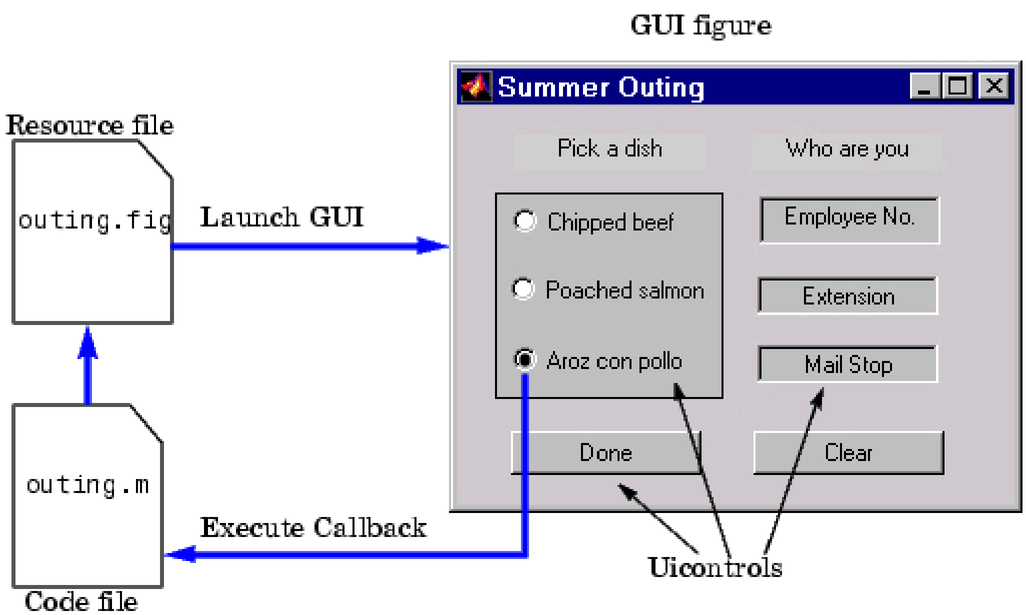


FIG 3.7.2 graphical user blocks

3.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

3.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes

- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)
button_state = get(h,'Value');
if button_state == get(h,'Max')
    % toggle button is pressed
```

```
elseif button_state == get(h,'Min')
   % toggle button is not pressed
end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);
a(:,:,2) = rand(16,128);
a(:,:,3) = rand(16,128);
set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)
set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)
off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];
mutual_exclude(off)
% Continue with callback
   .
   .
   .
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)
if (get(h,'Value') == get(h,'Max'))
   % then checkbox is checked-take approriate action
else
   % checkbox is not checked-take approriate action
end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)
user_string = get(h,'string');
```

% proceed with callback...

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)
user_entry = str2double(get(h,'string'));
if isnan(user_entry)
   errordlg('You must enter a numeric value','Bad Input','modal')
end
% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
switch val
case 1
% The user selected the first item
case 2
% The user selected the second item
% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)
val = get(h,'Value');
string_list = get(h,'String');
selected_string = string_list{val}; % convert from cell array to string
```

% etc.

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

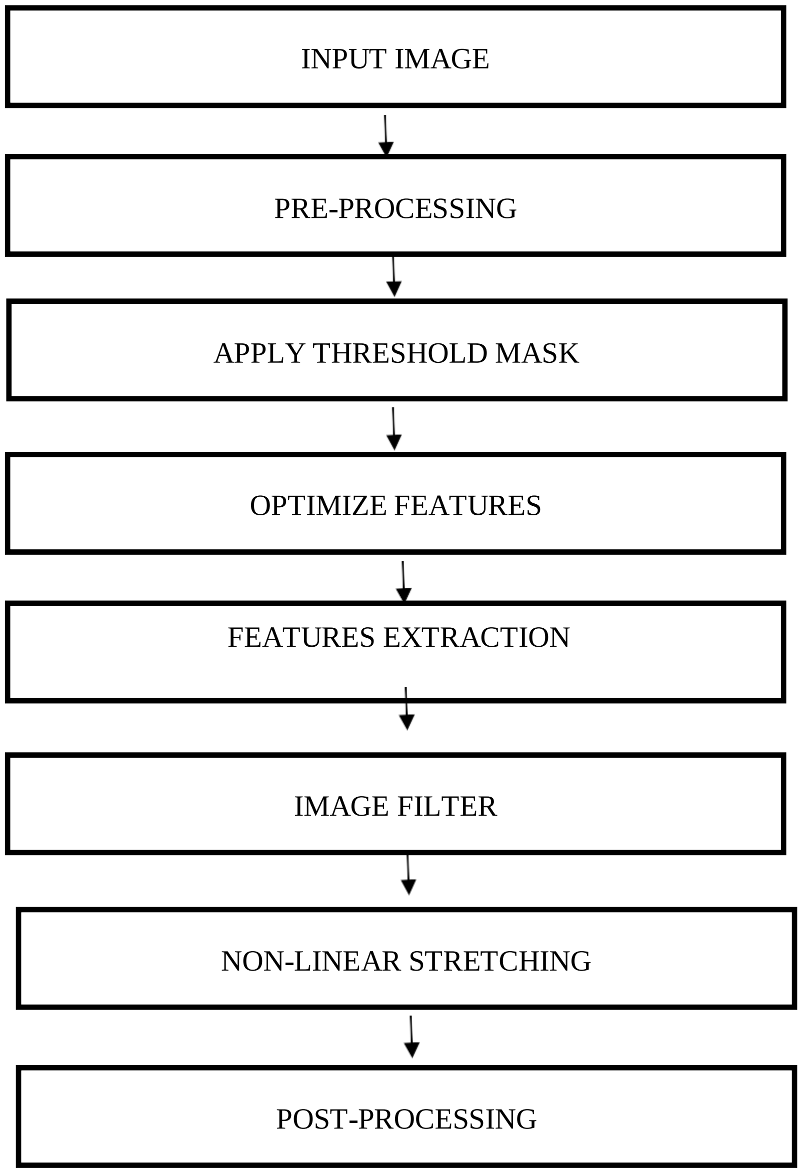

Fig.4.1: Block diagram of the project

4.1.1 INPUT IMAGE :

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

4.1.2 PRE-PROCESSING:

Image pre-processing is the name for operations on images at the lowest level of abstraction whose aim is an improvement of the image data that suppress undesired distortions or enhances some image features important for further processing. Image pre- processing use the redundancy in images.

4.1.3 APPLY THRESHOLD MASK:

Thresholds. Image thresholding is a simple form of image segmentation. It is a way to create a binary image from a single band or multi-band image. The process is typically done in order to separate "object" or foreground pixels from background pixels to aid in image processing.

4.1.4 OPTIMIZE FEATURES:

Optimizing web images is a process of delivering high-quality images in the right format, dimension, size, and resolution while keeping the smallest possible size. Image optimization can be done in different ways, be it by resizing the images, caching, or by compressing the size.

4.1.5 FEATURES EXTRACTION:

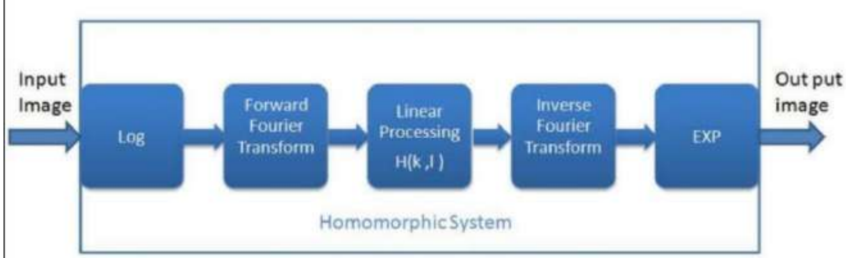
Feature extraction is a part of the dimensionality reduction process, in which, an initial set of the raw data is divided and reduced to more manageable groups. So when you want to process it will be easier. The most important characteristic of these large data sets is that they have a large number of variables. These variables require a lot of computing resources to process them. So Feature extraction helps to get the best feature from those big data sets by select and combine variables into features, thus, effectively reducing the amount of data. These features are easy to process, but still able to describe the actual data set with the accuracy and originality.

4.1.6 IMAGE FILTER:

An image filter is a technique through which size, colors, shading and other characteristics of an image are altered. An image filter is used to transform the image using different graphical editing techniques. Image filters are usually done through graphic design and editing software

4.1.6.1 HOMOMORPHIC FILTER

Homomorphic filtering is a generalized technique for signal and image processing, involving a nonlinear mapping to a different domain in which linear filter techniques are applied, followed by mapping back to the original domain.



4.1.7 NON-LINEAR STRETCHING:

Non linear stretching is the work horse for producing "pretty pictures" with astrophotography. This process completely destroys the data for any scientific use and is frowned upon by some purists. However, this is the only way to simultaneously show the faint and bright detail. Here's how to do it.

4.1.8 POST PROCESSING:

Image post processing enhances the quality of a finished image to prepare it for publication and distribution. It includes techniques to clean up images to make them visually clearer as well as the application of filters and other treatments to change the look and feel of a picture.

4.2 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 4.1.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

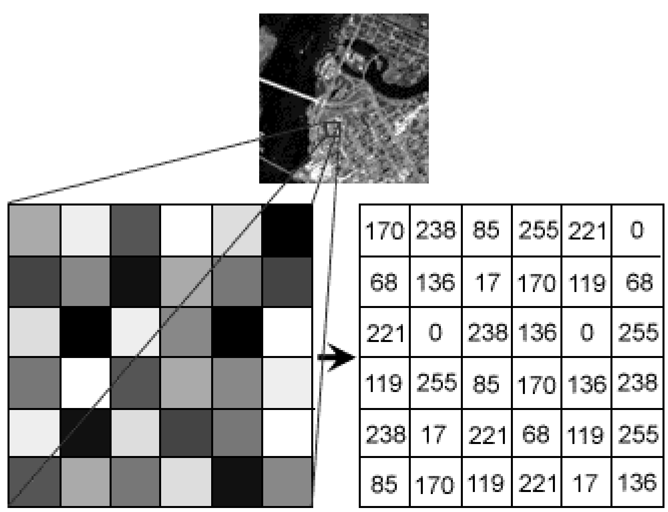


Fig 4.1.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

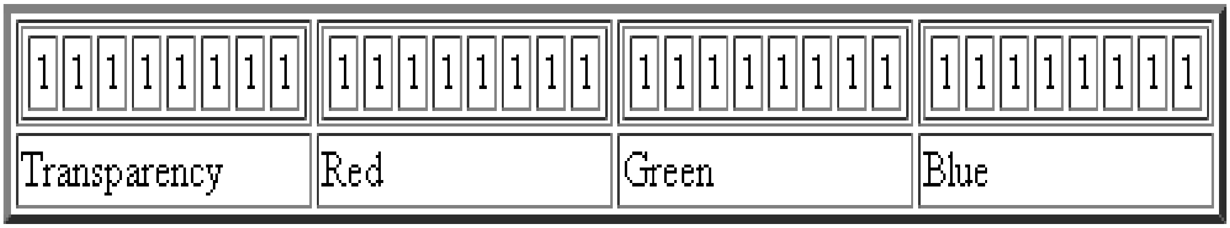

Fig 4.1.3. Transparency image

4.2.1 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

4.2.2 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

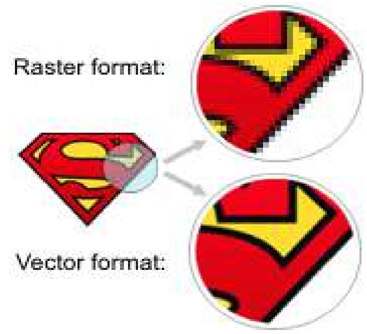

Fig4.1.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

4.2.3 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

4.2.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man’s ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

4.3 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

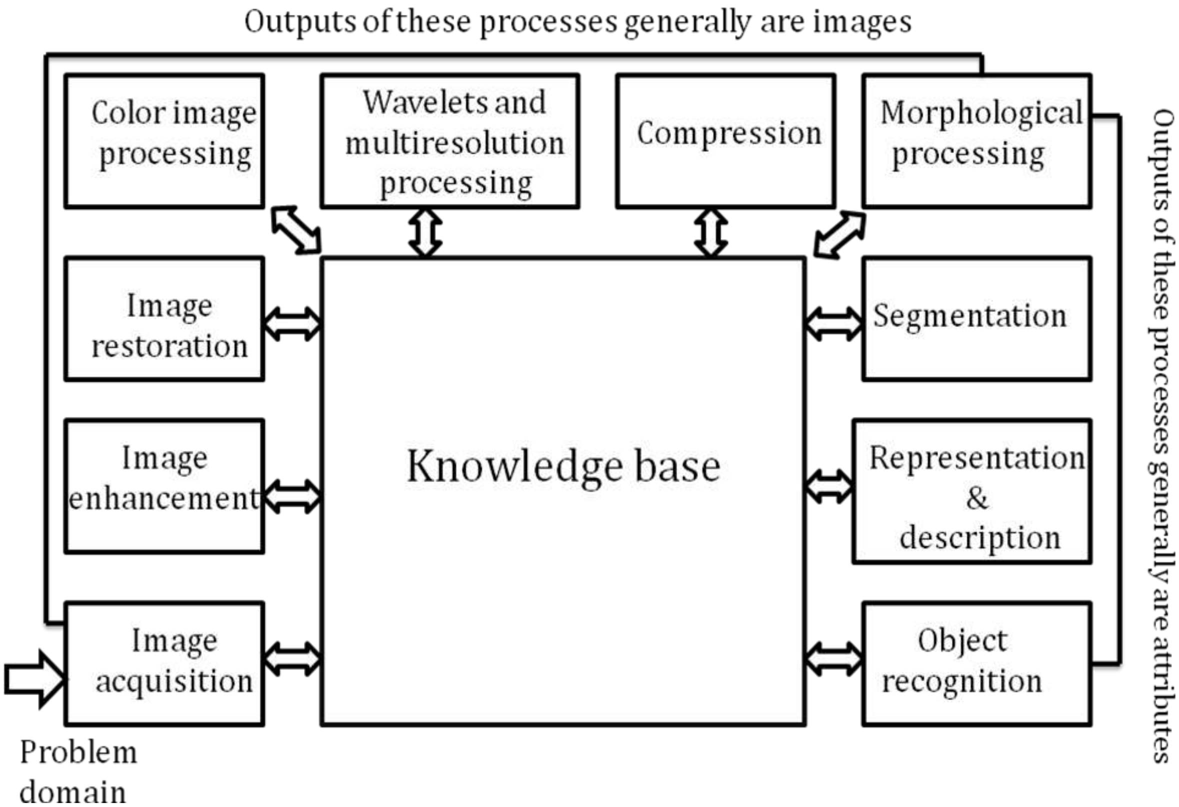

Fig 4.1.5 Image fundamental

4.3.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 4.1.6 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 4.1.7 digital camera cell

4.3.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 4.1.8 Image enhancement

4.3.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 4.1.9 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

4.3.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 4.1.10 Color & Gray scale image

4.3.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950’s, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

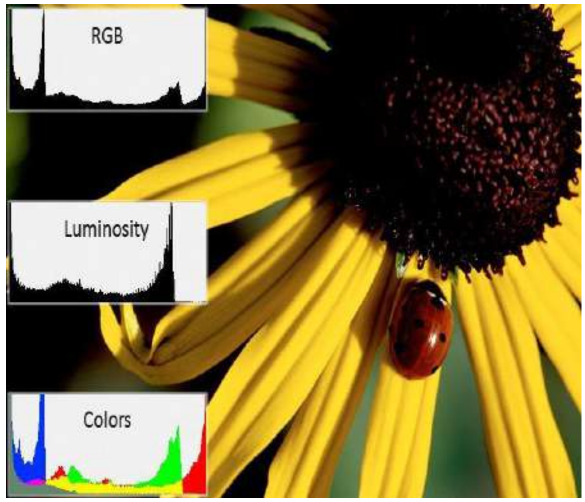

Fig 4.1.11 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

4.3.6 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 4.1.12 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

4.3.7 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

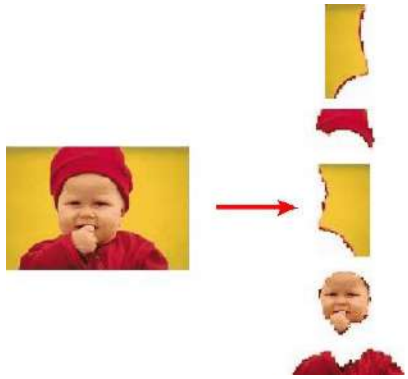

Fig 4.1.13 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

4.3.8 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

4.3.9 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

4.3.10 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

4.4 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

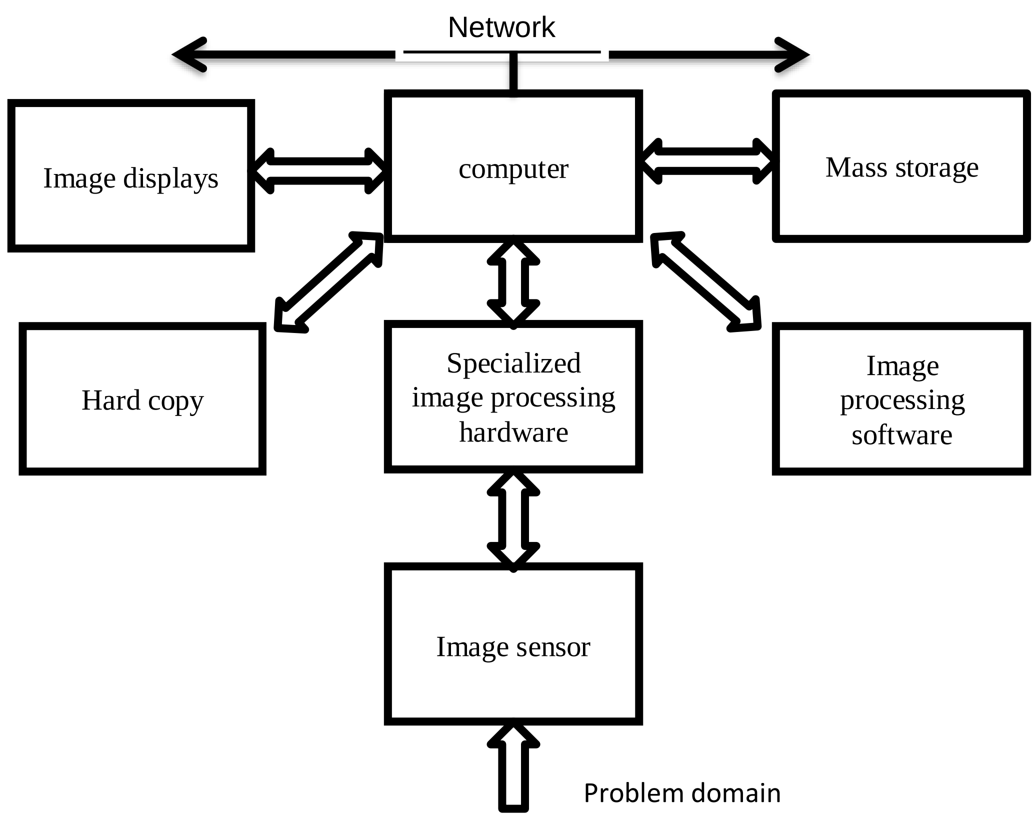

Fig 4.1.14 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

  With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

  Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

  One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image displays:**

  Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

  Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

  Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl∈{0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i,j) = \Pr((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i,j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance 'd' apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance 'd' apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance 'd' between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL}-1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i,j) = \Pr((\mathrm{hl}_\mathrm{p}, \mathrm{hl}_{N_\mathrm{p}}) = (i,j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

$$mcmUV(i; j) = Pr((up; vNp) = (i; j))$$

$$mcmLU(i; j) = Pr((lp; uNp) = (i; j))$$

$$mcmLV(i; j) = Pr((lp; vNp) = (i; j))$$

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

4.5 <u>NON INTERVAL QUANTIZATION:</u>

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V) In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then G = 9H+3S+V

$$H = \begin{cases} 0 \ \textit{if} \ \ h \in [316,20] \\ 1 \ \textit{if} \ \ h \in [21,40] \\ 2 \ \textit{if} \ \ h \in [41,75] \\ 3 \ \textit{if} \ \ h \in [76,155] \\ 4 \ \textit{if} \ \ h \in [156,190] \\ 5 \ \textit{if} \ \ h \in [191,270] \\ 6 \ \textit{if} \ \ h \in [271,295] \\ 7 \ \textit{if} \ \ h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \ \textit{if} \ \ s \in [0,0.2) \\ 1 \ \textit{if} \ \ s \in [0.2,0.7) \\ 2 \ \textit{if} \ \ s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \ \textit{if} \ \ v \in [0,0.2) \\ 1 \ \textit{if} \ \ v \in [0.2,0.7) \\ 2 \ \textit{if} \ \ v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

4.6 IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

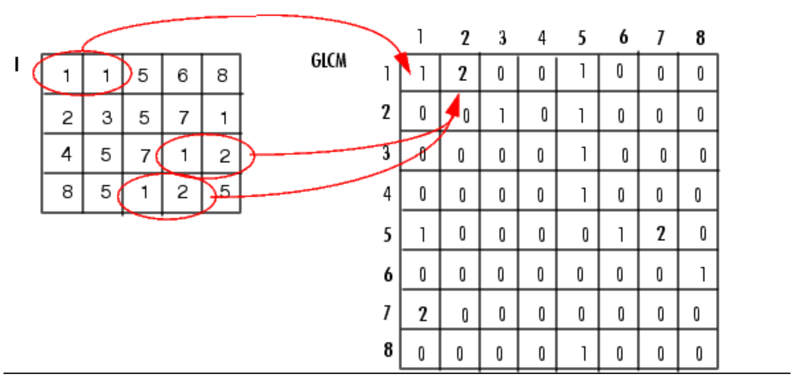
An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

4.7 <u>OVERVIEW OF TEXTURE:</u>

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:



4.8 FLOW CHART

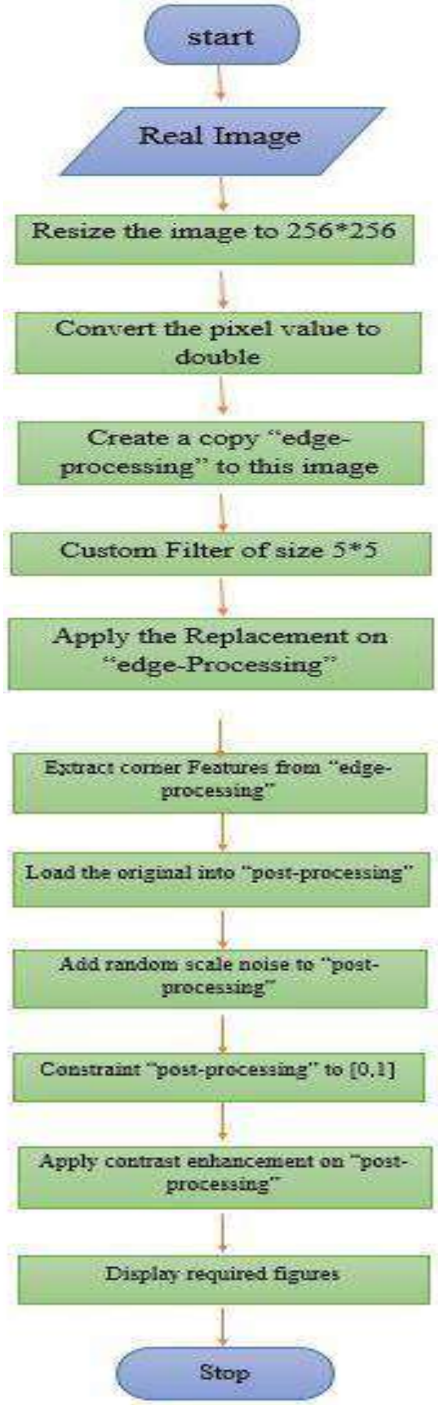


Fig.4.2 Flow Chart

4.8.1 START:

The 'start' parameter defines the starting centroids. The 'replicates' parameter indicates how many times to repeat the clustering. You only gave one set of starting values, so it doesn't know what to make of that.

4.8.2 REAL IMAGE:

This object is naturally suited to the representation of images, real-valued ordered sets of color or intensity data. MATLAB stores most images as two-dimensional matrices, in which each element of the matrix corresponds to a single discrete pixel in the displayed image.

4.8.3 RESIZE THE IMAGE 256*256:

Double is the default numeric data type (class) in MATLAB, providing sufficient precision for most computational tasks. Numeric variables are automatically stored as 64-bit (8-byte) double-precision floating-point values.

4.8.4 CONVERT THE PIXEL VALUE TO DOUBLE:

Double(s) converts the symbolic value s to double precision. Converting symbolic values to double precision is useful when a MATLAB function does not accept symbolic values. For differences between symbolic and double-precision numbers, see Choose Numeric or Symbolic Arithmetic.

4.8.5 CREATE A COPY ”EDGE PROCESSING” TO IMAGE:

Edges are one such feature. Edges are significant local changes in the image and are important features for analyzing images. An edge in an image is a significant local change in the image intensity, usually associated with a discontinuity in either the image intensity or the first derivative of the image intensity.

The edge function calculates the gradient using the derivative of a Gaussian filter. This method uses two thresholds to detect strong and weak edges, including weak edges in the output if they are connected to strong edges

4.8.6 CUSTOM FILTER OF SIZE 5*5:

Filters are data processing techniques that can smooth out high-frequency fluctuations in data or remove periodic trends of a specific frequency from data. In MATLAB, the filter function filters a vector of data x according to the following difference equation, which describes a tapped delay-line filter.

4.8.7 MEAN FILTER:

Median filtering is a nonlinear operation often used in image processing to reduce "salt and pepper" noise. A median filter is more effective than convolution when the goal is to simultaneously reduce noise and preserve edges.

4.8.8 VARIANCE FILTER:

V = var(A) returns the variance of the elements of A along the first array dimension whose size does not equal 1. If A is a vector of observations, the variance is a scalar. The variance is normalized by the number of observations -1 by default. If A is a scalar, var(A) returns 0.

4.8.9 APPLY THE REPLACEMENT ON ”EDGE-PROCESSING” :

newStr = replace(str , old , new) replaces all occurrences of the substring old with new . If old contains multiple substrings, then new either must be the same size as old , or must be a single substring.

After finding the mean and variance value we are replacing starting original pixel values with respect to the minimum value.

4.8.10 EXTRACT CORNER FEATURES FROM ”EDGE-PROCESSING”

Examples

1.Extract Corner Features from an Image. Open Live Script. Read the image. I = imread('cameraman. tif');

2.Extract SURF Features from an Image. Open Live Script. Read image. I = imread('cameraman. tif');

3.Extract MSER Features from an Image. Open Live Script. Read image. I = imread('cameraman. tif');

Feature extraction for image data represents the interesting parts of an image as a compact feature vector.

...

Feature extraction techniques provided by Computer Vision Toolbox™ and Image Processing Toolbox™ include:

1.Histogram of oriented gradients (HOG)

2.Speeded-up robust features (SURF)

3.Local binary pattern (LBP) features.

4.8.11 LOAD THE ORIGINAL INTO ”POST-PROCESSING” :

load (filename,'-mat',variables) loads the specified variables from filename. S = load (_) loads data into S, using any of the input arguments in the previous syntax group. If filename is a MAT-file, then S is a structure array. If filename is an ASCII file, then S is a double-precision array containing data from the file.

Load the original image into post-processing and normalize it.

4.8.12 ADD RANDOM SCALE NOSE TO ”POST-PROCESSING” :

J = imnoise(I ,'speckle') adds multiplicative noise using the equation J = I+n*I

where n is uniformly distributed random noise with mean 0 and variance 0.05.

Image noise is random variation of brightness or color information in images, and is usually an aspect of electronic noise. .... Image noise is an undesirable by-product of image capture that obscures the desired information.

4.8.13 CONSTRAINT TO ”POST-PROCESSING” TO [0,1] :

Constraints limit the set of x over which a solver searches for a minimum. You can have any number of constraints, which are inequalities or equalities. All Optimization Toolbox optimization functions minimize an objective function. To maximize a function f, apply an optimization routine to minimize –f.

In mathematical optimization, constrained optimization (in some contexts called constraint optimization) is the process of optimizing an objective function with respect to some variables in the presence of constraints on those variables.

4.8.14 APPLY CONTRAST ENHANCEMENT ON ”POST-PROCESSING” :

One of the important techniques in digital image processing is to enhance images. Contrast enhancement is a method that is used to enhance images for viewing process or for further analysis of images. Main idea behind contrast enhancement techniques is to increase contrast and to preserve original brightness of images. In this paper a contrast enhancement technique is proposed that first segments histogram of image recursively and then applies Adaptive Gamma Correction with Weighting Distribution (AGCWD) Technique. The proposed technique is basically an improvement over AGCWD technique and aims to get better contrast enhancement and brightness preservation than AGCWD technique. The image enhancement is one of the significant techniques in digital image processing. It has an important role in various fields where images are to be understood and analyzed. Image enhancement is done on an image to improve its visual effects and quality or to make it more appropriate for further processing by another application. An image can have low contrast or bad quality due to a number of reasons like poor quality of imaging device, adverse external conditions at the time of image acquisition and many more. The contrast enhancement is one of the commonly used image enhancement method .

Enhance the image using the three contrast adjustment techniques. pout = imread('pout. tif'); pout_imadjust = imadjust(pout); pout_histeq = histeq(pout); pout_adapthisteq = adapthisteq(pout); Display the original image and the three contrast adjusted images as a montage.

4.8.15 DISPLAY REQUIRED FIGURES:

To display image data, use the imshow function. The following example reads an image into the workspace and then displays the image in a figure window using the imshow function. moon = imread('moon. tif'); imshow(moon);

4.8.16 STOP:

To stop execution of a MATLAB command, press Ctrl+C or Ctrl+Break. On Apple Macintosh platforms, you also can use Command+

4.9 IMPLEMENTATION STAGES:

4.9.1 IMPLEMENTATION STAGES ON IMAGE 1:

Stage-1: original image with low contrast and high noise .

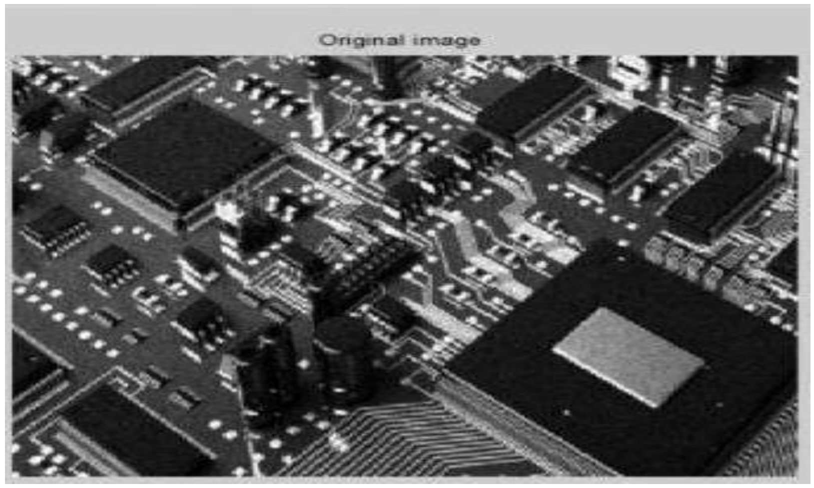

Fig 4.3.1 original image

Stage-2: processing image under goes many stages like contrast enhancement,so this contrast enhacement will produces an image that subjectively looks better than the original image by changing the pixel intensity.

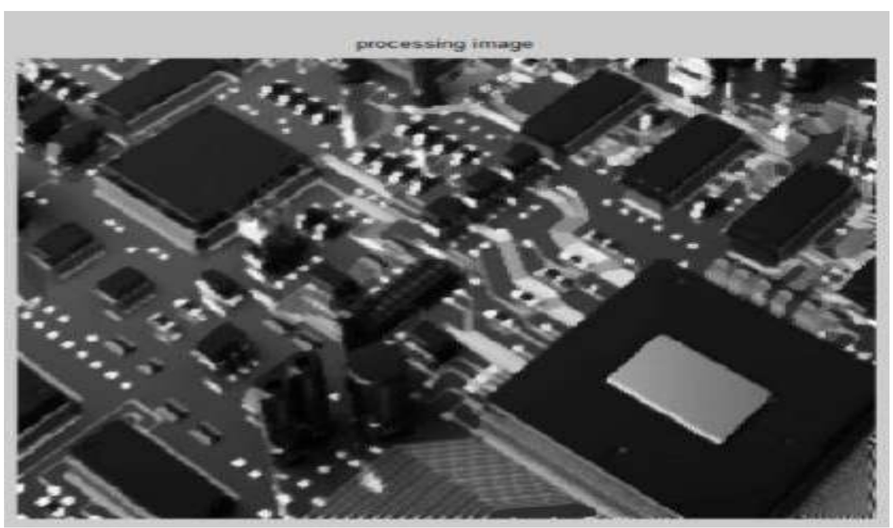

Fig.4.3.2 processing image

Stage-3: It is the output image by avoiding unwanted noise and low contrast and giving a high quality less noise and high contrast image.

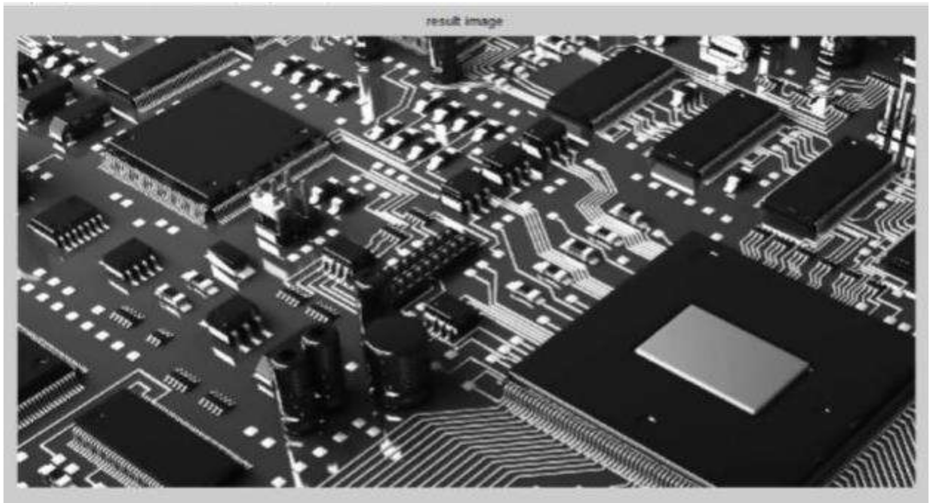

Fig.4.3.3 Result image

4.9.2 : IMPLEMENTATION STAGES ON IMAGE 2:

Stage-1: original image with low contrast and high noise .

Fig 4.3.4 original image

Step-2: Original image to gray scale image.

Fig 4.3.5 Original image to gray scale image

Stage-2: processing image under goes many stages like contrast enhancement,so this contrast enhacement will produces an image that subjectively looks better than the original image by changing the pixel intensity.

Fig 4.3.6 processing image

Stage-3: It is the output image by avoiding unwanted noise and low contrast and giving a high quality less noise and high contrast image.

Fig 4.3.7 Result image

CHAPTER-5
PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

This project proposes to investigate and test a number of image processing techniques that enhance the identification of persons in consumer digital images. The final product of the research in an integrated software tool that allows for :

- Image marking : load an image from the database and mark important features on it (e.g. faces). Save the location within the picture and the type of marking into the database.
- Algorithm Testing : automatically apply an image processing algorithm (e.g. face detection and recognition) to a set of marked images (only to those that meet a specific criteria)

This masters research in carried out as part of the “Tools and Algorithms to Assist in Automatically Recognizing and Deducing Information about People in Consumer Digital Images” Enterprise Ireland funded project

The Research Team

Dr. Peter Corcoran Mentoring Supervisor NUIG Dr. Dana Vasiloaica Research Supervisor Department of Business & Humanities, IT, Sligo. Mr. Collin Callanan Research Student Department of Business & Humanities, IT Sligo.

Project Details

Aims and Objectives of the proposed programme of research.

– Research into the following topics

– User Interface Design

– Software Testing

– Distributed Databases

Prepare a series of test image databases for testing and verification of the algorithms developed as part of the “Tools and Algorithms to Assist in Automatically Recognizing and Deducing Information about People in Consumer Digital Images” Project.

Develop automatic and semi automatic tools to facilitate the marking and categorisation of the images mentioned in Objective 2.

Process image data-sets to generate test-sets for specific algorithm verification and comparative evaluation test.

Develop batch tests to support the testing of algorithms.

Prepare user manual and help files to assist users in working with the image marking and algorithm testing software application.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

In this project the problem of operative (in real-time) image enhancement in automatic mode (with acceptable level of computational costs) for complex monochrome images was considered. The various known approaches to the image enhancement based on nonlinear statistical non-inertial transformations of image were considered. A new method of image enhancement by adaptive nonlinear stretching using piecewise linear transformation of the brightness scale was proposed at which the average value of the brightness of transformed image is closest to the middle of the brightness range. Research of the proposed and well-known histogram-based methods of image contrast enhancement in automatic mode was carried out using known no-reference contrast metrics. The proposed method of nonlinear stretching by adaptive piece-wise linear transformation of the dynamic range of image brightness provides an effective image enhancement for all test images without reducing the contrast of small-sized objects. The proposed method of adaptive nonlinear stretching provide effective contrast enhancement and can be recommended for image enhancement in automatic mode..

6.2 FUTURE ENHANCEMENT

The future of image processing will involve scanning the heavens for other intelligent life out in space. Also new intelligent, digital species created entirely by research scientists in various nations of the world will include advances in image processing applications.

APPENDICES

Histogram equalization is a method in image processing of contrast adjustment using the image's histogram.

A histogram which is zero apart from a central area containing strong peaks is transformed by stretching the peaked area to fill the entire x-axis.

Histograms of an image before and after equalization.

Spread out the frequencies in an image(or equalising the image) is a simple way to improve dark or washed out images.

The formula for histogram equalisation is given below

$$\boxed{\begin{aligned} s_k &= T(r_k) \\ &= \sum_{j=1}^{k} p_r(r_j) \\ &= \sum_{j=1}^{k} \frac{n_j}{n} \end{aligned}}$$

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research andproviding us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr.A.Anand, Professor** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for along time to come.

Finally, we are highly grateful and obliged to our project guide **Mr.V.V RAMANA RAO, Associate Professor,**for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co-operation that is difficult to express in words.

ABSTRACT

Car parking is a major issues in modern congested cities of today. There simply are too many vehicles on the road and not enough parking space. This has led to the need for efficient parking management systems. Thus we demonstrate the use of IOT based parking management system that allows for efficient parking space utilization using IOT technology. To demonstrate the concept we use IR sensors for sensing parking slot occupancy along with a dc motors to simulate as gate opener motors. We now use a WIFI modem for internet connectivity and an AVR microcontroller for operating the system. We use IOT Gecko for online connectivity and IOT management GUI design. The system detects if parking slots are occupied using IR sensors. Also it uses IR technology to sense if a vehicle has arrived on gate for automated gate opening. The system reads the number of parking slots available and updates data with the cloud server to allow for checking parking slot availability online. This allows users to check for available parking spaces online from anywhere and avail hassle free parking. Thus the system solves the parking issue for cities and get users an efficient IOT based parking management system.

TABLEOFCONTENTS

1

LIST OF TABLES

LISTOF FIGURES

GLOSSARY OF COMMONLY USED TERMS

ARRIVAL EXPERIENCE:

The arrival experience is the first impression customers/guests get after they have arrived. The moment the customer parks is the first experience he/she has with your service level. That is why it is so important to create a pleasant arrival experience.

(TRAFFIC) CONGESTION:

Congestion is also described as overcrowding or blockage. Traffic congestion occurs when the space of the road is not enough anymore to handle the amount of vehicles in traffic.

FLOATING PARKING SPACES:

Floating parking spaces are parking spaces that aren't marked with lines on the ground, for example along the street. Cars can freely park in a line depending on the size of the car. As floating parking spaces cannot be detected by ground sensors, Cleverciti works with overhead sensors that view the object, not the space.

INTERNET OF THINGS (IOT):

IoT refers to a system of objects that are interconnected and together make it possible to collect and transfer data over a wireless network without human intervention.

MULTIMODAL TRANSPORT:

Multimodal transport is the transportation of goods under a single contract(or), but performed with at least two different modes of transport.

ON-STREET PARKING:

On-street parking is parking by taking up room on the actual street alongside the curb, as opposed to parking in a parking garage or a designated parking lot.

OVERHEAD PARKING SENSORS:

Overhead parking sensors, unlike ground parking sensors, are mounted above parking areas to more efficiently analyze the individual cars below. This type of sensor uses AI and IoT technology while being conveniently mounted on existing lampposts or buildings.

PARKING ASSETS:

Assets are items of property owned by a person or a company, regarded as having value and available to meet debts, commitments, or legacies. With parking assets are meant: any assets that can be used for parking, such as surface parking lots, parking garages, on -street parking, etc.

PARKING CAPACITY / OCCUPANCY:

The parking capacity or occupancy is the measurement of the number of taken parking spots, preferably measured in real-time, so that data on how many parking spots are still free is available at any given time.

PARKING DATA:

Parking data is any data related to parking, e.g. parking occupancy, length of stay, specific rush hours in a region, average parking price, parking revenue generated.

PARKING GUIDANCE:

Parking guidance is a system that guides the driver to the best available parking space. The most reliable way to do this is with local digital signage.

PARKING REQUEST FOR PROPOSAL (RFP):

A parking request for proposal (RFP) is a public business document that announces and provides details about a parking project, as well as solicits bids from suppliers who will help complete the project. RFPs are commonly used by governments. RFPs usually don’t go into as much detail as tenders.

PARKING REVENUE:

Parking revenue is the revenue that is derived from the rental of parking space against a certain price.

(SMART) PARKING TENDER:

A (smart) parking tender is a formal, structured procedure for generating competing offers from different potential smart parking solutions providers.

PAYMENT COMPLIANCE:

Payment compliance is the inclination of drivers to pay for their parking spot when they are requested to do so. Cities around the globe struggle to increase parking payment compl iance.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

As quote says" why walk when drive " that is when journey on wheels started and which has created hard ongoing problem to park vehicles into parking slots.in urban cities as population is going on increasing the production of vehicles has also increased but parking space available has become congested to park N number of vehicles out of that people are finding it a great problem to search the available space during peak hours and festive times which consumes lot of energy and waste valuable time which is a major drawback, in order to replace the above issue.

Internet of things was first introduced in 1999 at auto ID center and first used by Kevin Aston. As evolving this latest burning technology, it promises to connect all our surrounding things to a network and communicating with each other with less human involvement. Still internet of things is in its beginning stage and there is no common architecture exists till today. There is lot of research and implementations are currently being going on in all the respective areas. Thus there is no guidelines or boundaries exists to define the definition of internet of things. So depending on the context, application the internet of things has different definitions.

Some smart applications which it has implementing currently such as on smart grids, smart lighting, smart energy, smart city, smart health etc. This is broadly classified into three categories such as sensing, processing and connectivity. Whereas sensing includes sensing the speed of vehicles and humans or any objects (accelerometer), sensing of temperature, pressure etc. [9]. And these can be processing by using some processors such as network processor, hybrid processor MCU/MPU etc. And the devices are connected by using some technologies called GPS, Wi-Fi, BT/BTLE, RFID etc.

1.2 OBJECTIVES OF THE STUDY:

The main objectives of this project Industrial Protection Systems are:

i. It is to reduces the risk of finding the parking slots in any parking area.

ii. These connected devises are called as smart devices. or smart objects.

iii. It consists of smart machines which communicating interacting with other machines, environment, objects etc.

iv. It incorporates to connect any two machines, machine to human and vice versa etc.

v. IOT technology grows in various fields of smart applications but we have not yet found boundary constraints of this technology.

vi. IoT, in general consists of inter-network of the devices and physical objects, number of objects can gather the data at remote locations and communicate to units managing, acquiring, organizing and analyzing the data in the processes and services.

vii. It provides a vision where things (wearable, watch, alarm clock, home devices, surrounding objects with) become smart and behave alive through sensing, computing and communicating by embedded small devices which interact with remote objects or persons through connectivity.

viii. It eliminates the unnecessary travelling of vehicles across the filled parking slots in a city.

1.2.1 Specific Objectives

i. The devices could be tracked, controlled or monitored using remote computers connected through Internet.

ii. IoT extends the use of Internet providing the communication, and thus inter-network of the devices and physical objects, or ‘Things’.

iii. The two prominent words in IoT are “internet” and “things”. Internet means a vast global network of connected servers, computers, tablets and mobiles using the internationally used protocols and connecting systems.

iv. Internet enables sending, receiving, or communicating of information. To interface LM35 temperature sensor, GSM SIM800l Modem, 16X2 LCD, and process control devices (through relays) with the Arduino UNO.

v. These factors gave rise to the amalgamation of both technologies thus leading to the formation of a new technology called Cloud of Things (CoT).

vi. Due to high scalability in cloud any number of nodes could be added or removed from the IoT system on a real time basis.

vii. In simple terms IoT can be explained in form of an equation stating.

1.3 SCOPE OF THE STUDY:

The scope for this project is to adopt this automatic Smart Parking System (SPS) so that availability of spaces could be displayed on a smart phone Application or even to satellite navigation device so that drivers will always aware of whether there are free spaces are not. And also enhance to send some notifications to users smart phone when vehicle enters to particular shopping places and some streets in a city etc.The smart car parking system is expected to be significantly influenced by the arrival of automated vehicles(AVs).several cities around the world are already beginning to trial self-parking vehicles,specialized AV parking iots, and robotic parking valets. Here, there is no need of man. The circuit itself checks the presence of vehicle and automatically closes the gate by rising an alarm. Once we switch on the circuit, it automatically performs all these actions without man handling. It is the most advantage of this project. For this reason, in future, this project may be used in railways and also in apartments, military, etc. Future car collision-avoidance systems may be smart phone based. You could stick your cell phone on the dashboard, and it would use to provide the feedback needed by the system.

1.4 Significance of the project

i. Time saved,43% reduction in time spent looking for a parking space and reduction in traffic volumes in build-up areas.

ii. Decreased searching for spaces can reduce accidents by ensuring drivers maintain their attention rather than browsing for spaces for making rash manoeuvres.

1.5 MATERIAL REQUIREMENT:

1.5.1 HARDWARE REQUIREMENT:

- Arduino UNO
- LCD
- Power Supply
- IR Sensor
- Servo motor

1.5.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.6 PROCUMENT OF EQUIPMENT:

About hardware pursuing…………………

Assembling it…………….

Connecting to Arduino…………

Coding is done in ide…………

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

Parking scheduling is converted into an off-line problem. The offline problem is described as a linear problem. The linear problem was solved using an algorithm. Finally, experimental simulations were done. However, this paper does not deal with the guiding of vehicles. Paper proposes a solution for parking lot based on wireless sensor network and radio-frequency identification (RFID). The paper however does not deal with a large-scale parking lot. Paper has proposed a parking system based on ZigBee network. Here, a web service is used to collect information about the parking space. Our approach is based on 8051 type microcontroller that is Arduino microcontroller, Arduino runs with Arduino IDE application that should be installed in system. We do simple embedded C code in microcontroller and directly put it into the Arduino system. We do simple embedded C code in microcontroller and directly put it into the Arduino microcontroller. Hence, it works according to code system keeps track of number of cars entered in parking building. The counting will be display using liquid crystal display board.

This project introduces the concept of using IoT and Cloud based technology in car parking services in cities. A high-level view of the proposed system is outlined. Our solution makes the ancient parking system smarter by leveraging the power of IoT and embedding it with the latest innovation of electronic sensors & computers. An IoT-based intelligent car parking system is described. A number of software solutions, including Python, PHP web gateway with MySQL database, Cloud based storage and mobile applications, are proposed to provide pleasant parking experience to mobile users. Also, Data generated by the sensors, Image detection cameras and mobile application will be used to gain insights by storing it in cloud foundry and applying Big Data analytics using Hadoop.

2.2 REVIEW ON RELATED LITERATURE:

Car parking issue is a major contributor and has been yet a noteworthy issue with limited parking spots in urban communities. In this paper we present an IoT based smart parking system for large parking lot that can be used to efficiently manage the parking system by providing information on the nearest parking slot available through the mobile application and thereby reducing the congestion of parking seekers. In order to efficiently manage the parking system, a successful cloud-based smart parking system solution using the Internet of Things technology is been developed to guide the user to the nearest parking spot available.

TRAFFIC a direct or an indirect outcome of many minor issues has been creating havoc for an individual especially in urban areas. This paper proposes an architecture that introduces an efficient and eminent; rather a smart way to resolve the small module that actually counts i.e. Parking Area. We design a system so as to eliminate the time wastage and irrelevant frustration faced by the drivers based on IoT for real time monitoring of the empty slots for car parking from anywhere using a webpage or a mobile app; IoT the emerging research domain is the heart of the proposed system. Traditional parking systems are very dependent on manual labors and possess multiple problems. A long time to find available parking slot, a big amount of cost to pay parking staffs, and unavailability of parking data are some of the most common problems in this parking system. In this paper, we propose an Internet of Things (IoT) based smart parking system that has three main components, which are an application for parking management, application for parking users, and IoT platform. The IoT platform consists of two different granularities, which are in each parking slot and in each parking lot. IoT hardware in parking slot will send information regarding the slot status, and IoT hardware in parking lot will send information regarding any car that goes in or out. To reduce the number of sensors, crowd sensing from parking users and parking staffs is used. This proposed design is implemented in the case study of X University. We conduct an evaluation for the implemented system and receive multiple feedbacks from parking system staffs and parking users. Using the System Usability scale, we receive a score of 91 from parking system staffs and 80.14 from parking users. This evaluation result shows that the proposed IoT-based parking system is helpful and easy to use for parking staffs and users.

In the current decade we are facing parking problem with the advancement in the technology. The population in urban cities is dense due to which lots of vehicles are running on road leads to parking problem, traffic problem. World is facing new challenge of Car parking. It is observed that one million of vehicles consumes oil on daily basis. In this paper, an automatic real-time system for automated car parking is proposed. This system is implemented with the help of internet of things (IOTs). IOT generally exchanges information or data between the two physical devices. Arduino Uno is a microcontroller used in proposed system. The main use of Arduino in the proposed system is to provide platform to communicate digital devices and interactive objects that can sense and control physical devices. The proposed system is implemented with the help of Arduino Uno board for car parking and Node MCU to connect parking area with web or internet. The proposed system incorporated with an infrared sensor in each slot for getting information about vacancy position of parking slot. The user book parking slot well in advance, all the necessary information is available on server. Every user has exclusive username and password. In case any misuse happened then the system will alert the responsible person.

Traditional parking systems are very dependent on manual labors and possess multiple problems. A long time to find available parking slot, a big amount of cost to pay parking staffs, and unavailability of parking data are some of the most common problems in this parking system. In this paper, we propose an Internet of Things (IoT) based smart parking system that has three main components, which are an application for parking management, application for parking users, and IoT platform. The IoT platform consist of two different granularities, which are in each parking slot and in each parking lot. IoT hardware in parking slot will send information regarding the slot status, and IoT hardware in parking lot will send information regarding any car that goes in or out. To reduce the number of sensors, crowdsensing from parking users and parking staffs is used. This proposed design is implemented in the case study of X University. We conduct an evaluation for the implemented system and receive multiple feedbacks from parking system staffs and parking users. Using the System Usability scale, we receive a score of 91 from parking system staffs and 80.14 from parking users. This evaluation result show that the proposed IoT-based parking system is helpful and easy to use for parking staffs and users.

Since all people used vehicles as a necessity, the growing number of vehicles is increasing day by day. With the increasing number of vehicles on the road, the requirement of parking lot will also be restricted. Thus, it become a problem for the people to find a free parking space in the busy building especially in shopping complex. Internet of Things (IoT) is an interesting technology that can be applied in this paper because this technology has a capability to transfer the data over a network without requiring human intervention in almost all applications in today's society. In this paper, a user-friendly mobile application, named as Android-based Car Parking Monitoring System (ACPMS) is built to aid in locating a particular parking place. ACPMS can provide a user with the ability to check vacant parking space and locate the nearest parking lot. ACPMS obtained the parking location from the current user's position with the sensor located in the shopping complex's parking lot. ACPMS is testing in a realistic environment for the purpose of movement detection and location service to notify user using the mobile application. By considering seven test case scenarios, the combination of the ACPMS mobile application with a parking prototype kit shows that the proposed work able to solve the parking problem.

Nowadays, technology has become more reliable that allowed human interaction to decrease while the machines have started to take over in many fields of interest. The Internet of things (IoT) represents the idea of machines ability to control entire systems without any human interactions. This paper proposes an IoT system that takes a picture of parked cars in a garage, extract the plate number and the location of the car, and places this information in a database. At the garage entrance, a terminal linked to the system allows the user to locate the parked car using the license plate no. The system is tested for reading license plates several times, and is shown to perform with a low probability of error. The proposed IoT parking system is an integrated system combining the RPi operating system Motion Eye, with MATLAB segmentation code for character recognition, database tools, as well as web services all in order to make the user interface as friendly as possible.

A simple and easy task such as parking is thought as a tedious and time-consuming process due to mismanagement of parking system. Current parking systems involve huge manpower for management and requires user to search for parking space floor by floor. Such conventional systems utilize more power, along with user's valuable time. This paper presents a Smart Parking Energy Management solution for a structured environment such as a multi-storied office parking area. The system proposes implementation of state-of-the-art Internet of Things (IoT) technology to mold with advanced Honeywell sensors and controllers to obtain a systematic parking system for users. Unoccupied vehicle parking spaces are indicated using lamps and users are guided to an empty parking space, thus eliminating need for searching for a parking space. The occupied parking spaces are virtually stored to the cloud to be accessed by central system and direct the upcoming cars to empty spaces. The automatically controlled light illuminance helps reduce energy usage, along with lighting up the parking space to the user whilst in the parking space. The entire system being fully automatic leads to reduced manpower involved and improves illuminance aesthetics of the parking area. This paper aims at improving user's time value and convenience in a parking system.

2.3 CONCLUSION ON REVIEWS:

In recent times the concept of smart cities have gained grate popularity. Thanks to the evolution of Internet of things the idea of smart city now seems to be achievable. Consistent efforts are being made in the field of IoT in order to maximize the productivity and reliability of urban infrastructure.

Problems such as, traffic congestion, limited car parking facilities and road safety are being addressed by IoT. In this paper, we present an IoT based cloud integrated smart parking system. The proposed Smart Parking system consists of an on-site deployment of an IoT module that is used to monitor and signalize the state of availability of each single parking space. A mobile application is also provided that allows an end user to check the availability of parking space and book a parking slot accordingly. The paper also describes a high-level view of the system architecture. Towards the end, the paper discusses the working of the system in form of a use case that proves the correctness of the proposed model.

One of the main problems in many big and crowded cities is finding parking spaces for vehicles. With IoT technology and mobile applications, in this paper, we propose a design and development of a real smart parking system that can provide more than just information about vacant spaces but also help user to locate the space where the vehicle can be parked in order to reduce traffics in the parking area. Moreover, we use computer vision to detect vehicle plate number in order to monitor the vehicles in the parking area for enhancing security and also to help user find his/her car when he/she forgets where the car is parked. In our system, we also design the payment process using mobile payment in order to reduce time and remove bottleneck of the payment process at the entry/exit gate of the parking area.

Internet of Things (IoT) plays an indispensable role in bridging the gap between all the day to day things to the networking system, and creates an ease to access all the un-internet things from any distant location. Adaption to the growth in the recent trends is inexorable for the people. With all the advancement in the technology, finding a particular place to park our automobile becomes an exasperating issue. In our work we have designed a Smart Car Parking System (SCPS) with the help of infrared sensor and a database based on application of Iot, which permits the driver to find the proximate parking slot, and gives the number of free places available in that respective parking zone. This ideology mainly focuses on diminishing the time involved in discovering the parking space and also it decreases the unwanted travelling, through filled parking slots in a parking arena. This will in turn reduce the consumption of fuel, which would reduce carbon footprints in our environment. Thus, this will pave way for an eco-friendly surrounding.

CHAPTER-3

PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

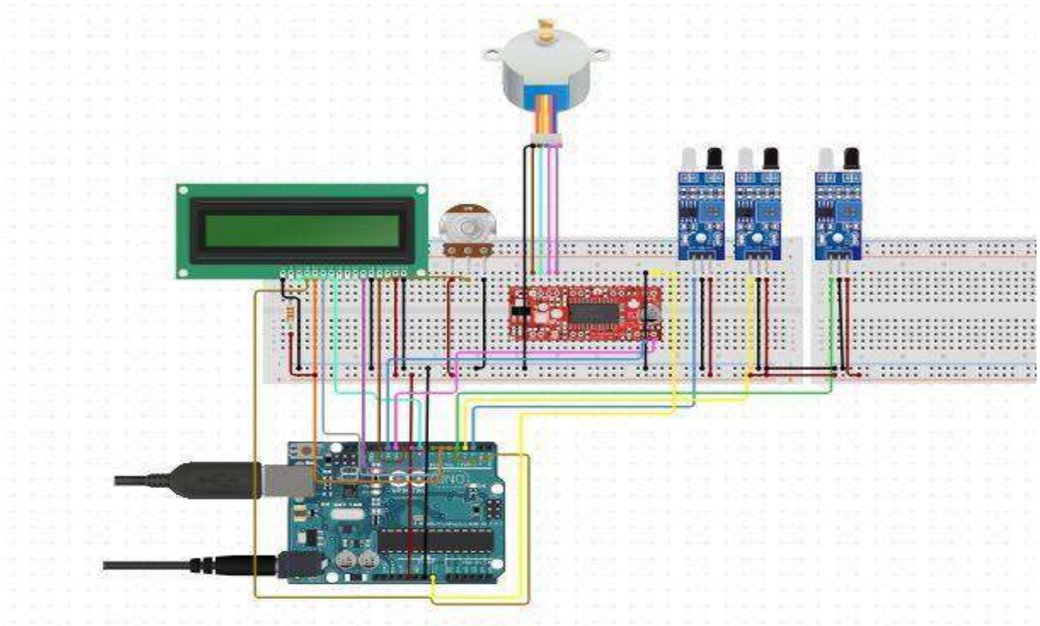

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

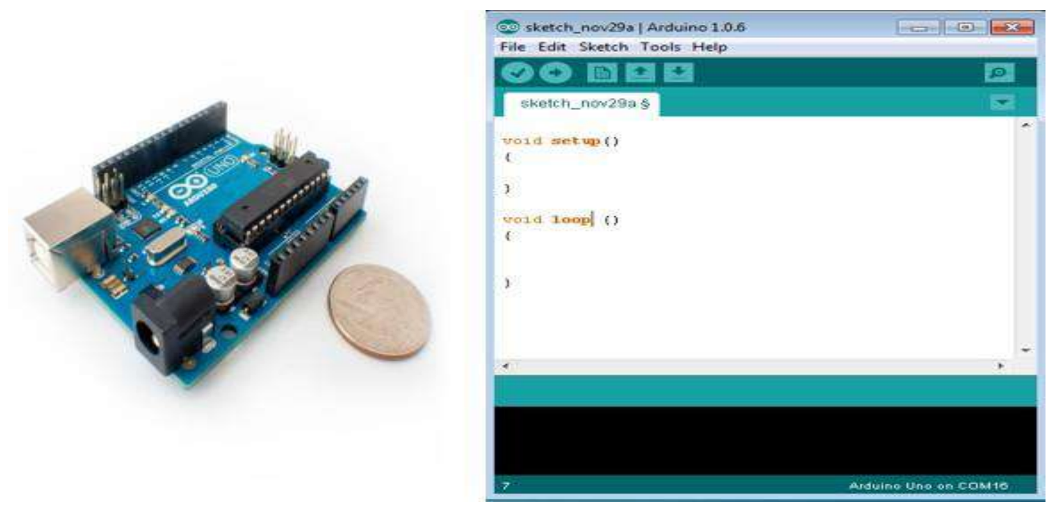

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs,

and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.
Here is a list of different Arduino boards available.

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

Table 3.2.1.2.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**
Arduino Leonardo	5V	16MHz	20	12	7	1	Native USB

Pro micro 5V/16MHz	5V	16MHz	14	6	6	1	Native USB
Pro micro 3.3V/8MHz	5V	16MHz	14	6	6	1	Native USB
LilyPad Arduino USB	3.3V	8MHz	14	6	6	1	Native USB

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

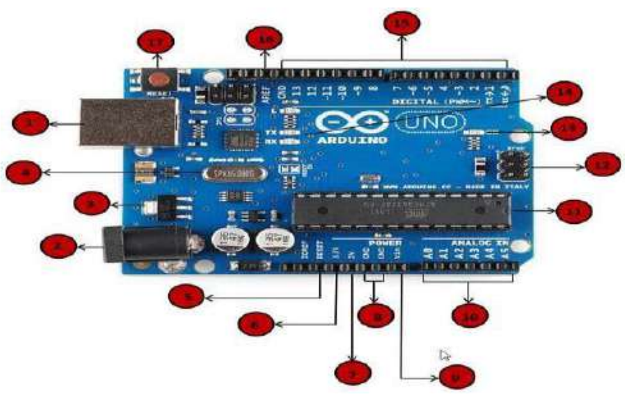

Fig.3.2.1.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC

	your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.3: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.4: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

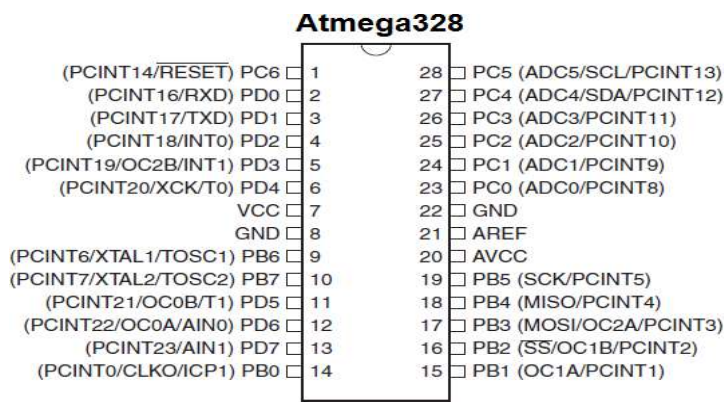

Fig.3.2.1.5 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

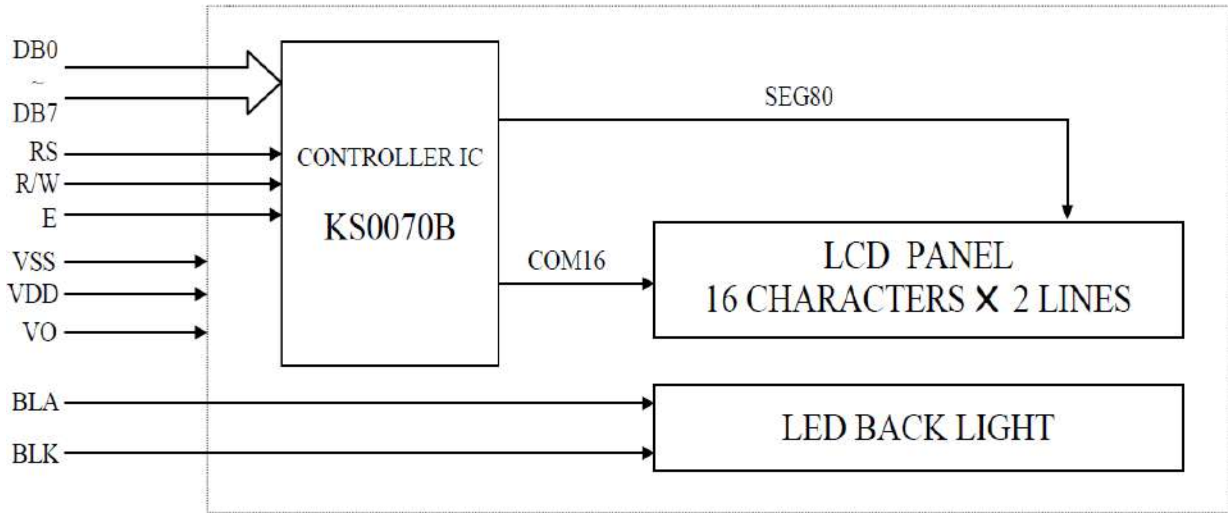

fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

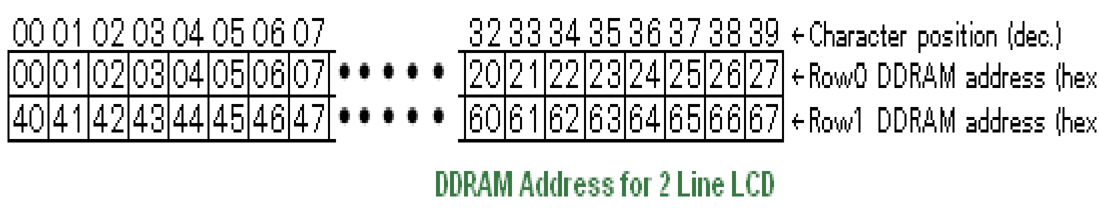

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD. Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing

- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 MOTOR

3.2.3.1 INTRODUCTION:

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
    - AC motor, an electric motor that is driven by alternating current
        - Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it
        - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction
    - DC motor, an electric motor that runs on direct current electricity
        - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
        - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
    - Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
    - Servo motor, an electric motor that operates a servo, commonly used in robotics
    - Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

3.2.3.2 SERVO MOTOR

A **servo motor** is a type of motor that can rotate with great precision. Normally this type of motor consists of a control circuit that provides feedback on the current position of the motor shaft, this feedback allows the servo motors to rotate with great precision. If you want to rotate an object at some specific angles or distance, then you use a servo motor. It is just made up of a simple motor which runs through a **servo mechanism**. If motor is powered by a DC power supply, then it is called DC servo motor, and if it is AC-powered motor then it is called AC servo motor. For this tutorial, we will be discussing only about the DC servo motor working**.** Apart from these major classifications, there are many other types of servo motors based on the type of gear arrangement and operating characteristics. A servo motor usually comes with a gear arrangement that allows us to get a very high torque servo motor in small and lightweight packages. Due to these features, they are being used in many applications like toy car, RC helicopters and planes, Robotics, etc.

Servo motors are rated in kg/cm (kilogram per centimetre) most hobby servo motors are rated at 3kg/cm or 6kg/cm or 12kg/cm. This kg/cm tells you how much weight your servo motor can lift at a particular distance. For example: A 6kg/cm Servo motor should be able to lift 6kg if the load is suspended 1cm away from the motors shaft, the greater the distance the lesser the weight carrying capacity. The position of a servo motor is decided by electrical pulse and its circuitry is placed beside the motor.

3.2.3.3 Servo Motor Working Mechanism

It consists of three parts:

1. Controlled device
2. Output sensor
3. Feedback system

It is a closed-loop system where it uses a positive feedback system to control motion and the final position of the shaft. Here the device is controlled by a feedback signal generated by comparing output signal and reference input signal.

Here reference input signal is compared to the reference output signal and the third signal is produced by the feedback system. And this third signal acts as an input signal to the control the device. This signal is present as long as the feedback signal is generated or there is a difference between the reference input signal and reference output signal. So the main task of servomechanism is to maintain the output of a system at the desired value at presence of noises.

3.2.3.4 Servo Motor Working Principle

A servo consists of a Motor (DC or AC), a potentiometer, gear assembly, and a controlling circuit. First of all, we use gear assembly to reduce RPM and to increase torque of the motor. Say at initial position of servo motor shaft, the position of the potentiometer knob is such that there is no electrical signal generated at the output port of the potentiometer. Now an electrical signal is given to another input terminal of the error detector amplifier. Now the difference between these two signals, one comes from the potentiometer and another comes from other sources, will be processed in a feedback mechanism and output will be provided in terms of error signal. This error signal acts as the input for motor and motor starts rotating.

Now motor shaft is connected with the potentiometer and as the motor rotates so the potentiometer and it will generate a signal. So as the potentiometer's angular position changes, its output feedback signal changes. After sometime the position of potentiometer reaches at a position that the output of potentiometer is same as external signal provided. At this condition, there will be no output signal from the amplifier to the motor input as there is no difference between external applied signal and the signal generated at potentiometer, and in this situation motor stops rotating.

3.2.3.5 Interfacing Servo Motors with Microcontrollers:

Interfacing hobby Servo motors like s90 servo motor with MCU is very easy. **Servos have three wires coming out of them**. Out of which two will be used for Supply (positive and negative) and one will be used for the signal that is to be sent from the MCU. An **MG995 Metal Gear Servo Motor** which is most commonly used for RC cars humanoid bots etc. The picture of MG995 is shown below:

The colour coding of your servo motor might differ hence check for your respective datasheet.

All servo motors work directly with your +5V supply rails but we have to be careful on the amount of current the motor would consume if you are planning to use more than two servo motors a proper servo shield should be designed.

3.2.3.6 Controlling Servo Motor:

All motors have three wires coming out of them. Out of which two will be used for Supply (positive and negative) and one will be used for the signal that is to be sent from the MCU.

Servo motor is controlled by PWM (Pulse with Modulation) which is provided by the control wires. There is a minimum pulse, a maximum pulse and a repetition rate. Servo motor can turn 90 degree from either direction form its neutral position. The servo motor expects to see a pulse every 20 milliseconds (ms) and the length of the pulse will determine how far the motor turns. For example, a 1.5ms pulse will make the motor turn to the 90° position, such as if pulse is shorter than 1.5ms shaft moves to 0° and if it is longer than 1.5ms than it will turn the servo to 180°.

Servo motor works on **PWM (Pulse width modulation)** principle, means its angle of rotation is controlled by the duration of applied pulse to its Control PIN. Basically servo motor is made up of **DC motor which is controlled by a variable resistor (potentiometer) and some gears**. High speed force of DC motor is converted into torque by Gears. We know that WORK= FORCE X DISTANCE, in DC motor Force is less and distance (speed) is high and in Servo, force is High and distance is less. The potentiometer is connected to the output shaft of the Servo, to calculate the angle and stop the DC motor on the required angle.

Servo motor can be rotated from 0 to 180 degrees, but it can go up to 210 degrees, depending on the manufacturing. This degree of rotation can be controlled by applying the **Electrical Pulse** of proper width, to its Control pin. Servo checks the pulse in every 20 milliseconds. The pulse of 1 ms (1 millisecond) width can rotate the servo to 0 degrees, 1.5ms can rotate to 90 degrees (neutral position) and 2 ms pulse can rotate it to 180 degree.

All servo motors work directly with your +5V supply rails but we have to be careful about the amount of current the motor would consume if you are planning to use more than two servo motors a proper servo shield should be designed.

3.2.3.7 Applications for servo motors

- Rotating stages for machine tools or inspection systems
- Control of presses
- Control of bonding machines
- Control of plastic moulding machines
- Control of amusement machines
- Radio control and other hobby applications
- Coating or vapor deposition machines
- Spin cleaning machines for LCDs and semiconductors

3.2.4 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.4.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing.

Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments.

All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.4.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments.

Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step-by-step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phi gets, MIT's Handy board, and many others offer similar functionality.

All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows. Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version.
Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money.
- Getting Started with Arduino and Genuine products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.4.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.4.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.4.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig.3.2.4.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

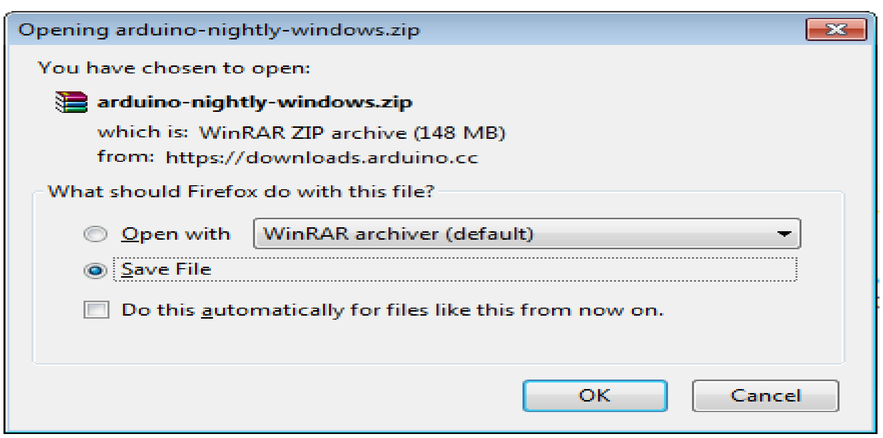

Fig.3.2.4.4.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

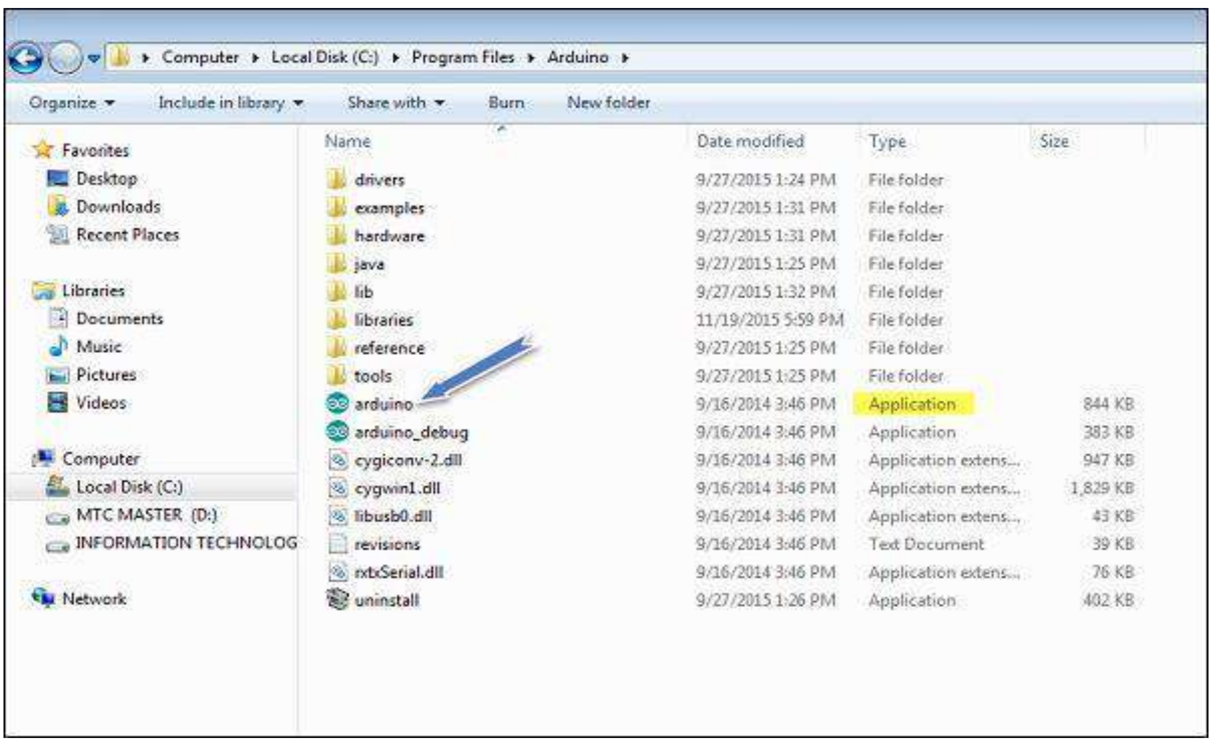

Fig.3.2.4.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

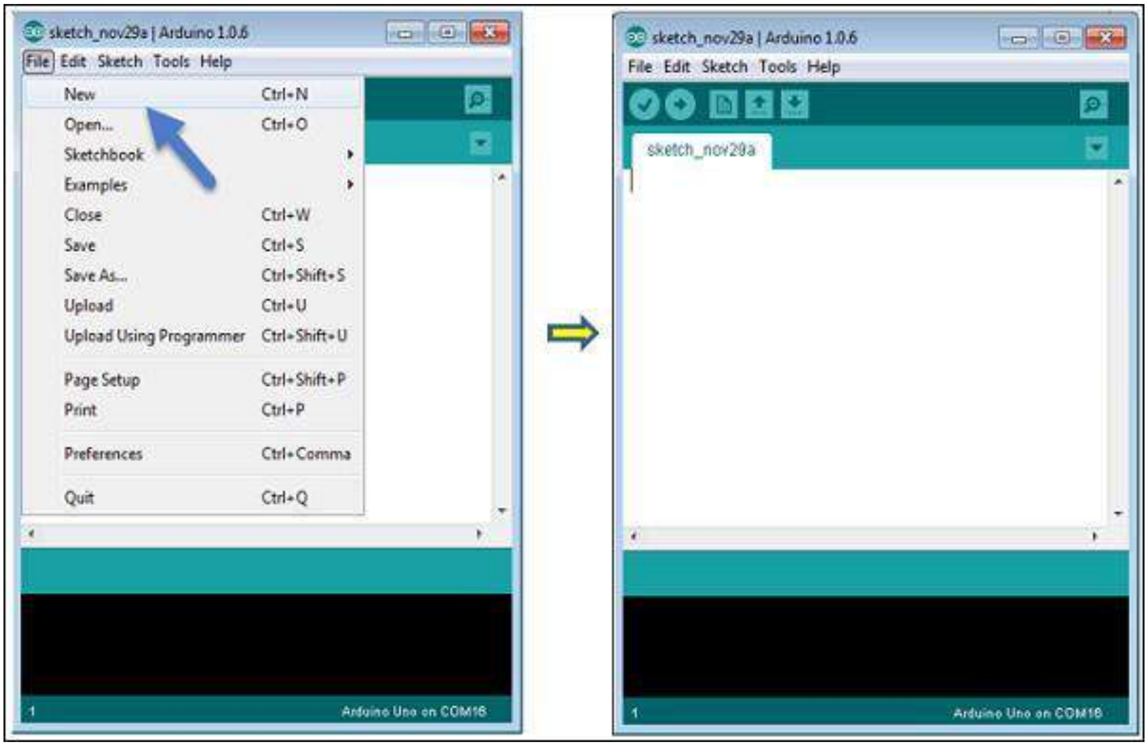

Fig.3.2.4.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

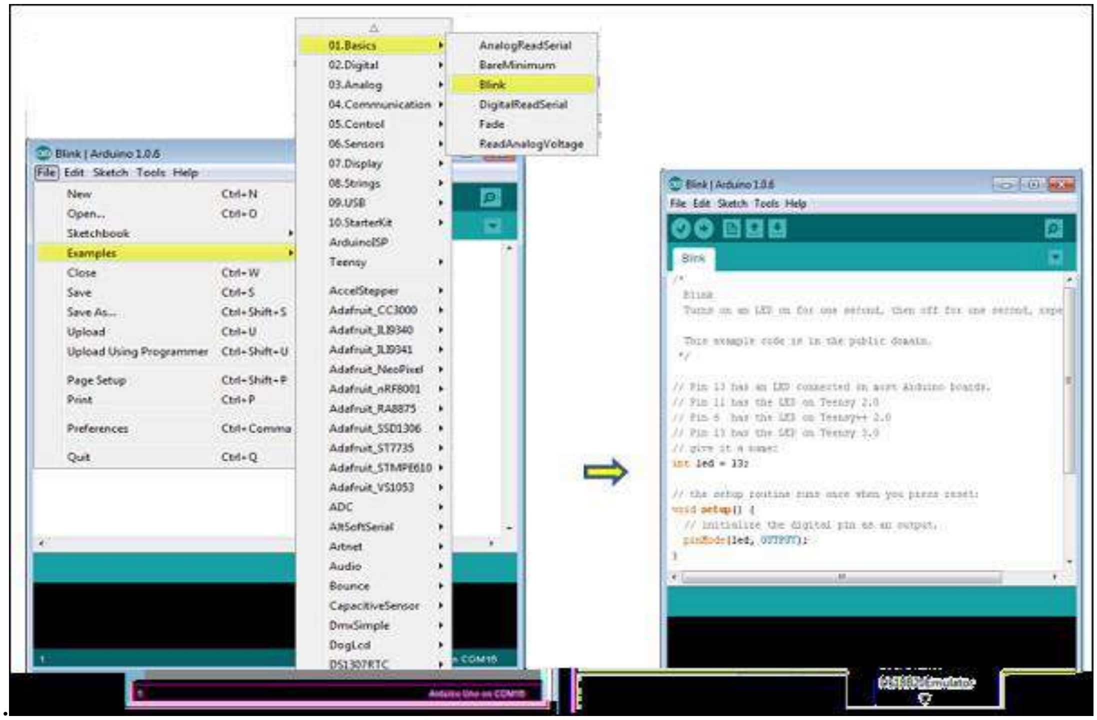

Fig.3.2.4.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

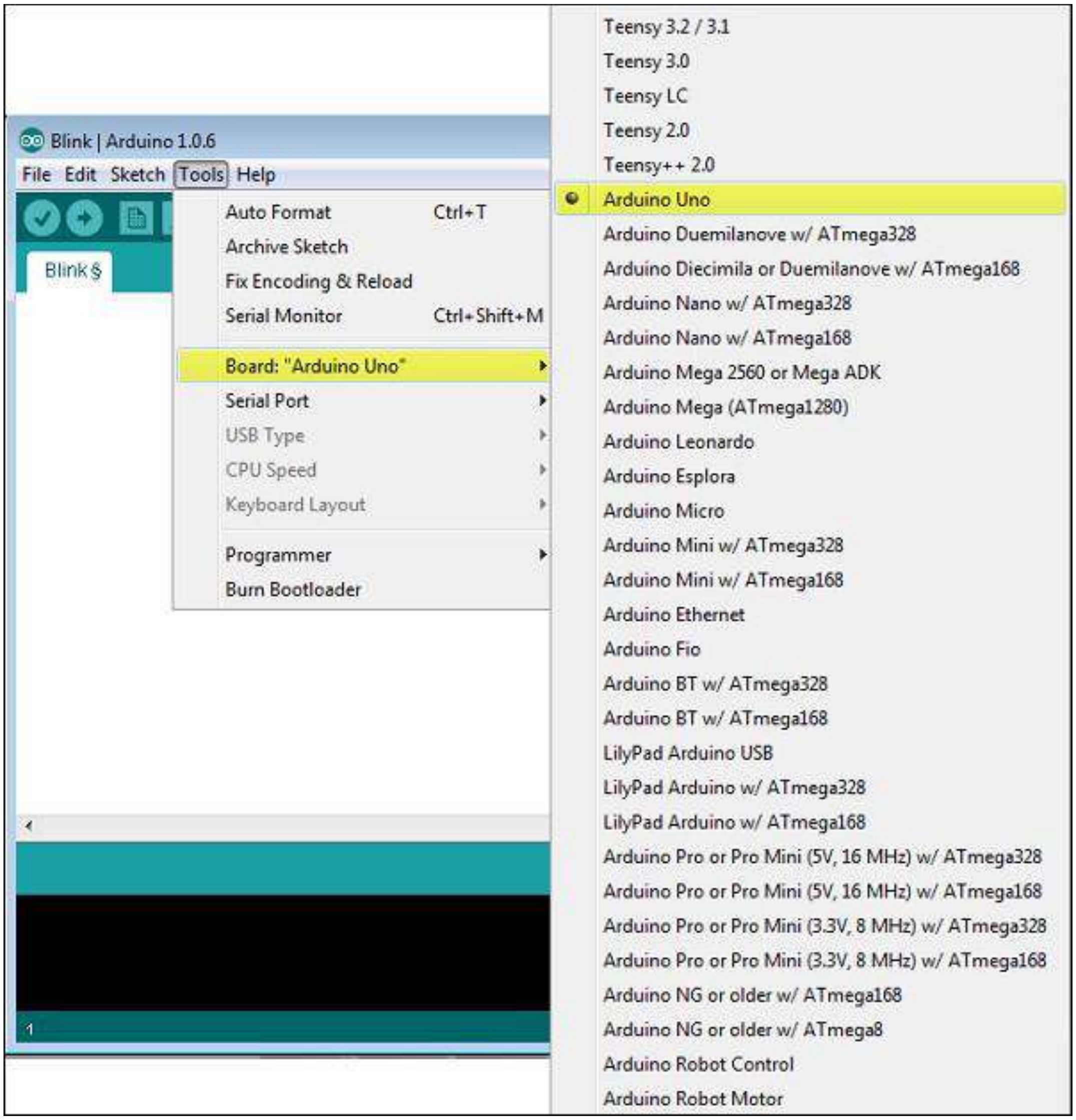

Fig.3.2.4.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 – Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

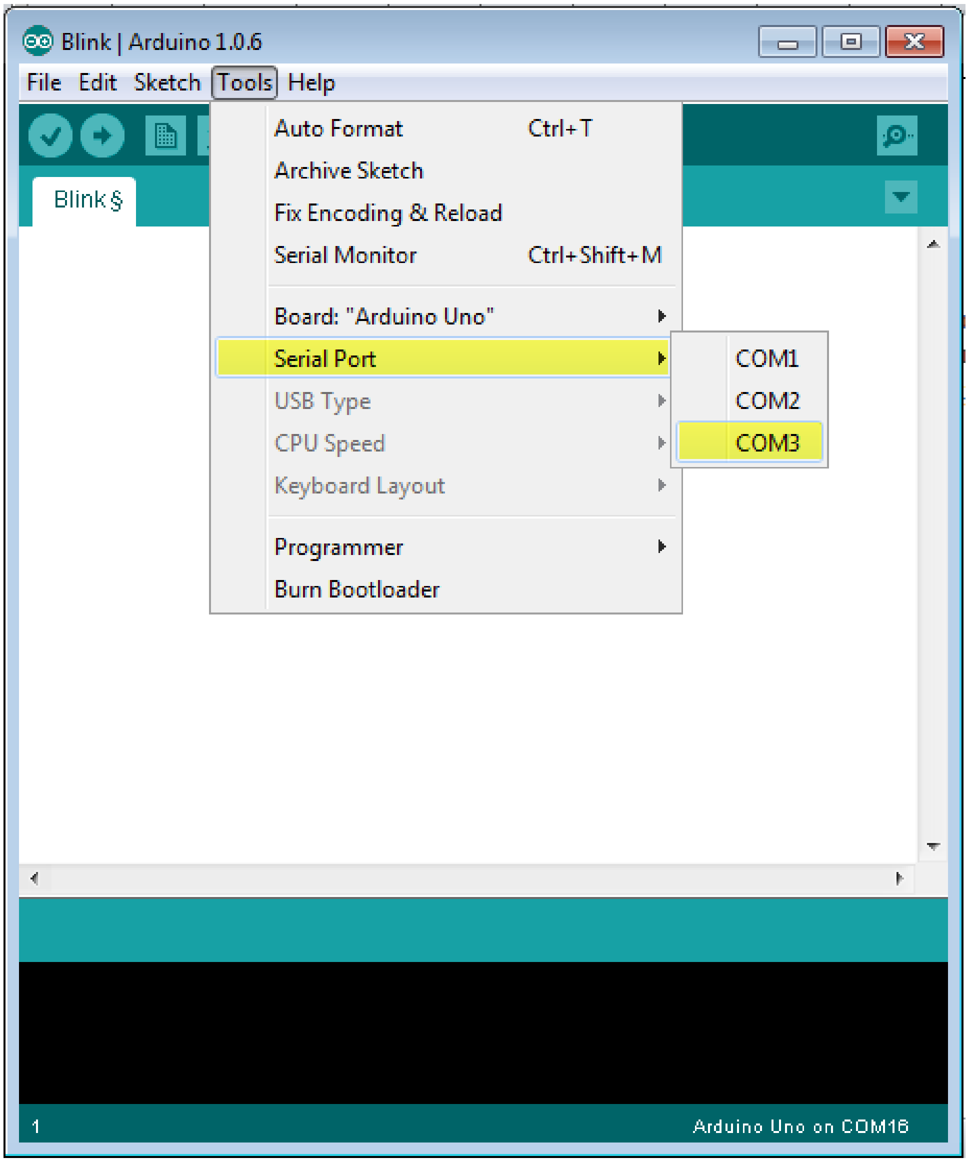

Fig.3.2.4.4.8 Select your serial port.

Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

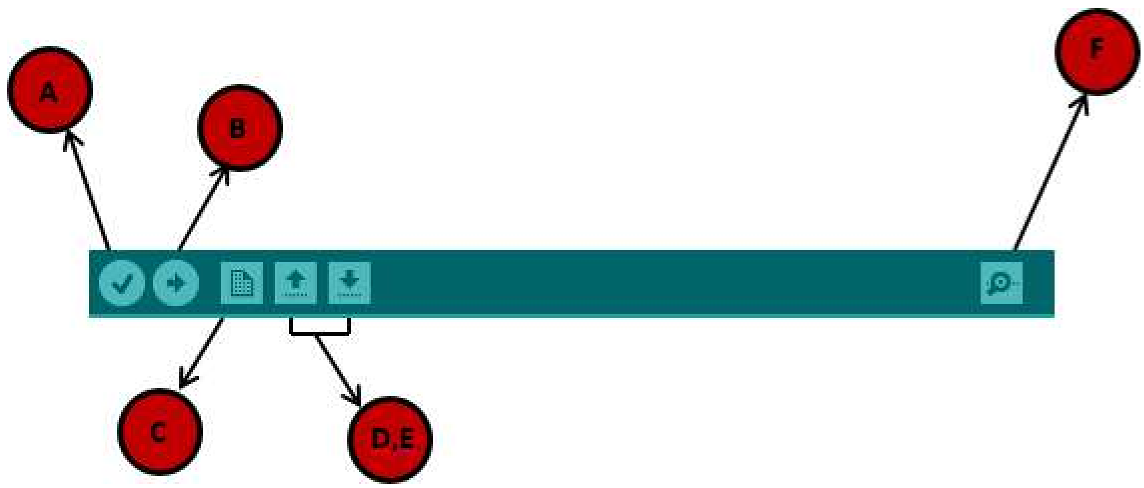

Fig.3.2.4.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

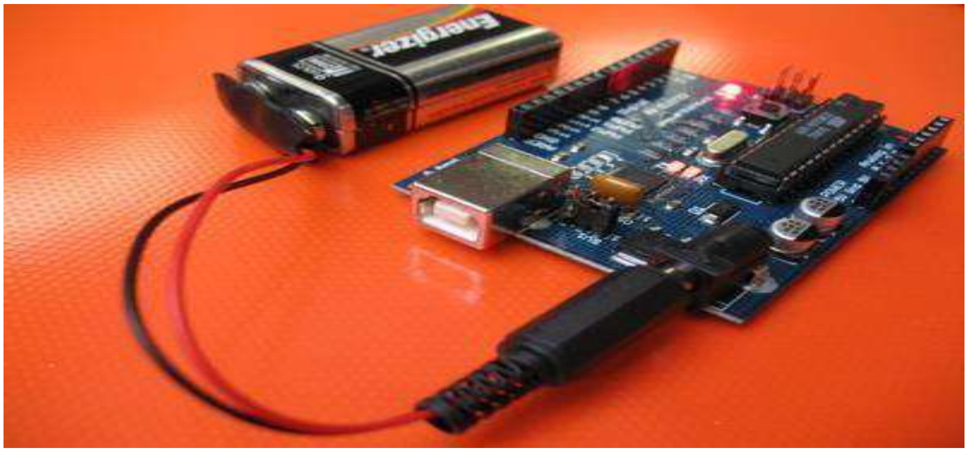

Fig.3.2.4.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

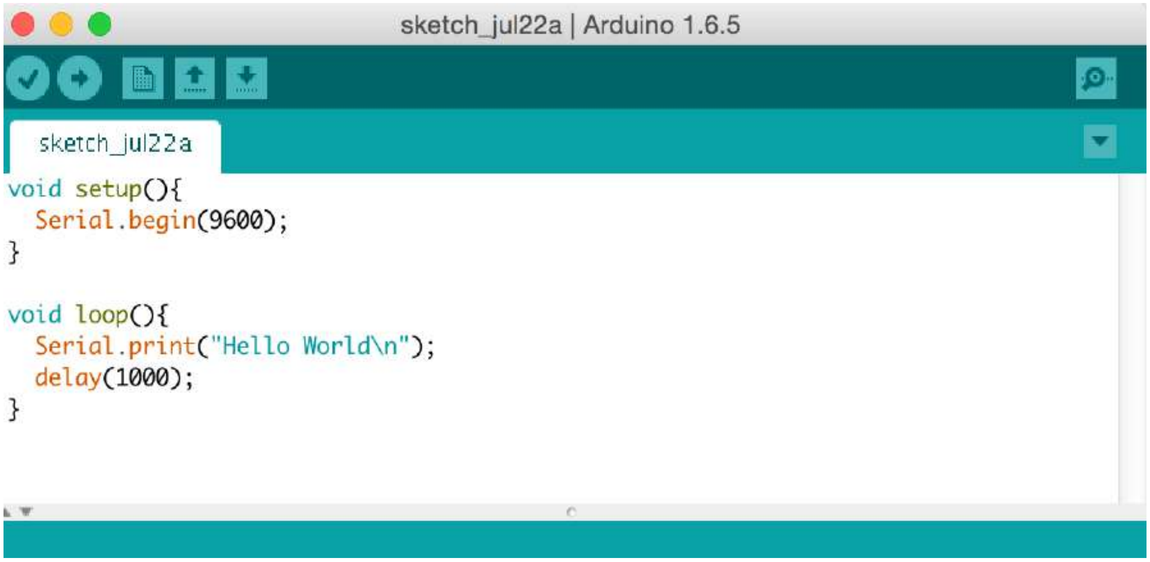

Fig.3.2.4.4.11 Example Program

3.2.5 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab center Electronics for Electrical and. It also possesses 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select new design in File menu

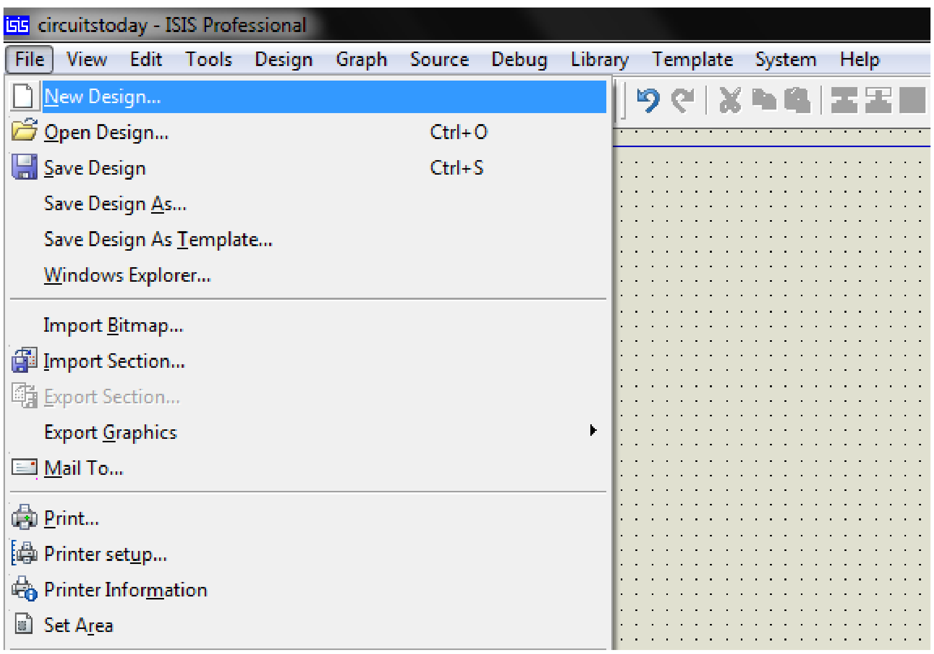

Fig.3.2.5.1Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

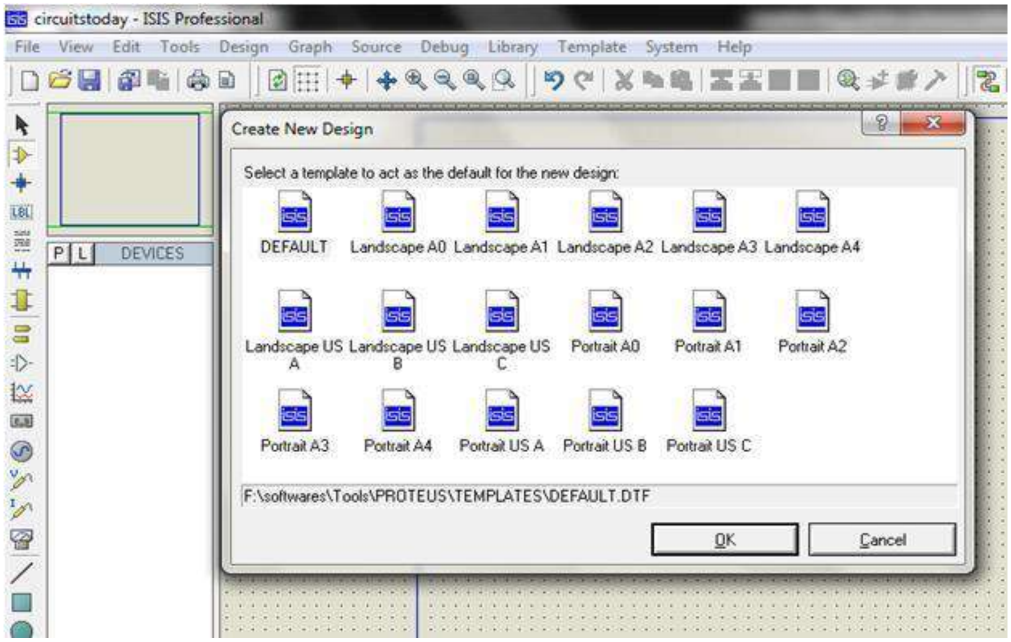

Fig. 3.2.5.2Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

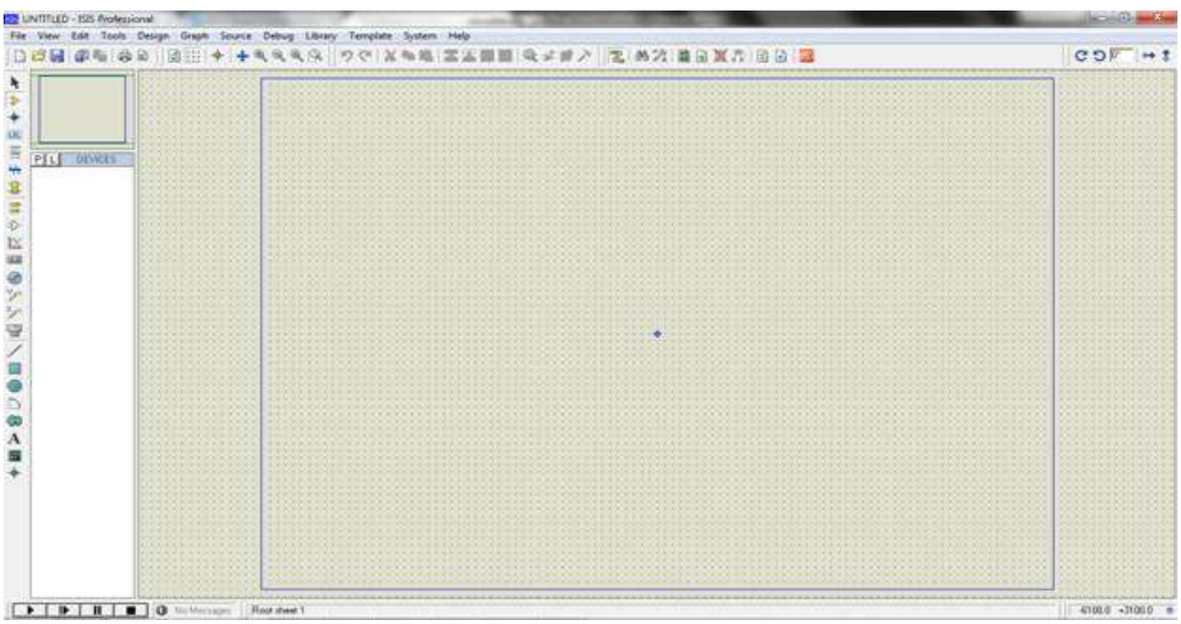

Fig. 3.2.5.3Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

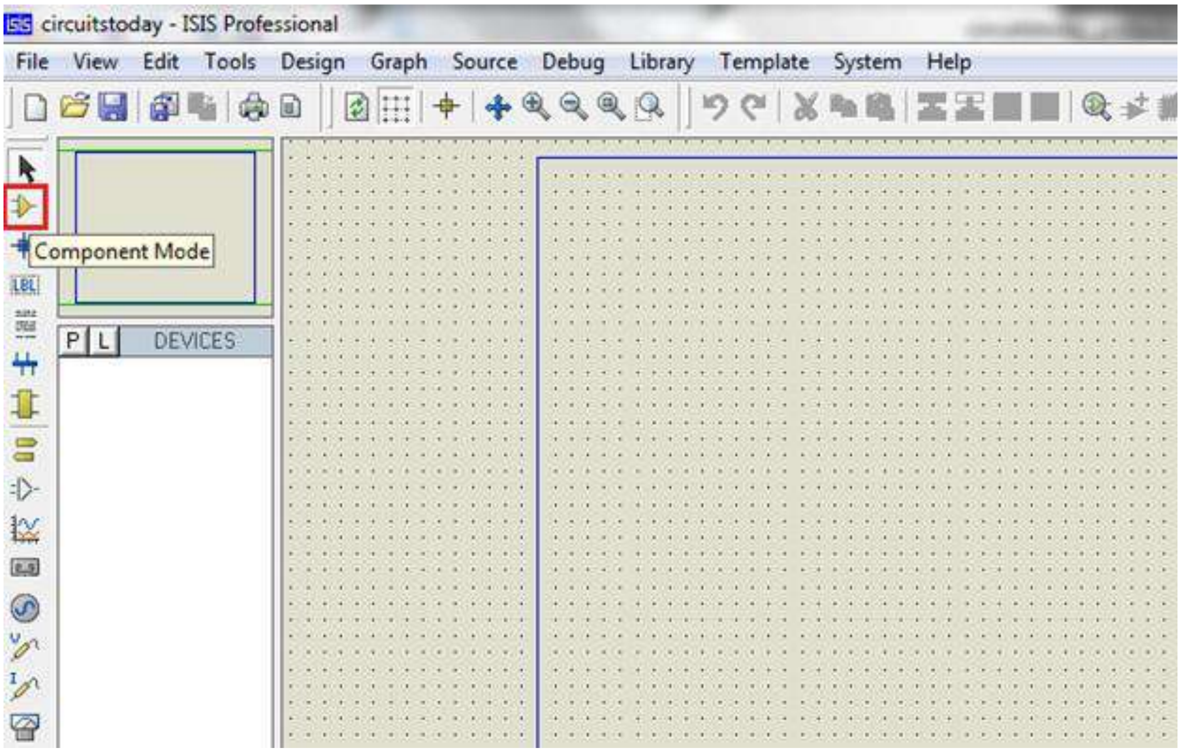

Fig. 3.2.5.4Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

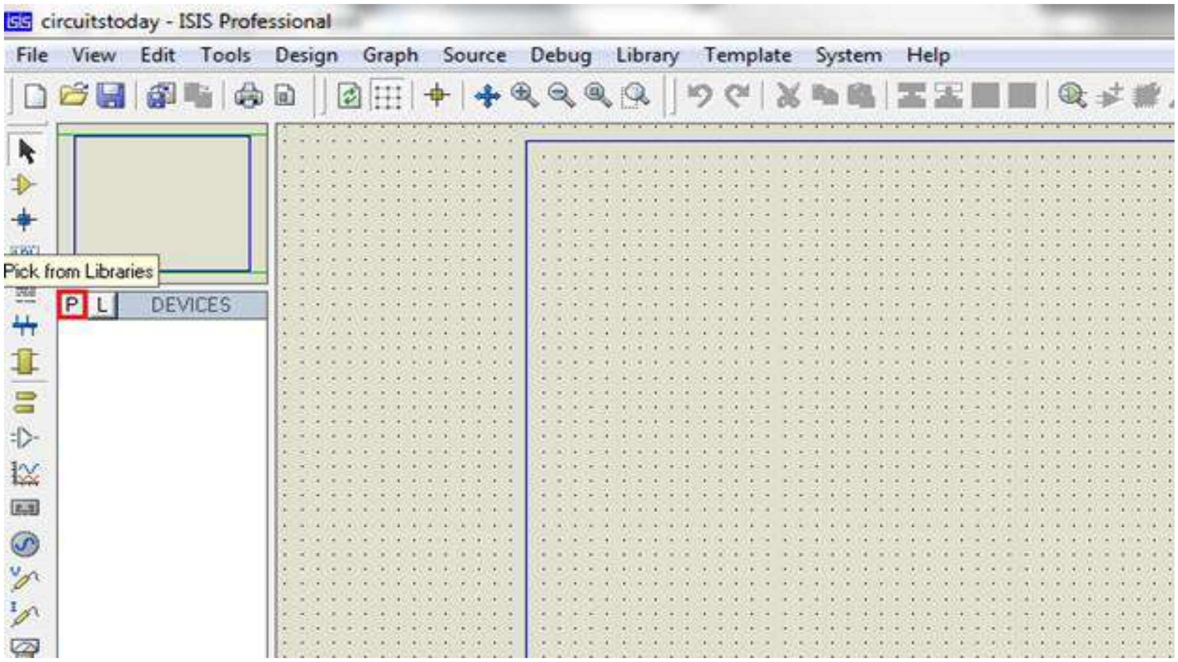

Fig. 3.2.5.5Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

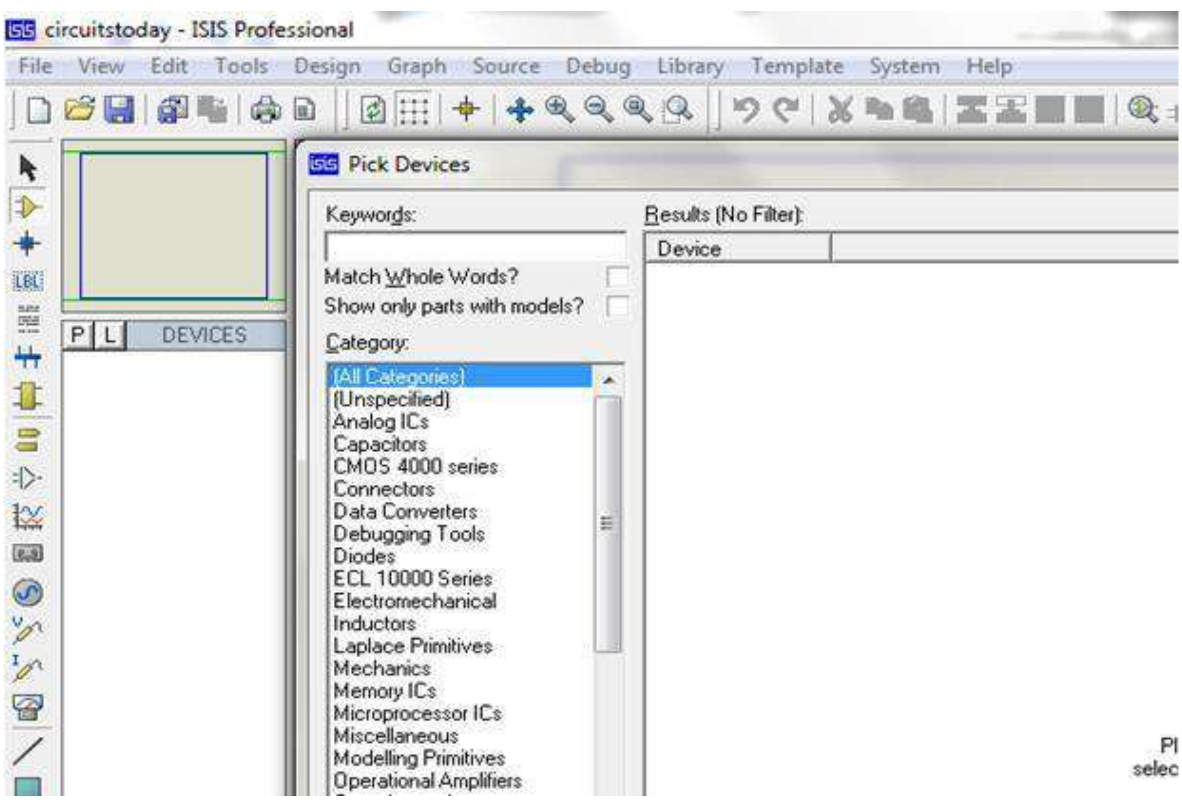

Fig. 3.2.5.6Keywords Textbox

Example shows selection of push button. Select the components accordingly.

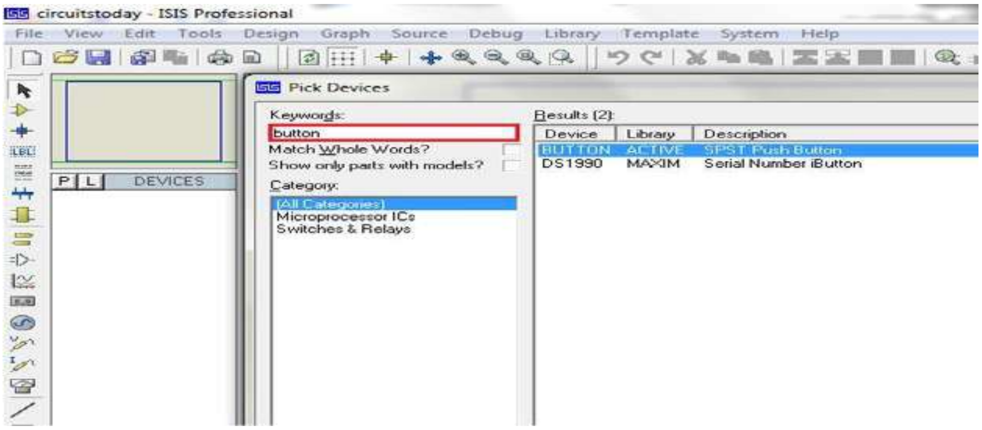

Fig.3.2.5.7Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

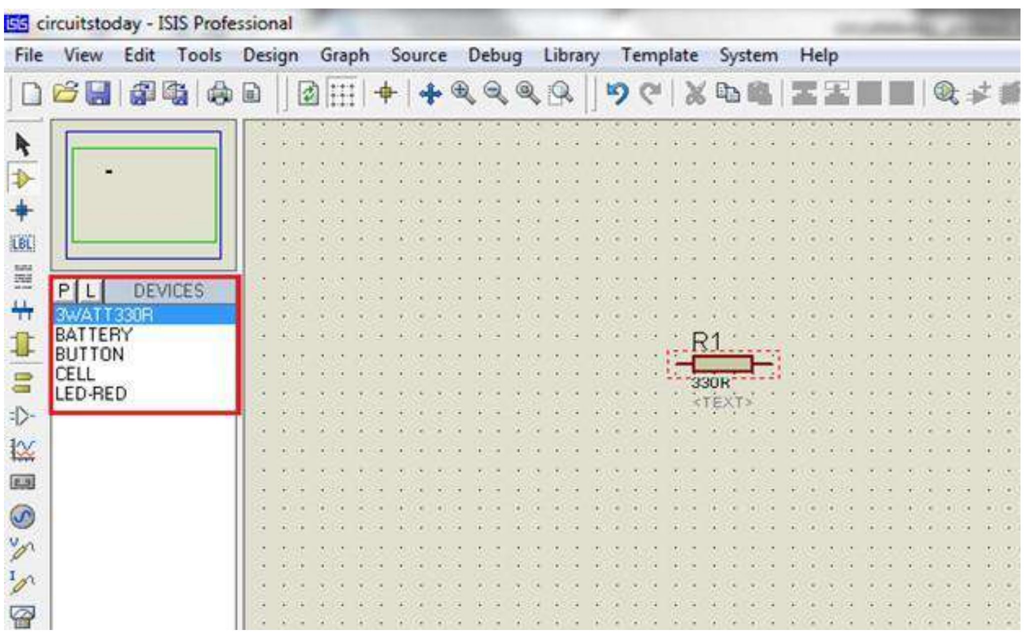

Fig.3.2.5.8Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

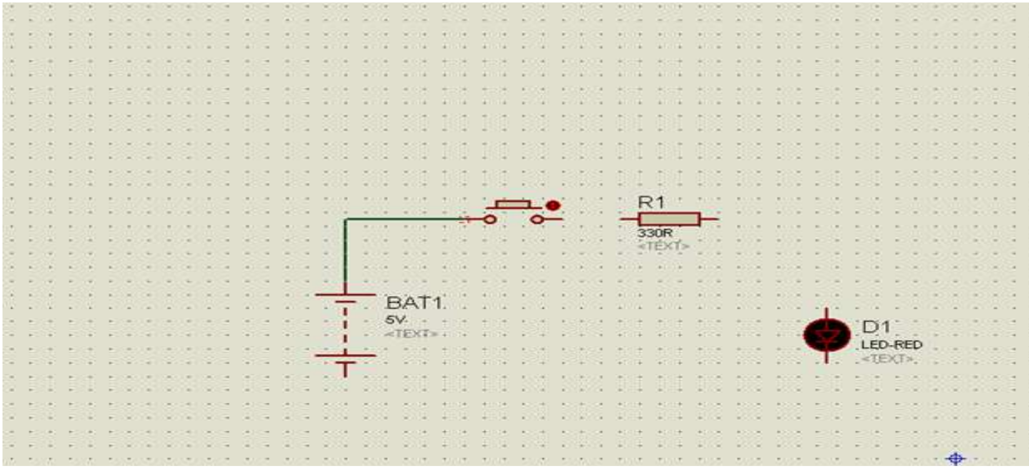

Fig.3.2.5.9Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

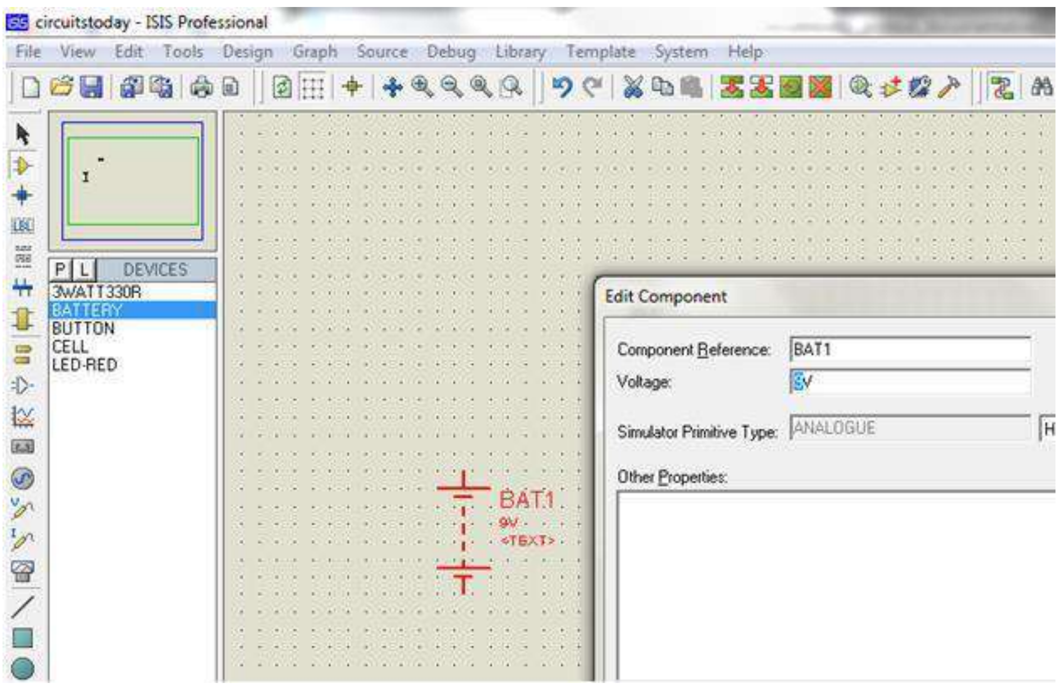

Fig. 3.2.5.10Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

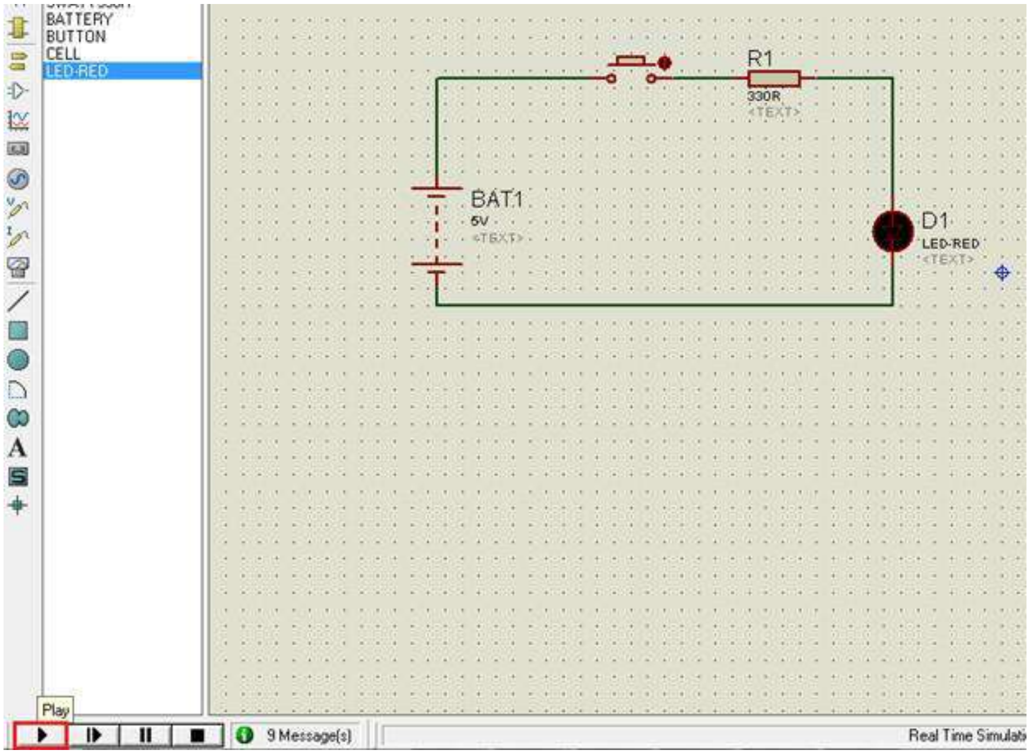

Fig. 3.2.5.11Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

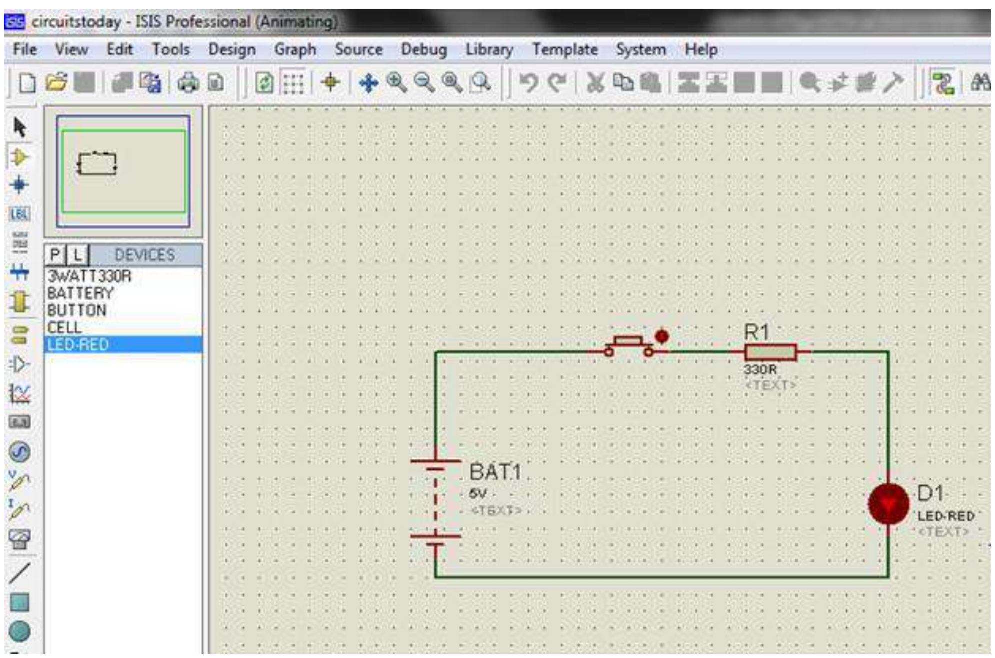

Fig. 3.2.5.12Simulation Animating

Simulation can be stepped, paused or stopped at any time.

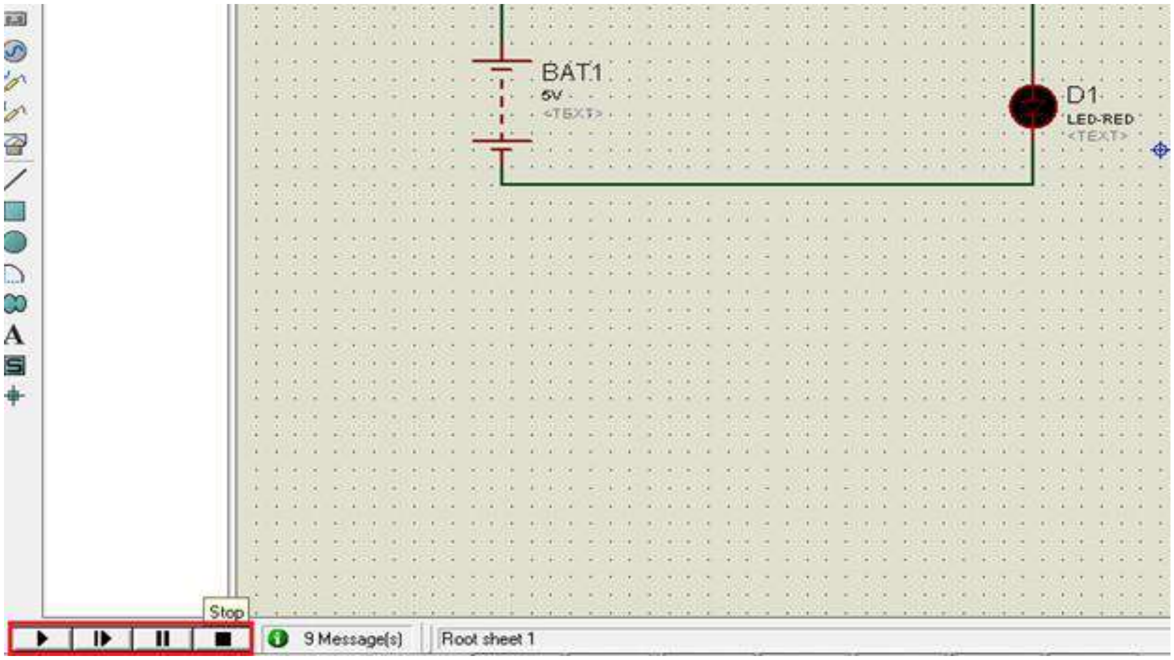

Fig. 3.2.5.13Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works. [citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' MATLAB documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.3 DEFINE

3.3.1 IR SENSOR

- IR stands infrared red spectrum, by using this region we can detect number of obstacles passing through a region.

- IR consists of two sections one is transmitter section and other is receiver section.

    - Transmitter section: it consists of a LED which continuously transmits a modulated signal of range (40 to 250khz).

    - Receiver section: Receiver section consists of a photo diode it will continuously track and receive the IR rays from LED.

- Functionality: The IR transmitter will continuously transmit IR rays and receiver (photo diode) will continuously receive the rays whenever some obstacle passes through the IR pair the transmission will be breaked by which we come to know that an intruder have been detected. In this way this communication will help us in safeguarding and many other applications.

3.3.2 LED

A light-emitting diode (LED) is a semiconductor light source. LEDs are used as indicator lamps in many devices, and are increasingly used for lighting. Introduced as a practical electronic component in 1962, early LEDs emitted low-intensity red light, but modern versions are available across the visible, ultraviolet and infrared wavelengths, with very high brightness.

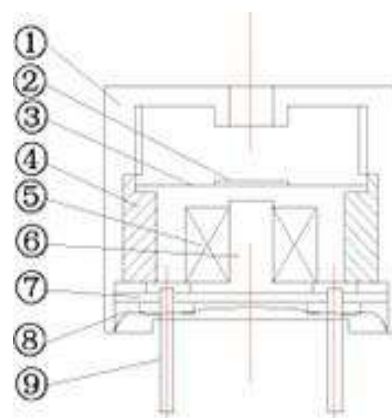

Fig.3.3.1 Magnetic Transducer

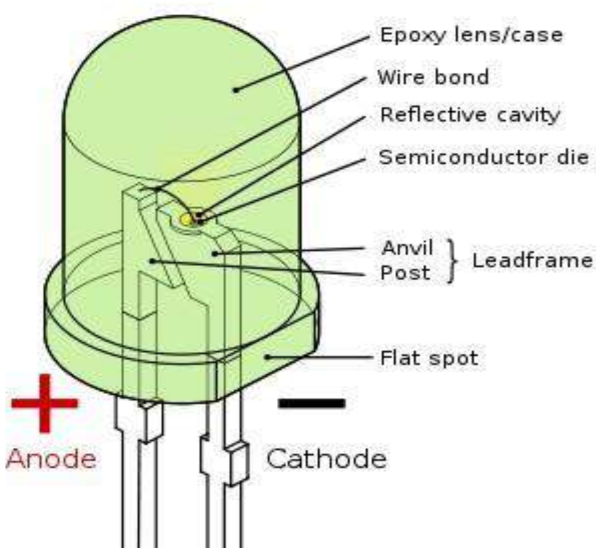
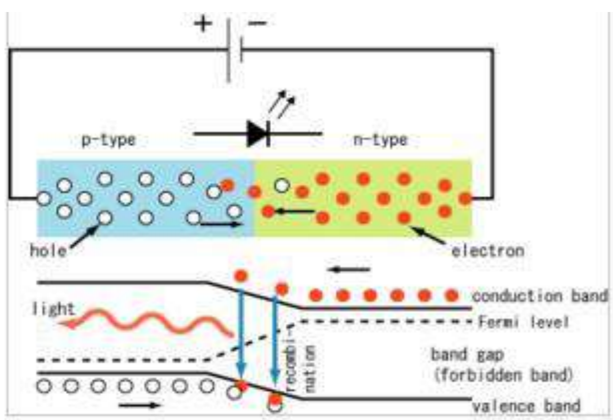
The LED is based on the semiconductor diode. When a diode is forward biased, electrons are able to recombine with holes within the device, releasing energy in the form of photons. This effect is called electroluminescence and the color of the light (corresponding to the energy of the photon) is determined by the energy gap of the semiconductor. An LED is usually small in area (less than 1 mm^2), and integrated optical components are used to shape its radiation pattern and assist in reflection. LEDs present many advantages over incandescent light sources including lower energy consumption, longer lifetime, improved robustness, smaller size, faster switching, and greater durability and reliability. However, they are relatively expensive and require more precise current and heat management than traditional light sources. Current LED products for general lighting are more expensive to buy than fluorescent lamp sources of comparable output.



Working: Charge-carriers electrons and holes—flow into the junction from electrodes with different voltages. When an electron meets a hole, it falls into a lower energy level, and releases energy in the form of a photon. The wavelength of the light emitted, and therefore its color, depends on the band gap energy of the materials forming the *p-n junction*. In silicon or germanium diodes, the electrons and holes recombine by a *non-radiative transition* which produces no optical emission, because these are indirect band gap materials. The materials used for the LED have a direct band gap with energies corresponding to near-infrared, visible or near-ultraviolet light.



The inner workings of an LED

Colors and materials :

	Color	Wavelength (nm)	Voltage (V)	Semiconductor Material
	Infrared	$\lambda > 760$	$\Delta V < 1.9$	Gallium arsenide (GaAs) Aluminum gallium arsenide (AlGaAs)
	Red	$610 < \lambda < 760$	$1.63 < \Delta V < 2.03$	Aluminum gallium arsenide (AlGaAs) Gallium arsenide phosphide (GaAsP) Aluminium gallium indium phosphide (AlGaInP) Gallium(III) phosphide (GaP)
	Orange	$590 < \lambda < 610$	$2.03 < \Delta V < 2.10$	Gallium arsenide phosphide (GaAsP) Aluminum gallium indium phosphide (AlGaInP) Gallium(III) phosphide (GaP)
	Yellow	$570 < \lambda < 590$	$2.10 < \Delta V < 2.18$	Gallium arsenide phosphide (GaAsP) Aluminium gallium indium phosphide (AlGaInP) Gallium(III) phosphide (GaP)
	Green	$500 < \lambda < 570$	1.9[42] < $\Delta V < 4.0$	Indium gallium nitride (InGaN) / Gallium(III) nitride (GaN) Gallium(III) phosphide (GaP) Aluminium gallium indium

			phosphide (AlGaInP) Aluminium gallium phosphide (AlGaP)
Blue	$450 < \lambda < 500$	$2.48 < \Delta V < 3.7$	Zinc selenide (ZnSe) Indium gallium nitride (InGaN) Silicon carbide (SiC) as substrate Silicon (Si) as substrate — (under development)
Violet	$400 < \lambda < 450$	$2.76 < \Delta V < 4.0$	Indium gallium nitride (InGaN)
Purple	multiple types	$2.48 < \Delta V < 3.7$	Dual blue/red LEDs, blue with red phosphor, or white with purple plastic
Ultraviolet	$\lambda < 400$	$3.1 < \Delta V < 4.4$	Diamond (235 nm) Boron nitride (215 nm) Aluminium nitride (AlN) (210 nm) Aluminium gallium nitride (AlGaN) Aluminium gallium indium nitride (AlGaInN) — (down to 210 nm)
White	Broad spectrum	$\Delta V = 3.5$	Blue/UV diode with yellow phosphor

3.4. POWER SUPPLY UNIT

3.4.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

3.4.2 BLOCK DIAGRAM OF POWER SUPPLY:

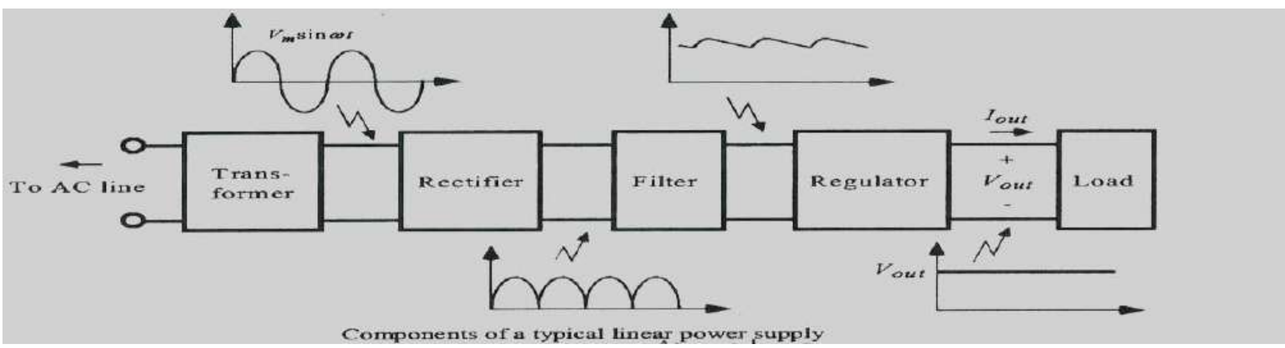


Fig.3.4.2: Block Diagram of Power Supply

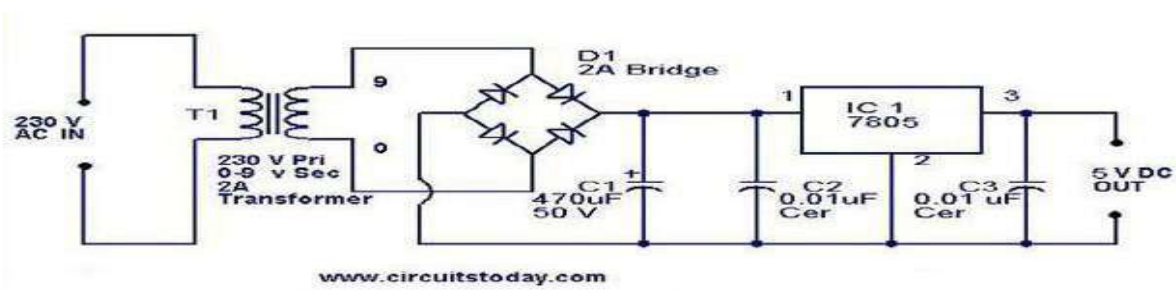

Fig.3.4.2(A): Schematic Diagram of Power Supply

3.4.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.4.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

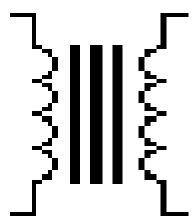

Fig.3.4.4: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

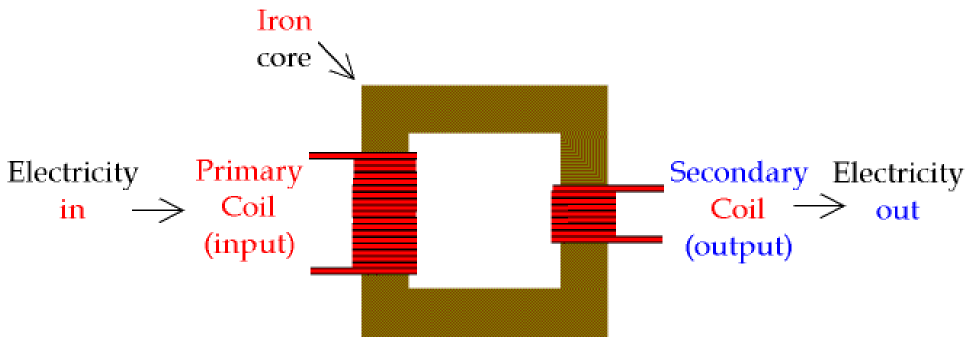

Fig.3.4.4.(A): Transformer

3.4.4.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

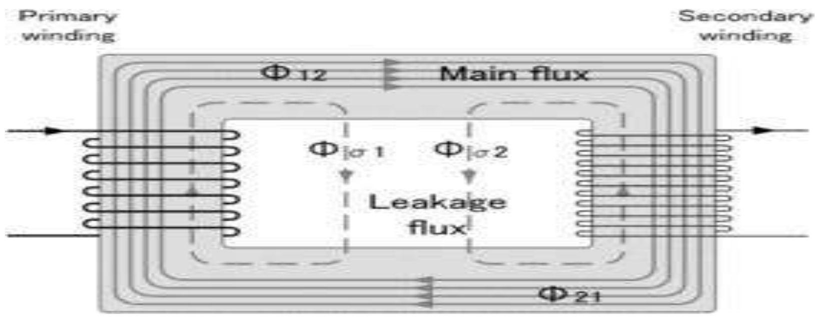

Fig.3.4.4.1: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.4.4.2Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn’s ratio of the two sets of windings determines the amount of voltage transformation.

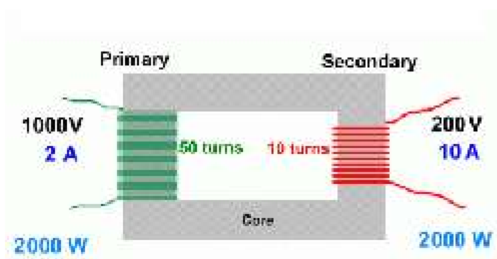

Fig.3.4.4.2: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn’s ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn’s ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, Nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

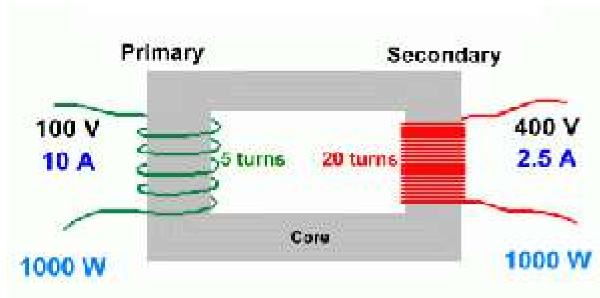

Fig.3.4.4.2(a): Step-Up Transformer

3.4.5 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

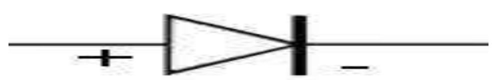

Fig.3.4.5: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.4.6 RECTIFIER:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

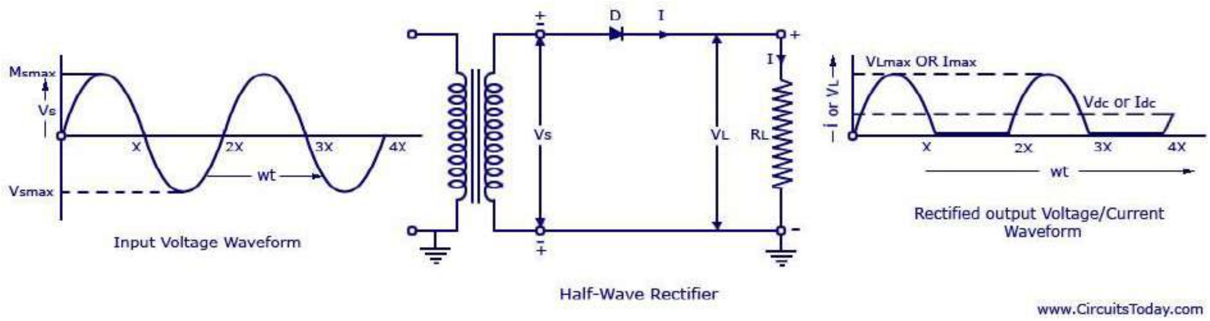

Fig.3.4.6(a): Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

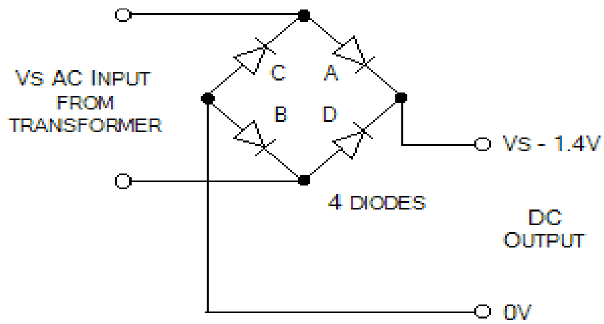

Fig.3.4.6(b): Full-Wave Rectifier

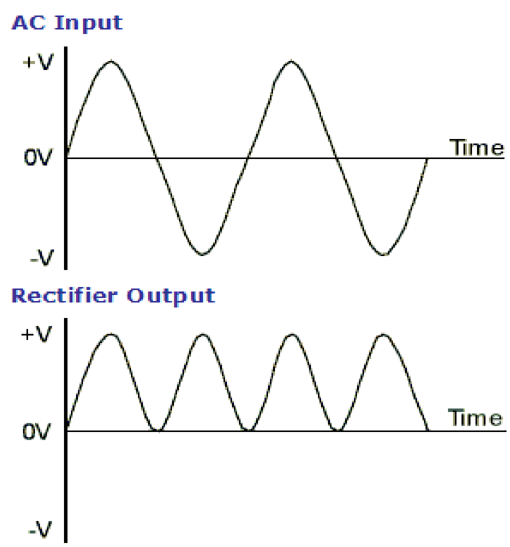

Fig.3.4.6(c): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put ACin, you will 10.6V DC out.

3.4.7 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

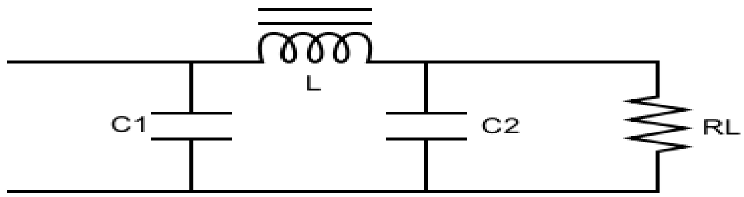

Fig.3.4.7: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

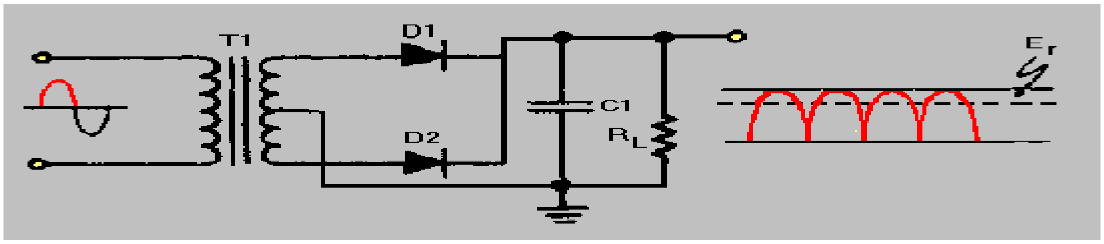

Fig.3.4.7(A): Cantered Tapped Full-Wave Rectifier with a Capacitor Filter

3.4.8 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx 'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx 'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

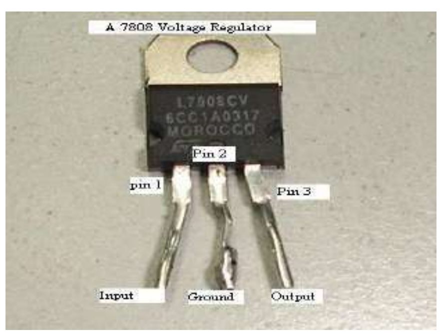

Fig.3.4.8 VOLTAGE REGULATOR

4.5 RESULTS

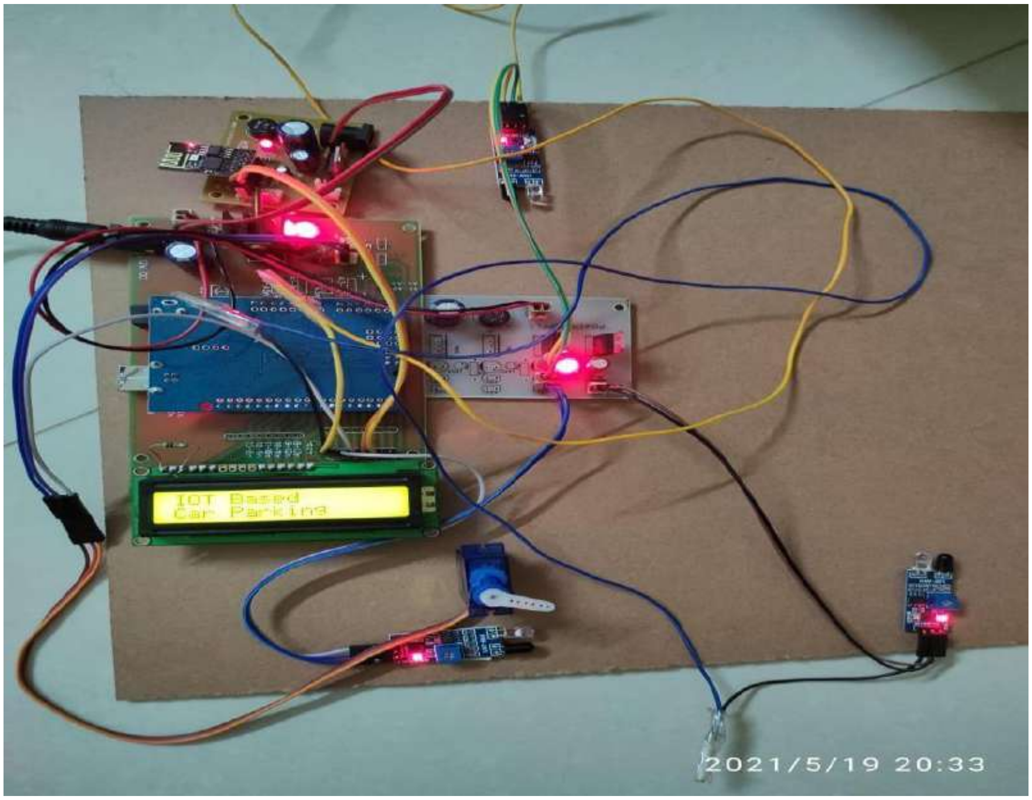

Fig.4.5 Final Output

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

The test of the circuit data communication of the whole circuit to and from cloud is done by detecting the existence of the car 10 times with the assumption of 150 cm car height and floor to ceiling distance of 350 cm. The measuring point of this test is the success of the circuit in sending data, the length of time required, and the validity of the data. Calculation of respond time on the Arduino and server is done by the progr am by recording the difference betweenstart and end time of the program.

The calculation of respond time on cloud is done by calculating the difference between server sent time and Ubidots received time. Based on the testing result as shown in Table 1 below, The sensor circuit has 100 % success rate for sending data to cloud with an average total required time of 6.4004 s for each data. Data errors were not found during the test.

Testing the accuracy of sensor readings conducted by car detection test with the assumption that the car has a height of 150 cm. Testing is done as much as ten times for each circuit of sensors by shifting obstacles. If there is a parking car, then the obstacles will be placed between the sensor and the floor. If the condition of the parking slot is empty, then the barrier will be removed so that the sensor will immediately detect the floor.

- When a driver knows exactly where they need to go; it reduces idling and unnecessary driving – therefore optimises traffic flows in built-up areas.
- Smart Parking creates the possibility of new business models that are only made possible using technology.
- Decreased searching for spaces can reduce accidents by ensuring drivers maintain their attention rather than browsing for spaces or making rash maneuvers.
- One goal of Smart Parking is to reduce the time taken and the hassle factor of locating an available parking space detecting the existence of the car 10 times with the assumption of 150

cm car height and floor to ceiling distance of 350 cm. The measuring point of this test is the success of the circuit in sending data, the length of time required, and the validity of the data calculation of respond time on the Arduino and server is done by the pstart and end time of the program.

The calculation of respond time on cloud is done by calculating the difference between server sent time and Ubidots received time. Based on the testing result as shown in Table 1below, The sensor circuit has 100% success rate for sending data to cloud with an average total required time of 6.4004 s for each data.

The method used to test RFID circuit communications to cloud is by tapping RFID cards ten times. In the program, there are already methods of calculating the respond time such as testing the sensor circuit. The measured points are the success of the circuit sending the data, the time it takes to send from the circuit to cloud, and the validity of the data sent with the received.

Security: IoT is a combination of physical objects ("things"), sensors, embedded software and keeps a goal of effective connectivity and faithful data exchange. The current graphs imply that IoT market growing at remarkable rate. However, some of these devices suffer from limited memory, power consumption and processing power. These issues may cause IoT to become penetrable and hence security is at utmost priority to IoT domain.

As stated in a 2015 report by Hewlett-Packard on IoT research [3]:

1. Per 100, 70 devices still use un-encrypted network services.

2. Per 100, 90 devices collected at least one piece of personally identifiable information (via device, cloud or mobile app).

3. Per 100, 70 devices (with cloud and mobile app components) enabled an attacker to identify valid user accounts through enumeration.

4. 80% of devices (with cloud and mobile app components) failed to require passwords of sufficient complexity.

5.Behind every 10 device every 6 devices user interfaces (UI) were vulnerable

Following are the vulnerabilities of the IoT as per The Open Web Application Security Project (OWASP)

1) Insufficient protection compositions.

2) Dubiously secured Software/Firmware

3) Doubtful Network Services

4) Doubtful Web Interface

5) Worst Physical Security

6) Doubtful Cloud Interface

7) Doubtful Mobile Interface

8)Privacy Concerns

9) Doubtful Authentication/Authorization

10) Inadequate Transport Encryption Ongoing approaches to secure IoT have attempted to put a grip on communication protocol-based mechanisms, such as encryption for data-at-rest or in-transit. But this itself is doubtful if the respective endpoints themselves are capable of being modified either by local access or remote connections. Gartner claims that by year 2020 more than 25% of identified attacks in a particular company will be on IoT devices or systems, even though IoT will only contribute to less than 10% of IT security budgets.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

The smart parking system based on IoT concept has been implemented using various sensor circuitry and cloud (server). It is an efficient system for car parking which prevails traffic congestion. Smart parking systems gives rise to new solutions with the help of Internet of things . The system have always been at the core of constructing smart cities. In this project, we address the issue of parking. It presents an IoT based Cloud integrated smart parking system. With the help of this mobile application all the updated information can be checked. The efforts made in this project are indented to improve the parking facilities of a city and thereby aiming to enhance the quality. This designed automatic smart parking system which is simple, economic and provides effective solution to reduce carbon footprints in the atmosphere.

Thus it reduces the crisis of car parking across a remote city and also it eliminates unnecessary travelling of vehicles across the filled parking slots in a city. So it reduces time and it is cost effective.

6.2 FUTURE ENHANCEMENT

This work is further extended as smart car parking system with automatic billing system also fully automated system using multilayer parking method. Safety measures such as vehicle no. tracing, driver face recognition. Also care has taken so that there is no malfunction of wrong vehicle entering into the allocated slot by providing an unique OTP to each person and ensuring the same person parks in the given slot.

The future enhancement can be in such a way that by using GPS system we can find where the car is being parked and and also the number of vacancy available in the parking system.

PUBLICATION

Submitted Paper in the Conference ICISMEC-21 with Paper ID (ICISMEC21-0090) and got Acceptance for the Paper.

APPENDICES

Now a days the concept of smart cities have gained grate popularity. Thanks to the evolution of Internet of things the idea of smart city now seems to be achievable. Major efforts are being made in the field of IOT in order to maximize the productivity and reliability of urban areas. Problems such as, traffic congestion, limited car parking facilities and road safety are being addressed by IOT. In this paper, we present an IOT based Server integrated smart parking system. This system consists of an IOT module which check the state of availability of parking lot. A mobile application is also provided that allows an end user to check the availability of parking space and book a parking slot accordingly. The paper also describes a high-level view of the system architecture. Towards the end, the paper discusses the working of the system in form of a use case that proves the correctness of the proposed model.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would b incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude to **Dr.B.HARI KRISHNA Head &Professor**, the Dept. of Information Technology for his/her advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to our dept .project coordinator Dr.ANAND.A KUMAR,PROFESSOR,for his/her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide,**Mr.Dr.A.Chaitanya Krishna professer**, department ECE and our class project coordinator **Ms.P.Pushpa Assistanat professer**,department of ECE for guidance and encoragment in carrying out this project work

Finally, we are highly grateful and obliged to our college level Project Coordinator **Project Coordinators Dr.Maalyadri**, **Professor in IT** and **Dr.R.Santhosh Kumar**, **Associate Professor in CSE** and for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

ABSTRACT

Ultrasound imaging is a safe and cost-effective diagnostic tool, but the quality of the images is affected by speckle noise and artifacts. Anisotropic diffusion filters can be used to reduce noise and preserve the edges in the image. However,this technique is very sensitive to the number of iterationsselected. This paper proposes a stopping criterion for effective noise removal without blurring the edges, based on the relativevariance between the estimated denoised image and the original one. Different quality metrics were evaluated in 25 test images.The results suggest that the proposed stopping criterion can be implemented efficiently and aids in the process of automation of the filter.Ultrasound image enhancement, speckle reduction,anisotropic diffusion filtering

.

LIST OF TABLES

LIST OF FIGURES

LIST OF GRAPHS

GLOSSARY OF COMMONLY USED TERMS:

Anisotropic diffusion filter: This filter as commonly used in medical image enhacement.They are effective to reduces noise in homegeous regiouns eith out bluring the edges by preventing intra region smoothing.

Images shading shapes: The image shading shapes caused by the object surface illumation in space is used to reconstruct the surface orinetion.

Magnetism: Magnetism is a property of matter that is a result of the orbiting electrons in atoms. The orbiting electrons cause the atoms to have a magnetic moment associated with an intrinsic angular momentum called 'spin'. Magnetic field strengths are measured in units of Tesla (T).

Ferromagnetism: Ferromagnetic materials generally contain iron, nickel, or cobalt. These materials have a large positive magnetic susceptibility, i.e., when placed in a magnet field, the field strength is much stronger inside the material than outside

Para magnetism: Paramagnetic materials include oxygen and ions of various metals like Fe, Mg, and Gd. These ions have unpaired electrons, resulting in a positive magnetic susceptibility. The magnitude of this susceptibility is less than one one-thousand of that of ferromagnetic materials

Superparamagnetism: Superparamagnetic materials consist of individual domains of elements that have ferromagnetic properties in bulk. Their magnetic susceptibility is between that of ferromagnetic and paramagnetic materials. Figure illustrates the effect of a superparamagnetic material (grey circle) on the magnetic field flux lines (blue). Examples of superparamagnetic materials include iron containing contrast agents for bowel, liver, and lymph node imaging

Diamagnetism: weak negative magnetic susceptibility contributes to the loss of signal seen in bowel on MRI after administration of ba Diamagnetic materials have no intrinsic atomic magnetic moment, but when placed in a magnetic field weakly repel the field, resulting in a small negative magnetic susceptibility. Materials like water, copper, nitrogen, barium sulfate, and most tissues are diamagnetic. Figure 2.12 illustrates the effect of a diamagnetic material (grey circle) on the magnetic field flux lines (blue). The rium sulfate suspensions.

RF Coils: RF coils are the "antenna" of the MRI system that broadcasts the RF signal to the patient and/or receives the return signal. RF coils can be receive-only, in which case the body coil is used as a transmitter; or transmit and receive (transceiver)

Surface Coils : Surface coils are the simplest design of coil. They are simply a loop of wire, either circular or rectangular, that is placed over the region of interest. The depth of the image of a surface coil is generally limited to about one radius. Surface coils are commonly used for spines, shoulders, and other relatively small body parts.

Paired Saddle Coils: Paired saddle coils are commonly used for imaging of the knee. These coils provide better homogeneity of the RF in the area of interest and are used as volume coils, unlike surface coils. By running current in opposite directions in the two halves of the gradient coil, the magnetic field is made stronger near one and weaker near the other

The Helmholtz Pair Coils: The Helmholtz pair coils consist of two circular coils parallel to each other. They are used as z gradient coils in MRI scanners. They are also used occasionally as RF coils for pelvis imaging and cervical spine imaging.

The Bird Cage Coil: The bird cage coil provides the best RF homogeneity of all the RF coils. It has the appearance of a bird cage; hence, its name. This coil is commonly used as a transceiver coil for imaging of the head. This type of coil is also used occasionally for imaging of the extremities, such as the knees

Gradient Coils: Gradient coils are used to produce deliberate variations in the main magnetic field (Bo). There are usually three sets of gradient coils, one for each direction. The variation in the magnetic field permits localization of image slices as well as phase encoding and frequency encoding.

Image Reconstruction: The raw data generated by most sequences is separated into phase and frequency components by a mathematical procedure called Fourier transformation. To generate an anatomic image, the raw data must be inverse Fourier transformed

Aliasing or "Wrap-around: Aliasing or wrap-around is a common artifact that occurs when the field of view (FOV) is smaller than the body part being imaged. The part of the body that lies beyond the edge of the FOV is projected on to the other side of the image. This can be corrected, if necessary, by oversampling the data

Radio Frequency : The radio frequency power that is capable of being produced matches that of many smradio stations (15-20 kW). As a result there is the presence of heating effects from the RF.

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

In this chapter, we will discuss the basic principles behind the physics of magnetic resonance imaging (MRI). Some of these principles are explained using Newtonian physics, and some using quantum mechanics, whichever can convey the message more clearly. Although this might be confusing at times, it seems to be unavoidable. In any case, we'll try to keep it straight-forward. MRI is a powerful imaging modality because of its flexibility and sensitivity to a broad range of tissue properties. One of the original reasons for the excitement about MRI was, and continues to be, its relative safety, where the 'noninvasive' nature of the magnetic fields employed makes it possible to diagnose conditions of people of almost any age. Today MRI also offers great promise in understanding much more about the human body, both its form and function.

Magnetic Resonance Imaging:

The Name MRI stems from the application of nuclear magnetic resonance (NMR) to radiological imaging. The adjective 'magnetic' refers to use of an assortment of magnetic fields and 'resonance' refers the need to match the (radio)frequency of an oscillating field to the 'professional' frequency of the spin of some nucleus (hence the 'nuclear') in a tissue molecule. It might be more accurate to refer to this field as NMRI rather than MRI, but there is widespread concern over any phrase containing the word 'nuclear.' Although the nuclear component simply refers to a benign role of the 'spin' of the nucleus in the process, the word has been suppressed and the public and the profession have embraced the MRI acronym.

The Origin of Magnetic Resonance Imaging:

To describe the history of any technological advance in a given field is a very difficult. Still, the beginning student may be aided and inspired by even a short historical discussion. The concept of nuclear magnetic resonance had its underpinnings with the discovery of the spin nature of the proton. Learning on the work of Stern and Gerlach from the early 1920's, Rabi and coworkers pursued the spin of the proton and its interaction with a magnetic field in the 1930's. With this foundation in hand in 1946, Bloch and Purcell extended these early quantum mechanical concepts to a measurement of an effect of the precession of the spins around a magnetic field. These gentlemen successfully measure a precessional signal from a water sample and a paraffin sample, respectively. It may be said that MRI had its beginnings in 1973 with the seminal papers by Lauterbur and Mansfield. It was already well known that the intrinsic angular momentum (or 'spin') of a hydrogen nucleus (the proton) in a magnetic field precesses about that field at the 'Larmor frequency' which in

turn, depends linearly on the magnitude of the field itself. Their idea was very simple. If a spatially varying magnetic field is introduced across the object, the Larmor frequencies are also spatially varying. They proposed and showed that the different frequency components of the signal could be separated to give spatial information about the object. This key point of spatially encoding the data opened the door to MR imaging. Others also recognized the importance of this area, with early attention brought to tumor detection by Damadian.

Historical Development of MRI:

A brief developmental history is given below which proven to be the milestone in the journey of MRI.

1946 Elucidation of NMR phenomena and technique—Bloch, Purcell

1951 Single dimension spatial localization—Gabillard

1952 Nobel Prize to Bloch and Purcell

1959 Blood flow by NMR—Singer

1971 In vitro cancer detection by NMR—Damadian

1972 In vivo cancer detection by NMR—Weisman

1972 NMR imaging—Damadian.

1.2 OBJECTIVES OF THE STUDY:

1.2.1 Electromagnetism of MRI

Atomic Structure:

The atom consists of a central nucleus and orbiting electrons. The nucleus contains nucleons which are subdivided into protons and neutrons; protons are positively charged, neutrons have no net charge, and electrons are negatively charged. The atom is electrically stable if the number of negatively charged electrons orbiting the nucleus equals the number of positively charged protons in the nucleus. Atoms that are electrically unstable due to a deficit, or an excess number of electrons, are called ions.

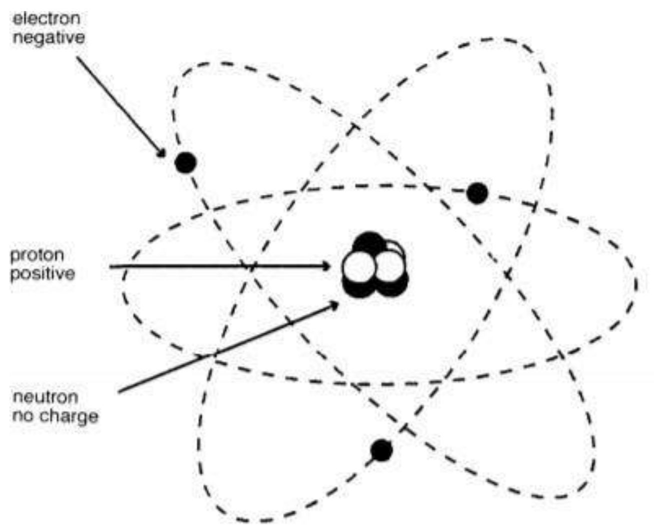

Figure 1.1: Atomic Structure.

Motion within the Atom:

Three types of motion are present within the atom. These are:

(1) Electrons spinning on their own axis,

(2) Electrons orbiting the nucleus

(3) The nucleus itself, spinning about its own axis.

The principles of MRI rely on the spinning motion of specific nuclei present in biological tissues. These are known as MR active nuclei.

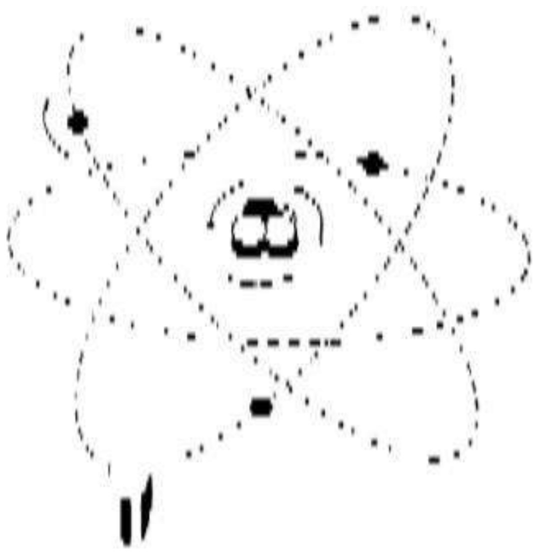

Figure 1.2: Motion of particles in the Atom.

MR Active Nuclei:

MR active nuclei are characterized by their tendency to align their axis of rotation to an applied magnetic field. Due to the laws of electromagnetic induction, nuclei that have a net charge and are spinning acquire a magnetic moment and are able to align with an external magnetic field. This occurs if the mass number is odd, i.e. there are even number of neutrons and odd number of protons or vice versa. The process of this interaction is angular momentum or spin.

Important examples of MR active nuclei are 1 H, 13C, 15N, 17O, 19F, 23Na and 31P.

Alignment can be measured as the total of the nuclear magnetic moments and is expressed as a vector sum. The strength of the total magnetic moment is specific to every nucleus and determines the sensitivity to magnetic resonance.

The Hydrogen Nucleus:

The hydrogen nucleus is the MR active nucleus used in clinical MRI. The hydrogen nucleus contains a single proton. It is used because it is very abundant in the human body, and because its solitary proton gives it a relatively large magnetic moment.

The Hydrogen Nucleus as a Magnet:

The laws of electromagnetism state that a magnetic field is created when a charge particle moves. The hydrogen nucleus has a magnetic field, because of a spinning positively charged proton that acts as a small magnet. The magnet of each hydrogen nucleus has in effect a north and a south pole of equal strength. The north/south axis of each nucleus is represented by a magnetic moment. The magnetic moment of each nucleus has vector properties, i.e. it has size and direction and is denoted by an arrow. The direction of the vector designates the direction of the magnetic moment, and the length of the vector designates the size of the magnetic moment.

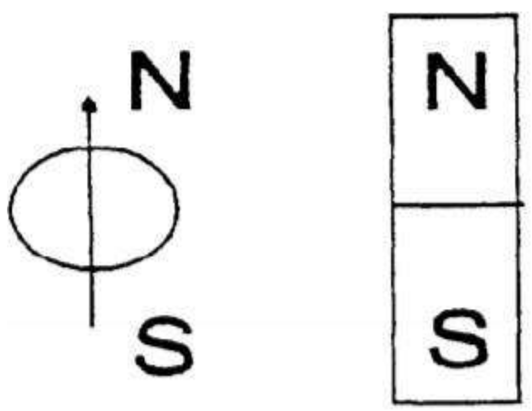

Figure 1.3: The magnetic moment of hydrogen nucleus.

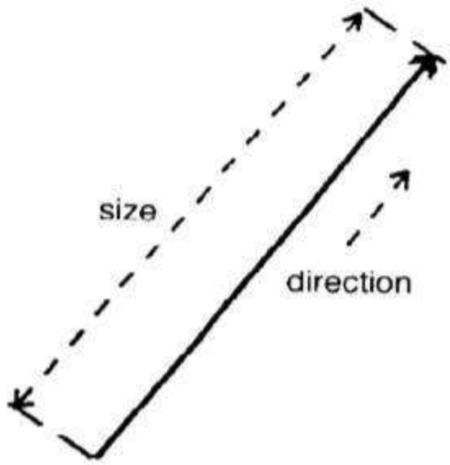

Figure 1.4: The magnetic vector.

Electromagnetic Waves:

To understand MRI, we first need to understand what electromagnetic waves are. All electromagnetic waves have certain fundamental properties in common:

(i) They all travel at the speed of light c = 3 × 108 m/sec.

(ii) They all have two components—an electric field E and a magnetic field B— that are perpendicular to each other and both are traveling at the speed of light (c).

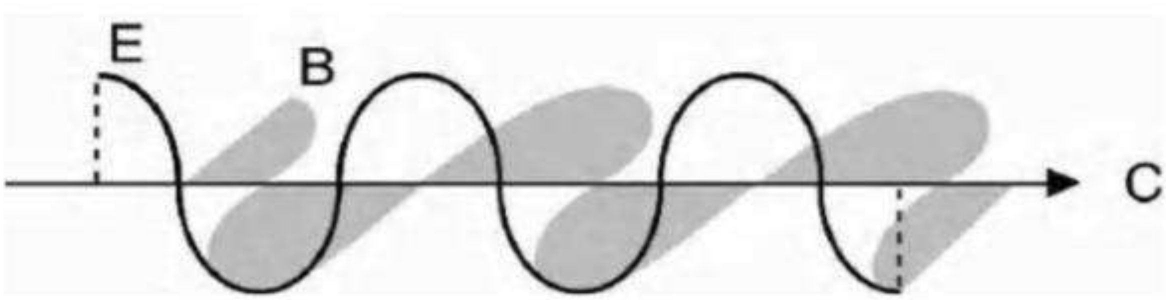

Figure 1.5: Two components of an electromagnetic wave, the electric component E and the magnetic component B. These two components are perpendicular to each other, are 90° out of phase, and travel at the speed of light (C).

(iii) We are interested in the magnetic field component—the electric field component is undesirable because it generates heat.

In MRI, we deal with much lower energies and lower frequencies than X-ray or even visible light. The wave lengths are much longer in the radio frequency (RF) window. Table 2.1 contains a few examples of frequency ranges in the electromagnetic spectrum.

AM radio frequency	0.54-1.6 MHz (540-1600 kHz)
TV (Channel 2)	Slightly over 64 MHz
FM radio frequency	88.8-108.8 MHz
RF used in MRI	3-100 MHz

Table 1.1: Frequency ranges in the EM spectrum.

This is why the electromagnetic pulse used in MRI to get a signal is called an RF (radio frequency) pulse—it is in the radio frequency range. It belongs to the radio frequency window of the electromagnetic spectrum.

Fundamental Interaction of a Proton Spin with the Magnetic Field:

MRI is based on the interaction of a nuclear spin with an external magnetic field, B0. The dominant nucleus in MRI is the proton in hydrogen and its interaction with the external field results in the precession of the proton spin about the field direction. Imaging of humans rests on the ability to manipulate, with a combination of magnetic fields, and then detect, the bulk precession of the hydrogen spins in water, fat and other organic molecules.

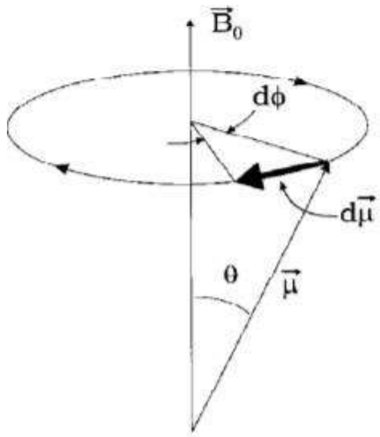

Figure 1.6: Precession of the proton spins about magnetic field direction.

By definition, precession is the circular motion of the axis of rotation of a spinning body about another fixed axis caused by the application of a torque in the direction of the precession. The interaction of the proton's spin with the magnetic field produces the torque, causing it to precess about B0 as the fixed axis. When looking down from above the vector B0, the precession of the magnetic moment vector μ, which is proportional to the spin vector, is clockwise. For the customary counterclockwise definition of polar angles, the differential dφ shown is negative.

It thus possesses an effective loop of electric current around the same axis about which it is spinning.

This effective current loop is capable of interacting with external magnetic fields as well as producing its own magnetic field. We describe the strength with which the loop produces its own field, in terms of the same 'magnetic dipole moment' vector µ. The direction of this vector is nothing other than the spin axis itself and, like a compass needle; the magnetic moment vector will tend to align itself along any external static magnetic field, B0. It can also be found that the precession angular frequency for the proton magnetic moment vector (and for the spin axis as well) is given by ω0 = B0

Where is a constant called the gyromagnetic ratio. In water, the hydrogen proton has a value of roughly 2.68 x 106 Gy/s/Tesla. For a 2 T field, for example, the spins precess at a radiofrequency of 85.2 MHz, just below the FM range for radio broadcasting. This precession frequency is referred to as the Larmor frequency and is referred to as the Larmor equation.

Relaxation

Relaxation is the process whereby nuclear magnetization returns to its resting state following a perturbation, such as by an RF pulse. Magnetic resonance is characterized by three forms of relaxation, T1 (longitudinal or spin-lattice) relaxation, T2 (transverse of spin-spin) relaxation, and T2* relaxation.

T1 Relaxation

The return of excited nuclei from the high energy state to the low energy or ground state is associated with loss of energy to the surrounding nuclei. Nuclear magnetic resonance was originally used to examine solids in the form of lattices, hence the name "spinlattice" relaxation. Macroscopically, T1 relaxation is characterized by the longitudinal return of the net magnetization to its ground state of maximum length in the direction of the main magnetic field. The rate of return is an exponential process as is shown in the following figure.

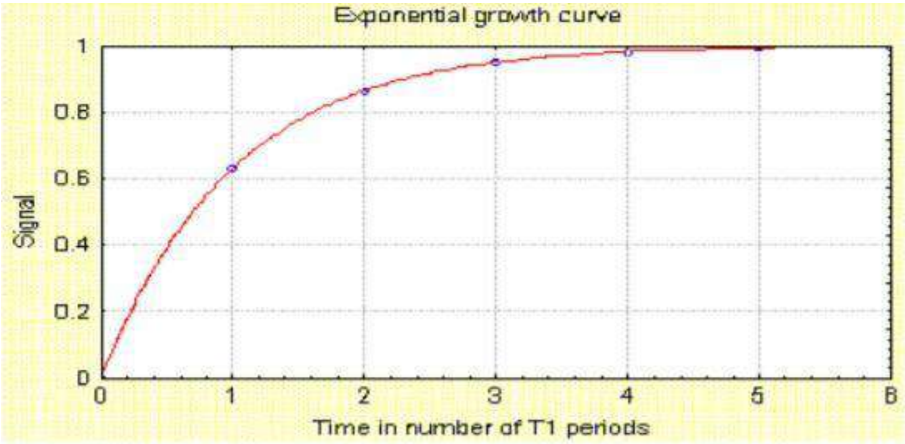

Figure 1.7: T1 relaxation graph.

The T1 relaxation time is the time for the magnetization to return to 63% of its original length. After two T1 times, the magnetization is at 86% of its original length. Three T1 times results in 95% recovery. Spins are considered completely relaxed after 3-5 T1 times. Another term that you may hear is the T1 relaxation rate. This is merely the reciprocal of the T1 time(1/T1). T1 relaxation is fastest when the motion of the nucleus (rotations and translations) matches that of the Larmor frequency. As a result, T1 relaxation is dependent on the main magnetic field strength which specifies the Larmor frequency. Higher magnetic fields are associated with longer T1 times.

T2 Relaxation

Microscopically, T2 relaxation or spin-spin relaxation occurs when spins in the high and low energy state exchange energy but do not loose energy to the surrounding lattice. 10 Macroscopically, this results in loss of the transverse magnetization. In pure water, The T2 and T1 times are approximately the same, 2-3 seconds. In biological materials, the T2 time is considerably shorter than the T1 time. T2 relaxation occurs exponentially like T1 relaxation with 63% of the transverse magnetization gone after one T2 period as shown in the graph.

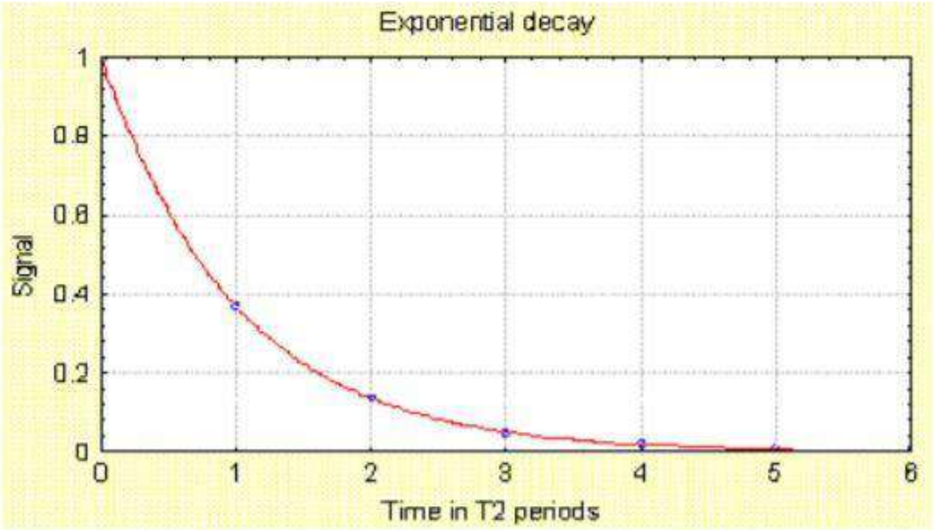

Figure 1.8: T2 relaxation graph.

T2* Relaxation

T2* relaxation is the loss of signal seen with dephasing of individual magnetizations. Macroscopically, it is characterized by a loss of transverse magnetization at a rate greater than T2. T2* relaxation is caused by the magnetic field inhomogeneity that is found in all magnets. Unlike spin echo sequences, gradient echo sequences do not refocus T2* decay. Therefore, gradient echo sequences are more susceptible to magnetic field inhomogeneity caused by ferromagnetic foreign bodies.

Magnetic Susceptibility

The intensity of magnetization, I, is related to the strength of the inducing magnetic field, H, through a constant of proportionality k, known as the magnetic susceptibility. $I = kH$

The magnetic susceptibility is a unit less constant that is determined by the physical properties of the magnetic material. It can take on either positive or negative values. Positive values imply that the induced magnetic field I is in the same direction as the inducing field, H. Negative values imply that the induced magnetic field is in the opposite direction as the inducing field.

Magnetic susceptibility represents a material's tendency to distort a magnetic field. Paramagnetic materials like gadolinium have some electrons that tend to line up with the magnetic field, producing an additive effect. Supermagnetic substances like hemosiderin more strongly attract magnetic lines of force. Ferromagnetic substances (e.g., iron alloys) remain permanently magnetized after being removed from a magnetic field.

Magnetism

Magnetism is a property of matter that is a result of the orbiting electrons in atoms. The orbiting electrons cause the atoms to have a magnetic moment associated with an intrinsic angular momentum called 'spin'. Magnetic field strengths are measured in units of Tesla (T). We will run across four terms describing the magnetic properties of materials, such as contrast agents, used in MRI. These terms are ferromagnetism, paramagnetism, superparamagnetism, and diamagnetism.

Ferromagnetism

Ferromagnetic materials generally contain iron, nickel, or cobalt. These materials have a large positive magnetic susceptibility, i.e., when placed in a magnet field, the field strength is much stronger inside the material than outside. Ferromagnetic materials are also characterized by being made up of clusters of 1017 to 1021 atoms called magnetic domains, that all have their magnetic moments pointing in the same direction. The moment of the domains is random in unmagnetized materials, and point in the same direction in magnetized materials. Figure 2.9 illustrates the effect of a ferromagnetic material (grey circle) on the magnetic field flux lines (blue). The ability to remain magnetized when an external magnetic field is removed is a distinguishing factor compared to paramagnetic, superparamagnetic, and diamagnetic materials. On MR images, these materials cause susceptibility artifacts characterized by loss of signal and spatial distortion.

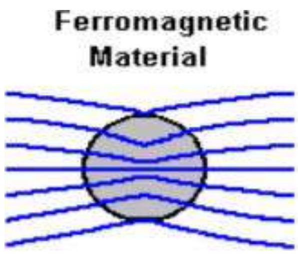

Figure 1.9: Ferromagnetism.

Para magnetism

Paramagnetic materials include oxygen and ions of various metals like Fe, Mg, and Gd. These ions have unpaired electrons, resulting in a positive magnetic susceptibility. The magnitude of this susceptibility is less than one one-thousand of that of ferromagnetic materials. The effect on MRI is increase in the T1 and T2 relaxation rates (decrease in the T1 and T2 times). Figure 2.10 illustrates the effect of a paramagnetic material (grey circle) on the magnetic field flux lines (blue). Gd is used as an MR contrast agent. At the proper concentration, Gd contrast agents cause preferential T1 relaxation enhancement, causing increase in signal on T1-weighted images. At high concentrations, as is sometimes seen in the urinary bladder, loss of signal is seen instead, a result of the T2 relaxation effects dominating.

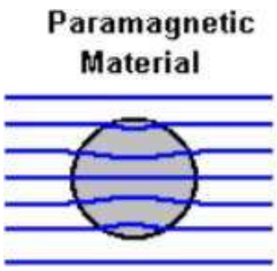

Figure 1.10: Paramagnetism.

Superparamagnetism

Superparamagnetic materials consist of individual domains of elements that have ferromagnetic properties in bulk. Their magnetic susceptibility is between that of ferromagnetic and paramagnetic materials. Figure illustrates the effect of a superparamagnetic material (grey circle) on the magnetic field flux lines (blue). Examples of superparamagnetic materials include iron containing contrast agents for bowel, liver, and lymph node imaging.

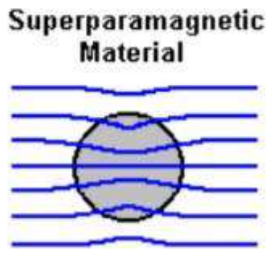

Figure 1.11: Superparamagnetism.

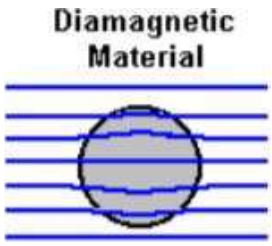
Diamagnetism

weak negative magnetic susceptibility contributes to the loss of signal seen in bowel on MRI after administration of ba Diamagnetic materials have no intrinsic atomic magnetic moment, but when placed in a magnetic field weakly repel the field, resulting in a small negative magnetic susceptibility. Materials like water, copper, nitrogen, barium sulfate, and most tissues are diamagnetic. Figure 2.12 illustrates the effect of a diamagnetic material (grey circle) on the magnetic field flux lines (blue). The rium sulfate suspensions.



1.12.DIAMAGNETIC MATERIAL

1.2.2 Hardware Considerations:

Resonance and RF Protons in a magnetic field have a microscopic magnetization and act like tiny toy tops that wobble as they spin. The rate of the wobbling or precession is the resonant or Larmor frequency. In the magnetic field of an MRI scanner at room temperature, there is approximately the same number of proton nuclei aligned with the main magnetic field Bo as counter-aligned. The aligned position is slightly favored, as the nucleus is at a lower energy in this position. For every one-million nuclei, there is about one extra nucleus aligned with the Bo field as opposed to the field. This results in a net or macroscopic magnetization pointing in the direction of the main magnetic field. Exposure of individual nuclei to RF radiation (B1 field) at the Larmor frequency causes nuclei in the lower energy state to jump into the higher energy state.

On a macroscopic level, exposure of an object or person to RF radiation at the Larmor frequency causes the net magnetization to spiral away from the Bo field. In the rotating frame of reference, the net magnetization vector rotates from a longitudinal position to an angle proportional to the length of time of the RF pulse. After a certain length of time, the net magnetization vector rotates 90 degrees and lies in the transverse or x-y plane. It is in this position that the net magnetization can be detected by an MRI receiver coil. The angle of rotation of the net magnetization vector is commonly called the "flip" or "tip" angle. At angles greater than or less than 90 degrees there will still be a component of the magnetization that will be in the x-y plane, and therefore be detectable.

RF and Gradient Coils

I have grouped these two topics together, although they serve different purposes.

RF Coils

RF coils are the "antenna" of the MRI system that broadcasts the RF signal to the patient and/or receives the return signal. RF coils can be receive-only, in which case the body coil is used as a transmitter; or transmit and receive (transceiver).

Surface Coils

Surface coils are the simplest design of coil. They are simply a loop of wire, either circular or rectangular, that is placed over the region of interest. The depth of the image of a surface coil is generally limited to about one radius. Surface coils are commonly used for spines, shoulders, and other relatively small body parts.

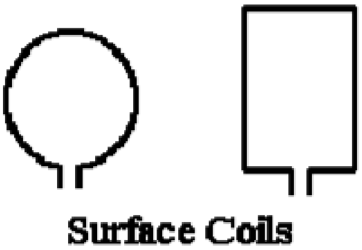


Figure 1.13: Surface Coils.

Paired Saddle Coils

Paired saddle coils are commonly used for imaging of the knee. These coils provide better homogeneity of the RF in the area of interest and are used as volume coils, unlike surface coils. By running current in opposite directions in the two halves of the gradient coil, the magnetic field is made stronger near one and weaker near the other.

Figure 1.14: Paired Saddle Coil.

The Helmholtz Pair Coils

The Helmholtz pair coils consist of two circular coils parallel to each other. They are used as z gradient coils in MRI scanners. They are also used occasionally as RF coils for pelvis imaging and cervical spine imaging.

Figure 1.15: Helmholtz Pair Coil.

The Bird Cage Coil

The bird cage coil provides the best RF homogeneity of all the RF coils. It has the appearance of a bird cage; hence, its name. This coil is commonly used as a transceiver coil for imaging of the head. This type of coil is also used occasionally for imaging of the extremities, such as the knees.

Figure 1.16: Bird Cage Coil.

Gradient Coils

Gradient coils are used to produce deliberate variations in the main magnetic field (Bo). There are usually three sets of gradient coils, one for each direction. The variation in the magnetic field permits localization of image slices as well as phase encoding and frequency encoding. The set of gradient coils for the z axis are Helmholtz pairs, and for the x and y axes, paired saddle coils.

1.2.3 Producing a Magnetic Resonance Signal

Spatial Encoding of the MR Signal

As the tissue protons are perturbed and then realign with the main magnetic field, they produce characteristic radiofrequency signals. This phenomenon is the basis for nuclear magnetic spectroscopy. To produce images however, this information must be capable of being localized. This is achieved by spatially encoding the magnetic spins. The most common way of achieving spatial encoding is to employ two-dimensional Fourier transform (2DFT) imaging. By applying incremental changes across the magnetic field, three orthogonal axes are imposed on the system as follows:

1. **Slice selection**: One gradient is applied at the same time as the RF pulse to selectively excite the spins in a specific slice.
2. **Frequency encoding:** A second gradient encodes location along one in plane dimension based on the frequency of the MR signal.
3. **Phase encoding:** A third gradient encodes along the other in plane dimension based on the phase differences of the MR signal.

These three gradients define three orthogonal planes and they may be aligned arbitrarily to produce any desired oblique projection.

Image Reconstruction

The raw data generated by most sequences is separated into phase and frequency components by a mathematical procedure called Fourier transformation. To generate an anatomic image, the raw data must be inverse Fourier transformed. The Fourier co domain of the image space is referred to as the k-space. k- and image spaces have an identical matrix size and contain equivalent imaging information in terms of spatial resolution and contrast. An exact one-to-one relationship does not exist, however, as the signal contains information from the entire image. The k-space data points are ordered according to the phase and frequency conferred on them by the spatial encoding process. The data points nearest the center of k-space contain the strongest signal elements because they are the least dephased by spatial encoding gradients. In contrast, data points at the periphery of k-space, though weaker, are responsible for reproducing the finer details in the image.

Pulse Sequences

There are many pulse sequences available for imaging (and spectroscopy). Listed below are two of the commonly used pulse sequences in MRI.

Spin Echo Sequence

The spin echo pulse sequence is the most commonly used pulse sequence. The pulse sequence timing can be adjusted to give T1-weighted, Proton or spin density, and T2- weighted images. Dual echo and multiecho sequences can be used to obtain both proton density and T2-weighted image simultaneously. The two variables of interest in spin echo sequences is the repetition time (TR) and the echo time (TE). All spin echo sequences include a slice selective 90 degree pulse followed by one or more 180 degree refocusing pulses as shown in Figure.

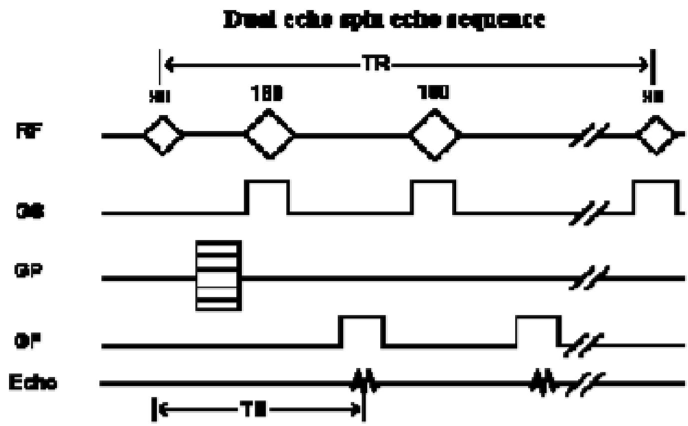

Figure 1.17: Dual echo spin echo sequence.

In this diagram, RF is the radio frequency pulse, a slice selective 90 degree pulse followed by two 180 degree refocusing pulses. GS, GP, and GF are the slice selective, phase encoding, and frequency encoding gradients, respectively. "Echo" represents the signal received from the slice of interest in the body. A short TR an short TE will give a T1-weighted image, a long TR and short TE (first echo) will give a proton density image, and a long TR and long TE (second echo) will give a T2-weighted image. An example of the changes in the net magnetization vector for a spin echo sequence with one echo is shown below. After 1/2 of the TE time, dephasing of individual spins in the volume occurs as represented by the black and red arrows. The 180 degree RF pulse flips these spins to the opposite side in the x-y plane so that after another 1/2 TE, they refocus and are detected.

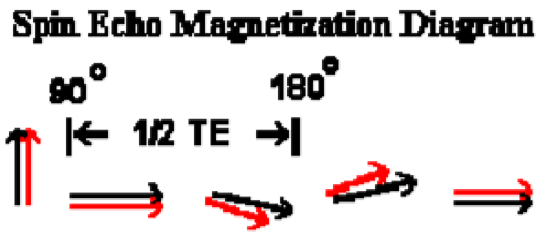

Figure 1.18: Spin Echo Magnetization Diagram.

Inversion Recovery Sequence

Inversion recovery pulse sequences are used to give heavy T1-weighting. The basic part of an inversion recovery sequence is a 180 degree RF pulse that inverts the magnetization followed by a 90 degree RF pulse that brings the residual longitudinal magnetization into the x-y or transverse plane where it can be detected by an RF coil. In imaging, the signal is usually refocused with a 180 degree pulse as in a spin echo sequence. The time between the initial 180 degree pulse and the 90 degree pulse is the inversion time (TI). A diagram of the sequence is shown below.

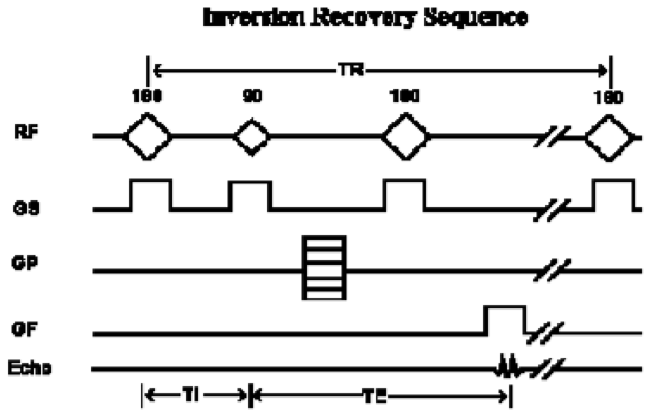

Figure 1.19: Inversion recovery sequence.

With a TI of about 140 ms on a 1.5 T MRI machine, the fat signal is nulled while the water proton signal is still present. This occurs because the T1 of fat is significantly smaller than the T1 of water. The diagram below shows the magnetization of water (black arrow) and fat (red arrow) during the STIR sequence used for fat suppression. One drawback of this sequence is the partial loss of proton signal during the TI time. Also the TR time must be longer than that of a spin echo sequence for recovery of longitudinal magnetization.

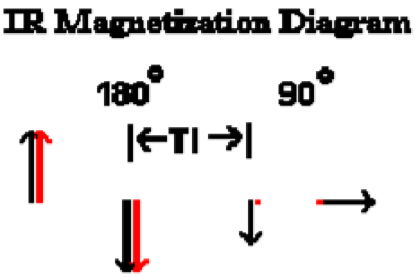

Figure 1.20: IR Magnetization Diagram.

1.2.4 - MRI Artifacts

There are many kinds of artifacts that can occur in MRI. Some affect the quality of the MRI exam while others do not affect the quality but may be confused with pathology.

Phase-Encoded Motion Artifacts

Phase-encoded motion artifacts appear as bright noise or repeating densities oriented in the phase direction, occurring as the results of motion during acquisition of a sequence. These artifacts may be seen from arterial pulsations, swallowing, breathing, peristalsis, and physical movement of a patient. Phase-encoded artifacts can be reduced by various techniques depending on their cause and location. Surface coil localization can reduce artifacts generated at a distance from the area of interest. The following axial image of the head shows a phase-encoded motion artifact running transversely across the back of the head as a result of venous flow in the transverse sinuses.

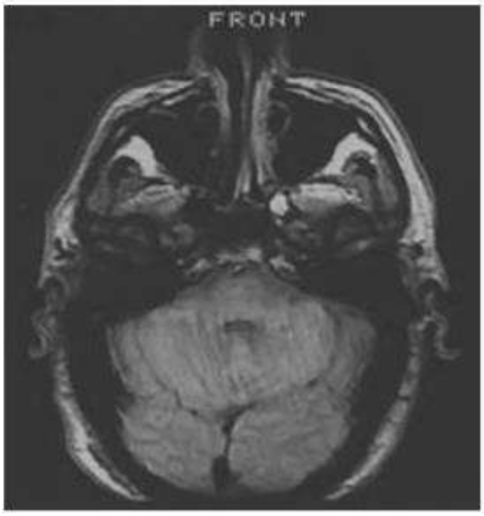

Figure 1.21: Axial image of the head showing a phase-encoded motion artifact running transversely across the back of the head.

Aliasing or "Wrap-around”

Aliasing or wrap-around is a common artifact that occurs when the field of view (FOV) is smaller than the body part being imaged. The part of the body that lies beyond the edge of the FOV is projected on to the other side of the image. This can be corrected, if necessary, by oversampling the data. The following axial images of the brain demonstrate this artifact. Figure shows wraparound of the back of the head on to the front of the head, where the phase-encoded direction is anterior-posterior. Figure has the phase and frequency directions reversed resulting in absence of the aliasing artifact. Oversampling was used in the frequency direction to eliminate the aliasing.

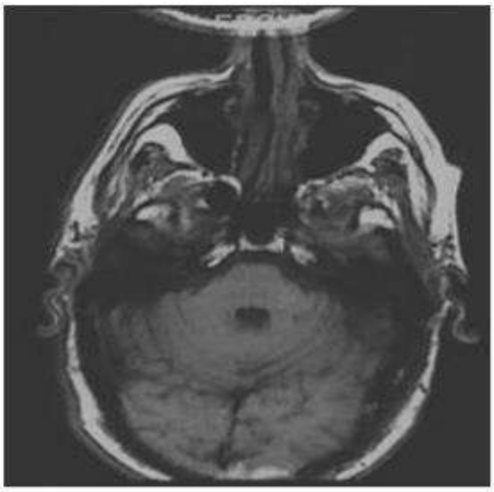

Figure 1.22: Axial images of the brain demonstrate Aliasing or wrap-around artifact.

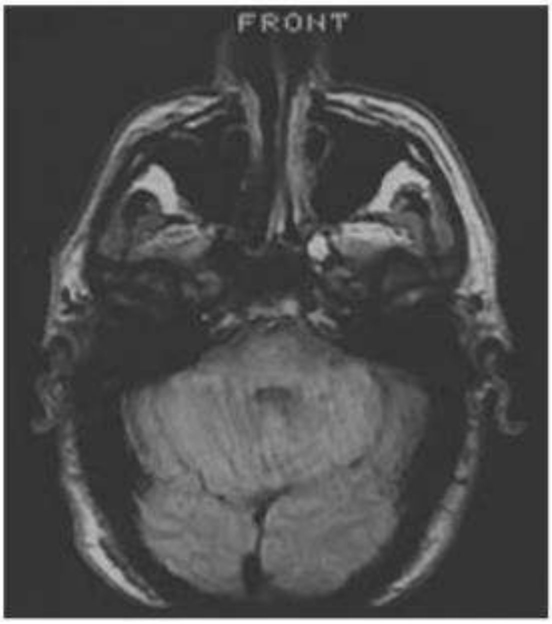

Figure 1.23: Oversampling used in the frequency direction to eliminate the aliasing.

Moirés Fringes

Moirés fringes are an interference pattern most commonly seen when doing gradient echo images with the body coil as shown in the figure 5.4A.

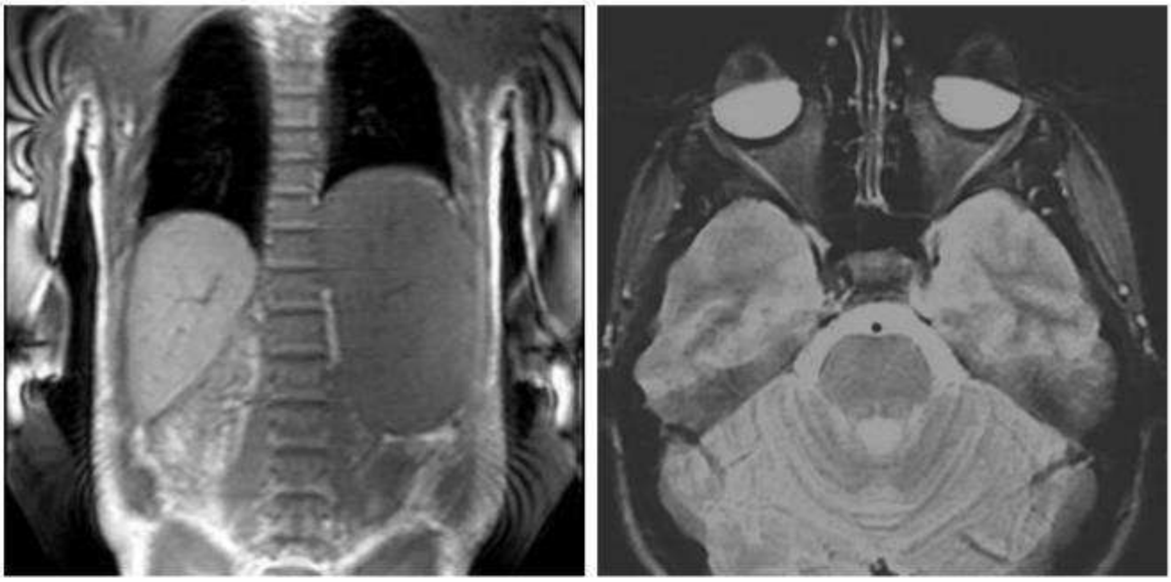

Figure 1.24: A: Moirés fringes in image of one side of the body. B: Susceptibility artifacts in axial MRI of the head in a patient with mascara on her eyelids.

Because of lack of perfect homogeneity of the main magnetic field from one side of the body to the other, aliasing of one side of the body to the other results in superimposition of signals of different phases that alternatively add and cancel. This causes the banding appearance and is similar to the effect of looking though two screen windows.

Susceptibility Artifacts

Susceptibility artifacts occur as the result of microscopic gradients or variations in the magnetic field strength that occurs near the interfaces of substance of different magnetic susceptibility. Large susceptibility artifacts are commonly seen surrounding ferromagnetic objects inside of diamagnetic materials (such as the human body). These gradients cause dephasing of spins and frequency shifts of the surrounding tissues. The net result is bright and dark areas with spatial distortion of surrounding anatomy. These artifacts are worst with long echo times and with gradient echo sequences. Figure 5.4B is showing an axial MRI of the head in a patient with mascara on her eyelids. Susceptibility artifacts from the mascara obscure the front half of the globes.

Practical Aspects of Magnetic Resonance Imaging

Biologic Effects

Three areas have received attention in terms of the biologic effects of MRI. The first area concerned the use of strong static magnetic fields (Bo). The primary theoretical concerns had to do with the effects of the magnetic field on the protons and electrons within molecules that could affect chemical bonding or biochemical reactions. Experiments have been conducted both in vitro as well as in vivo for cellular preparations, tissues, and organisms. The conclusion from these data is that no deleterious biologic effects have been demonstrated for magnetic field strengths commonly found in MRI. Currently, 8 T is accepted as the limit below which no deleterious biologic effects have been demonstrated.

The second area of concern centered on the use of time-varying magnetic fields (gradient fields). Changing magnetic fields can induce electric currents in biologic tissues. The two tissues of primary concern are the heart and the nervous system. In addition, it is possible to stimulate the retina with an appropriate gradient. Current induction is dependent upon the rate of magnetic field change (dB/dt). In the systems studied, the thresholds for these biological effects are sufficiently high that a biological stimulation does not occur for the gradient fields typically found in MRI, usually less than 400 T/s.

The third area of concern centered on the biological effects associated with the use of radio frequency radiation. This field of investigation has been the subject of scientific inquiry (apart from MRI) for quite a long time. The primary biologic effect of interest is that of heating due to the oscillation of the atoms and molecules stimulated by the radio frequency radiation. The amount of heating is dependent on several factors, including the RF frequency, the absorption of the RF energy, and the thermoregulatory mechanisms within humans.

Although a rise in body temperature is possible, it is usually not a problem in patients whose cardiovascular or thermoregulatory systems are not compromised. Hence, RF heating is not deemed a contraindication for the use of routine clinical MRI

Safety

Safety can be divided up into three areas:

Main Magnetic Field and Safety

The main magnetic field of a 1.5 T magnet is about 30,000 times the strength of the earth's magnetic field. It is strong enough to pull fork-lift tines off of machinery, pull heavy-duty floor buffers and mop buckets into the bore of the magnet, pull stretchers across the room and turn oxygen bottles into flying projectiles. Deaths have occurred from trauma as a result of these effects. Smaller objects such as pagers, bobby pins and pens have been known to be pulled off the person carrying them.

Some types of heart valves are torqued in a magnetic field: however, this torque is less than the stresses that occur normally as a result of blood flow. Therefore, heart valves are now considered not to be an absolute contraindication for MRI. More of an annoyance than a safety problem is the ability of the magnetic field of a MRI machine to erase the information contained on the magnetic strip on ATM and credit cards. This may occur a short distance inside of the scanner room of a MRI machine.

Varying Magnetic (Gradient) Fields

Varying magnetic fields are necessary in order to obtain images from MRI scanners. Changing magnetic field induce electrical currents in conductors. In patients with metal in their body, the potential exists for electrical currents being induced in the metal with subsequent heating. This may occur with metal foreign bodies or some surgical implants. It does not universally occur and patients may be scanned without harm. Very rapidly changing magnetic fields as may be achieved with echo planar imaging can cause nerve stimulation. This stimulation can affect motor nerves with resulting muscle contraction as well as the retina with resulting flickering lights.

Radio Frequency

The radio frequency power that is capable of being produced matches that of many small radio stations (15-20 kW). As a result there is the presence of heating effects from the RF. In most pulse sequences, the heating is insignificant and does not exceed the FDA guidelines. New pulse sequences such as for echo planar imaging and some spectroscopy localization techniques are capable of exceeding the FDA guidelines. Monitoring of the power deposition in patients is a requirement for FDA approval of clinical MRI scanners. Potential for electrical shock exists with RF coils so proper grounding and insulation of coils is necessary. Any damage to coils or their cables needs prompt attention. Also looping of the cable to a coil can result in burns to patients that come into contact with them. It is best to avoid all contact with the RF coil cables.

1.3 SCOPE OF THE STUDY:

- **EURASIP** journal on image and video processing is intended for researchers from both acasemia and industry, who are active in the multidisciplinary field of image and video processing

- The scope of the journal covers all therotical and practical aspect of the domain from, basic research to development of applicaton

- Contributed articles on image and video processing may be focused an specific techniques

- The classification of image processing comopression, recognition, restoration, and segmention. With in the context of various medical aaerial robitcs, security , communications arts are employing divers data format

- The image processing we have diifernt format black and white gary scale ,color, multi spectral , infra red ,video,stereo,3-d

1.4 MATERIAL REQUIREMENT

1.4.1 SOFTWARE REQUIREMENT:

MAT LAB SOFTWARE R2013B

PRESONAL COMPUTER

1.5 PROCUMENT OF EQUIPMENT:

Searchig mat lab programming ………………

CHAPTER-2
SOFTWARE USED

2.1 Introduction to MATLAB:

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation.

- Typical uses include
- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN. The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation. MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

2.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment:**

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library:**

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language:**

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

Graphics:

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

The MATLAB Application Program Interface (API):

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files. Various toolboxes are there in MATLAB for computing recognition techniques, but we are using IMAGE PROCESSING toolbox.

2.3. GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based Mfunction is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed. To launch GUIDE from the MATLAB command window, type guide filename Where filename is the name of an existing FIG-file on the current path. If filename is omitted, GUIDE opens a new (i.e., blank) window.

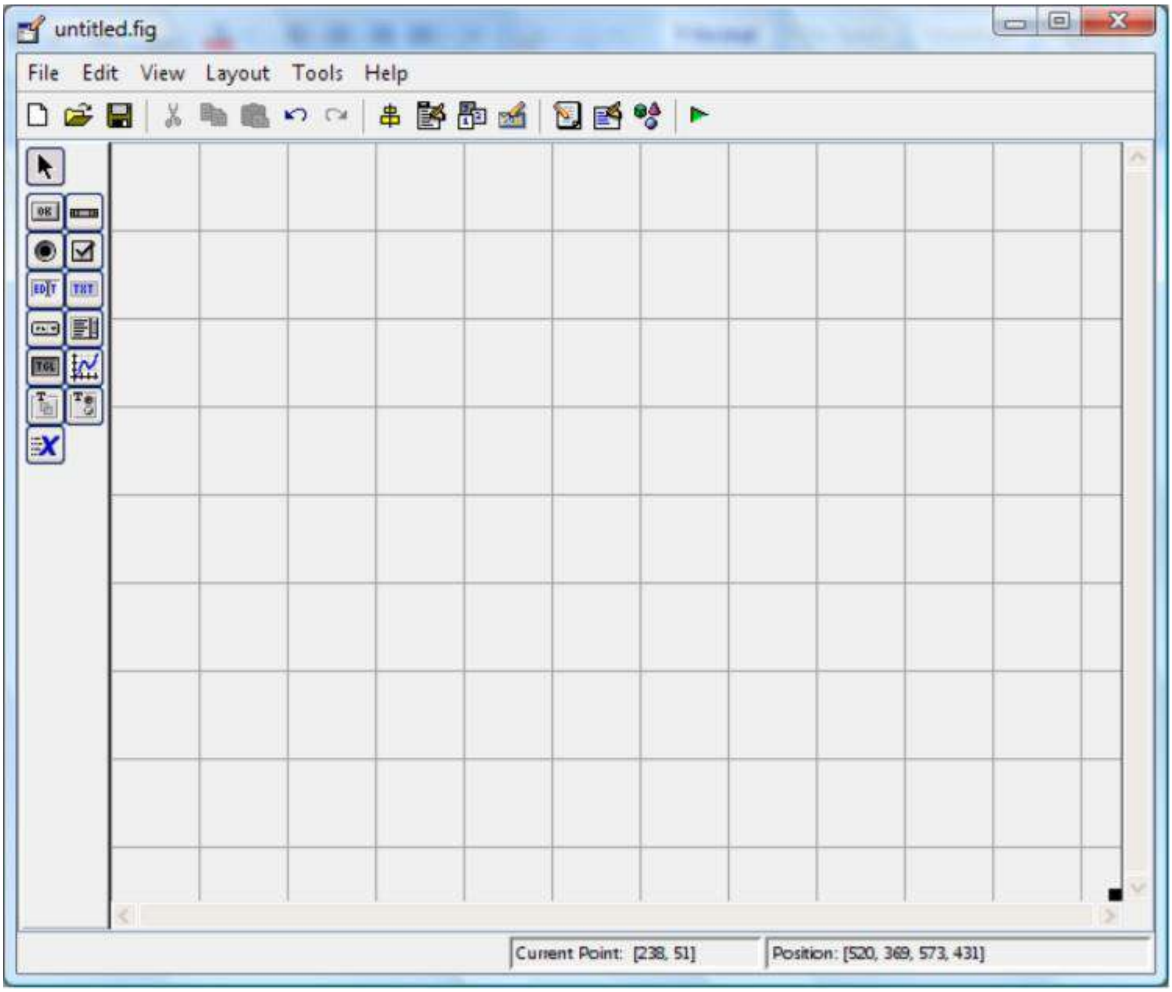

Figure 2.1 matlab procedure

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed. GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots

. **2.4 Getting Started:**

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos. At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

2.4.1 Introduction - describes the components of the MATLAB system.

2.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

2.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

2.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

2.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

2.5 DEVELOPMENT ENVIRONMENT

2.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

2.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop. On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop. You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

2.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

2.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

2.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools.

The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents. To open the Help browser, click the help button in the toolbar, or type help browser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go. Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find Mfiles and other MATLAB-related files, which are organized in directories on your file system.

Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos. To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function. The workspace is not maintained after you end the MATLAB session.

To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic textediting, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint

CHAPTER-3

PROJECT DESIGN

3.1 Anisotropic diffusion filters :

A large and growing body of literature has investigated about enhancement methods. Image enhancement deals with improving the quality of images, where the objective is to emphasize wanted features and make them less obscured. The area of image enhancement is very appealing, where many fundamental image enhancement techniques are developed based on a very simple concept. In the recent decades, image enhancement based on contrast enhancement has been focused

Many researchers argued that Histogram equalization (HE) is a simple and an easy method to enhance the contrast and improve the image quality. Since 1997, Yeong Kim raised several concerns about contrast problem and suggested Brightness preserving Bi-Histogram Equalization (BBHE) in order to enhance the contrast. The average intensity value was applied as a separating point to differentiate between a dark area and bright area. The above finding contradicts the study by Wang et al. The author presented that a median intensity value is more accurate as the separating point compared to the average intensity. These results were contradicted that suggested the minimum mean brightness between original and output image as the separating point is more specific and accurate compared to the BBHE and Dualistic Sub Image Histogram Equalization (DSIHE).

Research conducted by Ooi and Isa proposed a new improvement in histogram equalization known as Quadrant Dynamic Histogram Equalization (QDHE). The first step in this technique was to divide the histogram into four sub-quadrant histograms based on the median value of the original image. After normalizing each sub-histogram, finally, the image was equalized. A major advantage of QDHE is that it's enhanced the image without any intensity saturation, noise amplification, and over-enhancement. In 2010, Ooi et al. presented a new method based on Plateau level equation, namely Bi-Histogram Equalization with a Plateau Level (BHEPL). The main objective of this paper is to improve the BBHE technique in term of processing time.

The process of this method also involved mean brightness preserving histogram equalization method with a clipped histogram equalization method. However, interestingly, this is contrary to a study conducted by Sengee et al. They suggest an extension method of BBHE based on the Neighbourhood Metric. This method involved a few steps: First, a large histogram was divided into the sub-region using Neighbourhood Metric. Second, based on mean, the histogram of the original image was separated into two sub-regions and process independently. The results enhanced the local contrast and preserved the brightness of the original image. The comparison of result performance is illustrated in Figure 3.1.

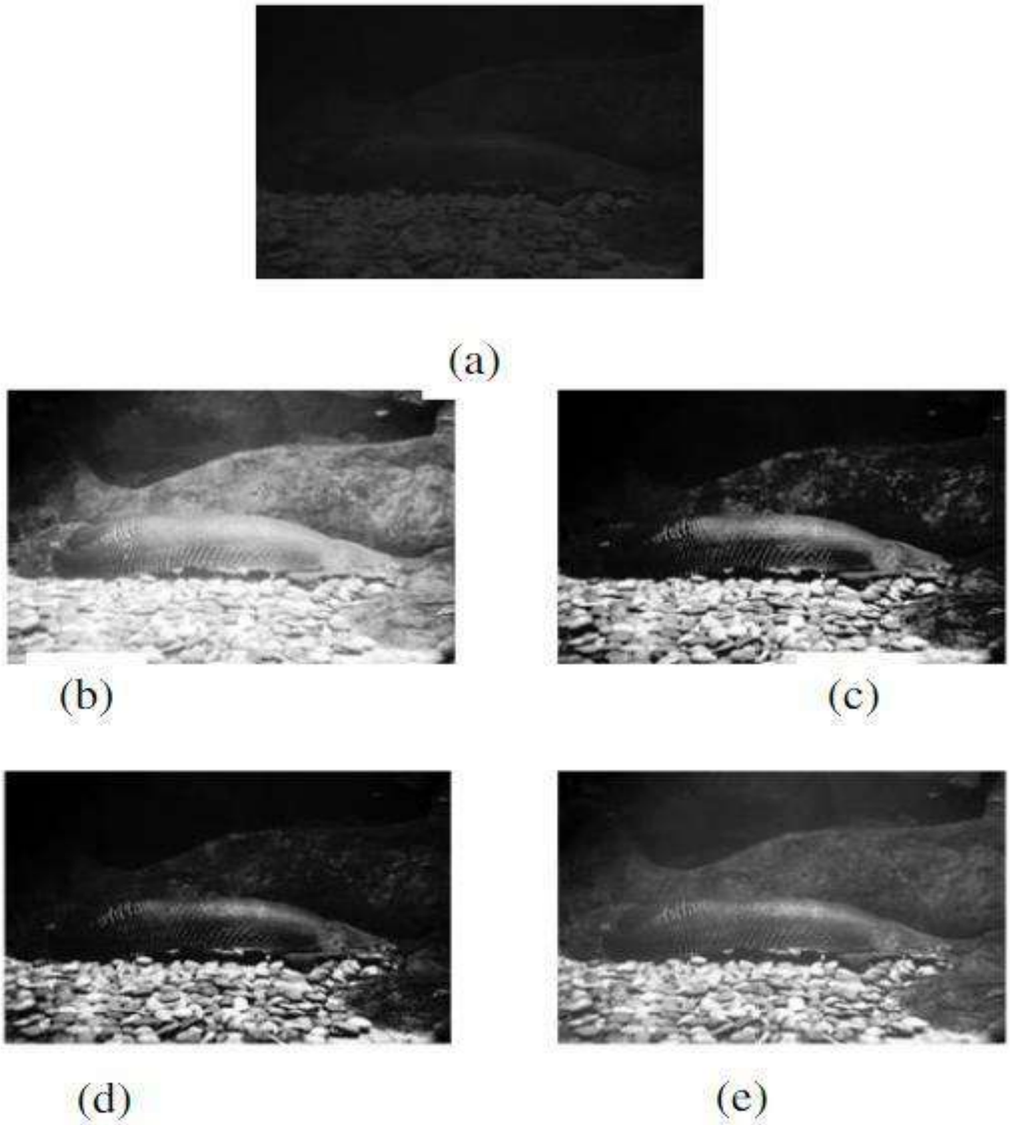

Figure 3.1. The comparison of enhancement result based on histogram modification: (a) Original image, (b)HE, (c) BBHE, (d) BHEPL, and (e) QDHE.

In a different study, Salah et al. explained a new approach to solving the illumination problem on the face images using Histogram Equalization (HE). The technique is based on the combination of gamma correction and the Retinal filter's compression function namely GAMMA-HM-COMP. The Retinal filter is a new enhancement method, and the result was effective compared to the three conventional enhancement methods which are histogram equalization, gamma correction and log transformation. In another study, Tan et al. proposed a Background Brightness Preserving Histogram Equalization (BBPHE) method based on non-linear Histogram equalization (HE). Based on the background and non-background level techniques, the original image was separated into three interval histograms:

(1) low grey level,
(2) medium grey level, and
(3) high grey level.

The objective of this method is to enhance the object contrast and maintaining the background brightness. Similarly, Moniruzzaman et al. proposed a modification of Brightness Preserving Bi-Histogram Equalization (BPBHE) using the edge pixels data. In order to prove the effectiveness, the Average Mean Brightness Error (AMBE) was calculated and the result was presented in table 3.1. The lowest of AMBE shows the high quality image and good performance technique.

Image	HE	BBHE	BPBHE
A	24.3350	29.7404	3.4737
B	42.0428	35.4111	2.5079
C	53.9887	13.6073	13.6073
D	11.386	8.5763	3.3188

Table 3.1. The AMBE result on different histogram technique.

Hashemi et al. proposed a novel enhancement method based on Genetic Algorithm using a simple chromosome structure and corresponding operator. The method was tested on the image that has a low dynamic range. In 2013, research finding by Chaudhary and Patil also suggested a simple method based on Genetic Algorithm. The advantages of both methods are fast processing time, efficient, and produce a high-quality image. Besides that, they also produced a comprehensive comparison between a BBHE, DSIHE, MMBBHE, MPHE, and RMSHE. The analyses were done based on PSNR and contrast ratio.

In another study, Shome et al. examined a method using Contrast Limited Adaptive Histogram Equalization (CLAHE) in order to normalize the contrast variation in the retinal image. CLAHE is an adaptive extension of Histogram Equalization followed by thresholding, which helps in the dynamic preservation of the local contrast features of an image. This proposed method used a non-mean based approach to improve the quality of the Diabetic Retinopathy (DR) image while preserving the sharpness and minutes of the details. The method also increased the local contrast pixels. The above view was supported studied by Sundaram et al.

where a CLAHE technique with a slight modification was suggested in order to enhance the mammogram images. The method was known Histogram ModifiedHashemi et al. proposed a novel enhancement method based on Genetic Algorithm using a simple chromosome structure and corresponding operator.

The method was tested on the image that has a low dynamic range. In 2013, research finding by Chaudhary and Patil also suggested a simple method based on Genetic Algorithm. The advantages of both methods are fast processing time, efficient, and produce a high-quality image. Besides that, they also produced a comprehensive comparison between a BBHE, DSIHE, MMBBHE, MPHE, and RMSHE. The analyses were done based on PSNR and contrast ratio.

In another study, Shome et al. examined a method using Contrast Limited Adaptive Histogram Equalization (CLAHE) in order to normalize the contrast variation in the retinal image. CLAHE is an adaptive extension of Histogram Equalization followed by thresholding, which helps in the dynamic preservation of the local contrast features of an image. This proposed method used a non-mean based approach to improve the quality of the Diabetic Retinopathy (DR) image while preserving the sharpness and minutes of the details. The method also increased the local contrast pixels. The above view was supported studied by Sundaram et al. where a CLAHE technique with a slight modification was suggested in order to enhance the mammogram images. The method was known Histogram ModifiedContrast Limited Adaptive Histogram Equalization (HM-CLAHE). The optimization technique was used to adjust the level of strong contrast and the local details for more relevant interpretation. Based on Enhancement Measure (EME) result, this method was better compared to the HE, Unsharp masking (USM), and CLAHE. Tan et al. introduced a modification of HE based on non-linear technique.

The aim is to enhance the image contrast, while preserving the background brightness for images with well-defined background brightness. The original image was divided into three sub-images by using the proposed algorithm. Finally, only the problem region was normalized. The correction process based on sub-images technique also was supported by Shanmugavadivu and Balasubramanian. They proposed a new method called as Thresholded and Optimized Histogram Equalization (TOHE). The main process has divided the histogram using the Otsu thresholding. Based on the result performance, this approaches is successful compared to the HE, BBHE, Range-Limited Bi-Histogram Equalization (RLBHE). Figure 3.2 shows the comparison result between TOHE and a few histogram methods. Circle in figure 3.2 represent the improvement and drawback of each method.

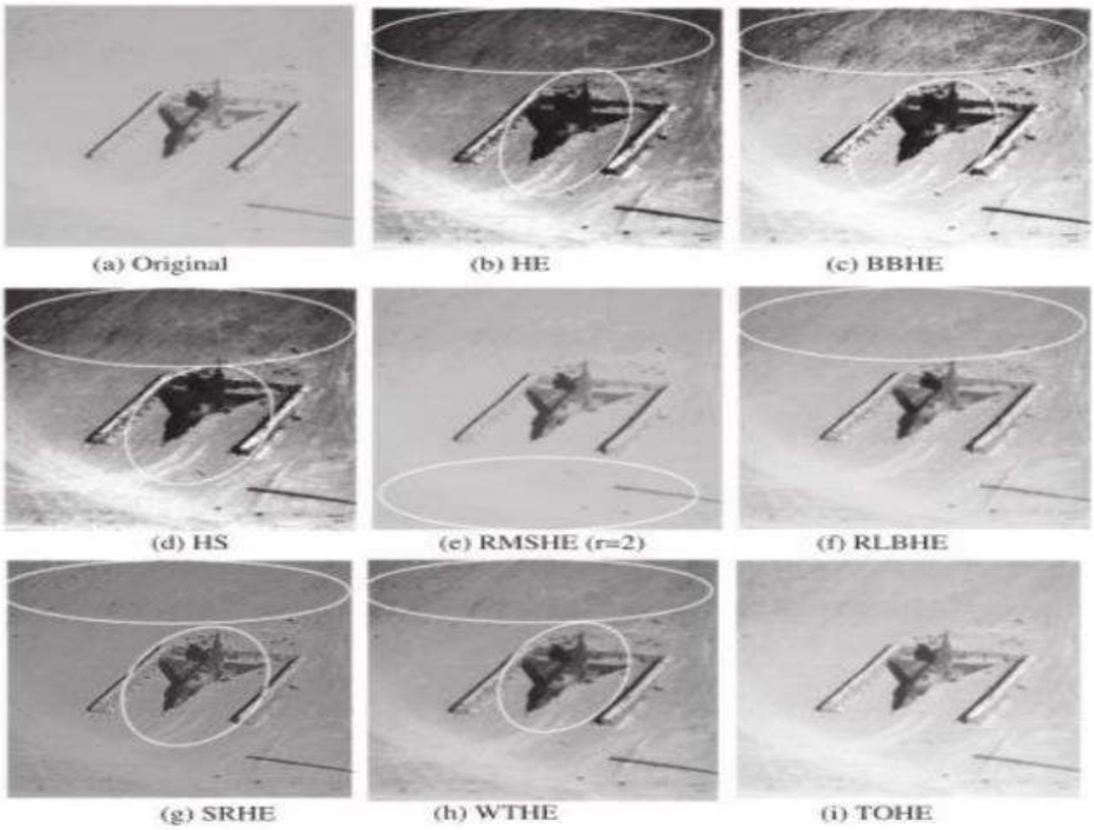

Figure 3.2. Comparison of the result performance after applying a different histogram process.

On the other side, Lin et al. [33] suggested a new HE method was applied to the colour image known as Averaging Histogram Equalization (AVHEQ). The technique also separates the original image into sub-images and equalized independently. A new mathematical algorithm in order to determine the optimal averaging threshold was proposed. The result is better compared to the conventional methods such as BBHE, DSIHE, and BHEPL.

Contrast-enhancement is an essential pre-processing step towards efficient clinical diagnosis of MR images. Various HE-based contrast-enhancement techniques are reported in literature. The main motivation of these variants HE is to preserve the best features of the classical HE technique in terms of brightness and contrast, while introducing modifications that will overcome the disadvantages associated to HE. In the next subsections we are going to study and describe some of these HE-based techniques.

3.2 Adaptive histogram equalization (AHE):

For images which contain local regions of low contrast bright or dark regions, global histogram equalization won't work effectively. A modification of histogram equalization called the Adaptive Histogram Equalization can be used on such images for better results. Adaptive histogram equalization works by considering only small regions and based on their local cdf, performs contrast enhancement of those regions.

Adaptive histogram equalization can be implemented by various methods and each of those methods have multiple variation. For the purpose of this project I have implemented AHE using a "tiled windows with interpolated mapping" method as described in the paper - "Adaptive Histogram Equalization and its Variations" by Pizer.

This function is implemented in the program ahe.cpp by the function tiledAHE. The main steps performed by this function are:

1. Calculate a grid size based on the maximum dimension of the image. The minimum grid size is 32 pixels square.
2. If a window size is not specified chose the grid size as the default window size.
3. Identify grid points on the image, starting from top-left corner. Each grid point is separated by grid size pixels.
4. For each grid point calculate the cdf of the region around it, having area equal to window size and centered at the grid point.
5. After calculating the mappings for each grid point, repeat steps 6 to 8 for each pixel in the input image.
6. For each pixel find the four closest neighboring grid points that surround that pixel.
7. Using the intensity value of the pixel as an index, find its mapping at the four grid points based on their cdfs.
8. Interpolate among these values to get the mapping at the current pixel location. Map this intensity to the range [min:max] and put it in the output image.

I have noticed that the interpolation equation given in the paper is incorrect. It is using the inverse interpolating factors for interpolating between the mapped value which would give incorrect results.

The command line parameters for this program are:

```
$ ./ahe inImage bins [w:windowsize] [c:clipLevel]
```

where in Image is the input image, bins specifies the number of bins to use for calculating the cdfs, windowsize specifies the window size to use and clipLevel specifies histogram clipping level for contrast limited ahe which will be discussed in the next section. The default and minimum window size is equal to the grid size, which in turn depends on the maximum dimension of the image. Having the window size the as the grid size results in dividing the image into non-overlapping regions. The user may specify a larger window size if he wants to.

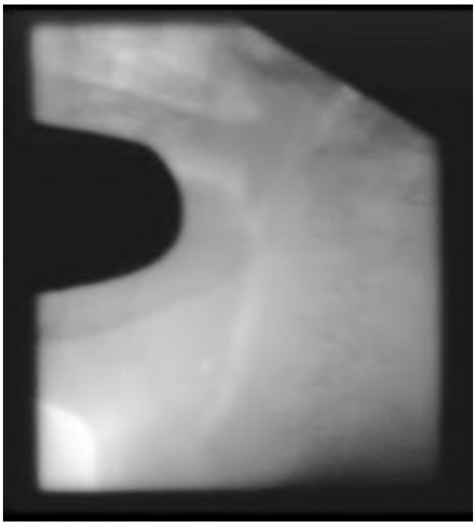

Figure 3.3: Input Image

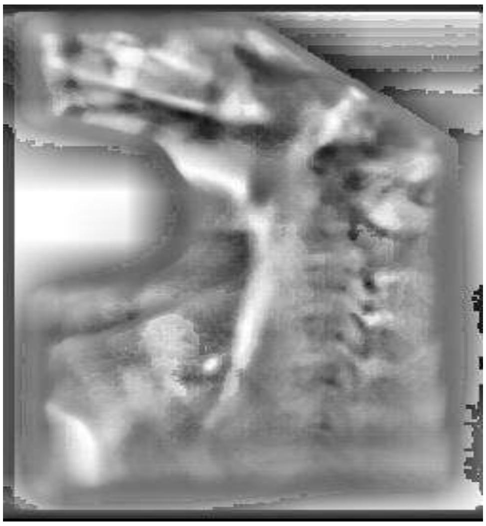

Figure 3.4: Output Image

Contrast-limited adaptive histogram equalization

While performing AHE if the region being processed has a relatively small intensity range then the noise in that region gets more enhanced. It can also cause some kind of artifacts to appear on those regions. To limit the appearance of such artifacts and noise, a modification of AHE called Contrast Limited AHE can be used. The amount of contrast enhancement for some intensity is directly proportional to the slope of the CDF function at that intensity level. Hence contrast enhancement can be limited by limiting the slope of the CDF. The slope of CDF at a bin location is determined by the height of the histogram for that bin. Therefore if we limit the height of the histogram to a certain level we can limit the slope of the CDF and hence the amount of contrast enhancement.

The only difference between regular AHE and CLAHE is that there is one extra step to clip the histogram before the computation of its CDF as the mapping function is performed. Hence CLAHE is implemented in the same function tiledAHE in ahe.cpp. The program "ahe" takes an additional optional parameter which specifies the level at which to clip the histogram. By default no clipping is performed. Valid values for clipping fall in the range from 1 to 1/bins.

Following is the overview of the algorithm for this function:

1. Calculate a grid size based on the maximum dimension of the image. The minimum grid size is 32 pixels square.
2. If a window size is not specified chose the grid size as the default window size.
3. Identify grid points on the image, starting from top-left corner. Each grid point is separated by grid size pixels.

4. For each grid point calculate the histogram of the region around it, having area equal to window size and centered at the grid point.
5. If a clipping level is specified clip the histogram computed above to that level and then use the new histogram to calculate the CDF.
6. After calculating the mappings for each grid point, repeat steps 6 to 8 for each pixel in the input image.
7. For each pixel find the four closest neighboring grid points that surround that pixel.
8. Using the intensity value of the pixel as an index, find its mapping at the four grid points based on their cdfs.
9. Interpolate among these values to get the mapping at the current pixel location. Map this intensity to the range [min:max) and put it in the output image.

Clipping the histogram itself is not quite straight forward because the excess after clipping has to be redistributed among the other bins, which might increase the level of the clipped histogram. Hence the clipping should be performed at a level lower than the specified clip level so that after redistribution the maximum histogram level is equal to the clip level.

To identify the point at which the clipping should be performed, I am using the binary search method as specified in the paper "Adaptive Histogram Equalization and its Variations". Following is an overview of the clipping algorithm.

1. Let the specified clip level be Top and 0 be the Bottom.
2. Until the difference between Top and Bottom become very small, perform the following steps:
    1. Calculate the Middle between Top and Bottom
    2. Find the sum of excess above Middle in each bin of the histogram
    3. If excess + Middle is greater than Clip level set Top = middle
    4. If excess + Middle is less than Clip level set Bottom = middle
    5. If excess + Middle is equal to Clip then Middle is the value at which clipping needs to be performed. Hence break out of the binary search loop.
3. Clip the histogram at the value of middle and redistribute the excess into each bin equally.

The function to clip the histogram and other histogram related functions are implemented in the C++ file - histogram.cpp.

The command line parameters for this program are:

$ ./ahe inImage bins [w:windowsize] [c:clipLevel]

where inImage is the input image, bins specifies the number of bins to use for calculating the cdfs, windowsize specifies the window size to use and clipLevel specifies histogram clipping level for contrast limited

CLAHE is only effective for images which contain relatively homogenous ere enhanced noise or artifacts may appear due to AHE.

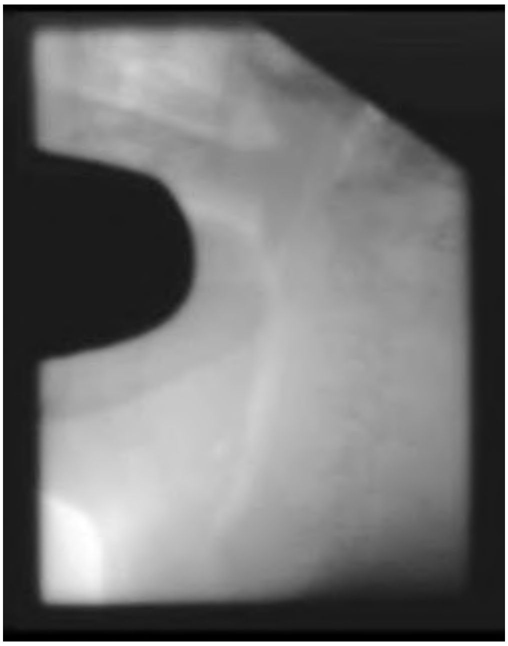

Figure 3.5: Input Image

Figure 3.6: Output Image

Brightness Preserving Dynamic Histogram Equalization (BPDHE)

Brightness preserving dynamic histogram equalization (BPDHE) which is proposed in this paper consists of five steps:

1. Smooth the histogram with Gaussian filter.
2. Detection of the location of local maximums from the smoothed histogram.
3. Map each partition into a new dynamic range.
4. Equalize each partition independently.
5. Normalize the image brightness.

Figure 3.7: Input Image

Figure 3.8: Output Image

Average Intensity Replacement based on Adaptive Histogram Equalization (AIR-AHE)

This study proposes an adaptive algorithm for brain MRI images called the Average Intensity Replacement based on Adaptive Histogram Equalization (AIR-AHE). AIR-AHE can automatically enhance the WMH region in FLAIR images. This work is served as the most important part of automatic segmentation of WMH on MRI (T2-WI and FLAIR) images in the brain at 1.5 T. The implementation of the proposed image enhancement algorithm for FLAIR sequences mode is chosen because it is capable of providing complimentary information of the WMH development as stated by Maillard et al. This algorithm combines several established enhancement algorithms (with some modification where needed), to improve the contrast of the image. The proposed algorithm consists of partial contrast stretching, contrast enhancement, window sliding neighborhood operation and new pixel centroid replacement. The sequences of MRI FLAIR images which have been used for segmentation have low contrast. Therefore, firstly, the contrast stretching is used to improve the quality of the image particularly the WMH region. After improving the quality of the image, the regions of high intensity are determined to represent the potential WMH area. Then, the Contrast-Limited Adaptive Histogram Equalization algorithm is used to enhance the contrast of each tile during the mapping of the WMH area to avoid amplifying any noise that might be present in the image, especially in the FLAIR image. A 3 by 3 window is used to scan the overall ROI to determine the average intensity among the local neighborhood pixels. Generally, the overall proposed algorithm procedure is as follows.

1. Load the image to be segmented.

2. Apply partial contrast stretching. Adjust the contrast in the image to setthe limits by saturating the upper and the lower contrasts by 1% respectively.

3. Apply the Contrast-Limited Adaptive Histogram Equalization algorithm with clipping limits in the range of 0–1.

4. Find the highest or maximum intensity regions of the WMH image.

5. Find the intensity of each pixel using 3 by 3 window sliding neighborhood operation. The new intensity for every pixel value of the center image is calculated based on the average value of the tile's window.

6. Use the new intensity pixel to update the center of the window while the other remaining pixels remain unchanged.

7. Repeat steps 5 to 7 for the sliding neighborhood operation to calculate and update all the pixels with a new calculated intensity value.

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Over the past several years, numerous MRI contrast enhancement and denoising approaches have been reported in the literature. This step of image preprocessing is very crucial for the efficiency of the subsequent image processing steps, for instance segmentation, classification and reconstruction. Among these approaches, one could report the linear filtering (spatial and temporal) and nonlinear filtering approaches, e.g. anisotropic diffusion filter (ADF), bilateral filtering. There are also the transform-based approaches, e.g. wavelet and curvelet transforms as well as statistical-based approaches e.g. maximum likelihood (ML), random forest and Markov Random Field (MRF), etc.

For MRI contrast enhancement, the histogram modificationsbased approaches have gained a great research interest by scientists due to their advantages: simplicity and ease of use, higher SNR as well as its low computational complexity. In fact, the most employed classical images contrast enhancement technique is the Histogram Equalization (HE), which provides good performance for ordinary images, such as human portraits or natural images. However, in MRI brain images, there are often more complex situations where the brain tumor White matter hyper intensities (WMH) signal is high but it may mistakenly be considered as other brain tissues such as Cerebrospinal fluid (CSF). In this paper, we will focus on the study of the major histogram modifications based approaches when applied to brain MRI images for contrast enhancement. Sazanita et al. proposed a new approach applied for FLAIR MRI images, known as the Average Intensity Replacement–Adaptive Histogram Equalization (AIR-AHE), which enhances the contrast without over amplifying the entire image. It improves the contrast of WMH relying on the intensity adjustment and contrast mapping techniques, more details of this method are explained in this paper.

The authors proposed a Hierarchical Correlation Histogram Analysis algorithm (HCHA) which provides an automatic contrast enhancement of images during the examination of atrophic cell areas of Parkinson Disease (PD) patients. This algorithm is based on the grayscale distribution degree of pixel intensity by constructing a correlation histogram. This method has as objective to provide the best segmentation accuracy result and facilitates subsequently CAD processes. SENTHILKUMARAN et al. performed a comparative study of different histogram-based techniques, mainly the histogram equalization (HE), BHE, modified BHE, AHE and CLAHE, in order to enhance the contrast of general MRI brain images. They used different evaluation metrics as Michelson contrast, RMS contrast, absolute mean brightness error (AMBE) and Pixel Distance. While the major comparative studies of histogram-based techniques are performed on general

MRI brain images, to the best our knowledge, there is no comparative study performed on MRI glioma brain tumors.

In fact, the main objective of the present comparative study is to find, over the existing recent contrast-enhancement methods, the most preferment and effective techniques for the MRI Glioma brain tumors images, specifically glioblastoma. Since glioblastomas are infiltrative tumors, their borders are often fuzzy and hard to distinguish from healthy tissues. Furthermore in some cases, the tumor region might share the same intensity profile with other normal regions within the image.These characteristics make the localization of tumor core edges a very difficult task for radiologists. Thus, the MRI contrast-enhancement is important on the one hand, it is a clinical necessity that facilitate, for radiologists and neurologists, the tumor detection and distinguish it from other tissues (edema and necrosis), and on the other hand, it makes easier for the CAD to have more efficiency and accuracy in different tasks such as automatic segmentation and even the classification task.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION:

- The main objective of this paper is to provide a comparative study of some existing techniques of contrast enhancement based on histogram equalization for MRI Glioblastoma brain tumor.

- we selected the most relevant slices where the tumor core appears clearly, then we computed the average value (with a standard deviation) of the quality evaluation metrics which makes the evaluation to be more precise.

- Through this study one could notice that, ADF technique provides efficient performances for MRI contrast enhancement compared to other studied techniques. For future works, we will focus on enhancing the AHE techniques by introducing filtering approaches that could improve the results in terms of accuracy and treatment efficiency

6.2 FUTURE ENHANCEMENT

- Future work includes the validation of the proposed method with a larger data base of the images.

- The use of the other mathods to evaluate the quality of the edges in the during the procee , this is the future enhancemrnt of the project.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, we would like to express our deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express our deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

We would like to express our gratitude to **Dr.B.Hari Krishna**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in our memory for years to come.

We would like to express our gratitude to our dept. project coordinator **Dr. A. Anand kumar, Professor** for his involvement with originality has triggered and nourished ourintellectual maturity that will help us for a long time to come.

We sincerely thank our **Class Project Coordinator, Ms. P. Pushpa,** Department of ECE and our project **Internal guide, Ms. K. Pritika, Assistant Professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level **Project Coordinators Dr. Maalyadri**, **Professor in IT** and **Dr. R. Santhosh Kumar**, **Associate Professor in CSE** for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. K. Prem Nikit (17K81A04L5)
2. M.Shiva Vamshi (17K81A04N2)
3. P.Shashi Varma (17K81A04N6)

ABSTRACT

For human life and the health of the environment, water is important. We have created an automated water quality management system for home, workplaces, etc. in order to achieve the good water quality needed by the citizens through IoT. Besides this, liquid level control systems are widely used for monitoring of liquid levels, reservoirs, silos, and dams etc.

To monitor the quality of water with the help of information sensed by the sensors immersed in water, so as to keep the water resource within a standard described for domestic usage and to be able to take necessary actions to restore the health of the degraded water body. Water pipelines leak detection, Pipeline systems are responsible for transporting vital materials such as water, oil and gas. We have used different sensors to design a device to calculate the water pH, the water pressure, flow, temperature etc. In this project, we have recommended the use of a smart interface sensor to track water, contamination and monitor leakages from water pipelines. A system with a higher spatial resolution would provide operators with a better understanding of their network. In buried pipeline monitoring, sensor nodes are deployed in soil. The underground environment imposes major limitations on sensor nodes, such as poor RF transmission and lack of maintainability

The water tank level, the water leak detector in the pipelines and the pH sensor have been used to monitor water quality and the water temperature sensor to track the water temperature. They use the ultrasonic sensor for tests.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

Water is a limited resource and is essential for agriculture, industry and for creatures existence on earth including human beings. Lots of people don’t realize the true importance of drinking enough water every day. More water are wasted by many uncontrolled way. This problem is quietly related to poor water allocation, inefficient use, and lack of adequate and integrated water management. Therefore, efficient use and water monitoring are potential constraint for home or office water management

Every living thing on earth needs water to survive. Human bodies are made up of more than 60 percent water. We use clean water to drink, grow crops for food, operate factories, and for swimming, surfing, fishing and sailing. Water is vitally important to every aspect of our lives. Monitoring the quality of surface water will help protect our waterways from pollution. Farmers can use the information to help better manage their land and crops. Our local, state and national governments use monitoring information to help control pollution levels By using water monitoring system, we avoid the water wastage, power consumption and easily prevent the water for our generation. Water monitoring day was established in 2003 by America’s clean water foundation as a global educational outreach program that aims to build public awareness and involvement in protecting water resources around the world. world water monitoring day is celebrated on September 18.

Tank Water Level Monitoring, is used to avoid overflowing and intimate level of water in the tank. Water controlling system implementation makes potential significance in home applications. The existing automated method of level detection is described and that can be used to make a device on/off.

Moreover, the common method of level control for home appliance is simply to start the feed pump at a low level and allow it to run until a higher water level is reached in the water tank. This is not properly supported for adequate controlling system. Besides this, liquid level control systems are widely used for monitoring of liquid levels, reservoirs, silos, and dams etc.

to monitor the quality of water with the help of information sensed by the sensors immersed in

1.2 OBJECTIVES OF THE STUDY:

The proposed method is to use an IoT system to automate most of the water leak detection system. In this method a system consisting of Arduino, flow sensor, solenoid valve and

GSM sim is connected to each end of the pipe which is saved in the database. The water flow through the pipes is recorded by the flow meter. This has an IoT sim card which sends the usage data to the server. The system checks the and compares the flow meter reading from the flow sensor at both ends of the same pipe. If the readings from both the sensors match the solenoid valve allows the water flow to continue, in case the readings d not match the solenoid valve shuts down the water flow at both ends of the pipe. Following closing the solenoid valve the sim card sends a message [2] to the concerned authority with the GPS coordinates of the shutdown valves. It is possible to remotely open the valve through the dashboard after the problem is fixed.

1.3 SCOPE OF THE STUDY:

To monitor the quality of water with the help of information sensed by the sensors immersed in water, so as to keep the water resource within a standard described for domestic usage and to be able to take necessary actions to restore the health of the degraded water body.

Monitoring the quality of surface water will help protect our waterways from pollution. Farmers can use the information to help better manage their land and crops. Our local, state and national governments use monitoring information to help control pollution levels By using water monitoring system Pipeline systems are responsible for transporting vital materials such as water, oil and gas. Any leakage in the pipe can cause major financial losses and possible environmental damages. Currently, buried pipelines are only monitored at key points, which can be spaced several kilometers apart.

CHAPTER-2
LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH:

We analyzed numerous existing systems built by researchers in order to construct a model of good quality [1]. During the study of parameters like temperature, pH and electrical conductivity, pressure different authors proposed differential model to test water quality and water leakage. We have developed a smart water control device that can perform all these monitoring functions by looking at all these details [2]. The [3] author indicated that the Internet of Things applications has been rising tremendously in smart homes recently. The wide variety of various IoT systems typically contributes to interoperability needs. Current IoT projects are implemented using physical platforms which lack decision-making intelligence [4]. In order to solve management of the heterogeneous IoTs in smart home, it is proposed an architecture that implements Event Condition-Action (ECA) process. Developed using a central repository for continuous data on IoT schedules, the constructive architecture has proven perfect for addressing interoperability in clever homes [5]. International Journal of Advanced Science and Technology Vol. 29, No. 9s, (2020), pp. 683-689 ISSN: 2005-4238 IJAST Copyright ⓒ 2020 SERSC 684 There must also be systems in place that actively test water quality and provide articulated sources to villages, towns and communities and the rivers, creeks and shores surrounding our towns and towns for drinking [6]. Better water quality is important to avoid waterborne diseases outbreaks as well as to improve the quality of life. Fiji islands are located in the vast Pacific which demands a frequent water quality monitoring network and the current measurements can be enhanced by IoT and RS. This paper presents a smart water quality monitoring system for Fiji, using IoT and remote sensing technology [7]. This problem affects various processes in water management, such as water consumption, distribution, system identification and equipment maintenance. OPC UA (Object Linking and Embedding for Process Control Unified Architecture) is a platform independent service-oriented architecture for the control of processes in the logistic and manufacturing sectors [8]. Based on this standard we propose a smart water management model combining Internet of Things technologies with business processes coordination and decision support systems. We provide an architecture for sub-system interaction and a detailed description of the physical scenario in which we will test our implementation, allowing specific vendor equipment to be manageable and interoperable in the specific context of processes water management [9]. In [10] the author shown how to monitor the water level of water systems such as water tanks, rivers, ground water table, and bore wells remotely. They also have shown that how to control the working of pump automatically and remotely. It can be used to remotely monitor the flood affected areas wirelessly and information can be sent to mobile wirelessly [11]. This system is designed to monitor the level of water with the help of water level sensors. This article includes an IoT tool for monitoring and preparing water use. This system is simple and long-lasting to install and maintain. The laser sensor is located on the tank that controls water level continuously in real time. This data is stored in the cloud and users can analyze water quantity [12]. The motor function is operated automatically, depending on the water level in the tank. The motor will automatically be turned on when the water level goes below the threshold level. In [13] paper, we present an IoT architecture for water monitoring and control that supports in real-time online data collection. The program addresses new problems in calculating the water flow rate and the need to research the water supply to minimize and encourage water pollution. By using pH and conductivity sensors, we also calculate the consistency of water distributed throughout every house. The conventional water measurement systems need frequent human maintenance intervention to make it uncomfortable and therefore less effective. In the absence of modern models, wired systems are used for smart monitoring and wireless communication of data The paper [14] explored various technologies and platforms required for an intelligent world. An architectural framework concept is proposed for intelligent water management and an implementation description is discussed of the intelligent water monitoring system.

2.2 REVIEW ON RELATED LITERATURE:

Nikhil Kedia entitled “Water Quality Monitoring for Rural Areas-A Sensor Cloud Based Economical Project.” Published in 2015 1st International Conference on Next Generation Computing Technologies (NGCT-2015) Dehradun, India. This paper highlights the entire water quality monitoring methods, sensors, embedded design, and information dissipation procedure, role of government, network operator and villagers in ensuring proper information dissipation. It also explores the Sensor Cloud domain. While automatically improving the water quality is not feasible at this point, efficient use of technology and economic practices can help improve water quality and awareness among people.[1] Jayti Bhatt,Jignesh Patoliya entitled “Real Time Water Quality Monitoring System”. This paper describes to ensure the safe supply of drinking water the quality should be monitored in real time for that purpose new approach IOT (Internet of Things) based water quality monitoring has been proposed. In this paper, we present the design of IOT based water quality monitoring system that monitor the quality of water in real time. This system consists some sensors which measure the water quality parameter such as pH, turbidity, conductivity, dissolved oxygen, temperature. The measured values from the sensors are processed by microcontroller and this processed values are transmitted remotely to the core controller that is raspberry pi using Zigbee protocol. Finally, sensors data can view on internet browser application using cloud computing.[2] Michal Lom, Ondrej Pribyl, Miroslav Svitek entitled “Industry 4.0 as a Part of Smart Cities”. This paper describes the conjunction of the Smart City Initiative and the concept of Industry 4.0. The term smart city has been a phenomenon of the last years, which is very inflected especially since 2008 when the world was hit by the financial crisis. The main reasons for the emergence of the Smart City Initiative are to create a sustainable model for cities and preserve quality of life of their citizens. The topic of the smart city Water Quality Monitoring System Based on IOT 1109 cannot be seen only as a technical discipline, but different economic, humanitarian or legal aspects must be involved as well. In the concept of Industry 4.0, the Internet of Things (IoT) shall be used for the development of so–called smart products. Subcomponents of the product are equipped with their own intelligence. Added intelligence is used both during the manufacturing of a product as well as during subsequent handling, up to continuous monitoring of the product lifecycle (smart processes). Other important aspects of the Industry 4.0 are Internet of Services (IoS), which includes especially intelligent transport and logistics (smart mobility, smart logistics), as well as Internet of Energy (IoE), which determines how the natural resources are used in proper way (electricity, water, oil, etc.). IoT, IoS, IoP and IoE can be considered as an element that can create a connection of the Smart City Initiative and Industry 4.0 – Industry 4.0 can be seen as a part of smart cities.[3] Zhanwei Sun,Chi Harold Li,Chatschik Bisdikian,Joel W.Branch and Bo Yang entitled “QOI-Aware Energy Management in Internet-of-Things Sensory Environments”. In this paper an efficient energy management frame work to provide satisfactory QOI experience in IOT sensory environments is studied. Contrary to past efforts, it is transparent and compatible to lower protocols in use, and preserving energy-efficiency in the long run without sacrificing any attained QOI levels. Specifically, the new concept of QOI-aware “sensor-to-task relevancy” to explicitly consider the sensing capabilities offered by an sensor to the IOT sensory environments, and QOI requirements required by a task. A novel concept of the “critical covering set” of any given task in selecting the sensors to service a task over time. Energy management decision is made dynamically at runtime, as the optimum for long-term traffic statistics under the constraint of the service delay. Finally, an extensive case study based on utilizing the sensor networks to perform water level monitoring is given to demonstrate the ideas and algorithms proposed in this paper, and a simulation is made to show the performance of the proposed algorithms.[4] Sokratis Kartakis, Weiren Yu, Reza Akhavan, and Julie A. McCann entitled “Adaptive Edge Analytics for Distributed Networked Control of Water Systems” This paper presents the burst detection and localization scheme that combines lightweight compression and anomaly detection with graph topology analytics for water distribution networks. We show that our approach not only significantly reduces the amount of communications between sensor devices and the back end servers, but also can effectively localize water burst events by using the difference in the arrival times of the vibration variations detected at sensor locations. Our results can save up to 90% communications compared with traditional periodical reporting situations.[5]

2.3 CONCLUSION ON REVIEWS:

Monitoring of Turbidity, PH & Temperature of Water makes use of water detection sensor with unique advantage and existing GSM network. The system can monitor water quality automatically, and it is low in cost and does not require people on duty. So the water quality testing is likely to be more economical, convenient and fast. The system has good flexibility. Only by replacing the corresponding sensors and changing the relevant software programs, this system can be used to monitor other water quality parameters. The operation is simple. The system can be expanded to monitor hydrologic, air pollution, industrial and agricultural production and so on. It has widespread application and extension value. By keeping the embedded devices in the environment for monitoring enables self protection (i.e., smart environment) to the environment. To implement this need to deploy the sensor devices in the environment for collecting the data and analysis. By deploying sensor devices in the environment, we can bring the environment into real life i.e. it can interact with other objects through the network. Then the collected data and analysis results will be available to the end user through the Wi-Fi.

CHAPTER-3

PROJECT DESIGN

3.0. OVERVIEW OF THE DESIGN

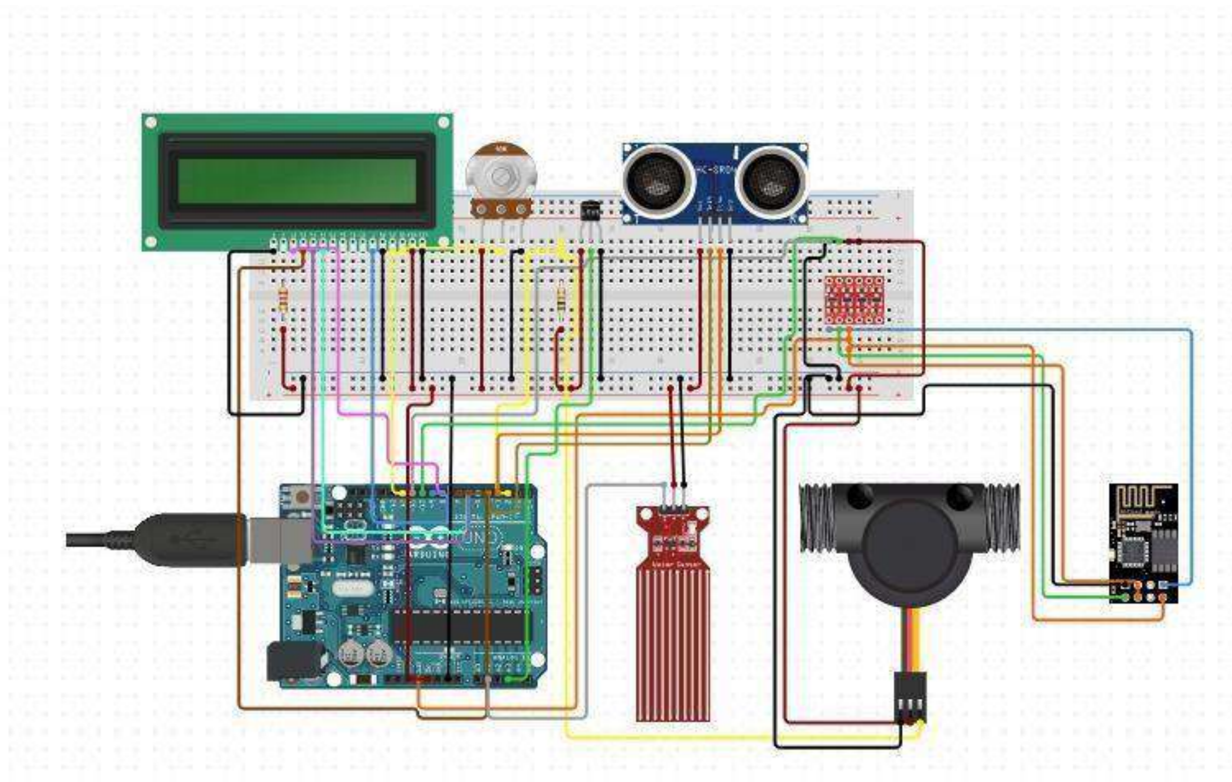

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

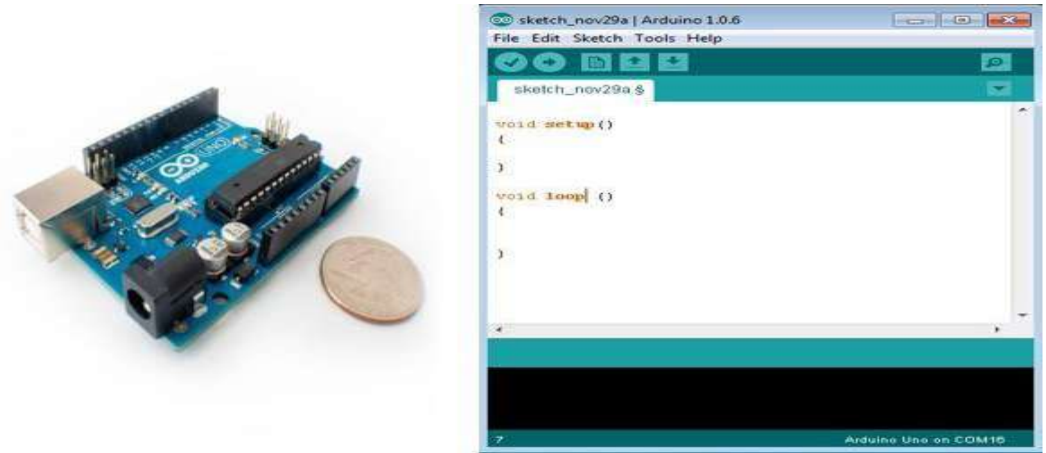

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.
Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

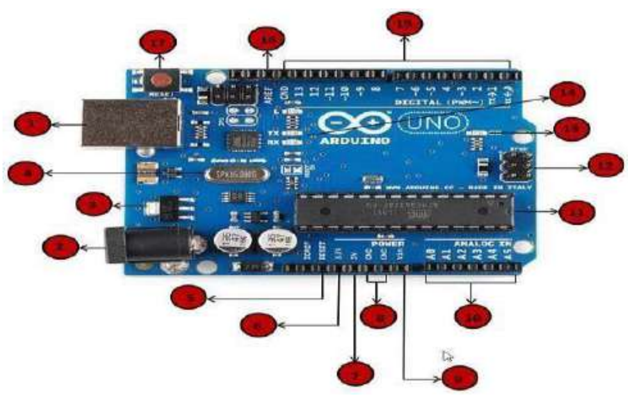

Fig.3.2.1.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).

3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC

	your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled “~” can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.3: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

Fig.3.2.1.4: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

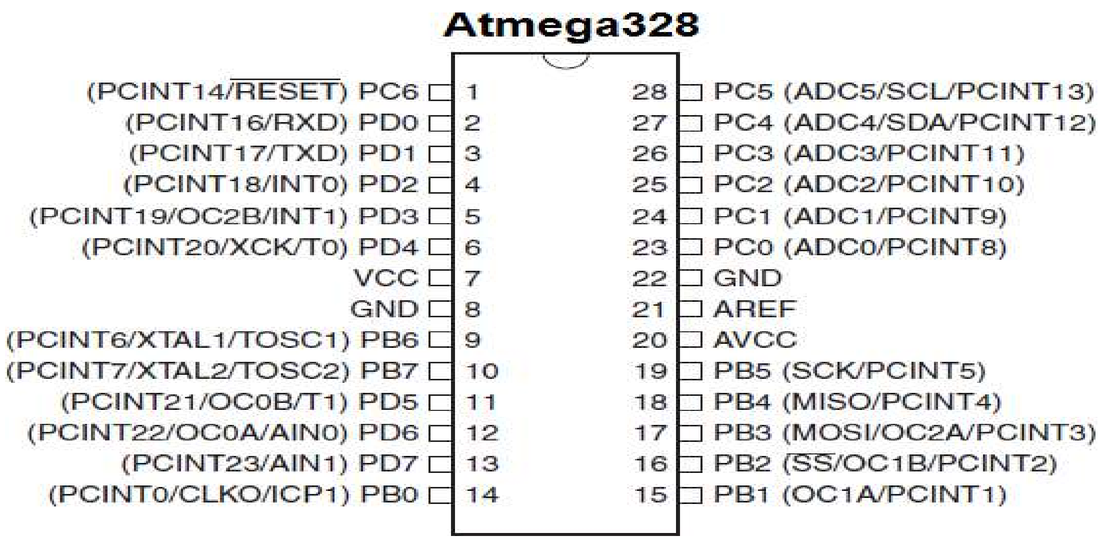

Fig.3.2.1.5 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

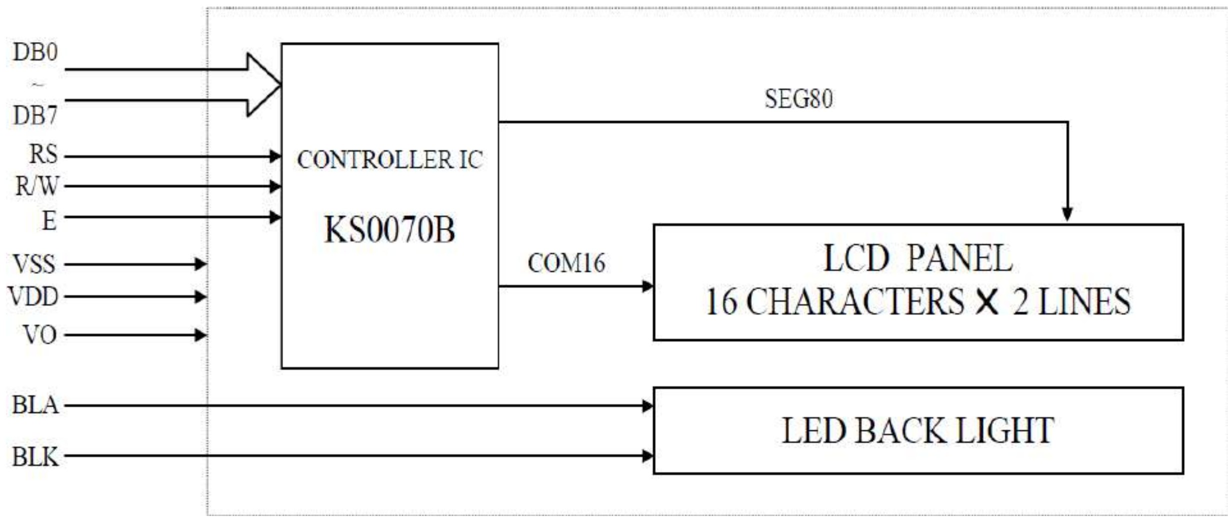

fig.3.2.2.1 Lcd block diagram

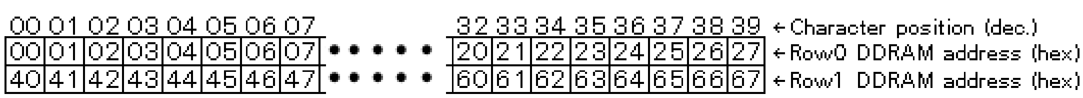
3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 POWER SUPPLY UNIT

3.2.3.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable l voltage supply for electronic circuits and other devices. A power supply can by broken down into a se of blocks, each of which performs a particular function. A d.c power supply which maintains the out voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regularted Power Supply”.

3.2.3.2 BLOCK DIAGRAM OF POWER SUPPLY:

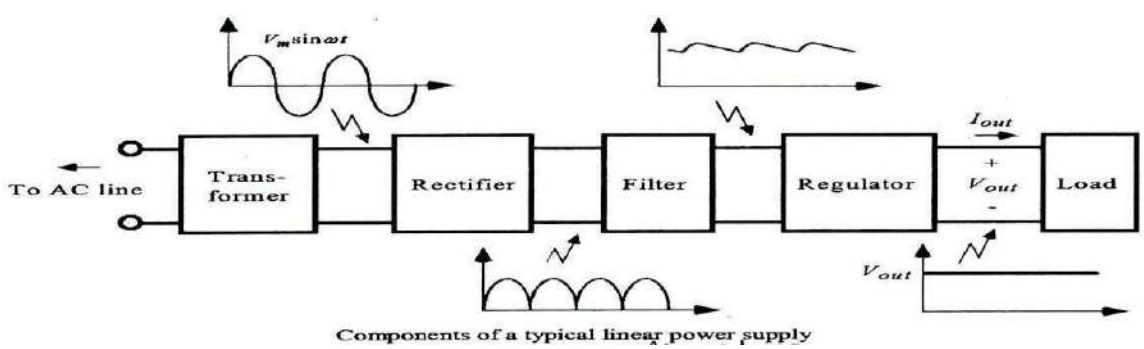


Fig.3.2.3.2: Block Diagram of Power Supply

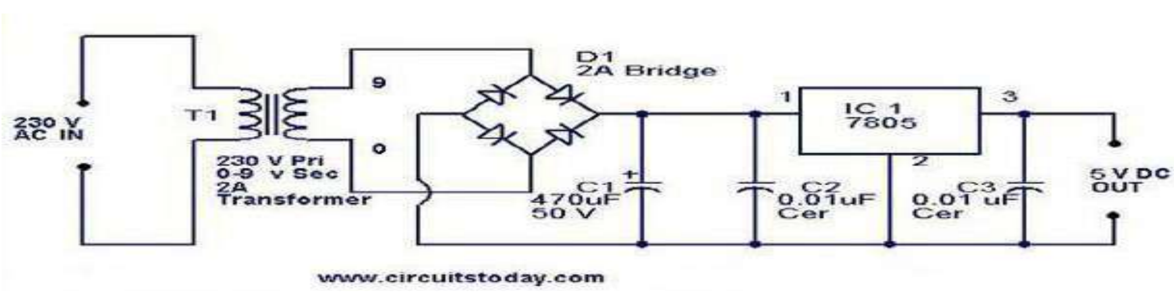

Fig.3.2.3.2(A): Schematic Diagram of Power Supply

3.2.3.3 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

3.2.3.4 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

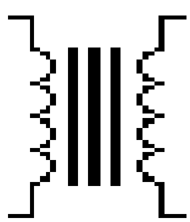

Fig.3.2.3.4: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

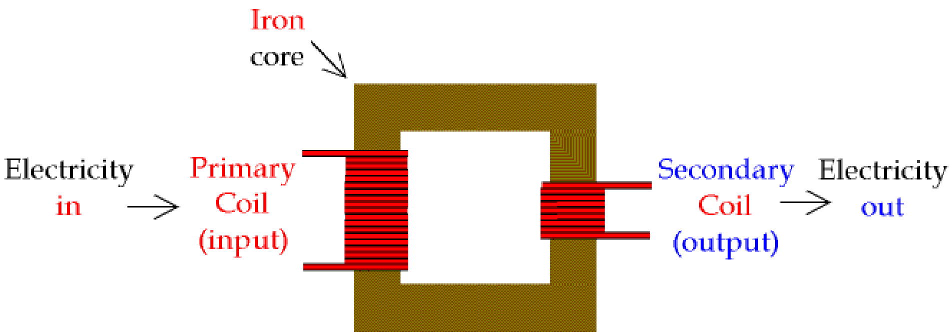

Fig.3.2.3.4(A):Transformer

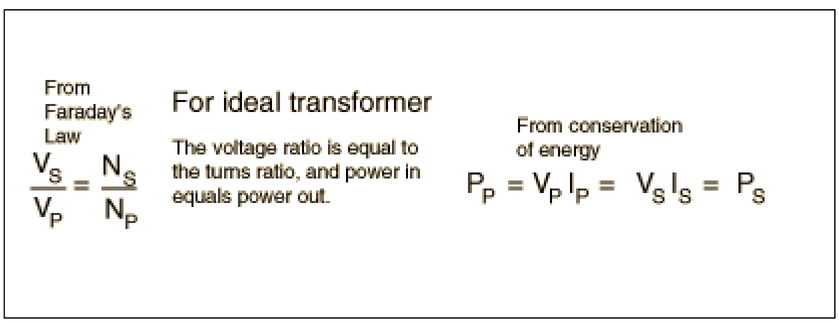
3.2.3.5 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.



Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

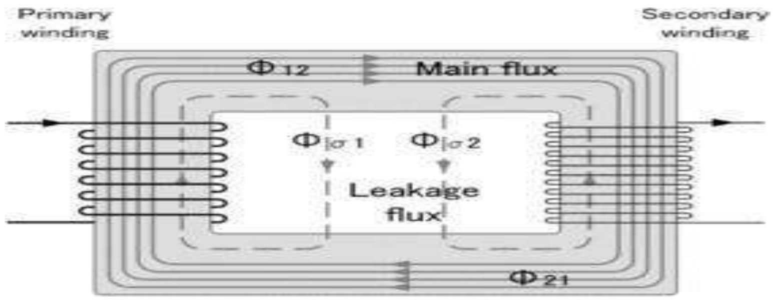


Fig.3.2.3.5: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

3.2.3.6 Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

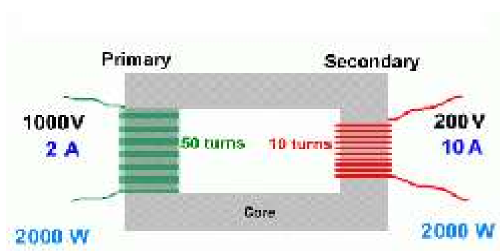

Fig.3.2.2.6: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to

1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

Fig.3.2.3.6(a): Step-Up Transformer

3.2.3.7 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

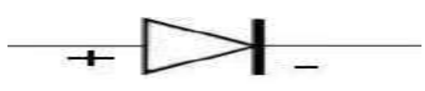

Fig.3.2.3.7: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

3.2.3.8 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

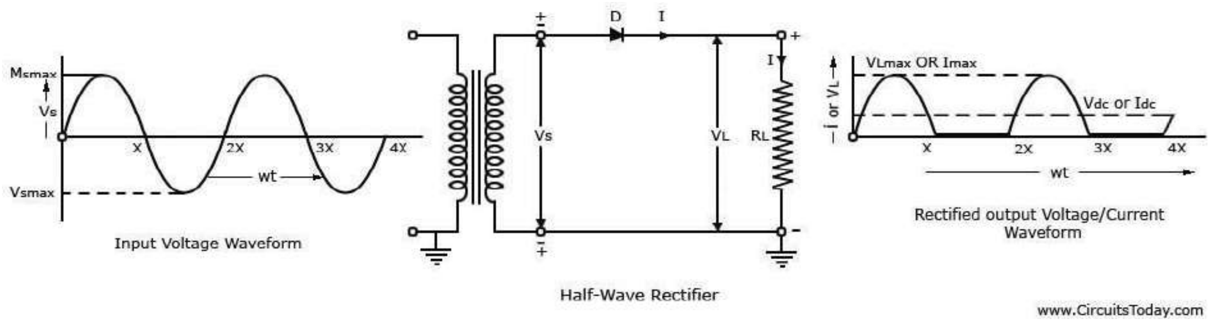

Fig.3.2.3.8(a): Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

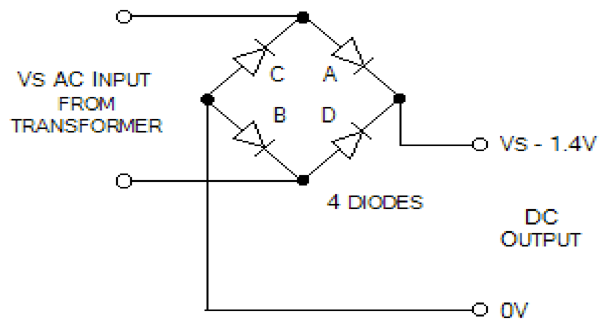

Fig.3.2.3.8(b): Full-Wave Rectifier

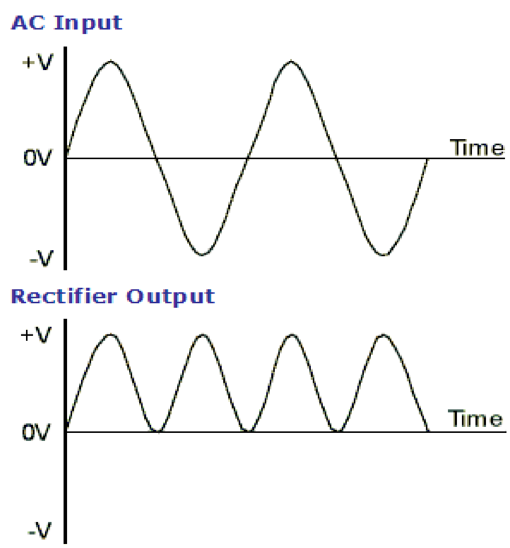

Fig.3.2.3.8(c): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

3.2.4 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

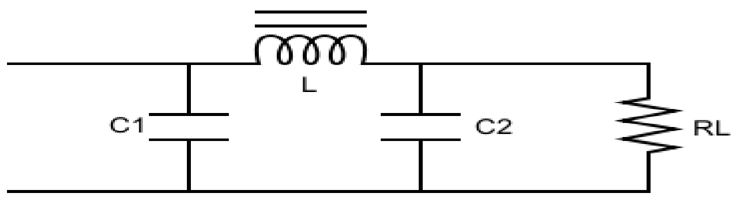

Fig.3.2.4: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

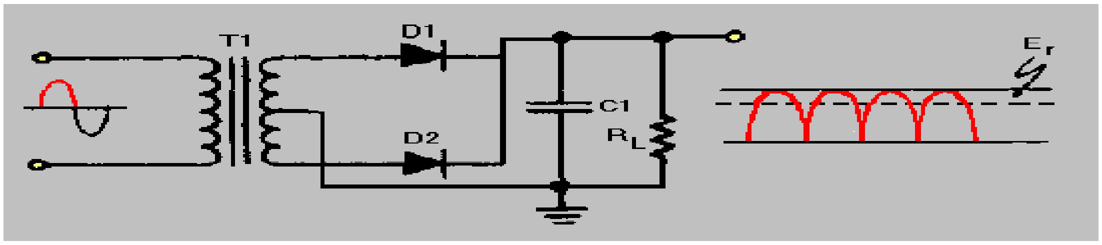

Fig.3.2.4.0(A): Centered Tapped Full-Wave Rectifier with a Capacitor Filter

3.2.5 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:'78' indicate the positive series and 'xx'indicates the voltage rating. Suppose 7805 produces the maximum 5V.'05'indicates the regulator output is 5V.

79xx:'78' indicate the negative series and 'xx'indicates the voltage rating. Suppose 7905 produces the maximum -5V.'05'indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

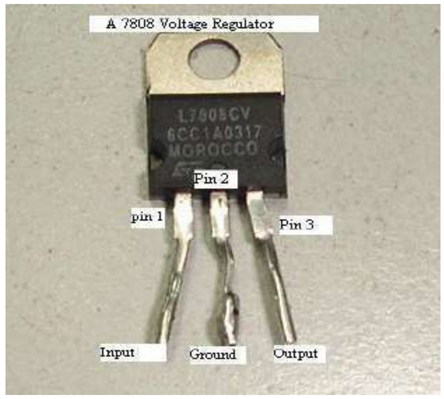

Fig.3.2.5: Regulator

3.2.6 SOFTWARE EXPLANATION:

- Arduino software.
- Proteus simulation.

3.2.6.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino

boards are
completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics
principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and
wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some

advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.
- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-
This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software (IDE)

✓ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the

Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 – Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

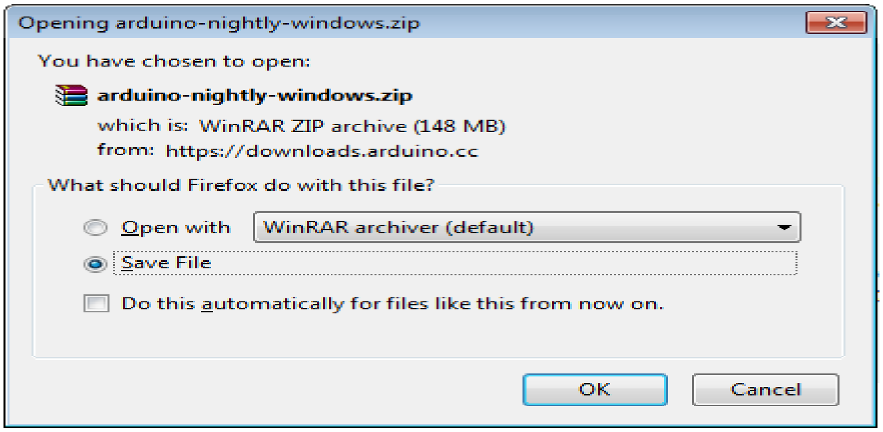

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

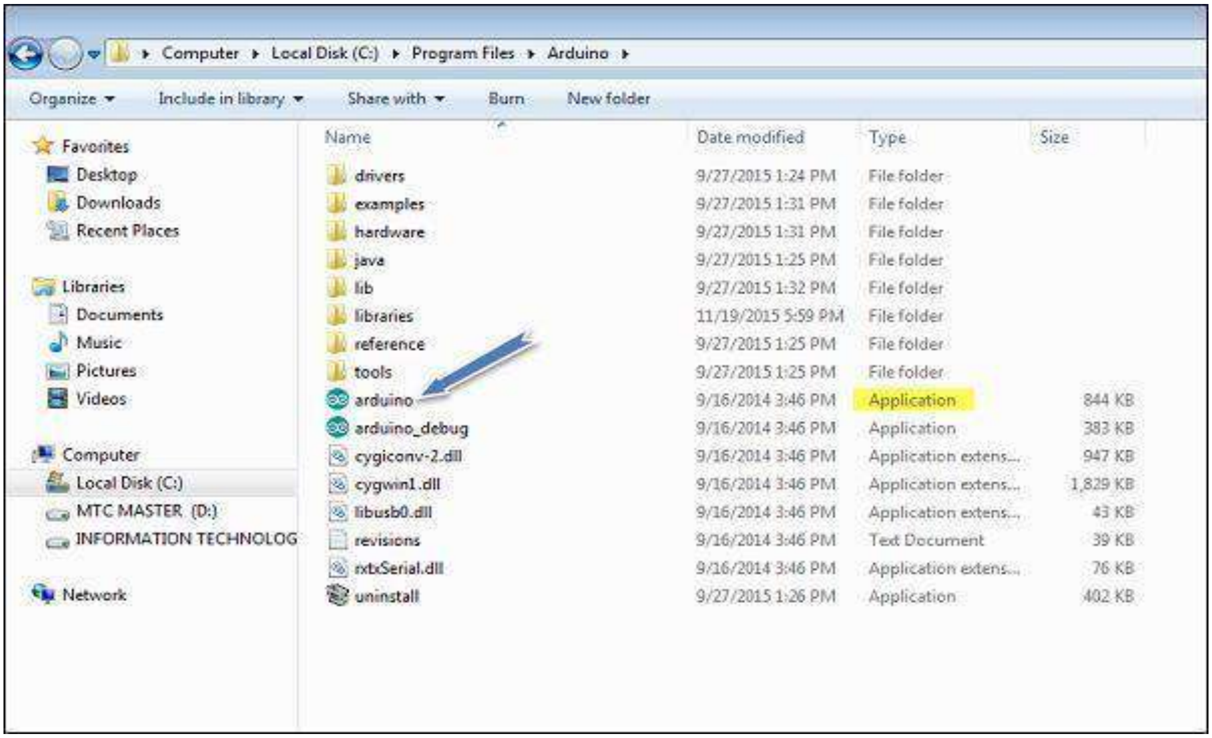

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

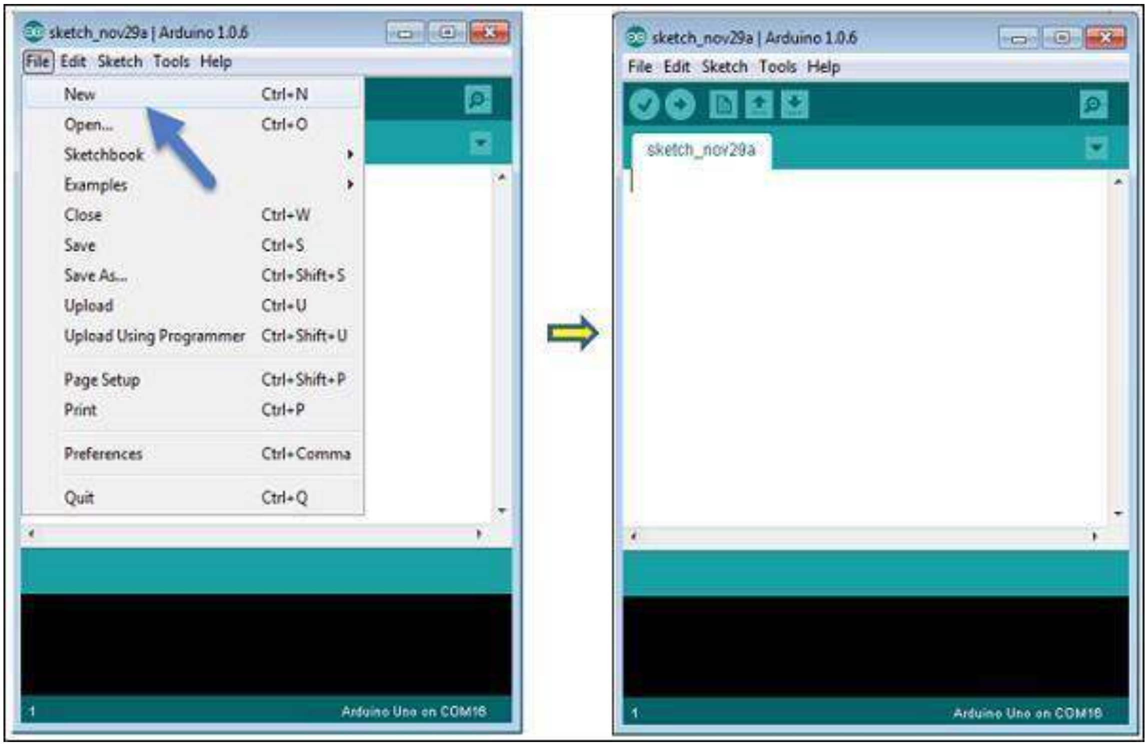

Fig. 3.2.6.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

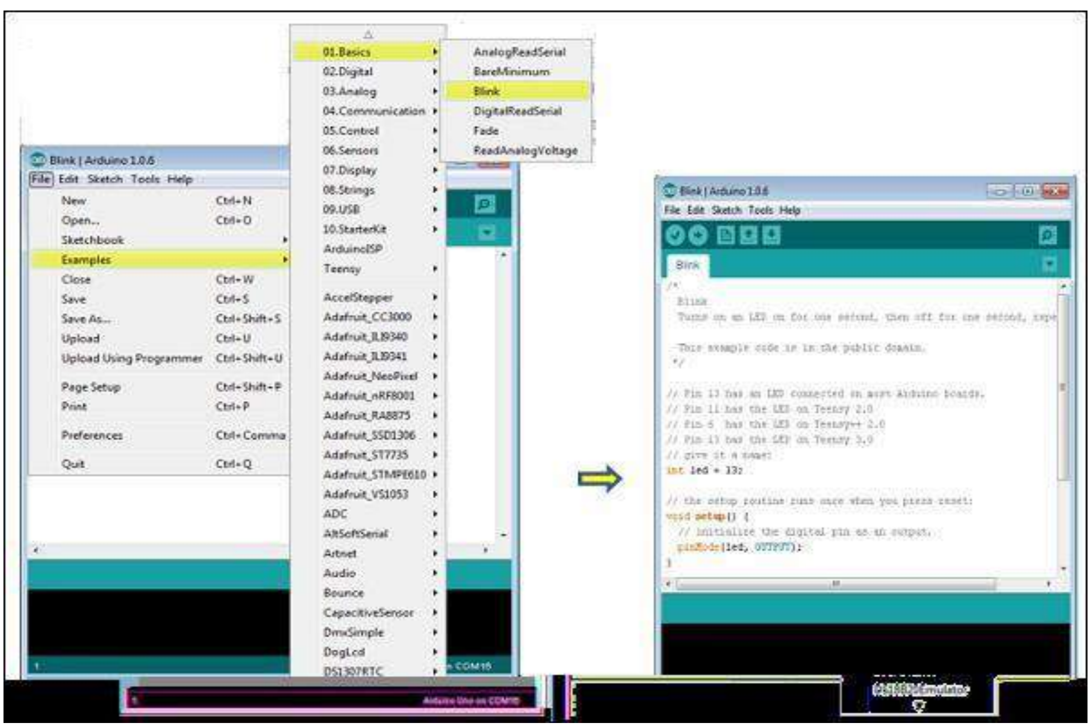

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

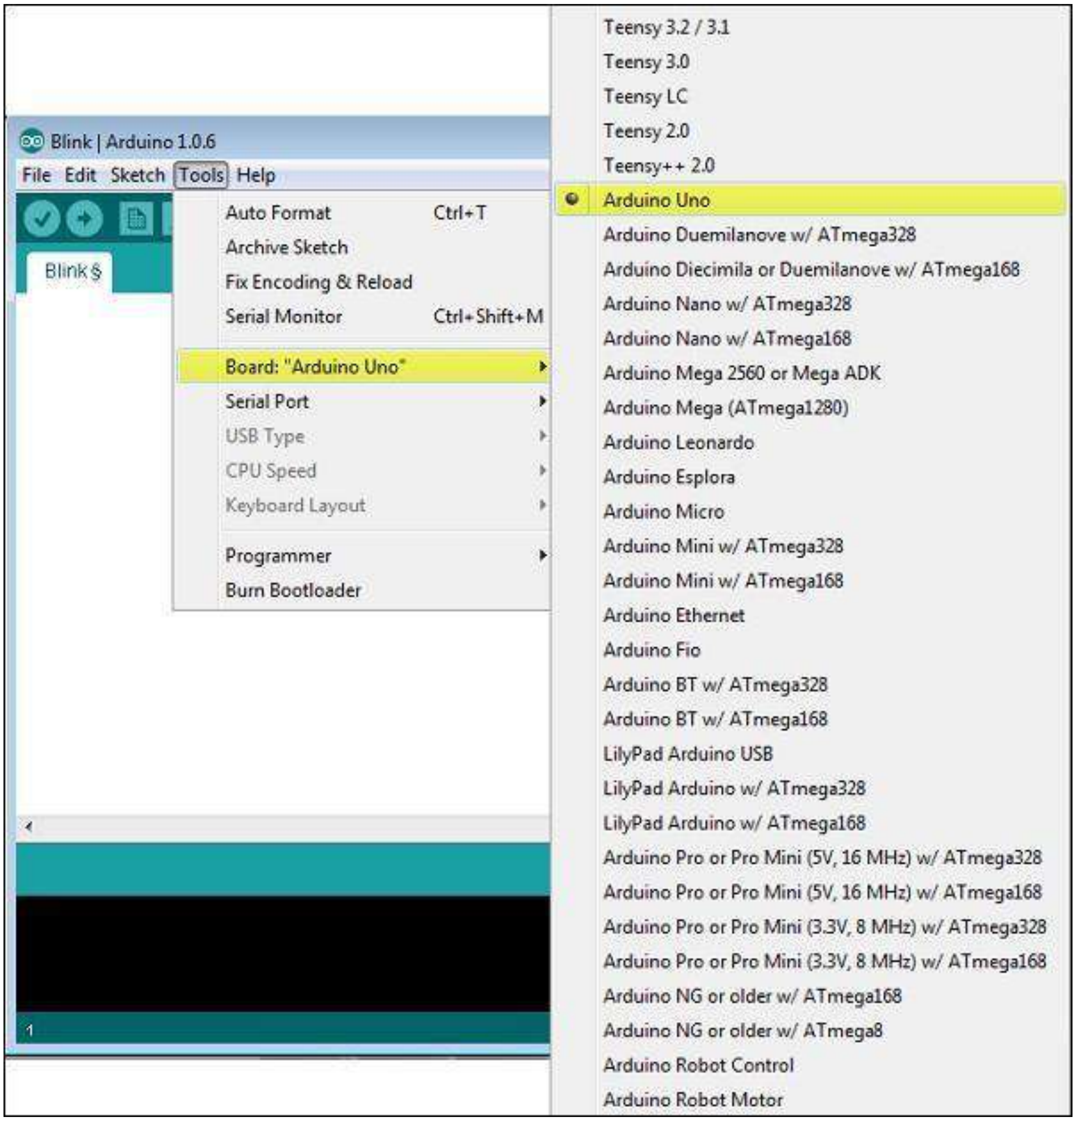

Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 – Select your serial port.

Select the serial device of the Arduino board. Go to **Tools** → **Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

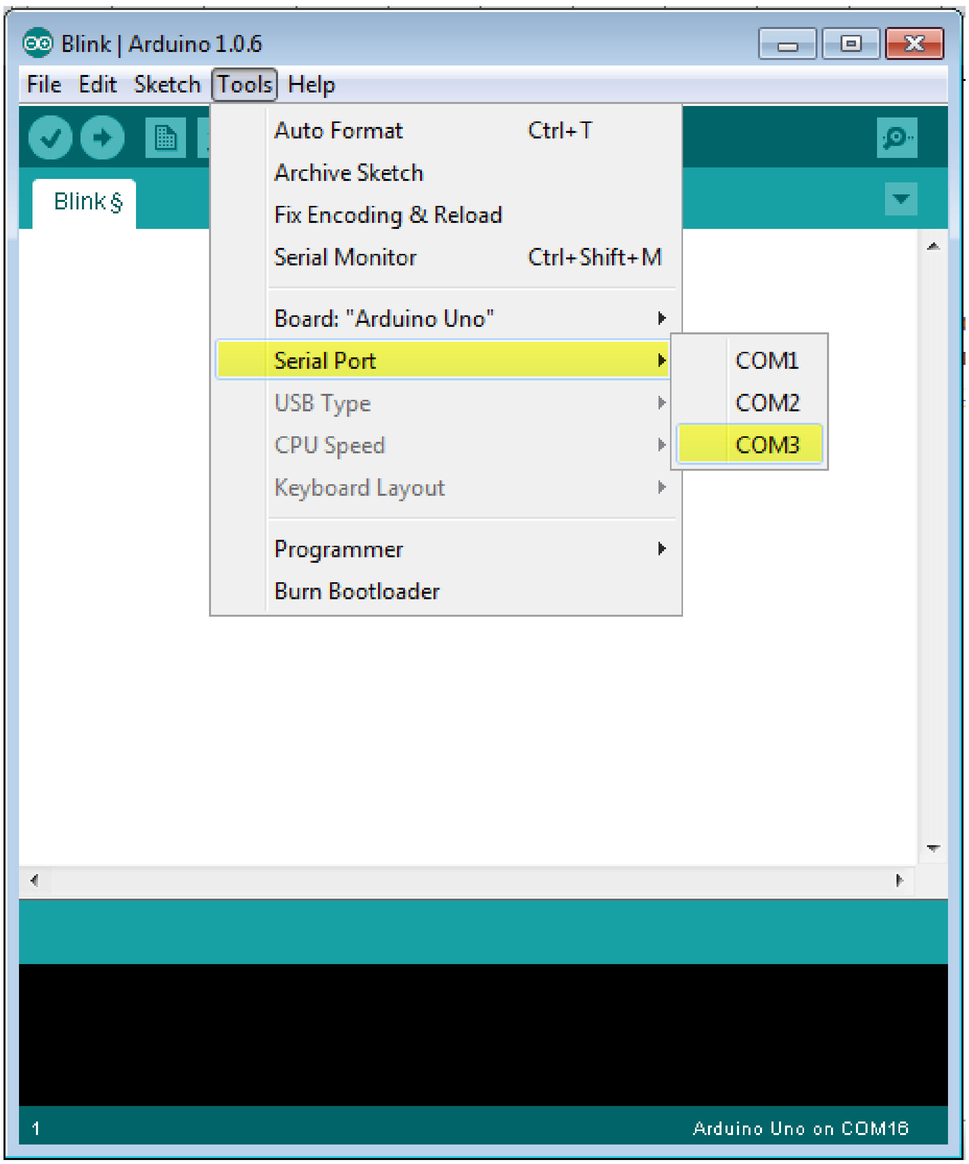

Fig. 3.2.6.4.8 Select your serial port.

Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

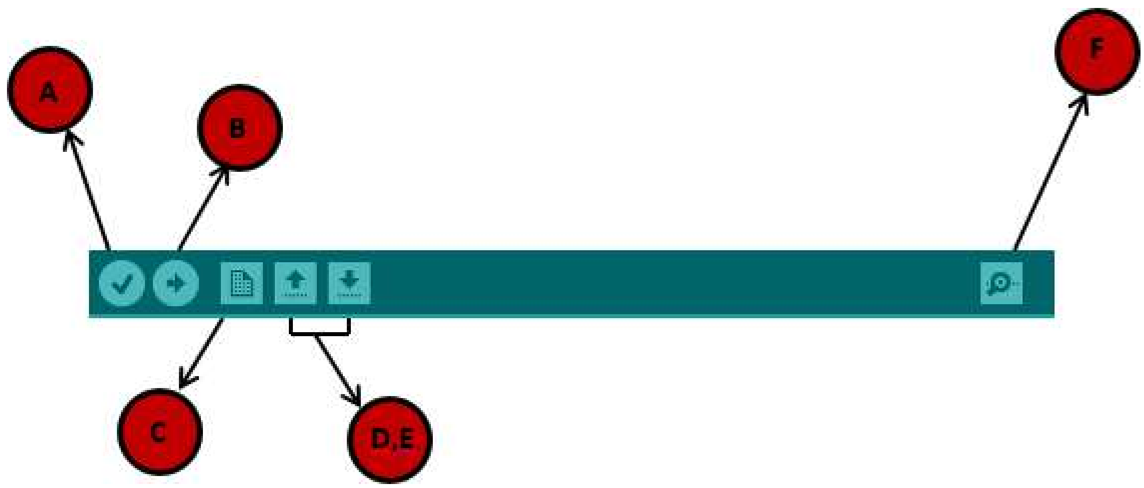

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

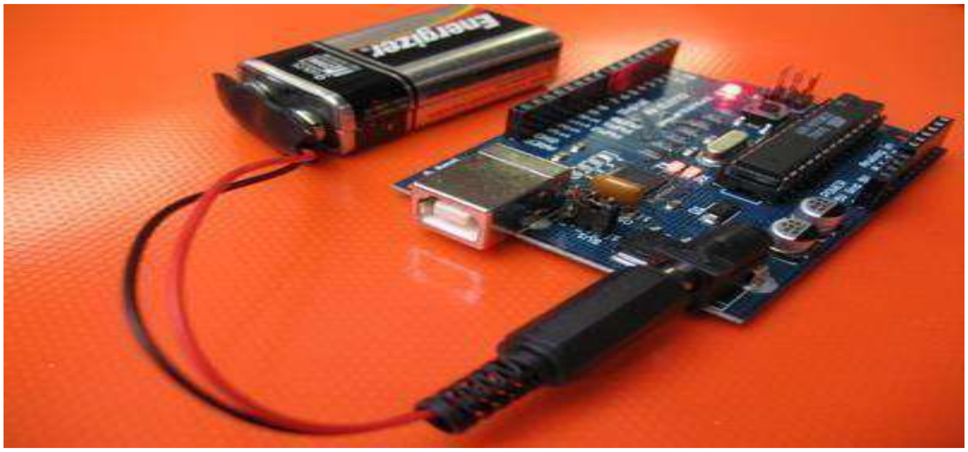

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

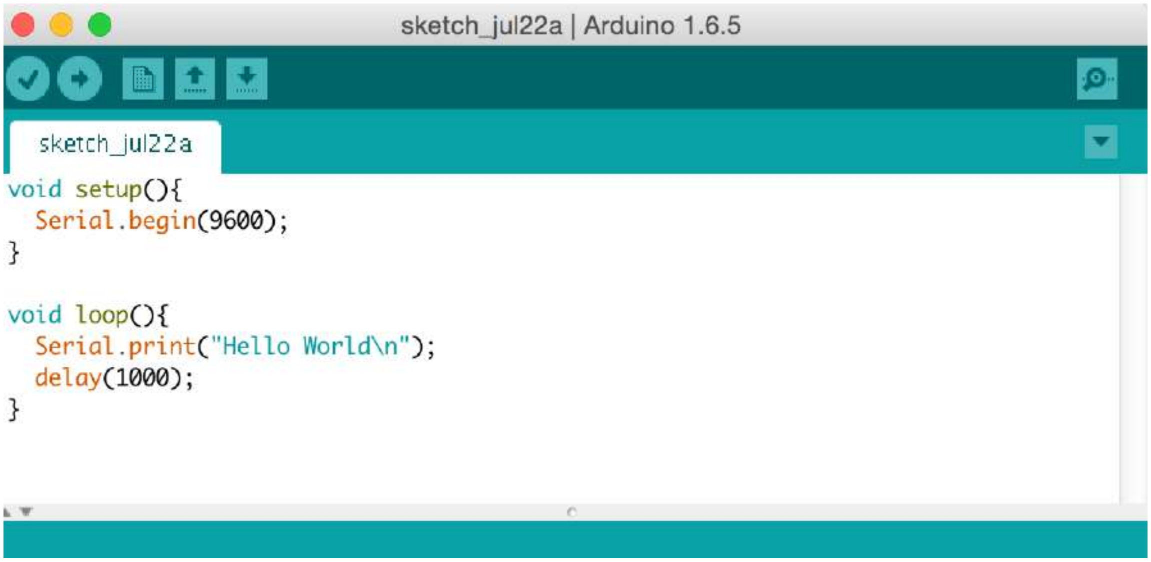

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

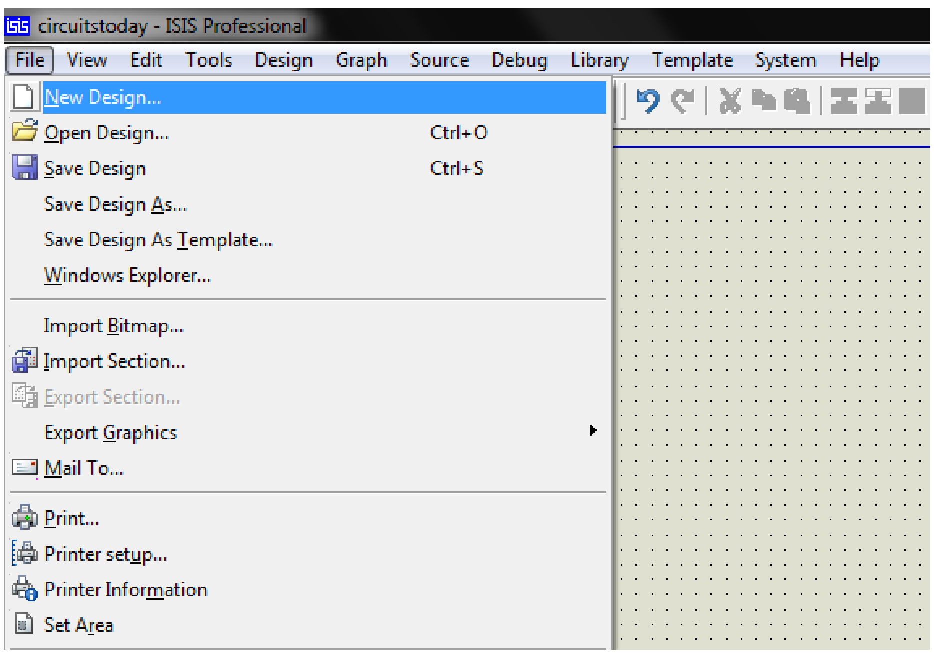

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit

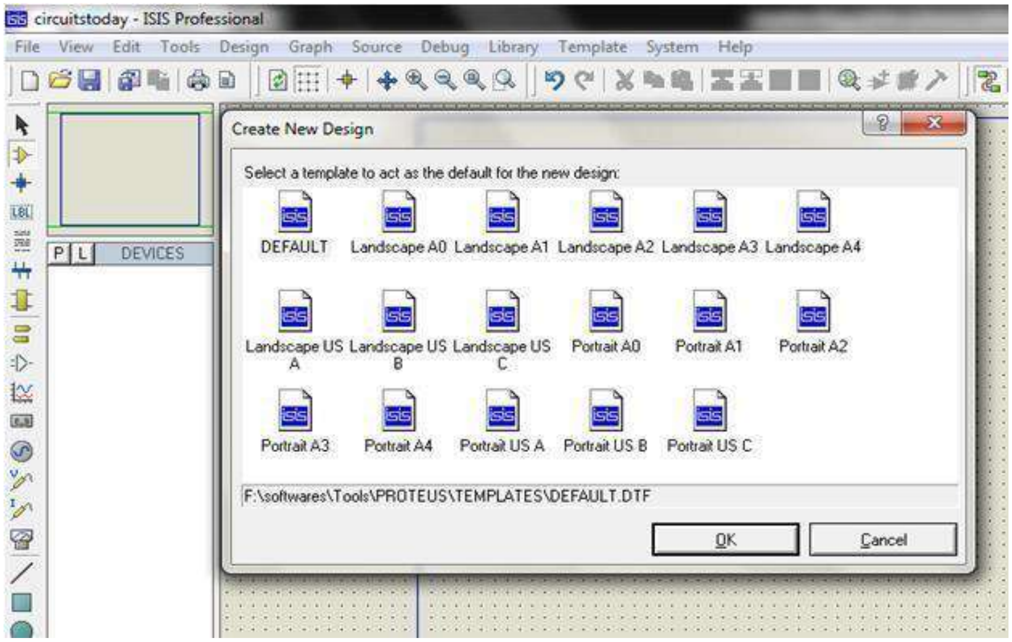

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

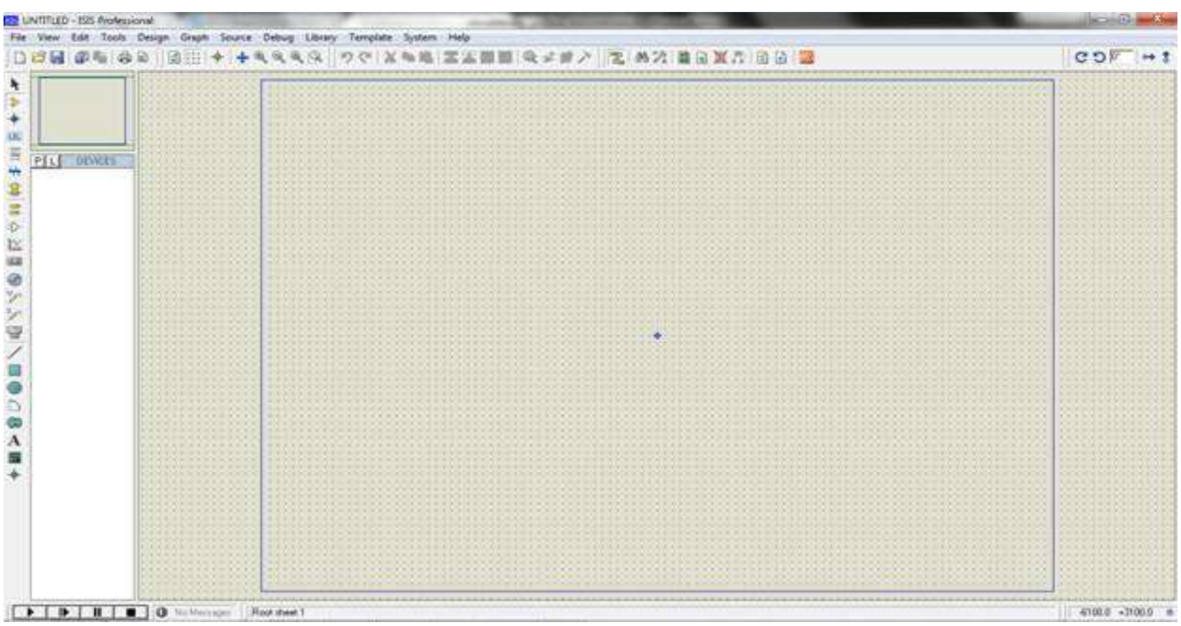

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

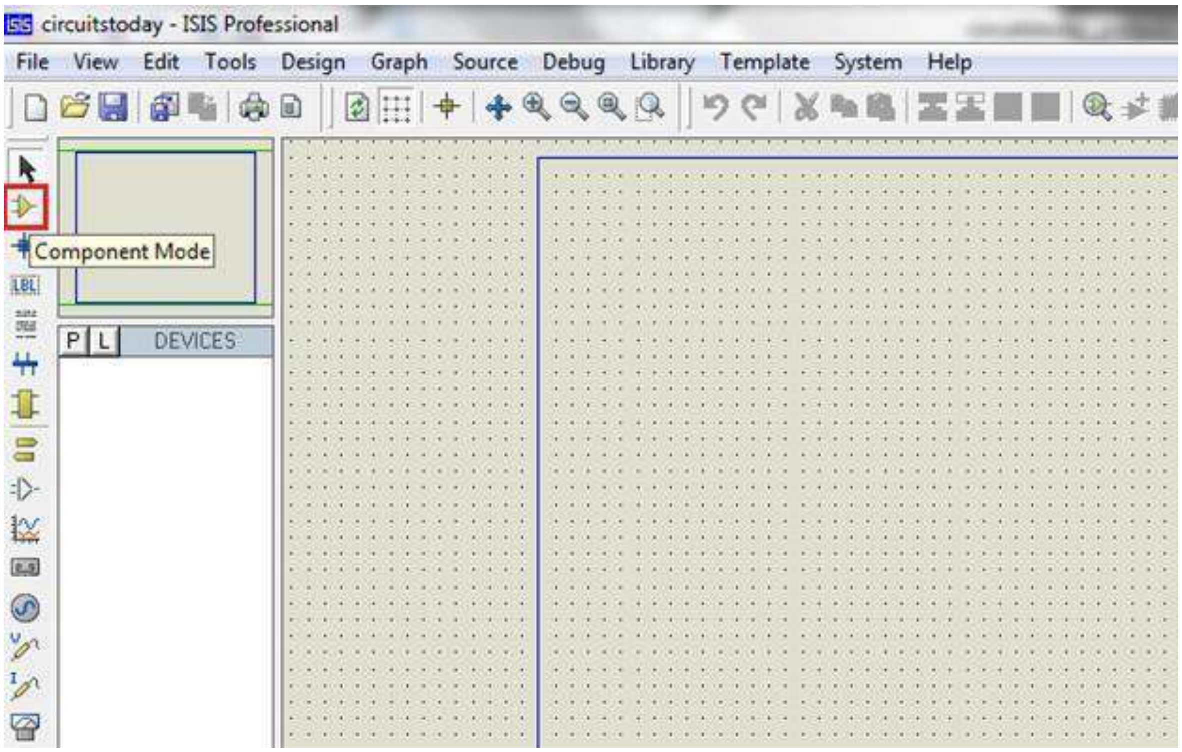

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

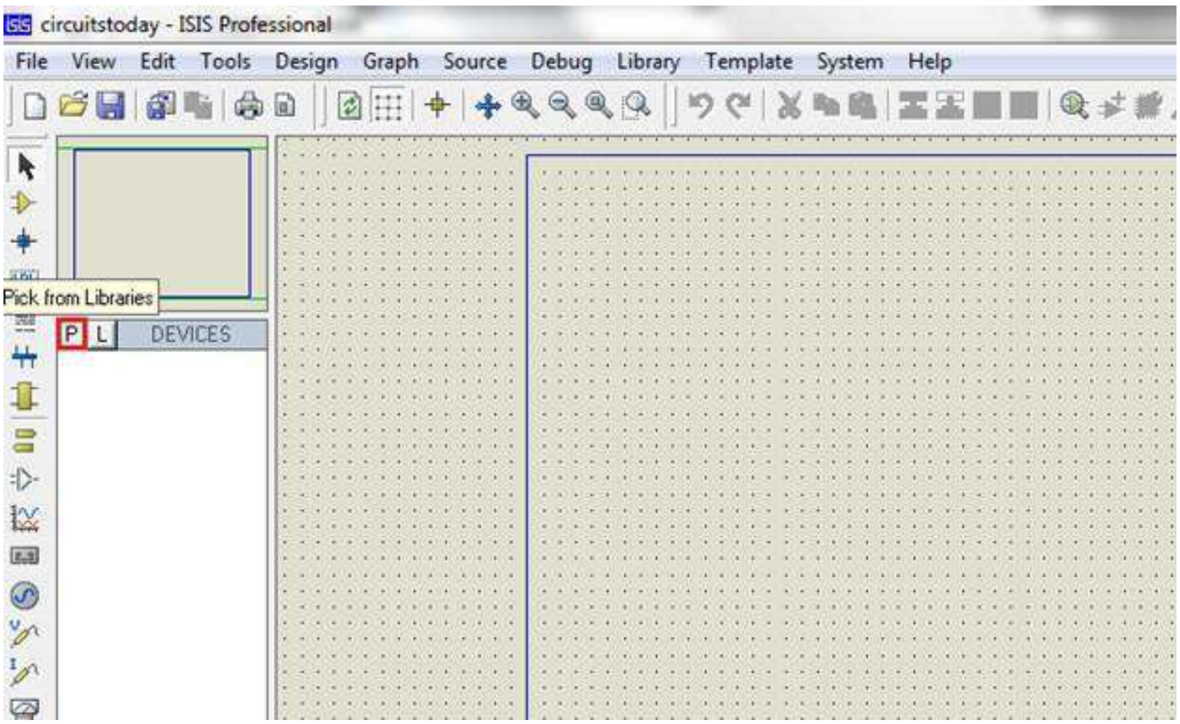

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

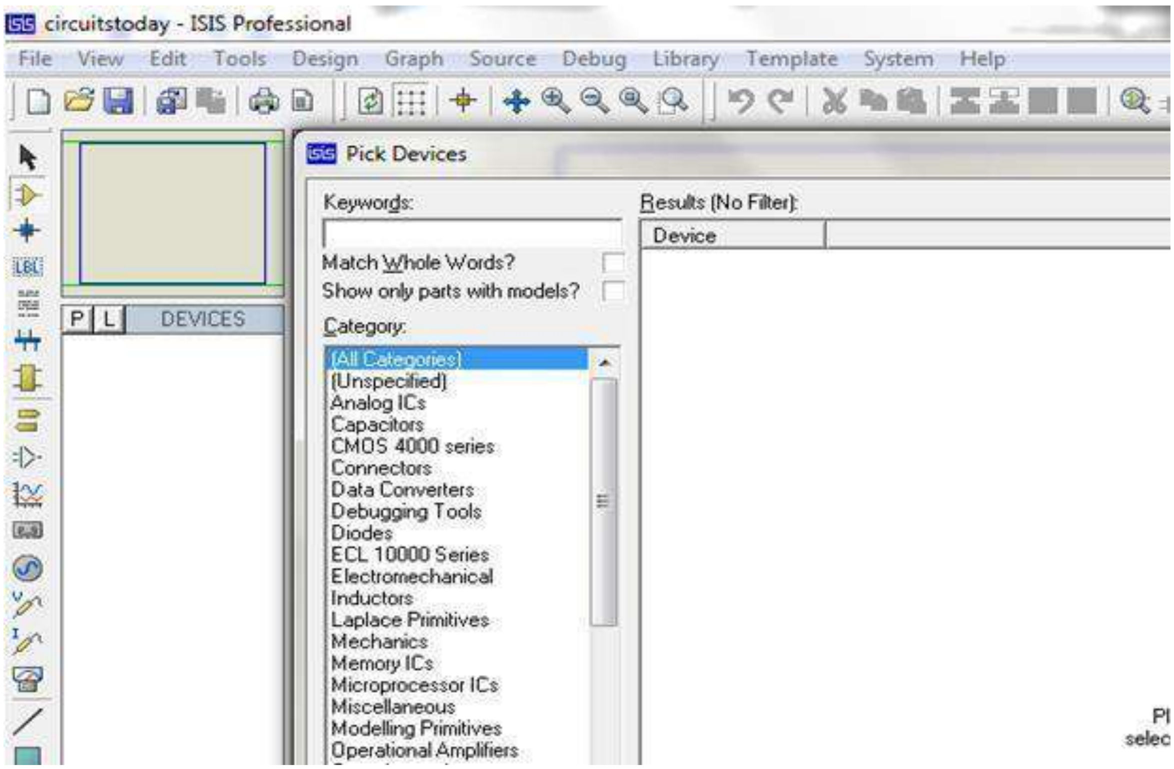

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

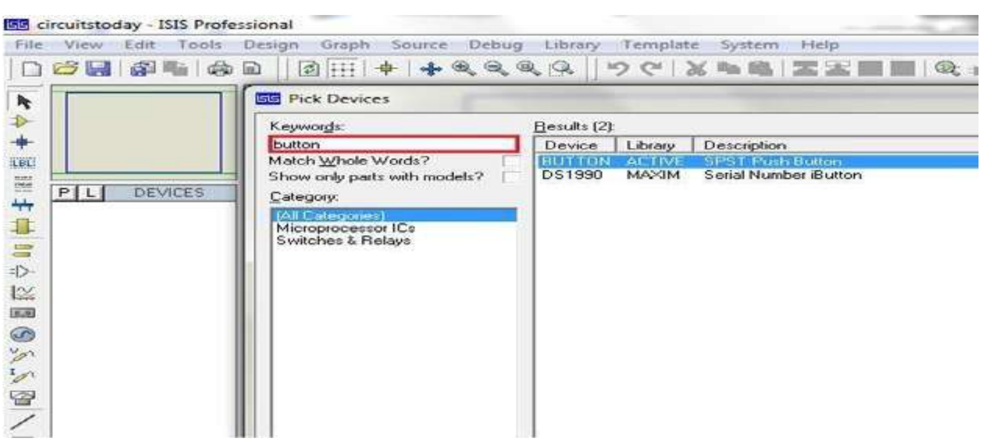

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

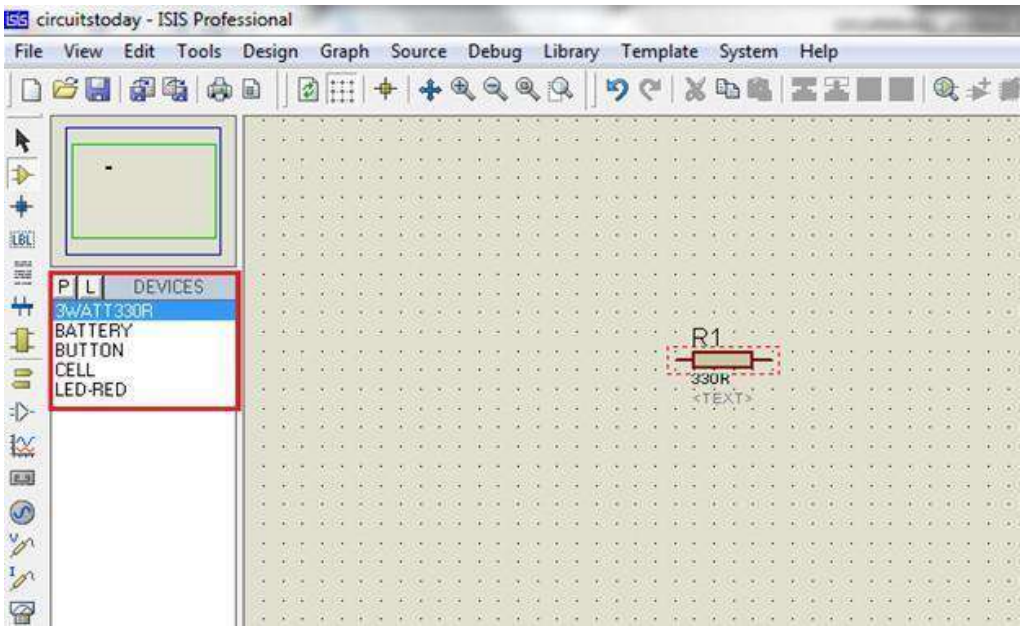

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

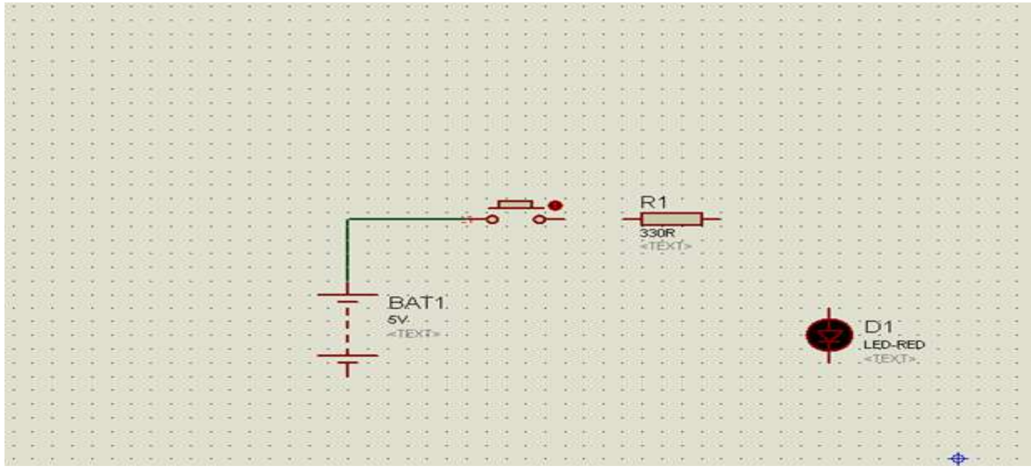

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

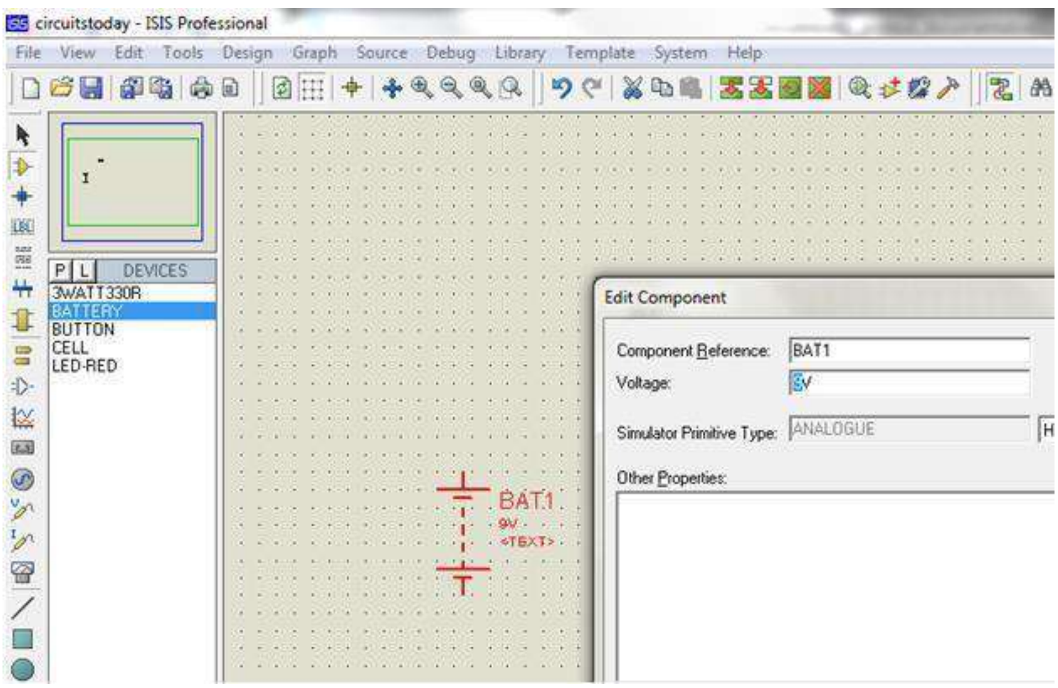

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

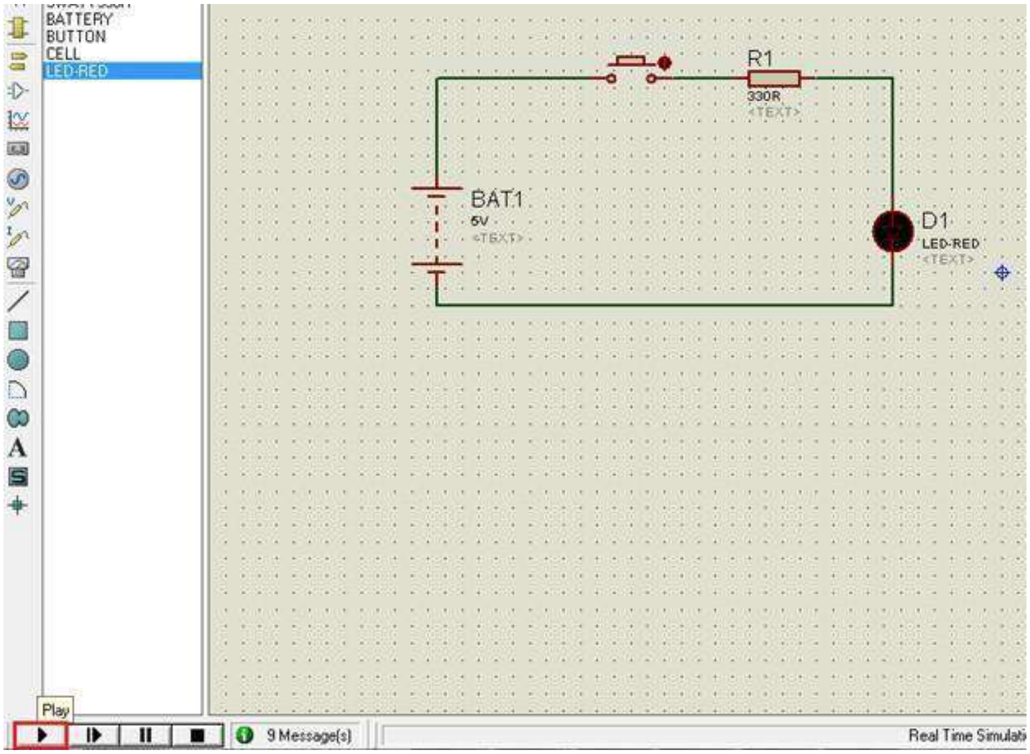

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

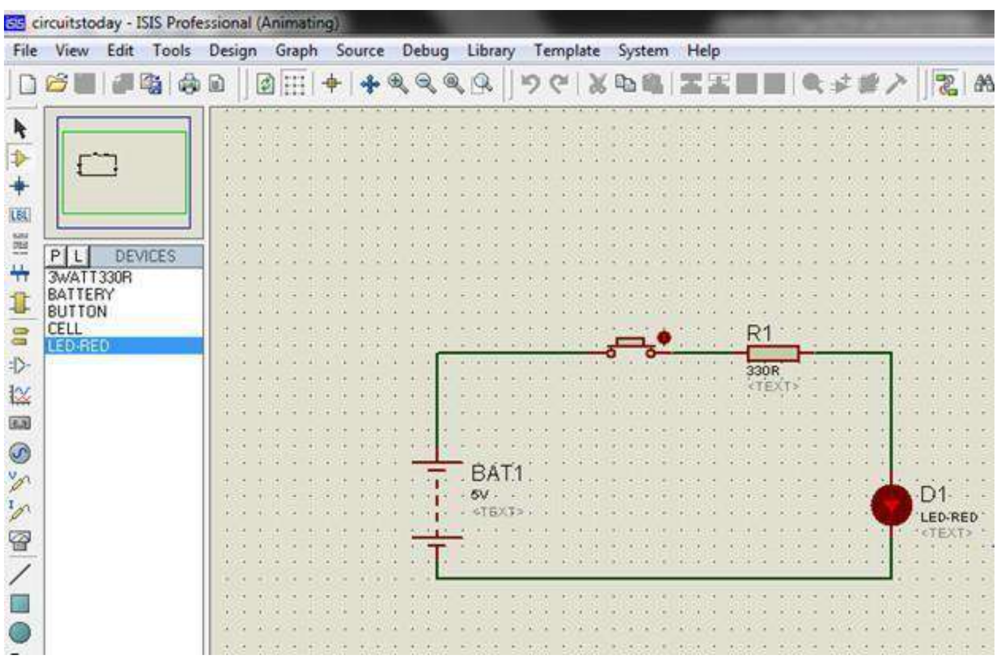

Fig . 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

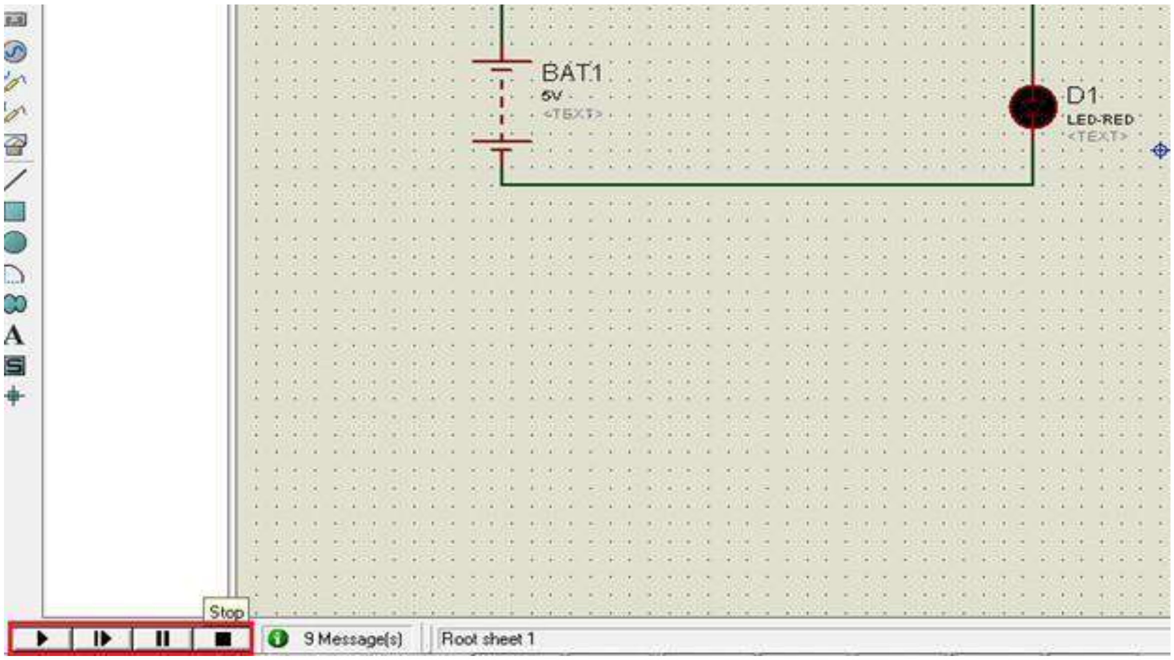

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.2.8.1 TEMPERATURE SENSOR:

Temperature Sensor which converts temperature value into electrical signals. We used IC called LM 35 as a temperature sensor. LM35 series sensors are precision integrated-circuit temperature sensors whose output voltage is linearly proportional to the Celsius temperature. The LM35 requires no external calibration since it is internally calibrated. . The LM35 does not require any external calibration or trimming to provide typical accuracies of ±1⁄4°C at room temperature and ±3⁄4°C over a full −55 to +150°C temperature range.

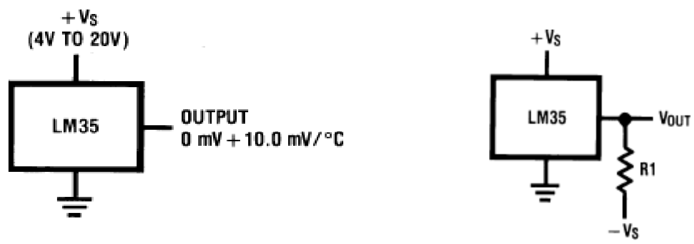
The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 μA from its supply, it has very low self-heating, less than 0.1°C in still air.

Features:

- Calibrated directly in ° Celsius (Centigrade)
- Linear + 10.0 mV/°C scale factor
- 0.5°C accuracy guaranteed (at +25°C)
- Rated for full −55° to +150°C range
- Suitable for remote applications

- Low cost due to wafer-level trimming
- Operates from 4 to 30 volts
- Less than 60 μA current drain
- Low self-heating, 0.08°C in still air
- Nonlinearity only ±1⁄4°C typical
- Low impedance output, 0.1 W for 1 mA load

Figure 3.2.8.1: Temperature Sensor



The characteristic of this LM35 sensor is:

For each degree of centigrade temperature it outputs 10milli volts. ADC accepts the output from LM35 and converts that data into digital form which is sent to microcontroller for further processing.

TEMPERATURE SENSING CIRCUIT:

The methods of temperature measurement may be divided into two main classes according as the exchange of heat between the testing body and the hot system takes place by contact, or by radiation across a space. In the contact methods, thermometers or thermocouples are used and they are immersed in solids or liquids. The thermodynamic equilibrium between the hot body and the testing body is established by material contact.

In the non-contact methods, the thermodynamic equilibrium is established by the radiation emitted as excited atom and molecules in the hot body return to the ground state.

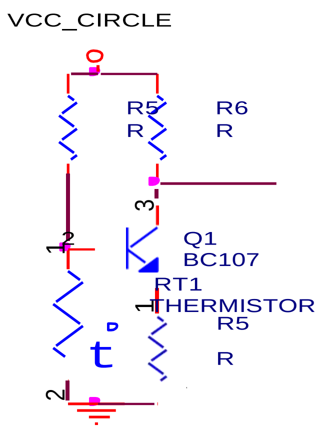


Figure 3.2.8.1(A). Temperature Sensing Circuit

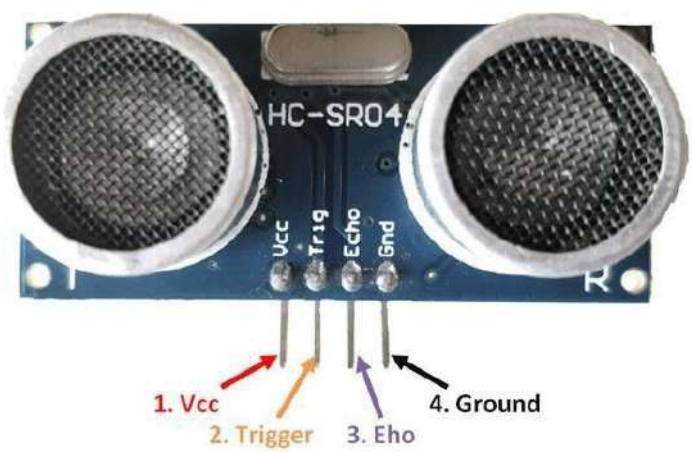
3.2.9.1 ULTRA SONIC SENSOR :

HC-SR04 Ultrasonic Sensor



Ultrasonic Sensor HC SR04

Ultrasonic Sensor Pin Configuration

Pin Number	Pin Name	Description
1	Vcc	The Vcc pin powers the sensor, typically with +5V
2	Trigger	Trigger pin is an Input pin. This pin has to be kept high for 10us to initialize measurement by sending US wave.
3	Echo	Echo pin is an Output pin. This pin goes high for a period of time which will be equal to the time taken for the US wave to return back to the sensor.
4	Ground	This pin is connected to the Ground of the system.

3.2.9.2 HC-SR04 Sensor Features

- Operating voltage: +5V
- Theoretical Measuring Distance: 2cm to 450cm
- Practical Measuring Distance: 2cm to 80cm
- Accuracy: 3mm
- Measuring angle covered: <15°
- Operating Current: <15mA
- Operating Frequency: 40Hz

3.2.9.3 HC-SR04 Ultrasonic Sensor - Working

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4 pin module, whose pin names are Vcc, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver. The sensor works with the simple high school formula that,**Distance = Speed × Time.**The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

Fig3.2.9.3 Ultrasonic Sensor

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

3.2.9.4 How to use the HC-SR04 Ultrasonic Sensor:

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

Power the Sensor using a regulated +5V through the Vcc ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to be made high for 10uS and then turned off. This action will trigger an ultrasonic wave at frequency of 40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information the distance is measured as explained in the above heading.

Applications:

- Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot, path finding robot etc.
- Used to measure the distance within a wide range of 2cm to 400cm
- Can be used to map the objects surrounding the sensor by rotating it
- Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water

2D model of the ultra sonic

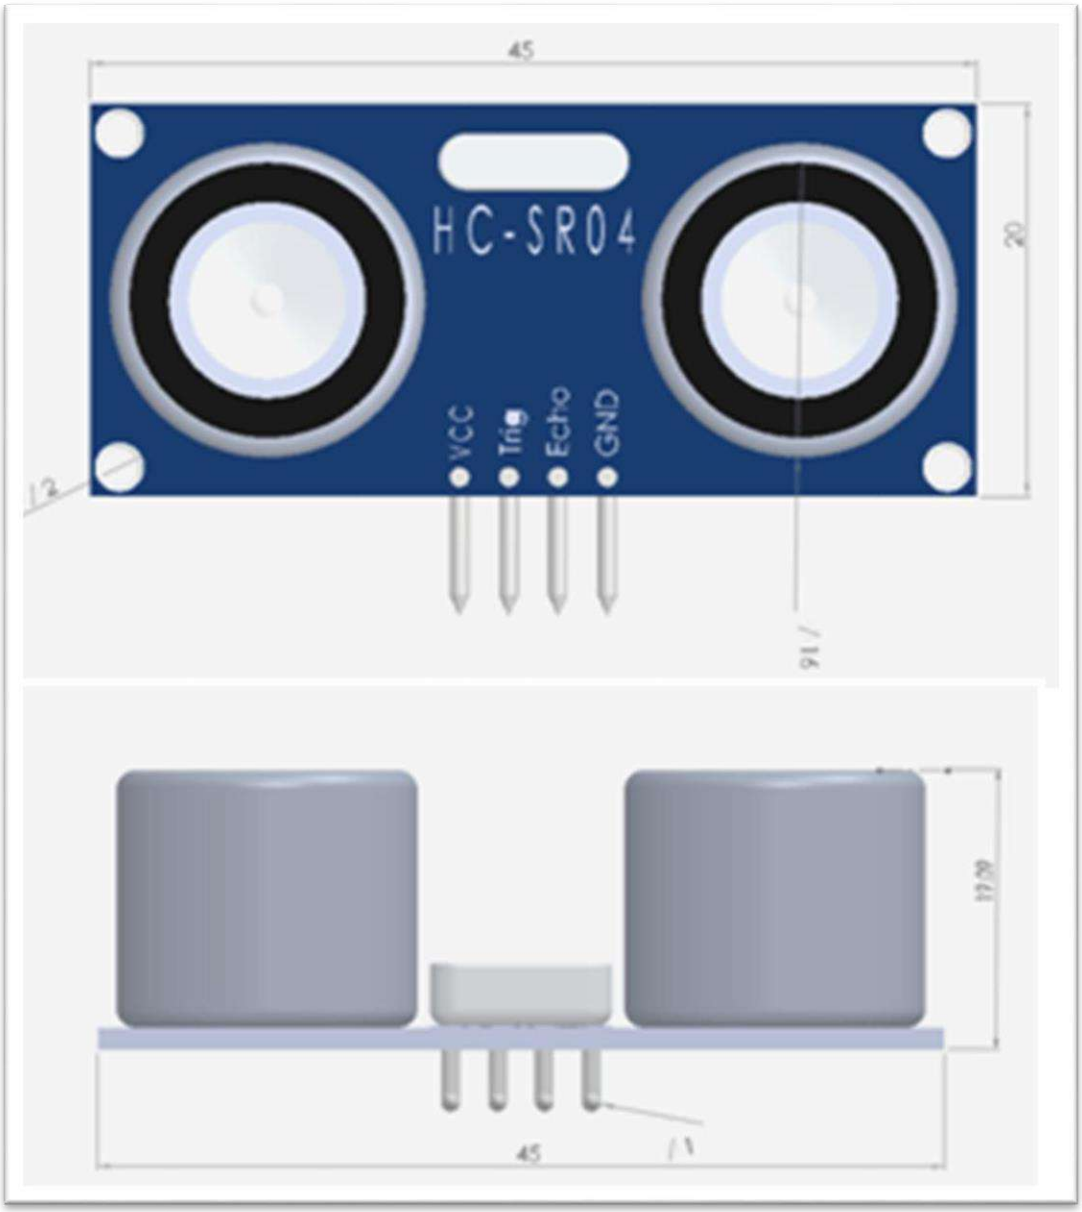


Fig3.2.9.5:2D model of the ultra sonic

3.3.1 Flow Sensor:

Flow sensor to detect leakage in a pipe is used for flow measurement. Precise measurement of the flow is an important step in qualitative and economic terms. The panel sits next to the water line and includes a panel to calculate the volume of water that has passed through. An integrated Hall-Effect magnet sensor generates an electric pulse with every turn.

Water Flow Sensor is an instrument that uses Hall effect to measure linear, nonlinear, The mass or volumetric flow rate of a liquid or a gas. The flow sensor consists of a plastic valve body, a rotor, and a hall-effect sensor. When water or gas flows through the rotor, the rotor rotates, the speed of the rotor changes with different rate of flow. The hall-effect sensor records these rotations as pulses and according to the pulses outputs the amount of water or gas flowing through the sensor. It operates on a maximum working voltage of 5V and minimum of 4.5V.

Working Principle

Water flow sensor consists of a plastic valve from which water can pass. A water rotor along with a hall effect sensor is present the sense and measure the water flow.

When water flows through the valve it rotates the rotor. By this, the change can be observed in the speed of the motor. This change is calculated as output as a pulse signal by the hall effect sensor. Thus, the rate of flow of water can be measured.

The main working principle behind the working of this sensor is the Hall effect. According to this principle, in this sensor, a voltage difference is induced in the conductor due to the rotation of the rotor. This induced voltage difference is transverse to the electric current.

When the moving fan is rotated due to the flow of water, it rotates the rotor which induces the voltage. This induced voltage is measured by the hall effect sensor and displayed on the LCD display.

The water flow sensor can be used with hot waters, cold waters, warm waters, clean water, and dirty water also. These sensors are available in different diameters, with different flow rate ranges.

These sensors can be easily interfaced with microcontrollers like Arduino. For this, an Arduino microcontroller board for processing, a Hall effect water flow sensor, a 16×2 LCD display, and Breadboard connecting wires are required. The sensor is placed at the water source inlet or at the opening of the pipe.

The sensor contains three wires. Red wire to connect with supply voltage. Black wire to connect to ground and a yellow wire to collect output from Hall effect sensor. For supply voltage 5V to 18V of DC is required.

3.3.2 ESP8266 WIFI MODULE:

3.3.2.1 INTRODUCTION

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

3.3.2.2 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),
- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I^2C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I^2S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

3.3.2.3 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring

- Natural Language-based voice assistants.

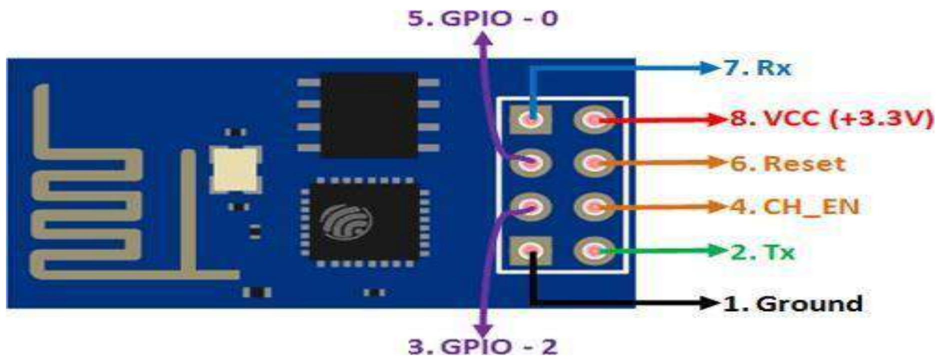

Fig.3.3.2.3 ESP8266 wifi module pin out

3.3.2.4 STRUCTURE AND CONFIGURATION:

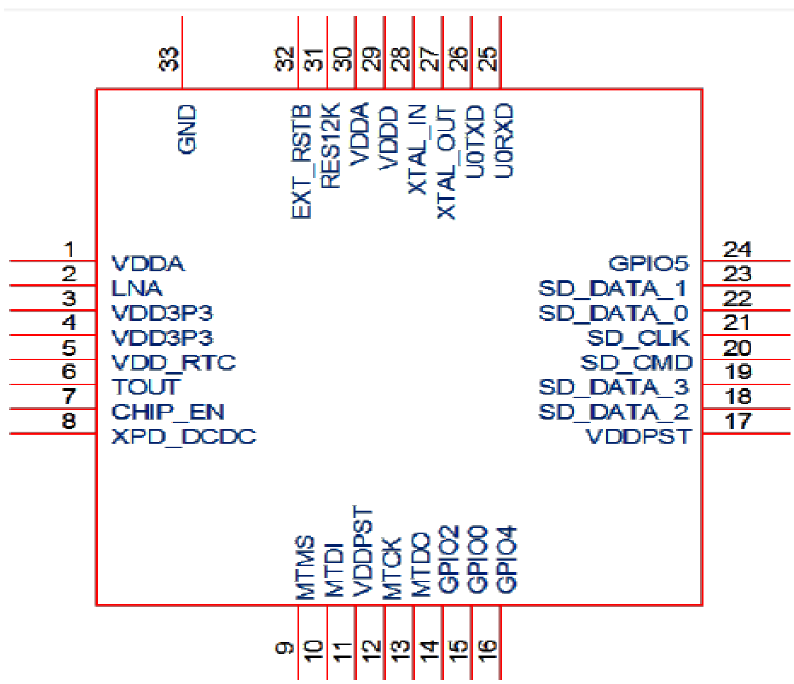

Fig.3.3.2.4 Structure and configuration

3.4.2 ESP8266 WIFI MODULE

The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution.

CHAPTER-4

PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:

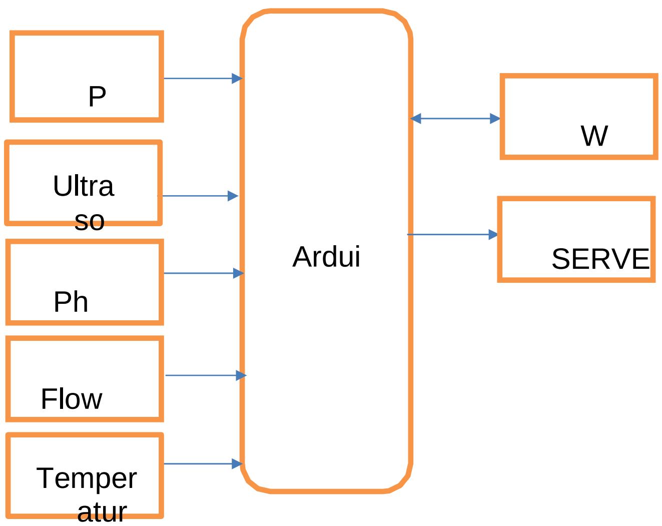

Fig4.0:Block diagram of project

4.2 FLOW CHART

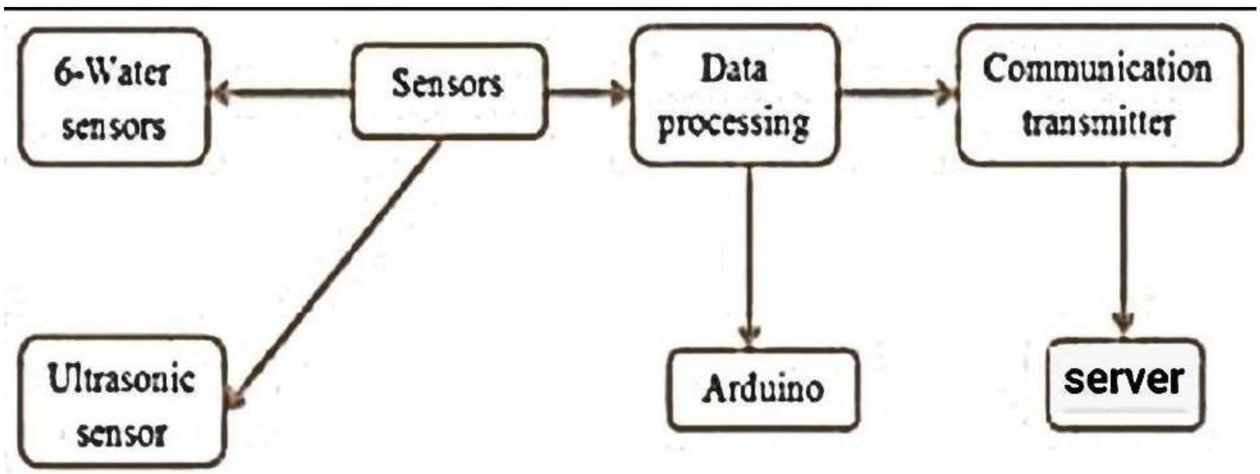

Fig.4.2 Flow Chart

4.3 IMPLEMENTATION STAGES:

In the figure we, notice that using server we can observe the readings in the Arduino here, in the display we can clearly identify that readings for our project in which D1-ultra sonic sensor, F-Flow sensor, PH - sensor, T-temperature. All the information is directly send this information to the Arduino through server, here we can clearly identify the readings or values of the components.

4.4 PROJECT CODE

```
#include <LiquidCrystal.h>
 LiquidCrystal lcd(13,12,11,10,9,8);
 #include <SoftwareSerial.h>
 SoftwareSerial mySerial(2,3);
  //adc
 int temp = A0,flow = A1,ultrasonic = A2,ph = A3;
char res[130];
 //pins

////////////////////

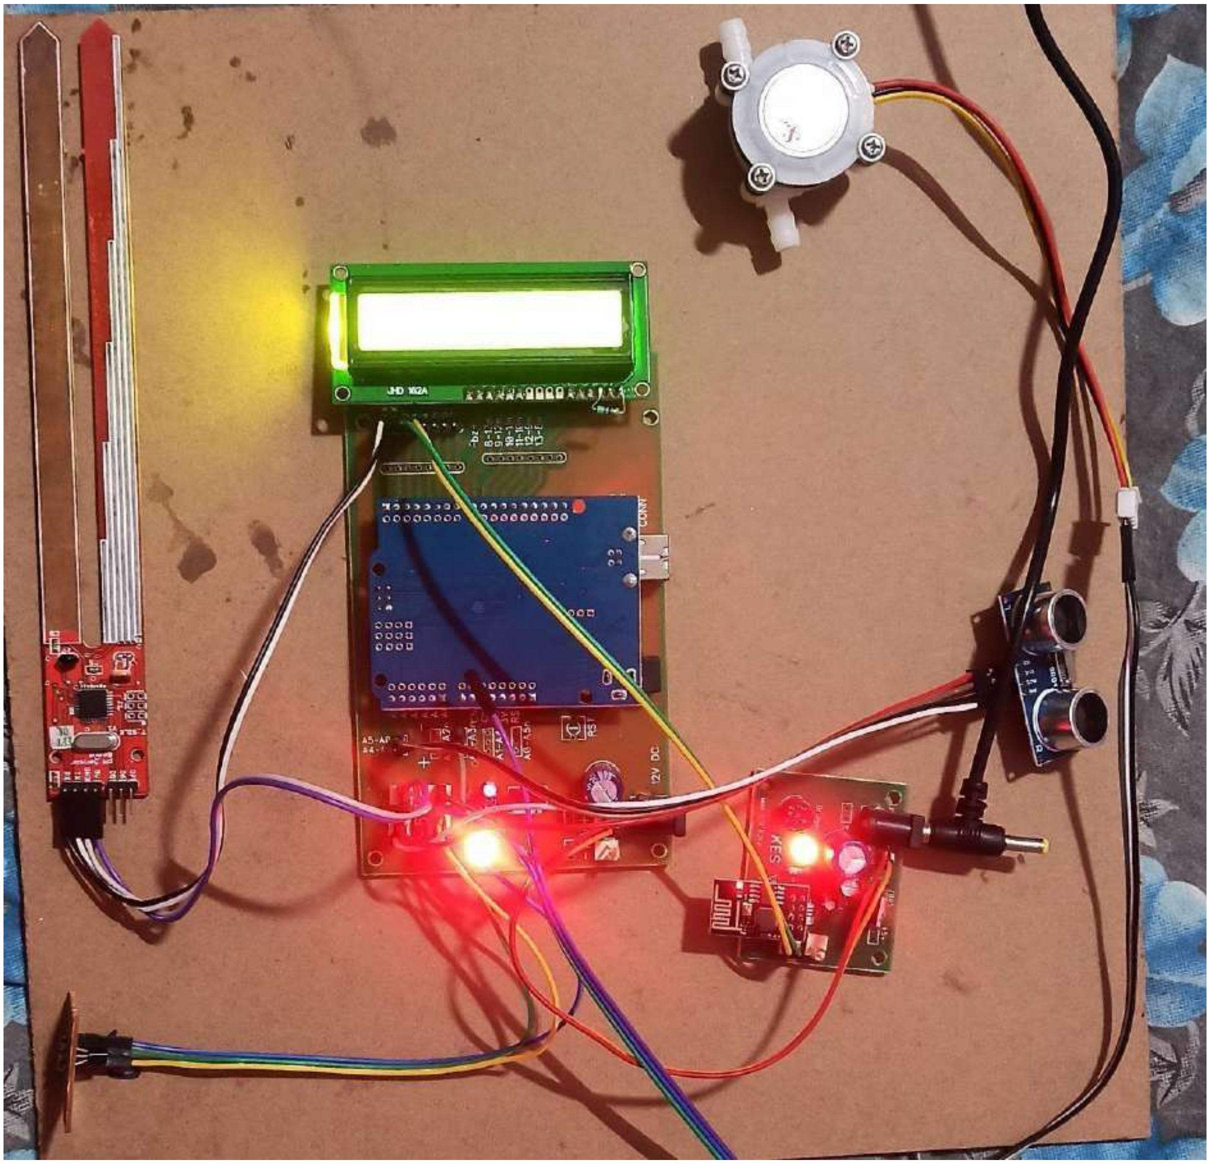

Fig.4.5 Final Output

CHAPTER-5

PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

- As people continues to lay more pipelines, the asset base grows, which translates to more potential points of failure. As we're adopting a proactive and systematic approach to manage the asset base in order to optimize the lifespan of existing pipelines and pre-empt failures of critical pipelines To facilitate the implementation of the new asset management system, we will leverage widely on condition assessment technologies to retrieve more dynamic and real time data. The challenge is that pipelines are buried, lined & have undulating profiles. In addition, the network is interconnected & "live" 24/7 reliable supply is required. This makes it difficult to implement condition assessment technologies on a large scale. However, once these challenges are surmounted, these data can be uploaded into an asset management software to improve the identification of high-risk pipelines so that pipeline renewal works can be prioritized. With a better understanding of the circumstances leading to pipe failures, we can also improve pipeline designs to prevent future failures. Leveraging on a Smart Water Grid system for asset management thus allows us to plan, design, operate and manage assets cost-effectively for safe and reliable supply to customers.

- Our project goal is to monitor and model network water quality in real-time, so as to detect contamination early and control its spread to minimize impact to customers. There is a need to move away from depending on customers to act as sensors for water quality issues like discolored water. Furthermore, in today's volatile socio-political climate, we need to be even more vigilant to deter and prevent acts of sabotage that may threaten the quality of the water supply.

- We’re exploring how real time information and feedback from smart water-efficient gadgets/fittings & technologies could drive water consumption behavioral changes of domestic customers. Trust and data protection is important as water consumption data could be sensitive and personal. In addition, cost effectiveness is a major consideration for any home water management solutions and it is often challenging to justify the cost effectiveness of smart water-efficient gadgets

- However, with increasing public expectations, there is a need to find methods to further reduce response time towards leak incidents. We aims to deploy more advanced leak detection equipment/systems to continuously monitor and analyse leaks, thereby improving response time and minimizing impact to customers. With more leak monitoring systems installed island-wide, there can be significant reduction in the manpower which is normally required to perform the routine site inspection.

CHAPTER-6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

In order to save water for the future world, the IoT Based Water Saving and Leakage Detection and Manager for apartments and homes has been built. The findings of this analysis International Journal of Advanced Science and Technology Vol. 29, No. 9s, (2020), pp. 683-689 ISSN: 2005-4238 IJAST Copyright ⓒ 2020 SERSC 688 study are presented and discussed in various parts on the basis of the framework for research methodology. Important results of each study, including the most promising wearable devices and sensors for building safety surveillance applications and trends are presented. We have seen how this architecture can be used to handle actual water management systems. However, organizational processes need to be clearly defined to resolve other specific problems, such as physical network specification or identity mapping. In conclusion, we explain the scenario we identify for validation and the list of features that we will test at this station established an experimental station. We may conclude that IoT adoption and water management companies can promote exposure to a wider global market and will bring new benefits to support systems decisions, monitoring, water storage, and water energy ties. Future research will define the test carried out and will focus on solving coordination issues in multiple recipes using the same physical resources, taking into account priority and conditional output and also optimization of processes.

6.2FUTURE ENHANCEMENT

- In future we use IOT concept in this project
- Detecting the more parameters for most secure purpose
- Increase the parameters by addition of multiple sensors
- By interfacing relay we controls the supply of water

PUBLICATION

- Submitted Paper at Online Mega International Conference on “Smart Modernistic in Electronics and Communication” (ICSMEC – 21).

- Got Acceptance for the Paper with Paper ID (ICSMEC21-0024).

BIBILOGRAPHY

© 2015 International Institute for Sustainable Development Published by the International Institute for Sustainable **Development INTERNATIONAL INSTITUTE FOR SUSTAINABLE DEVELOPMENT** The International Institute for Sustainable Development (IISD) is one of the world's leading centres of research and innovation. The Institute provides practical solutions to the growing challenges and opportunities of integrating environmental and social priorities with economic development. We report on international negotiations and share knowledge gained through collaborative projects, resulting in more rigorous research, stronger global networks, and better engagement among researchers, citizens, businesses and policymakers. IISD is registered as a charitable organization in Canada and has 501(c)(3) status in the United States. IISD receives core operating support from the Government of Canada, provided through the International Development Research Centre (IDRC) and from the Province of Manitoba. The Institute receives project funding from numerous governments inside and outside Canada, United Nations agencies, foundations, the private sector, and individuals. Water Quality Monitoring System Design September 2015 Written by Carter Borden and Dimple Roy Head Office 111 Lombard Avenue, Suite 325 Winnipeg, Manitoba .

APPENDICES

The project shows functionalities of leakages and the quality of water using the concept of 'Internet of things'(IOT) based on Arduino in reference to a survey conducted by Government of USGS in the year 2018 on Monitoring Quality of Water. We examine and report on the conditions of the leakage of the pipelines based on the local water quality , to provide them optimal solution and we consent with the idea of making a System for Monitoring the Water Aspects and Leaks.

DECLARATION

I, the student of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATION ENGINEERING, session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "AUTOMATIC POWER SAVING WITH THE HELP OF IOT" is the outcome of my own bonafide work and is correct to the best of my knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Mr. Astik Achary (16K81A0402)

Mr. Buddavarapu Krishna Vardhan (16K81A0467)

Mr. B. Shravan Babu (16K81A04J5)

ACKNOWLEDGEMENTS

The satisfaction and mpletion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success

First and foremost, I would like to express our deep sense of gratitude and indebtedness to my **College Management** for their kind support and permission to use the facilities available in the Institute.

I especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

I would like to express my gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. I am proud to record that I had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

I would like to express my gratitude to my dept. project coordinator **Dr.A.ANAND, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

.

I sincerely thank my internal guide Mr. G. Ramesh Reddy, Assistant professor, De partment of ECE and my Class project Coordinator Ms. P. Pushpa, Assistant Professor , Department of ECE for guidance and encouragement in carrying out this project.

Finally, I am highly grateful and obliged to my project guide **Mr.S.P.MANIKANTA, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

Astik Achary (16K81A0402)

Buddavarapu Krishna Vardhan (16K81A0467)

B. Shravan Babu (16K81A04J5)

ABSTRACT

Humans have been communicating with each other for ages in order to solve problems and do complex work but with the advancement of technology. IOT or internet of things promises a great future for the communication between machines that can be implemented to perform many tasks that can benefit the human community. Many problems are saving electricity, which is one of the major responsibilities of everyone yet few people could actually do so be it carelessness or lack of time. This paper aims to solve the problem of electricity wastage in school and college classrooms by using an automatic electricity control system for a room made by applying IOT sensors and microcontrollers.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

GLOSSARY OF COMMONLY USED TERMS:

Active Tag – An RFID tag that uses a battery to power its microchip and communicate with a reader. Active tags can transmit over the greatest distances (100+ feet). Typically they can cost $20.00 or more and are used to track high value goods like vehicles and large containers of merchandise.

Agile Reader – A reader that can read different types of RFID tags – either made by different manufacturers or operating on different frequencies.

Antenna – A device for sending or receiving electromagnetic waves.

Anti-Collision – A feature of RFID systems that enables a batch of tags to be read in one reader field by preventing the radio waves from interfering with one another. It also prevents individual tags from being read more than once.

Automatic Data Capture (ADC) – Methods of collecting data and entering it directly into a computer system without human intervention. Automatic Identification (Auto-ID) Refers to any technologies for capturing and processing data into a computer system without using a keyboard. Includes bar coding, RFID and voice recognition.

Auto-ID Center – A group of potential RFID end users, technology companies and academia. The Auto-ID center began at the Massachusetts Institute of Technology (MIT) and is now a global entity. It is focused on driving the commercialization of ultra-low cost RFID solutions that use Internet like infrastructure for tracking goods throughout the global supply chain. The Auto-ID Center organization is now EPC global.

Electronic Product Code (EPC)

A standard format for a 96-bit code that was developed by the Auto-ID Center. It is designed to enable identification of products down to the unique item level. EPC's have memory allocated for the product manufacturer, product category and the individual item. The benefit of EPC's over traditional bar codes is their ability to be read without line of sight and their ability to track down to the individual item versus at the SKU level.

EPC global – The association of companies that are working together to set standards for RFID in the retail supply chain. EPC global is a joint venture between EAN International and the Uniform Code Council, Inc.

Radio Frequency Identification (RFID)

A method of identifying items uniquely using radio waves. Radio waves do not require line of site and can pass through materials like cardboard and plastic but not metals and some liquids.

Read Range

The distance from which a reader can communicate with a tag. Several factors including frequency used orientation of the tag, power of the reader and design of the antenna affect range.

Reader

Also called an interrogator. The RFID reader communicates via radio waves with the RFID tag and passes information in digital form to the computer system. Readers can be configured with antennas in many formats including handheld devices, portals or conveyor mounted.

Read Only Tags

Tags that contain data that cannot be changed. Read only chips are less expensive than read-write chips

Read-Write Tags

RFID chips that can be read and written multiple times. Read/Write tags can accept data at various points along the distribution cycle. This may include transaction data at the retail point of sale. They are typically more expensive than read only tags but offer more flexibility.

RFID Transponder

Another name for a RFID tag. Typically refers to a microchip that is attached to an antenna, which communicates with a reader via radio waves. RFID tags contain serial numbers that are permanently encoded, and which allow them to be uniquely id

"WORM" Chip (Write Once Read Many) and then becomes "Read only" afterwards

CHAPTER-1
INTRODUCTION

1.1 OVERVIEW OF THE PROJECT:

With the growth in the number of vehicles the need for expansive roads catering to thousands of vehicles moving across India has become inevitable. However, considering the present situation the current toll system has several drawbacks. Due to the limited number of toll booths and slow collection process, the average waiting time per vehicle is 10 minutes. This results in losses worth thousands of crores of Rupees in terms of fuel wastage. This long wait time often results in drivers getting irritated resulting in verbal spats and physical fights among people and the toll attendants. Several such incidents have been reported in the press with some of these fights even resulting in the death of the toll plaza attendants. In addition, there are numerous cases of toll plaza accidents which happen due to the sudden lane changing by drivers for faster clearance. The major reason behind this is that, the security at the tolls is insufficient and it is beyond the traffic polices control to manage the vast number of vehicles. We keep hearing of many such incidents at toll plazas which mostly occur due to negligence either on the people’s side or due to lack of control from the government agencies including the police. In case of events, where lives are lost, such losses are a life shattering experience.

As is well known, in such a scenario, the general public is a little hesitant in taking responsibilities of any such incident. Hence the government has to come up with an effective plan which bridges the gap between the toll management and the public expectation of the service that they experience. Introduction of an elective toll plaza operation plan by the government, its strict implementation and monitoring which would result in a more efficient and a more responsive and efficient system could be a good option for easing the challenges associated with the existing tolling process.

The requirements for new web applications supporting different types of devices an purposes are continuously growing. The main advantages of web application development as well as popular development features covering integration with different technologies are considered.

Integration and possibilities of application of cloud-based web applications in real scenarios with different embedded Internet of Things (IoT) devices are considered and described. The design and implementation of a cloud-based web application supporting vehicle toll payment system using IoT device is presented and described. The development framework as well as featured and popular technologies used to realize a vehicle toll payment by IoT device are described. The concept of vehicle toll payment over an online payment system is also described. Processing, monitoring and control in the cloud-based web application of such payments using IoT devices are described and presented. Also, system allows to store data of all the vehicles passed at particular time intervals for later reference and surveillance. This system thus automates the entire toll booth collection and monitoring process with ease using RFID plus IoT based system.

1.2 OBJECTIVES OF THE STUDY:

The use of automated toll collection system in many metropolitan cities would be an efficient step towards the overcrowding of the city highways in heavy congestion of traffic. As we all know, transportation is the strength of our country's economy. There are various implementation, protocols in wireless sensor network and components such as RFID thus enabling reduction in operation costs and motivating cashless transactions. In case of manual toll collection system time consumption is much far worse as well as fuel depletion and most important is the environment, the amount of air pollution that is created at the toll booth site is at high level, so our developed system will reduce time wastage and not only reduce air pollution but also conserve fuel. The sole purpose of this paper is to reduce the hardships caused by manual toll collection system and pass the subject's vehicle through toll barrier in a matter of few seconds without halt.

Each and every day more and more vehicles are increasing rapidly and the graph of the rate of buying vehicles is exponential, which has become a major problem at the site of toll booths due to heavy traffic causing endless number of problems such as high petrol/diesel consumption leading to depletion of hydrocarbon deposits below earth's crust and also death causalities due to heavy traffic. The sole purpose of this paper is to motivate cashless transactions by installing automated e-toll collection system and the technology that we used is the use of RFID readers/tags. Basically to tackle this problem, the use of RFID tags that must be uniquely fixed onto subject's vehicle and RFID reader module must be fixed at e-toll tooth. When a subject's vehicle passes through the gate, the reader will detect an incoming frequency of 125 kHz of the RFID tag and read a unique no that has been assigned by govt. authority and the toll fee will be deducted from linked bank a/c or the e-wallet of system. This system is capable of saving time as well as fuel conservation which can save a lot of individual’s economy. This particular system is far much better and very efficient towards people as they will not stay in a long and lengthy queue thus automated e-toll system will eliminate the hardships of people parking vehicles in a long queue. RFID has the potential of eliminating corruption at local level and also reduce operational costs as well as errors in human operations. WSN’s i.e. wireless sensor networks are basically used in different scenarios such as home, office, healthcare, agriculture and also at toll collection plaza which can capture and transmit data from all incoming vehicles and outgoing vehicles because of their consistent and distinctive properties.

1.3 SCOPE OF THE STUDY:

- **IOT (internet of things)** based toll booth manager system is such type of a system that provides the automatic toll collection process with the help of internet resources and RFID (radio frequency identification) technology.

- If we talk about accountability, then manually toll collection process is very complicated because it is not so much easy to manage hundred and thousands of vehicles at same time.

- It required more man power as well as with more toll collection booth, which could be so much costly and difficult for toll collection department.

- On other hand, so much time is wasted by the vehicle owners when they are stand in so much long toll collection row.

- To manage all these above situations and to facilitate the vehicles owners, so many toll booth manager systems are available in market but that one’s are so much costly as well as they are not so much efficient, reliable, precise and friendly to use.

- Here we have proposed a system that is called IOT based toll booth manager system which is so much efficient, reliable and friendly to use. In this system every vehicle owner possess a RFID based card, which would be scanned this card during pass through toll collection both.

1.4 MATERIAL REQUIREMENT:

1.4.1 HARDWARE REQUIREMENT:

- Arduino uno
- LCD
- Power Supply
- RFID
- Buzzer
- WIFI
- L293D
- Motor

1.4.2 SOFTWARE REQUIREMENT:

- Proteus software
- Arduino software

1.5 PROCUMENT OF EQUIPMENT:

We brought all the required hardware components in an electronic manufacturing shop and before assembling and interfacing hardware components to Arduino UNO micro-controller, we connected individual components to Arduino in Proteus Software and understood working of every individual component in Proteus Software.

Now, we assembled all components and interfaced to Arduino UNO micro-controller using connecting wires through bread board and we wrote program to work all the hardware components in Arduino IDE we understood the working of all components in a practical way.

We were able to monitor the toll booth system with better efficiency, with less time delay and the results were also satisfactory and we successfully got the output in mobile telnet app and LCD screen. We would like to improve the project in future for further developments.

CHAPTER-2

LITERATURE SURVEY

2.1 LITERATURE REVIEW ON RESEARCH AREA:

The ATC system in the paper "A review on automated toll collection system" the two types of study were compared namely the RFID based study and Leach-C based study showed promising and efficient way to develop the system but it also showed us lack of a point where the Leach-C system worked on digital image processing where the number plate of subject's vehicle was scanned using high-tech camera. Using the RFID based implementation and eliminating the DIP based implementation to make system better time efficient. The survey done in the paper named "A 5.8 GHz ISM band Microstrip antenna for RFID applications" showed us the path using and developing RFID antenna for scanning the details of subject's vehicles from a handy distance thus enhancing the distance of vehicle and RFID reader would cover a large area. Smart Toll Collection System based on IoT (IJSTE/ Volume 3 / Issue 12 / 002) All rights reserved by www.ijste.org 10 The review was done of the paper "Automated toll collection system using RFID" Enlighted us the various components that can used while developing our own system in time saving and in efficient way so as to make a hybrid system that is mentioned in the paper "A review on automated toll collection system". "A Survey in Image Mining" showed a path towards machine learning and data mining concepts and helped us in mining databases in the form of people's feedback.

2.2 REVIEW ON RELATED LITERATURE:

The first person to propose electronic toll system was William Vickrey. He proposed this system for Washington Metropolitan Area. He was also the recipient of Nobel Economics prize in 1959 [5] The transponder and reader technology spread all around Norway. The system was broached in the Bergen (1986). World"s first completely automated electronic toll collection system was introduced in Trondheim (1991). Norway too has electronic fee collection EFC. [5] In different places in the United States like California, Pennsylvania, Texas, Delaware and Florida, vehicles can pass through electronic toll collecting booths directly. For the same no of cars, operations in electronic toll booths take place faster as the users are preregistered. Toll collecting gates are usually broader than the original width of the road but this made it possible to fit them into smaller narrower roads. Although these limitations are present, if the time taken for operation at the toll booth is reduced, then the speed of operation can be increased. The greater the speed of operation, less number of total lanes was required and as more number of lanes started getting automated, there was a reduction in the overall short term cost of the project. Also if the long term cost of the project is considered, larger number of vehicles started using electronic toll and vehicles using manual toll reduced. [5] According to references, the methodology proposes use of Infrared sensors to gather real time data from the waste bins and that of the microcontroller board to communicate this information to the waste managers.

These sensors collect information about the objects, their surroundings and communicate this information to other stations, linked through wired or wireless networks. The system will check using the IR sensors when the bin becomes full and will notify the waste managers upon filling up of the bins and will provide an optimal and effective collection route. [10] According to reference, The initial technical realization of IoT was achieved by utilizing RFID (Radio Frequency Identification) technology, which was limited to identification, object tracking and extracting information of specific objects. However, The implemented IoT based system performs sensing, actuating, data gathering, storing, and processing by connecting physical or virtual devices to the Internet. [10] According to reference, To facilitate vehicle monitoring, toll collection and faithful vehicle authentication on the highways and to have an efficient usage of communication link between RF Modems over a wireless channel, a module is proposed. There are two types of implementation modules-the Vehicle Module (Active RFID Tag) and the Base Module. Microcontroller contains user-specific information associated with vehicle, such as the owners information with his billing address, vehicle engine number and vehicle registration number. The base module allows the base module to check the activities of vehicles in range, including the vehicles in range, their status, and the detailed information about any registered vehicle.[6] According to reference, Open Road Tolling uses video evidence to identify vehicle usage of a toll facility without the use of toll booths for toll collection without having to stop or even slow down to pay the toll.

The application, for Open Road Tolling, utilizes pattern recognition and image processing methods. This paper presents Open Road Tolling (ORT) using number plate recognition. The proposed Number Plate Recognition (NPR) techniques consist of mainly two modules: histogram based number plate localization and number plate recognition using template matching, thus making it simple & faster. AVI technology uses Laser or Radio Frequency (RF) method. Laser systems uses barcode attached to the vehicle & read by vehicle scanner as the vehicle passes through the toll lane. [7] According to reference, The German Federal

Ministry of Transport had conducted a fee collection experiment on German motorways called ChipTicket systems. The ChipTicket system assumes that vehicles are equipped with a chip card, and an in-vehicle unit. The in-vehicle unit contains transmitting and receiving facilities for communication with the toll stations - the so-called charge collection stations. The chip card is a plastic card contains an integrated microprocessor. When a driver passes a charge collection station, payment is made automatically by the vehicle the chip ticket is made and the fee is registered and stored in the station computer.[8]

A microcontroller has been programmed to operate a remotely operated positioning system of a satellite. Earlier, if we wanted to get an exact angle of the satellite, it needed manual adjustment. To overcome this drawback, this paper was aimed at developing a system to remotely operate the satellite. The IR signal from the remote (Transmitter) is sent and is received by the IR sensor (Receiver) which has been interfaced with the main microcontroller. The data from the transmitter is sent in an encoded format which is received by the receiver sensor and is the suitably sent to the main microcontroller. Corresponding signal is sent by the microcontroller to the motor driver which in turn rotates the motor and thereby the satellite accordingly. [9] According to reference, the ESP826 is a Wi-Fi module that has very efficient on chip storage and processing capabilities with lower cost and higher quality. ESP is based on IEEE 802.11 Wi-Fi protocol and it supports various network protocols. For connecting the machine to server a level shifter is used. [12]

This system on chip (SOC) design has been provided with a TCP/IP protocol stack which is used to provide Wi-Fi connection to any microcontroller that has been used by the system. There are three different methods to implement ESP8266. Using AT commands for communication is the simplest way that can be used. AT commands can be sent via the computer through a USB to serial adapter cable to the controller for setup and testing purposes. The second way is peripheral mode by interfacing compatible microcontroller with the module. The third method can be implemented by directly programming the GPIO pins of the module and interfacing them with external peripherals and sensors. An ESP8266 device can be used as an access point or as a station or both at the same time. Usually the access point also has a network data connection.

Therefore itcan act as a bridge between the wireless network and the TCP/IP network which is the internet. Once it has been finalized which mode the device will be used in, then we set a global mode which indicates the state in which the device will be used (As an access point or a station or both). Wi-Fi module is connected to the controller through this level shifter and have used SPI protocol.. Here considering the need for consistency of data we have utilized

TCP/IP network protocol for communicating with the server [11] The ESP8266 is designed to occupy minimal PCB area, without compromising on providing maximum inbuilt features. Cost Effective - Among the major advantages of the module include its price. You can get a module at lower than $5. Power - The power saving architecture operates in 3 modes: active mode, sleep mode and deep sleep mode, thus yielding very power efficient system. Ease of Interfacing - Module can be easily calibrated when required by reprogramming it for interfacing wide range of sensors.[13]

There are various of protocol is used in IoT (Internet of Things) devices. One of the most useful protocols is MQTT (Message Queuing Telemetry Transport). Second basic protocol is TCP. MQTT is broker based publishing/subscribing messaging protocol. It is open, lightweight, and very easy to implement. Moreover it has low bandwidth protocol.[14] The ATmega328 is the microcontroller used for this project. It shows important specifications like 14 digital input/output pins, 6 analog inputs, a USB connection, a 16 MHz ceramic resonator, an ICSP header, a power jack, and a reset button. The Arduino can be powered via the USB connection or with an external power supply. The power source is selected automatically. External (non-USB) power can come either from an ACto-DC adapter (wall-wart) or battery. The board can operate on an external supply of 6 to 20 volts. However it suffers form possibilities of overheating which may damage the board. The recommended range is 7 to 12 volts.[21] Controller –ATmega328 controller has been used which is an 8-bit microcontroller based on AVR. It has built-in communication protocol like I2C and UART and many other essential features. Real Time Clock-RTC module of DS1307 is connected to ATmega328 through two wire interface for reading the on and off time of the machine. Level shifter: MOSFET based level shifter is needed to drop down voltage in between, as ATmega328 operate on 5V and ESP-12 on 3.3V.[12]

2.3 CONCLUSION ON REVIEWS:

The ATC system in the paper “A review on automated toll collection system” the two types of study were compared namely the RFID based study and Leach-C based study showed promising and efficient way to develop the system but it also showed us lack of a point where the Leach-C system worked on digital image processing where the number plate of subject’s vehicle was scanned using high-tech camera. Using the RFID based implementation and eliminating the DIP based implementation to make system better time efficient. The survey done in the paper named “A 5.8 GHz ISM band Microstrip antenna for

RFID applications” showed us the path using and developing RFID antenna for scanning the details of subject’s vehicles from a handy distance thus enhancing the distance of vehicle and RFID reader would cover a large area.

The review was done of the paper “Automated toll collection system using RFID” Enlighted us the various components that can used while developing our own system in time saving and in efficient way so as to make a hybrid system that is mentioned in the paper “A review on automated toll collection system”. “A Survey in Image Mining” showed a path towards machine learning and data mining concepts and helped us in mining databases in the form of people’s feedback. The survey done in the paper named ATC turned out to be good step for developing ATC as we tried the best option in choosing the components in terms of reducing operation costs, time saving, flexible and also added the theft detection module in our system enabling security on high alert and detecting of stolen vehicles. During the period of learning and reviewing we also tried in improving and eliminating the costs of GSM kits embedded on the micro-controller board by replacing by use of private SMS gateway or govt. running GSM Company, which has reduced the operation cost much and has made our system more independent of using GSM kit.

CHAPTER-3
PROJECT DESIGN

3.1 OVERVIEW OF THE DESIGN:

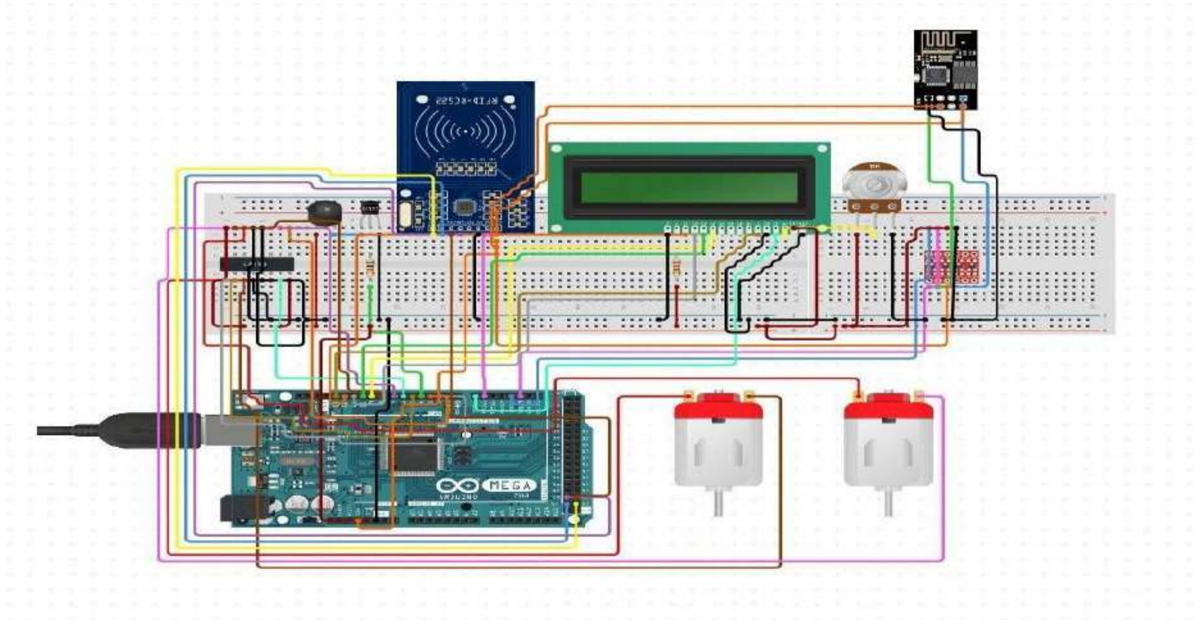

Fig.3.1 Overview of the design

3.2 EQUIPMENT ANALYSIS:

3.2.1 ARDUINO:

3.2.1.1 INTRODUCTION:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.

- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

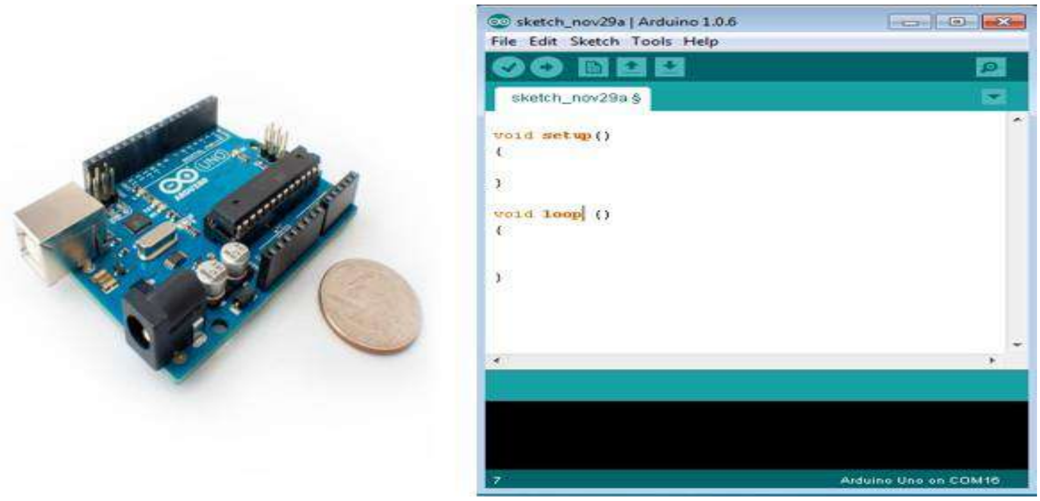

Fig 3.2.1.1 Arduino Uno

3.2.1.2 BOARD TYPES

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programmed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Board Name	Operating Volt	Clock Speed	Digital i/o	Analog Inputs	PWM	UART	Programming Interface
Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header

Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
LilyPad Arduino 328 main board	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
LilyPad Arduino simple board	3.3V	8MHz	9	4	5	0	FTDI-Compatible Header

3.2.1.3 BOARD DESCRIPTION:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.

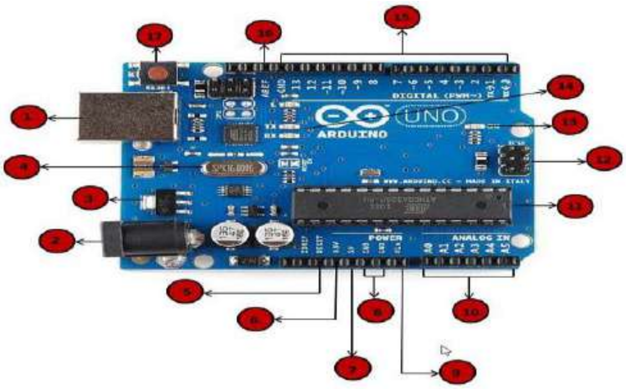

Fig.3.2.1.2 Board Description

1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset** You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt

	• 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in

	two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.2.1.4 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open-source hardware means that others can modify and produce derivatives of Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project, check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.2.1.3: Arduino Family

3.2.1.5 SHIELDS:

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

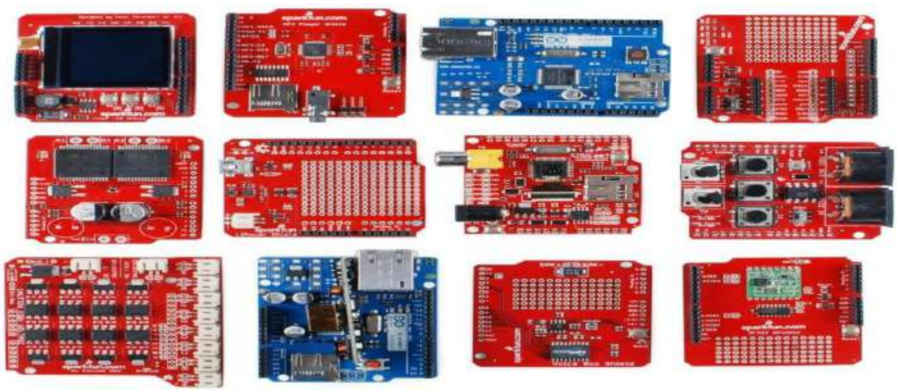

Fig.3.2.1.4: Arduino Shields

3.2.1.6 PIN DESCRIPTION OF ATMEGA328:

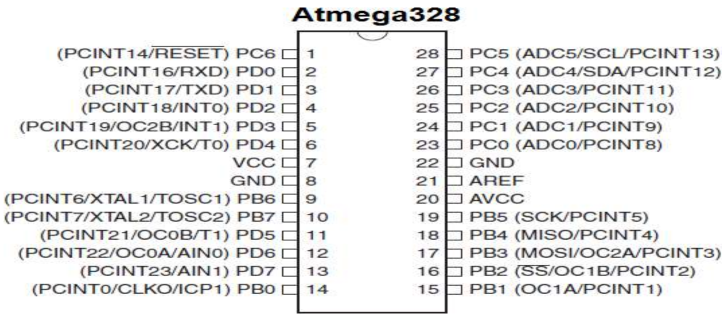

Fig.3.2.1.5 Pin description of ATMEGA328

3.2.1.7 APPLICATIONS:

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

3.2.2 16*2 LCD SCREEN DISPLAY

3.2.2.1 INTRODUCTION

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

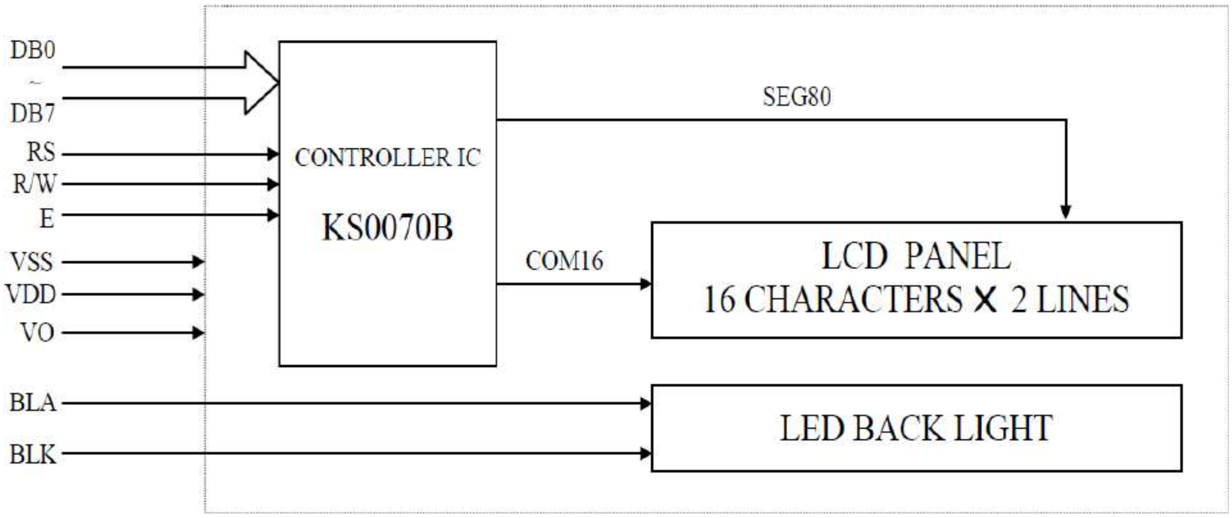

fig.3.2.2.1 Lcd block diagram

3.2.2.2 DISPLAY DATA RAM:

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.

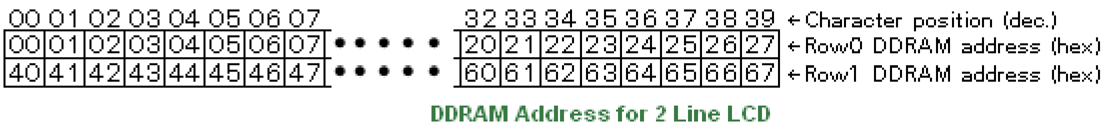

Fig.3.2.2.2 DDRAM addresses of 2 Line LCD

3.2.2.3 CHARACTER GENERATOR ROM:

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. User defined character patterns are also available by mask-programmed ROM.

3.2.2.4 BUS FLAG:

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e. BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact amount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

3.2.2.5 INSTRUCTION REGISTER (IR) AND DATA REGISTER (DR):

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g. LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

3.2.2.6 16 X 2 ALPHANUMERIC LCD MODULE FEATURES:

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers

3.2.2.7 CIRCUIT DESCRIPTION:

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

3.2.3 BUZZER

3.2.3.1 MAGNETIC TRANSDUCER

Magnetic transducers contain a magnetic circuit consisting of a iron core with a wound coil and a yoke plate, a permanent magnet and a vibrating diaphragm with a movable iron piece. The diaphragm is slightly pulled towards the top of the core by the magnet's magnetic field. When a positive AC signal is applied, the current flowing through the excitation coil produces a fluctuating magnetic field, which causes the diaphragm to vibrate up and down, thus vibrating air. Resonance amplifies vibration through resonator consisting of sound hole(s) and cavity and produces a loud sound.

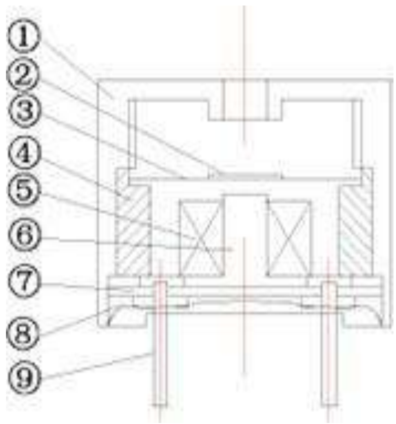

Fig.3.2.3.1 Magnetic Transducer

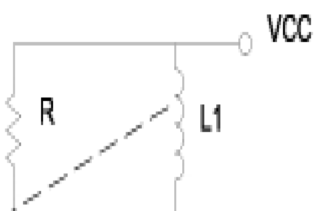
3.2.3.2 MAGNETIC BUZZER(SOUNDER)

Buzzers like the TMB-series are magnetic audible signal devices with built-in oscillating circuits. The construction combines an



oscillation circuit unit with a detection coil, a drive coil and a magnetic transducer. Transistors, resistors, diodes and other small devices act as circuit devices for driving sound generators. With the application of voltage, current flows to the drive coil on primary side and to the detection coil on the secondary side. The amplification circuit, including the transistor and the feedback circuit, causes vibration. The oscillation current excites the coil and the unit generates an AC magnetic field corresponding to an oscillation frequency. This AC magnetic field magnetizes the yoke comprising the magnetic circuit. The oscillation from the intermittent magnetization prompts the vibration diaphragm to vibrate up and down, generating buzzer sounds through the resonator.

3.2.3.3 SPECIFICATIONS:

Fig.3.2.3.2 Magnetic Buzzer

Rated Voltage: A magnetic buzzer is driven by 1/2 square waves (V o-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum Sound Pressure Level (SPL) under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

Direct Current Resistance: The direct current resistance is measured by ammeter directly.

Sound Output: The sound output is measured by decibel meter. Applying rated voltage and 1/2 square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp. : Keep working well between -30℃ and +70℃.

How to choose:

Driving methods: AX series with built drive circuit will be the best choice when we cannot provide frequency signal to a buzzer, it only needs direct current.

Dimension: Dimension affects frequency, small size result in high frequency.

Voltage: Depend on V o-p (1/2 square waves)

Fixed methods: From the highest cost to the lowest- DIP, wires/ connector, SMD.

Soldering methods: AS series is soldered by hand, the frequency is lower because of the holes on the bottom. On the other hand, we suggest AC series for the reflow soldering, the reliability is better.

3.2.3.4 HOW TO CHOOSE A BUZZER:

There are many different kinds of buzzer to choose, first we need to know a few parameters, such as voltage, current, drive method, dimension, mounting type, and the most important thing is how much SPL and frequency we want.

Operating voltage: Normally, the operating voltage for a magnetic buzzer is from 1.5V to 24V, for a piezo buzzer is from 3V to 220V. However, in order to get enough SPL, we suggest giving at least 9V to drive a piezo buzzer.

Consumption current: According to the different voltage, the consumption current of a magnetic buzzer is from dozens to hundreds of mill amperes; oppositely, the piezo type saves much more electricity, only needs a few mill amperes, and consumes three times current when the buzzer start to work.

Driving method: Both magnetic and piezo buzzer have self drive type to choose. Because of the internal set drive circuit, the self drive buzzer can emit sound as long as connecting with the direct current. Due to the different work principle, the magnetic buzzer need to be driven by 1/2 square waves, and the piezo buzzer need square waves to get better sound output.

Dimension: The dimension of the buzzer affects its SPL and the frequency, the dimension of the magnetic buzzer is from 7 mm to 25 mm; the piezo buzzer is from 12 mm to 50 mm, or even bigger.

Connecting way: Dip type, Wire type, SMD type, and screwed type for big piezo buzzer are usually seen.

Sound Pressure Level (SPL): Buzzer is usually tested the SPL at the distance of 10 cm, if distance double, the SPL will decay about 6 dB; oppositely, the SPL will increase 6 dB when the distance is shortened by one time. The SPL of the magnetic buzzer can reach to around 85 dB/ 10 cm; the piezo buzzer can be designed to emit very loud sound, for example, the common siren, are mostly made of piezo buzzer.

3.2.3.5 INTRODUCTION OF PIEZO BUZZER:

Piezo buzzers are simple devices that can generate basic beeps and tones. They work by using a piezo crystal, a special material that changes shape when voltage is applied to it. If the crystal pushes against a diaphragm, like a tiny speaker cone, it can generate a pressure wave which the human ear picks up as sound. Simple change the frequency of the voltage sent to the piezo and it will start generating sounds by changing shape very quickly!

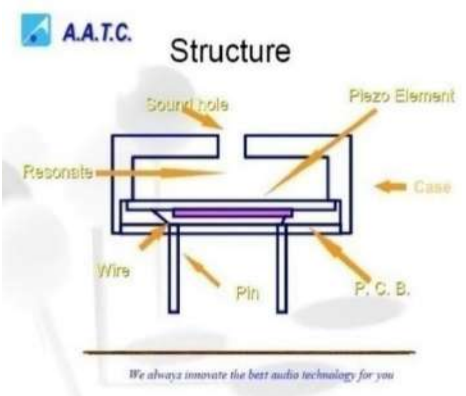


Fig.3.2.3.5 piezo buzzer

3.2.3.6 SPECIFICATIONS:

Rated Voltage: A piezo buzzer is driven by square waves(Vp-p).

Operating Voltage: For normal operating. But it is not guaranteed to make the minimum SPL under the rated voltage.

Consumption Current: The current is stably consumed under the regular operation. However, it normally takes three times of current at the moment of starting to work.

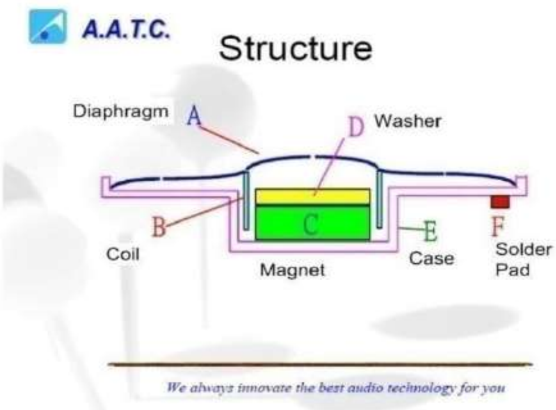

Fig. 3.2.3.6 structure of piezo buzzer

Capacitance: A piezo buzzer can make higher SPL with higher capacitance, but it consumes more electricity.

Sound Output: The sound output is measured by decibel meter.

Applying rated voltage and square waves, and the distance of 10 cm.

Rated Frequency: A buzzer can make sound on any frequencies, but we suggest that the highest and the most stable SPL comes from the rated frequency.

Operating Temp.: Keep working well between -30℃ and +70℃.

3.2.4 L293D

3.2.4.1 INTRODUCTION

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

L293D is basically a motor driver or controller. It has two built-in H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g. stepper motor & DC motors. Its features include large input voltage supply range, large output current high noise immunity input signals etc. Its common real-life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

Fig. 3.2.4.1 L293D Motor Driver

3.2.4.2 L293D PINS:

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

3.2.4.3 L293D PIN FUNCTIONS:

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

Table 3.2.4.3 L293D Pin Functions

3.2.4.4 L293D PINOUT:

- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.

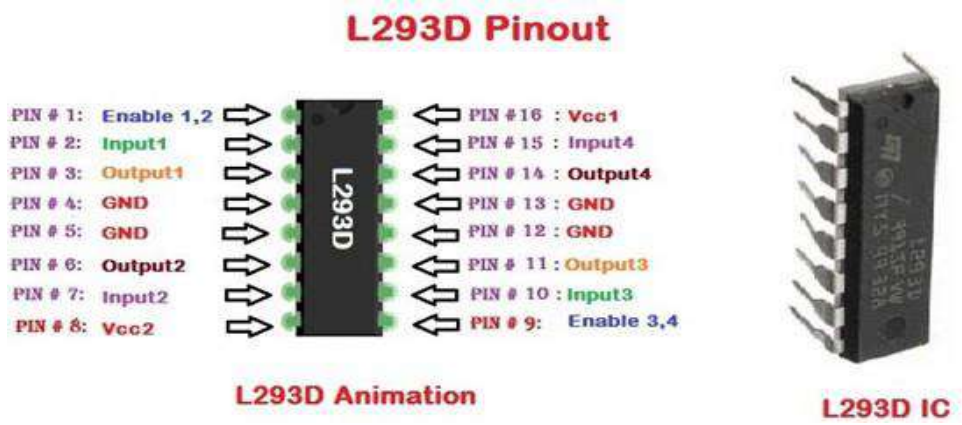

Fig. 3.2.4.4 L293D Pinout

3.2.5 MOTOR

Motors usually operates on this higher current. L-293D has to built-in H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g. relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

3.2.6 SOFTWARE EXPLANATION:

- Arduino software
- Proteus simulation

3.2.6.1 ARDUINO SOFTWARE:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals has gathered around thisopen-source platform, their contributions have added up to an incredible amount ofaccessible knowledge that can be of great help to novices and experts alike. Arduino wasborn at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed atstudents without a background in electronics and programming. As soon as it reached awider community, the Arduino board started changing to adapt to new needs andchallenges, differentiating its offer from simple 8-bit boards to products for IoTapplications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventuallyadapt them to their particular needs. The software, too, is open-source, and it is growingthrough the contributions of users worldwide.

3.2.6.2 WHY ARDUINO?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and
wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.Wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50.

- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as

well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under

a Creative Commons license, so experienced circuit designers c an make their own version Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money

- Getting Started with Arduino and Genuino products: -

Install the Arduino Software (IDE) on Windows PCs-

This document explains how to install the Arduino Software (IDE) on Windows machines.

✔ Download the Arduino Software (IDE)

✔ Proceed with board specific instructions.

3.2.6.3 HOW TO DOWNLOAD THE ARDUINO SOFTWARE (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

3.2.6.4 INSTALLATION:

In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favourite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

Fig.3.2.6.4.1 Standard USB Cable (A plug to B plug)

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Fig. 3.2.6.4.2 Standard USB Cable (an A to Mini-B plug)

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.

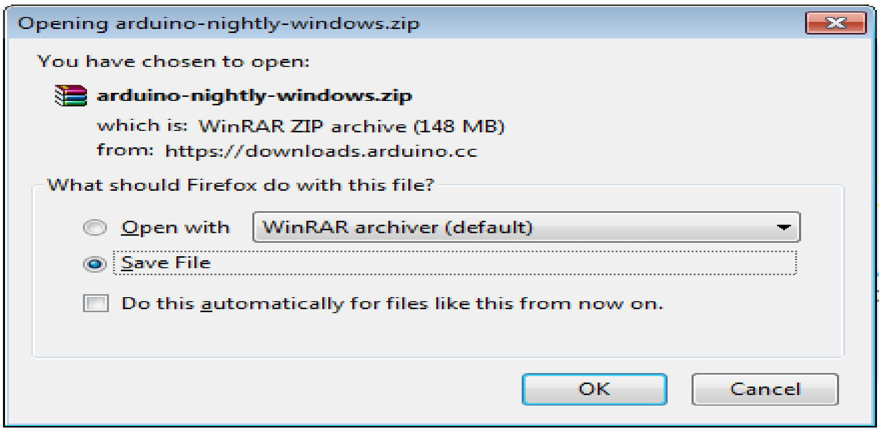

Fig. 3.2.6.4.3 Download Arduino IDE Software

Step 3 − Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 − Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

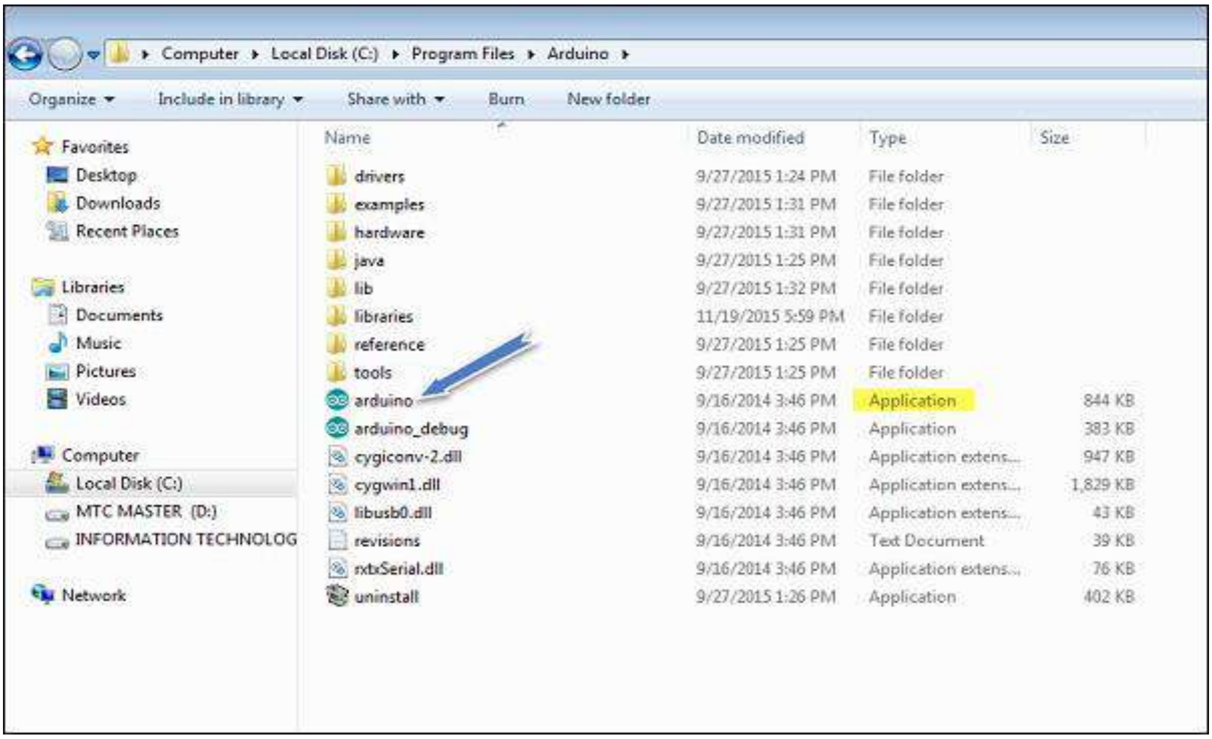

Fig. 3.2.6.4.4 Launch Arduino IDE

Step 5 − Open your first project.

Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**

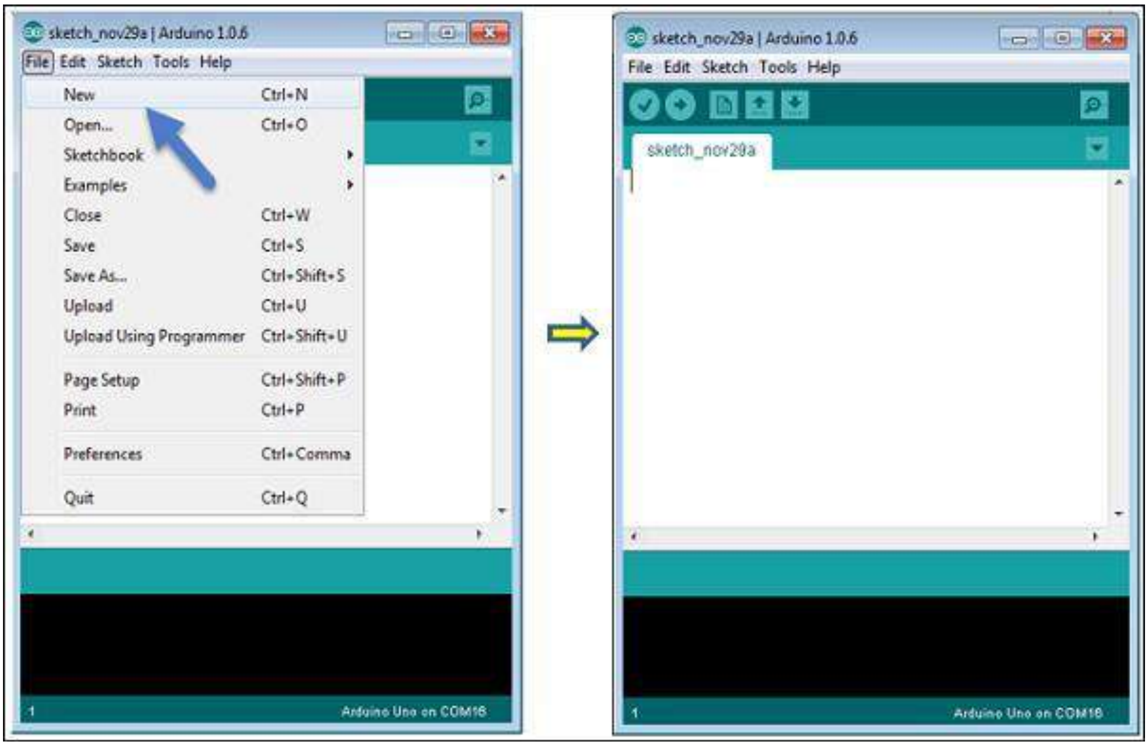

Fig. 3.2.6.4.5 Open your first project.

To open an existing project example, select File → Example → Basics → Blink.

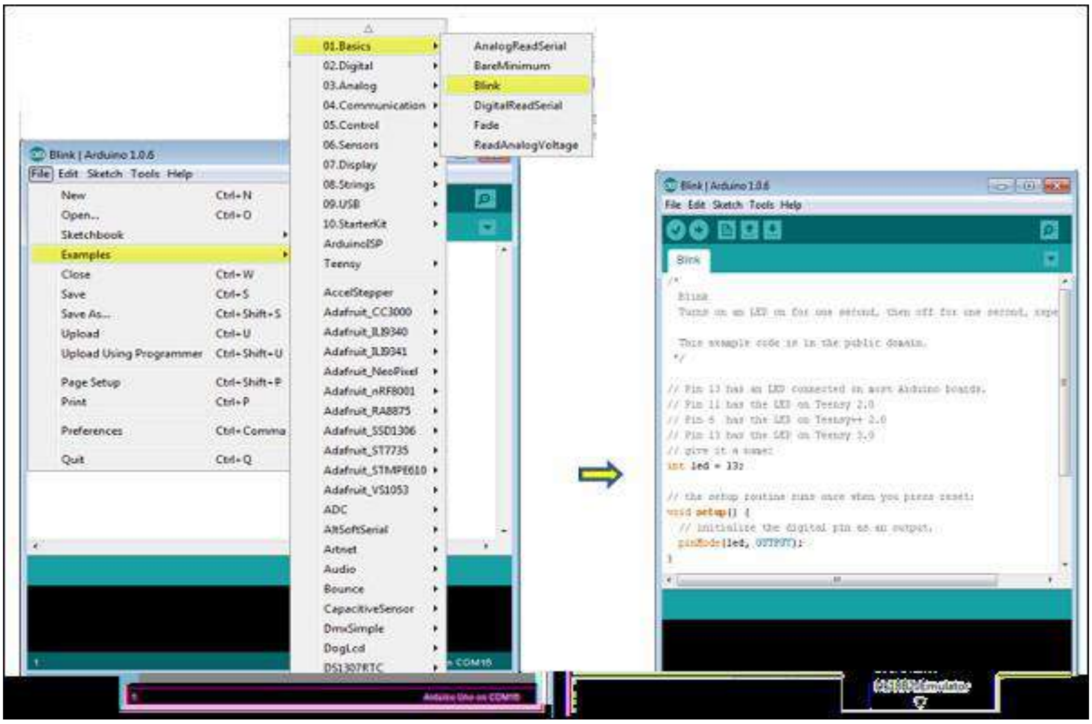

Fig. 3.2.6.4.6 Open your first program.

Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 − Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

Go to Tools → Board and select your board.

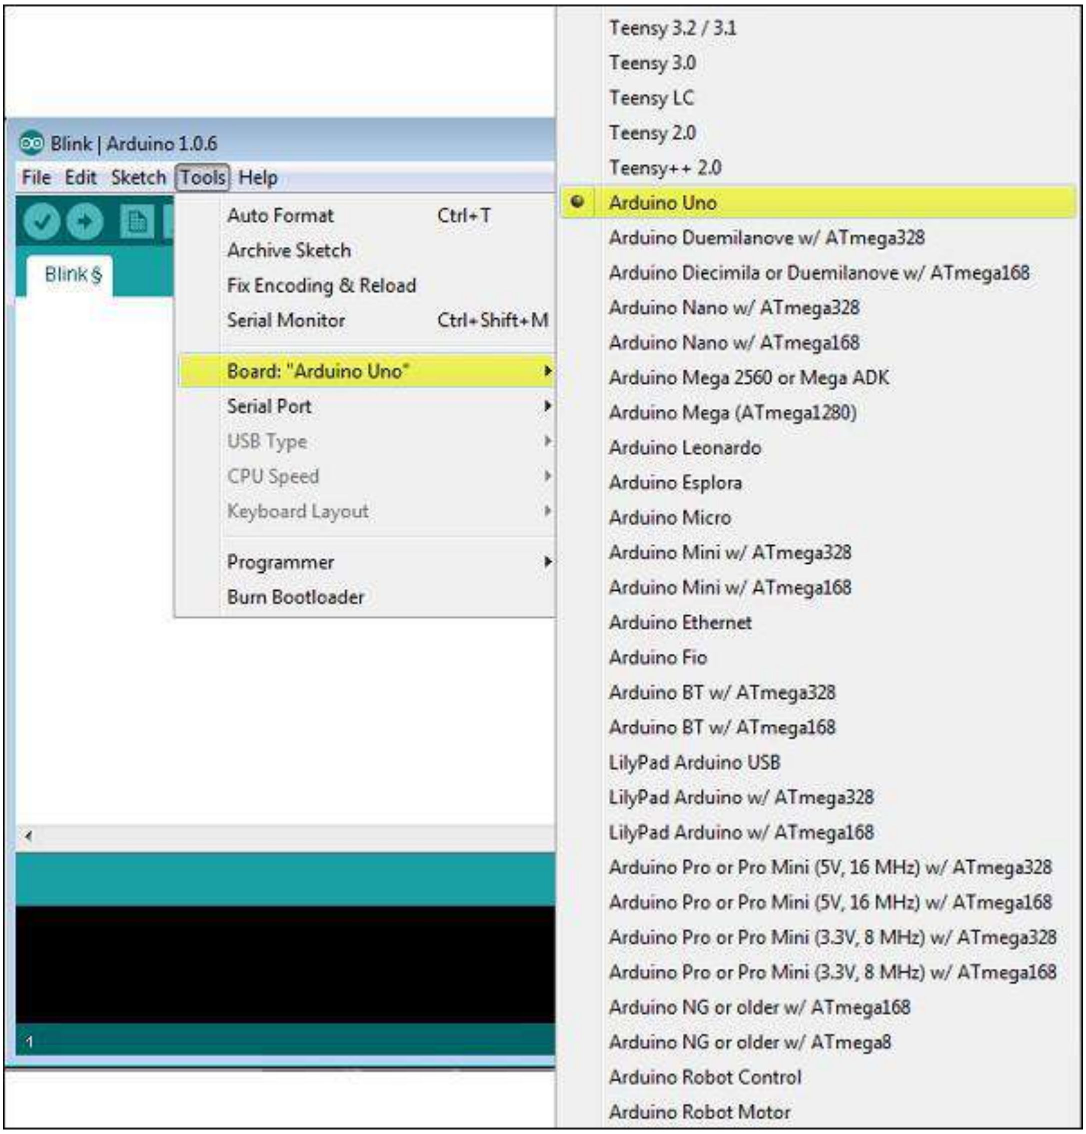

Fig. 3.2.6.4.7 Select your Arduino board.

Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

Step 7 − Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.

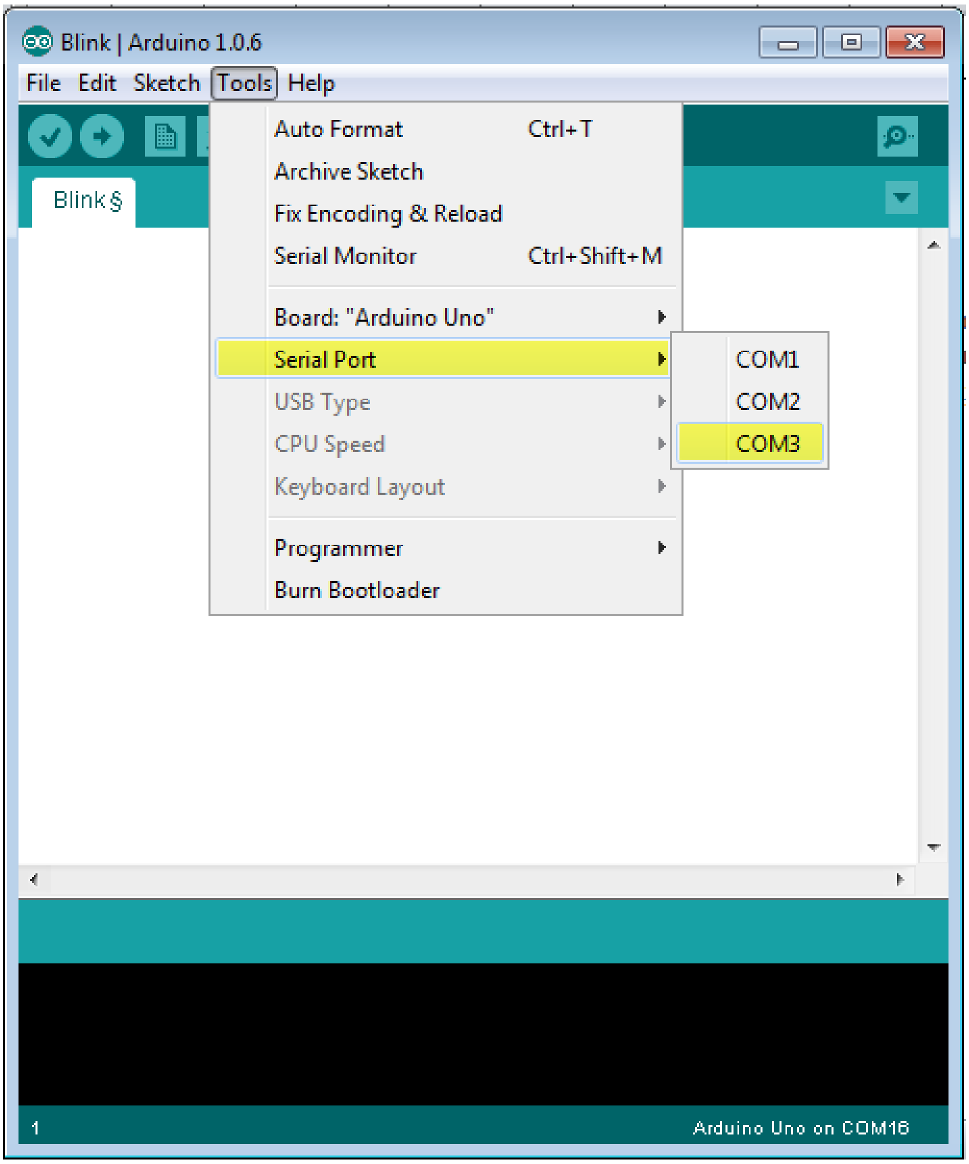

Fig. 3.2.6.4.8 Select your serial port.

Step 8 − Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.

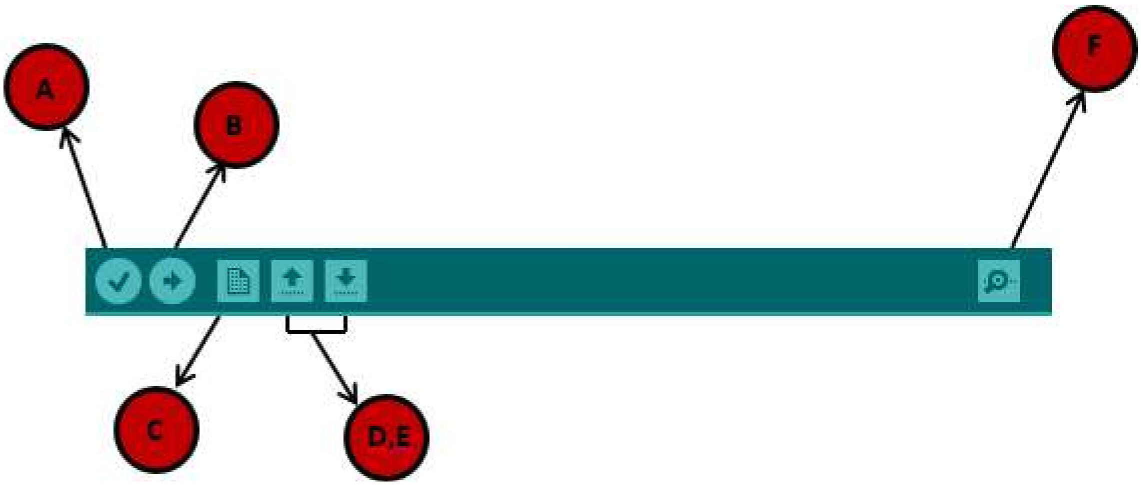

Fig. 3.2.6.4.9 Upload the program to your board

A − Used to check if there is any compilation error.

B − Used to upload a program to the Arduino board.

C − Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from board & send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

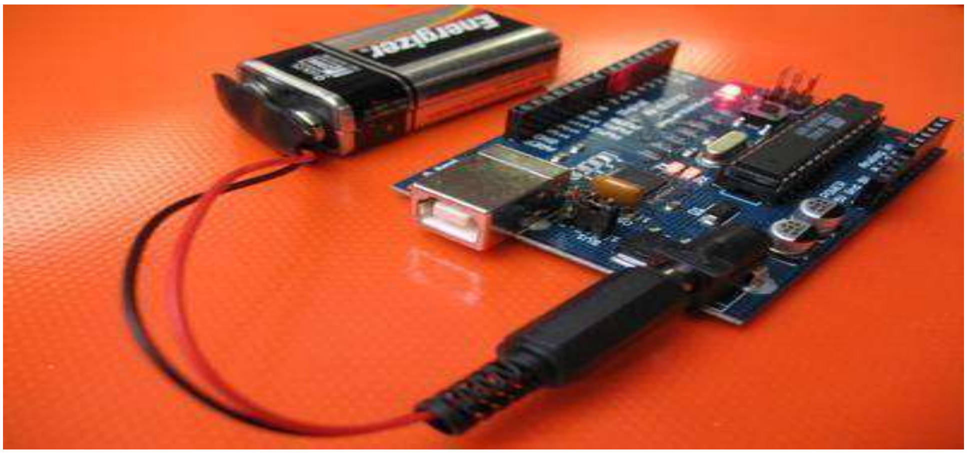

Fig. 3.2.6.4.10 Connecting a Battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called "sketches", but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
 {
   Serial.begin(9600);
   Serial.println("Hello World");
 }
void loop() {}
```

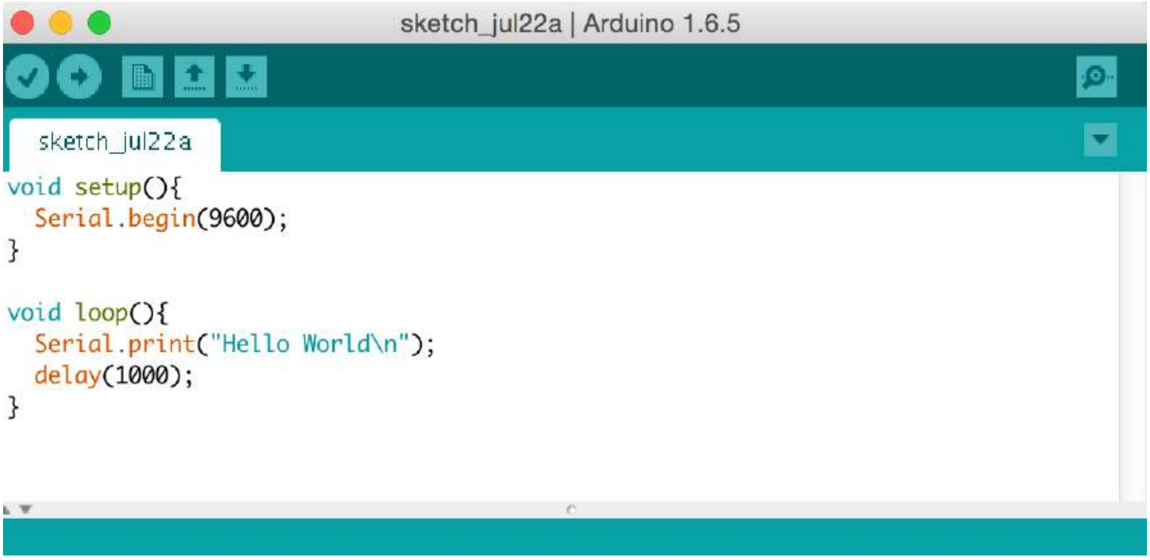

Fig. 3.2.6.4.11 Example Program

3.2.7 PROTEUS:

PROTEUS:

Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline "From concept to completion".

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation. ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components. The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semi-conductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole

packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design:

Step 1: Open ISIS software and select New design in File menu

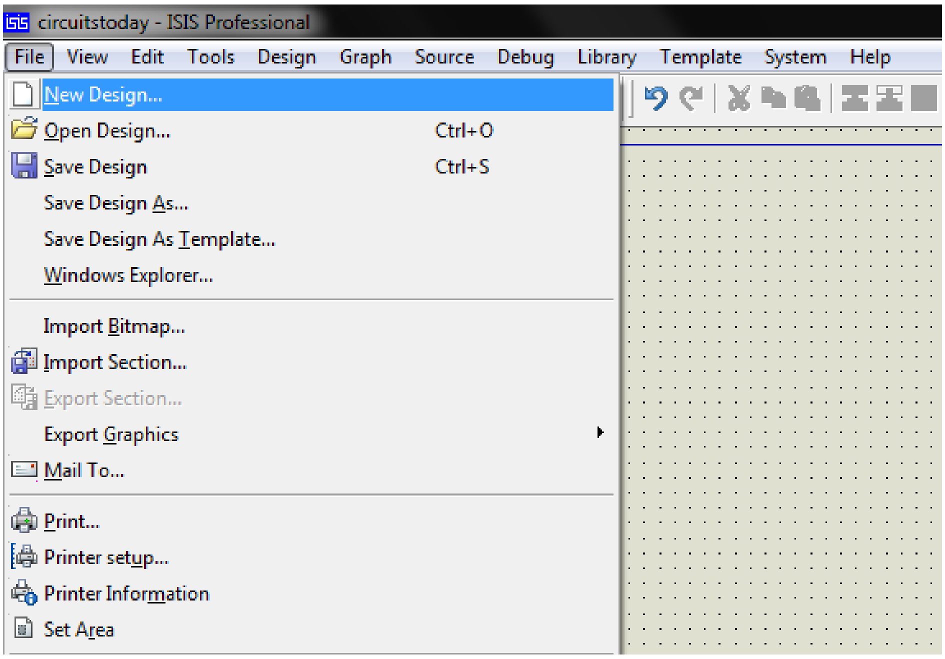

Fig. 3.2.7.1 Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

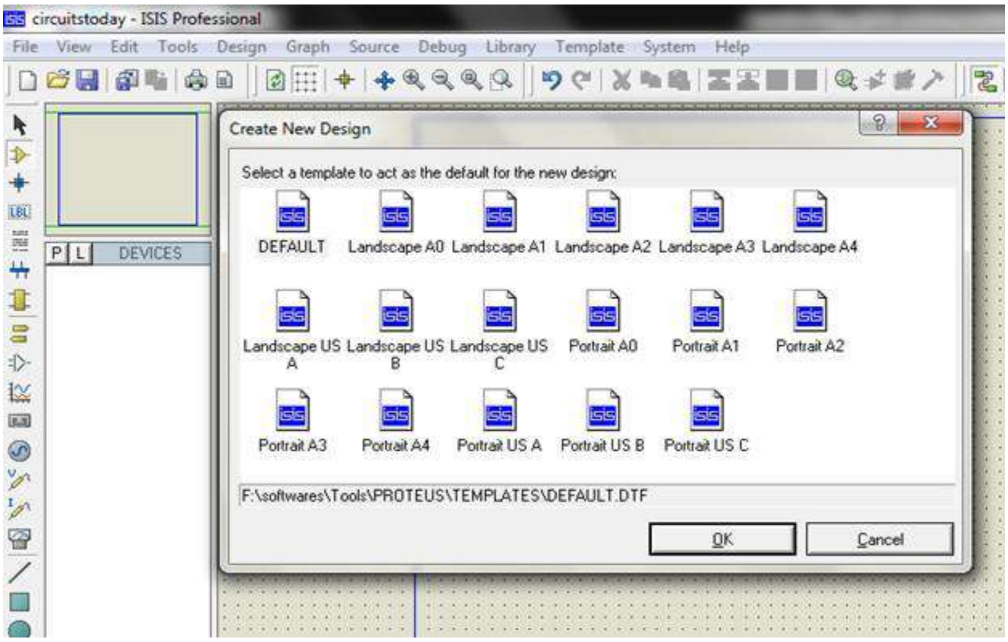

Fig. 3.2.7.2 Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

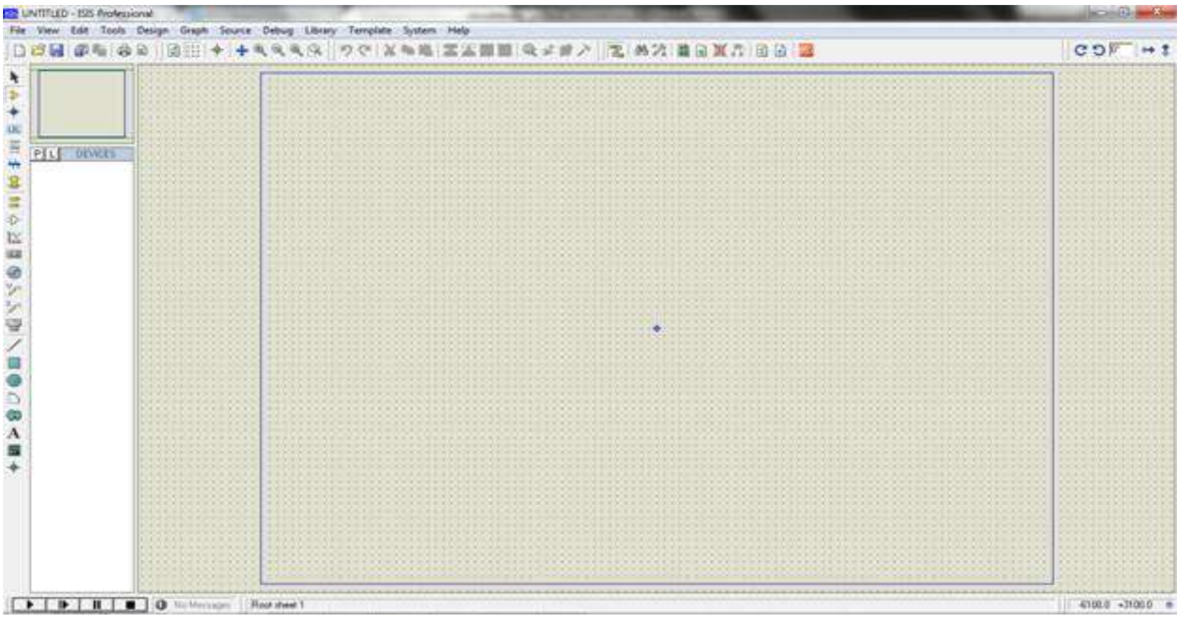

Fig. 3.2.7.3 Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

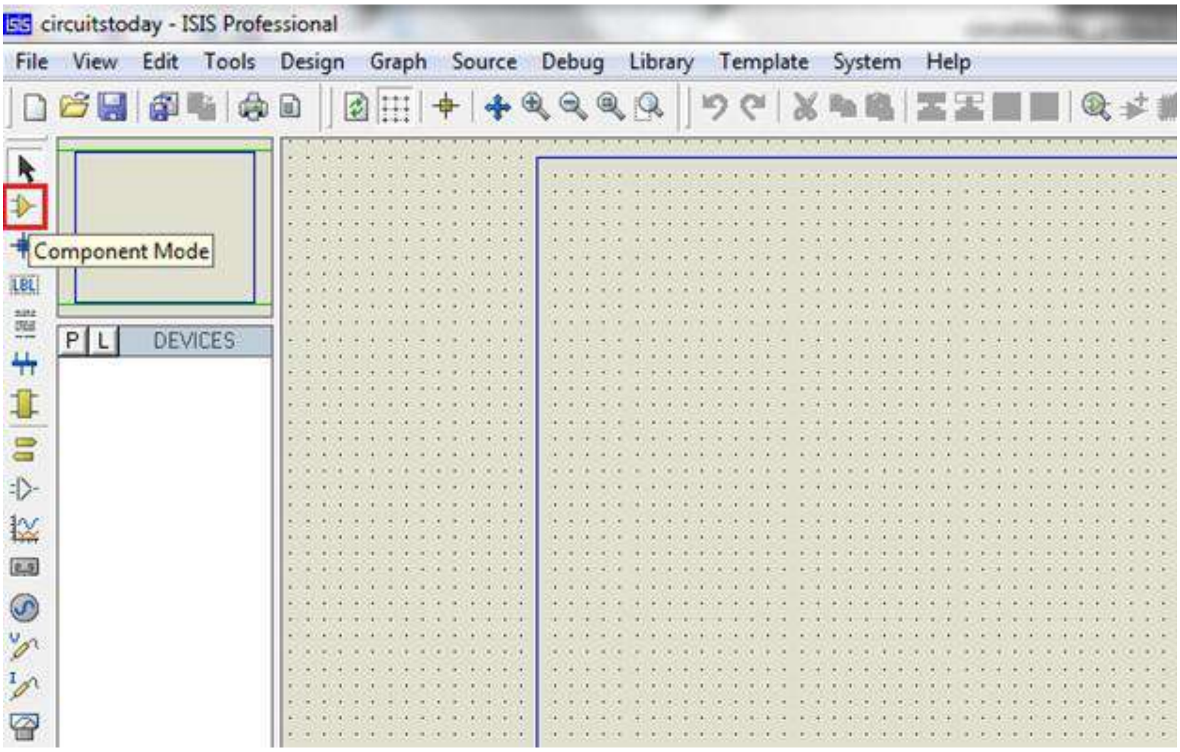

Fig. 3.2.7.4 Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

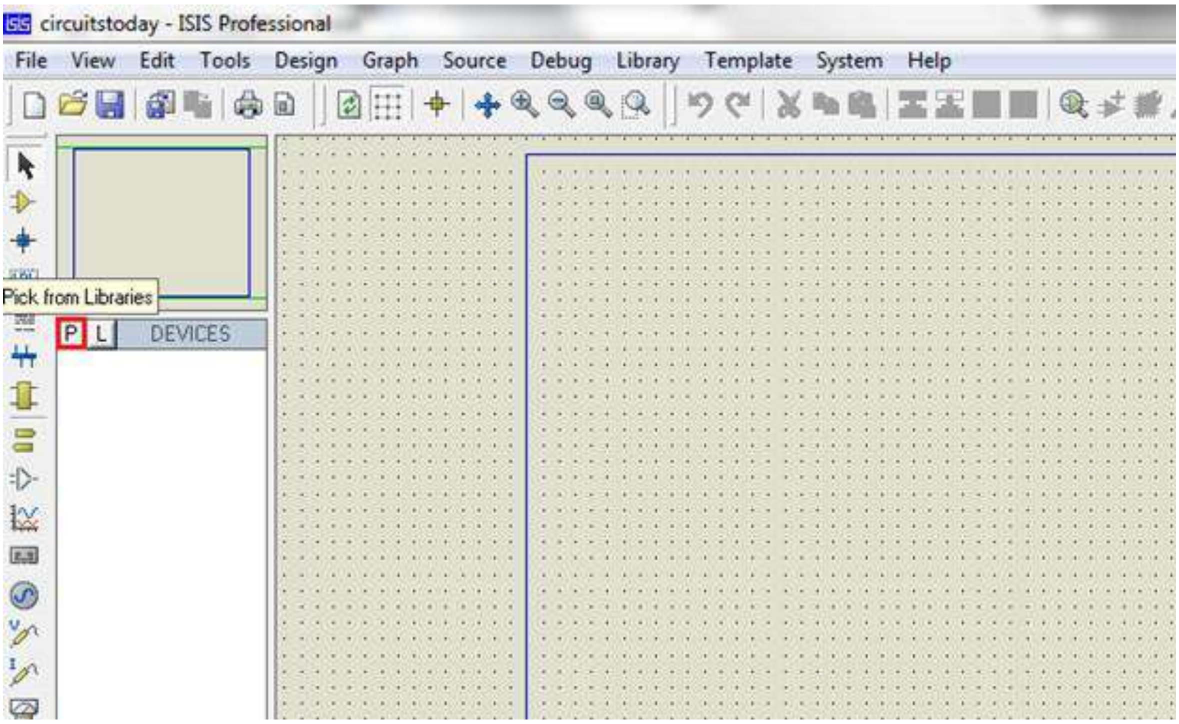

Fig. 3.2.7.5 Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

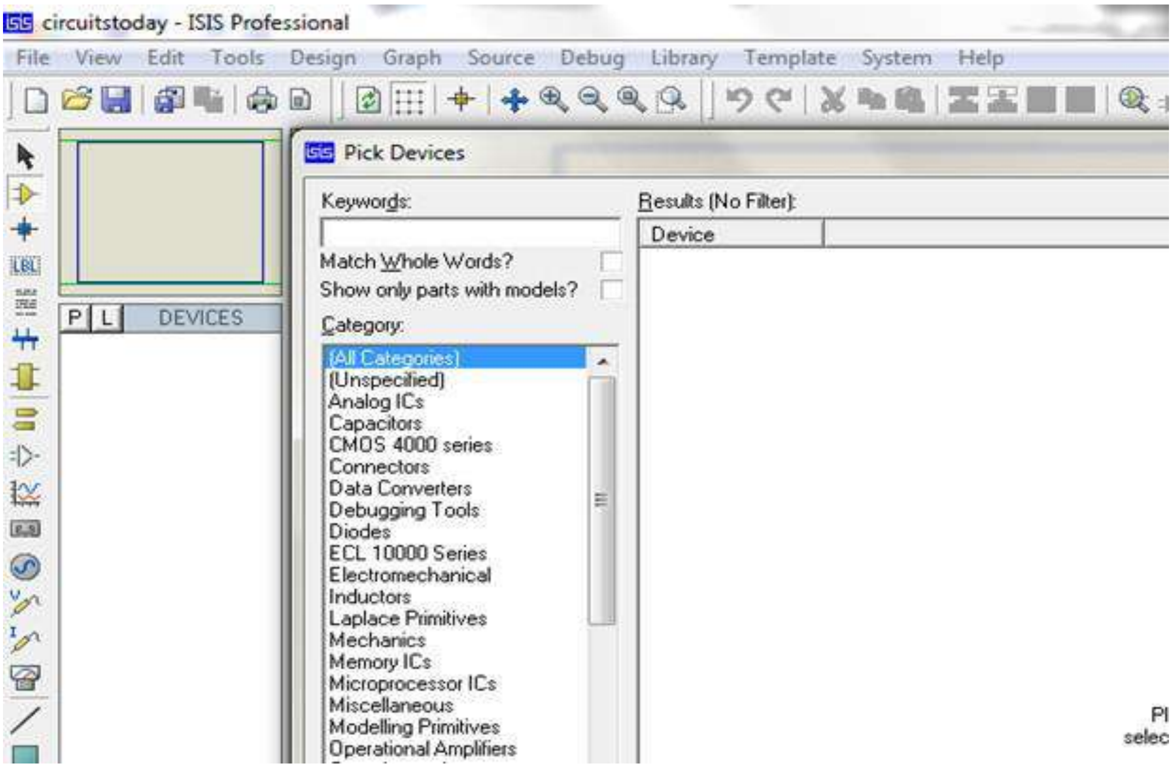

Fig. 3.2.7.6 Keywords Textbox

Example shows selection of push button. Select the components accordingly.

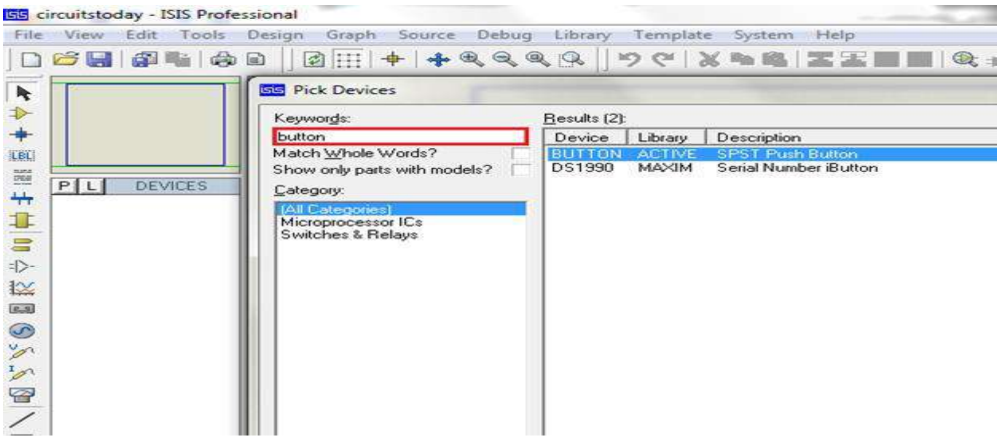

Fig. 3.2.7.7 Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

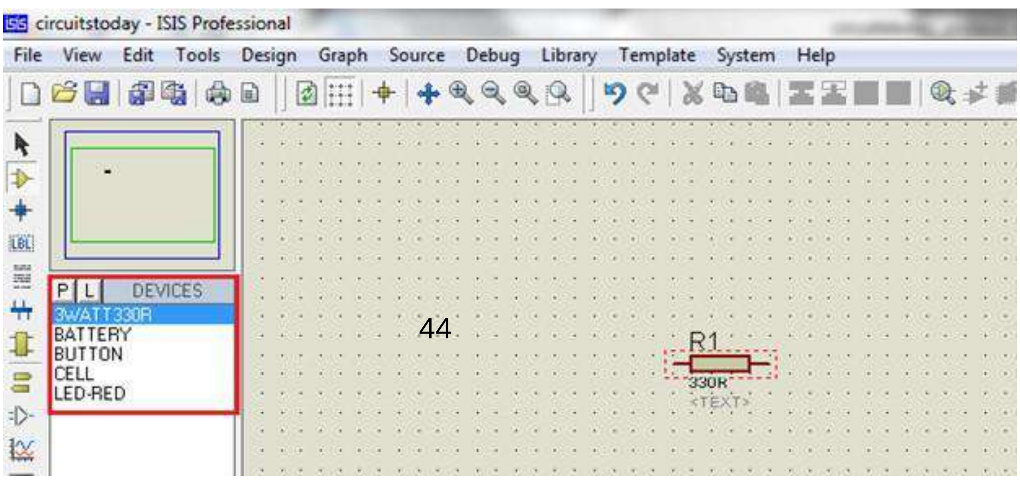

Fig. 3.2.7.8 Component Selection

Place all the required components and route the wires i.e., make connections. Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

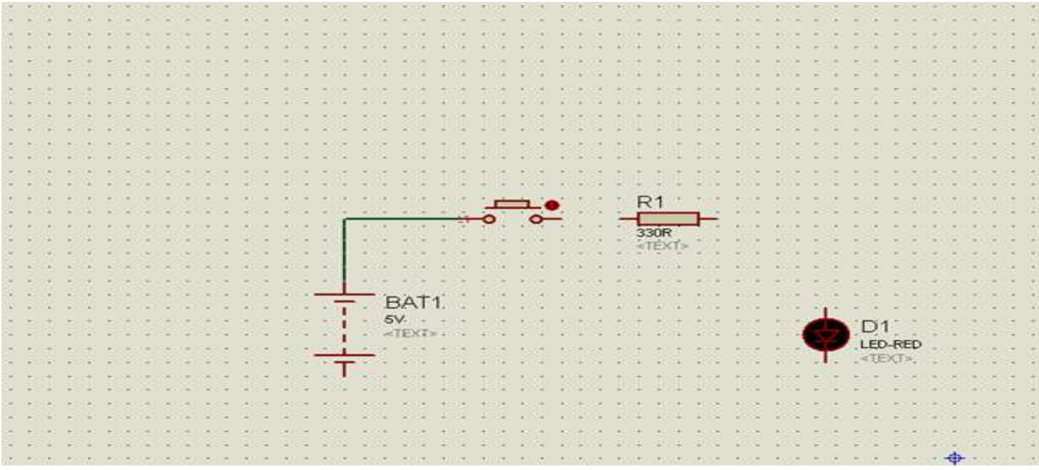

Fig. 3.2.7.9 Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

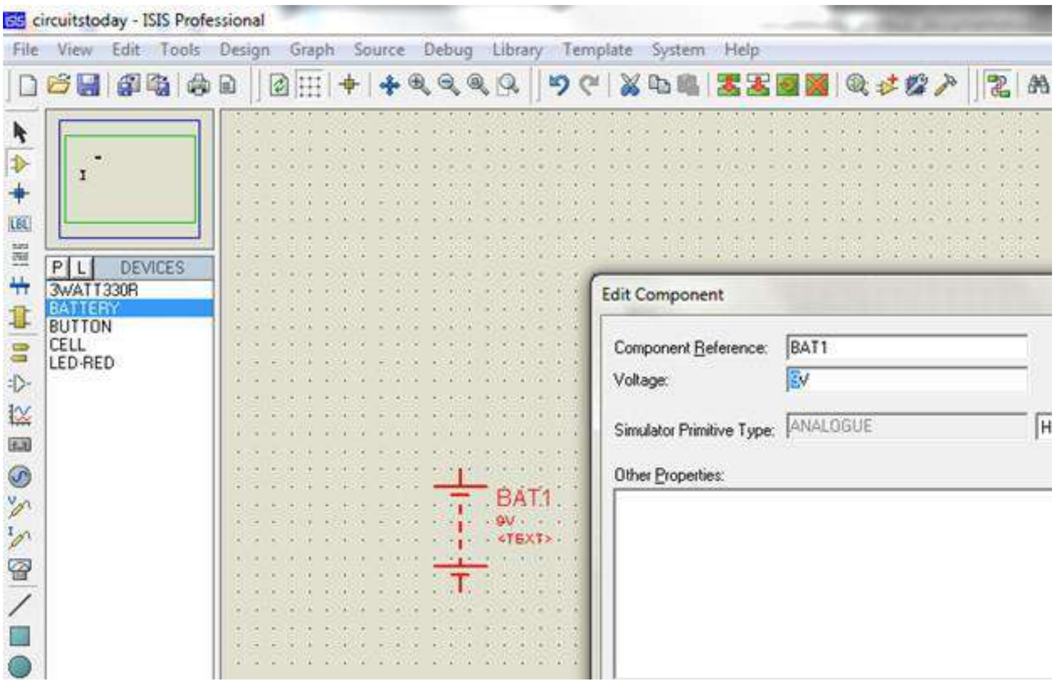

Fig. 3.2.7.10 Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

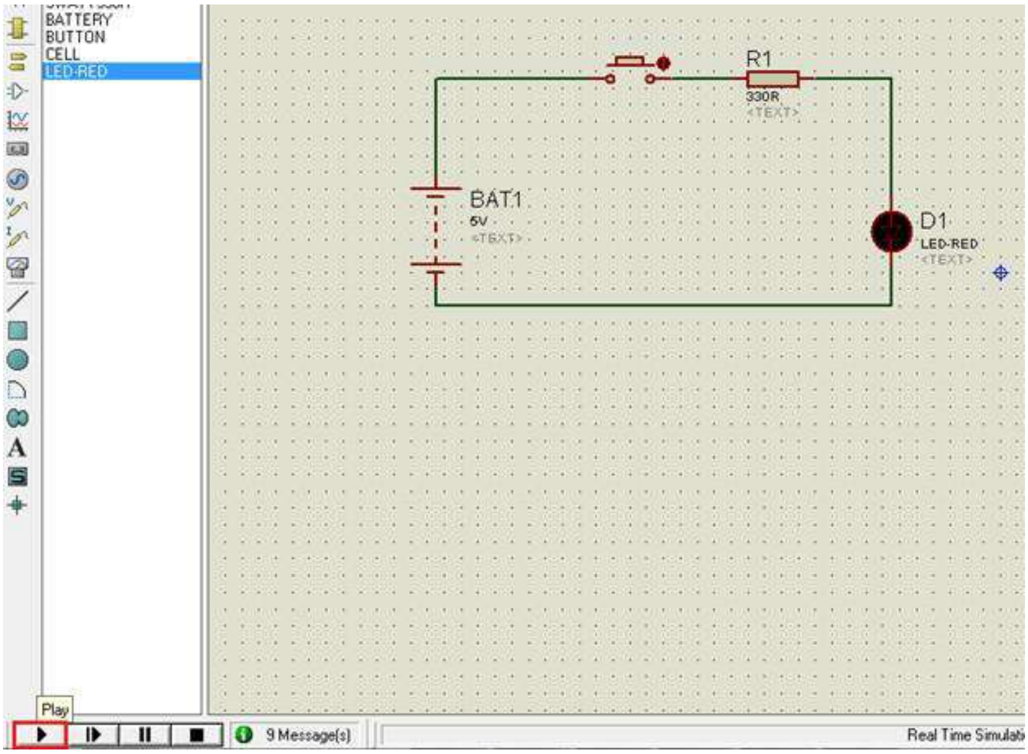

Fig. 3.2.7.11 Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

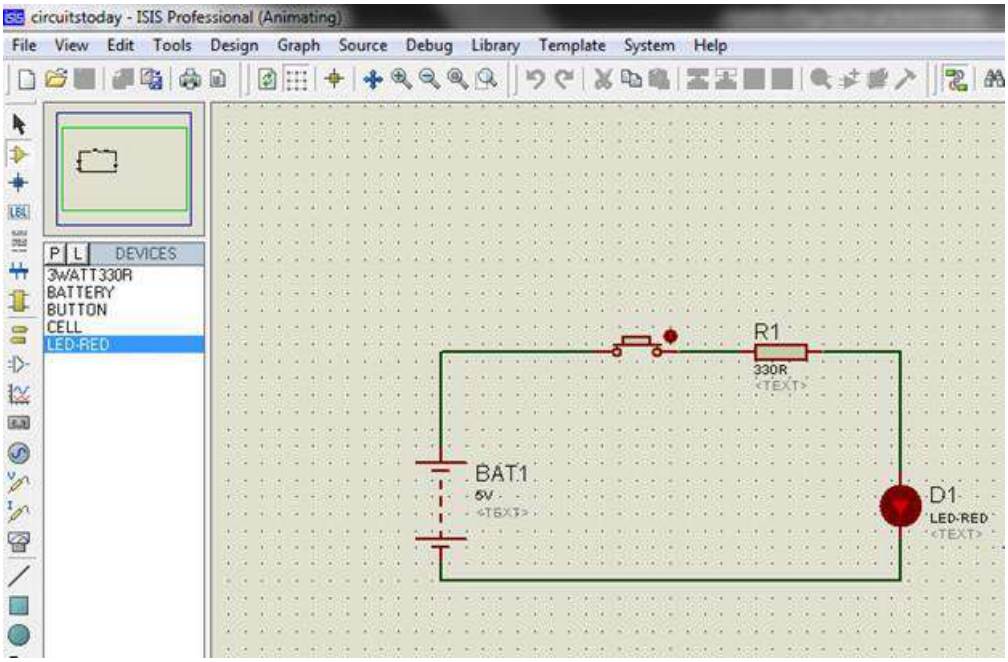

Fig . 3.2.7.12 Simulation Animating

Simulation can be stepped, paused or stopped at any time.

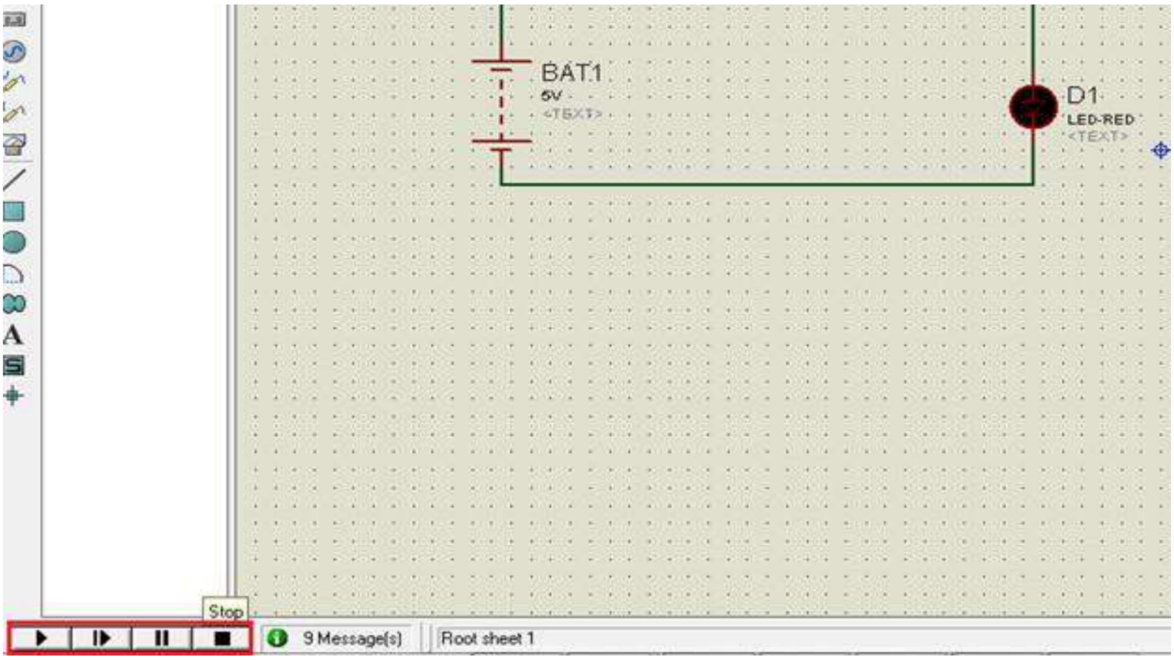

Fig. 3.2.7.13 Simulation Step-Pause-Stop Buttons

According to its developers, Things Speak is an open-source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP and MQTT protocol over the Internet or via a Local Area Network. Things Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

Things Speak was originally launched by iot Bridge in 2010 as a service in support of IoT applications.

Things Speak has integrated support from the numerical computing software MATLAB from MathWorks, allowing Things Speak users to analyse and visualize uploaded data using MATLAB without requiring the purchase of a MATLAB license from Math works.[citation needed].

Things Speak has a close relationship with Math works, Inc. In fact, all of the Things Speak documentation is incorporated into the Math works' Matlab documentation site and even enabling registered Math works user accounts as valid login credentials on the Things Speak website. The terms of service and privacy policy of ThingSpeak.com are between the agreeing user and Math works, Inc.

Setup Things Speak

Create a free MathWorks account or sign into Things Speak using an existing account.

Select the Things Speak channel you want your data to stream into. See Collect Data in a New Channel for help creating a new channel.

Record the following for the selected channel:

Channel ID, which is listed at the top of the channel view.

Write API key, which can be found on the API Keys tab of your channel view.

3.2.8 TELNET MOBILE APP:

Telnet is a client-server protocol, based on a reliable connection-oriented transport. Typically, this protocol is used to establish a connection to Transmission Control Protocol (TCP) port number 23, where a Telnet server application (telnetd) is listening. Telnet, however, predates TCP/IP and was originally run over Network Control Program (NCP) protocols.

Even though Telnet was an ad hoc protocol with no official definition until March 5, 1973,[3] the name actually referred to *Teletype Over Network Protocol* as the RFC 206 (NIC 7176) on Telnet makes the connection clear:[4]

The TELNET protocol is based upon the notion of a virtual teletype, employing a 7-bit ASCII character set. The primary function of a User TELNET, then, is to provide the means by which its users can 'hit' all the keys on that virtual teletype.[5]

Essentially, it used an 8-bit channel to exchange 7-bit ASCII data. Any byte with the high bit set was a special Telnet character. On March 5, 1973, a Telnet protocol standard was defined at UCLA[6] with the publication of two NIC documents: Telnet Protocol Specification, NIC 15372, and Telnet Option Specifications, NIC 15373.

Many extensions were made for Telnet because of its negotiable options protocol architecture. Some of these extensions have been adopted as Internet standards, IETF documents STD 27 through STD 32. Some extensions have been widely implemented and others are proposed standards on the IETF standards track (see below) Telnet is best understood in the context of a user with a simple terminal using the local Telnet program (known as the client program) to run a logon session on a remote computer where the user's communications needs are handled by a Telnet server program.

When Telnet was initially developed in 1969, most users of networked computers were in the computer departments of academic institutions, or at large private and government research facilities. In this environment, security was not nearly as much a concern as it became after the bandwidth explosion of the 1990s. The rise in the number of people with access to the

Internet, and by extension the number of people attempting to hack other people's servers, made encrypted alternatives necessary.

3.3 DEFINE THE MODULES:

3.3.1 RFID (RADIO FREQUENCY IDENTIFICATION) MODULE

3.3.1.1 INTRODUCTION:

Radio Frequency Identification (RFID) technology has been attracting considerable attention with the expectation of improved supply chain visibility for both suppliers and retailers. It will also improve the consumer shopping experience by making it more likely that the products they want to purchase are available.

Recent announcements from some key retailers have brought the interest in RFID to the forefront. This guide is an attempt to familiarize the reader with RFID technology so that they can be asking the right questions when considering the technology.

3.3.1.2 WHAT IS RFID?

RFID (Radio Frequency Identification) is a method of identifying unique items using radio waves. Typical RFID systems are made up of 2 major components: readers and tags. The reader, sometimes called the interrogator, sends and receives RF data to and from the tag via antennas. A reader may have multiple antennas that are responsible for sending and receiving the radio waves. The tag, or transponder, is made up of the microchip that stores the data, an antenna, and a carrier to which the chip and antenna are mounted.

RFID technology is used today in many applications, including security and access control, transportation and supply chain tracking. It is a technology that works well for collecting multiple pieces of data on items for tracking and counting purposes in a cooperative environment.

3.3.1.3 THREE PRIMARY FREQUENCY BANDS HAVE BEEN ALLOCATED FOR RFID USE.

Low Frequency (125/134 KHz):

Most commonly used for access control and asset tracking.

Mid-Frequency (13.56 MHz):

Used where medium data rate and read ranges are required.

Ultra-High-Frequency (850 MHz to 950 MHz and 2.4 GHz to 2.5 GHz): offer the longest read ranges and high reading speeds.

Applications for RFID within the supply chain can be found at multiple frequencies and different RFID solutions may be required to meet the varying needs of the marketplace. Many of today's RFID technologies cannot reliably cover areas wider than 4 to 5 feet, making them unsuitable for wide openings that are the norm in manufacturing, distribution and stor receiving dock environments. Since UHF (Ultra High Frequency) can cover portals up to 9 feet
wide it is gaining industry support as the choice bandwidth for inventory tracking applications including pallets and cases.
Technology providers are developing readers that work with multiple system protocols and frequencies so that users will be able to choose the RFID products that work best for their market and products.

3.3.1.4 RFID TAGS ARE FURTHER BROKEN DOWN INTO TWO CATEGORIES:

Active RFID Tags are battery powered. They broadcast a signal to the reader and can transmit over the greatest Distances (100+ feet). Typically, they can cost \$4.00 - \$20.00 or more and are used to track high value goods like vehicles and large containers of goods. Shipboard containers are a good example of an active RFID tag application

Passive RFID Tags do not contain a battery. Instead, they draw their power from the reader. The reader transmits a low power radio signal through its antenna to the tag, which in turn receives it through its own antenna to power the integrated circuit (chip). The tag will briefly converse with the reader for verification and the exchange of data. As a result, passive tags can transmit information over shorter distances (typically 10 feet or less) than active tags. They have a smaller memory capacity and are considerably lower in cost (\$1.00 or less) making them ideal for tracking lower cost items

There are two basic types of chips available on RFID tags, Read-Only and **Read-Write**. Read only chips are programmed with unique information stored on them during the manufacturing process. The information on read-only chips can never be changed.

With Read-Write chips, the user can add information to the tag or write over existing information when the tag is within range of the reader. Read-Write chips are more expensive that Read Only chips. Another method used is something called a "WORM" chip (Write Once Read Many). It can be written once and then becomes "Read only" afterwards. This is a desirable format since companies will be able to write an EPC (electronic product code) to the tag when the product is produced and packaged.

3.3.1.5 HOW WILL RFID AFFECT OUR INDUSTRY?

RFID is expected to provide huge advantages to manufacturers by offering the tools to better plan production and respond more quickly to market demand. It will facilitate automation of inventory counts and speed shipping and receiving at the distribution level. For retailers, it will help to reduce stock-outs, enable product tracking and potentially reduce theft and streamline the POS function. RFID will also open other merchandising opportunities and help with the overall consumer buying experience.

Due to the current cost of the technology (both tags and infrastructure), the initial phase of adoption for retailers is at carton and pallet marking applications. The current technology being adopted for carton and pallet labelling is passive UHF tags (850 MHz – 950 MHz). As the cost of tags and readers comes down, a wider adoption at the item marking level will develop.

In order for RFID to grow quickly, it is important that standards be developed so that the technology providers are working toward a common goal of providing low cost and compatible technologies. Not only will it drive down costs, but standards will also help users to reap the greatest benefit from their investment by providing value throughout the whole supply chain.

3.3.1.6 ORGANIZATIONS FOCUSED ON DEVELOPING RFID STANDARDS:

EPC global, Inc., a division of the Uniform Code Council, and its sponsors are working to standardize a new Electronic Product Code (EPC) as the next standard for identifying products. Their goal is not to replace existing bar code standards but to expand the information available down to unique identifiers for each marked item, and to enable more automatic reading. EPC utilizes the basic structure of the Global Trade Item Number (GTIN).

EPC global, Inc. has proposed open standards for tags and readers with the intention of bringing the costs down to a level where RFID tags could be applied to individual items. The work may lead to the creation of a new global Internet network that would allow companies to track items and enable end users to access the full benefits of RFID.

EPC global, Inc. has developed a specification for RFID tags to be used in the retail sector. The specification does not mandate what type of tag to be used but is intended to provide guidelines on data structure and how the tags should perform so that they can be used over a common platform.The specification requires that the chip contain an Electronic Product Code (EPC). The chip must be able to communicate according to an open standard and meet some minimum requirements so that it can be read by reading devices anywhere.

3.3.1.7 THE ELECTRONIC PRODUCT CODE (EPC):

The EPC is a number made up of a header and 3 sets of data as shown in the figure below. The header identifies the EPC version number – which will allow for different lengths or types of EPC later on. The second part of the number identifies the EPC manager – typically this would be the manufacturer of the item the EPC is attached to. The third part is called object class and refers to the exact type of product– most often the stock-keeping unit (SKU). The fourth series of numbers is the serial number that is unique to the item. (The second and third sets of data are similar in function to the numbers in UPC barcodes.)

ELECTRONIC PRODUCT CODE TYPE 1			
01.0000A89.00016F.000169DCO			
Header	EPC Manager	Object Class	Serial Number
8-bits	28-bits	24-bits	36-bits

Table 3.3.1.7 The Electronic Product Code (EPC)

Above is an example of a 96-bit EPC. It will allow sufficient capacity for 268 million companies. Each manufacturer will have the ability to create up to 16 million object classes with 68 billion serial numbers in each class. This should provide sufficient capacity to cover all products manufactured in the world for many years to come. As an interim step, the Auto-ID center is also proposing a 64-bit tag in order to minimize cost in the near term.

Potential Issues That Need Consideration When Choosing the Type of RFID and

Method for Application to Your Products or Packaging.

Enthusiasm within the RFID industry has resulted in much hype about the technology over the past several years. As a result, it is important to embrace the technology with a bit of caution. The following are some of the issues that require close scrutiny when investigating RFID:

Tag Cost – This should not to be confused with chip cost. Although the goal is to bring the cost of the tag (chip and antenna) down to 5 cents, this goal is in the future since it both assumes manufacturing breakthroughs and is predicated on consumption in the billions of tags per year. Today, the cost is closer to "less than 50 cents" for a read/write solution in high (millions) volume. Ultimate tag cost will also be very much dependent on the type of chip required (read only versus read/write), size of the antenna needed and how it is packaged to meet a specific application.

Tag Size – Tag size is dependent on the read range desired. Although the chips are very tiny, they will not operate without being mounted to an antenna. The size of the antenna will determine the read distance performance of the tag so understanding the size of the antenna needed for the application is more important than the size of the chip alone.

Infrastructure Cost – Much focus appears to be placed on the tag cost since it is a recurring expenditure. Reader cost and infrastructure costs for implementing RFID must also be looked at very closely as well. Both the software systems requirements and physical environment, in which RFID is intended to be used, are critical to the ultimate performance of a system and may require changes to accommodate using it effectively. As an example, RFID chips cannot be read through metal objects. Other forms of electromagnetic interference may also impede performance of he technology and require changes to the physical environment where RFID will be used. The number and types of readers will also be a major expenditure depending on your application.

Read Distances – Read distances for RFID are very much dependent on the frequency chosen for the application. Tag orientation also affects the read range as the range diminishes as the tag is rotated from

being perpendicular to the path to the reader. Reading reliability is quite good when labels are alone in a reader field like cases on a conveyor line, but less certain when the labels are randomly oriented as with labelled cases on a skid. The antenna size (both on the tag and the readers) will also be a determining factor. Hand held readers are not capable of using as much power as stationary readers and as result provide shorter read distances.

Government Regulation – Governments around the world regulate the use of the frequency spectrum. Different countries have already assigned certain parts of the spectrum for other uses and as a result, there is virtually no part of the spectrum that is available everywhere in the world for use by RFID. This means that a RFID tag may not work in all countries. As an example if you choose the Ultra High Frequency (UHF) frequency that

Operates at 915MHz in the U.S. and you ship your product to Europe, they may not be able to be read it since Europe operates in the UHF spectrum at 869 MHz. This is an important consideration when operating in a global environment.

Anti-Collision – This is an important feature of RFID chips/readers since it will allow multiple tags to be read while grouped in one reader field. It is not available on all RFID tags but is an important feature if you are planning to use RFID for inventory counts, shipping and receiving where multiple tags need to be read at the same time.

Privacy Issues – Consumer groups have expressed concern over the potential (real or imagined) privacy invasion that might result with widespread RFID item marking. These groups are pushing for legislation that will require manufacturers to advise consumers that the products contain RFID devices and must provide a means so that the devices can be disabled at point of purchase. These issues are most prevalent at the item marking level and will have little impact on the implementation of carton and pallet labelling.

3.3.2 ESP8266 WIFI MODULE

3.3.2.1 INTRODUCTION

The **ESP8266 Wi-Fi Module** is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your **Wi-Fi** network. The **ESP8266** is capable of either hosting an application or offloading all Wi-Fi networking functions from another application processor.

3.3.2.2 CHARACTER CONFIGURATION:

- 2.4 GHz Wi-Fi (802.11 b/g/n, supporting WPA/WPA2),

- general-purpose input/output (16GPIO),
- Inter-Integrated Circuit (I²C) serial communication protocol,
- analog-to-digital conversion (10-bitADC)
- Serial Peripheral Interface (SPI) serial communication protocol,
- I²S (Inter-IC Sound) interfaces with DMA(Direct Memory Access) (sharing pins with GPIO),
- UART (on dedicated pins, plus a transmit-only UART can be enabled on GPIO2),and
- Pulse-width modulation (PWM).

3.3.2.3 APPLICATIONS:

- Smart Home Appliances
- Improved Home safety and security
- Home air quality and water quality monitoring
- Natural Language-based voice assistants.

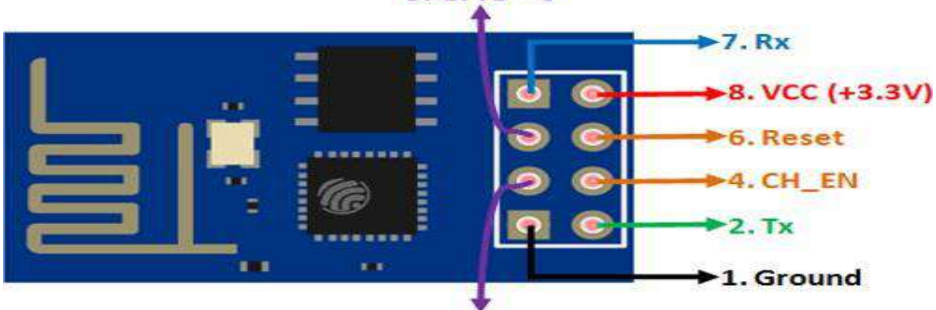

Fig.3.3.2.3 ESP8266 wifi module pin out

3.3.2.4 STRUCTURE AND CONFIGURATION:

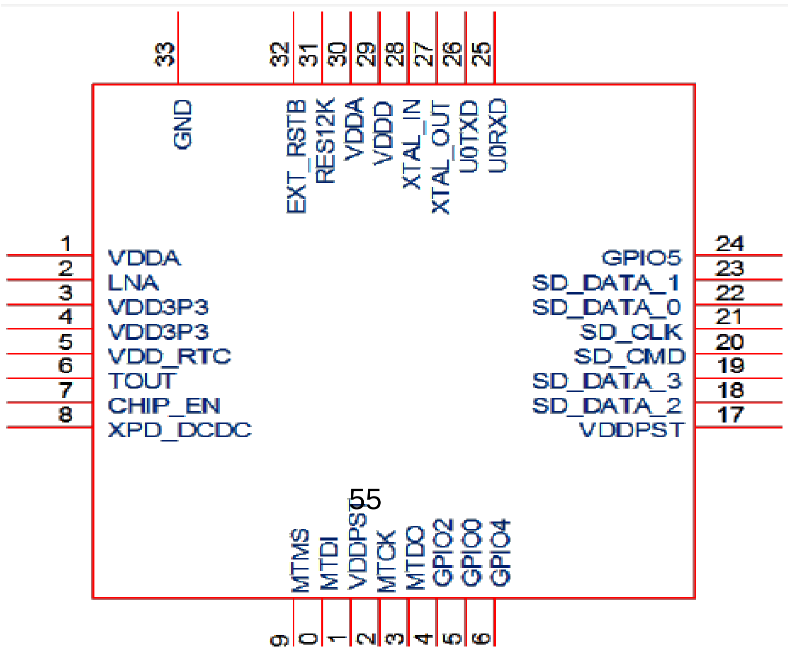

Fig.3.3.2.4 Structure and configuration

3.4 MODULE FUNCTIONALITIES:

3.4.1 RFID MODULE

3.4.1.1 Functionality of Radio Frequency Identification: The Transponder

The RFID transmitter is called a **transponder**, sometimes also a tag or simply a radio tag. It consists of an antenna (often a coil), a computer chip and a carrier material or housing. The chip is equipped with analog and digital circuits, and it also has a memory that can sometimes be written to several times. In some cases, the transponder is a semiconductor chip. Tags differ in several factors. Among other things, they have different sizes, lifetimes, clock frequencies, memory sizes or ranges.

The chips have a unique identity in the form of a **serial number** so that they can be clearly identified. The identity cannot be changed, which can prevent abuse. If it is a rewritable memory, the identity can be extended continuously and fully automatically by additional information (Auto-ID). In this respect, for example, previous locations of goods are interesting. RFID technology is also essential when it comes to choosing the right order picking procedure.

Tags usually do not have their **own energy supply**. In this case, the transponder is called passive. The reader delivers the necessary energy for data transmission to the tag. The antenna must be a coil that charges a capacitor by induction. Exceptions called active transponders have their own battery. Their use is worth it if the tag is to have a long range and various additional functions.

Transponders can be attached to or in the object to be marked. For example, they are stuck on (e.g. on pallets or cartons), embedded directly in objects (e.g. in screws, shoe soles, banknotes or documents) and even implanted in living beings (in pets behind the ear, in people's hands). Successful research and development have made it possible to use temperature-resistant transponders since 2006. Since then, they can even be cast in metals, which has various advantages: the risk of damage, wear and tear or loss is minimised and they are also invisible.

3.4.1.2 Functionality of Radio Frequency Identification: The Reader

A reader that must be in close range reads the tag's data using an alternating electromagnetic field or high-frequency radio waves. The receiver is also known as a **reader**. In addition to purely readout readers, there are also readers that can **write new information to the transponder's memory**. The transmitted radio waves are influenced by the tag because it reflects part of the energy. First, the unique identity and any other requested information are transmitted. In addition, different things can be stored.

The reader is a **combination of hardware and specially programmed software**. The **more range a reader should have, the more energy in the form of electrical current must be used for its use**. Typical ranges are between a few centimeters and a few meters. The smaller the range, the more precisely selected transponders can be addressed.

A longer range can be chosen, for example, if two objects should not be too close together. This is the case, for example, with containers containing flammable liquids and spark spraying equipment. Readers for radio frequency identification are available as handheld versions for manual operation, but can also take on various other forms, for example in the form of a gate through which goods flows.

3.4.2 ESP8266 WIFI MODULE

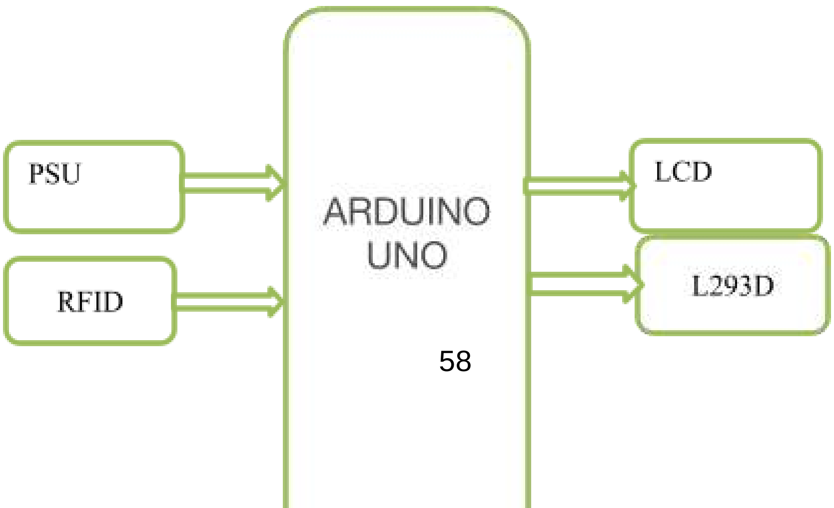
The ESP8266 WiFi Module is a self-contained SOC with integrated TCP/IP protocol stack that can give any microcontroller access to your WiFi network. The ESP8266 is capable of either hosting an application or offloading all WiFi networking functions from another application processor. Each ESP8266 module comes pre-programmed with an AT command set firmware, meaning, you can simply hook this up to your Arduino device and get about as much WiFi-ability as a WiFi Shield offers (and that's just out of the box)! The ESP8266 module is an extremely cost effective board with a huge, and ever growing, community.

This module has a powerful enough on-board processing and storage capability that allows it to be integrated with the sensors and other application specific devices through its GPIOs with minimal development up-front and minimal loading during runtime. Its high degree of on-chip integration allows for minimal external circuitry, including the front-end module, is designed to occupy minimal PCB area. The ESP8266 supports APSD for VoIP applications and Bluetooth co-existance interfaces, it contains a self-calibrated RF allowing it to work under all operating conditions, and requires no external RF parts.

There is an almost limitless fountain of information available for the ESP8266, all of which has been provided by amazing community support. In the Documents section below you will find many resources to aid you in using the ESP8266, even instructions on how to transform this module into an IoT (Internet of Things) solution!

CHAPTER-4
PROJECT IMPLEMENTATION

4.1 BLOCK DIAGRAM OF PROJECT:



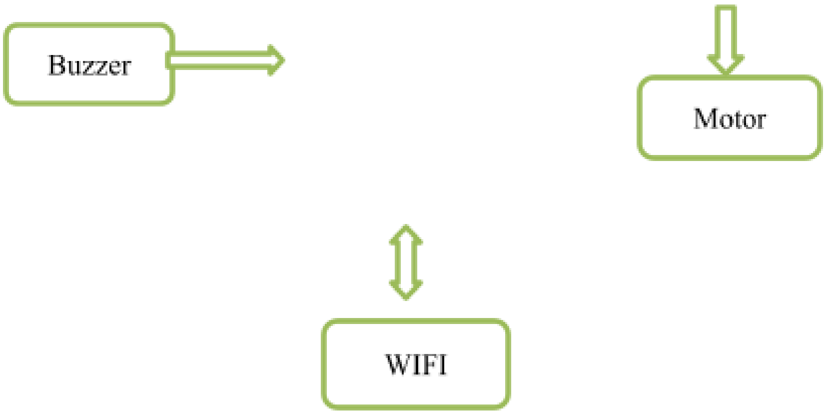


Fig.4.1: Block diagram of the project

4.2 FLOW CHART

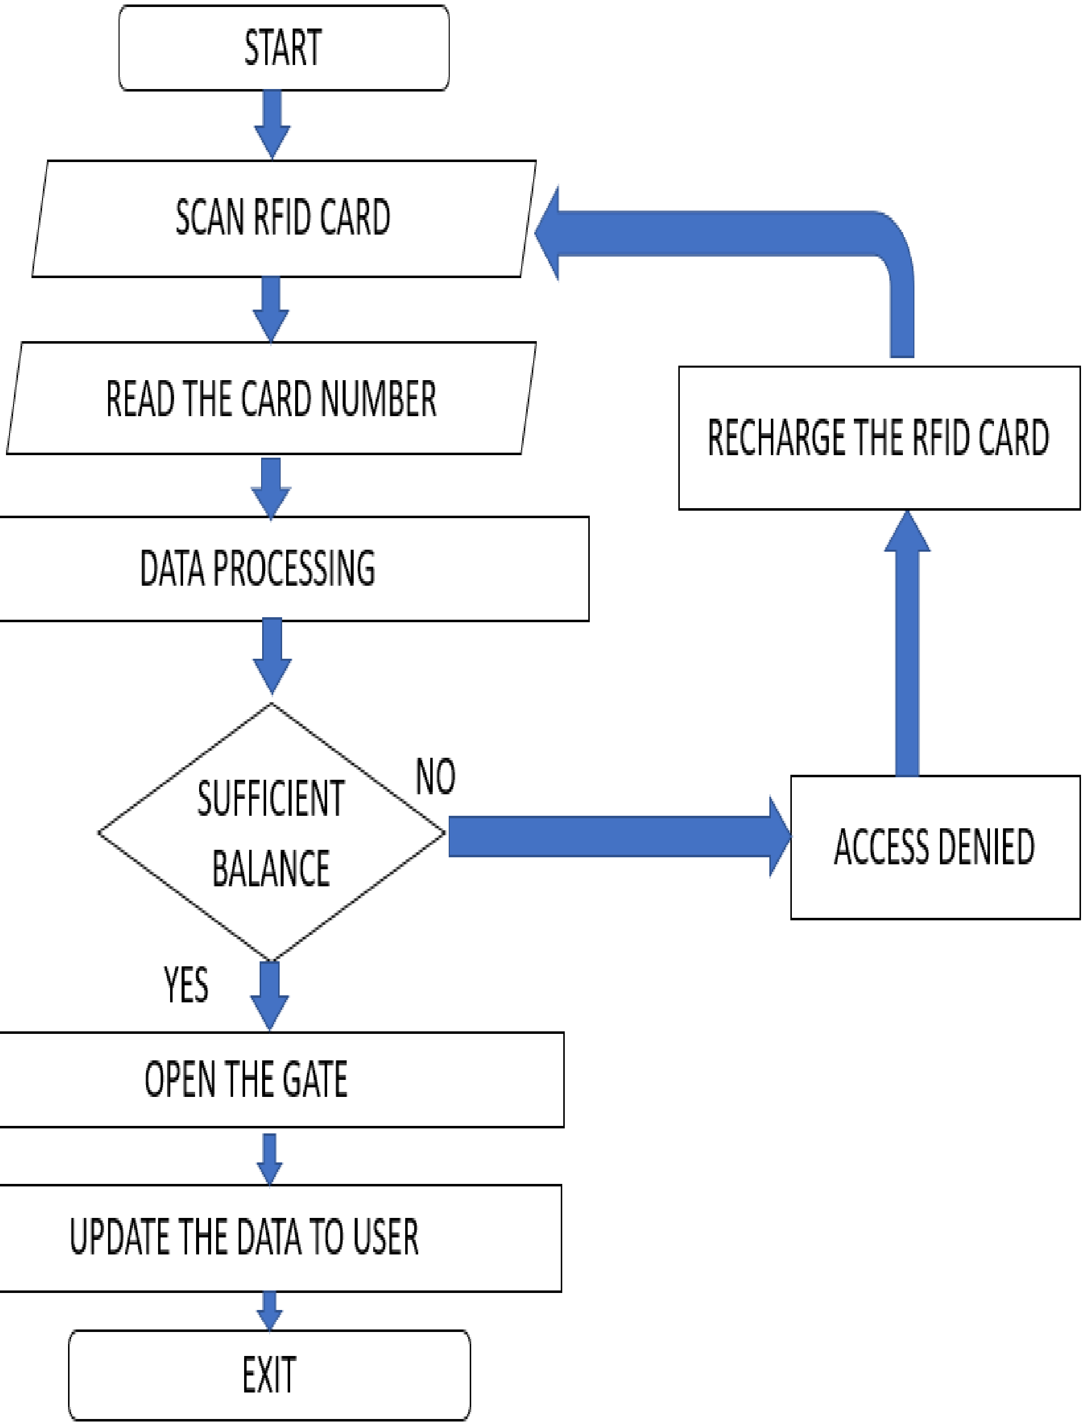

Fig.4.2 Flow Chart

4.3 IMPLEMENTATION STAGES

Stage-1: First on lcd we will get a message displaying waiting for link that indicates the wifi is not yet connected.

Fig.4.3.1 WAITING FOR LINK

Stage-2: In Mobile Telnet App, we will get a message like welcome when the wifi is connected to ESP8266 WIFI Module.

Fig.4.3.2 WELCOME

Stage-3: After the wifi is connected,we will get a message on LCD displaying Please Scan UR Card.

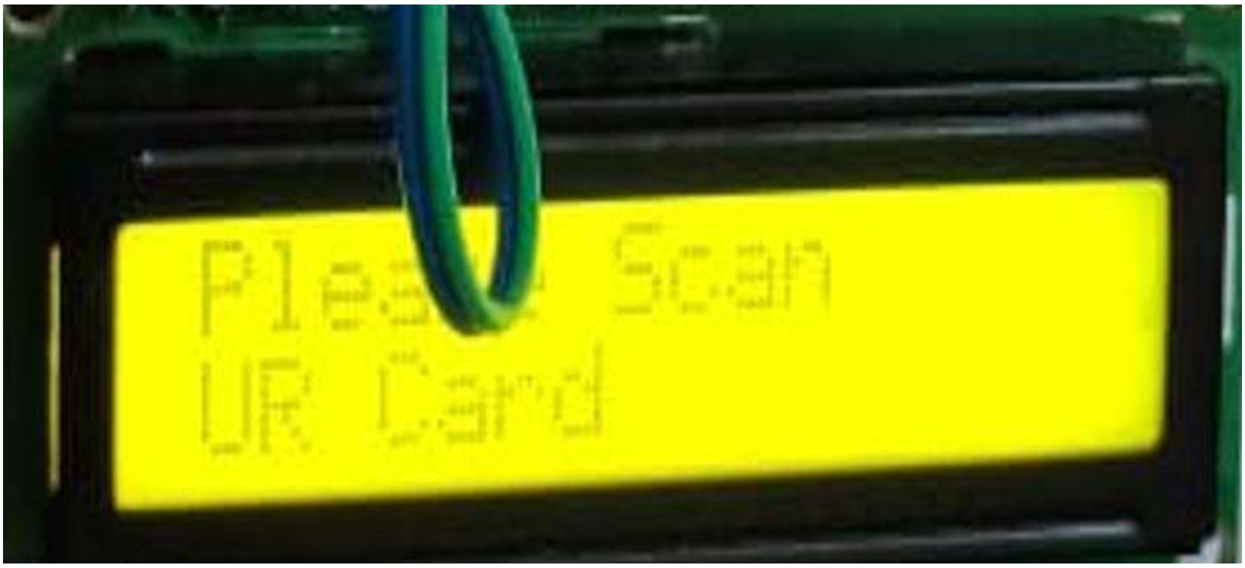

Fig.4.3.3 Please Scan UR Card

Stage-4: When we scan the card, if sufficient amount is available, we will get a message access granted for person and remaining balance will be displayed on LCD.

Fig.4.3.4 Access Granted

Stage-5: When we scan the card, if sufficient amount is not available, we will get a message access denied for person and balance will be displayed on LCD.

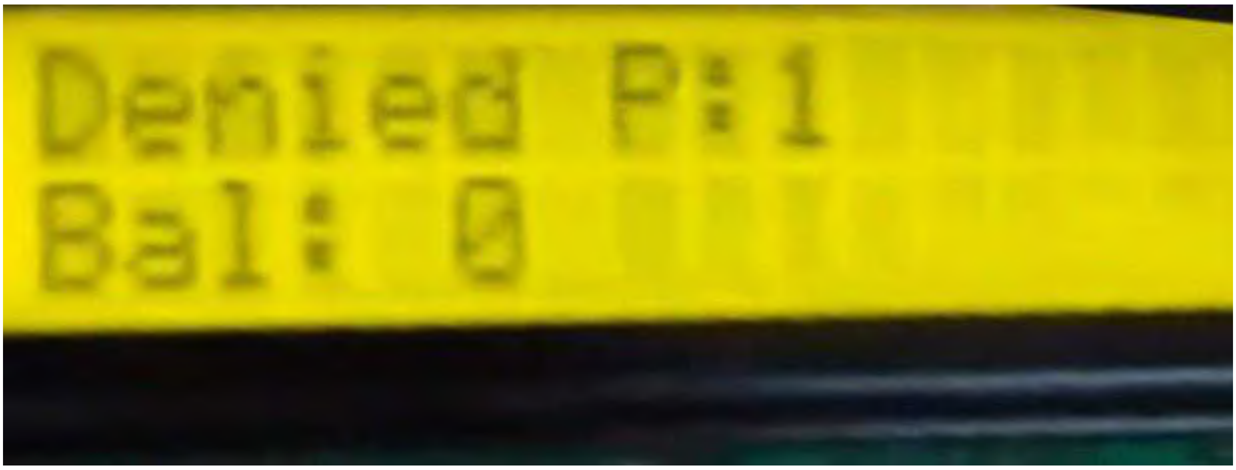

Fig.4.3.5 Access Denied

Stage-6: When card is recharged, amount will be added to card and display’s person recharge done on LCD Screen.

Fig.4.3.6 Recharge Done

4.5 RESULTS

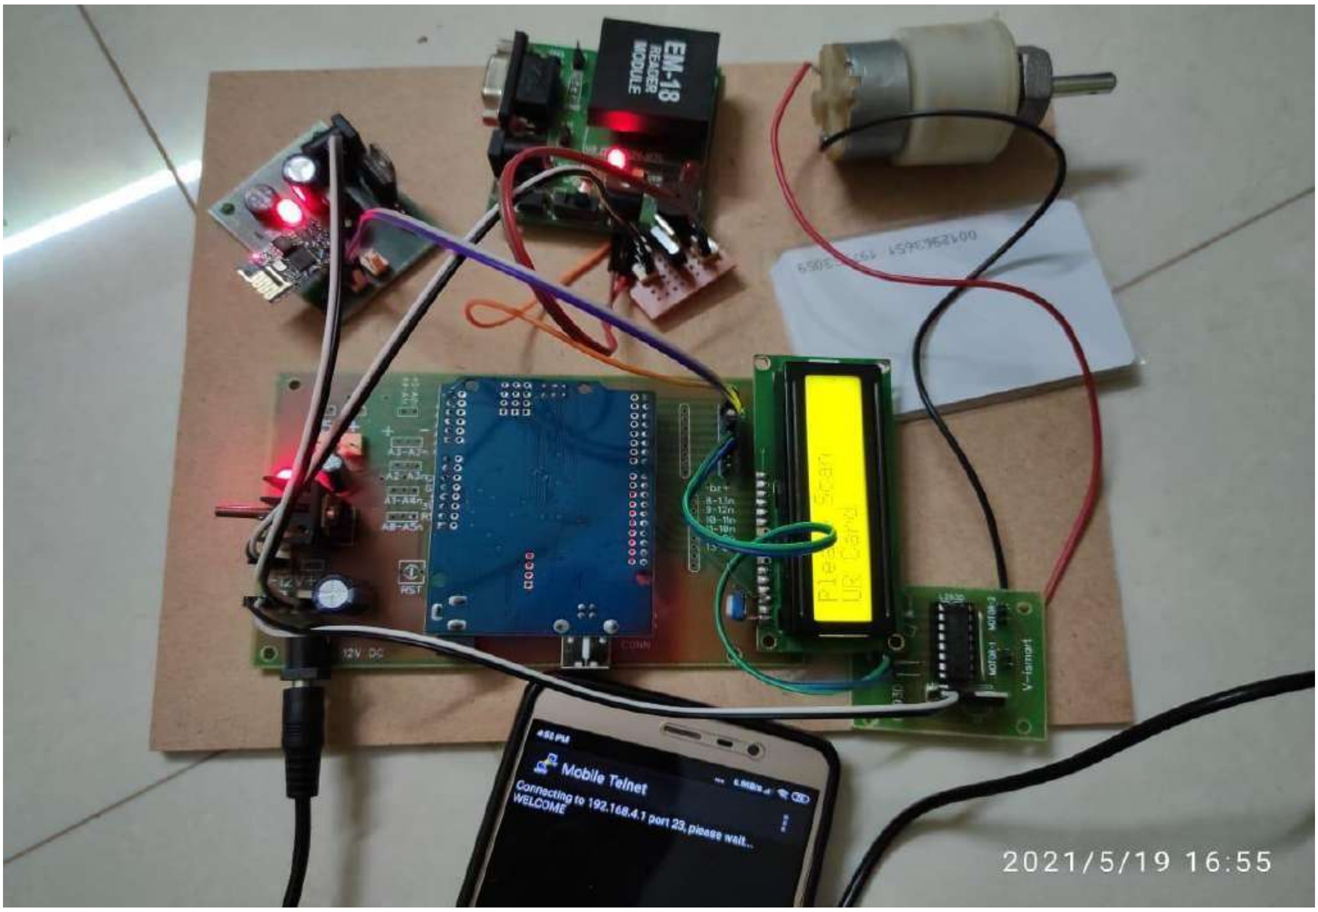

Fig.4.5 Final Output

CHAPTER-5
PROJECT TESTING

5.1 OVERVIEW OF TESTING METHODS

Today, governments want to take these ETC solutions one step further, with more sophisticated systems that not only eliminate the need for toll booths, but also enable governments to charge for road usage based on a variety of factors, including time of day, vehicle weight, distance driven, type of road and the pollution produced by the vehicle. These new systems enable governments to implement programs that charge tolls that better reflect the vehicle's impact on road infrastructure, traffic and the environment, helping them:

- Reduce congestion during peak periods of the day by lowering tolls during low-traffic periods;
- Reduce congestion in specific areas by lowering tolls on specific roads;
- Encourage individuals and companies to purchase low-carbon-emission vehicles by charging higher tolls for vehicles that pollute more; and
- Transition the source of revenue financing road infrastructure from fuel-based taxes to toll on road usage, which will include any type of vehicle (from electric vehicles with small tolls to high-gas-consumption vehicles with high tolls).

Security: IoT is a combination of physical objects ("things"), sensors, embedded software and keeps a goal of effective connectivity and faithful data exchange. The current graphs imply that IoT market growing at remarkable rate. However, some of these devices suffer from limited memory, power consumption and processing power. These issues may cause IoT to become penetrable and hence security is at utmost priority to IoT domain.

As stated in a 2015 report by Hewlett-Packard on IoT research [3]:

1. Per 100, 70 devices still use un-encrypted network services
2. Per 100, 90 devices collected at least one piece of personally identifiable information (via device, cloud or mobile app)
3. Per 100, 70 devices (with cloud and mobile app components) enabled an attacker to identify valid user accounts through enumeration.
4. 80% of devices (with cloud and mobile app components) failed to require passwords of sufficient complexity
5.Behind every 10 device every 6 devices user interfaces (UI) were vulnerable

Following are the vulnerabilities of the IoT as per The Open Web Application Security

Project (OWASP)

1) Insufficient protection compositions.

2) Dubiously secured Software/Firmware

3) Doubtful Network Services

4) Doubtful Web Interface

5) Worst Physical Security

6) Doubtful Cloud Interface

7) Doubtful Mobile Interface

8) Privacy Concerns

9) Doubtful Authentication/Authorization

10) Inadequate Transport Encryption Ongoing approaches to secure IoT have attempted to put a grip on communication protocol-based mechanisms, such as encryption for data-at-rest or in-transit.

But this itself is doubtful if the respective endpoints themselves are capable of being modified either by local access or remote connections. Gartner claims that by year 2020 more than 25% of identified attacks in a particular company will be on IoT devices or systems, even though IoT will only contribute to less than 10% of IT security budgets.

The testing methods of our project that is iot based toll booth manager systemThe requirements for testing this project is mobile app,wifi connection.First on lcd we will get a message displaying waiting for link that indicates the wifi is not yet connected.In Mobile Telnet App, we will get a message like welcome when the wifi is connected to ESP8266 WIFI Module.After the wifi is connected,we will get a message on LCD displaying Please Scan UR Card.When we scan the card, if sufficient amount is available, we will get a message access granted for person and remaining balance will be displayed on LCD.When we scan the card, if sufficient amount is not available, we will get a message access denied for person and balance will be displayed on LCD.When card is recharged, amount will be added to card and display’s person recharge done on LCD Screen.

CHAPTER-6
CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

- The sole purpose of this project was to promote cashless transactions under Digital India initialization. Smooth trafficking at the toll plaza site corruption less transactions as well as reducing air pollution, stagnant long queue traffic will be reduced.

- The system has successfully overcome the drawbacks of the existing system by reducing the man power at the toll booth. It provides easy way of toll collection and maintenance of the information in a reliable and efficient manner.

- We aim to show that Toll booth can be completely managed by „Internet of Things" technology with the help of RFID reader. We present a related literature and market survey to show need of such design. We now discuss the potential directions for improving the design presented in this paper.

- **High data rates**: While the data rates of transmission and reception of data by Wi-Fi module and RFID reader are sufficient for our target application scenarios, we believe that with better access to the hardware functionality of RFID sensors, one can achieve higher data rates.

6.2 FUTURE ENHANCEMENT

- We can add GPS to our project to know live location, if anyone skips the toll booth.

- Voice System can be added in this project to indicate if the card is invalid or has insufficient balance.

- Cloud data can be handled using android application. Person will be granted permissions to register, recharge and renew toll account with the help of android application. Moreover, security system needs to be integrated within this module. Thus, when module is implemented on a greater level, it will result in cost reduction and increase in reliability.

PUBLICATION

Submitted Paper in the Conference ICISECT - 21 with Paper ID (ICISECT21-0003) and got Acceptance for the Paper.

APPENDICES

This project shows, that the functionalities of the Toll booth can be completely managed using the 'Internet of Things' concept based on the RFID technology. In reference to survey of annual toll collection on toll plazas, conducted by government of Maharashtra in year 2010, we examine and report on the conditions of total time spent, for money transaction on toll plaza, by a particular vehicle and further evaluate total fuel wastage as well as human errors involvement, while doing so. Finally, to provide an optimal solution, we consent with the idea of making toll plazas completely automated, with assistance of IoT technology.

FULLY AUTOMATED SOLAR GRASS CUTTER ROBOT

INTERNSHIP CERTIFICATE

THIS IS TO CERTIFY THAT ABDUL RAQUEEB MOHAMMAD WITH ROLL NO.16K81A0496, D RAHUL KUMAR WITH ROLL NO.16K81A0471, METTA GOUTHAM WITH ROLL NO.16K81A0495, OF B.TECH – IV YEAR, ELECTRONICS AND COMMUNICATIONS ENGINEERING DEPARTMENT OF ST. MARTIN'S ENGINEERING COLLEGE, KOMPALLY, SECUNDERABAD HAVE COMPLETED ONE MONTH INTERNSHIP PROGRAM AT LASYA IT SOLUTION PVT. LTD, KOMPALLY.

DURING THE PERIOD, THEY HAVE SUCCESSFULLY COMPLETED MAJOR PROJECT TITLED "FULLY AUTOMATED SOLAR GRASS CUTTER" AT OUR DEVELOPMENT CENTER, KOMPALLY.

WE WISH THEM SUCCESS IN THEIR FUTURE ENDEVOUR.

Lasya IT Solutions Pvt. Ltd. Kompally-500014.

ORUGANTI VENKAT
DIRECTOR
TRAININGS & PLACEMENTS
LASYA IT SOLUTIONS PVT LTD.

DECLARATION

We, the students of '**Bachelor of Technology in Department of Electronics and Communication Engineering**', session: 2020 – 2021, **St. Martin's Engineering College**, hereby declare that the project work entitled '**Fully Automated Solar Grass Cutter Robot**' is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

D.Rahul Kumar	M.Goutham	M.A.Raqueeb

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragement and guidance have crowded effects with success.

First and foremost, I would like to express our deep sense of gratitude and indebtedness to my **College Management** for their kind support and permission to use the facilities available in the Institute.

I especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St.Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

I would like to express my gratitude to **Dr.B.HARI KRISHNA**, **Head &Professor**, Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. I am proud to record that I had the opportunity to work with an exceptionally experienced Professor like him. The time spent with him will remain in my memory for years to come.

I would like to express my gratitude to my department. Project coordinator **Dr.A.ANAND, Professor** for his involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We are highly grateful and obliged to **our college level Project Coordinators**, **Ms.P.Pusha Assistant Professor,** Department of Electronics & Communication Engineering for their advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

Finally, I am highly grateful and obliged to my project guide **Mr.N.Vishwanath, Associate Professor,** for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

D.Rahul Kumar	M.Goutham	M.A.Raqueeb

TABLE OF CONTENTS

ABSTRACT

The fully automated solar grass cutter is a fully automated grass cutting robotic vehicle powered by solar energy that also avoids obstacles and is capable of fully automated grass cutting without the need of any human interaction. The system uses 6V batteries to power the vehicle movement motors as well as the grass cutter motor. We also use a solar panel to charge the battery so that there is no need to charge it externally. The grass cutter and vehicle motors are interfaced to an Arduino family microcontroller that controls the working of all the motors. It is also interfaced to an ultrasonic sensor for object detection. The microcontroller moves the vehicle motors in forward direction in case no obstacle is detected. On obstacle detection the ultrasonic sensor monitors it and the microcontroller thus stops the grass cutter motor to avoid any damage to the object/human/animal whatever it is. Microcontroller then turns the robot as long as it gets clear of the object and then moves the grass cutter in forward direction again

CHAPTER-1

INTRODUCTION

1.1. Introduction to the project:

Present days the very large lawns in colleges, public parks, botanical gardens are kept up manually. To cut the grass the gardener uses hands and scissors. But it is not uniform as well as it is not an easy task to finish within the time limit. Most of the lawn mowers are used with electrical energy, gasoline and also need a lot of human effort. In present days the energy sources, electricity and the other non-renewable sources are becoming short and in the future, they may get exhausted. So we focused on renewable resources i.e. solar energy. The solar grass cutter is a fully automated grass cutting vehicle powered by solar energy. It cuts the grass at a very high RPM.The solar grass cutting machine is a fully automated machine power-driven by solar energy. It also detects the obstacles in the path based on that changes the movement direction. It does not require any human interaction. The motors i.e vehicle and grass cutter motors are interfaced to a microcontroller. working of all motors completely controlled by the PICmicrocontroller. An ultrasonic sensor is incorporated into a microcontroller to detect the obstacles which are in the predefined path. The sensors are working as the eyes of an automated machine. Suppose if no sensors are equipped to the machine, the vehicle goes straight and may hit the objects and the vehicle damages. For object detection, we are using two ultrasonic sensors. If the object was detected by the left sensor the vehicle moves to the right with the help of the motor driver and cuts the grass. The smart grass cutter structure is an automated yard mover element. A grasscutter is an edge that is outfitted to an automated machine that takes into account that grass cutting at a very high RPM. The background has smart practicality that permits it to cover the total territory of the yard by distinguishing corners to make use of ultrasonic sensors. The end goal is to cover the whole region by moving the machine is loaded with blades. A microcontroller-based circuit is used in this productive based framework to accomplish the task. There are two batteries are used in this machine. In these two batteries, one is used to run the DC engines and the other one is used to control the engine of the grass cutter. Solar panels are used to charge the batteries which are loaded on the top of the machine.

Ultrasonic sensors are also used in this machine. The framework also makes use of a gyro sensor as a part of the request to accomplish consummate 180 degree turns keeping in mind the end goal to accomplish finish grass/cultivate scope. In this manner, this framework takes into deliberation a mechanized grass-cutting framework without the prerequisite for any human intervention.

1.2 Literature survey:

In this project, the author mainly focused on a grass cutter with helix-shaped cutting blades. Nowadays, grass cutters are functioned by using electrical energy as well as fuel. The main objective behind this design is a machine with a mower that is handy, durable, easy to control and it has a low maintenance cost. Particularly in our, we focused on agricultural needs. We developed an automated machine for agricultural field works i.e to cuts the crops in the different types of fields. There are different types of components are used to develop this simple automated machine. Those are the base frame, wheels, bearings, roller, and gear arrangements. A revolve cutting blade is fitted below the gear. The reel mover is rotated by the gear arrangements that tend to cut the crops or plants. The reel is made of several helix-shaped blades attached to a rotating shaft. The complete set up is positioned on a movable base that has wheel prearrangement. It is used to uphold and maintenance lawns in gardens, schools, colleges, etc.[1].

2.2. Paper-2: Fabrication and Analysis of Lawn Mower Revolving blades are used in grass cutter to cut the grass and garden land space at different lengths and different designs. A blade that rotates on a vertical axis is known as a cutter and a blade assembled on a horizontal axis is known as cylinder or reel cutters. There are different kinds of machines that are developed based on the requirements. For residential gardens and lawns, the compatible type is pushed by human beings. While, superior, autonomous,ride-on mowers are appropriate for large lawns. The biggest, multi-gang mowers dragged behind a tractor, are considered for large areas of grass such as golf courts metropolitan, public, community parks [2].

In 1827, the first grasscutter was developed by Edwin budding in Stroud, Gloucestershire. Primarily it is designed to cut the grass on the luxurious country parks, botanical gardens, and sports gardens. It became an alternative to the scythe. It was patented in 1830. Edwin Budding done an agreement with John Ferrabee dated 18 –May- 1830. As per the agreement between these two people the development cost paid by the Ferrabee obtained the patent letter and acquired rights to manufacture. He was sold the license to other industrialists in the manufacture of lawnmowers. The first chain-driven grass cutter is developed by Thomas Green in the year 1859. The production of lawnmowers commenced in the 1860s. By the year 1862, Farrabee's corporation was building eight models in different roller dimensions. The production was ceased in the year 1863. Until that he was built more than 5000 machines. A human-pushed grass-cutter was designed by Elwood McGuire of Richmond, Indiana in 1870. It was a very lightweight and profitable success. In the year 1899, a better-quality gyratory razor blade grasscutter was patented by John Burr. For better performance wheel alignment is altered in this machine. The Archimedean cutter was built by the Amariah Hills in the year 1871. About, 1900 the Ransomes' Automaton is the finest English instrument. It was available in two variants those are gear-driven and chain models. After world war-I, JP Engineering company situated in Leicester developed and produced popular chain-driven machines. The escalation in the fame of grassland games helped quickly the spread of the creation. Lawnmowers turn out to be a new resourceful alternate to the scythe and trained grazing creatures. In the year 1893, a steam-powered lawn mower was patented by James summer who lives in Lancashire. Petrol or kerosene was used as fuel for this machine. Afterward, several improvements, the pieces of machinery were sold by the Stott Fertilizer and Insecticide Company of Manchester. Later on, the Leyland Steam Motor Company took over the control of sales. Several industrialists go into the arena with gasoline-driven mowers afterward at the turn of the period. The roller drive lawn mower has altered very little meanwhile about 1930. In the United States, in the year 1919, Worthington assembled Gang mowers with various sets of blades. Then, Jacobsen Corporation bought this company but the name of Worthington is still cast on the structures of their gang machinery [2]. 2.3.

Paper-3: Modification of Solar Grass Cutting Machine Cutting grass can't be effortlessly done through elders and youngers. Grasscutter transforming using appliance creates sound pollution owing to the loud engine. and nearby air pollution also rises due to the combustion in the engine. Nearby air pollution as well increases because of the burning in the engine. Periodic maintenance is required for these types of machines for instance changing the oil. The photovoltaic lawnmower is ecologically friendly. Motor-powered machines are additionally dangerous and can't be situated without difficulty castoff through all thus we developed the automated grasscutter handy to function using the remote control. Also, the Battery operated grass cutter remains manual. These grass cutters are using the photovoltaic panels to charge the batteries using solar energy as well as charging done through Alternate Current. To increase the cutting efficiency of the machine is having the spiral cutting blades. It can be operated in two modes those are manual mode and automatic mode. The automatic mode of operation is controlled by remote control. Boxes are attached to the grass cutter to collect the grass cut by the blades automatically [3].

1.3 PROPOSED SYSTEM:

The source is determined commencing from solar energy using a solar panel that energizes the battery and makes use of for driving the process of the system. The microcontroller controls the entire system. A 40 kHz ultrasonic sensor, microcontrollers are used to automated the system. These are helpful for object detection. DC motors are used for wheel movement and cutting operations. An L298 driver circuit is used to achieve the compatibility of motors and the microcontrollers. Here, the output of the microcontroller enhances by using the driver circuit. The cutting action of the blade is delivered by a motor of 1000rpm. The previous technological know-how of grass slicing is hand-operated with the aid of the use of hand gadgets like cutters, scissors, these consequences in better human work, and abundant time necessary for accomplishing the work. Also in old techniques deficiency of uniformity of the remaining grasses. The usage of engine-powered machines will increase sound and air pollution. Additionally, these machines require high maintenance. Nowadays grass cutting machines are turning into very popular. In the olden model of grasscutter, the IC engine is used, and subsequently, due to the fact of ecological influence, air contamination level growths and ic engine grass cutters are also more costly. Looking after such a traditional grass cutter is more. Headed to cling away from these disadvantages we make a strategy to construct an innovative kind of photovoltaic power and this mannequin is additionally economical. The main goal behind this project is headed for reducing the grass which functions on photovoltaic power consequently except for electrical energy and diminishes manpower. In this project, a microcontroller is used for controlling quite several operations of the grass cutter. Also, the grass cutter operates automatically and much less usage of manpower, for this reason, it does now not require a professional individual to operate

CHAPTER-2

INTRODUCTION ABOUT EMBEDDED SYSTEMS

2.1 Introduction:

An embedded system is a system which is going to do a predefined specified task is the embedded system and is even defined as combination of both software and hardware. A general-purpose definition of embedded systems is that they are devices used to control, monitor or assist the operation of equipment, machinery or plant. "Embedded" reflects the fact that they are an integral part of the system. At the other extreme a general-purpose computer may be used to control the operation of a large complex processing plant, and its presence will be obvious.

All embedded systems are including computers or microprocessors. Some of these computers are however very simple systems as compared with a personal computer.

The very simplest embedded systems are capable of performing only a single function or set of functions to meet a single predetermined purpose. In more complex systems an application program that enables the embedded system to be used for a particular purpose in a specific application determines the functioning of the embedded system. The ability to have programs means that the same embedded system can be used for a variety of different purposes. In some cases, a microprocessor may be designed in such a way that application software for a particular purpose can be added to the basic software in a second process, after which it is not possible to make further changes.

The applications software on such processors is sometimes referred to as firmware.

The simplest devices consist of a single microprocessor (often called a "chip"), which may itself be packaged with other chips in a hybrid system or Application Specific Integrated Circuit (ASIC). Its input comes from a detector or sensor and its output goes to a switch or activator which (for example) may start or stop the operation of a machine or, by operating a valve, may control the flow of fuel to an engine.

As the embedded system is the combination of both software and hardware

2.2 Block diagram of embedded system:

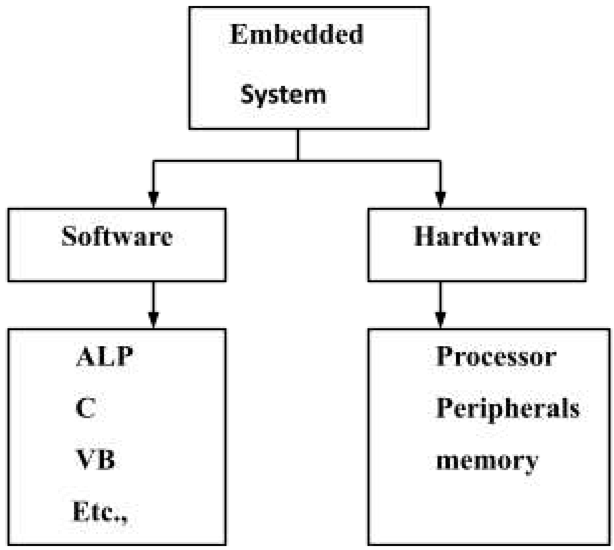

Fig.2.2: Block diagram of embedded system

Software deals with the languages like ALP, C, and VB etc., and Hardware deals with Processors, Peripherals, and Memory

2.3 Applications of embedded systems:

- Manufacturing and process control
- Construction industry
- Transport
- Buildings and premises
- Domestic service
- Communications
- Office systems and mobile equipment
- Banking, finance and commercial
- Medical diagnostics, monitoring and life support
- Testing, monitoring and diagnostic systems

2.4 Micro Processor (µp):

A silicon chip that contains a CPU. In the world of personal computers, the terms microprocessor and CPU are used interchangeably. At the heart of all personal computers and most workstations sits a microprocessor. Microprocessors also control the logic of almost all digital devices, from clock radios to fuel-injection systems for automobiles.

Processors are classified into four types like:

- Microprocessor (µp)
- Micro controller (µc)
- Digital Signal Processor (DSP)
- Application Specific Integrated Circuits (ASIC)

2.5 Three Basic Elements of a Microprocessor:

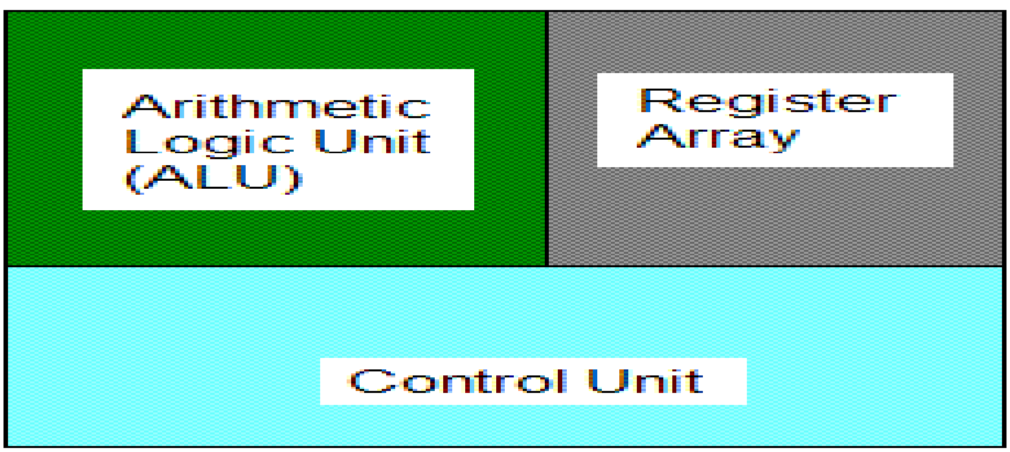

Fig.2.5: Three basic elements of a microprocessor

2.6 Harvard Architecture:

Computers have separate memory areas for program instructions and data. There are two or more internal data buses, which allow simultaneous access to both instructions and data. The CPU fetches program instructions on the program memory bus.

The Harvard architecture is a computer architecture with physically separate storage and signal pathways for instructions and data. The term originated from the Harvard Mark I relay-based computer, which stored instructions on punched tape (24 bits wide) and data in electro-mechanical counters. These early machines had limited data storage, entirely contained within the central processing unit, and provided no access to the instruction storage as data. Programs needed to be loaded by an operator, the processor could not boot itself.

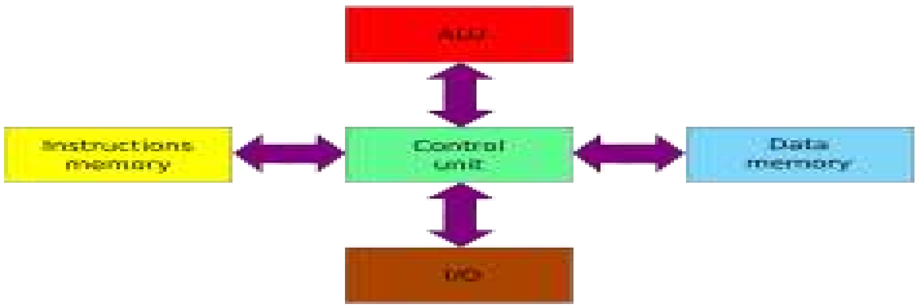

Fig.2.6: Harvard Architecture

2.6.1 Uses of the Harvard architecture:

The principal advantage of the pure Harvard architecture - simultaneous access to more than one memory system - has been reduced by modified Harvard processors using modern CPU cache systems. Relatively pure Harvard architecture machines are used mostly in applications where tradeoffs, such as the cost and power savings from omitting caches, outweigh the programming penalties from having distinct code and data address spaces.

- Digital signal processors (DSPs) generally execute small, highly-optimized audio or video processing algorithms. They avoid caches because their behaviour must be extremely reproducible. The difficulties of coping with multiple address spaces are of secondary concern to speed of execution. As a result, some DSPs have multiple data memories in distinct address spaces to facilitate SIMD and VLIW processing. Texas Instruments TMS320 C55x processors, as one example, have multiple parallel data busses (two write, three read) and one instruction bus.

- Microcontrollers are characterized by having small amounts of program (flash memory) and data (SRAM) memory, with no cache, and take advantage of the Harvard architecture to speed processing by concurrent instruction and data access. The separate storage means the program and data memories can have different bit depths, for example using 16-bit wide instructions and 8-bit wide data. They also mean that instruction prefetch can be performed in parallel with other activities. Examples include, the AVR by Atmel Corp, the PIC by Microchip Technology, Inc. and the ARM Cortex-M3 processor (not all ARM chips have Harvard architecture).

Even in these cases, it is common to have special instructions to access program memory as data for read-only tables, or for reprogramming.

2.6.2 Von-Neumann Architecture

A computer has a single, common memory space in which both program instructions and data are stored. There is a single internal data bus that fetches both instructions and data. They cannot be performed at the same time. The von Neumann architecture is a design model for a stored-program digital computer that uses a central processing unit (CPU) and a single separate storage structure ("memory") to hold both instructions and data. It is named after the mathematician and early computer scientist John von Neumann. Such computers implement a universal Turing machine and have a sequential architecture.

A stored-program digital computer is one that keeps its programmed instructions, as well as its data, in read-write, random-access memory (RAM). Stored-program computers were an advancement over the program-controlled computers of the 1940s, such as the Colossus and the ENIAC, which were programmed by setting switches and inserting patch leads to route data and to control signals between various functional units. In the vast majority of modern computers, the same memory is used for both data and program instructions. The mechanisms for transferring the data and instructions between the CPU and memory are, however, considerably more complex than the original von Neumann architecture.

The terms "von Neumann architecture" and "stored-program computer" are generally used interchangeably, and that usage is followed in this article.

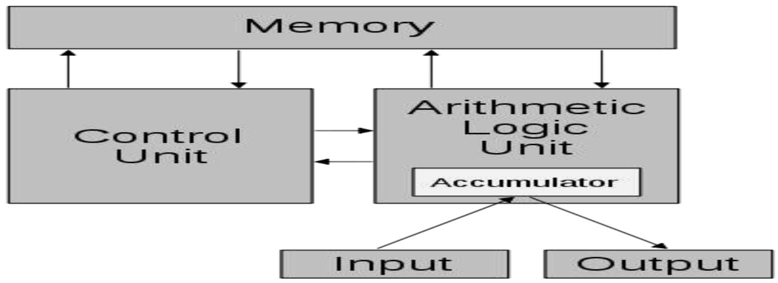

Fig.2.6.1: Schematic of the Von-Neumann Architecture.

CHAPTER-3

MICRO CONTROLLER UNIT

3.1 ATMEGA328

Arduino Uno is a microcontroller board based on 8-bit ATmega328P microcontroller. Along with ATmega328P, it consists other components such as crystal oscillator, serial communication, voltage regulator, etc. to support the microcontroller. Arduino Uno has 14 digital input/output pins (out of which 6 can be used as PWM outputs), 6 analog input pins, a USB connection, A Power barrel jack, an ICSP header and a reset button.

The ATmega8 microcontroller contains 32 general purpose working registers. As shown in the below figure these registers are directly connected to ALU. Two registers can carry one single instruction consequently in one clock cycle.

Specifications:

Microcontroller	ATmega328P – 8 bit AVR family microcontroller
Operating Voltage	5V
Recommended Input Voltage	7-12V
Input Voltage Limits	6-20V
Analog Input Pins	6 (A0 – A5)
Digital I/O Pins	14 (Out of which 6 provide PWM output)
DC Current on I/O Pins	40 Ma
DC Current on 3.3V Pin	50 Ma
Flash Memory	32 KB (0.5 KB is used for Boot loader)
SRAM	2 KB
EEPROM	1 KB

Frequency (Clock Speed)	16 MHz

Table 3.1: Atmega328 specifications

Arduino:

Arduino is a prototype platform (open-source) based on an easy-to-use hardware and software. It consists of a circuit board, which can be programmed (referred to as a microcontroller) and a ready-made software called Arduino IDE (Integrated Development Environment), which is used to write and upload the computer code to the physical board.

The key features are −

- Arduino boards are able to read analog or digital input signals from different sensors and turn it into an output such as activating a motor, turning LED on/off, connect to the cloud and many other actions.
- You can control your board functions by sending a set of instructions to the microcontroller on the board via Arduino IDE (referred to as uploading software).
- Unlike most previous programmable circuit boards, Arduino does not need an extra piece of hardware (called a programmer) in order to load a new code onto the board. You can simply use a USB cable.
- Additionally, the Arduino IDE uses a simplified version of C++, making it easier to learn to program.
- Finally, Arduino provides a standard form factor that breaks the functions of the micro-controller into a more accessible package.

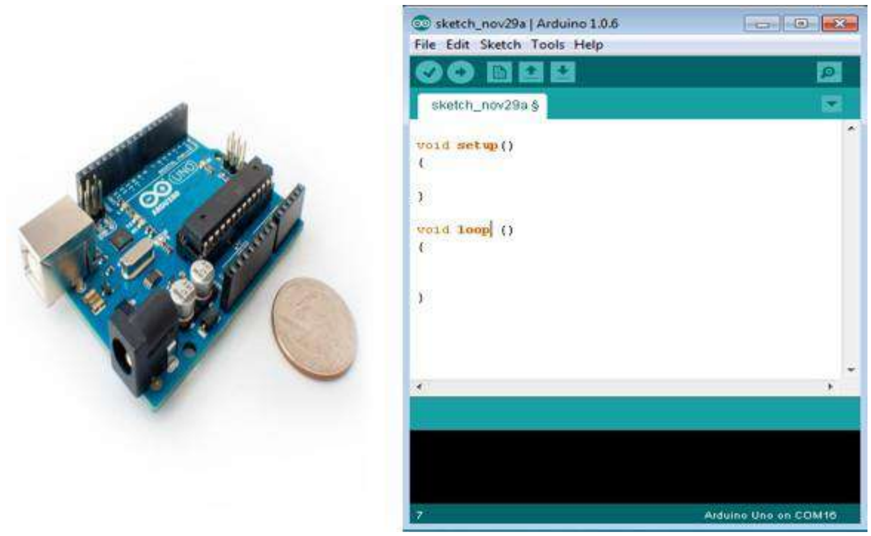

Fig 3.1 Arduino Uno

3.2 Board Types

Various kinds of Arduino boards are available depending on different microcontrollers used. However, all Arduino boards have one thing in common: they are programed through the Arduino IDE.

The differences are based on the number of inputs and outputs (the number of sensors, LEDs, and buttons you can use on a single board), speed, operating voltage, form factor etc. Some boards are designed to be embedded and have no programming interface (hardware), which you would need to buy separately. Some can run directly from a 3.7V battery, others need at least 5V.

Here is a list of different Arduino boards available.

Table 3.1 Arduino boards based on ATMEGA328 microcontroller

Board Name	**Operating Volt**	**Clock Speed**	**Digital i/o**	**Analog Inputs**	**PWM**	**UART**	**Programming Interface**

Arduino Uno R3	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Arduino Uno R3 SMD	5V	16MHz	14	6	6	1	USB via ATMega 16U2
Red Board	5V	16MHz	14	6	6	1	USB via FTDI
Arduino Pro 3.3v/8 MHz	3.3V	8MHz	14	6	6	1	FTDI-Compatible Header
Arduino Pro 5V/16MHz	5V	16MHz	14	6	6	1	FTDI-Compatible Header
Arduino mini 05	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 3.3v/8mhz	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header
Arduino Pro mini 5v/16mhz	5V	16MHz	14	8	6	1	FTDI-Compatible Header
Arduino Ethernet	5V	16MHz	14	6	6	1	FTDI-Compatible Header

Arduino Fio	3.3V	8MHz	14	8	6	1	FTDI-Compatible Header

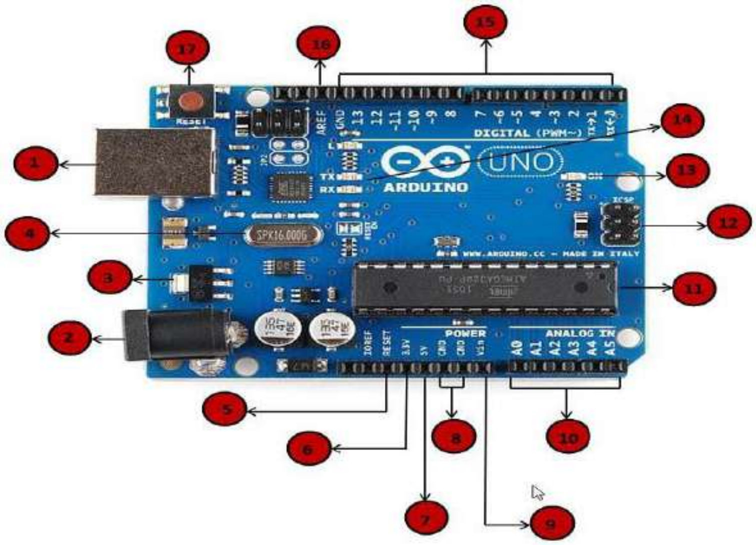
3.2.1 Board Description:

In this chapter, we will learn about the different components on the Arduino board. We will study the Arduino UNO board because it is the most popular board in the Arduino board family. In addition, it is the best board to get started with electronics and coding. Some boards look a bit different from the one given below, but most Arduinos have majority of these components in common.



1	**Power USB** Arduino board can be powered by using the USB cable from your computer. All you need to do is connect the USB cable to the USB connection (1).
2	**Power (Barrel Jack)** Arduino boards can be powered directly from the AC mains power supply by connecting it to the Barrel Jack (2).
3	**Voltage Regulator** The function of the voltage regulator is to control the voltage given to the Arduino board and stabilize the DC voltages used by the processor and other elements.
4	**Crystal Oscillator** The crystal oscillator helps Arduino in dealing with time issues. How does Arduino calculate time? The answer is, by using the crystal oscillator. The number printed on top of the Arduino crystal is 16.000H9H. It tells us that the frequency is 16,000,000 Hertz or 16 MHz.
5, 17	**Arduino Reset**

	You can reset your Arduino board, i.e., start your program from the beginning. You can reset the UNO board in two ways. First, by using the reset button (17) on the board. Second, you can connect an external reset button to the Arduino pin labelled RESET (5).
6, 7, 8, 9	**Pins (3.3, 5, GND, Vin)** • 3.3V (6) − Supply 3.3 output volt • 5V (7) − Supply 5 output volt • Most of the components used with Arduino board works fine with 3.3 volt and 5 volt. • GND (8)(Ground) − There are several GND pins on the Arduino, any of which can be used to ground your circuit. • Vin (9) − This pin also can be used to power the Arduino board from an external power source, like AC mains power supply.
10	**Analog pins** The Arduino UNO board has six analog input pins A0 through A5. These pins can read the signal from an analog sensor like the humidity sensor or temperature sensor and convert it into a digital value that can be read by the microprocessor.
11	**Main microcontroller** Each Arduino board has its own microcontroller (11). You can assume it as the brain of your board. The main IC (integrated circuit) on the Arduino is slightly different from board to board. The microcontrollers are usually of the ATMEL Company. You must know what IC your board has before loading up a new program from the Arduino IDE. This information is available on the top of the IC. For more details about the IC construction and functions, you can refer to the data sheet.
12	**ICSP pin** Mostly, ICSP (12) is an AVR, a tiny programming header for the Arduino consisting of MOSI, MISO, SCK, RESET, VCC, and GND. It is often referred to as an SPI (Serial Peripheral

	Interface), which could be considered as an "expansion" of the output. Actually, you are slaving the output device to the master of the SPI bus.
13	**Power LED indicator** This LED should light up when you plug your Arduino into a power source to indicate that your board is powered up correctly. If this light does not turn on, then there is something wrong with the connection.
14	**TX and RX LEDs** On your board, you will find two labels: TX (transmit) and RX (receive). They appear in two places on the Arduino UNO board. First, at the digital pins 0 and 1, to indicate the pins responsible for serial communication. Second, the TX and RX led (13). The TX led flashes with different speed while sending the serial data. The speed of flashing depends on the baud rate used by the board. RX flashes during the receiving process.
15	**Digital I/O** The Arduino UNO board has 14 digital I/O pins (15) (of which 6 provide PWM (Pulse Width Modulation) output. These pins can be configured to work as input digital pins to read logic values (0 or 1) or as digital output pins to drive different modules like LEDs, relays, etc. The pins labeled "~" can be used to generate PWM.
16	**AREF** AREF stands for Analog Reference. It is sometimes, used to set an external reference voltage (between 0 and 5 Volts) as the upper limit for the analog input pins.

3.5 ARDUINO FAMILY

Arduino makes several different boards, each with different capabilities. In addition, part of being open source hardware means that others can modify and produce derivatives of

Arduino boards that provide even more form factors and functionality. If you're not sure which one is right for your project , check this guide for some helpful hints. Here are a few options that are well suited to someone new to the world of Arduino.

Fig.3.5: Arduino Family

3.6 SHIELDS

Additionally, there are these things called shields - basically they are pre-built circuit boards that fit on top of your Arduino and provide additional capabilities -controlling motors, connecting to the internet, providing cellular or other wireless communication, controlling an LCD screen and much more.

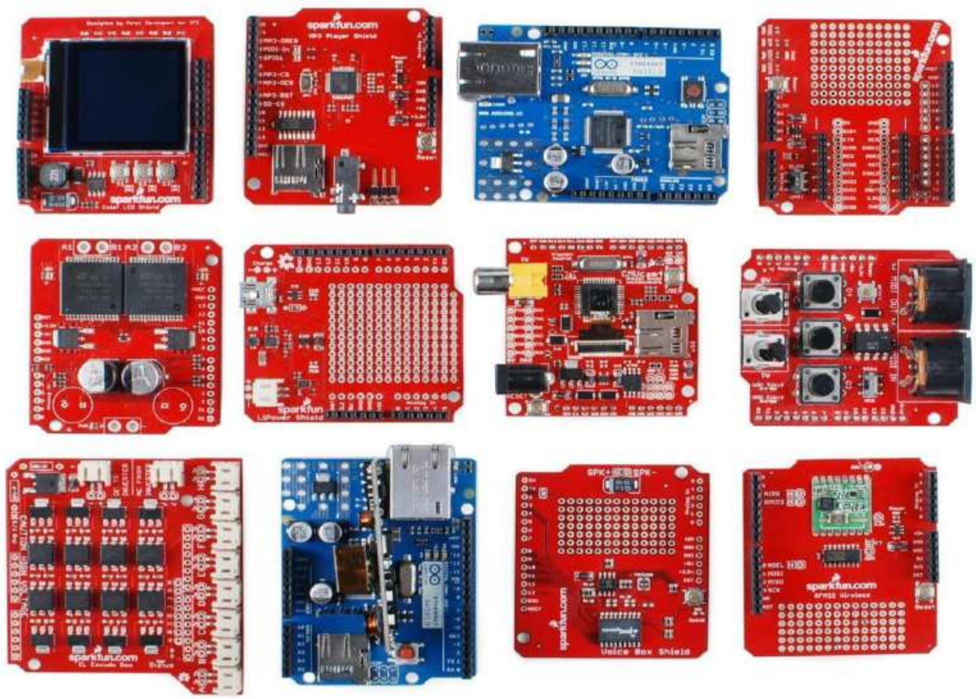


Fig.3.6: Arduino Shields

3.7 PIN DESCRIPTION OF ATMEGA328

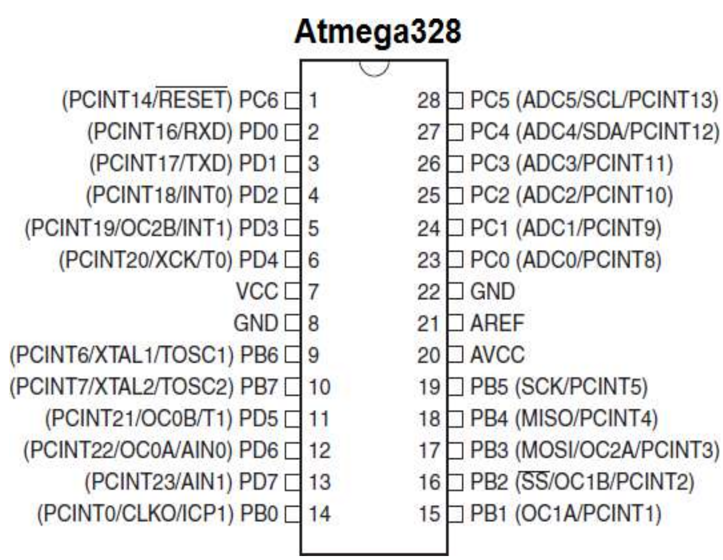

Fig.3.7: Pin description of ATMEGA328

ADVANTAGES OF ARDUINO

- It is cheap
- It comes with an open supply hardware feature that permits users to develop their own kit
- The software of the Arduino is well-suited with all kinds of in operation systems like Linux, Windows, and Macintosh, etc.
- It also comes with open supply software system feature that permits tough software system developers to use the Arduino code to merge with the prevailing programming language libraries and may be extended and changed.
- For beginners, it is very simple to use.

APPLICATIONS

ATMEGA328 is commonly used in many projects and autonomous systems where a simple, low- powered, low- cost microcontroller is needed. Perhaps the most common implementation of this chip is on the popular Arduino development platform, namely the Arduino UNO and Arduino Nano model

CHAPTER-4

POWER SUPPLY UNIT

4.1 INTRODUCTION:

The power supplies are designed to convert high voltage AC mains electricity to a suitable low voltage supply for electronic circuits and other devices. A power supply can by broken down into a series of blocks, each of which performs a particular function. A d.c power supply which maintains the output voltage constant irrespective of a.c mains fluctuations or load variations is known as “Regulated D.C Power Supply”.

4.1.1 BLOCK DIAGRAM OF POWER SUPPLY:

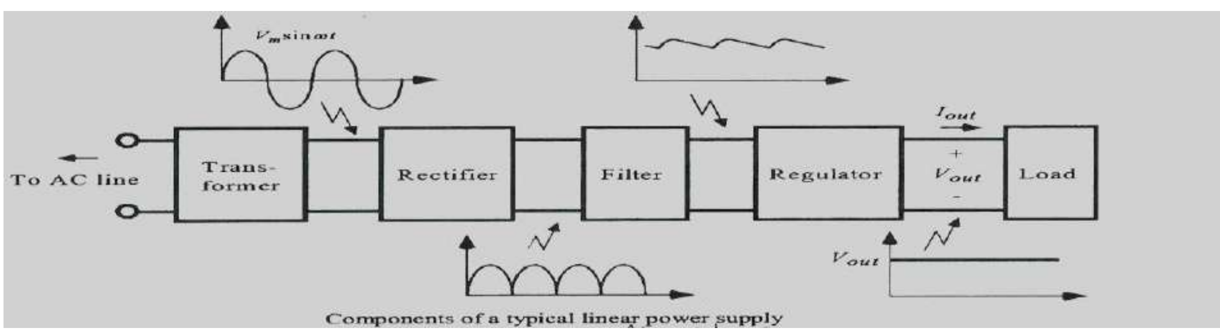

Fig.4.1.1: Block Diagram of Power Supply

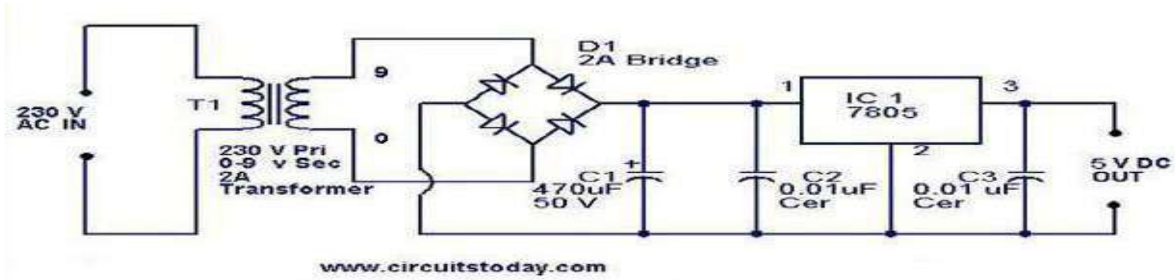

Fig.4.1.1(A): Schematic Diagram of Power Supply

4.1.2 DESCRIPTION OF POWER SUPPLY:

A power supply is a component that supplies power to at least one electric load. Typically, it converts one type of electrical power to another, but it may also convert a a different form of energy – such as solar, mechanical, or chemical - into electrical energy.

A power supply provides components with electric power. The term usually pertains to devices integrated within the component being powered. For example, computer power supplies convert AC current to DC current and are generally located at the rear of the computer case, along with at least one fan. A power supply is also known as a power supply unit, power brick or power adapter.

4.2 TRANSFORMER:

A transformer is a device that transfers electrical energy from one circuit to another through inductively coupled conductors—the transformer's coils. A varying current in the first or *primary* winding creates a varying magnetic flux in the transformer's core, and thus a varying magnetic field through the *secondary* winding. This varying magnetic field induces a varying electromotive force (EMF) or "voltage" in the secondary winding. This effect is called mutual induction.

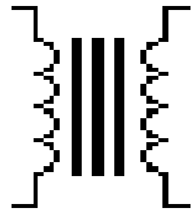

Fig.4.2: Transformer Symbol

(or)

Transformer is a device that converts the one form energy to another form of energy like a transducer.

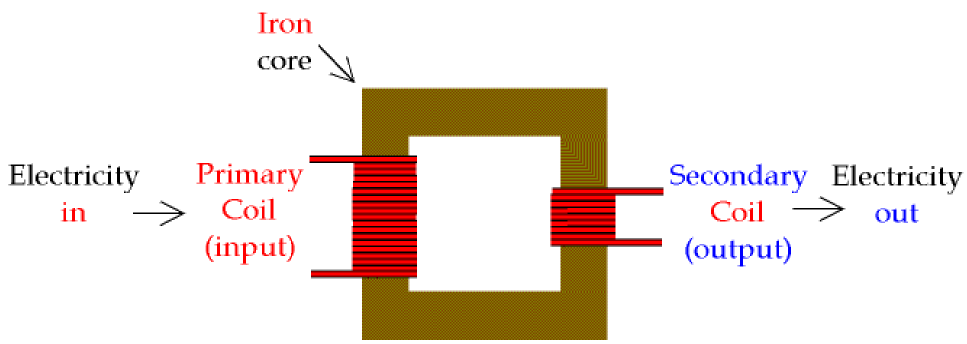

Fig.4.2(A): Transformer

4.2.1 Basic Principle of Transformer:

A transformer makes use of Faraday's law and the ferromagnetic properties of an iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

From Faraday's Law

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}$$

For ideal transformer

The voltage ratio is equal to the turns ratio, and power in equals power out.

From conservation of energy

$$P_P = V_P I_P = V_S I_S = P_S$$

Working of Transformer:

A transformer consists of two coils (often called 'windings') linked by an iron core, as shown in figure below. There is no electrical connection between the coils, instead they are linked by a magnetic field created in the core.

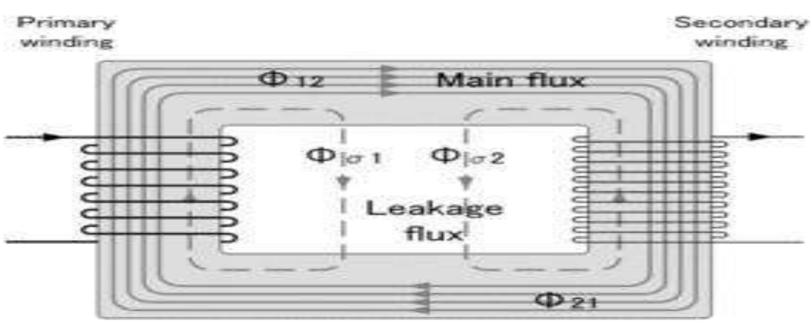

Fig.4.2.1: Basic Transformer

Transformers are used to convert electricity from one voltage to another with minimal loss of power. They only work with AC (alternating current) because they require a changing magnetic field to be created in their core. Transformers can increase voltage (step-up) as well as reduce voltage (step-down).

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f. The iron core is laminated to prevent 'eddy currents' flowing in the core.

These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

Transformers have two great advantages over other methods of changing voltage:

1. They provide total electrical isolation between the input and output, so they can be safely used to reduce the high voltage of the mains supply.
2. Almost no power is wasted in a transformer. They have a high efficiency (power out / power in) of 95% or more.

4.2.2 Classification of Transformer:

- Step-Up Transformer
- Step-Down Transformer

Step-Down Transformer:

Step down transformers are designed to reduce electrical voltage. Their primary voltage is greater than their secondary voltage. This kind of transformer "steps down" the voltage

applied to it. For instance, a step down transformer is needed to use a 110v product in a country with a 220v supply.

Step down transformers convert electrical voltage from one level or phase configuration usually down to a lower level. They can include features for electrical isolation, power distribution, and control and instrumentation applications. Step down transformers typically rely on the principle of magnetic induction between coils to convert voltage and/or current levels.

Step down transformers are made from two or more coils of insulated wire wound around a core made of iron. When voltage is applied to one coil (frequently called the primary or input) it magnetizes the iron core, which induces a voltage in the other coil, (frequently called the secondary or output). The turn's ratio of the two sets of windings determines the amount of voltage transformation.

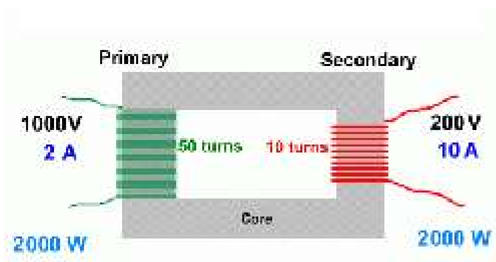

Fig.4.2.2: Step-Down Transformer

An example of this would be: 100 turns on the primary and 50 turns on the secondary, a ratio of 2 to 1.

Step down transformers can be considered nothing more than a voltage ratio device.

With step down transformers the voltage ratio between primary and secondary will mirror the "turn's ratio" (except for single phase smaller than 1 kva which have compensated secondary). A practical application of this 2 to 1 turn's ratio would be a 480 to 240 voltage step down. Note that if the input were 440 volts then the output would be 220 volts. The ratio between input and output voltage will stay constant. Transformers should not be operated at voltages higher than the nameplate rating, but may be operated at lower voltages than rated. Because of this it is possible to do some non-standard applications using standard transformers.

Single phase steps down transformers 1 kva and larger may also be reverse connected to step-down or step-up voltages. (Note: single phase steps up or step down transformers sized less than 1 KVA should not be reverse connected because the secondary windings have additional turns to overcome a voltage drop when the load is applied. If reverse connected, the output voltage will be less than desired.)

Step-Up Transformer:

A step up transformer has more turns of wire on the secondary coil, which makes a larger induced voltage in the secondary coil. It is called a step up transformer because the voltage output is larger than the voltage input.

Step-up transformer 110v 220v design is one whose secondary voltage is greater than its primary voltage. This kind of transformer "steps up" the voltage applied to it. For instance, a step up transformer is needed to use a 220v product in a country with a 110v supply. A step up transformer 110v 220v converts alternating current (AC) from one voltage to another voltage. It has no moving parts and works on a magnetic induction principle; it can be designed to "step-up" or "step-down" voltage. So a step up transformer increases the voltage and a step down transformer decreases the voltage.

The primary components for voltage transformation are the step up transformer core and coil. The insulation is placed between the turns of wire to prevent shorting to one another or to ground. This is typically comprised of Mylar, nomex, Kraft paper, varnish, or other materials. As a transformer has no moving parts, it will typically have a life expectancy between 20 and 25 years.

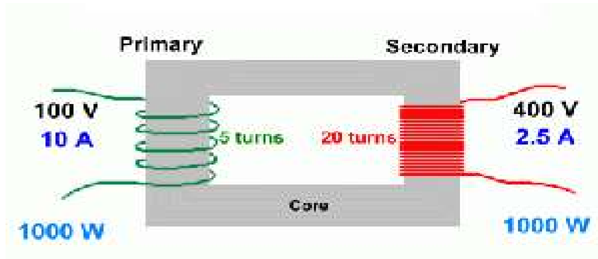

Fig.4.2.2(a): Step-Up Transformer

4.3 DIODES:

Diodes allow electricity to flow in only one direction. The arrow of the circuit symbol shows the direction in which the current can flow. Diodes are the electrical version of a valve and early diodes were actually called valves.

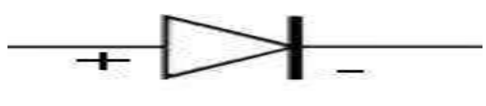

Fig.4.3: Diode Symbol

A **diode** is a device which only allows current to flow through it in one direction. In this direction, the diode is said to be 'forward-biased' and the only effect on the signal is that there will be a voltage loss of around 0.7V. In the opposite direction, the diode is said to be 'reverse-biased' and no current will flow through it.

4.4 Rectifier:

The purpose of a rectifier is to convert an AC waveform into a DC waveform (OR) Rectifier converts AC current or voltages into DC current or voltage. There are two different rectification circuits, known as **'half-wave'** and **'full-wave' rectifiers**. Both use components called **diodes** to convert **AC into DC**.

The Half-Wave Rectifier:

The half-wave rectifier is the simplest type of rectifier since it only uses one diode, as shown in figure.

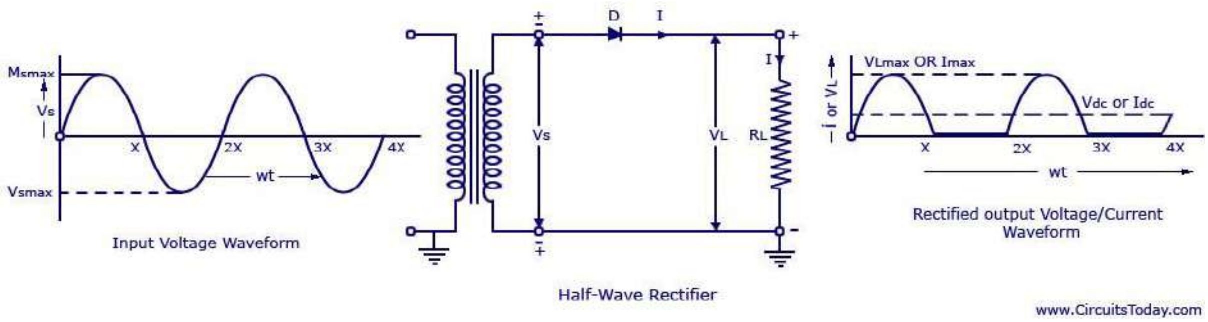

Fig.4.4(a): Half Wave Rectifier

Figure 2 shows the AC input waveform to this circuit and the resulting output. As you can see, when the AC input is positive, the diode is forward-biased and lets the current through. When the AC input is negative, the diode is reverse-biased and the diode does not let any current through, meaning the output is0V. Because there is a 0.7V voltage loss across the diode, the peak output voltage will be 0.7V less than Vs.

While the output of the half-wave rectifier is DC (it is all positive), it would not be suitable as a power supply for a circuit. Firstly, the output voltage continually varies between 0V and Vs-0.7V, and secondly, for half the time there is no output at all.

The Full-wave Rectifier:

The circuit in figure 3 addresses the second of these problems since at no time is the output voltage 0V. This time four diodes are arranged so that both the positive and negative parts of the AC waveform are converted to DC.

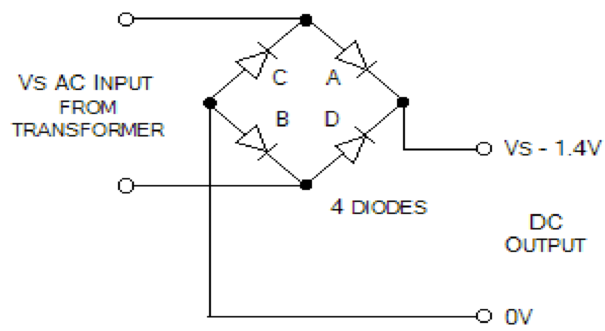

Fig.4.4(b): Full-Wave Rectifier

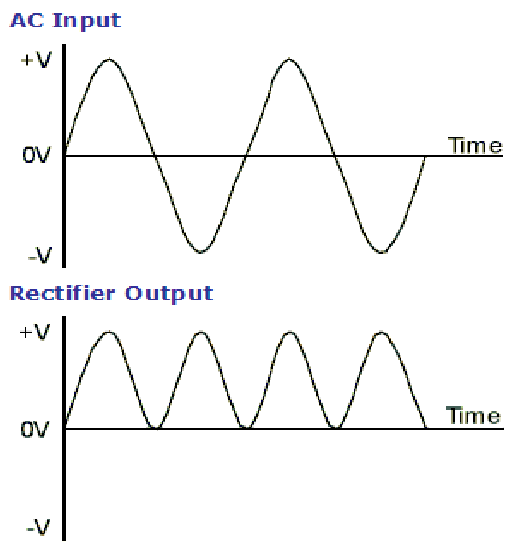

Fig.4.4(c): Full-Wave Rectification

When the AC input is positive, diodes A and B are forward-biased, while diodes C and D are reverse-biased. When the AC input is negative, the opposite is true - diodes C and D are forward-biased, while diodes A and B are reverse-biased. While the full-wave rectifier is an improvement on the half-wave rectifier, its output still isn't suitable as a power supply for most circuits since the output voltage still varies between 0V and Vs-1.4V. So, if you put 12V AC in, you will 10.6V DC out.

4.5 CAPACITOR FILTER:

The capacitor-input filter, also called "Pi" filter due to its shape that looks like the Greek letter pi, is a type of electronic filter. Filter circuits are used to remove unwanted or undesired frequencies from a signal.

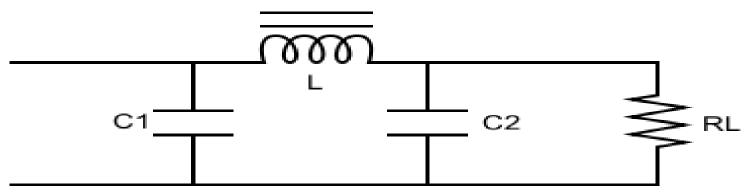

Fig.4.5: Capacitor Filter

A typical capacitor input filter consists of a filter capacitor C1, connected across the rectifier output, an inductor L, in series and another filter capacitor connected across the load.

1. The capacitor C1 offers low reactance to the AC component of the rectifier output while it offers infinite reactance to the DC component. As a result the capacitor shunts an appreciable amount of the AC component while the DC component continues its journey to the inductor L
2. The inductor L offers high reactance to the AC component but it offers almost zero reactance to the DC component. As a result, the DC component flows through the inductor while the AC component is blocked.
3. The capacitor C2 bypasses the AC component which the inductor had failed to block. As a result, only the DC component appears across the load RL.

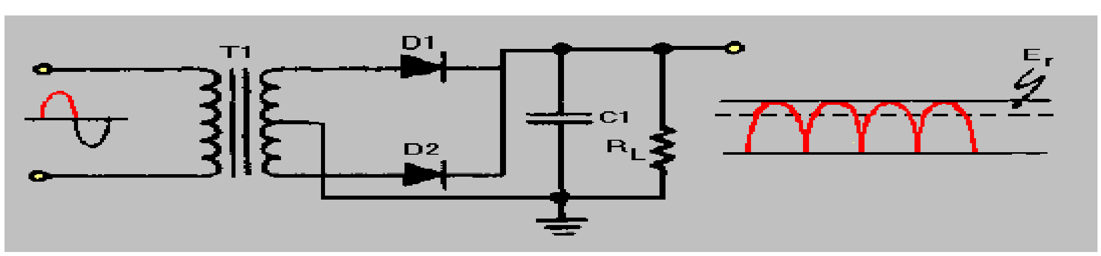

Fig.4.5(A): Centered Tapped Full-Wave Rectifier with a Capacitor Filter

4.6 VOLTAGE REGULATOR:

A voltage regulator is an electrical regulator designed to automatically maintain a constant voltage level. It may use an electromechanical mechanism, or passive or active electronic components. Depending on the design, it may be used to regulate one or more AC or DC voltages. There are two types of regulator are they.

- Positive Voltage Series (78xx) and
- Negative Voltage Series (79xx)

78xx:’78’ indicate the positive series and ‘xx’indicates the voltage rating. Suppose 7805 produces the maximum 5V.’05’indicates the regulator output is 5V.

79xx:’78’ indicate the negative series and ‘xx’indicates the voltage rating. Suppose 7905 produces the maximum -5V.’05’indicates the regulator output is -5V.

These regulators consist the three pins there are

Pin1: It is used for input pin.

Pin2: This is ground pin for regulator

Pin3: It is used for output pin. Through this pin we get the output.

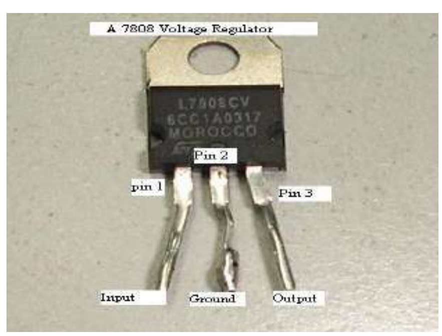

Fig.4.6: Regulator

CHAPTER-5

PROJECT DESCRIPTION

5.1 Hardware Specification:

- Battery
- LCD
- L293D
- Motors
- Arduino uno
- Solar panel
- Ultrasonic sensor
- IR Sensor

BLOCK DIAGRAM:

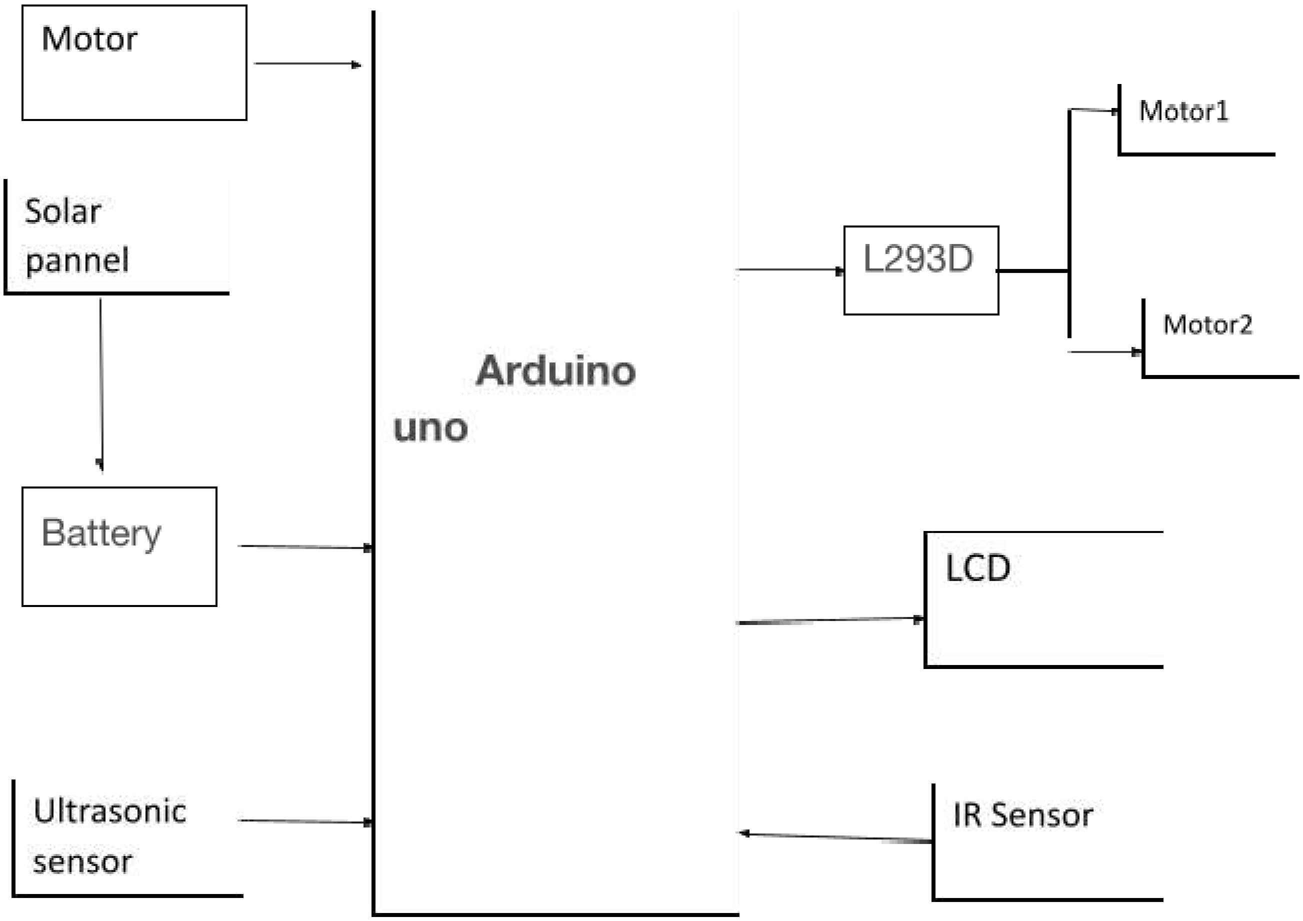

Fig.5.2: Block diagram of the project

Battery:

Batteries are a collection of one or more cells whose chemical reactions create a flow of electrons in a circuit. All batteries are made up of three basic components: an anode (the '-' side), a cathode (the '+' side), and some kind of electrolyte (a substance that chemically reacts with the anode and cathode).

When the anode and cathode of a battery is connected to a circuit, a chemical reaction takes place between the anode and the electrolyte. This reaction causes electrons to flow through the circuit and back into the cathode where another chemical reaction takes place. When the material in the cathode or anode is consumed or no longer able to be used in the reaction, the battery is unable to produce electricity. At that point, your battery is "dead."

Batteries that must be thrown away after use are known as **primary batteries**. Batteries that can be recharged are called **secondary batteries**.

Fig : Lithium Battery

Lithium polymer batteries, for example, can be recharged without batteries, your quadcopter would have to be tethered to the wall, you would have to hand crank your car, and your Xbox controller would have to plugged in all the time (like in the good old days). Batteries offer a way to store electrical potential energy in a portable container.

Fig : Batteries come in a variety of shapes, sizes, and chemistries.

History

The Term Battery

Historically, the word "battery" was used to describe a "series of similar objects grouped together to perform a function," as in a battery of artillery. In 1749, Benjamin Franklin first used the term to describe a series of capacitors he had linked together for his electricity experiments. Later, the term would be used for any electrochemical cells linked together for the purpose of providing electric power.

Battery of Leyden Jar "capacitors" linked together (Image courtesy of Alvinrune of Wikimedia Commons)

Invention of the Battery

One fateful day in 1780, Italian physicist, physician, biologist, and philosopher, Luigi Galvani, was dissecting a frog attached to a brass hook. As he touched the frog's leg with an iron scapel, the leg twitched. Galvani theorized that the energy came from the leg itself, but his fellow scientist, Alessandro Volta, believed otherwise.

Volta hypothesized that the frog's leg impulses were actually caused by different metals soaked in a liquid. He repeated the experiment using cloth soaked in brine instead of a frog corpse, which resulted in a similar voltage. Volta published his findings in 1791 and later created the first battery, the voltaic pile, in 1800.

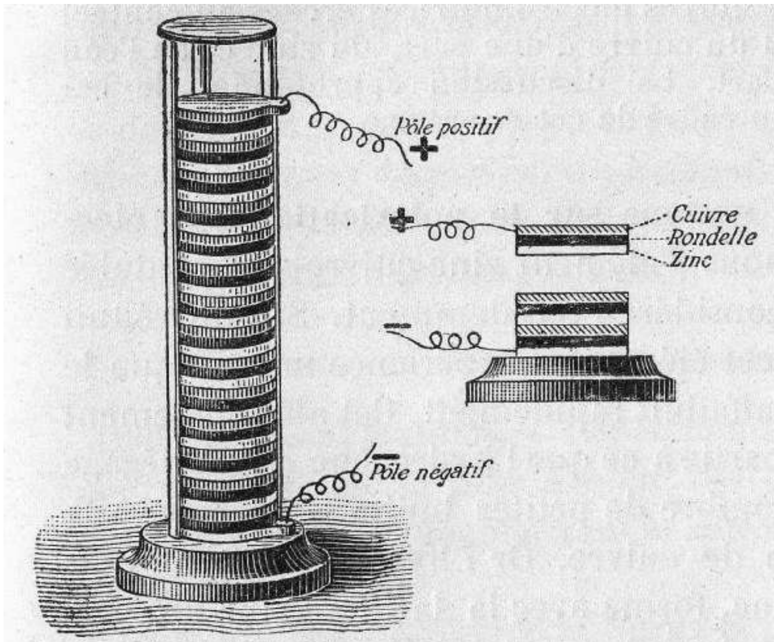

Fig. 283. — Pile de Volta.

The voltaic pile consisted of a stack of zinc and copper plates separated by cloth soaked in brine. Volta's pile was plagued by two major issues: the weight of the stack caused the electrolyte to leak out of the cloth, and the particular chemical properties of the components resulted in a very short life span (about an hour). The next two hundred years would be spent perfecting Volta's design and solving these issues.

Fixes to the Voltaic Pile

William Cruickshank of Scotland solved the leakage problem by laying the voltaic pile on its side to form the "trough battery."

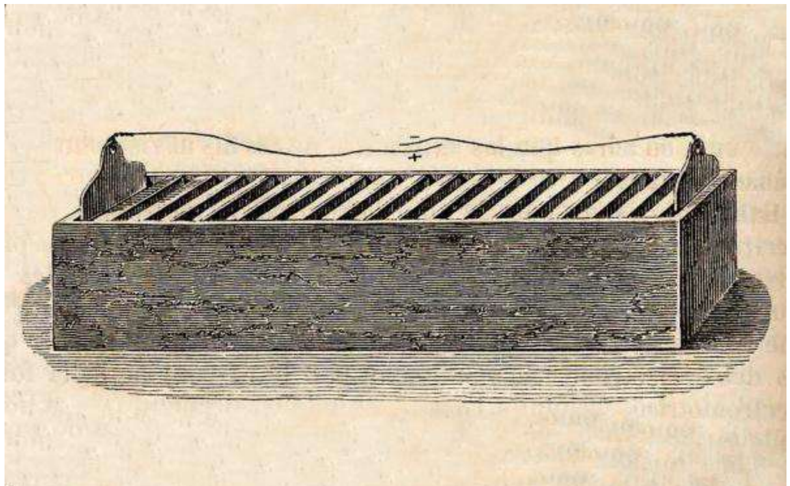

Fig : The trough battery solved the leakage problem of the voltaic pile

The second problem, short life span, was caused by the degradation of the zinc due to impurities and a build-up of hydrogen bubbles on the copper. In 1835, William Sturgeon discovered that treating the zinc with mercury would prevent degradation.

The British chemist John Frederic Daniell used a second electrolyte that reacted with the hydrogen, preventing buildup on the copper cathode. Daniell's two-electrolyte battery, known as the "Daniell cell," would become a very popular solution to providing power to the budding telegraph networks.

Fig : A collection of Daniell cells from 1836

The First Rechargeable Battery

In 1859, the French physicist Gaston Planté created a battery using two rolled sheets of lead submerged in sulfuric acid. By reversing the electrical current through the battery, the chemistry would return to its original state, thus creating the first rechargeable battery.

Later, in 1881, Camille Alphonse Faure improved Planté's design by forming the lead sheets into plates. This new design made the batteries easier to manufacture, and the lead acid battery saw wide-spread use in automobiles.

-> The design for the common "car battery" has been around for more than 100 years
(Image courtesy of Emilian Robert Vicol of Wikimedia Commons) <-

The Dry Cell

Up until the late 1800s, the electrolyte in batteries was in a liquid state. This made battery transportation a very careful endeavor, and most batteries were never intended to be moved once attached to the circuit.

In 1866, Georges Leclanché created a battery using a zinc anode, a manganese dioxide cathode, and an ammonium chloride solution for the electrolyte. While the electrolyte in the Leclanché cell was still a liquid, the battery's chemistry proved to be an important step for the invention of the dry cell.

Carl Gassner figured out how to create an electrolyte paste out of ammonium chloride and Plaster of Paris. He patented the new "dry cell" battery in 1886 in Germany.

These new dry cells, commonly called "zinc-carbon batteries," were massed produced and proved hugely popular until the late 1950s. While carbon is not used in the chemical reaction, it performs an important role as an electrical conductor in the zinc-carbon battery.

-> 3V zinc-carbon battery from the 1960s (Image courtesy of PhFabre of Wikimedia Commons) <- In the 1950s, Lewis Urry, Paul Marsal, and Karl Kordesch of the Union Carbide company (later known as "Eveready" and then "Energizer") replaced the ammonium chloride electrolyte with an alkaline substance, based on the battery chemistry formulated by Waldemar Jungner in 1899. Alkaline dry cell batteries could hold more energy than zinc carbon batteries of the same size and had a longer shelf life.

Alkaline batteries rose in popularity in the 1960s, overtook zinc-carbon batteries, and have since become the standard primary cell for consumer use.

-> Alkaline batteries come in many shapes and sizes (Image courtesy of Aney~commonswiki of Wikimedia Commons) <-

20th Century Rechargeable Batteries

In the 1970s, COMSAT developed the nickel-hydrogen battery for use in communication satellites. These batteries store hydrogen in a pressurized, gaseous form. Many man-made satellites, like the International Space Station, still rely on nickel-hydrogen batteries.

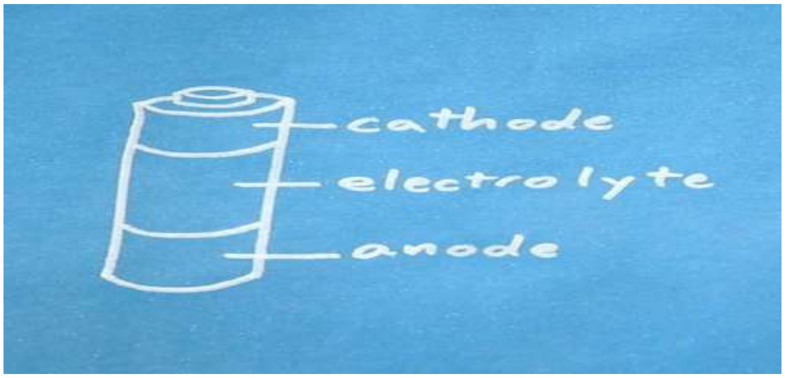
The research of several companies since the late 1960s resulted in the creation of the nickel-metal hydride (NiMH) battery. NiMH batteries were released to the consumer market in 1989, and provided a smaller, cheaper alternative to the rechargeable nickel-hydrogen cells.

Asahi Chemical of Japan built the first lithium-ion battery in 1985, and Sony created the first commercial lithium-ion battery in 1991. In the late 1990s, a soft, flexible casing was created for lithium-ion batteries and gave rise to the "lithium polymer" or "LiPo" battery.

The chemical reactions in the lithium polymer battery are essentially the same as those in the lithium-ion battery. Obviously, many more battery chemistries have been invented, manufactured, and become obsolete. If you would like to read more about modern, popular battery technologies, check out our Battery Technologies tutorial.

Components

Batteries are made up of three basic components: an **anode**, a **cathode**, and an **electrolyte**. A **separator** is often used to prevent the anode and cathode from touching, if the electrolyte is not sufficient. In order to store these components, batteries usually have some kind of **casing**.



OK, most batteries are not actually divided up in three equal sections, but you get the idea. A better cross-section of an alkaline cell can be found on Wikipedia.

Both the anode and cathode are types of **electrodes**. Electrodes are conductors through which electricity enters or leaves a component in a circuit.

Anode

Electrons flow out from the anode in a device connected to a circuit. This means that conventional "current" flows into an anode.

Fig: On batteries, the anode is marked as the negative (-) terminal

In a battery, the chemical reaction between the anode and electrolyte causes a build up of electrons in the anode. These electrons want to move to the cathode, but cannot pass through the electrolyte or separator.

Cathode

Electrons flow into the cathode in a device connected to a circuit. This means that conventional "current" flows out from a cathode.

Fig: On batteries, the cathode is marked as the positive (+) terminal

In batteries, the chemical reaction in or around the cathode uses the electrons produced in the anode. The only way for the electrons to get to the cathode is through a circuit, external to the battery.

Electrolyte

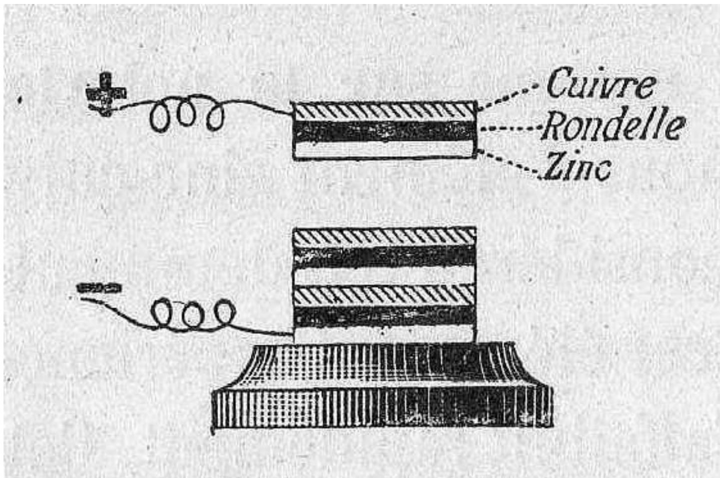
The electrolyte is the substance, often a liquid or gel, that is capable of transporting ions between the chemical reactions that happen at the anode and cathode. The electrolyte also inhibits the flow of electrons between the anode and cathode so that the electrons more easily flow through the external circuit rather than through the electrolyte.

-> Alkaline batteries can leak their electrolyte, potassium hydroxide, if subjected to high heat or reverse voltage (Image courtesy of Wiliam Davies of Wikimedia Commons)

<- The electrolyte is crucial in the operation of a battery. Because electrons cannot pass through it, they are forced to travel through electrical conductors in the form of a circuit that connect the anode to the cathode.

Separator

Separators are porous materials that prevent the anode and cathode from touching, which would cause a short circuit in the battery. Separators can be made from a variety of materials, including cotton, nylon, polyester, cardboard, and synthetic polymer films. Separators do not chemically react with either the anode, cathode, or electrolyte.



The voltaic pile used cloth or cardboard (separator) soaked in brine (electrolyte) to keep the electrodes apart. Ions in the electrolyte can be positively charged, negatively charged, and can come in a variety of sizes. Special separators can be manufactured that allow some ions to pass but not others.

Casing

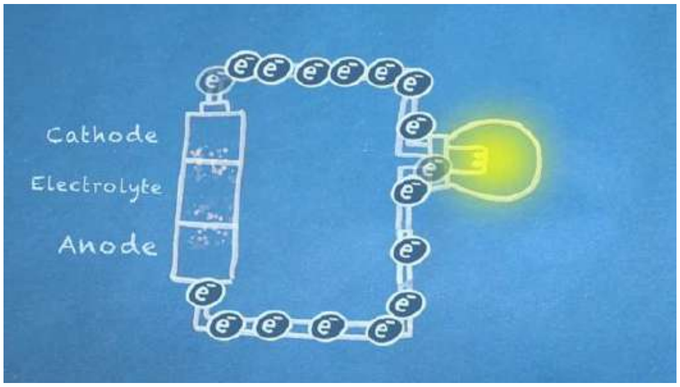
Most batteries need a way to contain their chemical components. Casings, otherwise known as "housings" or "shells," are simply mechanical structures meant to hold the battery's internals.

Fig :This lead-acid battery has a plastic casing

Battery casings can be made of almost anything: plastic, steel, soft polymer laminate pouches, and so on. Some batteries use a conducting steel casing that is electrically connected to one of the electrodes. In the case of the common AA alkaline cell, the steel casing is connected to the cathode.

Operation

Batteries generally require several chemical reactions in order to operate. At least one reaction occurs in or around the anode and one or more reactions occur in or around the cathode. In all cases, the reaction at the anode produces extra electrons in a process called **oxidation**, and the reaction at the cathode uses the extra electrons during a process known as **reduction**.



When the switch is closed, the circuit is complete, and electrons can flow from the anode to the cathode. These electrons enable the chemical reations at the anode and cathode.

In essence, we are separating a certain kind of chemical reaction, a reduction-oxidation reaction or redox reaction, into two separate parts. Redox reactions occur when electrons are transferred between chemicals. We can harness the movement of electrons in this reaction to flow outside the battery to power our circuit.

Anode Oxidation

This first part of the redox reaction, oxidation, occurs between the anode and electrolyte, and it produces electrons (marked as e^-).

Some oxidation reactions produce ions, such as in a lithium-ion battery. In other chemistries, the reaction consumes ions, like in the common alkaline battery. In either case, ions are able to flow freely through the electrolyte where electrons cannot.

Cathode Reduction

The other half of the redox reaction, reduction, occurs in or near the cathode. Electrons produced by the oxidation reaction are consumed during reduction.

In some cases, like lithium-ion batteries, positively charged lithium ions produced during the oxidation reaction are consumed during reduction. In other cases, like alkaline batteries, negatively charged ions are produced during reduction.

Electron Flow

In most batteries, some or all of the chemical reactions can occur even when the battery is not connected to a circuit. These reactions can impact a battery's shelf life.

For the most part, the reactions will only occur at full force when an electrically conductive circuit is completed between the anode and cathode. The less resistance between the anode and cathode, the more electrons are allowed to flow, and the quicker the chemical reactions occur.

Solar panel

The term **solar panel** is used colloquially for a photo-voltaic **(PV) module**.

A PV module is an assembly of photo-voltaic cells mounted in a frame work for installation. Photo-voltaic cells use sunlight as a source of energy and generate direct current electricity. A collection of PV modules is called a PV Panel, and a system of Panels is an Array. Arrays of a photovoltaic system supply solar electricity to electrical equipment.

The most common application of solar energy collection outside agriculture is solar water heating systems.[1]

Photovoltaic modules use light energy (photons) from the Sun to generate electricity through the photovoltaic effect. Most modules use wafer-based crystalline silicon cells or thin-film cells. The structural (load carrying) member of a module can be either the top layer or the back layer. Cells must be protected from mechanical damage and moisture. Most modules are rigid, but semi-flexible ones based on thin-film cells are also available. The cells are connected electrically in series, one to another to a desired voltage, and then in parallel to increase amperage. The wattage of the module is the mathematical product of the voltage and the amperage of the module.

A PV junction box is attached to the back of the solar panel and functions as its output interface. External connections for most photovoltaic modules use MC4 connectors to facilitate easy weatherproof connections to the rest of the system. A USB power interface can also be used.

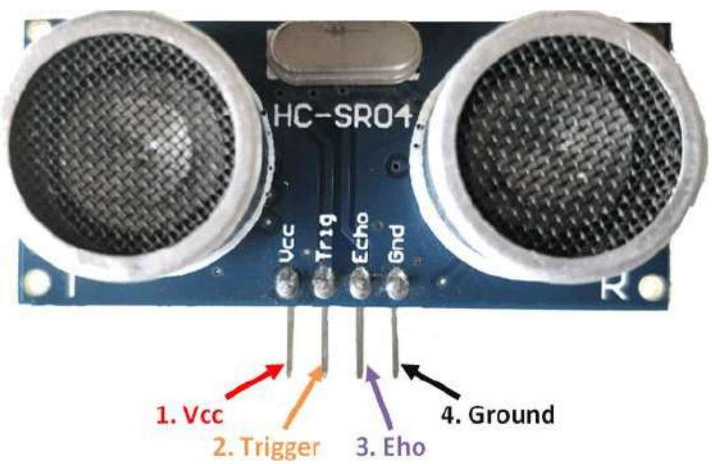
Module electrical connections are made in series to achieve a desired output voltage or in parallel to provide a desired current capability (amperes) of the solar panel or the PV system. The conducting wires that take the current off the modules are sized according to the ampacity and may contain silver, copper or other non-magnetic conductive transition metals. Bypass diodes may be incorporated or used externally, in case of partial module shading, to maximize the output of module sections still illuminated.

Some special solar PV modules include concentrators in which light is focused by lenses or mirrors onto smaller cells. This enables the use of cells with a high cost per unit area (such as gallium arsenide) in a cost-effective way.

Solar panels also use metal frames consisting of racking components, brackets, reflector shapes, and troughs to better support the panel structure.[2]

Ultrasonic sensor

HC-SR04 Ultrasonic Sensor



Ultrasonic Sensor HC SR04

Ultrasonic Sensor Pin Configuration

Pin Number	Pin Name	Description
1	Vcc	The Vcc pin powers the sensor, typically with +5V
2	Trigger	Trigger pin is an Input pin. This pin has to be kept high for 10us to initialize measurement by sending US wave.
3	Echo	Echo pin is an Output pin. This pin goes high for a period of time which will be equal to the time taken for the US wave to return back to the sensor.
4	Ground	This pin is connected to the Ground of the system.

HC-SR04 Sensor Features

- Operating voltage: +5V
- Theoretical Measuring Distance: 2cm to 450cm
- Practical Measuring Distance: 2cm to 80cm
- Accuracy: 3mm
- Measuring angle covered: <15°
- Operating Current: <15mA
- Operating Frequency: 40Hz

HC-SR04 Ultrasonic Sensor - Working

As shown above the **HC-SR04 Ultrasonic (US) sensor** is a 4 pin module, whose pin names are Vcc, Trigger, Echo and Ground respectively. This sensor is a very popular sensor used in many applications where measuring distance or sensing objects are required. The module has two eyes like projects in the front which forms the Ultrasonic transmitter and Receiver. The sensor works with the simple high school formula that

Distance = Speed × Time

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below

Now, to calculate the distance using the above formulae, we should know the Speed and time. Since we are using the Ultrasonic wave we know the universal speed of US wave at room conditions which is 330m/s. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken. Now simply calculate the distance using a microcontroller or microprocessor.

How to use the HC-SR04 Ultrasonic Sensor

HC-SR04 distance sensor is commonly used with both microcontroller and microprocessor platforms like Arduino, ARM, PIC, Raspberry Pie etc. The following guide is universally since it has to be followed irrespective of the type of computational device used.

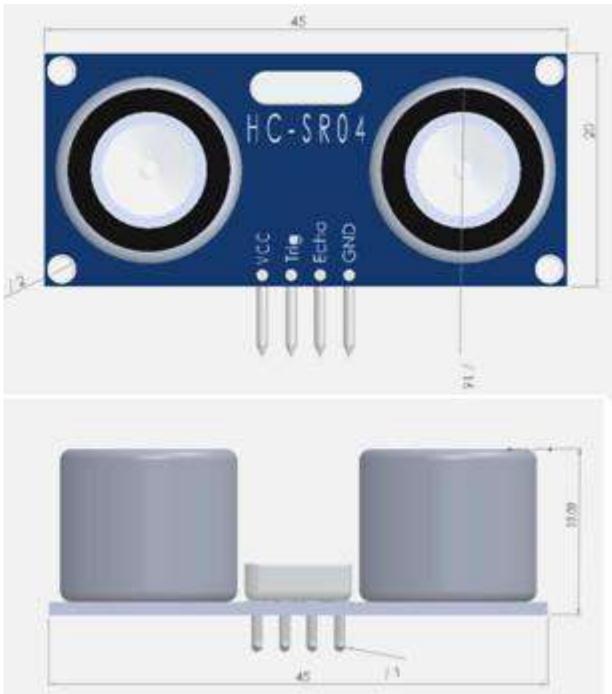
Power the Sensor using a regulated +5V through the Vcc ad Ground pins of the sensor. The current consumed by the sensor is less than 15mA and hence can be directly powered by the on board 5V pins (If available). The Trigger and the Echo pins are both I/O pins and hence they can be connected to I/O pins of the microcontroller. To start the measurement, the trigger pin has to be made high for 10uS and then turned off. This action will trigger an ultrasonic wave at frequency of 40Hz from the transmitter and the receiver will wait for the wave to return. Once the wave is returned after it getting reflected by any object the Echo pin goes high for a particular amount of time which will be equal to the time taken for the wave to return back to the sensor.

The amount of time during which the Echo pin stays high is measured by the MCU/MPU as it gives the information about the time taken for the wave to return back to the Sensor. Using this information the distance is measured as explained in the above heading.

Applications

- Used to avoid and detect obstacles with robots like biped robot, obstacle avoider robot, path finding robot etc.
- Used to measure the distance within a wide range of 2cm to 400cm
- Can be used to map the objects surrounding the sensor by rotating it
- Depth of certain places like wells, pits etc can be measured since the waves can penetrate through water

2D model of the component



Motor

Motor is a device that creates motion, not an engine; it usually refers to either an electrical motor or an internal combustion engine.

It may also refer to:

- Electric motor, a machine that converts electricity into a mechanical motion
    - AC motor, an electric motor that is driven by alternating current
        - Synchronous motor, an alternating current motor distinguished by a rotor spinning with coils passing magnets at the same rate as the alternating current and resulting magnetic field which drives it

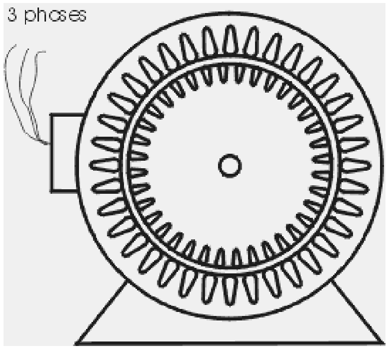
    - Induction motor, also called a squirrel-cage motor, a type of asynchronous alternating current motor where power is supplied to the rotating device by means of electromagnetic induction
- DC motor, an electric motor that runs on direct current electricity
    - Brushed DC electric motor, an internally commutated electric motor designed to be run from a direct current power source
    - Brushless DC motor, a synchronous electric motor which is powered by direct current electricity and has an electronically controlled commutation system, instead of a mechanical commutation system based on brushes
- Electrostatic motor, a type of electric motor based on the attraction and repulsion of electric charge
- Servo motor, an electric motor that operates a servo, commonly used in robotics
- Internal fan-cooled electric motor, an electric motor that is self-cooled by a fan, typically used for motors with a high energy density

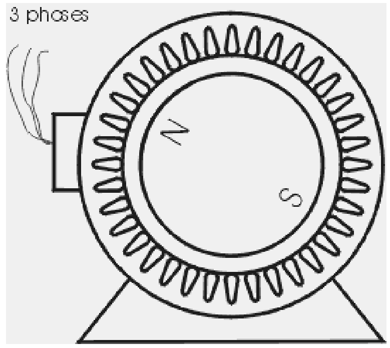
TYPES OF MOTORS

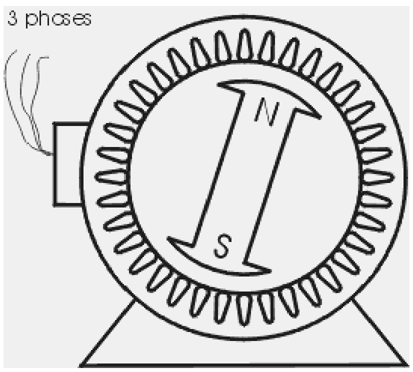
Industrial motors come in a variety of basic types. These variations are suitable for many different applications. Naturally, some types of motors are more suited for certain applications than other motor types are. This document will hopefully give some guidance in selecting these motors.

AC Motors

The most common and simple industrial motor is the three phase AC induction motor, sometimes known as the "squirrel cage" motor. Substantial information can be found about any motor by checking its (nameplate).







Advantages

- Simple Design
- Low Cost
- Reliable Operation
- Easily Found Replacements
- Variety of Mounting Styles
- Many Different Environmental Enclosures

Simple Design

The simple design of the AC motor -- simply a series of three windings in the exterior (stator) section with a simple rotating section (rotor). The changing field caused by the 50 or 60 Hertz AC line voltage causes the rotor to rotate around the axis of the motor.

The speed of the AC motor depends only on three variables:

1. The fixed number of winding sets (known as poles) built into the motor, which determines the motor's base speed.
2. The frequency of the AC line voltage. Variable speed drives change this frequency to change the speed of the motor.
3. The amount of torque loading on the motor, which causes slip.

Low Cost

The AC motor has the advantage of being the lowest cost motor for applications requiring more than about 1/2 hp (325 watts) of power. This is due to the simple design of the motor. For this reason, AC motors are overwhelmingly preferred for fixed speed applications in industrial applications and for commercial and domestic applications where AC line power can be easily attached. Over 90% of all motors are AC induction motors. They are found in air conditioners, washers, dryers, industrial machinery, fans, blowers, vacuum cleaners, and many, many other applications.

Reliable Operation

The simple design of the AC motor results in extremely reliable, low maintenance operation. Unlike the DC motor, there are no brushes to replace. If run in the appropriate environment for its enclosure, the AC motor can expect to need new bearings after several years of operation. If the application is well designed, an AC motor may not need new bearings for more than a decade.

Easily Found Replacements

The wide use of the AC motor has resulted in easily found replacements. Many manufacturers adhere to either European (metric) or American (NEMA) standards. (For Replacement Motors)

Variety of Mounting Styles

AC Motors are available in many different mounting styles such as:

- Foot Mount

- C-Face
- Large Flange
- Vertical
- Specialty

DC Motors

The brushed DC motor is one of the earliest motor designs. Today, it is the motor of choice in the majority of variable speed and torque control applications.

Advantages

- Easy to understand design
- Easy to control speed
- Easy to control torque
- Simple, cheap drive design

Easy to understand design

The design of the brushed DC motor is quite simple. A permanent magnetic field is created in the stator by either of two means:

- Permanent magnets
- Electro-magnetic windings

If the field is created by permanent magnets, the motor is said to be a "permanent magnet DC motor" (PMDC). If created by electromagnetic windings, the motor is often said to be a "shunt wound DC motor" (SWDC). Today, because of cost-effectiveness and reliability, the PMDC motor is the motor of choice for applications involving fractional horsepower DC motors, as well as most applications up to about three horsepower.

At five horsepower and greater, various forms of the shunt wound DC motor are most commonly used. This is because the electromagnetic windings are more cost effective than permanent magnets in this power range.

Caution: If a DC motor suffers a loss of field (if for example, the field power connections are broken), the DC motor will immediately begin to accelerate to the top speed which the loading will allow. This can result in the motor flying apart if the motor is lightly loaded. The possible loss of field must be accounted for, particularly with shunt wound DC motors.

Opposing the stator field is the armature field, which is generated by a changing electromagnetic flux coming from windings located on the rotor. The magnetic poles of the armature field will attempt to line up with the opposite magnetic poles generated by the stator field. If we stopped the design at this point, the motor would spin until the poles were opposite one another, settle into place, and then stop -- which would make a pretty useless motor!

However, we are smarter than that. The section of the rotor where the electricity enters the rotor windings is called the commutator. The electricity is carried between the rotor and the stator by conductive graphite-copper brushes (mounted on the rotor) which contact rings on stator. Imagine power is supplied:

The motor rotates toward the pole alignment point. Just as the motor would get to this point, the brushes jump across a gap in the stator rings. Momentum carries the motor forward over this gap. When the brushes get to the other side of the gap, they contact the stator rings again and -- the polarity of the voltage is reversed in this set of rings! The motor begins accelerating again, this time trying to get to the opposite set of poles. (The momentum has carried the motor past the original pole alignment point.) This continues as the motor rotates.

In most DC motors, several sets of windings or permanent magnets are present to smooth out the motion.

Easy to control speed

Controlling the speed of a brushed DC motor is simple. The higher the armature voltage, the faster the rotation. This relationship is linear to the motor's maximum speed.

The maximum armature voltage which corresponds to a motor's rated speed (these motors are usually given a rated speed and a maximum speed, such as 1750/2000 rpm) are available in certain standard voltages, which roughly increase in conjuntion with horsepower. Thus, the smallest industrial motors are rated 90 VDC and 180 VDC. Larger units are rated at 250 VDC and sometimes higher.

Specialty motors for use in mobile applications are rated 12, 24, or 48 VDC. Other tiny motors may be rated 5 VDC.

Most industrial DC motors will operate reliably over a speed range of about 20:1 -- down to about 5-7% of base speed. This is much better performance than the comparible AC motor. This is partly due to the simplicity of control, but is also partly due to the fact that most industrial DC motors are designed with variable speed operation in mind, and have added heat dissipation features which allow lower operating speeds.

Easy to control torque

In a brushed DC motor, torque control is also simple, since output torque is proportional to current. If you limit the current, you have just limited the torque which the motor can achieve. This makes this motor ideal for delicate applications such as textile manufacturing.

Simple, cheap drive design

The result of this design is that variable speed or variable torque electronics are easy to design and manufacture. Varying the speed of a brushed DC motor requires little more than a large enough potentiometer. In practice, these have been replaced for all but sub-fractional horsepower applications by the SCR and PWM drives, which offer relatively precisely control voltage and current. Common DC drives are available at the low end (up to 2 horsepower) for under US$100 -- and sometimes under US$50 if precision is not important.

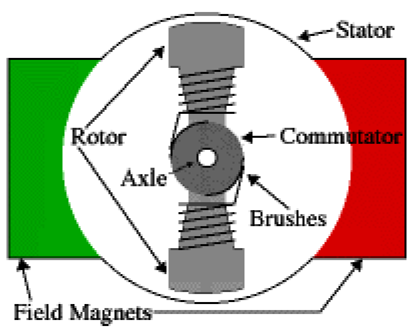
Large DC drives are available up to hundreds of horsepower. However, over about 10 horsepower careful consideration should be given to the price/performance tradeoffs with AC inverter systems, since the AC systems show a price advantage in the larger systems. (But they may not be capable of the application's performance requirments).

Disadvantages

- Expensive to produce
- Can't reliably control at lowest speeds
- Physically larger
- High maintenance
- Dust

WORKING OF DC MOTOR

In any electric motor, operation is based on simple electromagnetism. A current-carrying conductor generates a magnetic field; when this is then placed in an external magnetic field, it will experience a force proportional to the current in the conductor, and to the strength of the external magnetic field. As you are well aware of from playing with magnets as a kid, opposite (North and South) polarities attract, while like polarities (North and North, South and South) repel. The internal configuration of a DC motor is designed to harness the magnetic interaction between a current-carrying conductor and an external magnetic field to generate rotational motion.



Principle

When a rectangular coil carrying current is placed in a magnetic field, a torque acts on the coil which rotates it continuously.

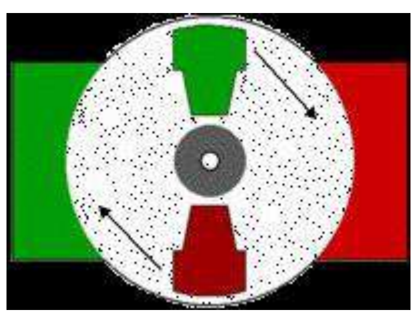
When the coil rotates, the shaft attached to it also rotates and thus it is able to do mechanical work.

Every DC motor has six basic parts -- axle, rotor (a.k.a., armature), stator, commutator, field magnet(s), and brushes. In most common DC motors (and all that BEAMers will see), the

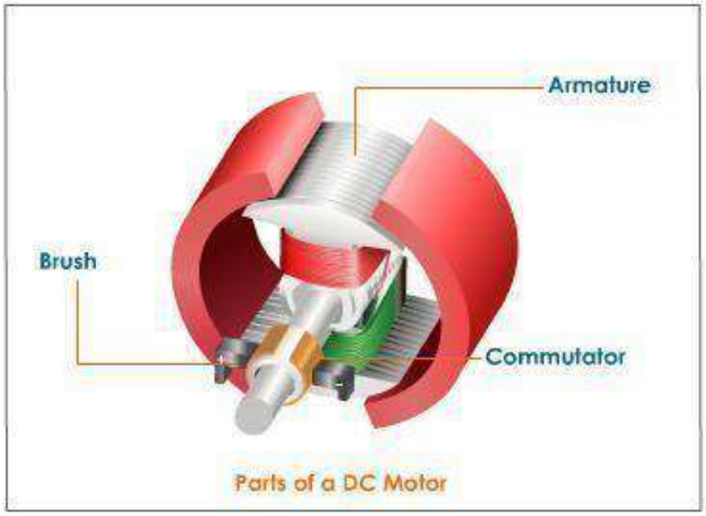
external magnetic field is produced by high-strength permanent magnets[1]. The stator is the stationary part of the motor -- this includes the motor casing, as well as two or more permanent magnet pole pieces. The rotor (together with the axle and attached commutator) rotate with respect to the stator. The rotor consists of windings (generally on a core), the windings being electrically connected to the commutator. The above diagram shows a common motor layout -- with the rotor inside the stator (field) magnets.

The geometry of the brushes, commentator contacts, and rotor windings are such that when power is applied, the polarities of the energized winding and the stator magnet(s) are misaligned, and the rotor will rotate until it is almost aligned with the stator's field magnets. As the rotor reaches alignment, the brushes move to the next commentator contacts, and energize the next winding. Given our example two-pole motor, the rotation reverses the direction of current through the rotor winding, leading to a "flip" of the rotor's magnetic field, driving it to continue rotating.

In real life, though, DC motors will always have more than two poles (three is a very common number). In particular, this avoids "dead spots" in the commutator. You can imagine how with our example two-pole motor, if the rotor is exactly at the middle of its rotation (perfectly aligned with the field magnets), it will get "stuck" there. Meanwhile, with a two-pole motor, there is a moment where the commutator shorts out the power supply (i.e., both brushes touch both commutator contacts simultaneously). This would be bad for the power supply, waste energy, and damage motor components as well. Yet another disadvantage of such a simple motor is that it would exhibit a high amount of torque "ripple" (the amount of torque it could produce is cyclic with the position of the rotor).



Construction and Working



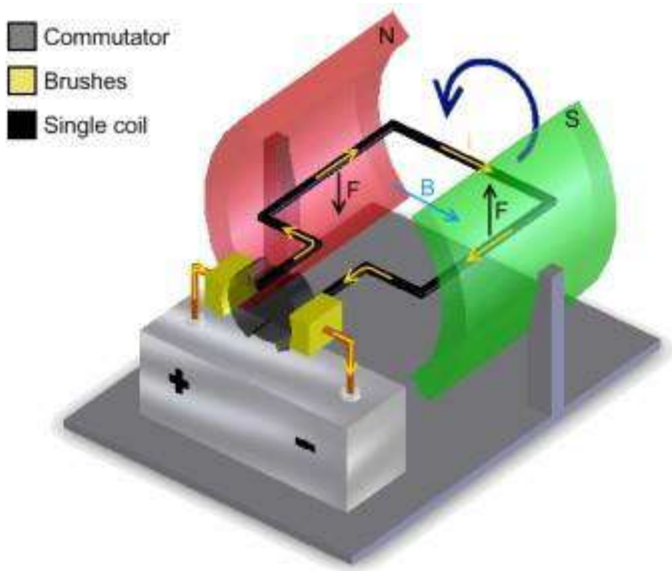
Parts of a DC Motor

Armature

A D.C. motor consists of a rectangular coil made of insulated copper wire wound on a soft iron core. This coil wound on the soft iron core forms the armature. The coil is mounted on an axle and is placed between the cylindrical concave poles of a magnet.

Commutator

A commutator is used to reverse the direction of flow of current. Commutator is a copper ring split into two parts C_1 and C_2. The split rings are insulated form each other and mounted on the axle of the motor. The two ends of the coil are soldered to these rings. They rotate along with the coil. Commutator rings are connected to a battery. The wires from the battery are not connected to the rings but to the brushes which are in contact with the rings.



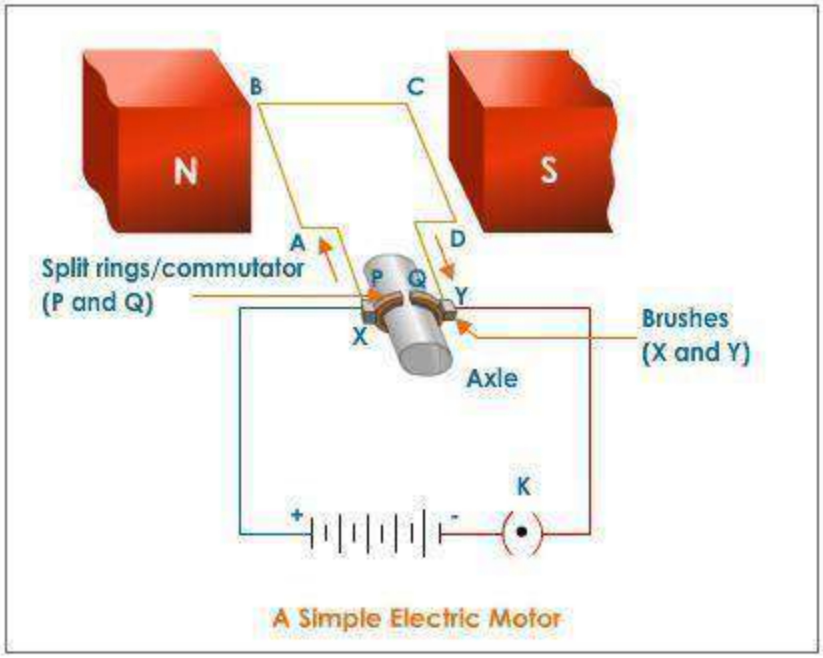
Brushes

Two small strips of carbon, known as brushes press slightly against the two split rings, and the split rings rotate between the brushes.

The carbon brushes are connected to a D.C. source.

Working of a DC Motor

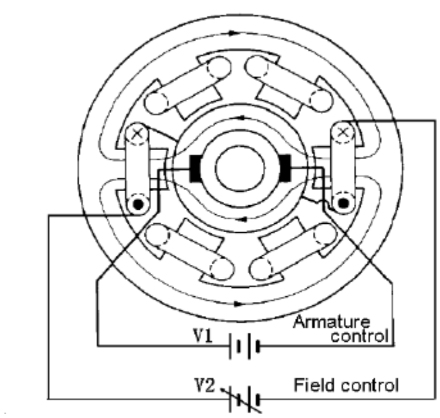
When the coil is powered, a magnetic field is generated around the armature. The left side of the armature is pushed away from the left magnet and drawn towards the right, causing rotation.

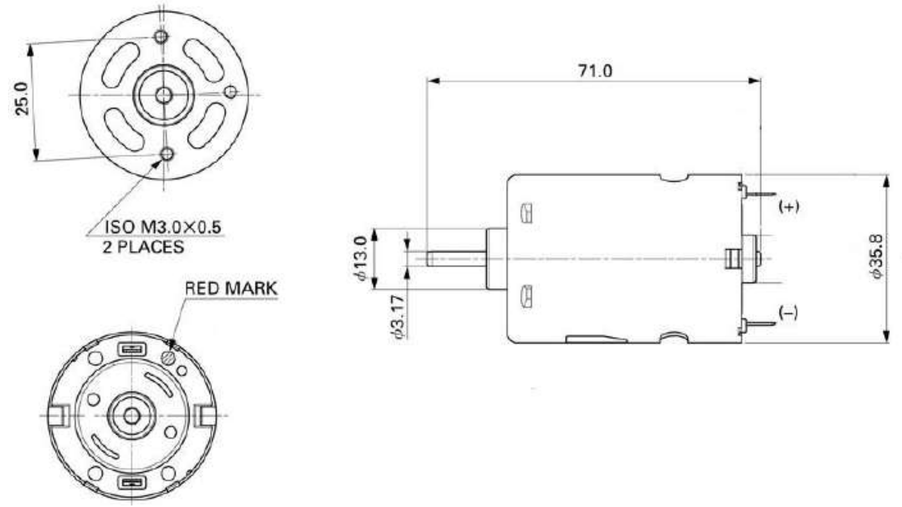


When the coil turns through 90^0, the brushes lose contact with the commutator and the current stops flowing through the coil.

However the coil keeps turning because of its own momentum.

Now when the coil turns through 180^0, the sides get interchanged. As a result the commutator ring C_1 is now in contact with brush B_2 and commutator ring C_2 is in contact with brush B_1. Therefore, the current continues to flow in the same direction.



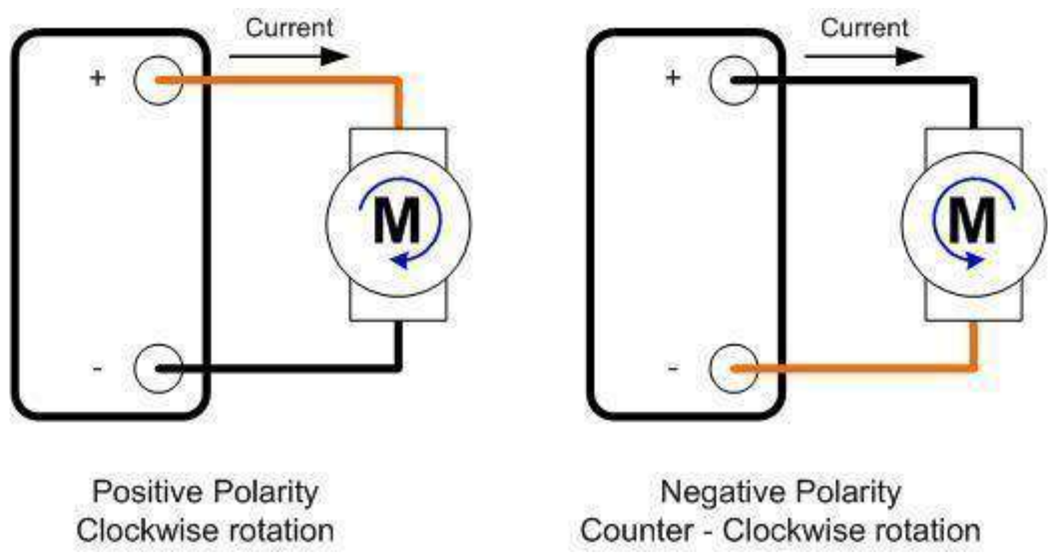


PARAMETERS OF THE DC MOTORS

1. Direction of rotation
2. Motor Speed
3. Motor Torque
4. Motor Start and Stop

Direction of Rotation

A DC Motor has two wires. We can call them the positive terminal and the negative terminal, although these are pretty much arbitrary names (unlike a battery where these polarities are vital and not to be mixed!). On a motor, we say that when the + wire is connected to + terminal on a power source, and the - wire is connected to the - terminal source on the same power source, the motor rotates clockwise (if you are looking towards the motor shaft). If you reverse the wire polarities so that each wire is connected to the opposing power supply terminal, then the motor rotates counter clockwise. Notice this is just an arbitrary selection and that some motor manufacturers could easily choose the opposing convention. As long as you know what rotation you get with one polarity, you can always connect in such a fashion that you get the direction that you want on a per polarity basis.



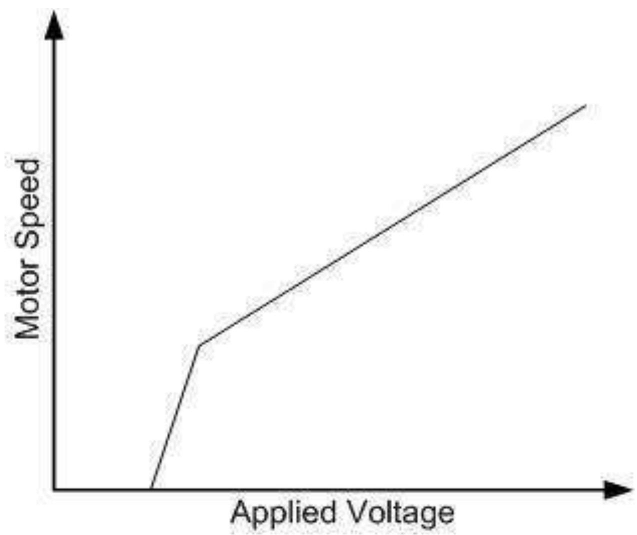
DC Motor Rotation vs Polarity

Facts:

- DC Motor rotation has nothing to do with the voltage magnitude or the current magnitude flowing through the motor.
- DC Motor rotation does have to do with the voltage polarity and the direction of the current flow.

DC Motor Speed

Whereas the voltage polarity controls DC motor rotation, voltage magnitude controls motor speed. Think of the voltage applied as a facilitator for the strengthening of the magnetic field. In other words, the higher the voltage, the quicker will the magnetic field
become strong. Remember that a DC motor has an electromagnet and a series of permanent magnets. The applied voltage generates a magnetic field on the electromagnet portion. This electromagnet field is made to oppose the permanent magnet field. If the electromagnet field is very strong, then both magnetic entities will try to repel each other from one side, as well as atract each other from the other side. The stronger the induced magnetic field, the quicker will this separation/attaction will try to take place. As a result, motor speed is directly proportional to applied voltage.



Motor Speed Curve

One aspect to have in mind is that the motor speed is not entirely lineal. Each motor will have their own voltage/speed curve. One thing I can guarantee from each motor is that at very low voltages, the motor will simply not move. This is because the magnetic field strength is not enough to overcome friction. Once friction is overcome, motor speed will start to increase as voltage increase.

The following video shows the concept of speed control and offers some ideas on how this can be achieved.

Motor Torque

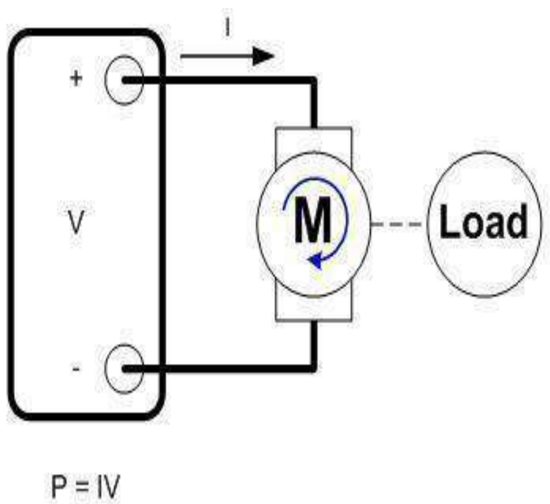
In the previous segment I kind of described speed as having to do with the strength of the magnetic field, but this is in reality misleading. Speed has to do with how fast the magnetic field is built and the attraction/repel forces are installed into the two magnetic structures. Motor strength, on the other hand, has to do with magnetic field strength. The stronger the electromagnet attracts the permanent magnet, the more force is exerted on the motor load.

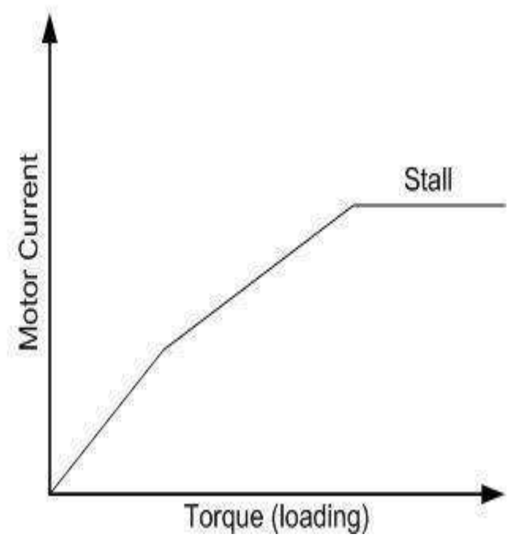
Per example, imagine a motor trying to lift 10 pounds of weight. This is a force that when multiplied by a distance (how much from the ground we are lifting the load) results in WORK. This WORK when exerted through a predetermined amount of time (for how long we are lifting the weight) gives us power. But whatever power came in, must come out as energy can not be created or destroyed. So that you know, the power that we are supplying to the motor is computed by

P = IV

Where P is power, I is motor current and V is motor voltage

Hence, if the voltage (motor speed) is maintained constant, how much load we are moving must come from the current. As you increase load (or torque requirements) current must also increase.





Motor Loading

One aspect about DC motors which we must not forget is that loading or increase of torque can not be infinite as there is a point in which the motor simply can not move. When this happens, we call this loading "Stalling Torque". At the same time this is the maximum amount of current the motor will see, and it is refer to Stalling Current. Stalling deserves a full chapter as this is a very important scenario that will define a great deal of the controller to be used. I promise I will later write a post on stalling and its intricacies.

Motor Start and Stop

You are already well versed on how to control the motor speed, the motor torque and the motor direction of rotation. But this is all fine and dandy as long as the motor is actually moving. How about starting it and stopping it? Are these trivial matters? Can we just ignore them or should we be careful about these aspects as well? You bet we should!

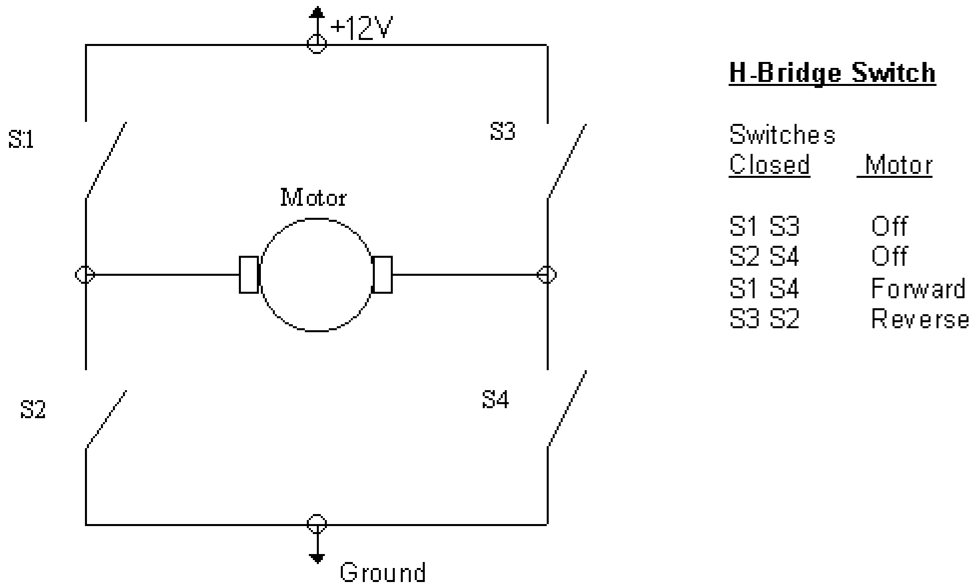
Starting a motor is a very hazardous moment for the system. Since you have an inductance whose energy storage capacity is basically empty, the motor will first act as an inductor. In a sense, it should not worry us too much because current can not change abruptly in an inductor, but the truth of the matter is that this is one of the instances in which you will see the highest currents flowing into the motor. The start is not necessarily bad for the motor itself as in fact the motor can easily take this Inrush Current. The power stage, on the other hand and if not properly designed for, may take a beating.

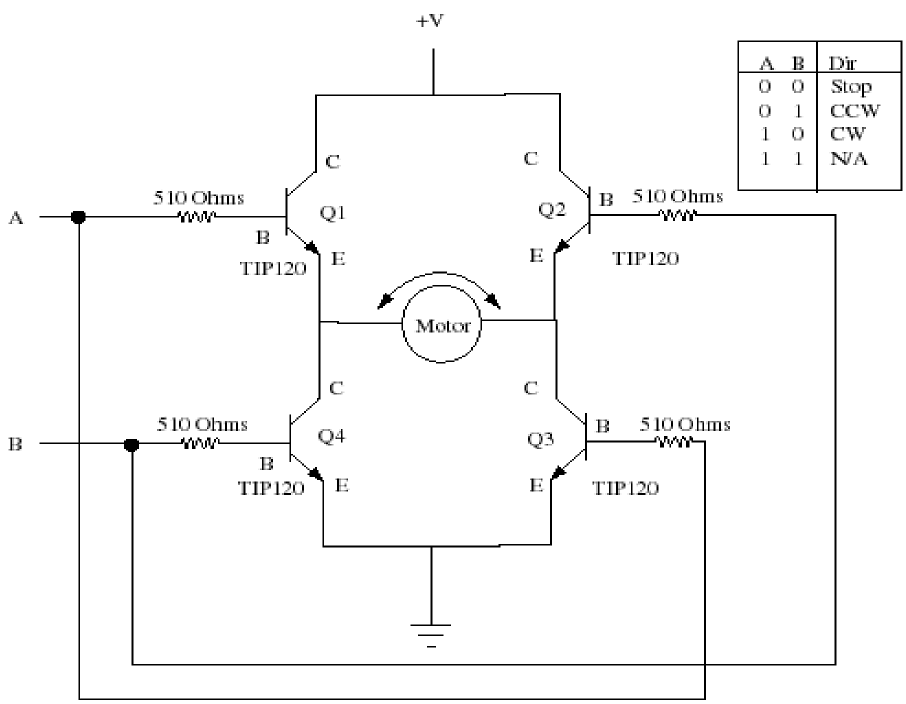
Once the motor has started, the motor current will go down from inrush levels to whatever load the motor is at. Per example, if the motor is moving a few gears, current will be proportional to that load and according to torque/current curves.

Stopping the motor is not as harsh as starting. In fact, stopping is pretty much a breeze. What we do need to concern ourselves is with how we want the motor to stop. Do we want it to coast down as energy is spent in the loop, or do we want the rotor to stop as fast as possible? If the later is the option, then we need braking. Braking is easily accomplished by shorting the motor outputs. The reason why the motor stops so fast is because as a short is applied to the motor terminals, the Back EMF is shorted. Because Back EMF is directly proportional to speed, making Back EMF = 0, also means making speed = 0.

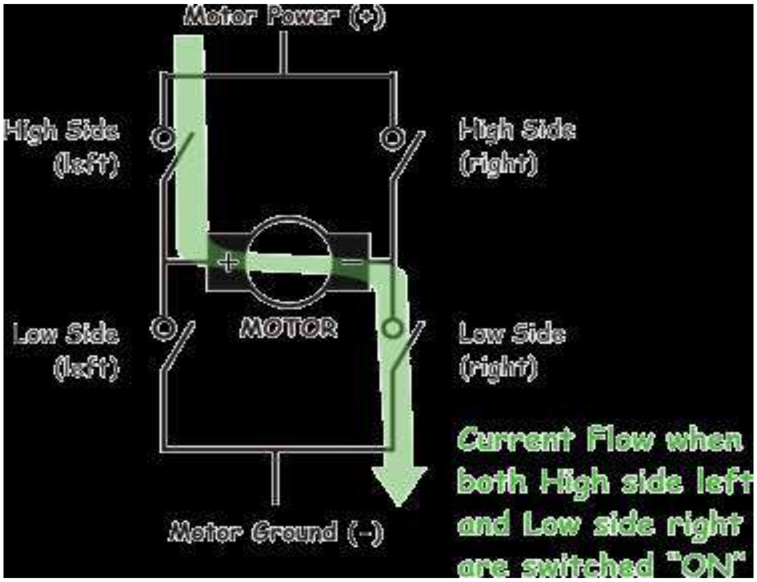
MOTORDRIVER CIRCUIT

The name "H-Bridge" is derived from the actual shape of the switching circuit which control the motion of the motor. It is also known as "Full Bridge". Basically there are four switching elements in the H-Bridge as shown in the figure below.





As you can see in the figure above there are four switching elements named as "High side left", "High side right", "Low side right", "Low side left". When these switches are turned on in pairs motor changes its direction accordingly. Like, if we switch on High side left and Low side right then motor rotate in forward direction, as current flows from Power supply through the motor coil goes to ground via switch low side right. This is shown in the figure below.



Similarly, when you switch on low side left and high side right, the current flows in opposite direction and motor rotates in backward direction. This is the basic working of H-Bridge. We can also make a small truth table according to the switching of H-Bridge explained above.

Truth Table

High Left	High Right	Low Left	Low Right	Description
On	Off	Off	On	Motor runs clockwise
Off	On	On	Off	Motor runs anti-clockwise
On	On	Off	Off	Motor stops or decelerates
Off	Off	On	On	Motor stops or decelerates

As already said, H-bridge can be made with the help of transistors as well as MOSFETs, the only thing is the power handling capacity of the circuit. If motors are needed to run with high current then lot of dissipation is there. So head sinks are needed to cool the circuit.

Now you might be thinking why i did not discuss the cases like High side left on and Low side left on or high side right on and low side right on. Clearly seen in the diagra, you don't want to burn your power supply by shorting them. So that is why those combinations are not discussed in the truth table.

L293D

L293D is basically a high current dual motor driver/controller Integrated Circuit (IC). It is able to drive load having current up to 1A at the voltage ranging from 4.5V to 36V. Motor driver usually act as current amplifier because they receive a low current signal as an input and provides high current signal at the output.

Motors usually operates on this higher current. L-293D has to builtin H-Bridge driver circuits and is able to control two DC motors at a time in both clockwise and counter clockwise direction. It has two enable pins and they should be kept high in order to control the motor. By changing the polarity of applied signal motor can be rotated in either clockwise or counter clockwise direction. If L 293D enable pin is high, its corresponding driver will provide the desired out. If the enable pin is low, there will be no output. L-293D has different features including internal ESD protection, large voltage supply range, large output current per channel, high noise immunity input etc. L 293D plays a vital role in electronics era and has several different applications e.g relay drivers, DC motor drivers, stepping motor drivers etc. The further detail about L 293D motor driver/controller will be given later in this tutorial.

Introduction to L293D

L293D is basically a motor driver or controller. It has two builtin H-bridge circuits which are able to control two DC motors simultaneously in both clockwise and counter clockwise direction. It acts as an current high amplifier because it take low current signal at its input and provides higher current signal at the output in order to drives different load e.g stepper motor & DC motors. Its features include large inpu voltage supply range, large output current high noise immunity input signals etc. Its common real life applications include stepping motor drivers, relay drivers, DC motor drivers etc. L-293D motor driver/controller is shown in the figure given below.

1. L293D Pins

- L-293D has sixteen (16) pins, having different individual functions.
- All of these sixteen pins along with their serial no, are given in the table shown below.

2. L293D Pin Functions

- L 293D each pin has different tasks to perform when they are in working condition.
- The tasks assigned to each pin are given in the table shown below.

L293D Pins	
Pin. No	Pin Name
1	Enable 1,2
2	Input 1
3	Output 1
4	GND
5	GND
6	Output 2
7	Input 2
8	Vcc2
9	Enable 3,4
10	Input 3
11	Output 3
12	GND
13	GND
14	Output put 4
15	Input 4
16	Vcc1

3. L293D Pinout

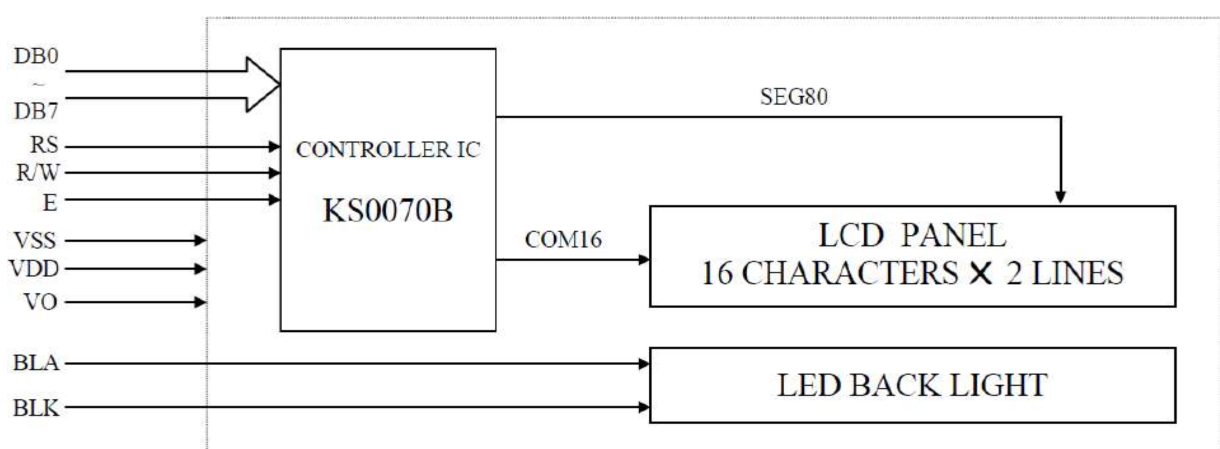
- Pinout diagram of any device presents the pins configuration through a completely labelled diagram.
- L293D pinout diagram is shown in the figure given below.

16 * 2 Alphanumeric LCD

Description

Liquid crystal display is very important device in embedded system. It offers high flexibility to user as he can display the required data on it. A liquid crystal display (LCD) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly. LCDs therefore need a light source and are classified as "passive" displays. Here the lcd has different memories to display data, those are discussed below.

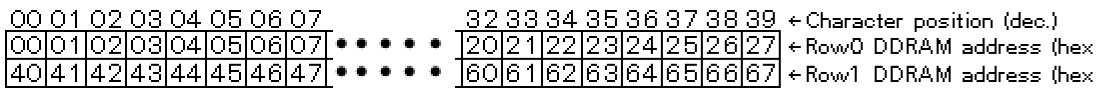
Block Diagram



Display Data RAM

Display data RAM (DDRAM) stores display data represented in 8-bit character codes. Its extended capacity is 80 X 8 bits, or 80 characters. The area in display data RAM (DDRAM) that is not used for display can be used as general data RAM. So whatever you send on the DDRAM is actually displayed on the LCD. For LCDs like 1x16, only 16 characters are visible, so whatever you write after 16 chars is written in DDRAM but is not visible to the user.

Figure below will show you the DDRAM addresses of 2 Line LCD.



DDRAM Address for 2 Line LCD

Character Generator ROM

Now you might be thinking that when you send an ascii value to DDRAM, how the character is displayed on LCD? so the answer is CGROM. The character generator ROM generates 5 x 8 dot or 5 x 10 dot character patterns from 8-bit character codes. It can generate 208 5 x 8 dot character patterns and 32 5 x 10 dot character patterns. Userdefined character patterns are also available by mask-programmed ROM.

Busy Flag

Busy Flag is an status indicator flag for LCD. When we send a command or data to the LCD for processing, this flag is set (i.e BF =1) and as soon as the instruction is executed successfully this flag is cleared (BF = 0). This is helpful in producing and exact ammount of delay for the LCD processing.

To read Busy Flag, the condition RS = 0 and R/W = 1 must be met and The MSB of the LCD data bus (D7) act as busy flag. When BF = 1 means LCD is busy and will not accept next command or data and BF = 0 means LCD is ready for the next command or data to process.

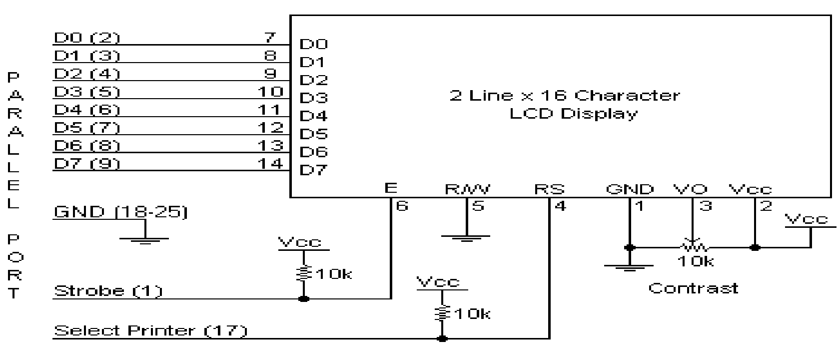
Instruction Register(IR) and Data Register(DR)

There are two 8-bit registers in HD44780 controller Instruction and Data register. Instruction register corresponds to the register where you send commands to LCD e.g LCD shift command, LCD clear, LCD address etc. and Data register is used for storing data which is to be displayed on LCD. When send the enable signal of the LCD is asserted, the data on the pins is latched in to the data register and data is then moved automatically to the DDRAM and hence is displayed on the LCD.
Data Register is not only used for sending data to DDRAM but also for CGRAM, the address where you want to send the data, is decided by the instruction you send to LCD.

16 x 2 Alphanumeric LCD Module Features

- Intelligent, with built-in Hitachi HD44780 compatible LCD controller and RAM providing simple interfacing
- 61 x 15.8 mm viewing area
- 5 x 7 dot matrix format for 2.96 x 5.56 mm characters, plus cursor line
- Can display 224 different symbols
- Low power consumption (1 mA typical)
- Powerful command set and user-produced characters
- TTL and CMOS compatible
- Connector for standard 0.1-pitch pin headers.

Schematic

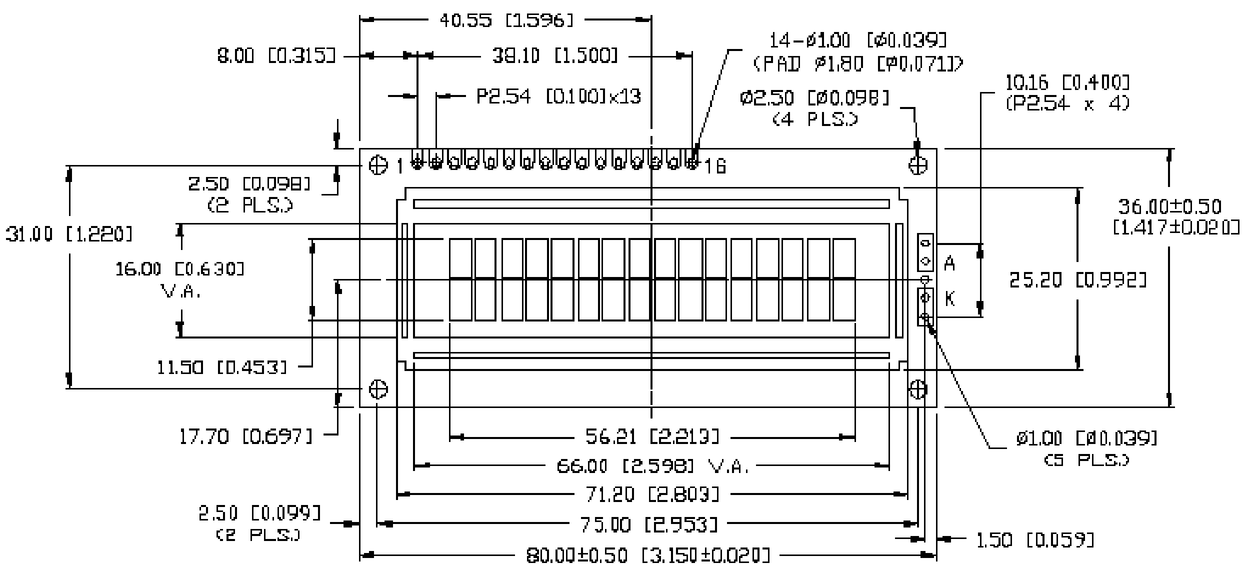


Specifications

Connector Pin Assignment:

Pin	*Symbol*	*Function*	*Pin*	*Symbol*	*Function*
14	DB7	Data Bus Line	6	E	Enable
13	DB6	Data Bus Line	5	R/W	Read/Write
12	DB5	Data Bus Line	4	RS	Register select input
11	DB4	Data Bus Line	3	Vcontrast	Contrast (0V for max contrast)
10	DB3	Data Bus Line	2	**GND (0V)**	Power supply
9	DB2	Data Bus Line	1	**Vcc +5V**	Power supply
8	DB1	Data Bus Line			
7	DB0	Data Bus Line			

Note1: Pin 1 is +5V and pin 2 is GND! This is different from most other HD44780 compatible models.
Note2: Pin 14 is marked with a “1” on the back of the PCB. Do not get confused by this.



Circuit Description

Above is the quite simple schematic. The LCD panel's Enable and Register Select is connected to the Control Port. The Control Port is an open collector / open drain output. While most Parallel Ports have internal pull-up resistors, there are a few which don't. Therefore by incorporating the two 10K external pull up resistors, the circuit is more portable for a wider range of computers, some of which may have no internal pull up resistors.

We make no effort to place the Data bus into reverse direction. Therefore we hard wire the *R/W* line of the LCD panel, into write mode. This will cause no bus conflicts on the data lines. As a result we cannot read back the LCD's internal Busy Flag which tells us if the LCD has accepted and finished processing the last instruction. This problem is overcome by inserting known delays into our program.

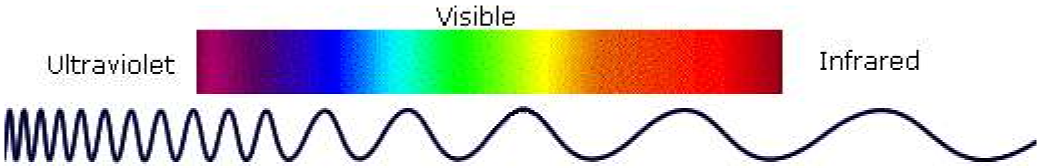
The 10k Potentiometer controls the contrast of the LCD panel. You can use a bench power supply set to 5v or use a onboard +5 regulator. Remember a few de-coupling capacitors, especially if you have trouble with the circuit working properly.The 2 line x 16 character LCD modules are available from a wide range of manufacturers and should all be compatible with the HD44780.

INFRARED TECHNOLOGY (IR)

Technically known as "infrared radiation", infrared light is part of the electromagnetic spectrum located just below the red portion of normal visible light – the opposite end to ultraviolet. Although invisible, infrared follows the same principles as regular light and can be reflected or pass through transparent objects, such as glass. Infrared remote controls use this invisible light as a form of communications between themselves and home theater equipment, all of which have infrared receivers positioned on the front. Essentially, each time you press a button on a remote, a small infrared diode at the front of the remote beams out pulses of light at high speed to all of your equipment. When the equipment recognizes the signal as its own, it responds to the command.

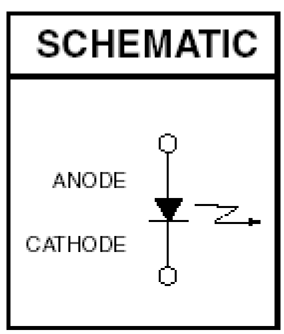
But much like a flashlight, infrared light can be focused or diffused, weak or strong. The type and number of emitters can affect the possible angles and range your remote control can be used from. Better remotes can be used up to thirty feet away and from almost any angle, while poorer remotes must be aimed carefully at the device being controlled.

The light our eyes see is but a small part of a broad spectrum of electromagnetic radiation. On the immediate high energy side of the visible spectrum lies the ultraviolet, and on the low energy side is the infrared. The portion of the infrared region most useful for analysis of organic compounds is not immediately adjacent to the visible spectrum, but is that having a wavelength range from 2,500 to 16,000 nm, with a corresponding frequency range from $1.9*10^{13}$ to $1.2*10^{14}$ Hz.(From http://hyperphysics.phy-astr.gsu.edu/hbase/ems3.html : the frequency of infrared ranges from 0.003 - 4 x 10^{14} Hz or about 300 gigahertz to 400 terahertz.).



Infrared imaging is used extensively for both military and civilian purposes. Military applications include target acquisition, surveillance, night vision, homing and tracking. Non-military uses include thermal efficiency analysis, remote temperature sensing, short-ranged wireless communication, spectroscopy, and weather forecasting. Infrared astronomy uses sensor-equipped telescopes to penetrate dusty regions of space, such as molecular clouds; detect cool objects such as planets, and to view highly red-shifted objects from the early days of the universe

IR LED QED234:



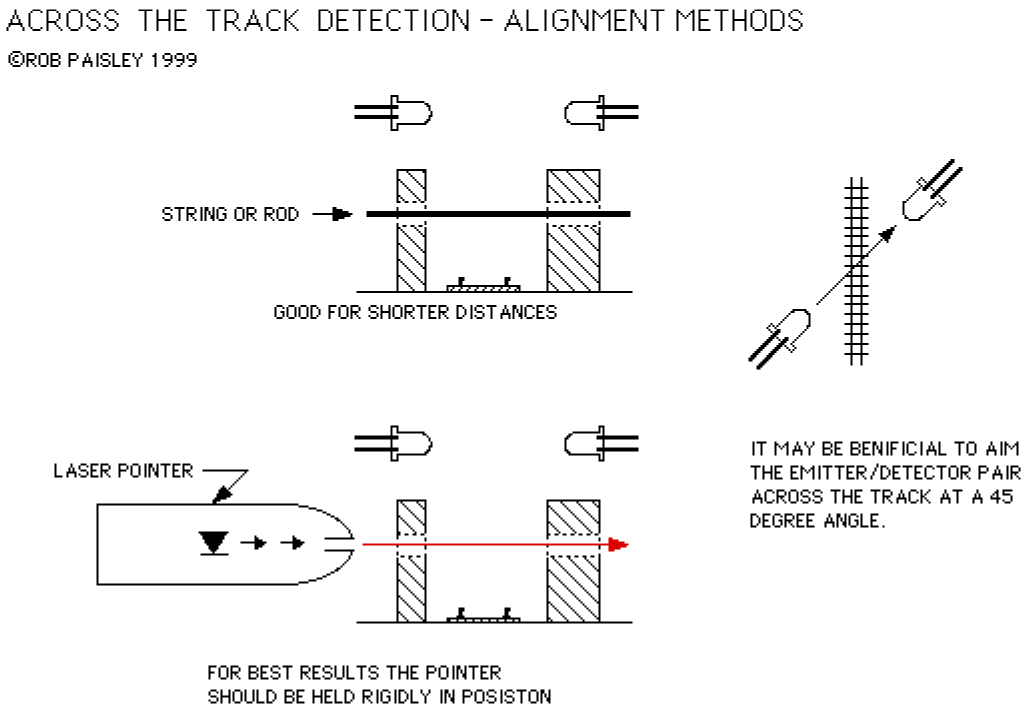
FEATURES:

- Wave length is 940 nm
- Chip material =GaAs with AlGaAs window
- Package type: T-1 3/4 (5mm lens diameter)
- Matched Photo sensor: QSD122/123/124
- Medium Emission Angle, 40°
- High Output Power
- Package material and color: Clear, untainted, plastic
- Ideal for remote control applications

Emitter/Detector Alignment:

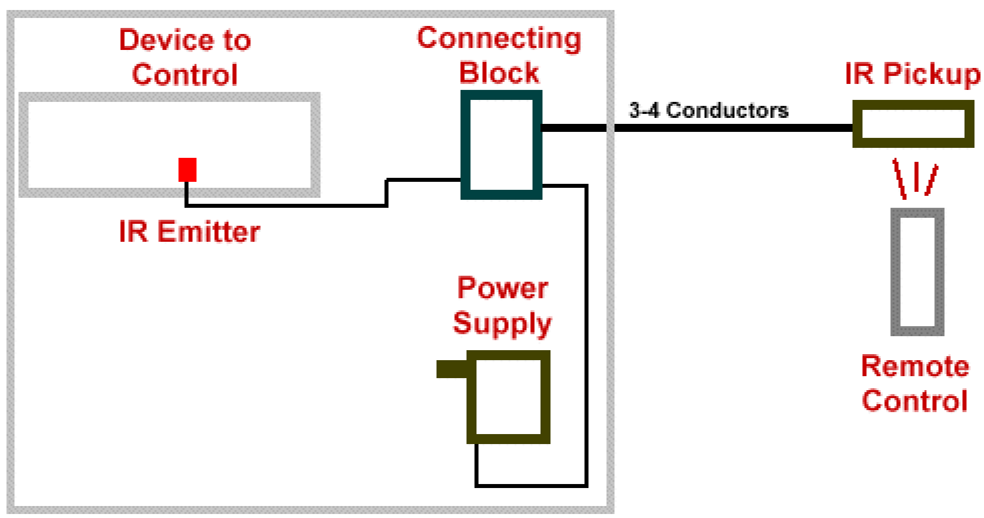
Good alignment of the emitter and detector is important for good operation, especially if the gap is large. This can be done with a piece of string stretched between and in line with LED and phototransistor. A length of dowel or stiff wire could be used to set the alignment. Another method that can be used for longer distances is a laser pointer shone through one of the mounting holes.

For best results the height of the "beam" should be at coupler height and at an angle across the tracks. The emitter could also be mounted above the track with the phototransistor placed between the rails in locations such as hidden yards. Placing the emitter and detector at an angle would again be helpful.



Emitter/Detector Alignment Methods

<u>A sample infrared remote control setup</u>:



A Simple Infrared Remote Control Setup

Infrared Receiver (Pickup)

This device picks up the infrared signal from your remote control just like a TV or VCR. It encodes the infrared signal into a signal suitable for transmission. Receivers must be located in the room you wish to use the remote control. The wire from the receiver to the connecting block needs at least three available conductors and can be several hundred feet long. Both quad wire and category 5wire work fine. See our IR receivers here.

Connecting Block

This is simply a place for all the parts to plug in or connect to. Connecting blocks are usually classified based on the number of outputs (how many IR emitters can connect to the block) Amplified connecting blocks can generally support more outputs. All connecting blocks can support many IR receivers wired in parallel. Connecting blocks are usually located near the equipment that is to be controlled, along with the power supply and emitters. See our connecting blocks here.

Infrared Emitters

IR Emitters generally "stick" onto the front of the device you want to control. Therefore you need one emitter for each device. "Dual" emitters have two emitters and one plug, so they only take up one jack of the connecting block. "Blink" emitters blink visibly as well as infrared, so they are easier to troubleshoot. All emitters come with long cords and extra double-stick tape. "Blast" style emitters, where one emitter blinks into several devices, are usually less reliable but can be used when the environment is tightly controlled and

Applications:

- Infrared Filters
- Night vision
- Thermograph
- Other imaging
- Tracking
- Heating
- Communications
- Spectroscopy
- Meteorology
- Climatology
- Astronomy
- Art history
- Biological systems
- Photobiomodulation
- Health hazard

CHAPTER -6

SOFTWARE EXPLANATION

6.1 SOFTWARE EXPLANATION:

Software Requirements

- Proteus simulation
- Arduino software
- Programming language

6.1.1 Arduino software:

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Over the years Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals

- has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike. Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open- source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Why Arduino?

Thanks to its simple and accessible user experience, Arduino has been used in thousands of different projects and applications. The Arduino software is easy-to-use for beginners, yet flexible enough for advanced users. It runs on Mac, Windows, and Linux. Teachers and students use it to build low cost scientific instruments, to prove chemistry and physics principles, or to get started with programming and robotics. Designers and architects build interactive prototypes, musicians and artists use it for installations and to experiment with new musical instruments. Makers, of course, use it to build many of the projects exhibited at the Maker Faire, for example. Arduino is a key tool to learn new things. Anyone - children, hobbyists, artists, programmers - can start tinkering just following the step by step instructions of a kit, or sharing ideas online with other members of the Arduino community. There are many other microcontrollers and microcontroller platforms available for physical computing. Parallax Basic Stamp, Net media's BX-24, Phidgets, MIT's Handyboard, and many others offer similar functionality. All of these tools take the messy details of microcontroller programming and wrap it up in an easy-to-use package. Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

- Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than$50
- Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.
- Simple, clear programming environment - The Arduino Software (IDE) is easy-to-use for beginners, yet flexible enough for advanced users to take advantage of as well. For teachers, it's conveniently based on the Processing programming environment, so students learning to program in that

environment will be familiar with how the Arduino IDE works.

- Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.
- Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers c an make their own version
- Of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money
- Getting Started with Arduino and Genuino products:-

Install the Arduino Software (IDE) on Windows PCs-

…This document explains how to install the Arduino Software (IDE) on Windows machines.

✓ Download the Arduino Software(IDE)

✓ Proceed with board specific instructions.

How to Download the Arduino Software (IDE):

Get the latest version from the download page. You can choose between the Installer (.exe) and the Zip packages. We suggest you use the first one that installs directly everything you need to use the Arduino Software (IDE), including the drivers. With the Zip package you need to install the drivers manually.

When the download finishes, proceed with the installation and please allow the driver installation process when you get a warning from the operating system.

Installation:

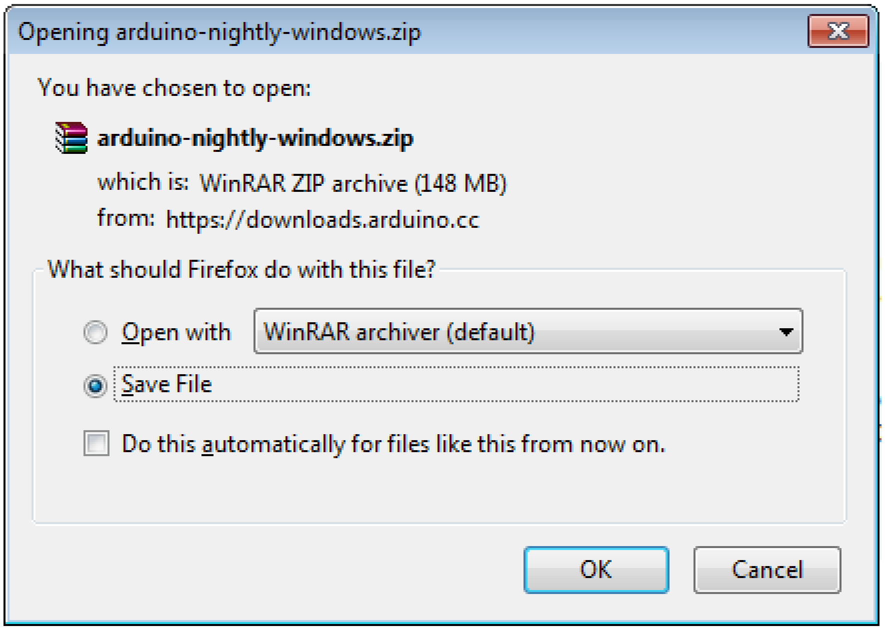
In this section, we will learn in easy steps, how to set up the Arduino IDE on our computer and prepare the board to receive the program via USB cable.

Step 1 − First you must have your Arduino board (you can choose your favorite board) and a USB cable. In case you use Arduino UNO, Arduino Duemilanove, Nano, Arduino Mega 2560, or Diecimila, you will need a standard USB cable (A plug to B plug), the kind you would connect to a USB printer as shown in the following image.

In case you use Arduino Nano, you will need an A to Mini-B cable instead as shown in the following image.

Step 2 − Download Arduino IDE Software.

You can get different versions of Arduino IDE from the Download page on the Arduino Official website. You must select your software, which is compatible with your operating system (Windows, IOS, or Linux). After your file download is complete, unzip the file.



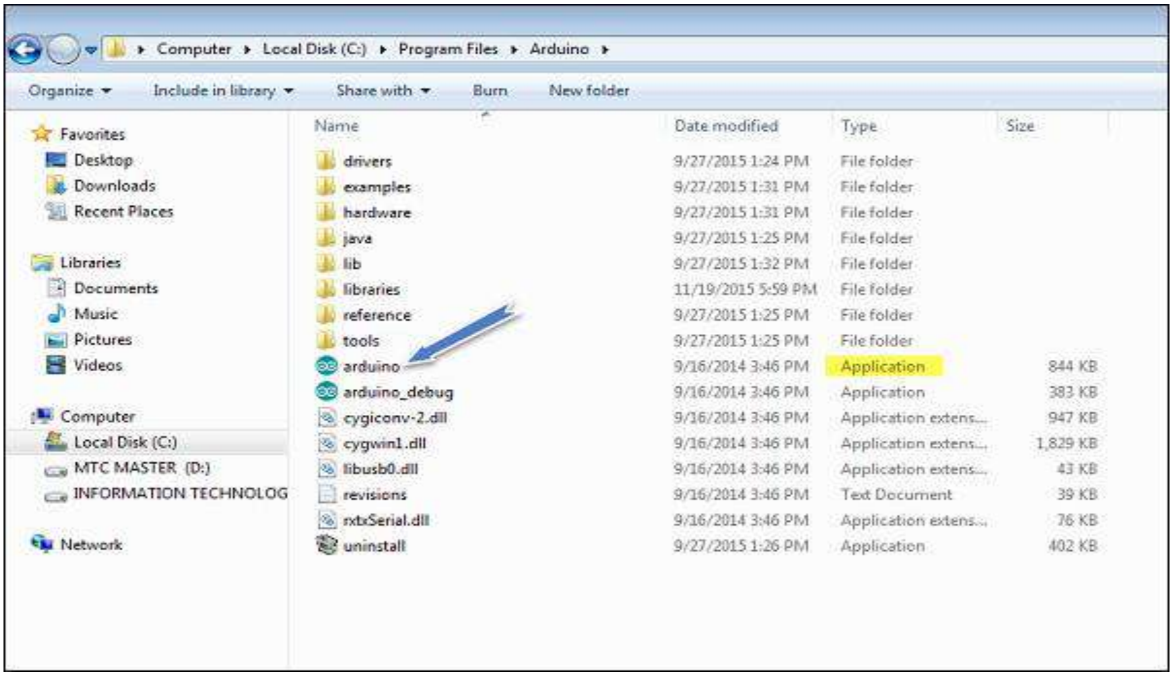
Step 3 – Power up your board.

The Arduino Uno, Mega, Duemilanove and Arduino Nano automatically draw power from either, the USB connection to the computer or an external power supply. If you are using an Arduino Diecimila, you have to make sure that the board is configured to draw power from the USB connection. The power source is selected with a jumper, a small piece of plastic that fits onto two of the three pins between the USB and power jacks. Check that it is on the two pins closest to the USB port.

Connect the Arduino board to your computer using the USB cable. The green power LED (labeled PWR) should glow.

Step 4 – Launch Arduino IDE.

After your Arduino IDE software is downloaded, you need to unzip the folder. Inside the folder, you can find the application icon with an infinity label (application.exe). Double-click the icon to start the IDE.

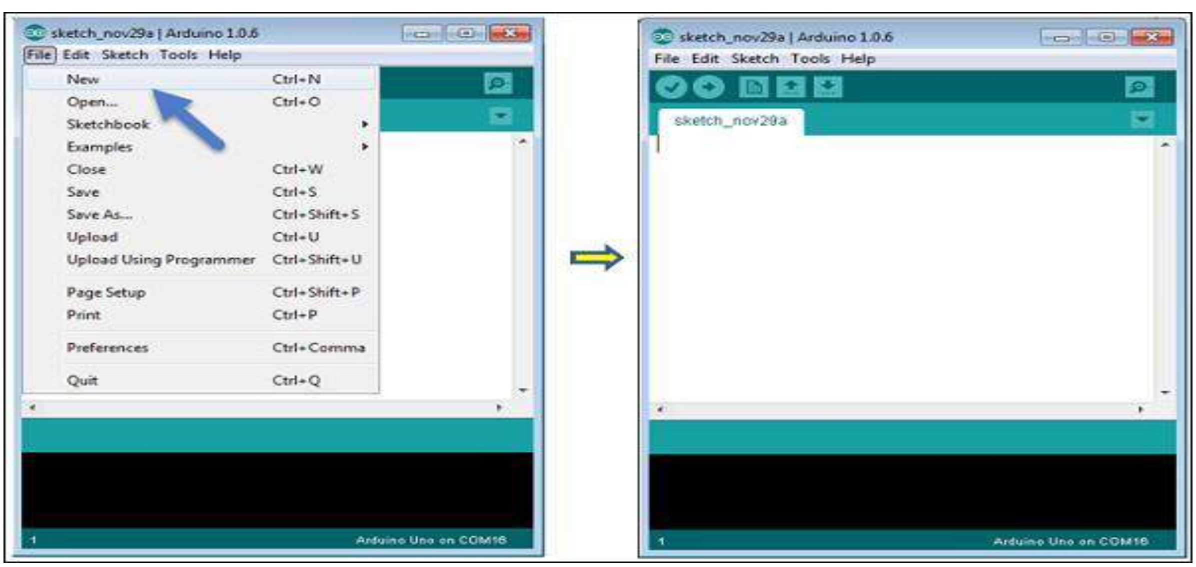


Step 5 − Open your first project.

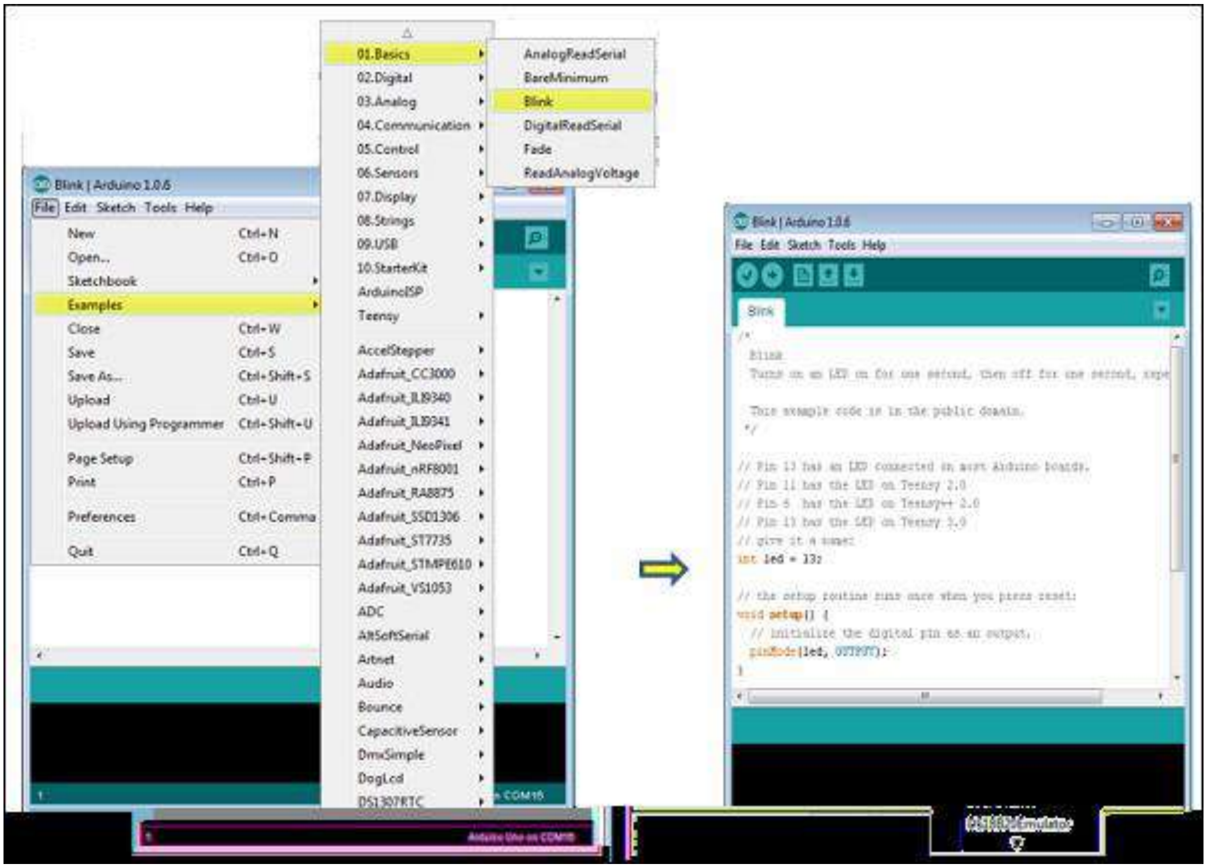
Once the software starts, you have two options −

- Create a new project.
- Open an existing project example.

To create a new project, select File → **New**.



To open an existing project example, select File → Example → Basics → Blink.

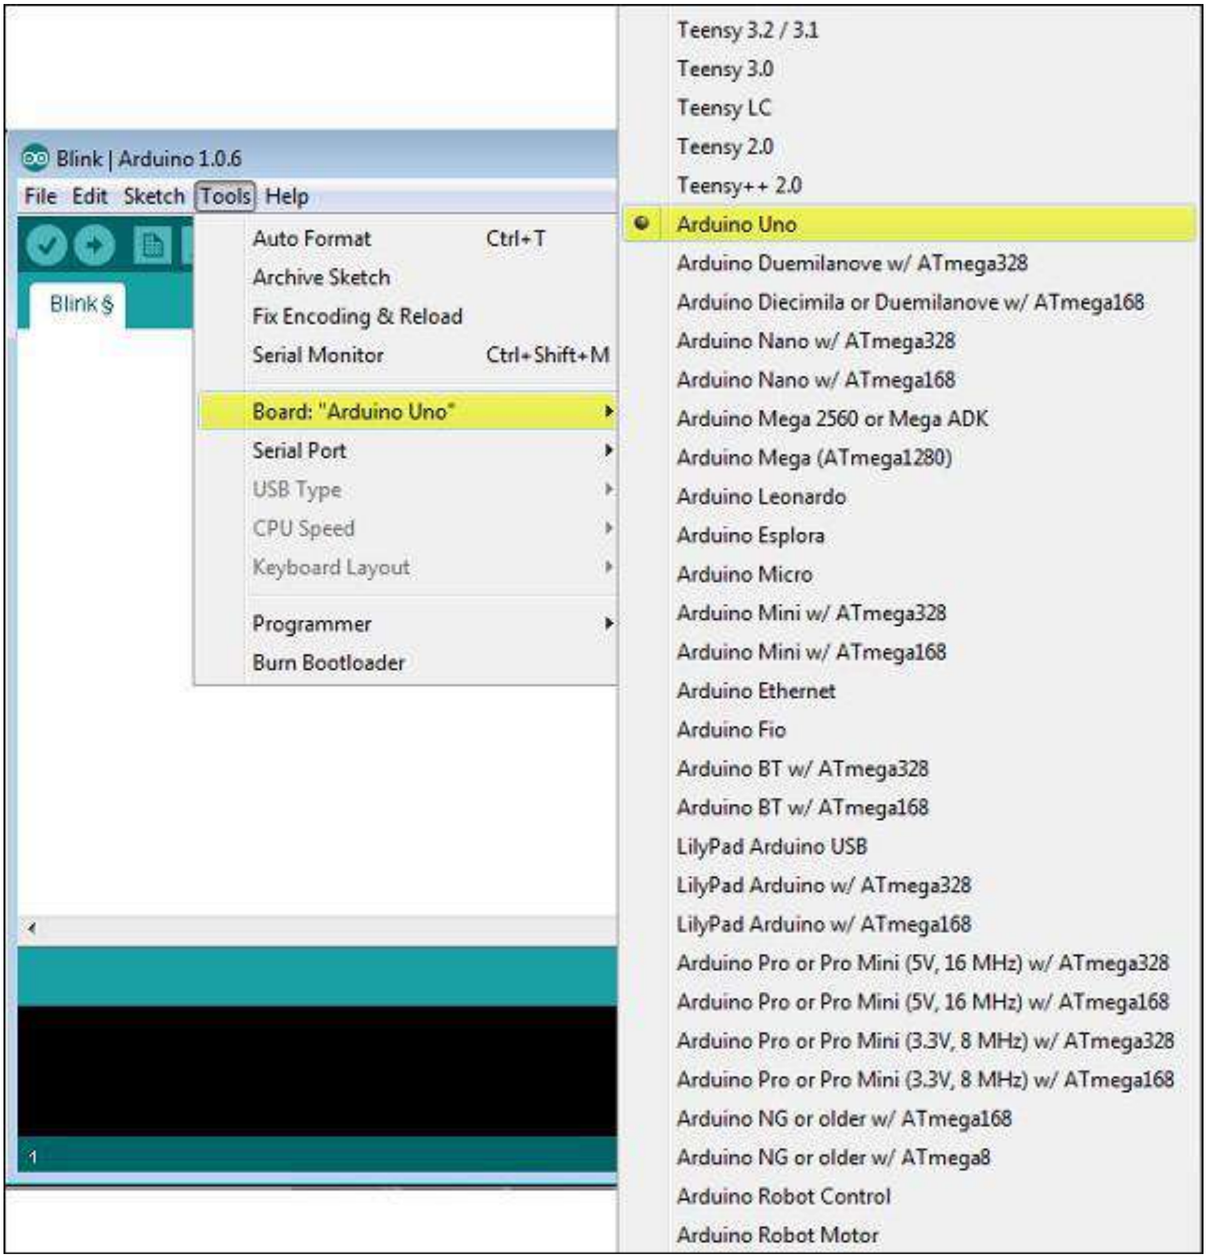


Here, we are selecting just one of the examples with the name **Blink**. It turns the LED on and off with some time delay. You can select any other example from the list.

Step 6 – Select your Arduino board.

To avoid any error while uploading your program to the board, you must select the correct Arduino board name, which matches with the board connected to your computer.

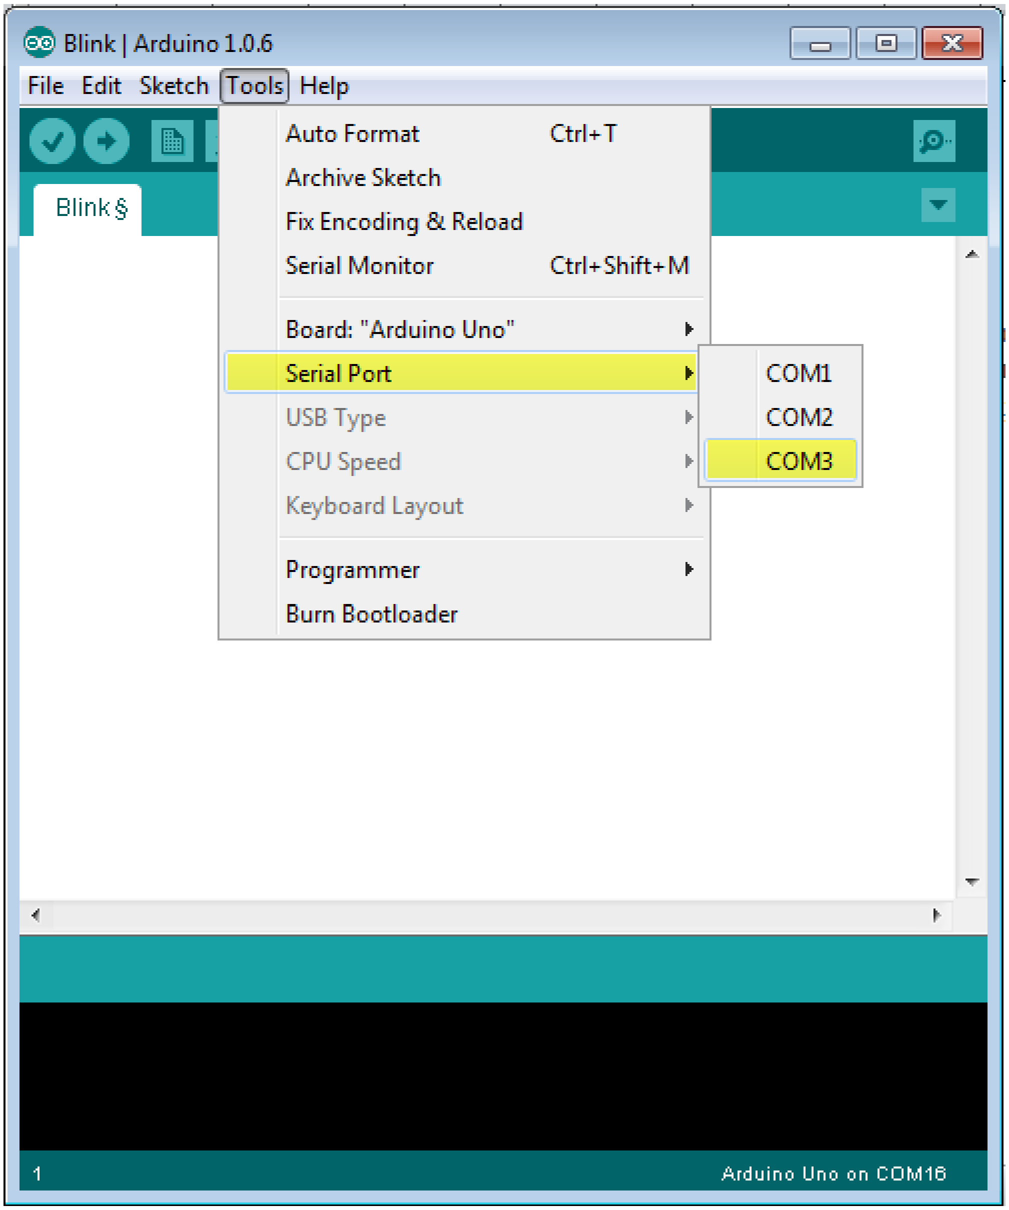
Go to Tools → Board and select your board.



Here, we have selected Arduino Uno board according to our tutorial, but you must select the name matching the board that you are using.

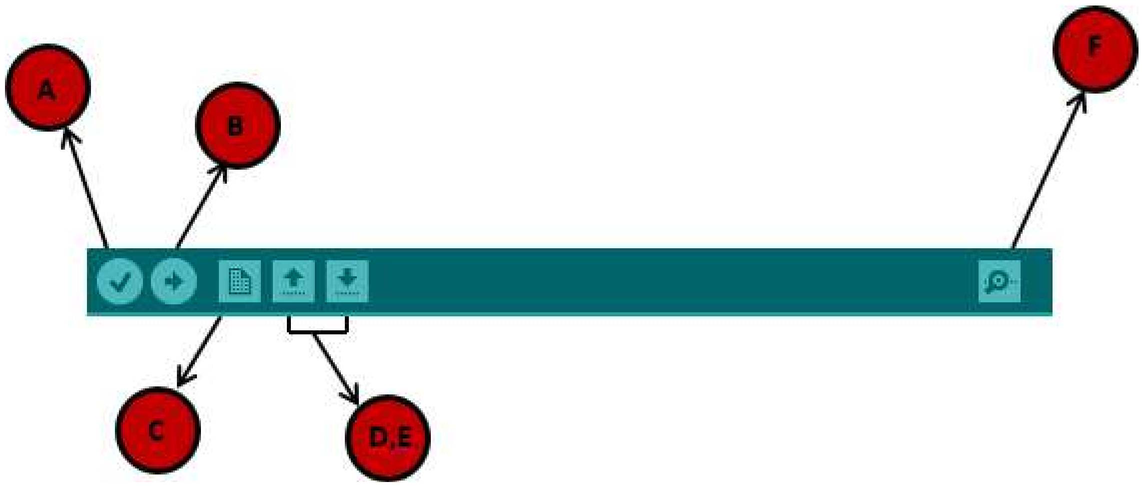
Step 7 – Select your serial port.

Select the serial device of the Arduino board. Go to **Tools → Serial Port** menu. This is likely to be COM3 or higher (COM1 and COM2 are usually reserved for hardware serial ports). To find out, you can disconnect your Arduino board and re-open the menu, the entry that disappears should be of the Arduino board. Reconnect the board and select that serial port.



Step 8 – Upload the program to your board.

Before explaining how we can upload our program to the board, we must demonstrate the function of each symbol appearing in the Arduino IDE toolbar.



A − Used to check if there is any compilation error. **B**

− Used to upload a program to the Arduino board.**C**

− Shortcut used to create a new sketch.

D − Used to directly open one of the example sketch.

E − Used to save your sketch.

F − Serial monitor used to receive serial data from the board and send the serial data to the board.

Now, simply click the "Upload" button in the environment. Wait a few seconds; you will see the RX and TX LEDs on the board, flashing. If the upload is successful, the message "Done uploading" will appear in the status bar.

Note − If you have an Arduino Mini, NG, or other board, you need to press the reset button physically on the board, immediately before clicking the upload button on the Arduino Software.

Connecting a Battery

For stand-alone operation, the board is powered by a battery rather than through the USB connection to the computer. While the external power can be anywhere in the range of 6 to 24 V (for example, you could use a car battery), a standard 9 V battery is convenient. While you could jam the leads of a battery snap into the Vin and Gnd connections on the board, it is better to solder the battery snap leads to a DC power plug and connect to the power jack on the board. A suitable plug is part number 28760 from www.jameco.com. Here is what this looks like.

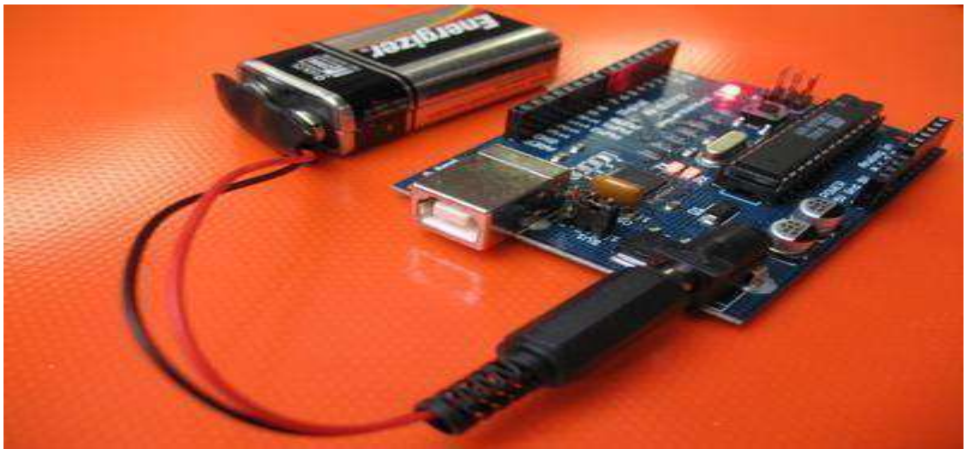


Fig.6.1: Arduino with battery

Disconnect your Arduino from the computer. Connect a 9 V battery to the Arduino power jack using the battery snap adapter. Confirm that the blinking program runs. This shows that you can power the Arduino from a battery and that the program you download runs without needing a connection to the host PC .

Moving On

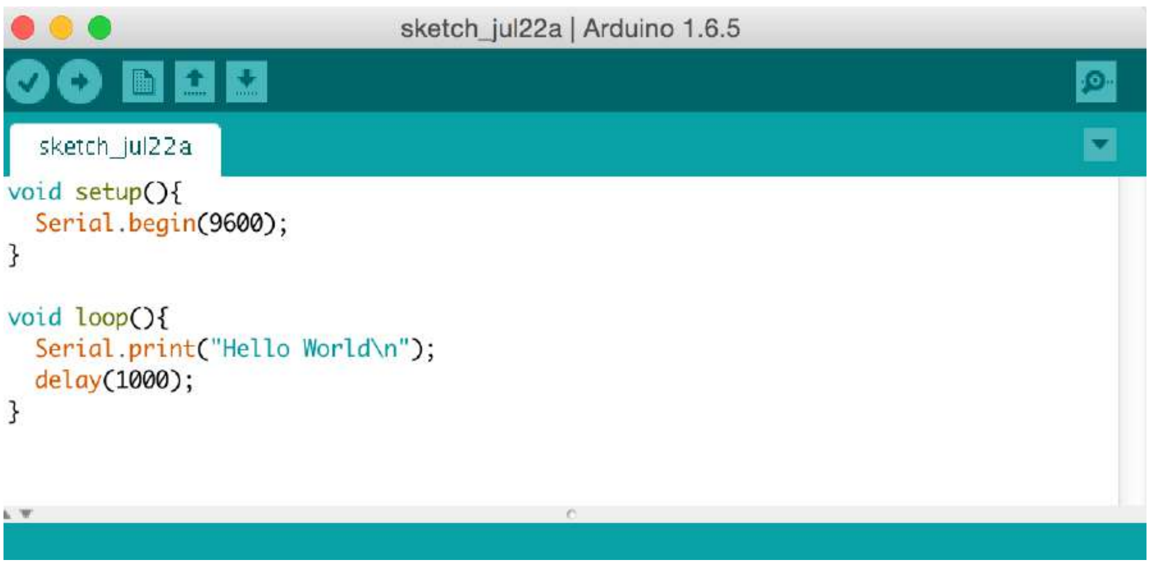
Connect your Arduino to the computer with the USB cable. You do not need the battery for now. The green PWR LED will light. If there was already a program burned into the Arduino, it will run.

Start the Arduino development environment. In Arduino-speak, programs are called “sketches”, but here we will just call them programs.

In the editing window that comes up, enter the following program, paying attention to where semi-colons appear at the end of command lines.

```
void setup()
```

```
{
  Serial.begin(9600);
  Serial.println("Hello World");
}
void loop() {}
```



6.2 MC Programming Language: Embedded C

This is the most widely used programming language for embedded processors/controllers. Assembly is also used but mainly to implement those portions of the code where very high timing accuracy, code size efficiency, etc. are prime requirements. Embedded C is perhaps the most popular languages among Embedded Programmers for programming Embedded Systems. There are many popular programming languages like Assembly, BASIC, C++ etc. that are often used for developing Embedded Systems but Embedded C remains popular due to its efficiency, less development time and portability.

6.3 Proteus:

Proteus: Proteus is a simulation and design software tool developed by Lab centre Electronics for Electrical and Electronic circuit design. It also possess 2D CAD drawing feature. It deserves to bear the tagline “From concept to completion”.

About Proteus

It is a software suite containing schematic, simulation as well as PCB designing. ISIS is the software used to draw schematics and simulate the circuits in real time. The simulation allows human access during run time, thus providing real time simulation.

ARES is used for PCB designing. It has the feature of viewing output in 3D view of the designed PCB along with components.

The designer can also develop 2D drawings for the product.

Features

ISIS has wide range of components in its library. It has sources, signal generators, measurement and analysis tools like oscilloscope, voltmeter, ammeter etc., probes for real time monitoring of the parameters of the circuit, switches, displays, loads like motors and lamps, discrete components like resistors, capacitors, inductors, transformers, digital and analog Integrated circuits, semiconductor switches, relays, microcontrollers, processors, sensors etc.

ARES offers PCB designing up to 14 inner layers, with surface mount and through hole packages. It is embedded with the foot prints of different category of components like ICs, transistors, headers, connectors and other discrete components. It offers Auto routing and manual routing options to the PCB Designer. The schematic drawn in the ISIS can be directly transferred ARES.

Starting New Design

Step 1: Open ISIS software and select New design in File menu

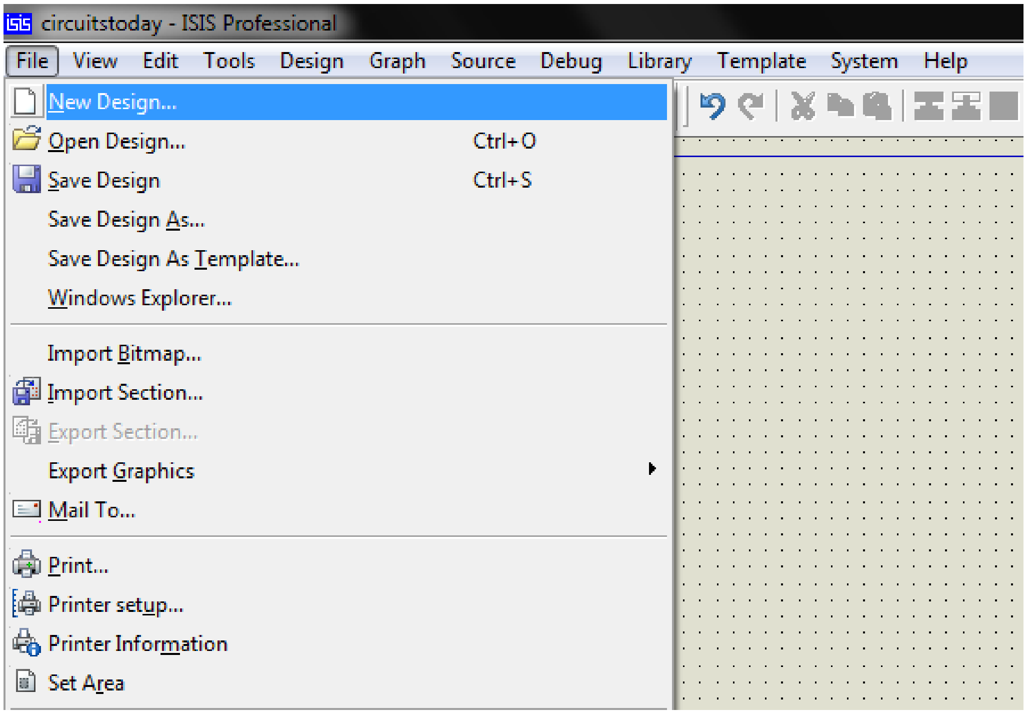


Fig Proteus File Menu

Step 2: A dialogue box appears to save the current design. However, we are creating a new design file so you can click Yes or No depending on the content of the present file. Then a Pop-Up appears asking to select the template. It is similar to selecting the paper size while printing. For now, select default or according to the layout size of the circuit.

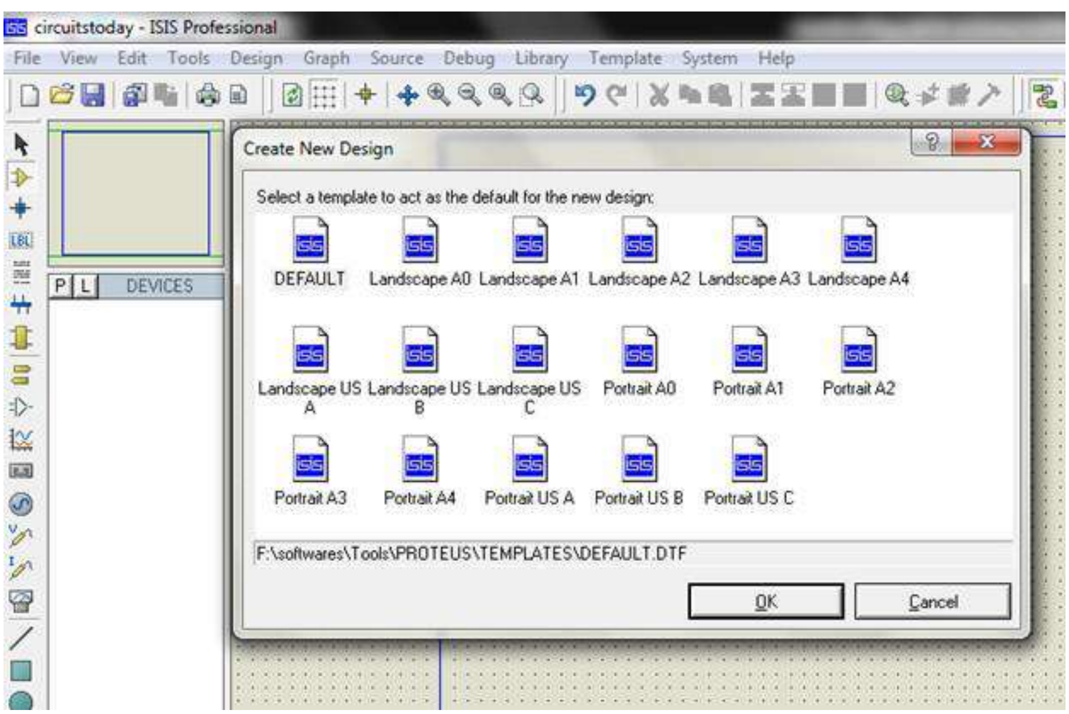

Fig Proteus Default Template Select

Step 3: An untitled design sheet will be opened, save it according to your wish, it is better to create a new folder for every layout as it generates other files supporting your design. However, it is not mandatory.

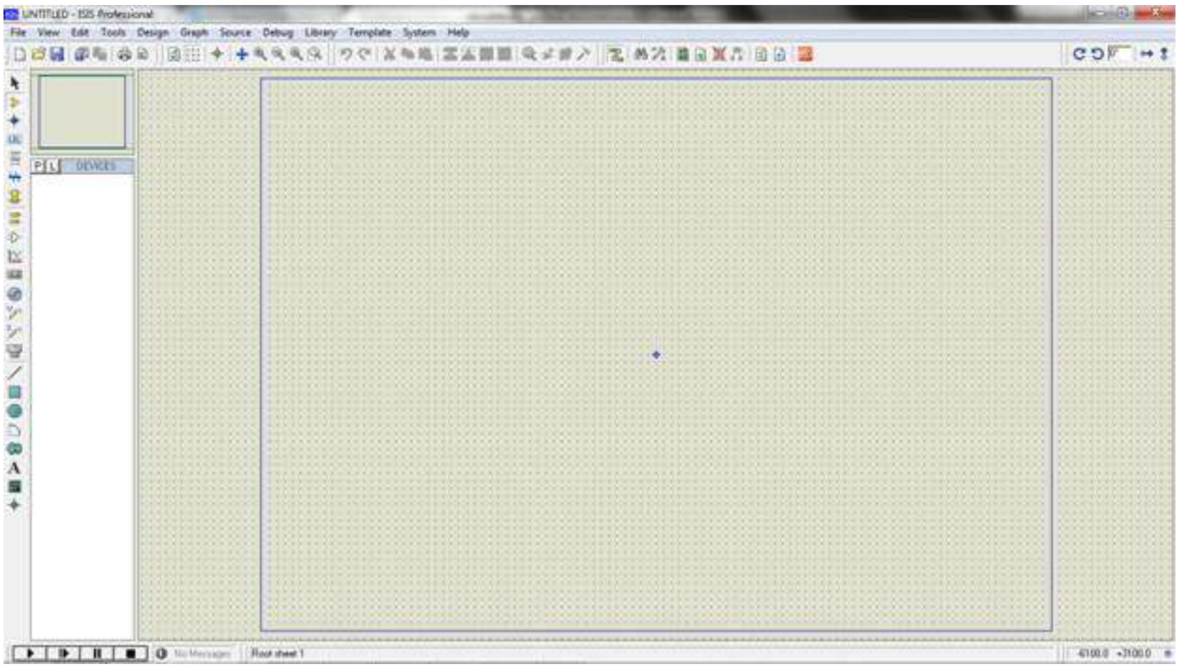

Fig Proteus Design Sheet

Step 4: To Select components, Click on the component mode button.

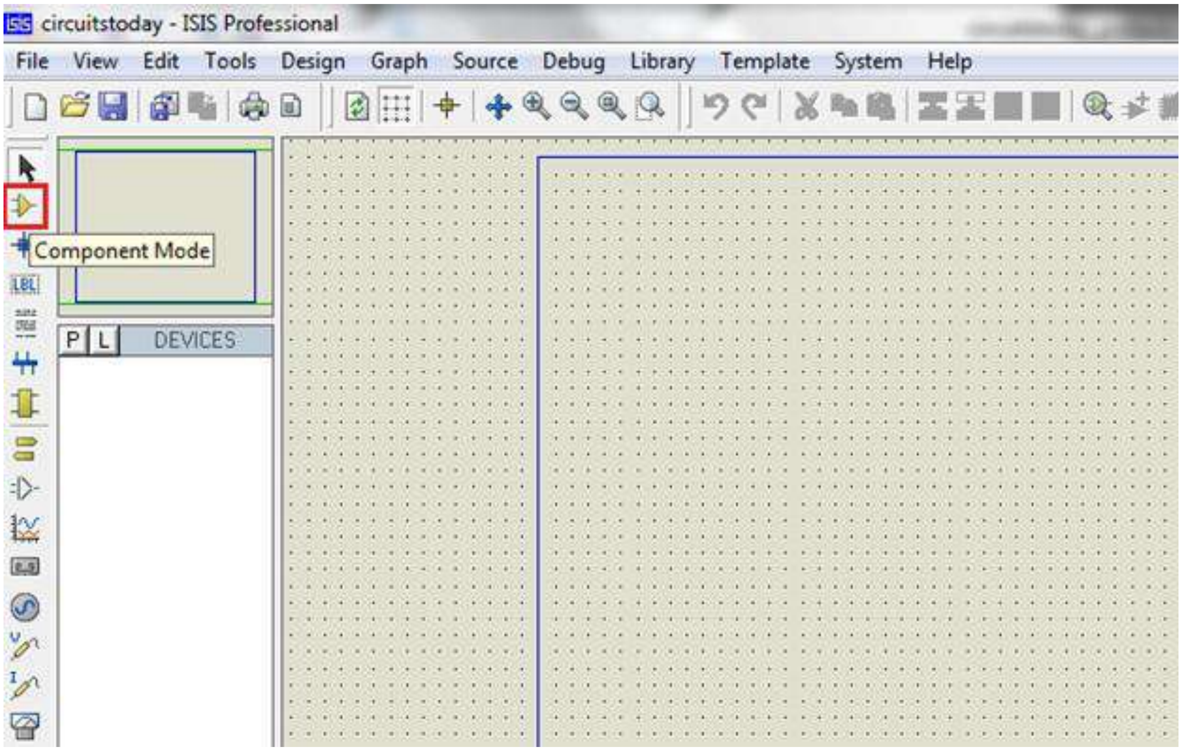

Fig Component Mode

Step 5: Click on Pick from Libraries. It shows the categories of components available and a search option to enter the part name.

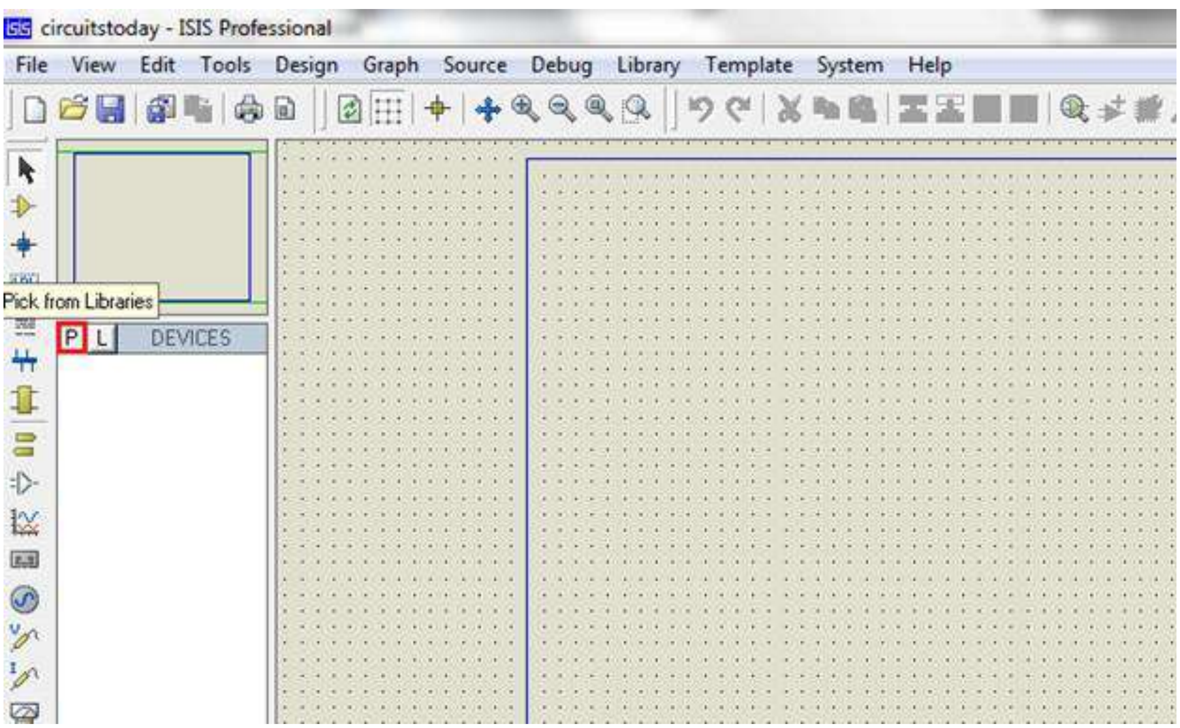

Fig Pick from Libraries

Step 6: Select the components from categories or type the part name in Keywords text box.

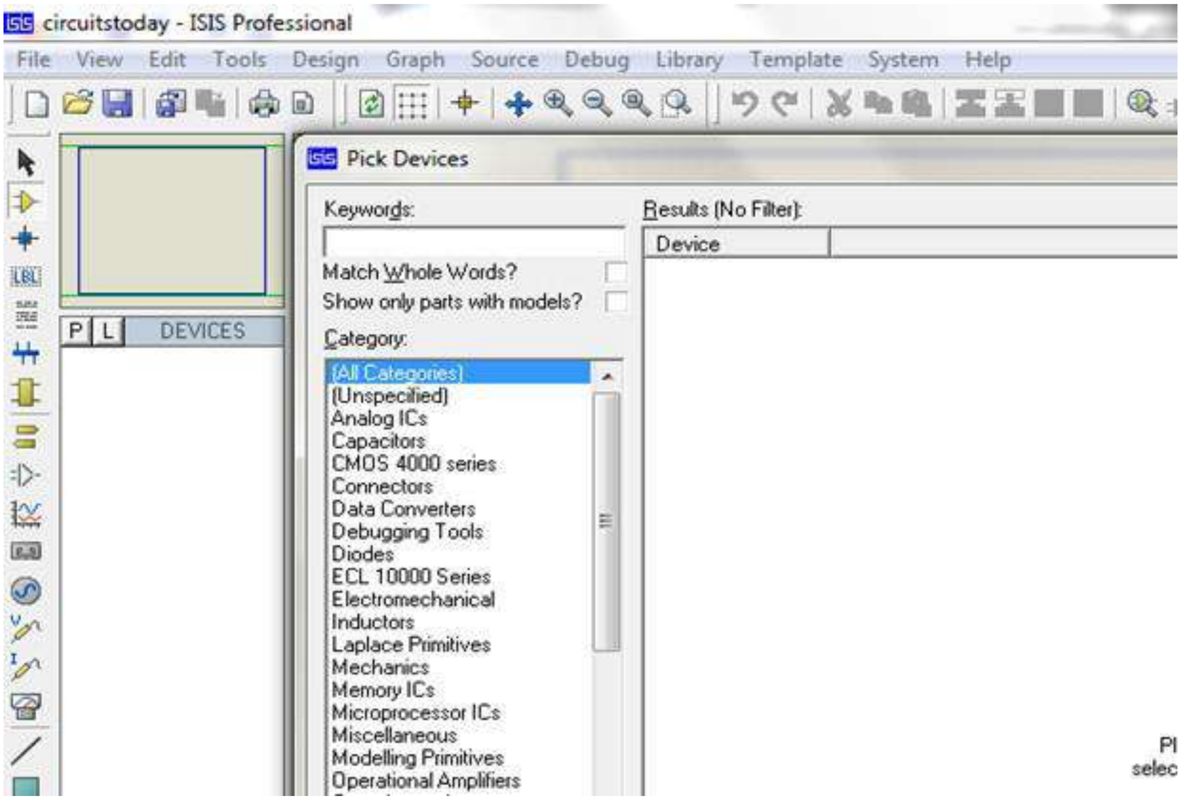

Fig Keywords Textbox

Example shows selection of push button. Select the components accordingly.

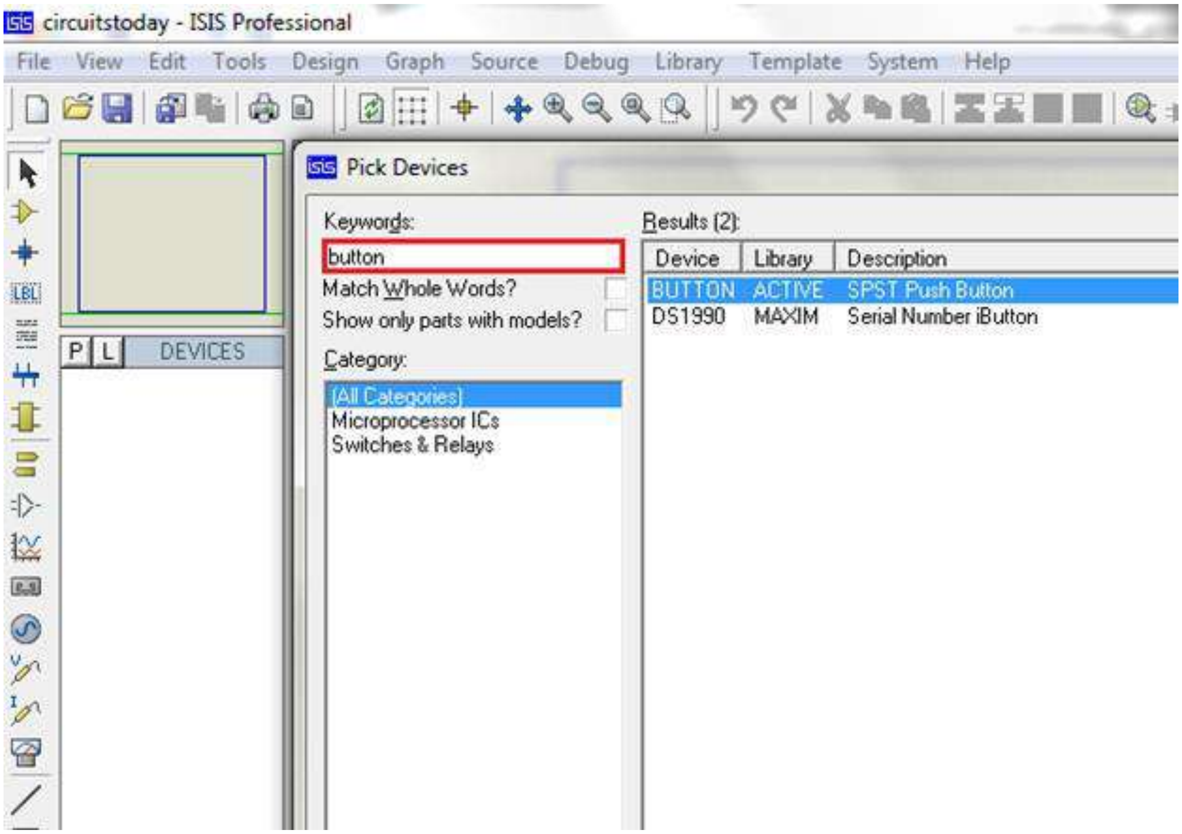

Fig Push Button Selection

Step 7: The selected components will appear in the devices list. Select the component and place it in the design sheet by left-click.

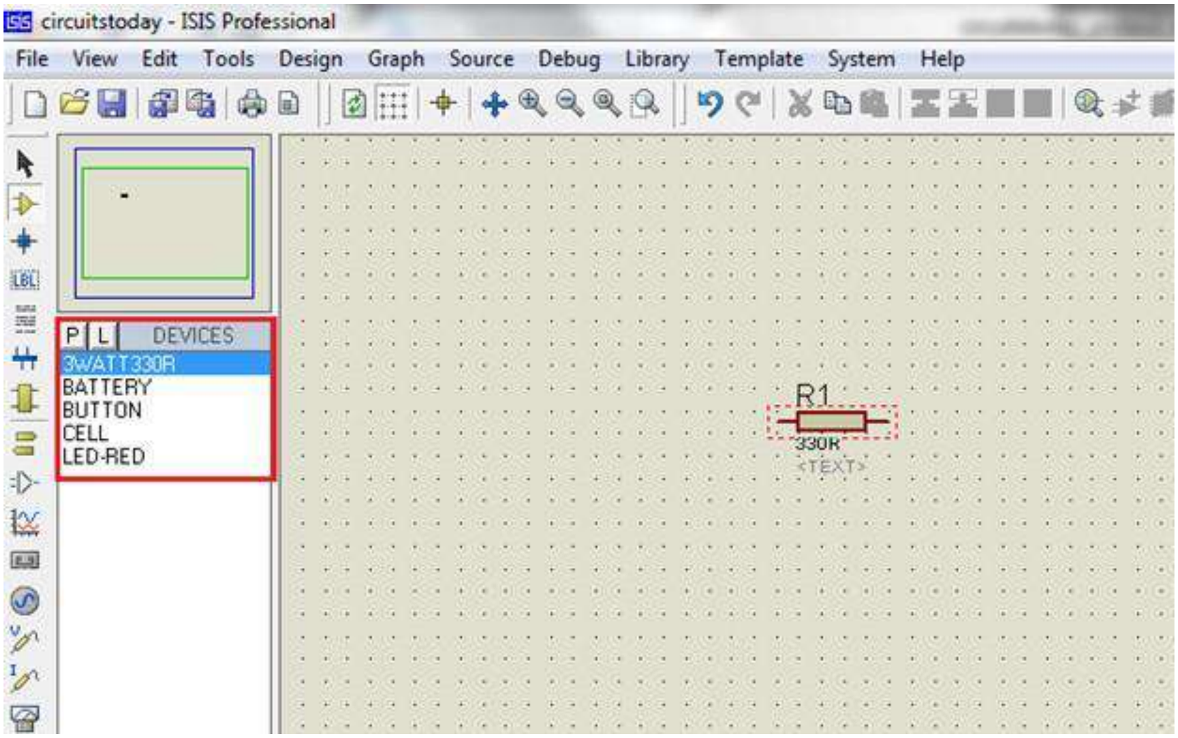

Fig Component Selection

Place all the required components and route the wires i.e., make connections.

Either selection mode above the component mode or component mode allows to connect through wires. Left click from one terminal to other to make connection. Double right-click on the connected wire or the component to remove connection or the component respectively.

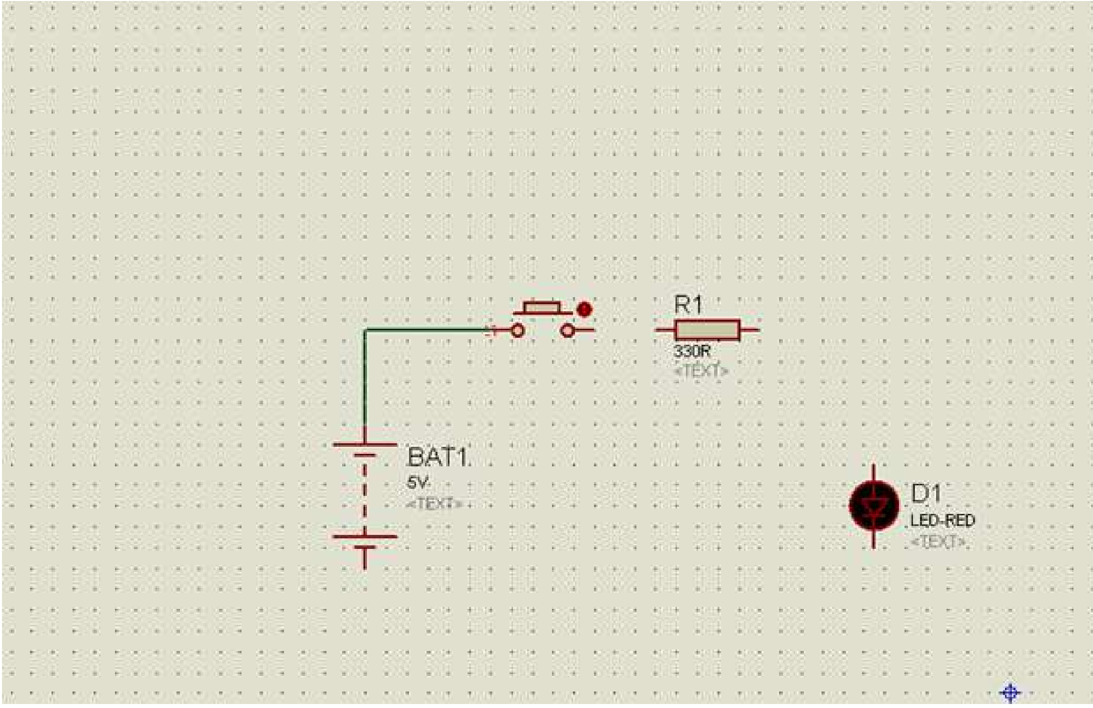

Fig Component Properties Selection

Double click on the component to edit the properties of the components and click on Ok.

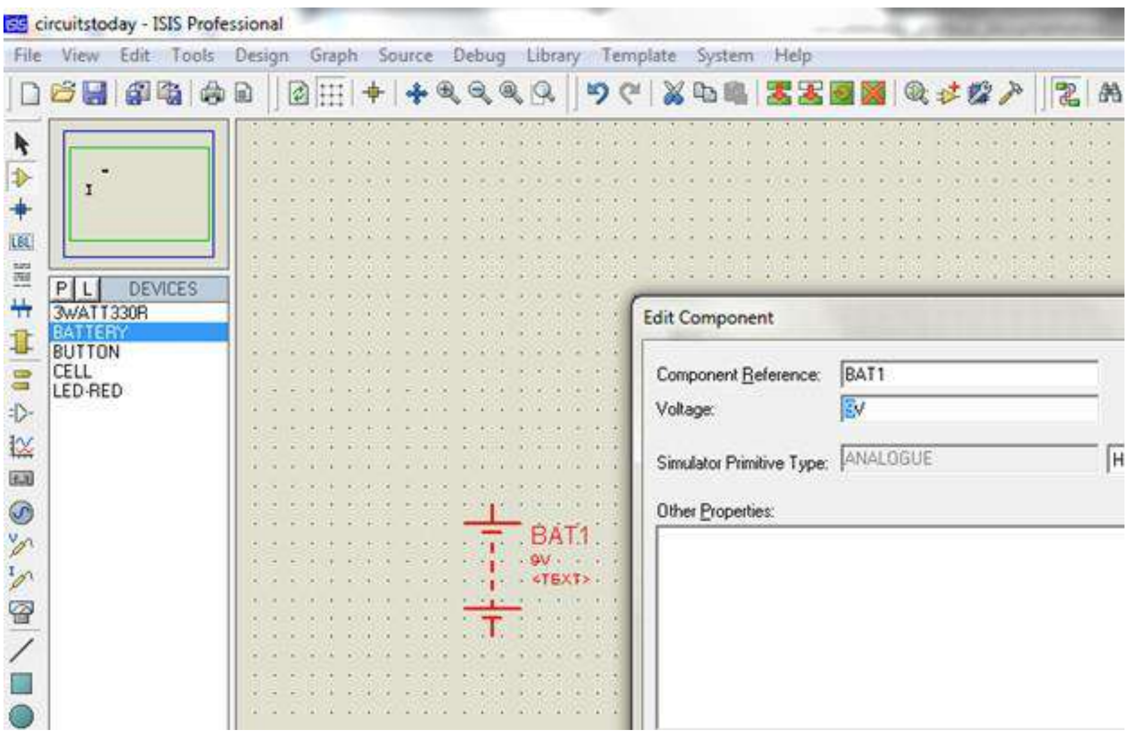

Fig Component Properties Edit

Step 8: After connecting the circuit, click on the play button to run the simulation.

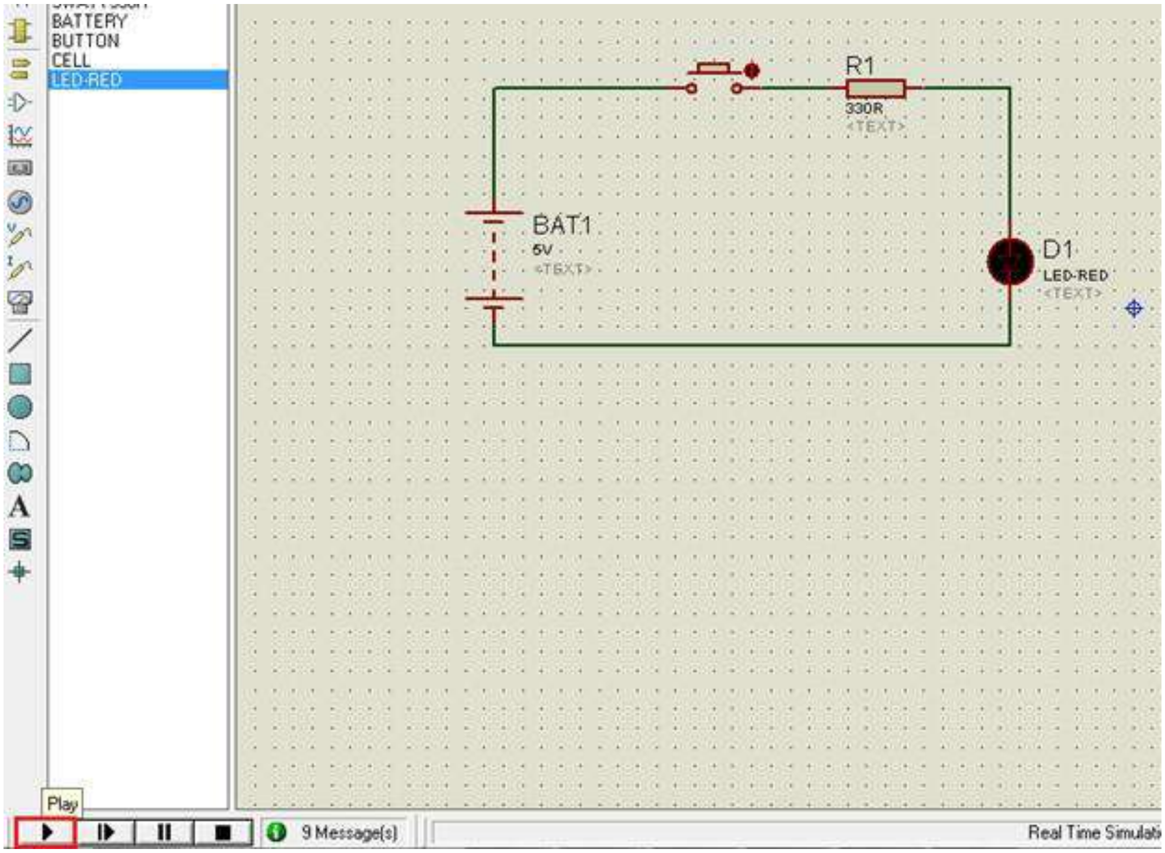

Fig Simulation Run

In this example simulation, the button is depressed during simulation by clicking on it to make LED glow.

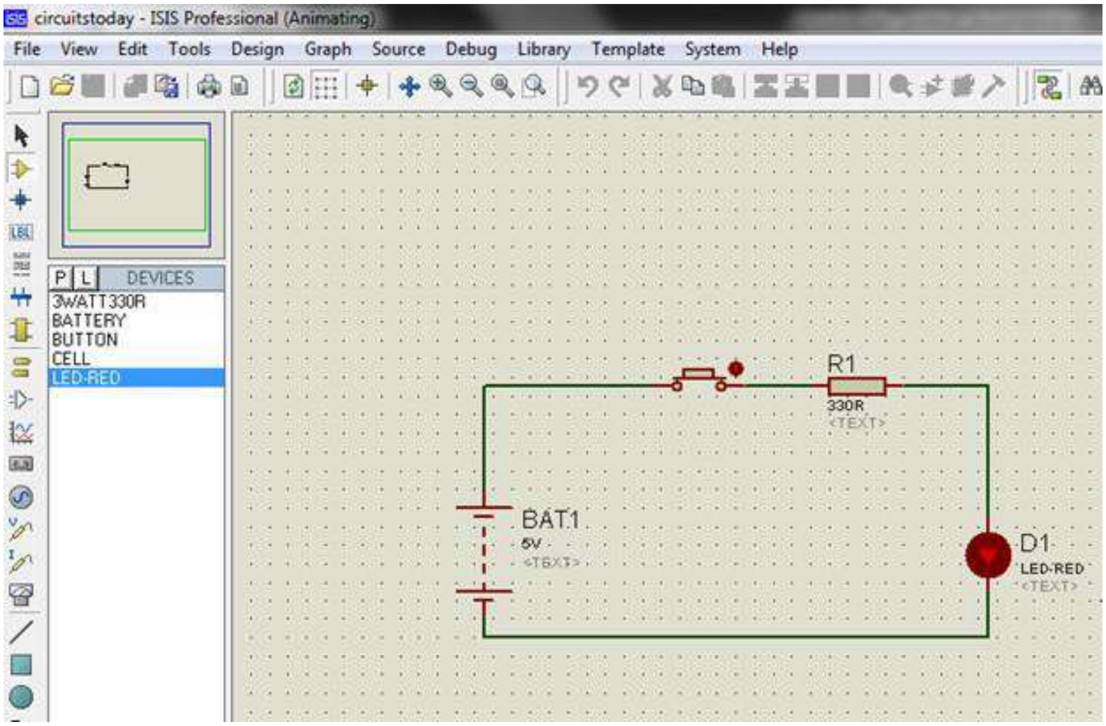

Fig Simulation Animating

Simulation can be stepped, paused or stopped at any time.

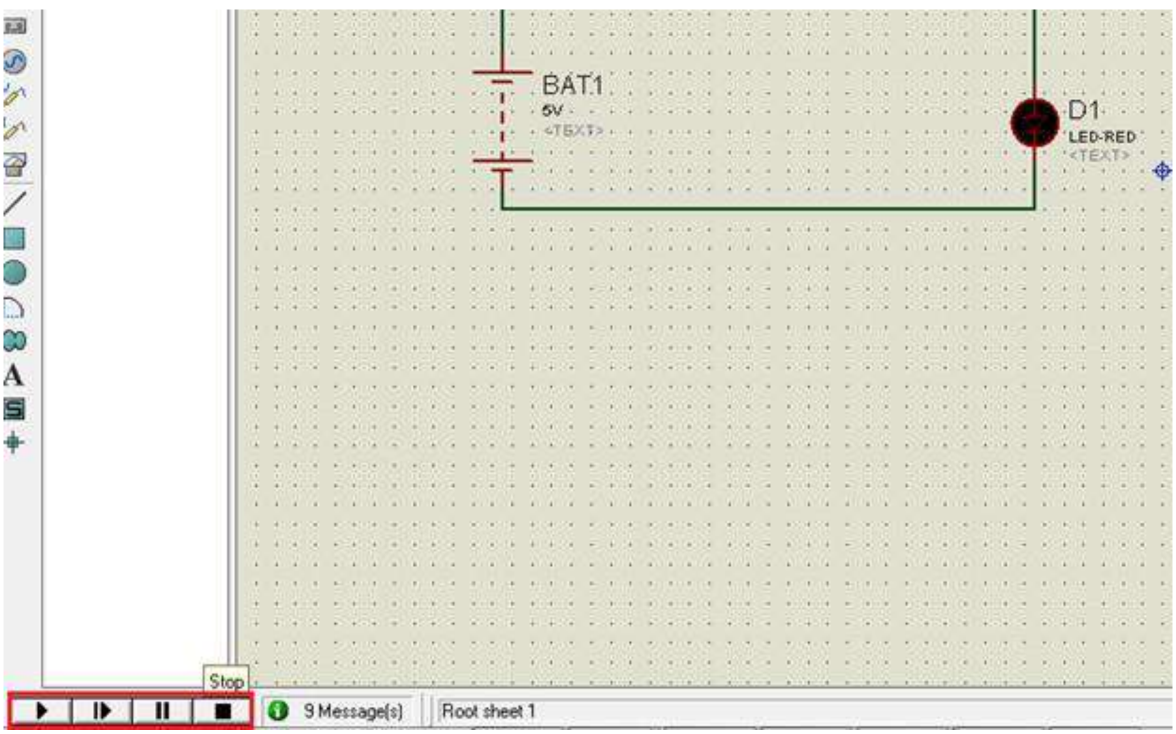

Fig Simulation Step-Pause-Stop Buttons

Project Code:

```
//#include <SoftwareSerial.h>
#include <LiquidCrystal.h>
LiquidCrystal lcd(13,12,11,10,9,8);
const int trigPin = A5;
const int echoPin = A4;

  }
```

CHAPTER-7

RESULT & CONCLUSION

7.1 APPLICATION OF THE PROJECT:

- Industries
- lawns.

7.2 ADVANTAGES OF THE PROJECT:

7.3 RESULT:

7.4 CONCLUSION:

The work done on solar grass cutter will come across the challenge of ecologically friendly production. The low cost of maintenance and operations possible due to no cost for fuelling. The automated machine i.e solar grass cutter has been technologically advanced for the use of houses and establishing that have grasslands where tractor driven mowers possibly will not be used. It is very simple for human beings, who practice this project work for further alterations. The automated grass cutter is light in weight and to place it occupies a very small area. As it makes use of a renewable energy sources for this reason there is a zero running price. It has the ability that can charge the battery while the machine is in workable condition. The automated machine is used to maintain the lawns are very clean and uniform in schools, playground, and public gardens.

7.5 FUTURE SCOPE:

Video cameras can be used to acquire pictures of the object being spotted. By fixing a metal detector to the robot, it can be send to battlefields, forests, coal mines, etc...to find out the metal objects. Temperature sensors are incorporated into the machine to get the extreme temperature of dangerous zones where human beings cannot go. As a result of attaching a smoke sensor to the machine, it can get the information related concentration of smoke or gases in the respective fields.The Size of the machine can be compact. The efficiency of the machine can be modified by increases the capacity of the battery. We can also place a bin to collect the grass and we can also configure the ultrasonic sensors depending on the distance. Additionally, sensors are integrated for perfect outcomes and upgraded robotics. Enhanced programs are used to update the machine and to perform different tasks.

DECLARATION

I, the student of **Bachelor of Technology** in Department of '**Electronics and Communications**' session: <2016 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled **A Heirarchical Image Matting Model For Blood Vessel Segmentation In Fundus Images.** is the outcome of my own bonafide work and is correct to the best of my knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

G. SOWMYA (16K81A0414)

// ACKNOWLEDGEMENT

While bringing out this project report to its final form, I came across a number of people whose contributions in various ways helped our field of research and they deserve a special thanks, It is a pleasure to convey our gratitude to all of them.

First and foremost, I would like to express our deep sense of gratitude and indebtedness to our C**ollege Management** for their kind support and permission to use facilities available in the institute.

I especially would like to express my deep sense of gratitude and indebtedness to **Dr. Santosh Kumar Patra, our beloved principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing us extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired us in innumerable ways.

I would like to express my gratitude to **Dr. B. Hari Krishna Head & Professor,** the Dept. of Electronics & Communications for his advice, supervision and the vital contribution as and when required during this research. I am proud to record that I had an opportunity to with an exponentially experienced professor like him. The time we spent with him will remain in our memories for years to come.

I would like to express my gratitude to our Dept. Coordinator **Mr. A. Anand Kumar,** for his involvement with originality has triggered and nourished our intellectual maturity that will help us for a long time come.

I sincerely thank our project internal guide **Mr. D. Prasad Assistant Professor,** Department of ECE and our class project coordinator **Ms. P. Pushpa Assistant Professor,** Department of ECE for guidance and encouragement in carrying out this project.

I am highly grateful to our college level project coordinators. **Dr.Malyadri, Professor in IT & Dr. R. Santosh Kumar Associate Professor in CSE** for their advice, supervision and the vital contribution as and when required during this research work and for their cooperation that is difficult to express in words.

G.SOWMYA

Abstract

A hierarchical image matting model is proposed to extract blood vessels from fundus images. More specifically, a hierarchical strategy utilizing the continuity and extendibility of retinal blood vessels is integrated into the image matting model for blood vessel segmentation. Normally the matting models require the user specified trimap, which separates the input image into three regions manually: the foreground, background and unknown regions. However, since creating a user specified trimap is a tedious and time-consuming task, region features of blood vessels are used to generate the trimap automatically in this paper. The proposed model has low computational complexity and outperforms many other state-of-art supervised and unsupervised methods in terms of accuracy, which achieves a vessel segmentation accuracy of 96.0%, 95.7% and 95.1% in an average time of 10.72s, 15.74s and 50.71s on images from three publicly available fundus image datasets DRIVE, STARE, and CHASE DB1, respectively.

LIST OF TABLES

Chapter 1

INTRODUCTION

Retinal blood vessels generally show a coarse to fine centrifugal distribution and appear as a wire mesh-like structure or tree-like structure. Their morphological features, such as length, width and branching, play an important role in diagnosis, screening, early detection and treatment of various cardiovascular and pharmacological diseases such as stroke, vein occlusions, diabetes and arteriosclerosis . The analysis of morphological features of retinal blood vessels can facilitate a timely detection and treatment of a disease when it is still in its early stage. Moreover, the analysis of retinal blood vessels can assist in evaluation of retinal image registration , the relationship between vessel tortuosity and hypertensive.

Image matting refers to the problem of accurately extracting a foreground object from an input image. Generally image matting includes two main steps. The first step is generating a user specified trimap. The trimap is a hand-drawn segmented image, which separates the input image into three regions: foreground (shown in white), background (shown in black) and unknown (shown in gray). The second step is applying the image matting model to extract the pixels belonging to the foreground object from the unknown regions, based on the samples of foreground and background pixels marked by the user. An exemplary result achieved .Image matting is very useful in many important applications, such as image (or video) segmentation, image editing, video production, new view synthesis, and film making. To the best of our knowledge, image matting has never been employed before to extract blood vessels from fundus images. The major reason is that for retinal blood vessel segmentation, generating a user specified trimap is a tedious and time consuming task. In other words, it is not appropriate to create a trimap manually for retinal blood vessel segmentation. In addition, a normal image matting model needs to be designed carefully to improve the performance of blood vessel segmentation. In order to overcome these problems, region features of blood vessels are applied to generate the trimap automatically. Then a hierarchical image matting model is proposed to extract the pixels of blood vessel from the unknown regions. More specifically, a hierarchical strategy utilizing the continuity and extendibility of retinal blood vessels is integrated into the image matting model for blood vessel segmentation. The proposed model is evaluated on three public available datasets DRIVE, STARE, and

CHASE DB1, which have been widely used by other researchers to develop their own methods. The vessel segmentation performance demonstrates the efficiency and effectiveness of the proposed hierarchical image matting model.

Chapter 2

LITERATURE REVIEW

The segmentation of retinal blood vessels has been a heavily researched area in recent years. Broadly speaking, existing algorithms can be divided into supervised and unsupervised methods. In supervised methods, a number of different features are extracted from fundus images, and applied to train the effective classifiers with the purpose of extracting retinal blood vessels. In [10], Staal et al. extracts 27 features for each image pixel with ridge profiles, and performs feature selection by using sequential forward selection method to pick those pixels that result in better segmentation performance by a K-Nearest Neighbor (KNN) classifier. Soares et al. [11] introduces a feature-based Bayesian classifier with Gaussian mixtures for vessel segmentation, which uses the intensity information and Gabor wavelet transform responses to build a 7-D feature vector for each pixel. In [12], Lupascu et al. utilizes an AdaBoost classifier and a 41-D feature vector which includes information on the local intensity structure, spatial properties, and geometry at multiple scales. Marin et al. [13] constructs a 7-D vector composed of gray-level and moment invariantsbased features, and then trains a neural network (NN) for pixel classification. Roychowdhury et al. [14] extracts the major vessel from the fundus images and uses a Gaussian Mixture Model classifier for vessel segmentation with a set of 8 features, which are extracted based on pixel neighborhood and first and second-order gradient images. In [15], Liskowski et al. employs a deep neural network to extract vessel pixels from fundus images. In unsupervised methods, the researchers try to find inherent properties of retinal blood vessels that can be applied to extract vessel pixels from fundus images. The unsupervised methods can be further divided into multiscale approaches, matched filtering, vessel tracking, mathematical morphology and model based methods [9]. The multiscale approach introduced by [16] develops a vessel enhancement filter with the analysis of multiscale second order local structure of an image (Hessian), and obtains a vesselness measure by using the eigenvalues of the Hessian. The matched filtering method described by [17] employs different threshold probes to extract blood vessels from matched filter response images. In [18], the methodology based on vessel tracking applies a wave propagation and traceback mechanism to label each pixel the likelihood of belonging to vessels in angiography images. The mathematical morphology with the extraction of vessel centerlines [19] is also developed to find the morphological characteristics of retinal blood vessels. Model based methods generally use geometric deformable models [20], parametric deformable models [21], vessel profile models [22] and active contour models [23] for blood vessel segmentation.

CHAPTER 3

INTRODUCTION TO IMAGE PROCESSING

INTRODUCTION

3.1.IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 3.1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

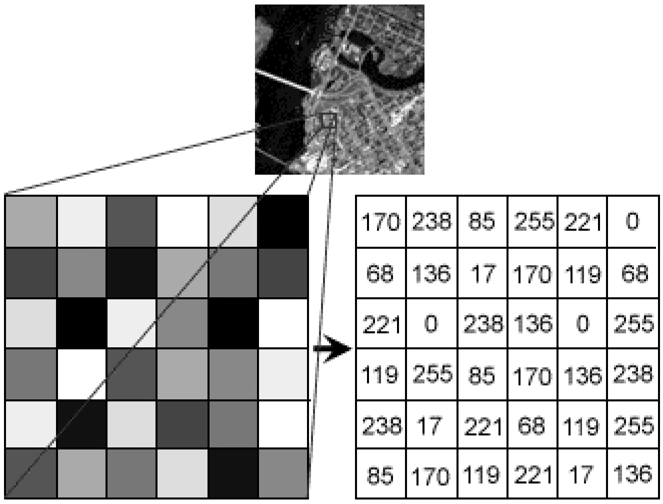

Fig 3.2 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

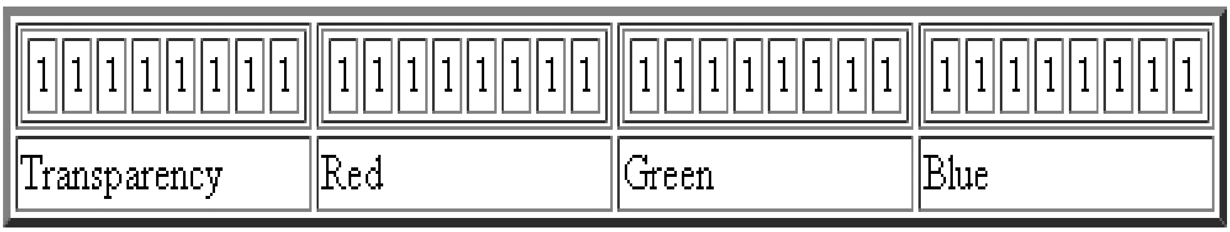

Fig 3.3. Transparency image

3.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

3.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

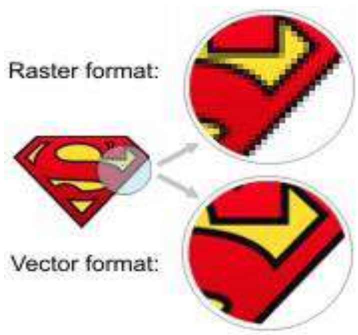

Fig3.4 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

3.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

- **PNG:**

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

3.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

3.4 IMAGE PROCESSING:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

3.5 FUNDAMENTAL STEPS IN DIGITAL IMAGE PROCESSING:

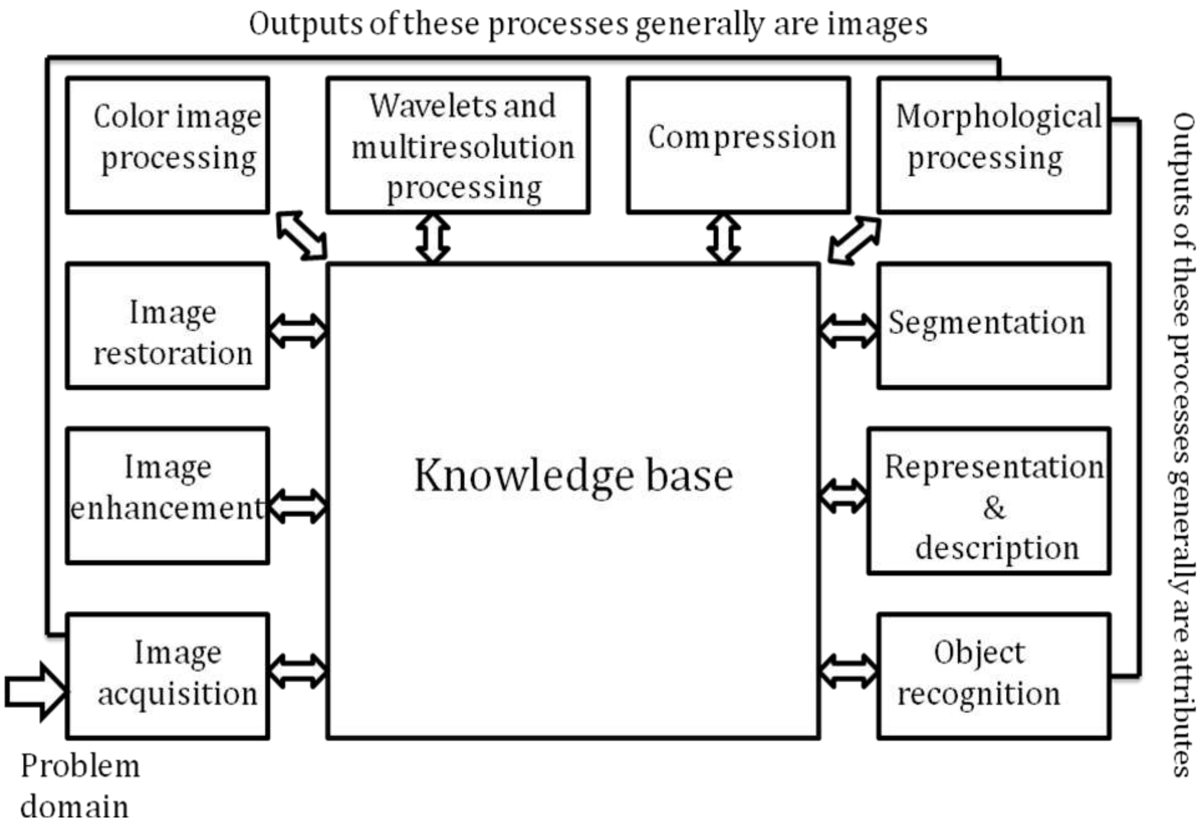

Fig 3.6 Image fundamental

3.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 3.5.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 3.5.2 digital camera cell

3.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because "it looks better." It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 3.5.3 Image enhancement

3.5.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 3.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a “good” enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, where as removal of image blur by applying a deblurring function is considered a restoration technique.

3.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 3.5.5 Color & Gray scale image

3.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

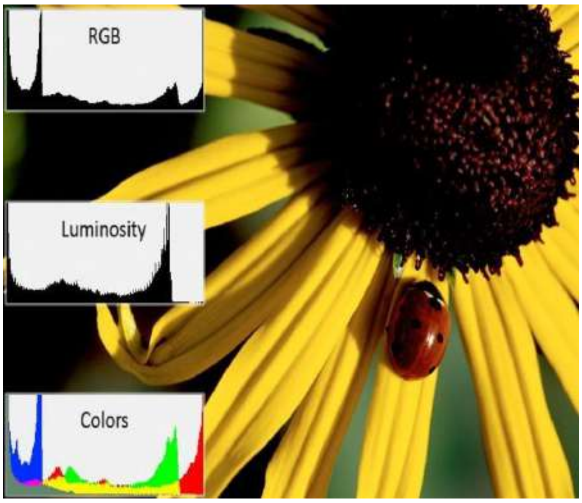

Fig 3.5.6rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

3.5.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

3.5.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 3.5.7 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

3.5.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

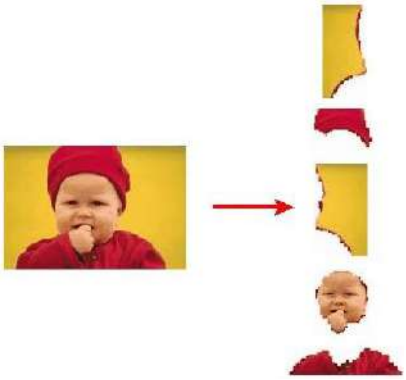

Fig 3.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

3.5.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

3.5.10 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

3.5.11 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

3.6 COMPONENTS OF AN IMAGE PROCESSING SYSTEM:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

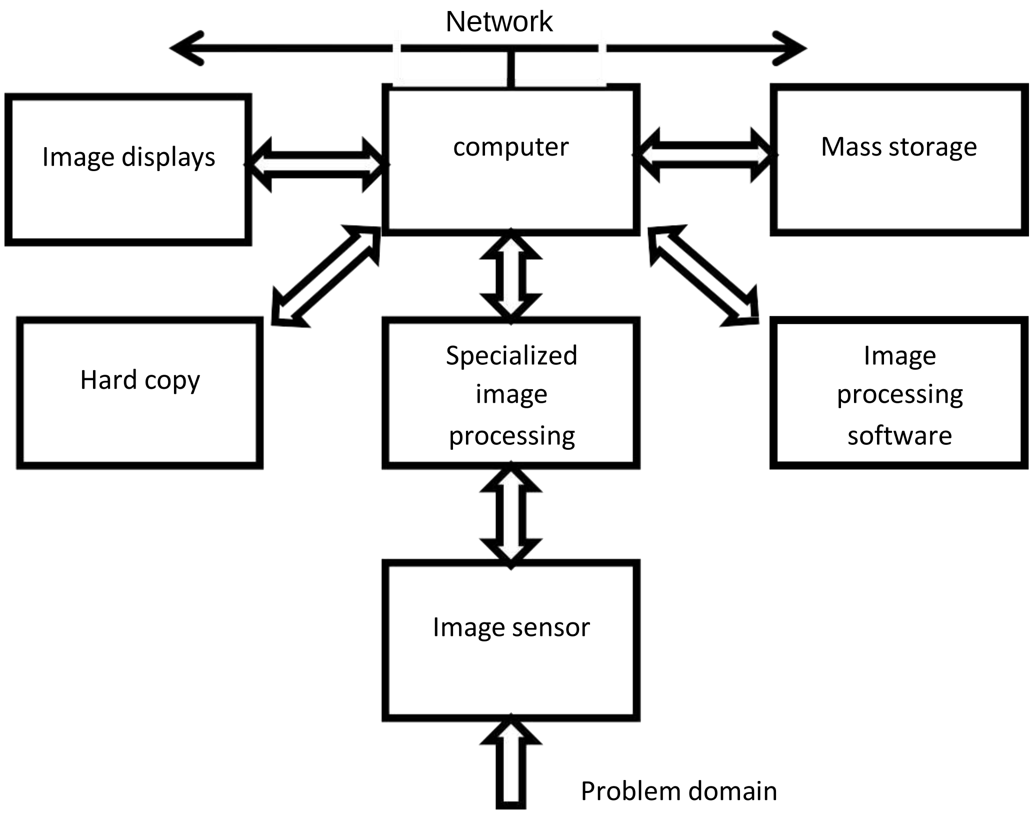

Fig 3.6 Component of image processing

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

  Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

  The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

  Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

  Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), M bytes (one million bytes), G bytes (meaning giga, or one billion, bytes), and T bytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in "jukeboxes" are the usual media for archival applications.

- **Image displays:**

  Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

  Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

  Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \Pr((\mathrm{gl}_p, \mathrm{gl}_{N_p}) = (i, j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This atproach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL} - 1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i, j) = \mathrm{Pr}((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i, j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights . One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from each image independently. As a result, correlation between the color channels is lost

However, in MCM, the count of pair wise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001)proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use ICICM feature in an image retrieval application from large image databases.

Early result on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

NON INTERVAL QUANTIZATION:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H ,S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$$G = Qs*Qv*H+Qv*s+V$$

Where Qs is quantized series of S and Qv is he quantized series of V. And now by setting Qs = Qv= 3, then G = 9H + 3S + V.

$$H = \begin{cases} 0 \text{ if } h \in [316,20] \\ 1 \text{ if } h \in [21,40] \\ 2 \text{ if } h \in [41,75] \\ 3 \text{ if } h \in [76,155] \\ 4 \text{ if } h \in [156,190] \\ 5 \text{ if } h \in [191,270] \\ 6 \text{ if } h \in [271,295] \\ 7 \text{ if } h \in [296,315] \end{cases} \qquad S = \begin{cases} 0 \text{ if } s \in [0,0.2) \\ 1 \text{ if } s \in [0.2,0.7) \\ 2 \text{ if } s \in [0.7,1) \end{cases} \qquad V = \begin{cases} 0 \text{ if } v \in [0,0.2) \\ 1 \text{ if } v \in [0.2,0.7) \\ 2 \text{ if } v \in [0.7,1) \end{cases}$$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

IMAGE RETRIEVAL:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google’s Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

OVERVIEW OF TEXTURE:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:

CHAPTER-4

DIGITAL IMAGE PROCESSING

Digital image processing

Background:

Digital image processing is an area characterized by the need for extensive experimental work to establish the viability of proposed solutions to a given problem. An important characteristic underlying the design of image processing systems is the significant level of testing & experimentation that normally is required before arriving at an acceptable solution. This characteristic implies that the ability to formulate approaches &quickly prototype candidate solutions generally plays a major role in reducing the cost & time required to arrive at a viable system implementation.

What is DIP

An image may be defined as a two-dimensional function f(x, y), where x & y are spatial coordinates, & the amplitude of f at any pair of coordinates (x, y) is called the intensity or gray level of the image at that point. When x, y & the amplitude values of f are all finite discrete quantities, we call the image a digital image. The field of DIP refers to processing digital image by means of digital computer. Digital image is composed of a finite number of elements, each of which has a particular location & value. The elements are called pixels.

Vision is the most advanced of our sensor, so it is not surprising that image play the single most important role in human perception. However, unlike humans, who are limited to the visual band of the EM spectrum imaging machines cover almost the entire EM spectrum, ranging from gamma to radio waves. They can operate also on images generated by sources that humans are not accustomed to associating with image.

There is no general agreement among authors regarding where image processing stops & other related areas such as image analysis& computer vision start. Sometimes a distinction is made by defining image processing as a discipline in which both the input & output at a process are images. This is limiting

& somewhat artificial boundary. The area of image analysis (image understanding) is in between image processing & computer vision.

There are no clear-cut boundaries in the continuum from image processing at one end to complete vision at the other. However, one useful paradigm is to consider three types of computerized processes in this continuum: low-, mid-, & high-level processes. Low-level process involves primitive operations such as image processing to reduce noise, contrast enhancement & image sharpening. A low- level process is characterized by the fact that both its inputs & outputs are images.

Mid-level process on images involves tasks such as segmentation, description of that object to reduce them to a form suitable for computer processing & classification of individual objects. A mid-level process is characterized by the fact that its inputs generally are images but its outputs are attributes extracted from those images. Finally higher- level processing involves "Making sense" of an ensemble of recognized objects, as in image analysis & at the far end of the continuum performing the cognitive functions normally associated with human vision.

Digital image processing, as already defined is used successfully in a broad range of areas of exceptional social & economic value.

What is an image?

An image is represented as a two dimensional function f(x, y) where x and y are spatial co-ordinates and the amplitude of 'f' at any pair of coordinates (x, y) is called the intensity of the image at that point.

Gray scale image:

A grayscale image is a function I(xylem) of the two spatial coordinates of the image plane.

I(x, y) is the intensity of the image at the point (x, y) on the image plane.

I (xylem)takes non-negative values assume the image is bounded by arectangle[0, a] ×[0, b]I: [0, a] × [0, b] → [0, info)

Color image:

It can be represented by three functions, R (xylem)for red,G (xylem)for green *and*B (xylem)for blue.

An image may be continuous with respect to the x and y coordinates and also in amplitude. Converting such an image to digital form requires that the coordinates as well as the amplitude to be digitized. Digitizing the coordinate’s values is calledsampling. Digitizing the amplitude values is called quantization.

Coordinate convention:

The result of sampling and quantization is a matrix of real numbers. We use two principal ways to represent digital images. Assume that an image f(x, y) is sampled so that the resulting image has M rows and N columns. We say that the image is of size M X N. The values of the coordinates (xylem) are discrete quantities. For notational clarity and convenience, we use integer values for these discrete coordinates.

In many image processing books, the image origin is defined to be at (xylem)=(0,0).The next coordinate values along the first row of the image are (xylem)=(0,1).It is important to keep in mind that the notation (0,1) is used to signify the second sample along the first row. It does not mean that these are the actual values of physical coordinates when the image was sampled. Following figure shows the coordinate convention. Note that x ranges from 0 to M-1 and y from 0 to N-1 in integer increments.

The coordinate convention used in the toolbox to denote arrays is different from the preceding paragraph in two minor ways. First, instead of using (xylem) the toolbox uses the notation (race) to indicate rows and columns. Note, however, that the order of coordinates is the same as the order discussed in the previous paragraph, in the sense that the first element of a coordinate topples, (alb), refers to a row and the second to a column. The other difference is that the origin of the coordinate system is at (r, c) = (1, 1); thus, r ranges from 1 to M and c from 1 to N in integer increments. IPT documentation refers to the coordinates. Less frequently the toolbox also employs another coordinate convention called spatial coordinates which uses x to refer to columns and y to refers to rows. This is the opposite of our use of variables x and y.

Image as Matrices:

The preceding discussion leads to the following representation for a digitized image function:

f (0,0)   f(0,1)   ………..   f(0,N-1)

f (1,0)   f(1,1)   …………   f(1,N-1)

f (xylem)=   .   .   .

.   .   .

f (M-1,0)   f(M-1,1).................f(M-1,N-1)

The right side of this equation is a digital image by definition. Each element of this array is called an image element, picture element, pixel or pel. The terms image and pixel are used throughout the rest of our discussions to denote a digital image and its elements.A digital image can be represented naturally as a MATLAB matrix:

f (1,1)   f(1,2) .... f(1,N)

f (2,1)   f(2,2) .... f (2,N)

.   .   .

f =   .   .   .

f (M,1)   f(M,2).......... f(M,N)

Where f (1,1) = f(0,0) (note the use of a monoscope font to denote MATLAB quantities). Clearly the two representations are identical, except for the shift in origin. The notation f(p ,q) denotes the element located in row p and the column q. For example f(6,2) is the element in the sixth row and second column of the matrix f. Typically we use the letters M and N respectively to denote the number of rows and columns in a matrix. A 1xN matrix is called a row vector whereas an Mx1 matrix is called a column vector. A 1x1 matrix is a scalar.

Matrices in MATLAB are stored in variables with names such as A, a, RGB, real array and so on. Variables must begin with a letter and contain only letters, numerals and underscores. As noted in the previous paragraph, all MATLAB quantities are written using mono-scope characters. We use conventional Roman, italic notation such as f(x ,y), for mathematical expressions

Reading Images:

Images are read into the MATLAB environment using function imread whose syntax is

Imread (‘filename’)

Format name	Description	recognized extension
TIFF	Tagged Image File Format	.tif, .tiff
JPEG	Joint Photograph Experts Group	.jpg, .jpeg
GIF	Graphics Interchange Format	.gif
BMP	Windows Bitmap	.bmp
PNG	. Portable Network Graphics	.png
XWD	X Window Dump	xwd

.

Here filename is a spring containing the complete of the image file(including any applicable extension).For example the command line

>> f = imread (‘8. jpg’);

Reads the JPEG (above table) image chestxray into image array f. Note the use of single quotes (‘) to delimit the string filename. The semicolon at the end of a command line is used by MATLAB for suppressing output If a semicolon is not included. MATLAB displays the results of the operation(s) specified in that line. The prompt symbol (>>) designates the beginning of a command line, as it appears in the MATLAB command window.

Data Classes:

Although we work with integers coordinates the values of pixels themselves are not restricted to be integers in MATLAB. Table above list various data classes supported by MATLAB and IPT are representing pixels values. The first eight entries in the table are refers to as numeric data classes. The ninth entry is the char class and, as shown, the last entry is referred to as logical data class.

All numeric computations in MATLAB are done in double quantities, so this is also a frequent data class encounter in image processing applications. Class unit 8 also is encountered frequently, especially when reading data from storages devices, as 8 bit images are most common representations found in practice. These two data classes, classes logical, and, to a lesser degree, class unit 16 constitute the primary data classes on which we focus. Many ipt functions however support all the data classes listed in table. Data class double requires 8 bytes to represent a number uint8 and int 8 require one byte each, uint16 and int16 requires 2bytes and unit 32.

Name Description

Double	Double precision, floating point numbers are approximate
Unit 8	Unsigned 8 bit integers in the range [0,255] (1 byte per element)
Unit 16	Unsigned 16 bit integers in the range [0, 65535] (2 bytes per element)
Unit 32	Unsigned 32 bit integers in the range [0, 4294967295] (4 bytes per element).
Int 8	Signed 8_bit integers in the range [-128,127] (1 byte per element)
Int 16	Signed 16_byte integers in the range [32768, 32767] (2 bytes per element).
Int 32	Signed 32_byte integers in the range [-2147483648, 21474833647] (4 byte per element).

Single single _precision floating _point numbers with values

In the approximate range (4 bytes per elements)

Char characters (2 bytes per elements).

Logical values are 0 to 1 (1byte per element).

Int 32 and single required 4 bytes each. The char data class holds characters in Unicode representation. A character string is merely a 1*n array of characters logical array contains only the values 0 to 1,with each element being stored in memory using function logical or by using relational operators.

Image Types:

The toolbox supports four types of images:

1 .Intensity images;

2. Binary images;

3. Indexed images;

4. R G B images.

Most monochrome image processing operations are carried out using binary or intensity images, so our initial focus is on these two image types. Indexed and RGB colour images.

Intensity Images:

An intensity image is a data matrix whose values have been scaled to represent intentions. When the elements of an intensity image are of class unit8, or class unit 16, they have integer values in the range [0,255] and [0, 65535], respectively. If the image is of class double, the values are floating point numbers. Values of scaled, double intensity images are in the range [0, 1] by convention.

Binary Images:

Binary images have a very specific meaning in MATLAB.A binary image is a logical array 0s and1s.Thus, an array of 0s and 1s whose values are of data class, say unit8, is not considered as a binary image in MATLAB .A numeric array is converted to binary using function logical. Thus, if A is a numeric array consisting of 0s and 1s, we create an array B using the statement.

B=logical (A)

If A contains elements other than 0s and 1s.Use of the logical function converts all nonzero quantities to logical 1s and all entries with value 0 to logical 0s.

Using relational and logical operators also creates logical arrays.

To test if an array is logical we use the I logical function: islogical(c).

If c is a logical array, this function returns a 1.Otherwise returns a 0. Logical array can be converted to numeric arrays using the data class conversion functions.

Indexed Images:

An indexed image has two components:

A data matrix integer, x

A color map matrix, map

Matrix map is an m*3 arrays of class double containing floating point values in the range [0, 1].The length m of the map are equal to the number of colors it defines. Each row of map specifies the red, green and blue components of a single color. An indexed images uses “direct mapping” of pixel intensity values color map values. The color of each pixel is determined by using the corresponding value the integer matrix x as a pointer in to map. If x is of class double ,then all of its components with values less than or equal to 1 point to the first row in map, all components with value 2 point to the second row and so on. If x is of class units or unit 16, then all components value 0 point to the first row in map, all components with value 1 point to the second and so on.

RGB Image:

An RGB color image is an M*N*3 array of color pixels where each color pixel is triplet corresponding to the red, green and blue components of an RGB image, at a specific spatial location. An RGB image may be viewed as “stack” of three gray scale images that when fed in to the red, green and blue inputs of a color monitor

Produce a color image on the screen. Convention the three images forming an RGB color image are referred to as the red, green and blue components images. The data class of the components images determines their range of values. If an RGB image is of class double the range of values is [0, 1].

Similarly the range of values is [0,255] or [0, 65535].For RGB images of class units or unit 16 respectively. The number of bits use to represents the pixel values of the component images determines the bit depth of an RGB image. For example, if each component image is an 8bit image, the corresponding RGB image is said to be 24 bits deep.

Generally, the number of bits in all component images is the same. In this case the number of possible color in an RGB image is (2^b) ^3, where b is a number of bits in each component image. For the 8bit case the number is 16,777,216 colors

CHAPTER 5

Software Introduction:

5.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

5.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigen values, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

  This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

5.3 GRAPHICAL USER INTERFACE (GUI):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

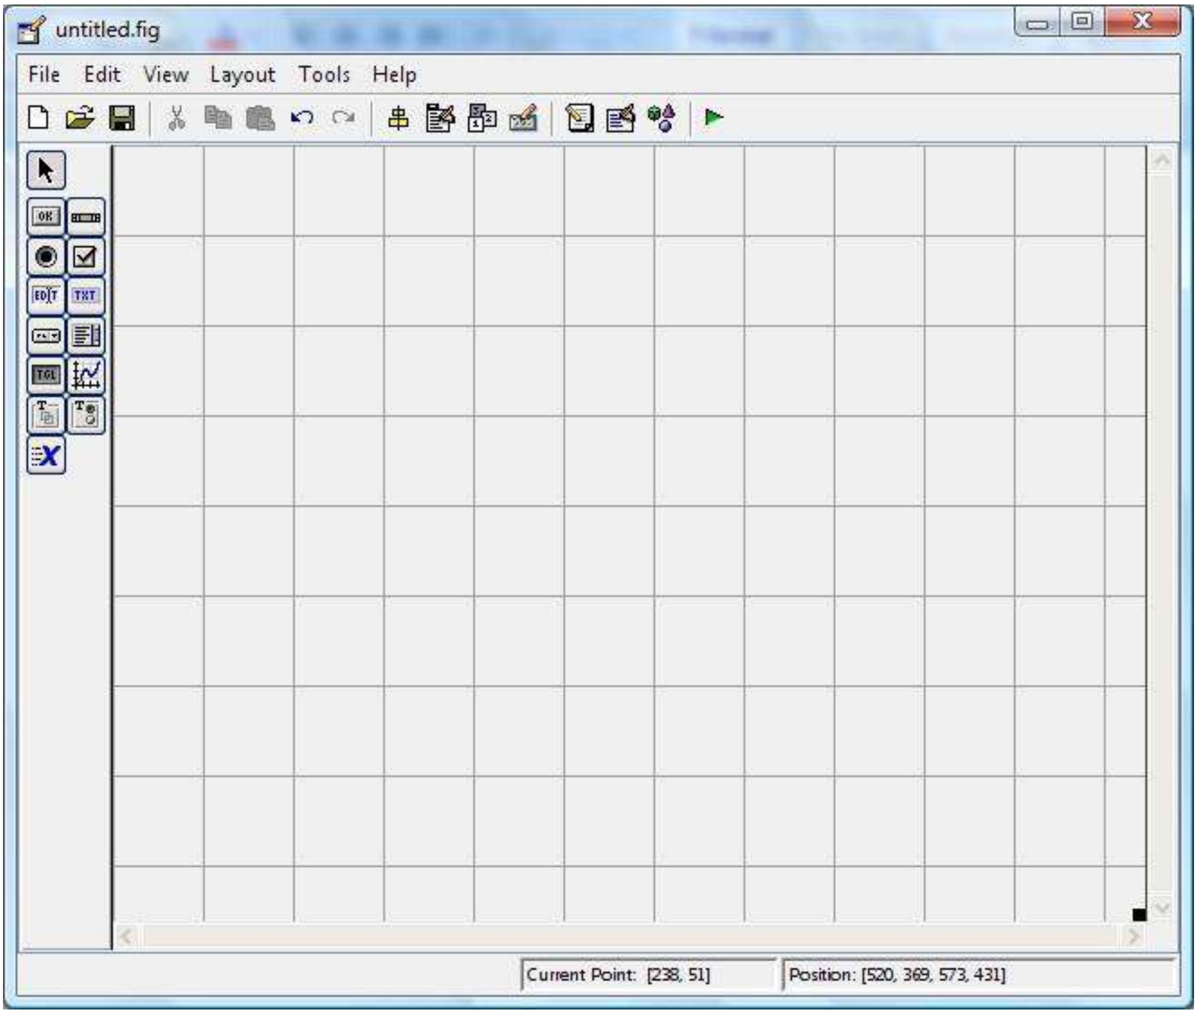
- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.
- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.



A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

5.4 Getting Started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator,

and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

5.4.1 Introduction - describes the components of the MATLAB system.

5.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

5.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

5.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

5.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

5.5 DEVELOPMENT ENVIRONMENT

5.5.1Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

5.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type

Matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

5.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

5.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

5.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window

- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacsmagik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use to Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic textediting, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

5.6 MANIPULATING MATRICES

5.6.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

```
A =  16    3    2   13

      5   10   11    8

      9    6    7   12

      4   15   14    1
```

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

5.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

5.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction
*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

5.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i
Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

5.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

5.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

5.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

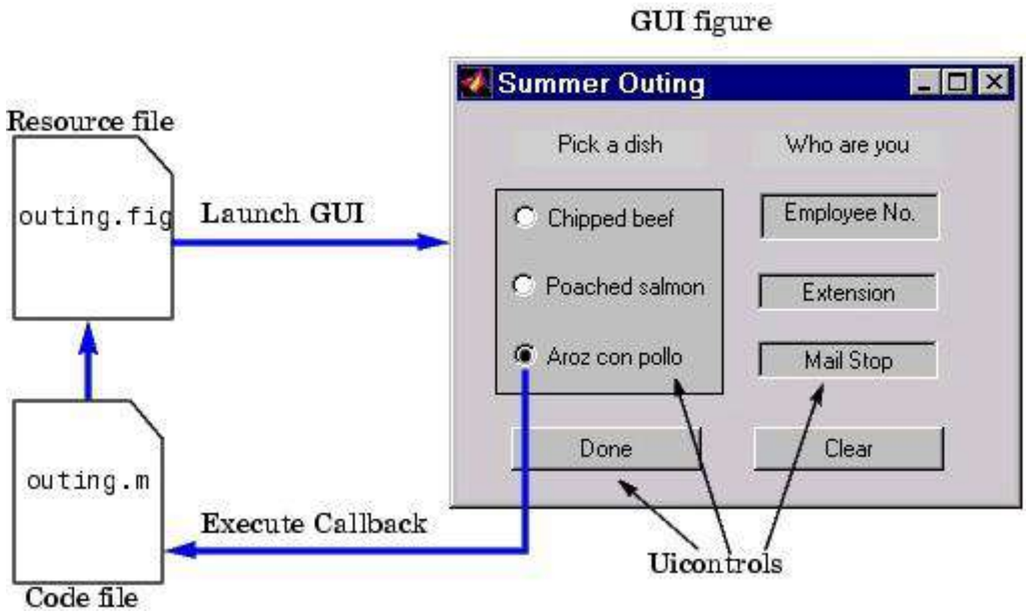


FIG 3.7.2 graphical user blocks

5.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted sub-function prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

5.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques

used in the application M-file.

Application Examples - a collection of examples that illustrate techniques

which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

5.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

   % toggle button is pressed

elseif button_state == get(h,'Min')

   % toggle button is not pressed

end
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);
```

```
a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

   % then checkbox is checked-takeapproriate action

else

   % checkbox is not checked-takeapproriate action

End
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');

% proceed with callback...
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

errordlg('You must enter a numeric value','BadInput','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute.

This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections.In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item

% etc.
```

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrolobjects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes ButtonDownFcn property to define the callback.

5.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axes

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

```
axes(handles.axes1)
```

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

Chapter 6

RELATED WORK

we will first review some background knowledge of image matting, and then briefly introduce vessel enhancement filters used in our work.

A. Image Matting

As aforementioned, image matting aims to accurately extract the foreground given a trimap of an image. Specifically, the input image I(z)(z = (x, y)) is modeled as a linear combination of a foreground image F(z) and a background image B(z):

$$I(z) = \alpha_z F(z) + (1 - \alpha_z) B(z) \qquad (1)$$

where αz, called alpha matte, is the opacity of the foreground. αz ranges from 0 to 1. If αz is constrained to be either 0 or 1, then the matting problem becomes the segmentation problem, where each pixel belongs to either foreground or background.

After obtaining the user specified trimap, to infer the alpha matte in the unknown regions, Chuang et al. uses sets of Gaussian distribution to model the color distributions of the foreground and background images, and estimates the optimal alpha value with a maximum-likelihood criterion. In , Levin et al. derives an effective cost function from the assumption that the foreground and background colors are locally smooth, and employs this function to find the optimal alpha matte. Zheng et al. proposes a local learning based approach and a global learning based approach to perform image matting. In ,Kaiming et al. solves a large kernel matting Laplacian, and achieves a fast matting algorithm. In ,Shahrian and Rajan analyze the texture and color features of the image, and optimize an objective function containing the color and texture components to choose the best foreground and background pair for image matting. Shahrian et al. expands the sampling range of foreground and background regions, and collects a representative set of samples to estimate the alpha matte. In , Cho et al. presents an image matting method to extract alpha mattes across sub-images of a light field image.

B. Vessel Enhancement filters

Vessel enhancement filters plays an important role in retinal blood vessel segmentation . Here two effective filters used in our work are introduced.

1) Morphologically Reconstructed Filter: Morphologically reconstructed filter is an effective tool for blood vessel enhancement [31]. For each input fundus image I, the green channel image Ig is extracted firstly since Ig has the best vessel-background contrast [13]. Then the morphological tophat transformation is performed:

$$I_{th}^{\theta} = I_g^c - (I_g^c \circ S_e^{\theta}) \qquad (2)$$

where I c g is the complement image of Ig, I θ th represents the top-hat transformed image, Se is a structuring element for morphological opening ◦, and θ specifies the angle (in degrees) of the structuring element. The structuring element is of 1- pixel width and 21-pixels length, which approximately fits the diameter of the biggest vessels in the fundus images [31]. Since the morphological top-hat transformation transformation given in Equation (2) can only brighten blood vessels in one direction, the sum of top-hat transformation I θ th along each direction is performed in order to enhance the whole vessel image:

$$I_{mr} = \sum_{\theta \in A} I_{th}^{\theta} \qquad (3)$$

where Imr represents the enhanced vessel image using morphologically reconstructed filter, ”A” is the set of angles of the structuring element and defined as $\{x|0 < x < \pi \;\&\; x \bmod (\pi/12) = 0\}$.

2) Isotropic Undecimated Wavelet Filter: The isotropic undecimated wavelet filter has been used for blood vessel segmentation, and has a good performance on vessel enhancement [32]. Applied to a signal c0 = Ig (Ig is the input green channel image), scaling coefficients are computed by convolution with a filter h ↑j firstly:

$$c_{j+1} = c_j * h^{\uparrow j} \qquad (4)$$

where h0 = [1, 4, 6, 4, 1]/16 is derived form the cubic Bspline, h ↑j is the upsampled filter obtained by inserting 2 j −1 zeros between each pair of adjacent coefficients of h0. Wavelet coefficients are the difference between two adjacent sets of scaling coefficients, i.e.,

$$w_{j+1} = c_j - c_{j+1} \qquad (5)$$

Reconstruction of the original signal from all wavelet coefficients and the final set of scaling coefficients is straightforward, and requires only addition. The final enhanced vessel image is depicted as follows:

$$I_{iuw} = c_n + \sum_{j=1}^{n} w_j \qquad (6)$$

where Iiuw represents the enhanced vessel image using isotropic undecimated wavelet filter. In blood vessel segmentation, wavelet scales: 2 − 3 are selected according to [32].

Chapter 7

METHODOLOGY

The process of generating the trimap of an input fundus image automatically is introduced, followed by detailing the proposed hierarchical image matting model

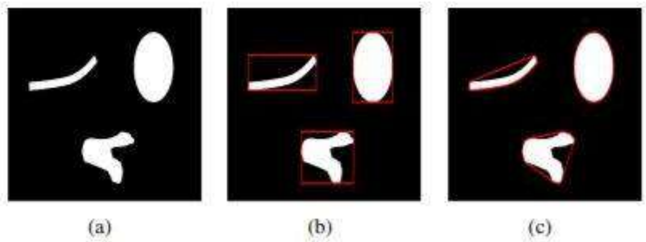

Fig. 2. An example to illustrate the bounding box and convex hull. (a) The exemplary image. (b) The image for the illustration of bounding box. The red boxes are the bounding boxes. (c) The image for the illustration of convex hull. The red polygons are the convex hulls.

A. Trimap Generation

Region features of blood vessels have been used for blood vessel segmentation and performed well on segmentation accuracy and computational efficiency [33]. In this paper, region features of blood vessels are applied to generate the trimap of the input fundus image automatically. The definitions of regions features are given as follows:

• Area indicates the actual number of pixels in the region.

• Bounding Box specifies the smallest rectangle containing the region. An example for the illustration of bounding box is shown in Fig.2(b).

• Extent is the ratio of pixels in the region to pixels in the total bounding box.

• VRatio is the ratio of the length to the width of the bounding box.

• Convex Hull specifies the smallest convex polygon that can contain the region. An example for the illustration of convex hull is shown in Fig.2(c).

• Solidity is the ratio of pixels in the region to pixels in the total convex hull.

The default threshold values of region features:Extent, VRatio, Solidity and their recommended ranges used in this work are reported in Table I. e1 and e2 are two threshold values of Extent features used in this work; r is the threshold value of V Ratio feature; s is the threshold value of Solidity feature. For Area feature, two threshold values: a1 = fi × 2 and a2 = fi×35 are used in this work. fi , called the internal factor, is calculated as d × max(h,w) min(h,w) , where d = 21 is approximately the diameter of the biggest vessels in fundus images [31], h and w are the height and width of the fundus image. The proposed model is not sensitive to above mentioned region features. In other words, these region features can be selected in a relatively large range without sacrificing the performance. In Section V(D)- ”Sensitivity analysis of threshold values of region features”, empirical study is conducted to verify the insensitivity of the proposed model to the threshold values of region features.

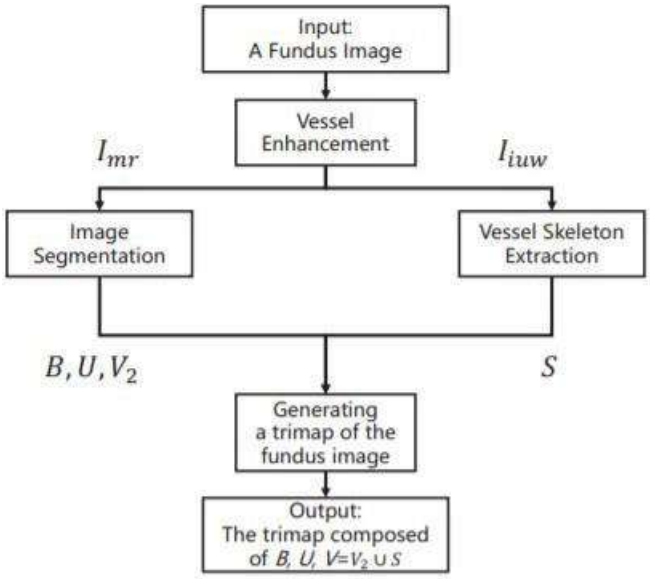

Fig. 3. The process of trimap generation. B represents the background regions; U represents the unknown regions; V2 represents the denoised preliminary vessel regions; S represents the skeleton of blood vessels; V represents the vessel regions.

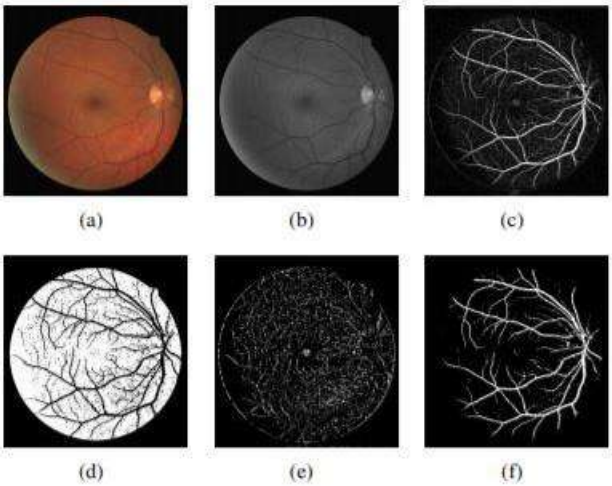

Fig. 4. Image segmentation. (a) The fundus image I. (b) The green channel of the fundus image Ig. (c) The enhanced vessel image Imr. (d) The background regions B. (e) The unknown regions U. (f) The denoised preliminary vessel regions V2

Creating the trimap of the input fundus image includes two main steps: 1) Image Segmentation and 2) Vessel Skeleton Extraction. The process of trimap generation is given in Fig.3.

1) Image Segmentation: The goal of image segmentation is to divide the input image into three regions: the vessel (foreground), background and unknown regions. Firstly the enhanced vessel image Imr is segmented into three regions: the background regions (B), unknown regions (U) and preliminary vessel regions (V1)

$$I_{mr} = \begin{cases} B & \text{if } 0 < I_{mr} < p_1 \\ U & \text{if } p_1 \leqslant I_{mr} < p_2 \\ V_1 & \text{if } p_2 \leqslant I_{mr} \end{cases} \qquad (7)$$

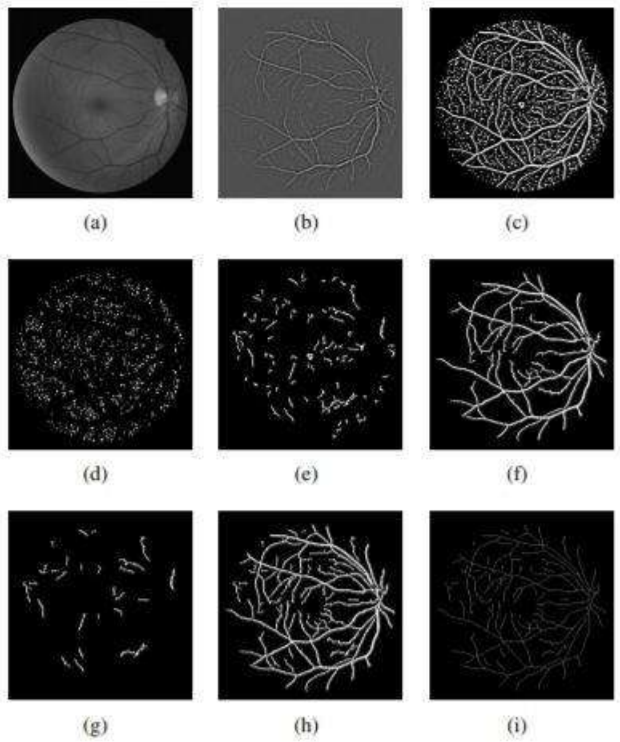

Fig. 5. Vessel skeleton extraction. (a) The green channel of the fundus image I_g. (b) The vessel enhanced image I_{iuw}. (c) The binary image T. (d) The background regions T_1. (e) The candidate regions T_2. (f) The vessel regions T_3. (g) T_4: The preserved regions in T_2. (h) The combined regions of T_3 and T_4. (i) The vessel skeletons S.

where p1 = 0.2 and p2 = 0.35 restrict the unknown region as thin as possible in order to achieve the better matting result [28], [34]. In order to remove the noise regions in V_1, the regions with Area > a1 in V_1 are extracted firstly (V ∗1). Then regions in V ∗ 1 whose Extent ≤ e1 && V Ratio ≤ r && Solidity ≥ s are abandoned, resulting in the denoised preliminary vessel regions V_2. An example of image segmentation is shown in Fig.4.

2) Vessel Skeleton Extraction: Vessel Skeleton Extraction aims to further distinguish the unknown regions and provide more information on blood vessels. In Section V(B)-"Vessel Segmentation Performance", the effectiveness of vessel skeleton extraction will be presented. Firstly, a binary image T is obtained by global thresholding the enhanced vessel image I_{iuw}.

$$T = \begin{cases} 1 & I_{iuw} > t \\ 0 & I_{iuw} \leqslant t \end{cases} \quad (8)$$

where $t = O_{tsu}(I_{iuw}) - \varepsilon$, ε is set as 0.03. Then T is divided into three regions-according to the Area feature

$$T = \begin{cases} T_1 & \text{if } 0 < Area < a_1 \\ T_2 & \text{if } a_1 \leq Area \leq a_2 \\ T_3 & \text{if } a_2 < Area \end{cases} \quad (9)$$

In vessel skeleton extraction, the regions in T_3 are preserved while the regions in T1 are abandoned. Then the regions in T_2 with Extent > e_2 && V Ratio ≤ r are preserved as T_4. Finally skeleton extraction [35] is performed on the combined regions of T_3 and T_4 in order to obtain the skeleton of blood

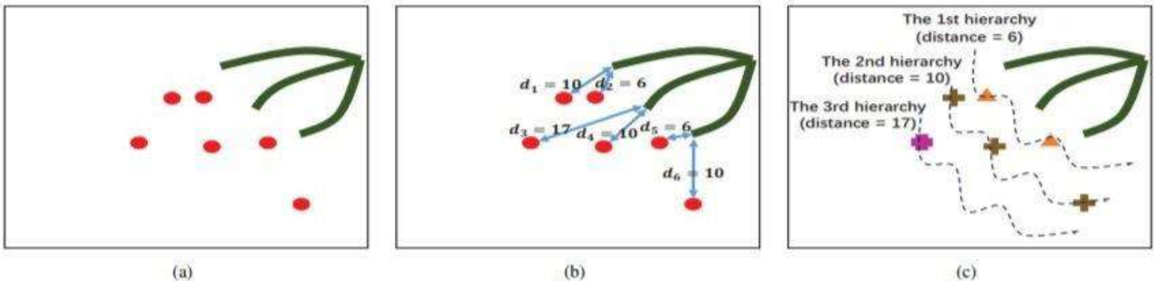

Fig. 6. An example to illustrate the process of initialization. (a) An exemplary image (green pixels represent vessel pixels, red pixels represent unknown pixels). (b) Calculating the closest distance for each unknown pixel (di means the closest distance for the ith unknown pixel). (c) Stratifying unknown pixels into different hierarchies.

vessels S. An example of vessel skeleton extraction is shown in Fig.5. After performing image segmentation and vessel skeleton extraction, the trimap of the input fundus image is generated (as shown in Fig.7(b)), which is composed of the background regions (B), unknown regions (U) and vessel (or foreground) regions ($V = V_2 \cup S$).

B. Hierarchical Image Matting

Model Hierarchical image matting model is proposed to label the pixels in the unknown regions as vessels or background in an incremental way. Specifically, after stratifying the pixels in unknown regions (called unknown pixels) into m hierarchies by a hierarchical strategy, let u j i indicates the ith unknown pixel in the jth hierarchy, the segmented vessel image Iv(u j i) is modeled as follows:

$$I_{mr} = \begin{cases} B & \text{if } 0 < I_{mr} < p_1 \\ U & \text{if } p_1 \leqslant I_{mr} < p_2 \\ V_1 & \text{if } p_2 \leqslant I_{mr} \end{cases} \tag{7}$$

where corre indicates the correlation function (depicted in Equation (13)). The implementation of the hierarchical image matting model consists of two main steps: Step 1 Stratifying the unknown pixels: Stratify pixels in the unknown regions into different hierarchies. Step 2 Hierarchical update: Assign new labels (V or B) to pixels in each hierarchy. The pseudo-code of implementing this model is given in Algorithm

Chapter 8

CONCLUSION

Image matting refers to the problem of accurately extracting a foreground object from an input image, which is very useful in many important applications. However, to the best of our knowledge, image matting has never been employed before to extract blood vessels from fundus image. The major reason is that for retinal blood vessel segmentation, generating a user specified trimap is a tedious and time-consuming task. In addition, a normal image matting model needs to be designed carefully to improve the performance of blood vessel segmentation. In order to overcome these problems, region features of blood vessels are applied to generate the trimap automatically. Then a hierarchical image matting model is proposed to extract the pixels of blood vessel from the unknown regions. More specifically, a hierarchical strategy utilizing the continuity and extendibility of retinal blood vessels is integrated into the image matting model for blood vessel segmentation. The proposed model is very efficient and effective in blood vessel segmentation, which achieves a segmentation accuracy of 96.0%, 95.7% and 95.1% on three public available datasets with an average time of 10.72s, 15.74s and 50.71s, respectively. The experimental results show that it is a very competitive model compared with many other segmentation approaches, and has a low computational time

DECLARATION

We, the student of **Bachelor of Technology** in Department of ELECTRONICS AND COMMUNICATIONS ENGINEERING', session: <2017 – 2021>, St. Martin's Engineering College, Dhulapally, Kompally, Secunderabad, hereby declare that work presented in this Project Work entitled "BREAST CANCER DETECTION FROM HISTOPATHALOGICAL IMAGES USING DEEP LEARNING" is the outcome of our own bonafide work and is correct to the best of our knowledge and this work has been undertaken taking care of Engineering Ethics. This result embodied in this project report has not been submitted in any university for award of any degree.

Manasseh John wesley	**J.Sunith**	**V.Sai yashwanth varda**
(17K81A04K4)	**(17K81A04L0)**	**(17K81A04P8)**

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompanies the successful completion of any task would be incomplete without the mention of the people who made it possible and whose encouragements and guidance have crowded effects with success.

First and foremost, we would like to express my deep sense of gratitude and indebtedness to **our College Management** for their kind support and permission to use the facilities available in the Institute.

We especially would like to express my deep sense of gratitude and indebtedness to **Dr.P.Santosh Kumar Patra**, **our beloved Principal, St. Martin's Engineering College** for his invaluable encouragement, suggestions and support from an early stage of this research and providing me extraordinary experiences throughout the work. Above all, his priceless and meticulous supervision at each and every phase of work inspired me in innumerable ways.

We would like to express our gratitude **to Dr.B.Hari krishna** sir, **Head &Professor**,Dept. of Electronics and Communication Engineering for his advice, supervision, and the vital contribution as and when required during this research. We are proud to record that we had the opportunity to work with an exceptionally experienced Professor like him/her. The time spent with him will remain in my memory for years to come.

We would like to express our gratitude to **our dept. project coordinator Ms.P.Pushpa** Ma'am for her involvement with originality has triggered and nourished my intellectual maturity that will help me for a long time to come.

We sincerely thank our project internal guide **Mr.K.Balasubramanyam Assistant professor**, Department of ECE and our class project coordinator **Ms.P.Pushpa Assistant professor**, Department of ECE for guidance and encouragement in carrying out this project work.

Finally, we are highly grateful and obliged to our college level Project guide **Mr.K.Balasubramanyam Assistant professor** Department of ECE for his advice, supervision, and the vital contribution as and when required during this research work and for their support and co- operation that is difficult to express in words.

1. Manasseh John wesley (17K81A04K4)
2. J.Sunith (17K81A04L0)
3 V.Sai yashwanth varda (17K81A04P8)

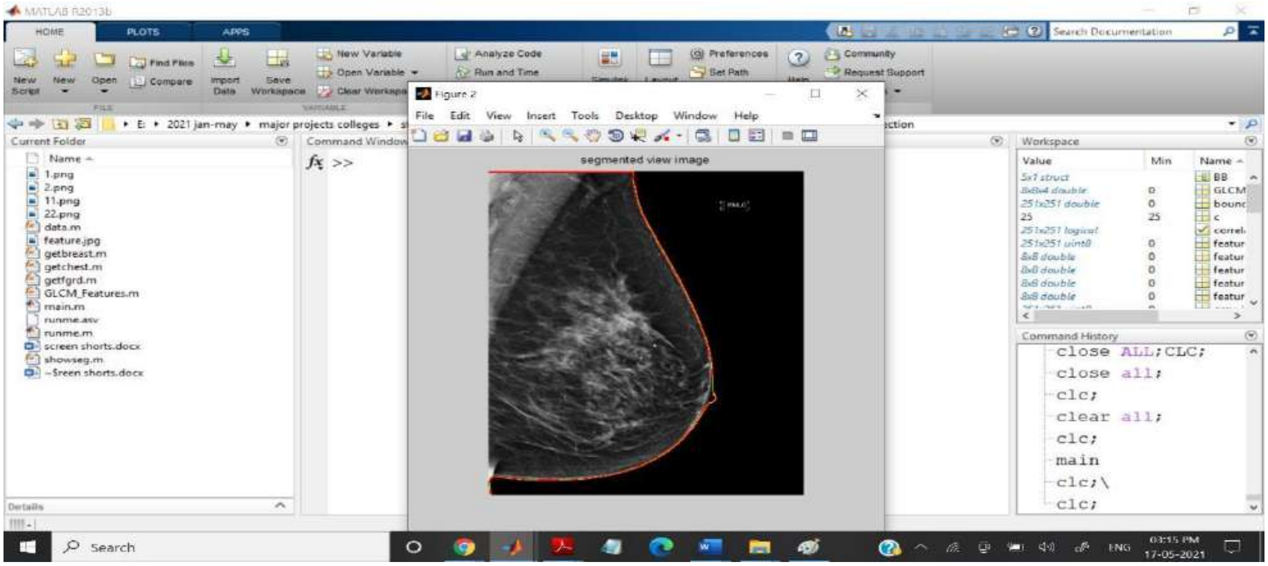
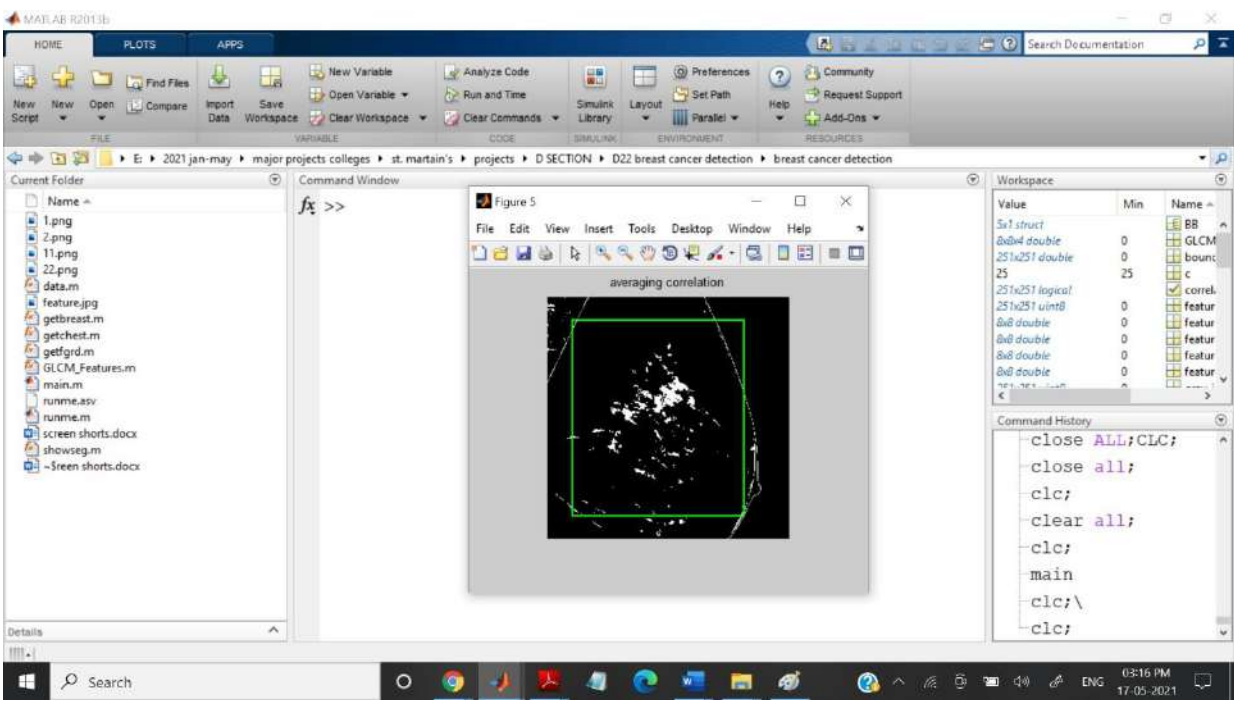
// Abstract

Cancer is the most dangerous disease in the world, it's mainly effective for women. So, our prime target must be curing cancer through scientific investigation and the second main target should be early detection of cancer because the early detection of cancer can be helpful for removing the cancer completely. After reviewing 41 papers we found that several techniques are available for cancer detection. In this paper we proposed Deep Learning algorithm convolutional neural network for diagnosed breast cancer using Mammography MIAS database. The paper shows how we can use deep learning technology for diagnosis of breast cancer using MIAS Dataset. Because deep learning techniques are almost used for high task objective Computer Vision, Image processing, Medical Diagnosis, Neural Language Processing. But in this paper, we are applying deep learning technology on the MIAS Database and we have seen that it is very beneficial for us to diagnose breast cancer with accuracy 98%. This paper is divided into three parts: first we have to collect a dataset and apply a pre-processing algorithm for scaled and filtered data, then we split the dataset for training and testing purposes and generate some graphs for visualization data. I last implemented a model on a training dataset and achieved accuracy 98%. So, we have seen that deep learning technology is a good way to diagnose breast cancer with the MIAS Dataset. This database provides 200 images and 12 features in the dataset. In this paper we have used 12 features for diagnosing breast cancer that we have got after preprocessing. But before the train model we have applied some preprocessing algorithms like Watershed Segmentation, Colour based segmentation and Adaptive Mean Filter For scaled dataset then applied model and achieved accuracy. In this paper we also compare deep learning algorithms with other machine learning and see our proposed system is proved best from others machine learning algorithms.

Keyboards–Deep Learning, Convolutional Neural Network,Neural Network, Random Forest, Support Vector Machine, MachineLearning,MIASDataset.

LIST OF OUTPUT SCREENS:





CHAPTER 1

INTRODUCTION

Breast Cancer is the most common female cancer worldwide. Almost 25% of all cancers with an estimated 1.67 million new cancer cases diagnosed in 2012. Breast cancer is the most common type of cancer among women and its incidence is increasing day by days. The life time risk of developing breast cancer in women is approximately 1/8 in USA, 1/ 12 in Europe, 1/40 in Asia (WHO 2008). As per the cancerindia.org one woman dies of cervical cancer every 8 minutes in India, around 2.5 million number of people living with cancer in India and over 7 lakh new cancer patients registered in every year. India also breast cancer is the most common cancer in women and account for 27% of all cancers. As per the previous study 1,44,937 new cases registered and deaths 70,218 in 2012. But in India the incidence rates begin to rise in the early thirties and peak at ages 50-60 years. According to the World Health Organization breast cancer was responsible for 502,000 deaths in 2005 alone and 1,301,867 of new cases of breast cancer resisted. Health case authorities continuously doing efforts to overcome this merciless disease in which one of the efforts is screening. By screening the breast cancer can be detected in early stages and thus the treatment can be more effective. Many other methods also available such as mammography, ultrasound, CT and MRI. Mammography is the most widely used screening method. In our proposed method we are using Break His[A1] dataset that provided Biopsy Images generated by Mammography method

1.1 IMAGE:

An image is a two-dimensional picture, which has a similar appearance to some subject usually a physical object or a person.

Image is a two-dimensional, such as a photograph, screen display, and as well as a three-dimensional, such as a statue. They may be captured by optical devices—such as cameras, mirrors, lenses, telescopes, microscopes, etc. and natural objects and phenomena, such as the human eye or water surfaces.

The word image is also used in the broader sense of any two-dimensional figure such as a map, a graph, a pie chart, or an abstract painting. In this wider sense, images can also be rendered manually, such as by drawing, painting, carving, rendered automatically by printing or computer graphics technology, or developed by a combination of methods, especially in a pseudo-photograph.

Fig 1 General image

An image is a rectangular grid of pixels. It has a definite height and a definite width counted in pixels. Each pixel is square and has a fixed size on a given display. However different computer monitors may use different sized pixels. The pixels that constitute an image are ordered as a grid (columns and rows); each pixel consists of numbers representing magnitudes of brightness and color.

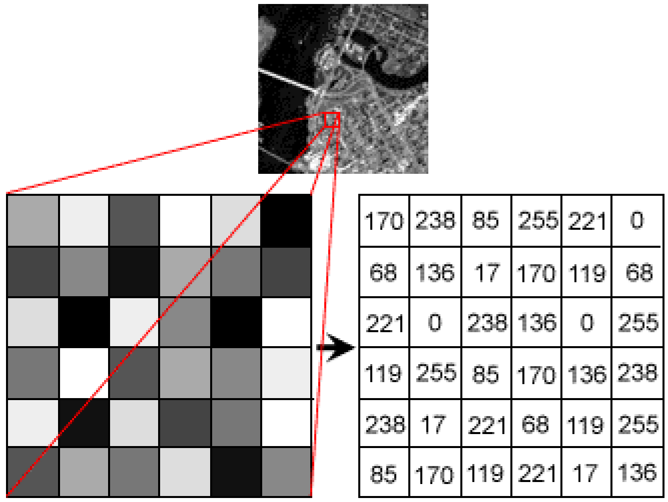


Fig 1.1 Image pixel

Each pixel has a color. The color is a 32-bit integer. The first eight bits determine the redness of the pixel, the next eight bits the greenness, the next eight bits the blueness, and the remaining eight bits the transparency of the pixel.

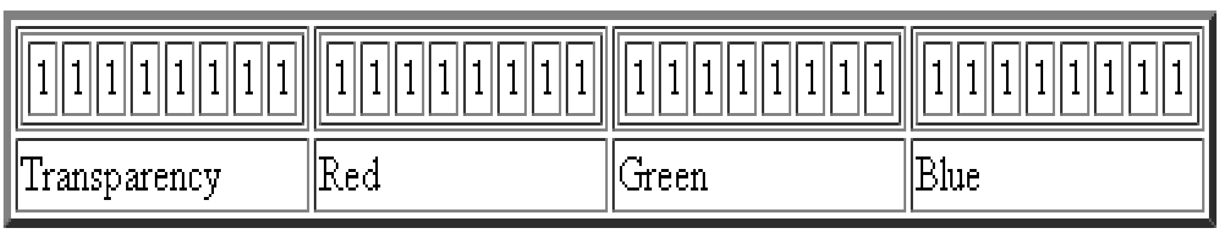

Fig1.2 Transparency image

1.2 IMAGE FILE SIZES:

Image file size is expressed as the number of bytes that increases with the number of pixels composing an image, and the color depth of the pixels. The greater the number of rows and columns, the greater the image resolution, and the larger the file. Also, each pixel of an image increases in size when its color depth increases, an 8-bit pixel (1 byte) stores 256 colors, a 24-bit pixel (3 bytes) stores 16 million colors, the latter known as true color.

Image compression uses algorithms to decrease the size of a file. High resolution cameras produce large image files, ranging from hundreds of kilobytes to megabytes, per the camera's resolution and the image-storage format capacity. High resolution digital cameras record 12 megapixel (1MP = 1,000,000 pixels / 1 million) images, or more, in true color. For example, an image recorded by a 12 MP camera; since each pixel uses 3 bytes to record true color, the uncompressed image would occupy 36,000,000 bytes of memory, a great amount of digital storage for one image, given that cameras must record and store many images to be practical. Faced with large file sizes, both within the camera and a storage disc, image file formats were developed to store such large images.

1.3 IMAGE FILE FORMATS:

Image file formats are standardized means of organizing and storing images. This entry is about digital image formats used to store photographic and other images. Image files are composed of either pixel or vector (geometric) data that are rasterized to pixels when displayed (with few exceptions) in a vector graphic display. Including proprietary types, there are hundreds of image file types. The PNG, JPEG, and GIF formats are most often used to display images on the Internet.

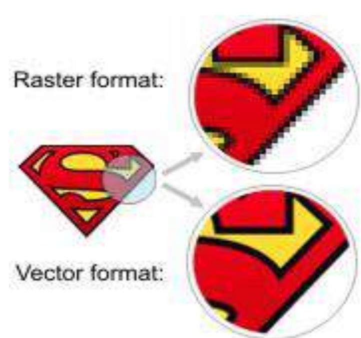

Fig1.3 Resolution image

In addition to straight image formats, Metafile formats are portable formats which can include both raster and vector information. The metafile format is an intermediate format. Most Windows applications open metafiles and then save them in their own native format.

1.3.1 RASTER FORMATS:

These formats store images as bitmaps (also known as pixmaps)

- **JPEG/JFIF:**

JPEG (Joint Photographic Experts Group) is a compression method. JPEG compressed images are usually stored in the JFIF (JPEG File Interchange Format) file format. JPEG compression is lossy compression. Nearly every digital camera can save images in the JPEG/JFIF format, which supports 8 bits per color (red, green, blue) for a 24-bit total, producing relatively small files. Photographic images may be better stored in a lossless non-JPEG format if they will be re-edited, or if small "artifacts" are unacceptable. The JPEG/JFIF format also is used as the image compression algorithm in many Adobe PDF files.

- **EXIF:**

The EXIF (Exchangeable image file format) format is a file standard similar to the JFIF format with TIFF extensions. It is incorporated in the JPEG writing software used in most cameras. Its purpose is to record and to standardize the exchange of images with image metadata between digital cameras and editing and viewing software. The metadata are recorded for individual images and include such things as camera settings, time and date, shutter speed, exposure, image size, compression, name of camera, color information, etc. When images are viewed or edited by image editing software, all of this image information can be displayed.

- **TIFF:**

The TIFF (Tagged Image File Format) format is a flexible format that normally saves 8 bits or 16 bits per color (red, green, blue) for 24-bit and 48-bit totals, respectively, usually using either the TIFF or TIF filename extension. TIFFs are lossy and lossless. Some offer relatively good lossless compression for bi-level (black & white) images. Some digital cameras can save in TIFF format, using the LZW compression algorithm for lossless storage. TIFF image format is not widely supported by web browsers. TIFF remains widely accepted as a photograph file standard in the printing business. TIFF can handle device-specific color spaces, such as the CMYK defined by a particular set of printing press inks.

PNG:

The PNG (Portable Network Graphics) file format was created as the free, open-source successor to the GIF. The PNG file format supports true color (16 million colors) while the GIF supports only 256 colors. The PNG file excels when the image has large, uniformly colored areas. The lossless PNG format is best suited for editing pictures, and the lossy formats, like JPG, are best for the final distribution of photographic images, because JPG files are smaller than PNG files. PNG, an extensible file format for the lossless, portable, well-compressed storage of raster images. PNG provides a patent-free replacement for GIF and can also replace many common uses of TIFF. Indexed-color, grayscale, and true color images are supported, plus an optional alpha channel. PNG is designed to work well in online viewing applications, such as the World Wide Web. PNG is robust, providing both full file integrity checking and simple detection of common transmission errors.

- **GIF:**

GIF (Graphics Interchange Format) is limited to an 8-bit palette, or 256 colors. This makes the GIF format suitable for storing graphics with relatively few colors such as simple diagrams, shapes, logos and cartoon style images. The GIF format supports animation and is still widely used to provide image animation effects. It also uses a lossless compression that is more effective when large areas have a single color, and ineffective for detailed images or dithered images.

- **BMP:**

The BMP file format (Windows bitmap) handles graphics files within the Microsoft Windows OS. Typically, BMP files are uncompressed, hence they are large. The advantage is their simplicity and wide acceptance in Windows programs.

1.3.2 VECTOR FORMATS:

As opposed to the raster image formats above (where the data describes the characteristics of each individual pixel), vector image formats contain a geometric description which can be rendered smoothly at any desired display size.

At some point, all vector graphics must be rasterized in order to be displayed on digital monitors. However, vector images can be displayed with analog CRT technology such as that used in some electronic test equipment, medical monitors, radar displays, laser shows and early video games. Plotters are printers that use vector data rather than pixel data to draw graphics.

- **CGM:**

CGM (Computer Graphics Metafile) is a file format for 2D vector graphics, raster graphics, and text. All graphical elements can be specified in a textual source file that can be compiled into a binary file or one of two text representations. CGM provides a means of graphics data interchange for computer representation of 2D graphical information independent from any particular application, system, platform, or device.

- **SVG:**

SVG (Scalable Vector Graphics) is an open standard created and developed by the World Wide Web Consortium to address the need for a versatile, scriptable and all purpose vector format for the web and otherwise. The SVG format does not have a compression scheme of its own, but due to the textual nature of XML, an SVG graphic can be compressed using a program such as gzip.

1.4 image processing:

Digital image processing, the manipulation of images by computer, is relatively recent development in terms of man's ancient fascination with visual stimuli. In its short history, it has been applied to practically every type of images with varying degree of success. The inherent subjective appeal of pictorial displays attracts perhaps a disproportionate amount of attention from the scientists and also from the layman. Digital image processing like other glamour fields, suffers from myths, mis-connect ions, mis-understandings and mis-information. It is vast umbrella under which fall diverse aspect of optics, electronics, mathematics, photography graphics and computer technology. It is truly multidisciplinary endeavor ploughed with imprecise jargon.

Several factor combine to indicate a lively future for digital image processing. A major factor is the declining cost of computer equipment. Several new technological trends promise to further promote digital image processing. These include parallel processing mode practical by low cost microprocessors, and the use of charge coupled devices (CCDs) for digitizing, storage during processing and display and large low cost of image storage arrays.

1.5 fundamental steps in digital image processing:

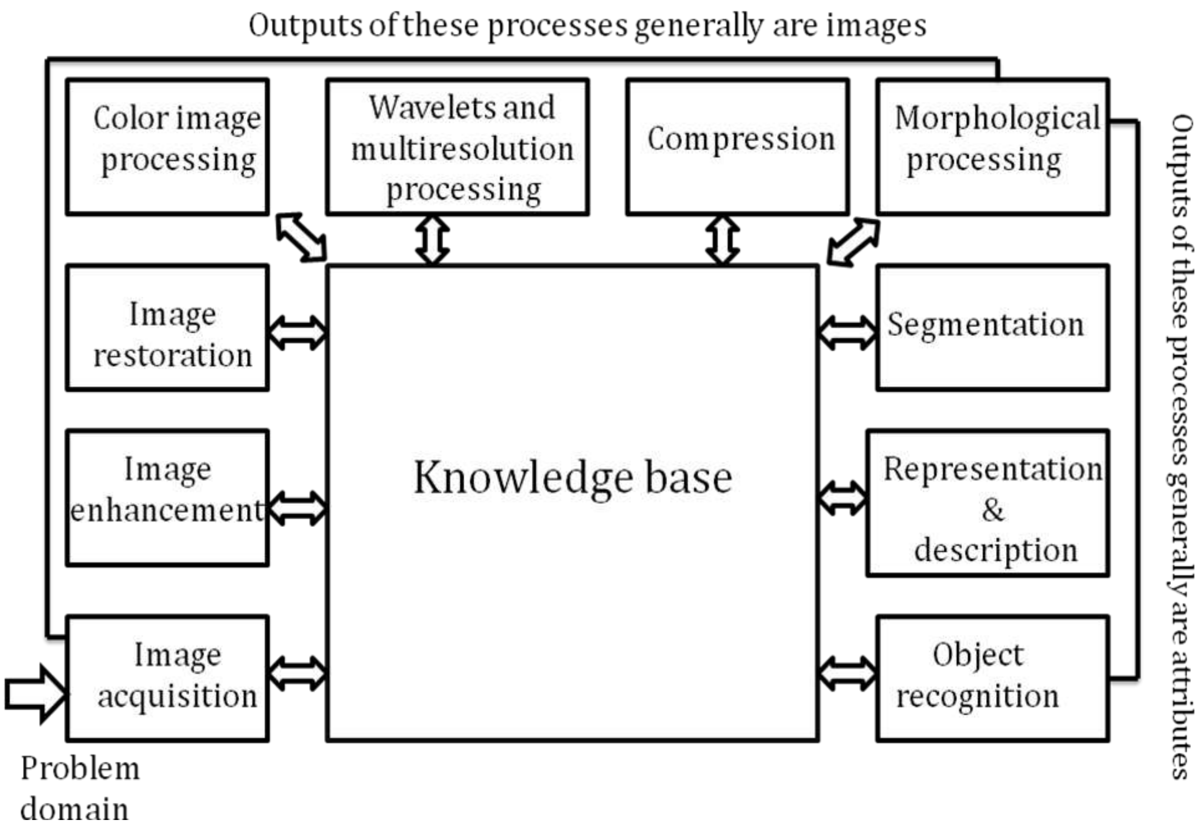

Fig 1.5 Image fundamental

1.5.1 Image Acquisition:

Image Acquisition is to acquire a digital image. To do so requires an image sensor and the capability to digitize the signal produced by the sensor. The sensor could be monochrome or color TV camera that produces an entire image of the problem domain every 1/30 sec. the image sensor could also be line scan camera that produces a single image line at a time. In this case, the objects motion past the line.

Fig 1.5.1 Digital camera image

Scanner produces a two-dimensional image. If the output of the camera or other imaging sensor is not in digital form, an analog to digital converter digitizes it. The nature of the sensor and the image it produces are determined by the application.

Fig 1.5.2 digital camera cell

1.5.2 Image Enhancement:

Image enhancement is among the simplest and most appealing areas of digital image processing. Basically, the idea behind enhancement techniques is to bring out detail that is obscured, or simply to highlight certain features of interesting an image. A familiar example of enhancement is when we increase the contrast of an image because “it looks better.” It is important to keep in mind that enhancement is a very subjective area of image processing.

Fig 1.5.3 Image enhancement

1.5.3 Image restoration:

Image restoration is an area that also deals with improving the appearance of an image. However, unlike enhancement, which is subjective, image restoration is objective, in the sense that restoration techniques tend to be based on mathematical or probabilistic models of image degradation.

Fig 1.5.4 Image restoration

Enhancement, on the other hand, is based on human subjective preferences regarding what constitutes a "good" enhancement result. For example, contrast stretching is considered an enhancement technique because it is based primarily on the pleasing aspects it might present to the viewer, whereas removal of image blur by applying a deblurring function is considered a restoration technique.

1.5.4 Color image processing:

The use of color in image processing is motivated by two principal factors. First, color is a powerful descriptor that often simplifies object identification and extraction from a scene. Second, humans can discern thousands of color shades and intensities, compared to about only two dozen shades of gray. This second factor is particularly important in manual image analysis.

Fig 1.5.5 Color & Gray scale image

1.5.5 Wavelets and multiresolution processing:

Wavelets are the formation for representing images in various degrees of resolution. Although the Fourier transform has been the mainstay of transform based image processing since the late1950's, a more recent transformation, called the wavelet transform, and is now making it even easier to compress, transmit, and analyze many images. Unlike the Fourier transform, whose basis functions are sinusoids, wavelet transforms are based on small values, called Wavelets, of varying frequency and limited duration.

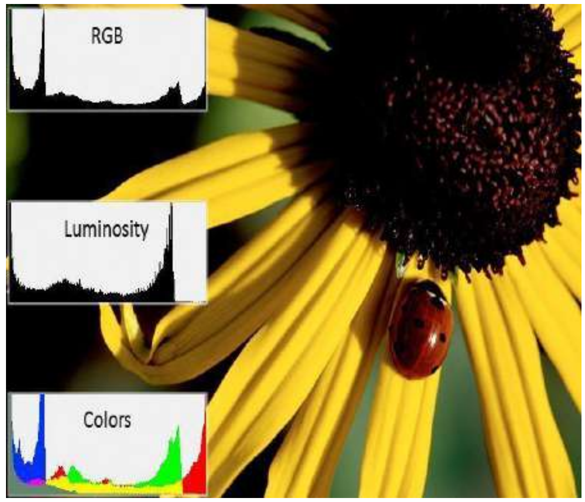

Fig 1.5.6 rgb histogram image

Wavelets were first shown to be the foundation of a powerful new approach to signal processing and analysis called **Multiresolution** theory. Multiresolution theory incorporates and unifies techniques from a variety of disciplines, including sub band coding from signal processing, quadrature mirror filtering from digital speech recognition, and pyramidal image processing.

1.5.6 Compression:

Compression, as the name implies, deals with techniques for reducing the storage required saving an image, or the bandwidth required for transmitting it. Although storage technology has improved significantly over the past decade, the same cannot be said for transmission capacity. This is true particularly in uses of the Internet, which are characterized by significant pictorial content. Image compression is familiar to most users of computers in the form of image file extensions, such as the jpg file extension used in the JPEG (Joint Photographic Experts Group) image compression standard.

1.5.7 Morphological processing:

Morphological processing deals with tools for extracting image components that are useful in the representation and description of shape. The language of mathematical morphology is set theory. As such, morphology offers a unified and powerful approach to numerous image processing problems. Sets in mathematical morphology represent objects in an image. For example, the set of all black pixels in a binary image is a complete morphological description of the image.

Fig 1.5.7 blur to deblur image

In binary images, the sets in question are members of the 2-D integer space Z^2, where each element of a set is a 2-D vector whose coordinates are the (x,y) coordinates of a black(or white) pixel in the image. Gray-scale digital images can be represented as sets whose components are in Z^3. In this case, two components of each element of the set refer to the coordinates of a pixel, and the third corresponds to its discrete gray-level value.

1.5.8 Segmentation:

Segmentation procedures partition an image into its constituent parts or objects. In general, autonomous segmentation is one of the most difficult tasks in digital image processing. A rugged segmentation procedure brings the process a long way toward successful solution of imaging problems that require objects to be identified individually.

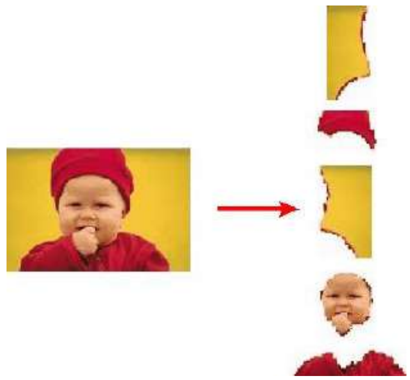

Fig 1.5.8 Image segmentation

On the other hand, weak or erratic segmentation algorithms almost always guarantee eventual failure. In general, the more accurate the segmentation, the more likely recognition is to succeed.

1.5.9 Representation and description:

Representation and description almost always follow the output of a segmentation stage, which usually is raw pixel data, constituting either the boundary of a region (i.e., the set of pixels separating one image region from another) or all the points in the region itself. In either case, converting the data to a form suitable for computer processing is necessary. The first decision that must be made is whether the data should be represented as a boundary or as a complete region. Boundary representation is appropriate when the focus is on external shape characteristics, such as corners and inflections.

Regional representation is appropriate when the focus is on internal properties, such as texture or skeletal shape. In some applications, these representations complement each other. Choosing a representation is only part of the solution for transforming raw data into a form suitable for subsequent computer processing. A method must also be specified for describing the data so that features of interest are highlighted. Description, also called feature selection, deals with extracting attributes that result in some quantitative information of interest or are basic for differentiating one class of objects from another.

1.5.10 Object recognition:

The last stage involves recognition and interpretation. Recognition is the process that assigns a label to an object based on the information provided by its descriptors. Interpretation involves assigning meaning to an ensemble of recognized objects.

1.5.11 Knowledgebase:

Knowledge about a problem domain is coded into image processing system in the form of a knowledge database. This knowledge may be as simple as detailing regions of an image when the information of interests is known to be located, thus limiting the search that has to be conducted in seeking that information. The knowledge base also can be quite complex, such as an inter related to list of all major possible defects in a materials inspection problem or an image data base containing high resolution satellite images of a region in connection with change deletion application. In addition to guiding the operation of each processing module, the knowledge base also controls the interaction between modules. The system must be endowed with the knowledge to recognize the significance of the location of the string with respect to other components of an address field. This knowledge glides not only the operation of each module, but it also aids in feedback operations between modules through the knowledge base. We implemented preprocessing techniques using MATLAB.

1.6 components of an image processing system:

As recently as the mid-1980s, numerous models of image processing systems being sold throughout the world were rather substantial peripheral devices that attached to equally substantial host computers. Late in the 1980s and early in the 1990s, the market shifted to image processing hardware in the form of single boards designed to be compatible with industry standard buses and to fit into engineering workstation cabinets and personal computers. In addition to lowering costs, this market shift also served as a catalyst for a significant number of new companies whose specialty is the development of software written specifically for image processing.

Although large-scale image processing systems still are being sold for massive imaging applications, such as processing of satellite images, the trend continues toward miniaturizing and blending of general-purpose small computers with specialized image processing hardware. Figure 1.24 shows the basic components comprising a typical general-purpose system used for digital image processing. The function of each component is discussed in the following paragraphs, starting with image sensing.

- **Image sensors:**

With reference to sensing, two elements are required to acquire digital images. The first is a physical device that is sensitive to the energy radiated by the object we wish to image. The second, called a digitizer, is a device for converting the output of the physical sensing device into digital form. For instance, in a digital video camera, the sensors produce an electrical output proportional to light intensity. The digitizer converts these outputs to digital data.

- **Specialized image processing hardware:**

Specialized image processing hardware usually consists of the digitizer just mentioned, plus hardware that performs other primitive operations, such as an arithmetic logic unit (ALU), which performs arithmetic and logical operations in parallel on entire images. One example of how an

ALU is used is in averaging images as quickly as they are digitized, for the purpose of noise reduction. This type of hardware sometimes is called a front-end subsystem, and its most distinguishing characteristic is speed. In other words, this unit performs functions that require fast data throughputs (e.g., digitizing and averaging video images at 30 frames) that the typical main computer cannot handle.

- **Computer:**

The computer in an image processing system is a general-purpose computer and can range from a PC to a supercomputer. In dedicated applications, sometimes specially designed computers are used to achieve a required level of performance, but our interest here is on general-purpose image processing systems. In these systems, almost any well-equipped PC-type machine is suitable for offline image processing tasks.

- **Image processing software:**

Software for image processing consists of specialized modules that perform specific tasks. A well-designed package also includes the capability for the user to write code that, as a minimum, utilizes the specialized modules. More sophisticated software packages allow the integration of those modules and general-purpose software commands from at least one computer language.

- **Mass storage:**

Mass storage capability is a must in image processing applications. An image of size 1024*1024 pixels, in which the intensity of each pixel is an 8-bit quantity, requires one megabyte of storage space if the image is not compressed. When dealing with thousands, or even millions, of images, providing adequate storage in an image processing system can be a challenge. Digital storage forimage processing applications fall into three principal categories: (1) short-term storage for use during processing, (2) on-line storage for relatively fast recall, and (3) archival storage, characterized by infrequent access. Storage is measured in bytes (eight bits), Kbytes (one thousand bytes), Mbytes (one million bytes), Gbytes (meaning giga, or one billion, bytes), and Tbytes (meaning tera, or one trillion, bytes)

One method of providing short-term storage is computer memory. Another is by specialized boards, called frame buffers that store one or more images and can be accessed rapidly, usually at video rates. The latter method allows virtually instantaneous image zoom, as well as scroll (vertical shifts) and pan (horizontal shifts). Frame buffers usually are housed in the specialized image processing hardware unit shown in Fig. 1.24. Online storage generally takes the form of magnetic disks or optical-media storage. The key factor characterizing on-line storage is frequent access to the stored data. Finally, archival storage is characterized by massive storage requirements but infrequent need for access. Magnetic tapes and optical disks housed in “jukeboxes” are the usual media for archival applications.

- **Image displays:**
- Image displays in use today are mainly color (preferably flat screen) TV monitors. Monitors are driven by the outputs of image and graphics display cards that are an integral part of the computer system. Seldom are there requirements for image display applications that cannot be met by display cards available commercially as part of the computer system. In some cases, it is necessary to have stereo displays, and these are implemented in the form of headgear containing two small displays embedded in goggles worn by the user.

- **Hardcopy:**

Hardcopy devices for recording images include laser printers, film cameras, heat-sensitive devices, inkjet units, and digital units, such as optical and CD-ROM disks. Film provides the highest possible resolution, but paper is the obvious medium of choice for written material. For presentations, images are displayed on film transparencies or in a digital medium if image projection equipment is used. The latter approach is gaining acceptance as the standard for image presentations.

- **Network:**

Networking is almost a default function in any computer system in use today. Because of the large amount of data inherent in image processing applications, the key consideration in image transmission is bandwidth. In dedicated networks, this typically is not a problem, but communications with remote sites via the Internet are not always as efficient. Fortunately, this situation is improving quickly as a result of optical fiber and other broadband technologies.

Color and texture are two low-level features widely used for image classification, indexing and retrieval. Color is usually represented as a histogram, which is a first order statistical measure that captures global distribution of color in an image One of the main drawbacks of the histogram- based approaches is that the spatial distribution and local variations in color are ignored. Local spatial variation of pixel intensity is commonly used to capture texture information in an image. Grayscale Co-occurrence Matrix (GCM) is a well-known method for texture extraction in the spatial domain. A GCM stores the number of pixel neighborhoods in an image that have a particular grayscale combination. Let I be an image and let p and Np respectively denote any arbitrary pixel and its neighbor in a given direction. If GL denotes the total number of quantized gray levels and gl denotes the individual gray levels, where, gl $\in$ {0, . . .,GL _ 1}, then each component of GCM can be written as follows:

$$\mathrm{gcm}(i, j) = \mathrm{Pr}((\mathrm{gl}_{\mathrm{p}}, \mathrm{gl}_{N_{\mathrm{p}}}) = (i, j))$$

gcm(i, j) is the number of times the gray level of a pixel p denoted by glp equals i, and the gray level of its neighbor Np denoted by glNp equals j, as a fraction of the total number of pixels in the image. Thus, it estimates the probability that the gray level of an arbitrary pixel in an image is i, and that of its neighbor is j. One GCM matrix is generated for each possible neighborhood direction, namely, 0, 45, 90 and 135.Average and range of 14 features like Angular Second Moment, Contrast, Correlation, etc., are generated by combining all the four matrices to get a total of 28 features. In the GCM approach for texture extraction, color information is completely lost since only pixel gray levels are considered.

To incorporate spatial information along with the color of image pixels, a feature called color correlogram has recently been proposed. It is a three-dimensional matrix that represents the probability of finding pixels of any two given colors at a distance ‘d’ apart Auto correlogram is a variation of correlogram, which represents the probability of finding two pixels with the same color at a distance ‘d’ apart. This approach can effectively represent color distribution in an image. However, correlogram features do not capture intensity variation Many image databases often contain both color as well as gray scale images. The color correlogram method does not constitute a good descriptor in such databases.

Another method called Color Co-occurrence Matrix (CCM) has been proposed to capture color variation in an image. CCM is represented as a three-dimensional matrix, where color pair of the pixels p and Np are captured in the first two dimensions of the matrix and the spatial distance ‘d’ between these two pixels is captured in the third dimension. This approach is a generalization of the color correlogram and reduces to the pure color correlogram for d = 1. CCM is generated using only the Hue plane of the HSV (Hue, Saturation and Intensity Value) color space. The Hue axis is quantized into HL number of levels. If individual hue values are denoted by hl, where $\mathrm{hl} \in \{0, \ldots, \mathrm{HL}-1\}$, then each component of CCM can be written as follows:

$$\mathrm{ccm}(i,j) = \Pr((\mathrm{hl}_{\mathrm{p}}, \mathrm{hl}_{N_{\mathrm{p}}}) = (i,j))$$

Four matrices representing neighbors at angles 0, 90, 180 and 270 are considered. This approach was further extended by separating the diagonal and the non-diagonal components of CCM to generate a Modified Color Co-occurrence Matrix (MCCM). MCCM, thus, may be written as follows: MCCM = (CCMD;CCMND)

Here, CCMD and CCMND correspond to the diagonal and off-diagonal components of CCM. The main drawback of this approach is that, like correlogram, it also captures only color information and intensity information is completely ignored.

An alternative approach is to capture intensity variation as a texture feature from an image and combine it with color features like histograms using suitable weights. One of the challenges of this approach is to determine suitable weights since these are highly application-dependent. In certain applications like Content-based Image Retrieval (CBIR), weights are often estimated from relevance feedback given by users.

While relevance feedback is sometimes effective, it makes the process of image retrieval user-dependent and iterative. There is also no guarantee on the convergence of the weight-learning algorithms. In order to overcome these problems, researchers have tried to combine color and texture features together during extraction.

proposed two approaches for capturing color and intensity variations from an image using the LUV color space. In the Single-channel Co-occurrence Matrix (SCM), variations for each color channel, namely, L, U and V are considered independently. In the Multi-channel Co-occurrence Matrix (MCM), variations are captured taking two channels at a time – UV, LU and LV. Since the LUV color space separates out chrominance (L and U) from luminance (V), SCM in effect, generates one GCM and two CCMs from However, in MCM, the count of pairwise occurrences of the values of different channels of the color space is captured. Thus, each component of MCM can be written as follows:

mcmUV(i; j) = Pr((up; vNp) = (i; j))

mcmLU(i; j) = Pr((lp; uNp) = (i; j))

mcmLV(i; j) = Pr((lp; vNp) = (i; j))

Here, mcmUV(i, j) is the number of times the U chromaticity value of a pixel p denoted by up equals i, and the V chromaticity value of its neighbor Np denoted by vNp equals j, as a fraction of the total number of pixels in the image. Similarly, mcmLU(i, j) and mcmLV(i, j) are defined. One MCM matrix is generated for each of the four neighborhood directions, namely, 0, 45, 90 and 135.

Deng and Manjunath (2001) proposed a two-stage method called JSEG, which combines color and texture after image segmentation. In the first stage, colors are quantized to the required levels for differentiating between various regions of an image. Pixel values of the regions are then replaced by their quantized color levels to form a color map. Spatial variation of color levels between different regions in the map is viewed as a type of texture composition of the image.

Yu et al. (2002) suggested the use of color texture moments to represent both color and texture of an image. This approach is based on the calculation of

Local Fourier Transformation (LFT) coefficients. Eight templates equivalent to LFT are operated over an image to generate a characteristic map of the image. Each template is a 3 · 3 filter that considers eight neighbors of the current pixel for LFT calculation. First and second order moments of the characteristic map are then used to generate a set of features.

In this paper, we propose an integrated approach for capturing spatial variation of both color and intensity levels in the neighborhood of each pixel using the HSV color space. In contrast to the other methods, for each pixel and its neighbor, the amount of color and intensity variation between them is estimated using a weight function. Suitable constraints are satisfied while choosing the weight function for effectively relating visual perception of color and the HSV color space properties. The color and intensity variations are represented in a single composite feature known as Integrated Color and Intensity Co-occurrence Matrix (ICICM). While the existing schemes generally treat color and intensity separately, the proposed method provides a composite view to both color and intensity variations in the same feature. The main advantage of using ICICM is that it avoids the use of weights to combine individual color and texture features. We use the ICICM feature in an image retrieval application from large image databases.

Early results on this work was reported in (Vadivel et al., 2004a). In the next section, we describe the proposed feature extraction technique after introducing some of the properties of the HSV color space. Choice of quantization levels for color and intensity axes, selection of parameter values and a brief overview of the image retrieval application

Integrated color and intensity co-occurrence matrix:

We propose to capture color and intensity variation around each pixel in a two-dimensional matrix called Integrated Color and Intensity Co-occurrence Matrix (ICICM). This is a generalization of the Grayscale Co-occurrence Matrix and the Color Co-occurrence Matrix techniques. For each pair of neighboring pixels, we consider

their contribution to both color perception as well as gray level perception to the human eye. Some of the useful properties of the HSV color space and their relationship to human color perception are utilized for extracting this feature. In the next sub-section, we briefly explain relevant properties of the HSV color space. In the subsequent subsection, we describe how the properties can be effectively used for generating ICICM.

HSV color space:

HSV Color space: Basically, there are three properties or three dimensions of color that being hue, saturation and value HSV means Hue, Saturation and Value. It is important to look at because it describes the color based on three properties. It can create the full spectrum of colors by editing the HSV values. The first dimension is the Hue. Hue is the other name for the color or the complicated variation in the color. The quality of color as determined by its dominant wavelength. This Hue is broadly classified into three categories. They are primary Hue, Secondary Hue and Teritiary Hue. The first and the foremost is the primary Hue it consists of three colors they are red, yellow and blue. The secondary Hue is formed by the combination of the equal amount of colors of the primary Hue and the colors of the secondary Hue which was formed by the primary Hue are Orange, Green and violet. The remaining one is the teritiary Hue is formed by the combination of the primary Hue and the secondary Hue. The limitless number of colors are produced by mixing the colors of the primary Hue in different amounts. Saturation is the degree or the purity of color. Then the second dimension is the saturation. Saturation just gives the intensity to the colors. The saturation and intensity drops just by mixing the colors or by adding black to the color. By adding the white to the color in spite of more intense the color becomes lighter. Then finally the third dimension is the Value. The value is the brightness of the color. When the value is zero the color space is totally black with the increase in the color there is also increase in the brightness and shows the various colors. The value describes the contrast of the color. That means it describes the lightness and darkness of the color. As similar to the saturation this value consists of the tints and shades. Tints are the colors with the added white and shades are the colors with the added black.

Properties of the HSV color space:

Sensing of light from an image in the layers of human retina is a complex process with rod cells contributing to scotopic or dim-light vision and cone cells to photopic or bright-light vision (Gonzalez and Woods, 2002). At low levels of illumination, only the rod cells are excited so that only gray shades are perceived. As the illumination level increases, more and more cone cells are excited, resulting in increased color perception. Various color spaces have been introduced to represent and specify colors in a way suitable for storage, processing or transmission of color information in images. Out of these, HSV is one of the models that separate out the luminance component (Intensity) of a pixel color from its chrominance components (Hue and Saturation). Hue represents pure color, which is perceived when incident light is of sufficient illumination and contains a single wavelength. Saturation gives a measure of the degree by which a pure color is diluted by white light. For light with low illumination, corresponding intensity value in the HSV color space is also low.

The HSV color space can be represented as a Hexa cone, with the central vertical axis denoting the luminance component, I (often denoted by V for Intensity Value). Hue, is a chrominance component defined as an angle in the range [0,2p] relative to the red axis with red at angle 0, green at 2p/3, blue at 4p/3 and red again at 2p. Saturation, S, is the other chrominance component, measured as a radial distance from the central axis of the hexacone with value between 0 at the center to 1 at the outer surface. For zero saturation, as the intensity is increased, we move from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from 0 to 1, the perceived color changes from a shade of gray to the purest form of the color represented by its hue. When saturation is near 0, all the pixels in an image look alike even though their hue values are different.

As we increase saturation towards 1, the colors get separated out and are visually perceived as the true colors represented by their hues. Low saturation implies presence of a large number of spectral components in the incident light, causing loss of color information even though the illumination level is sufficiently high. Thus, for low values of saturation or intensity, we can approximate a pixel color by a gray level while for higher saturation and intensity, the pixel color can be approximated by its hue. For low intensities, even for a high saturation, a pixel color is close to its gray value. Similarly, for low saturation even for a high value of intensity, a pixel is perceived as gray. We use these properties to estimate the degree by which a pixel contributes to color perception and gray level perception.

One possible way of capturing color perception of a pixel is to choose suitable thresholds on the intensity and saturation. If the saturation and the intensity are above their respective thresholds, we may consider the pixel to have color dominance; else, it has gray level dominance. However, such a hard thresholding does not properly capture color perception near the threshold values. This is due to the fact that there is no fixed level of illumination above which the cone cells get excited. Instead, there is a gradual transition from scotopic to photopic vision. Similarly, there is no fixed threshold for the saturation of cone cells that leads to loss of chromatic information at higher levels of illumination caused by color dilution. We, therefore, use suitable weights that vary smoothly with saturation and intensity to represent both color and gray scale perception for each pixel.

Non interval quantization:

Due to the large range for each component by directly calculating the characteristics for the retrieval then the computation will be very difficult to ensure rapid retrieval. It is essential to quantify HSV space component to reduce computation and improve efficiency. At the same time, because the human eye to distinguish colors is limited, do not need to calculate all segments. Unequal interval quantization according the human color perception has been applied on H , S ,V components.

Based on the color model of substantial analysis, we divide color into eight parts. Saturation and intensity is divided into three parts separately in accordance with the human eyes to distinguish. In accordance with the different colors and subjective color perception quantification, quantified hue(H), saturation(S) and value(V)

In accordance with the quantization level above, the H, S, V three-dimensional feature vector for different values of with different weights to form one dimensional feature vector and is given by the following equation:

$G = Qs*Qv*H+Qv*s+V$

Where Qs is the quantized series of S and Qv is the quantized series of V. And now by setting Qs = Qv = 3, Then $G = 9H+3S+V$

In this way three component vector of the HSV from one dimensional vector, Which quantize the whole color space for the 72 kinds of the main colors. So we can handle 72 bins of one dimensional histogram. This qualification is effective in reducing the images by the effect of the light intensity, but also reducing the computational time and complexity.

Image retrieval:

Image retrieval is nothing but a computer system used for browsing searching and retrieving images from a large database of digital images. Most traditional and common methods of image retrieval use some method of adding metadata by captioning, Keywords or the descriptions to the images so that the retrieval can be performed. Manual image annotation is time consuming, expensive and laborious. For addressing this there has been a large amount of research done on automatic image annotation. It is crucial to understand the scope and nature of the image data in order to determine the complexity of the image search system design. The design is also largely dependent on the factors. And some of the factors include archives, Domain specific collection, Enterprise collection, Personal collection and web etc..,

Invention of the digital camera has given the common man the privilege to capture his world in pictures, and conveniently share them with others. one can today generate volumes of images with content as diverse as family get-togethers and national park visits. Low-cost storage and easy Web hosting has fueled the metamorphosis of common man from a passive consumer of photography in the past to a current-day active producer. Today, searchable image data exists with extremely diverse visual and semantic content, spanning geographically disparate locations, and is rapidly growing in size. All these factors have created innumerable possibilities and hence considerations for real-world image search system designers.

As far as technological advances are concerned, growth in Content-based image retrieval has been unquestionably rapid. In recent years, there has been significant effort put into understanding the real world implications, applications, and constraints of the technology. Yet, real-world application of the technology is currently limited. We devote this section to understanding image retrieval in the real world and discuss user expectations, system constraints and requirements, and the research effort to make image retrieval a reality in the not-too-distant future.

An image retrieval system designed to serve a personal collection should focus on features such as personalization, flexibility of browsing, and display methodology. For example, Google's Picasa system [Picasa 2004] provides a chronological display of images taking a user on a journey down memory lane. Domain specific collections may impose specific standards for presentation of results. Searching an archive for content discovery could involve long user search sessions. Good visualization and a rich query support system should be the design goals. A system designed for the Web should be able to support massive user traffic. One way to supplement software approaches for this purpose is to provide hardware support to the system architecture. Unfortunately, very little has been explored in this direction, partly due to the lack of agreed-upon indexing and retrieval methods. The notable few applications include an FPGA implementation of a color-histogram-based image retrieval system [Kotoulas and Andreadis 2003], an FPGA implementation for sub image retrieval within an image database [Nakano and Takamichi 2003], and a method for efficient retrieval in a network of imaging devices [Woodrow and Heinzelman 2002].

Discussion. Regardless of the nature of the collection, as the expected user-base grows, factors such as concurrent query support, efficient caching, and parallel and distributed processing of requests become critical. For future real-world image retrieval systems, both software and hardware approaches to address these issues are essential. More realistically, dedicated specialized servers, optimized memory and storage support, and highly parallelizable image search algorithms to exploit cluster computing powers are where the future of large-scale image search hardware support lies.

Overview of texture:

We all know about the term Texture but for defining it is a hard time. One can differentiate the two different Textures by recognizing the similarities and differences. Commonly there are three ways for the usage of the Textures:

Based on the Textures the images can be segmented To differentiate between already segmented regions or to classify them.We can reproduce Textures by producing the descriptions. The texture can be analyzed in three different ways. They are Spectral, Structural and Statistical:

CHAPTER 2

LITERATURE REVIEW

Cancer is the most important disease which must be taken into consideration. The early detection of cancer can be helpful in curing the disease completely. There are some techniques available in the literature for the detection of cancer. Many researchers have contributed their idea in the detection of cancer.

Ahmad M. Sarhan [5] suggests that cancer classification is based on microarray gene expression data using DCT and ANN. He mainly deals about, a stomach cancer detection system based on Artificial Neural Network (ANN) [94,111 - 112], and the Discrete Cosine Transform (DCT). His model uses DCT to obtain classification features from stomach microarrays. The obtained features from the DCT coefficients are then employed to an ANN for classification (tumor or non tumor). Using the Stanford Medical Database he has studied a gene expression within a single sample or to evaluate gene expressions inside two tissue models, such as in tumor and non tumor tissues. Thus, a strong model for stomach cancer detection using microarrays is presented by the author. The system involves a feature extraction stage and an ANN classification stage. The feature extraction stage employs the 2D DCT to condense the input microarray. Low frequency parts of the DCT array comprises of most of the energy/information of the input microarray. These parts were, used as typical features and were obtained using a windowing approach. This work also examines through simulations, optimal parameters such as the optimal number of DCT coefficients/features and the best ANN structure for the detection of stomach cancer. His method produced a success rate of 99.7%. The sensitivity, specificity, and correctness of the system were found to be equal to 99.2%, 100%, and 99.66% correspondingly. Experimental tests on the SMD Database achieved 99.7% of recognition accuracy using only100 DCT coefficients, with a simple 2-layer ANN structure and low computational cost.

Woten et al., [120] proposed a numerical examination for the enhancement ANN in detection of breast cancer using a planar broadband antenna and a three-region breast technique. In this proposed technique, a Modified Four point antennas are used for constructing several wave polarizations. The result of wave polarization on statistical detection is fully described in this approach by the author. Mass spectrometry-based proteomics provides a significant approach for the efficient diagnosis of different diseases. However, there are some issues in the mass spectral data such as huge volume, data complexity and the presence of noise which make the investigation of the proteomic pattern very tough

Xu et al., [123] presented a neural network based approach for proteomic pattern analysis for prostate cancer screening. His approach consists of three stages namely feature selection depending on statistical significant test, classification by a Radial Basis Function Neural Network (RBFNN), a Probabilistic Neural Network (PNN), and ultimately results in optimization via ROC analysis. His approach has high sensitivity (97.1%) and specificity (96.8%) when combined with prostatic biopsy and is expected to help in early detection of prostate cancer

Fooladi et al., [32] proposed that the sensitivity to the induction of chromosomal damage by ionizing Gama Exposure is higher in breast cancer patients than in normal healthy controls. The Gamma effect in each person's lymphocytes and the comparison among two groups is examined, seventy two hours after blood example culturing, by exposing the examples to Gamma rays and then they are produced. The exposure of gamma rays cause abnormality in chromosomes. The database used in this approach includes chromosome breakage in seven chromosome groups and age of patients. In this technique Principle Component Analysis (PCA) is used for feature selection stage. Then Artificial Neural Networks (ANN) is used for classification of normal cases from abnormal cases.

Cheng et al., [22] proposed a novel texture analysis approach based on fuzzy co-occurrence matrix concept. This approach is used to handle early and exact breast cancer diagnosis by examining the microscope-slide biopsy images. A novel feature extraction algorithm is used to extract the features from the digitized images, and then the extracted features are given as input to a multilayer back-propagation neural network to categorize the images into three risk groups. The performances of the conventional cancer diagnosis methods and the proposed algorithm are evaluated and it is found that, this approach has higher performance compared to the existing methods. Cheng’s technique has wide applications in the areas of pattern recognition and image processing.

Shukla et al., [105] proposed a novel technique to simulate a Knowledge Based System for diagnosis of Breast Cancer using Soft Computing tools like Artificial Neural Networks (ANNs) and Neuro Fuzzy Systems

A vital early sign of breast cancer are Clusters of microcalcifications in mammograms. Songyang Yu Ling Guan [107] described a Computer-Aided Diagnosis (CAD) system for the automatic detection of clustered microcalcifications in digitized mammograms.

Architectural distortion is a frequently missed sign of breast cancer. Banik et al., [9] examines the detection of architectural distortion, in mammograms of interval-cancer cases taken prior to the diagnosis of breast cancer, using Gabor filters, phase portrait analysis, fractal dimension, and texture analysis. These approaches were applied to identify initial candidates for sites of architectural deformation in prior mammograms of interval-cancer and also normal cases. A total of 4212 Regions of Interest (ROIs) were routinely obtained from 106 prior mammograms of 56 interval-cancer scenarios, which includes 262 ROIs connected to architectural distortion, and from 52 prior mammograms of 13 normal cases. For every ROI, the fractal dimension and Haralick's texture features were calculated. Feature selection was obtained through stepwise logistic regression and in terms of the area under the Receiver Operating characteristics (ROC) Curve (AUC). The significant results obtained, in terms of AUC, are 0.75 with the Bayesian classifier, 0.71 with Fisher Linear Discriminant Analysis, and 0.76 with an Artificial Neural Network (ANN) based on Radial Basis Functions (RBF). The performance evaluation of the techniques with free-response receiver operating characteristics denoted a sensitivity of 0.80 at 10.5 false positives per image.

Hany Ayad Bastawrous Fukumoto et al., [43] proposed a CAD approach used for the detection of Ground Glass Opacity (GGO) nodules in chest CT images. Gabor filter on the CT image is used in this approach in order to enhance the detection process. Then some morphological process including threshold process and labeling to extract the objects having high intensity values are performed. Then, to observe these objects several feature analysis is utilized which determines that which of them are possible to be cancer candidates. A template matching among the potential cancer candidates and some Gaussian reference approaches is carried out by following the feature analysis, to find the similarity among them. The approach was applied on 715 slices containing 25 GGO nodules and achieved detection sensitivity of 92% with False Positive (FP) rate of 0.76 FP/slice. Ultimately, ANN is used to minimize the number of FP findings. The FP rate decreases to 0.25 FP/slice after applying ANN but at the expense of decreasing the detection sensitivity to 84%.

Land et al., [67] proposed an approach based on a modified form of Fogel's evolutionary programming approach for evolving neural networks for the detection of breast cancer using fine needle aspirate data. Data visualization and pre-processing description portrays the gentle and cruel raw data in graphical interpretative form. Moreover, it portrays a symmetrized dot pattern of the same data which may be used to corroborate the classification provided by the network. These developed architectures regularly achieved a classification accuracy of greater than 96% while, together, achieving a much smaller type II error. These results were attained with different data sets using the same architecture, and were also attained with the same data set over a family of developed architectures.

Mini et al., [77] presented a new approach to the problem of computeraided analysis of digital mammograms for breast cancer detection. This approach classified mammograms into normal and abnormal. The structures in mammograms formed by normal glandular tissue of diverse density were removed using a Wavelet Transform (WT) based local average subtraction. Then the linear markings produced by the normal connective tissue were identified and eliminated. Any irregularity that was present in the mammogram was hence improved in the residual image, which caused the choice concerning the normality of the mammogram much easier. Statistical descriptors based on high-order statistics obtained from the residual image were applied to a Probabilistic Neural Network (PNN) for classification. A recognition score of 71% was obtained by using the Mammographic Image Analysis Society (MIAS) database.

Baoyu Zheng et al., [10] proposed a novel Multistage Neural Network (MSNN) for locating and classifying micro-calcification in digital mammography. MSNN was trained using Back Propagation (BP) with Kalman Filtering (KF). A novel nonlinear decision approach to enhance the performance of the classification was proposed. From the experimental observation, it is clearly observed that the sensitivity of this classification/detection is 100% with the false positive detection rate of less than 1 Micro-Calcification Clusters (MCCs) per image. The proposed approaches were automatic or operator independent and offer realistic image processing time as needed for breast cancer screening programs.

Woten et al., [120] described the applicability of Artificial Neural Networks (ANNs) to breast cancer detection. A simplified sample of the breast containing a tumor was used to decide the scattering of electromagnetic waves in the microwave band. ANN was trained with this data which was then tested on new data to forecast the presence or absence of a tumor. [Synthetic variation was added to the data to realistic sample the breast.

Herold et al., [27] compares unsupervised and supervised gene selection methods. Recent mechanism learning approaches depend on matrix disintegration methods similar to Independent Component Analysis (ICA) offer innovative and well-organized investigation tools which are explored presently to evaluate gene expression outline. These tentative characteristic extraction methods gave instructive expression modes which provided indication of fundamental regulatory procedures. The gene which exhibited the strong behavior was taken for the classification of the tissue samples under examination. To verify this result, it was compared with supervised gene selection techniques which depended on numerical scores or support vector. This technique was used in macrophages loaded/de-loaded with chemically customized low density lipids.

A new nonparametric gene selection method for classification of microarray data was suggested by Lihua Ye et al., [69]. Selection of the gene was an essential step of gene appearance data investigation. An innovative nonparametric technique, Gene Selection for Multiclass (GSM), was implemented, which chose genes based on the measure of the large inter-class variation and the small intra-class variation. Using the default training and testing sets on two publicly available datasets, leukemia (two classes) and SRBCT (four classes), the method had been evaluated and compared with three relative methods, F-test, SAM and chi.

Dinc et al., [99] put forth a gene classification technique using appropriate feature selection method and Fukunaga-Koontz transform kernel. In his approach, a new algorithm related with feature selection method mostly implemented in data mining, machine learning and pattern recognition fields was proposed. Traditional Fukunaga-Koontz transform was broaden to a binary kernel classifier. This method used the cDNA microarrays to evaluate 11,000 gene expression profiles in 60 individual cancer cell lines which are utilized in a medicine discovery screen by the National Cancer Institute and Diffuse huge B-cell lymphoma data including 62 cells and higher than 4,000 genes. This approach used two stage algorithm applied on NCI60 and LYM dataset was compared with other characteristic selection models in detail.

Boyang Li et al., [13] presented a gene classification method using an improved SVM classifier with soft decision boundary. SVM classifier provided a well-organized technique to deal with a variety of categorization difficulties, because it depended on the margin maximization and arithmetical methods. Gene data was very different from other categorization data in many ways. One gene may have numerous different functions, so some gene may have more than one functional label. Since some kind of solid boundaries were generally used to categorize the data randomly in the majority of the traditional method, they were not legitimate for the data with a common part among the classes. An additional representative difficulty in gene data was data inequality that means the size of one class is greatly higher than other classes, which was the most important reason for causing the excursion of division boundary. The system defined a kind of confidence degree based on the decision values of the samples. The boundary was a categorization boundary that depends on confidence degree of data. Numerical approaches and curve fitting algorithms of SVM was utilized to categorize multi- label gene data and also deals with data inequality

Lee et al., [68] suggested a gene ranking method using text-mining for the identification of disease related genes. For the recognition of significant genes participated in particular diseases, microarray gene appearance profiles had been widely used to prioritize candidate genes. The author proposed a new gene ranking process that utilized gene-gene relations extracted from literature along with gene expression scores obtained from microarrays. Here the gene-gene relations were extracted by taking a hybrid method which was a combination of syntactic analysis and co-occurrence based approaches. Specifically, the author performed the syntactic parsing on the text and then, within each clause of the parsed sentence, the co-occurred gene names were considered to be mutually related. Both the gene network derived from the gene-gene relations obtained in the above way and the gene expression scores were given as the inputs to the Gene-Rank algorithm. For the evaluation of his approach, many experiments were conducted with the publicly available prostate cancer data. The results show that this method was superior in the precision and the recall to the original Gene-Rank which employs the genegene relations built from gene ontology annotations. Furthermore, this hybrid approach to the gene-gene relation extraction produces better prioritization of truly disease-related genes in top ranks than the existing popular cooccurrence approach.

A novel gene ranking algorithm based on random subspace method was presented by Ruichu Cai et al., [95]. Gene selection is to select the gene which contains the maximum information from the whole gene set. It's a significant preprocessing procedure for the discriminant examination of microarray information, because many of the genes were unrelated or redundant to the discriminant difficulty. The gene selection difficulty was considered as a gene ranking trouble and a Random Subspace Method based Gene Ranking (RSM-GR) algorithm was developed. In RSM-

GR, firstly subsets of the genes are randomly generated, then Support Vector Machines are respectively trained on each subset and thus produce the important factor of each gene; finally, the importance of each gene obtained from these randomly selected subsets was combined to constitute its final importance. Experiments on two public datasets show that RSM-GR obtains gene sets leading to more precise classification results than other gene selection methods, and it demanded less computational time. RSM-GR could also deal better with datasets with a large number of genes and a big number of genes to be selected.

Hero [3] put forth a gene selection and ranking with microarray data. Over many years, an explosion in the quantity of genomic data available to biomedical researchers due to advances in biotechnology. For instance, by utilizing gene microarrays, it was very easy to investigate a person's gene expression profile more than 30,000 genes of the person genome. Signals obtained from gene microarray experimentations can be associated to genetic features underlying disease, improvement, and aging in a population. This had significantly speeded up the gene detection. However, the enormous scale and investigational variability of genomic data made removal of biologically important genetic information was very challenging. One of the biggest disputes was to recognize the affected genes that were participated in that specific disease based on a gene microarray research. The authors illustrated multi criterion approaches that are proposed for this gene selection and ranking difficulty.

Shaik et al., [52] proposed an empirical CDF approach to estimate the significance of gene ranking for finding differentially expressed genes. It recommended an approach for finding importance of gene ranking. The microarray data usually had a huge number of genes that were not differentially conveyed across several circumstances. In microarray examination, it was a general practice to first reject these genes as uninformative, depends on some filtering condition. This filtering method resulted the information loss as the uninformative genes, may be used to assemble an empirical distribution of genes under the null hypothesis. The distribution of the non-differentially expressed genes is difficult and considered as a combination of distributions. The null hypothesis is that the gene is not differentially expressed. The importance of the differentially expressed genes can be approximated by using the empirical distribution function of the huge number of insignificant genes. The proposed approach was very effective, fewer computation intensive and implemented on microarray datasets of any sample size.

Yang Feng et al., [126] suggested a technique for improving robustness of gene ranking by re-sampling and permutation based score correction and normalization Feature ranking was one of the commonly used feature selection approach, which ranks features through their individual importance. Traditional feature ranking criteria were apt to produce inconsistent ranking results even with light perturbations in training samples when applied to high dimensional and small-sized gene expression data. A widely used strategy for solving the inconsistencies was the multi-criterion combination. But one problem encountered in combining multiple criteria was the score normalization. In his work, problems in existing methods are first analyzed, and a new gene importance transformation algorithm is then proposed. Experimental studies on three popular gene expression datasets showed that the multi-criterion combination based on the proposed score correction and normalization produced gene rankings with enhanced robustness.

Chen Liao et al., [20] presented a gene selection for cancer classification using Wilcoxon rank sum test and Support Vector Machine. Gene selection was an important difficulty in microarray data processing. A novel gene selection approach derived from Wilcoxon rank sum test and Support Vector Machine (SVM) was developed. Wilcoxon rank sum test was utilized to choose a subset is done first. Next step was to train and test the selected gene with the use of SVM classifier with linear kernel independently and genes with elevated testing accuracy rates are selected to form the last reduced gene subset. Leave-One-Out Cross Validation (LOOCV) categorization outputs on two datasets namely ALL/AML leukemia and breast cancer to exhibit the implemented method can obtain good result with final reduced subset. The resulted genes were listed and their expression levels were outlined to illustrate that the selected genes can produce clear separation between two classes.

Zhipeng Cai et al., [131] proposed the gene clustering to identify discriminatory genes with higher classification accuracy. A particular DNA microarray evaluated thousands to tens of thousands of gene expression levels, but investigational datasets usually contains very lower arrays of genes, most probably in tens to hundreds, taken over a selection of tissue samples. The biological understanding of these data concentrates on recognizing subsets of induced genes that could be used to differentiate numerous categories of tissue, to provide investigational evidence for connections between a subset of genes and the tissue pathology. Many methods were available to recognize discriminatory gene subsets which can be used and then it was ranked based on the classification accuracy. But the large dimensionality of the gene expression space when combined with comparatively smaller amount tissue samples which would definitely produce the dimensionality difficulty gene subsets that were too large to provide convincing evidence for any plausible causal connection between that gene subset and the tissue pathology. The author developed an innovative gene selection approach called Clustered Gene Selection (CGS). When this method was combined with the existing approaches will recognize gene subsets that overcome the dimensionality difficulty and enhance the classification accuracy. Observations on many real datasets proves that CGS can recognize many more cancer related genes and evidently enhance the classification accuracy, compared with three other non-CGS based gene selection methods.

A statistical method for ranking differentially expressed genes was recommended by Broberg [85]. Current methods have evaluated gene selection approaches by utilizing ROC curves calculated by simulation. But, no effort had been made to evaluate selection accuracy as a function of population parameters. In particular, simulation investigations are limited unavoidably when the multiplicity was considered, as only a small subset of conditions can possibly be explored. The authors summarized a technique for predicting an optimal test statistic with which to rank genes with respect to differential expression. A test of this approach demonstrated that it permitted generation of top gene lists that give a small number of false positives and a small amount of false negatives. Evaluation of the false-negative as well as the false-positive rate illustrated the main focus of this approach.

Identifying significant genes from microarray data was presented by Han-Yu Chuang et al., [44]. Microarray method was a latest improvement in investigational molecular biology which can produce quantitative expression magnitudes for large number of genes in a single, cellular mRNA sample. All these gene expression magnitudes outline a collective profile of the sample, which could be utilized to distinguish samples from dissimilar classes such as tissue types or treatments. In the gene expression profile data gathered in a specific evaluation, most likely only few genes would be differentially expressed among the classes, whereas many other genes had similar expression levels. Selecting a set of informative differential genes obtained from these large set of data was significant for microarray data analysis. The authors illustrate a framework for selecting informative genes which was called as Ranking And Combination Analysis (RAC). This method provided the combination of many existing better informative gene selection approaches. To evaluate this method they conducted many experiments using three data sets and six existing feature selection methods. The observations demonstrated that the RAC framework was a strong and effective method to categorize informative gene for microarray data. In many cases, the combined approach on two selecting techniques provided a better performance compared to the efficiency of the individual technique. Significantly, the combined approach outperformed each of the individual feature selection approach when considering all three data sets together. All these experimentation result showed that RCA was an effective and useful approach for the microarray gene expression analysis.

Kai-Bo Duan et al., [62] presented a multiple SVM-RFE for gene selection in cancer classification with expression data. It suggested an innovative feature selection method that employs a backward elimination method similar to that utilized in Support Vector Machine Recursive Feature Elimination (SVM-RFE). The proposed method was different from the SVMRFE method, as it evaluated the feature ranking score from a numerical examination of weight vectors of numerous linear Support Vector Machines trained on subsamples of the original training data in all the steps. This approach was tested on many gene expression datasets for cancer categorization. The outputs demonstrate that the implemented feature selection approach selects improved gene subsets compared to the original SVM-RFE and increases the classification accuracy. A Gene Ontology-based resemblance evaluation indicates that the selected subsets are functionally diverse, additionally validating this proposed gene selection approach. This examination also recommends that, for gene expression-based cancer classification, standard test error from several divisions of training and test sets can be suggested as an indication of performance quality.

Support vectors based correlation coefficient for gene and sample selection in cancer classification was recommended by Mundra et al., [84]. Correlation was an extensively used filter criterion for gene selection in cancer classification. However, it used all the training samples in ranking, which might not be equally significant for the classification. Using support vectors, the author demonstrated that classical correlation coefficient based gene selection was biased because of the sample points were away from classification margin. To remove such bias, this approach used only the support vectors for computation of correlation coefficient and proposed a backward elimination based SVcc-RFE algorithm. The method was tested on numerous benchmark cancer gene expression datasets and the outputs show enhancement in classification performance compared to other state-of-the-art methods.

Jin-Hyuk Hong Herold et al., [57] put forth a cancer classification with incremental gene selection based on DNA microarray data. Gene selection was significant issue for cancer classification. Filter and wrapper techniques are extensively used for gene selection, where the filter technique was hard to measure the relationship among the genes and the wrapper technique required lots of computation. The author proposed an innovative method called gene boosting which was used to select appropriate gene subsets by combining filter and wrapper approaches. This approach continuously selects a set of top-ranked informative genes using a filtering technique regarding to a chronological training dataset constructed according to the classification result for the original training dataset. Experiments conducted on few microarray benchmark datasets result showed that this technique was very efficient in predicting an appropriate gene subset. Aggressive performance was obtained with fewer genes in a reasonable time. This also led to the detection of some genes selected frequently as useful features

Runxuan Zhang et al., [97] developed Extreme Learning Machine (ELM) which was used for directing multicategory classification problems in the cancer diagnosis area. ELM evades problems such as local minima improper learning rate and overfitting. It had calculated the multicategory classification performance of ELM on three standard microarray data sets for cancer diagnosis, that is, the GCM data set, the Lung data set, and the Lymphoma data set. The results reveal that ELM created comparable or recovered classification accuracies with condensed training time and implementation complexity contrast to Artificial Neural Networks methods such as conventional back-propagation ANN, Linder's SANN, and Support Vector Machine methods like Support Vector Machine – One Versus One (SVM-OVO) and Support Vector Machine – One Versus All (SVM-OVA). ELM also attained better correctness for classification of individual categories.

A new Mutual Information (MI)-based feature-selection method to solve the so-called large p and small n problem experienced in a microarray gene expression-based data is presented by Huang et al., [48]. Firstly, a gridbased feature clustering algorithm was initiated to remove redundant features. A large gene set was then highly condensed in a very capable way. As a result, the computational effectiveness of the entire feature-selection process was largely improved. Secondly, MI was directly anticipated using quadratic MI mutually with Parzen window density estimators. This approach was capable of delivering dependable results even when only a small pattern set was accessible. Also, a novel MI-based criterion was planned to evade the greatly redundant selection results in a systematic way. Finally, credited to the direct evaluation of MI, the suitable selected feature subsets can be reasonably determined.

Extracting biologically pertinent information from DNA microarrays was a very imperative task for drug development and test, function annotation, and cancer diagnosis. Numerous clustering methods had been planned for the study of gene expression data, however when analyzing the huge and heterogeneous collections of gene expression data, conventional clustering algorithms cannot frequently create a satisfactory solution. Biclustering algorithm had been presented by Wen-Hui Yang et al., [118] as an alternative approach to standard clustering techniques to identify local structures from gene expression data set. The patterns gave clues on the most important biological processes connected with different physiological states. Unlike from existing bicluster patterns, it first introduces a further general pattern: correlated bicluster, which had instinctive biological interpretation. Subsequently, it planned a new transform technique based on singular value decomposition so that recognizing correlated-bicluster problem from gene expression matrix was changed into two global clustering problems. To produce δ-corBiclusters capably the Mixed-Clustering algorithm and the Lift algorithm are developed. The biclusters acquired using the method from gene expression data sets of many human organs and the yeast Saccharomyces cerevisiae demonstrates obvious biological meanings

Class discovery from gene expression data was a significant job for cancer diagnosis. In this work, Zhiwen Yu et al., [132] presented a new framework for class discovery. The novel framework incorporates the perturbation technique, the cluster ensemble approach, and the cluster validity index. Specially, it first produced a set of perturbed datasets from the original microarray data. Second, the Neural Gas, which provided as the basic clustering algorithm, was pertained to attain the partitions from the original dataset and the perturbed datasets. At last, a new cluster validity index called Disagreement/Agreement (DA) Index (DAI) was planned to recognize the number of classes in the dataset by considering the difference among the partition obtained from the original dataset and the partitions obtained from the perturbed datasets

Huang et al., [47] focused on effective identification of informative genes. It examined gene selection models from the perspective of optimization theory. As a result, a novel strategy was planned to change conventional search engines. Moreover, over fitting was possible to take place in microarray data because of their small sample set, a point injection technique was generated to deal with the problem of over fitting. The proposed strategies had been calculated on three kinds of cancer diagnosis.

Kai-Bo Duan et al., [62] proposed a new feature selection method that used a backward elimination procedure similar to that implemented in Support Vector Machine Recursive Feature Elimination (SVM-RFE). Not like the SVM-RFE method, at every step, the proposed approach calculated the feature ranking score from a statistical analysis of weight vectors of several linear SVMs trained on subsamples of the original training data. The proposed method was experienced on four gene expression datasets for cancer classification. A Gene Ontology-based comparison assessment showed that the selected subsets are functionally varied, further validating the gene selection method. This investigation suggested that, for gene expression-based cancer classification, average test error from several partitions of training and test sets could be recommended as a mention of presentation quality.

CHAPTER 3

SOFTWARE INTRODUCTION:

3.1. Introduction to MATLAB

MATLAB is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. Typical uses include

- Math and computation
- Algorithm development
- Data acquisition
- Modeling, simulation, and prototyping
- Data analysis, exploration, and visualization
- Scientific and engineering graphics
- Application development, including graphical user interface building

MATLAB is an interactive system whose basic data element is an array that does not require dimensioning. This allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar non-interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects. Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding the state of the art in software for matrix computation.

MATLAB has evolved over a period of years with input from many users. In university environments, it is the standard instructional tool for introductory and advanced courses in mathematics, engineering, and science. In industry, MATLAB is the tool of choice for high-productivity research, development, and analysis.

MATLAB features a family of add-on application-specific solutions called toolboxes. Very important to most uses of MATLAB, toolboxes allow you to learn and apply specialized technology. Toolboxes are comprehensive collections of MATLAB functions (M – files) that extend the MATLAB environment to solve particular classes of problems. Areas in which toolboxes are available include signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many others.

3.2 The MATLAB system:

The MATLAB system consists of five main parts

- **Development Environment**:

This is the set of tools and facilities that help you use MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and command window, a command history, an editor and debugger, and browsers for viewing help, the workspace, files, and the search path.

- **The MATLAB Mathematical Function Library**:

This is a vast collection of computational algorithms ranging from elementary functions, like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix Eigenvalues, Bessel functions, and fast Fourier transforms.

- **The MATLAB Language**:

This is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows both “programming in the small” to rapidly create quick and dirty throw-away programs, and “programming in the large” to create large and complex application programs.

- **Graphics:**

MATLAB has extensive facilities for displaying vectors and matrices as graphs, as well as annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics as well as to build complete graphical user interfaces on your MATLAB applications.

- **The MATLAB Application Program Interface (API):**

This is a library that allows you to write C and FORTRAN programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.

Various toolboxes are there in MATLAB for computing recognition techniques, but we are using **IMAGE PROCESSING** toolbox.

3.3 graphical user interface (gui):

MATLAB's Graphical User Interface Development Environment (GUIDE) provides a rich set of tools for incorporating graphical user interfaces (GUIs) in M-functions. Using GUIDE, the processes of laying out a GUI (i.e., its buttons, pop-up menus, etc.)and programming the operation of the GUI are divided conveniently into two easily managed and relatively independent tasks. The resulting graphical M-function is composed of two identically named (ignoring extensions) files:

- A file with extension .fig, called a FIG-file that contains a complete graphical description of all the function's GUI objects or elements and their spatial arrangement. A FIG-file contains binary data that does not need to be parsed when he associated GUI-based M-function is executed.

- A file with extension .m, called a GUI M-file, which contains the code that controls the GUI operation. This file includes functions that are called when the GUI is launched and exited, and callback functions that are executed when a user interacts with GUI objects for example, when a button is pushed.

To launch GUIDE from the MATLAB command window, type

guide filename

Where filename is the name of an existing FIG-file on the current path. If filename is omitted,

GUIDE opens a new (i.e., blank) window.

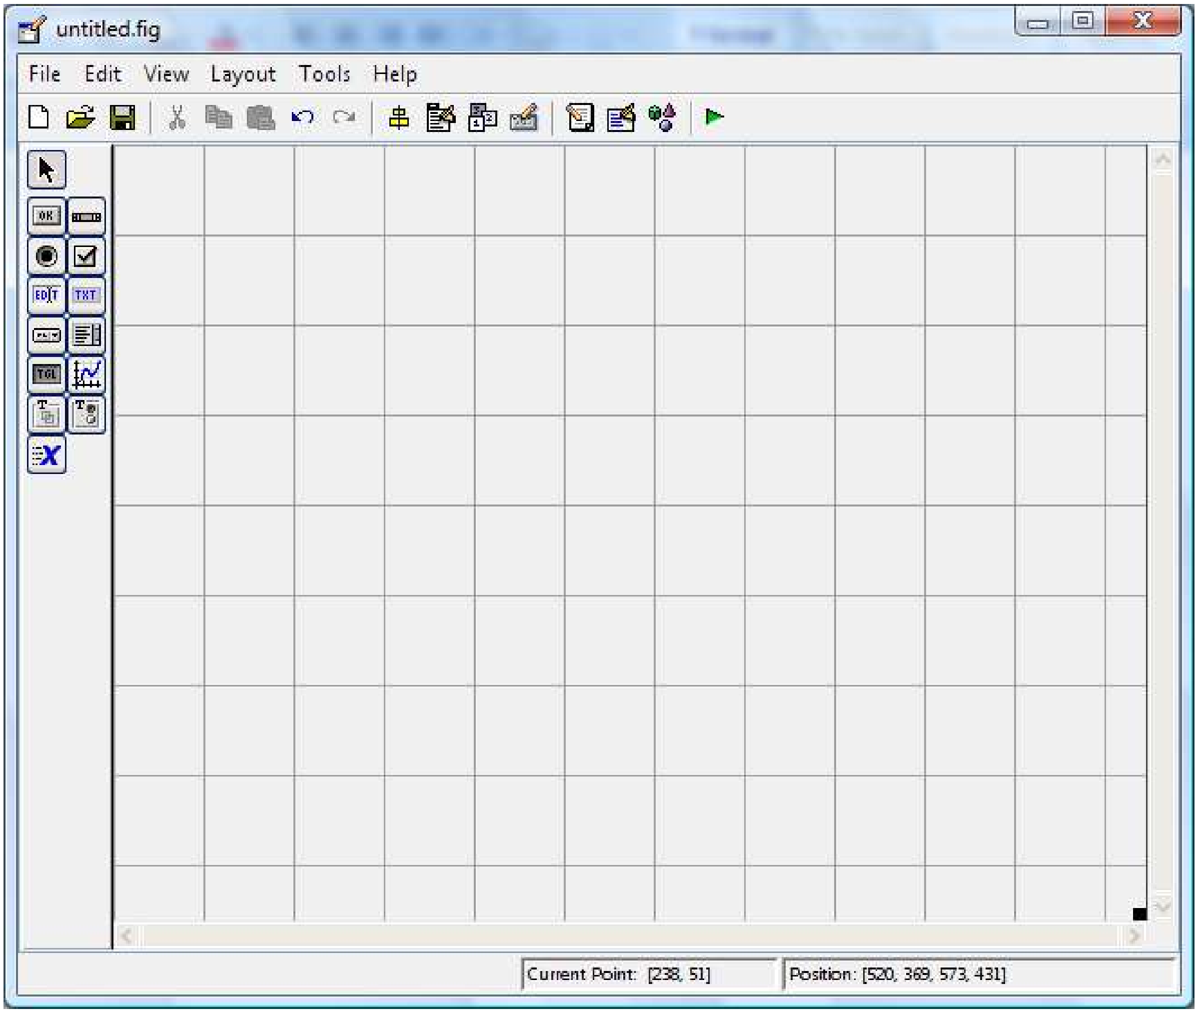

Fig-3.0 Graphical interface

A graphical user interface (GUI) is a graphical display in one or more windows containing controls, called components that enable a user to perform interactive tasks. The user of the GUI does not have to create a script or type commands at the command line to accomplish the tasks. Unlike coding programs to accomplish tasks, the user of a GUI need not understand the details of how the tasks are performed.

GUI components can include menus, toolbars, push buttons, radio buttons, list boxes, and sliders just to name a few. GUIs created using MATLAB tools can also perform any type of computation, read and write data files, communicate with other GUIs, and display data as tables or as plots.

3.4 getting started

If you are new to MATLAB, you should start by reading Manipulating Matrices. The most important things to learn are how to enter matrices, how to use the: (colon) operator, and how to invoke functions. After you master the basics, you should read the rest of the sections below and run the demos.

At the heart of MATLAB is a new language you must learn before you can fully exploit its power. You can learn the basics of MATLAB quickly, and mastery comes shortly after. You will be rewarded with high productivity, high-creativity computing power that will change the way you work.

3.4.1 Introduction - describes the components of the MATLAB system.

3.4.2 Development Environment - introduces the MATLAB development environment, including information about tools and the MATLAB desktop.

3.4.3 Manipulating Matrices - introduces how to use MATLAB to generate matrices and perform mathematical operations on matrices.

3.4.4 Graphics - introduces MATLAB graphic capabilities, including information about plotting data, annotating graphs, and working with images.

3.4.5 Programming with MATLAB - describes how to use the MATLAB language to create scripts and functions, and manipulate data structures, such as cell arrays and multidimensional arrays.

3.5 development environment

3.5.1 Introduction

This chapter provides a brief introduction to starting and quitting MATLAB, and the tools and functions that help you to work with MATLAB variables and files. For more information about the topics covered here, see the corresponding topics under Development Environment in the MATLAB documentation, which is available online as well as in print.

Starting and Quitting MATLAB

3.5.2 Starting MATLAB

On a Microsoft Windows platform, to start MATLAB, double-click the MATLAB shortcut icon on your Windows desktop.On a UNIX platform, to start MATLAB, type matlab at the operating system prompt. After starting MATLAB, the MATLAB desktop opens - see MATLAB Desktop.

You can change the directory in which MATLAB starts, define startup options including running a script upon startup, and reduce startup time in some situations.

3.5.3 Quitting MATLAB

To end your MATLAB session, select Exit MATLAB from the File menu in the desktop, or type quit in the Command Window. To execute specified functions each time MATLAB quits, such as saving the workspace, you can create and run a finish.m script.

3.5.4 MATLAB Desktop

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB.The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

You can change the way your desktop looks by opening, closing, moving, and resizing the tools in it. You can also move tools outside of the desktop or return them back inside the desktop (docking). All the desktop tools provide common features such as context menus and keyboard shortcuts.

You can specify certain characteristics for the desktop tools by selecting Preferences from the File menu. For example, you can specify the font characteristics for Command Window text. For more information, click the Help button in the Preferences dialog box.

3.5.5 Desktop Tools

This section provides an introduction to MATLAB's desktop tools. You can also use MATLAB functions to perform most of the features found in the desktop tools. The tools are:

- Current Directory Browser
- Workspace Browser
- Array Editor
- Editor/Debugger
- Command Window
- Command History
- Launch Pad
- Help Browser

Command Window

Use the Command Window to enter variables and run functions and M-files.

Command History

Lines you enter in the Command Window are logged in the Command History window. In the Command History, you can view previously used functions, and copy and execute selected lines. To save the input and output from a MATLAB session to a file, use the diary function.

Running External Programs

You can run external programs from the MATLAB Command Window. The exclamation point character! is a shell escape and indicates that the rest of the input line is a command to the operating system. This is useful for invoking utilities or running other programs without quitting MATLAB. On Linux, for example,!emacs magik.m invokes an editor called emacs for a file named magik.m. When you quit the external program, the operating system returns control to MATLAB.

Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation.

Help Browser

Use the Help browser to search and view documentation for all your Math Works products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button in the toolbar, or type helpbrowser in the Command Window. The Help browser consists of two panes, the Help Navigator, which you use to find information, and the display pane, where you view the information.

Help Navigator

Use Help Navigator to find information. It includes:

Product filter - Set the filter to show documentation only for the products you specify.

Contents tab - View the titles and tables of contents of documentation for your products.

Index tab - Find specific index entries (selected keywords) in the MathWorks documentation for your products.

Search tab - Look for a specific phrase in the documentation. To get help for a specific function, set the Search type to Function Name.

Favorites tab - View a list of documents you previously designated as favorites.

Display Pane

After finding documentation using the Help Navigator, view it in the display pane. While viewing the documentation, you can:

Browse to other pages - Use the arrows at the tops and bottoms of the pages, or use the back and forward buttons in the toolbar.

Bookmark pages - Click the Add to Favorites button in the toolbar.

Print pages - Click the print button in the toolbar.

Find a term in the page - Type a term in the Find in page field in the toolbar and click Go.

Other features available in the display pane are: copying information, evaluating a selection, and viewing Web pages.

Current Directory Browser

MATLAB file operations use the current directory and the search path as reference points. Any file you want to run must either be in the current directory or on the search path.

Search Path

To determine how to execute functions you call, MATLAB uses a search path to find M-files and other MATLAB-related files, which are organized in directories on your file system. Any file you want to run in MATLAB must reside in the current directory or in a directory that is on the search path. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

Workspace Browser

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces.

To view the workspace and information about each variable, use the Workspace browser, or use the functions who and whos.

To delete variables from the workspace, select the variable and select Delete from the Edit menu. Alternatively, use the clear function.

The workspace is not maintained after you end the MATLAB session. To save the workspace to a file that can be read during a later MATLAB session, select Save Workspace As from the File menu, or use the save function. This saves the workspace to a binary file called a MAT-file, which has a .mat extension. There are options for saving to different formats. To read in a MAT-file, select Import Data from the File menu, or use the load function.

Array Editor

Double-click on a variable in the Workspace browser to see it in the Array Editor. Use the Array Editor to view and edit a visual representation of one- or two-dimensional numeric arrays, strings, and cell arrays of strings that are in the workspace.

Editor/Debugger

Use the Editor/Debugger to create and debug M-files, which are programs you write to runMATLAB functions. The Editor/Debugger provides a graphical user interface for basic text editing, as well as for M-file debugging.

You can use any text editor to create M-files, such as Emacs, and can use preferences (accessible from the desktop File menu) to specify that editor as the default. If you use another editor, you can still use the MATLAB Editor/Debugger for debugging, or you can use debugging functions, such as dbstop, which sets a breakpoint.

If you just need to view the contents of an M-file, you can display it in the Command Window by using the type function.

3.6 manipulating matrices

3.6.1 Entering Matrices

The best way for you to get started with MATLAB is to learn how to handle matrices. Start MATLAB and follow along with each example.

You can enter matrices into MATLAB in several different ways:

- Enter an explicit list of elements.
- Load matrices from external data files.
- Generate matrices using built-in functions.
- Create matrices with your own functions in M-files.

Start by entering Dürer's matrix as a list of its elements. You have only to follow a few basic conventions:

- Separate the elements of a row with blanks or commas.
- Use a semicolon, ; , to indicate the end of each row.
- Surround the entire list of elements with square brackets, [ ].

To enter Dürer's matrix, simply type in the Command Window

A = [16 3 2 13; 5 10 11 8; 9 6 7 12; 4 15 14 1]

MATLAB displays the matrix you just entered.

A =

16 3 2 13

5 10 11 8

9 6 7 12

4 15 14 1

This exactly matches the numbers in the engraving. Once you have entered the matrix, it is automatically remembered in the MATLAB workspace. You can refer to it simply as A.

3.6.2 Expressions

Like most other programming languages, MATLAB provides mathematical expressions, but unlike most programming languages, these expressions involve entire matrices. The building blocks of expressions are:

- Variables
- Numbers
- Operators
- Functions

Variables

MATLAB does not require any type declarations or dimension statements. When MATLAB encounters a new variable name, it automatically creates the variable and allocates the appropriate amount of storage. If the variable already exists, MATLAB changes its contents and, if necessary, allocates new storage. For example,

num_students = 25

Creates a 1-by-1 matrix named num_students and stores the value 25 in its single element.

Variable names consist of a letter, followed by any number of letters, digits, or underscores. MATLAB uses only the first 31 characters of a variable name. MATLAB is case sensitive; it distinguishes between uppercase and lowercase letters. A and a are not the same variable. To view the matrix assigned to any variable, simply enter the variable name.

Numbers

MATLAB uses conventional decimal notation, with an optional decimal point and leading plus or minus sign, for numbers. Scientific notation uses the letter e to specify a power-of-ten scale factor. Imaginary numbers use either i or j as a suffix. Some examples of legal numbers are

3	-99	0.0001
9.6397238	1.60210e-20	6.02252e23
1i	-3.14159j	3e5i

All numbers are stored internally using the long format specified by the IEEE floating-point standard. Floating-point numbers have a finite precision of roughly 16 significant decimal digits and a finite range of roughly 10-308 to 10+308.

3.6.3 Operators

Expressions use familiar arithmetic operators and precedence rules.

+	Addition
-	Subtraction

*	Multiplication
/	Division
\	Left division (described in "Matrices and Linear Algebra" in Using MATLAB)
^	Power
'	Complex conjugate transpose
( )	Specify evaluation order

3.6.4 Functions

MATLAB provides a large number of standard elementary mathematical functions, including abs, sqrt, exp, and sin. Taking the square root or logarithm of a negative number is not an error; the appropriate complex result is produced automatically. MATLAB also provides many more advanced mathematical functions, including Bessel and gamma functions. Most of these functions accept complex arguments. For a list of the elementary mathematical functions, type help elfun, For a list of more advanced mathematical and matrix functions, type help specfun help elmat

Some of the functions, like sqrt and sin, are built-in. They are part of the MATLAB core so they are very efficient, but the computational details are not readily accessible. Other functions, like gamma and sinh, are implemented in M-files. You can see the code and even modify it if you want. Several special functions provide values of useful constants.

Pi	3.14159265...
I	Imaginary unit, $\sqrt{-1}$
I	Same as i

Eps	Floating-point relative precision, 2^{-52}
Realmin	Smallest floating-point number, 2^{-1022}
Realmax	Largest floating-point number, $(2-\varepsilon)2^{1023}$
Inf	Infinity
NaN	Not-a-number

3.7 GUI

A graphical user interface (GUI) is a user interface built with graphical objects, such as buttons, text fields, sliders, and menus. In general, these objects already have meanings to most computer users. For example, when you move a slider, a value changes; when you press an OK button, your settings are applied and the dialog box is dismissed. Of course, to leverage this built-in familiarity, you must be consistent in how you use the various GUI-building components.

Applications that provide GUIs are generally easier to learn and use since the person using the application does not need to know what commands are available or how they work. The action that results from a particular user action can be made clear by the design of the interface.

The sections that follow describe how to create GUIs with MATLAB. This includes laying out the components, programming them to do specific things in response to user actions, and saving and launching the GUI; in other words, the mechanics of creating GUIs. This documentation does not attempt to cover the "art" of good user interface design, which is an entire field unto itself. Topics covered in this section include:

3.7.1 Creating GUIs with GUIDE

MATLAB implements GUIs as figure windows containing various styles of uicontrol objects. You must program each object to perform the intended action when activated by the user of the GUI. In addition, you must be able to save and launch your GUI. All of these tasks are simplified by GUIDE, MATLAB's graphical user interface development environment.

3.7.2 GUI Development Environment

The process of implementing a GUI involves two basic task.

- Laying out the GUI components
- Programming the GUI components

GUIDE primarily is a set of layout tools. However, GUIDE also generates an M-file that contains code to handle the initialization and launching of the GUI. This M-file provides a framework for the implementation of the callbacks - the functions that execute when users activate components in the GUI.

The Implementation of a GUI

While it is possible to write an M-file that contains all the commands to lay out a GUI, it is easier to use GUIDE to lay out the components interactively and to generate two files that save and launch the GUI:

A FIG-file - contains a complete description of the GUI figure and all of its

children (uicontrols and axes), as well as the values of all object properties.

An M-file - contains the functions that launch and control the GUI and the

callbacks, which are defined as subfunctions. This M-file is referred to as the

application M-file in this documentation.

Note that the application M-file does not contain the code that lays out the uicontrols; this information is saved in the FIG-file.

The following diagram illustrates the parts of a GUI implementation.

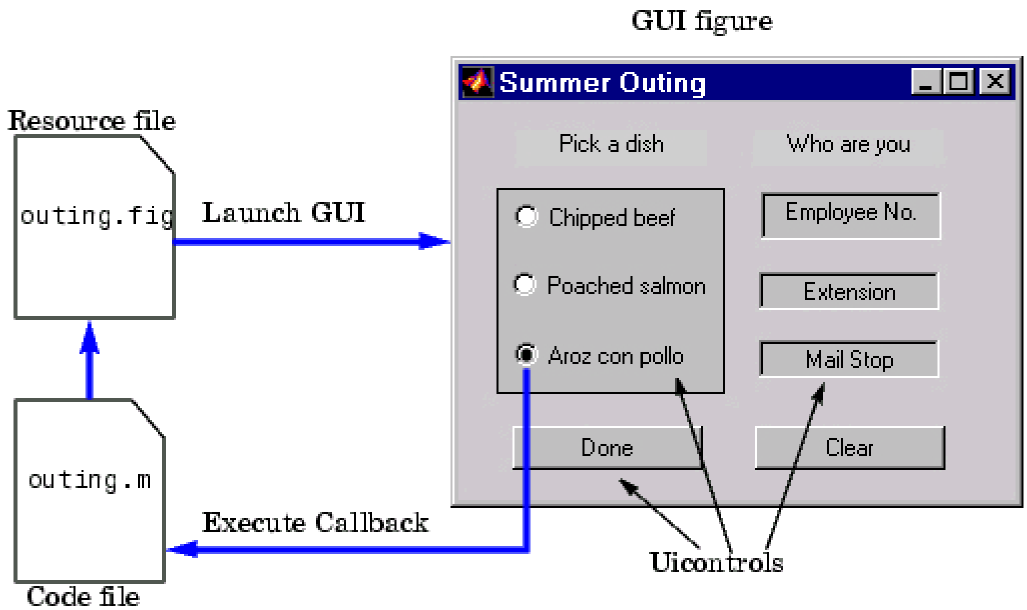

FIG 3.7.2 graphical user blocks

3.7.3 Features of the GUIDE-Generated Application M-Fil

GUIDE simplifies the creation of GUI applications by automatically generating an M-file framework directly from your layout. You can then use this framework to code your application M-file. This approach provides a number of advantages:

The M-file contains code to implement a number of useful features (see Configuring Application Options for information on these features). The M-file adopts an effective approach to managing object handles and executing callback routines (see Creating and Storing the Object Handle Structure for more information). The M-files provides a way to manage global data (see Managing GUI Data for more information).

The automatically inserted subfunction prototypes for callbacks ensure compatibility with future releases. For more information, see Generating Callback Function Prototypes for information on syntax and arguments.

You can elect to have GUIDE generate only the FIG-file and write the application M-file yourself. Keep in mind that there are no uicontrol creation commands in the application M-file; the layout information is contained in the FIG-file generated by the Layout Editor.

3.7.4 Beginning the Implementation Process

To begin implementing your GUI, proceed to the following sections:

Getting Started with GUIDE - the basics of using GUIDE.

Selecting GUIDE Application Options - set both FIG-file and M-file options.

Using the Layout Editor - begin laying out the GUI.

Understanding the Application M-File - discussion of programming techniques used in the application M-file.

Application Examples - a collection of examples that illustrate techniques which are useful for implementing GUIs.

Command-Line Accessibility

When MATLAB creates a graph, the figure and axes are included in the list of children of their respective parents and their handles are available through commands such as findobj, set, and get. If you issue another plotting command, the output is directed to the current figure and axes.

GUIs are also created in figure windows. Generally, you do not want GUI figures to be available as targets for graphics output, since issuing a plotting command could direct the output to the GUI figure, resulting in the graph appearing in the middle of the GUI.

In contrast, if you create a GUI that contains an axes and you want commands entered in the command window to display in this axes, you should enable command-line access.

3.7.5 User Interface Control

The Layout Editor component palette contains the user interface controls that you can use in your GUI. These components are MATLAB uicontrol objects and are programmable via their Callback properties. This section provides information on these components.

- Push Buttons
- Sliders
- Toggle Buttons
- Frames
- Radio Buttons
- Listboxes
- Checkboxes
- Popup Menus
- Edit Text
- Axes
- Static Text
- Figures

Push Buttons

Push buttons generate an action when pressed (e.g., an OK button may close a dialog box and apply settings). When you click down on a push button, it appears depressed; when you release the mouse, the button's appearance returns to its nondepressed state; and its callback executes on the button up event.

Properties to Set

String - set this property to the character string you want displayed on the push button.

Tag - GUIDE uses the Tag property to name the callback subfunction in the application M-file. Set Tag to a descriptive name (e.g., close_button) before activating the GUI.

Programming the Callback

When the user clicks on the push button, its callback executes. Push buttons do not return a value or maintain a state.

Toggle Buttons

Toggle buttons generate an action and indicate a binary state (e.g., on or off). When you click on a toggle button, it appears depressed and remains depressed when you release the mouse button, at which point the callback executes. A subsequent mouse click returns the toggle button to the nondepressed state and again executes its callback.

Programming the Callback

The callback routine needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is depressed (Max is 1 by default) and equal to the Min property when the toggle button is not depressed (Min is 0 by default).

From the GUIDE Application M-File

The following code illustrates how to program the callback in the GUIDE application M-file.

```
function varargout = togglebutton1_Callback(h,eventdata,handles,varargin)

button_state = get(h,'Value');

if button_state == get(h,'Max')

% toggle button is pressed

elseif button_state == get(h,'Min')

% toggle button is not pressed
```

Adding an Image to a Push Button or Toggle Button

Assign the CData property an m-by-n-by-3 array of RGB values that define a truecolor image. For example, the array a defines 16-by-128 truecolor image using random values between 0 and 1 (generated by rand).

```
a(:,:,1) = rand(16,128);

a(:,:,2) = rand(16,128);

a(:,:,3) = rand(16,128);

set(h,'CData',a)
```

Radio Buttons

Radio buttons are similar to checkboxes, but are intended to be mutually exclusive within a group of related radio buttons (i.e., only one button is in a selected state at any given time). To activate a radio button, click the mouse button on the object. The display indicates the state of the button.

Implementing Mutually Exclusive Behavior

Radio buttons have two states - selected and not selected. You can query and set the state of a radio button through its Value property:

Value = Max, button is selected.

Value = Min, button is not selected.

To make radio buttons mutually exclusive within a group, the callback for each radio button must set the Value property to 0 on all other radio buttons in the group. MATLAB sets the Value property to 1 on the radio button clicked by the user.

The following subfunction, when added to the application M-file, can be called by each radio button callback. The argument is an array containing the handles of all other radio buttons in the group that must be deselected.

```
function mutual_exclude(off)

set(off,'Value',0)
```

Obtaining the Radio Button Handles.

The handles of the radio buttons are available from the handles structure, which contains the handles of all components in the GUI. This structure is an input argument to all radio button callbacks.

The following code shows the call to mutual_exclude being made from the first radio button's callback in a group of four radio buttons.

```
function varargout = radiobutton1_Callback(h,eventdata,handles,varargin)

off = [handles.radiobutton2,handles.radiobutton3,handles.radiobutton4];

mutual_exclude(off)

% Continue with callback

.

.

.
```

After setting the radio buttons to the appropriate state, the callback can continue with its implementation-specific tasks.

Checkboxes

Check boxes generate an action when clicked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices that set a mode (e.g., display a toolbar or generate callback function prototypes).

The Value property indicates the state of the check box by taking on the value of the Max or Min property (1 and 0 respectively by default):

Value = Max, box is checked.

Value = Min, box is not checked.

You can determine the current state of a check box from within its callback by querying the state of its Value property, as illustrated in the following example:

```
function checkbox1_Callback(h,eventdata,handles,varargin)

if (get(h,'Value') == get(h,'Max'))

% then checkbox is checked-take approriate action

else

% checkbox is not checked-take approriate action

end
```

Edit Text

Edit text controls are fields that enable users to enter or modify text strings. Use edit text when you want text as input. The String property contains the text entered by the user.

To obtain the string typed by the user, get the String property in the callback.

```
function edittext1_Callback(h,eventdata, handles,varargin)

user_string = get(h,'string');
```

Obtaining Numeric Data from an Edit Test Component

MATLAB returns the value of the edit text String property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the str2double command, which converts strings to doubles. If the user enters non-numeric characters, str2double returns NaN.

You can use the following code in the edit text callback. It gets the value of the String property and converts it to a double. It then checks if the converted value is NaN, indicating the user entered a non-numeric character (isnan) and displays an error dialog (errordlg).

```
function edittext1_Callback(h,eventdata,handles,varargin)

user_entry = str2double(get(h,'string'));

if isnan(user_entry)

errordlg('You must enter a numeric value','Bad Input','modal')

end

% proceed with callback...
```

Triggering Callback Execution

On UNIX systems, clicking on the menubar of the figure window causes the edit text callback to execute. However, on Microsoft Windows systems, if an editable text box has focus, clicking on the menubar does not cause the editable text callback routine to execute. This behavior is consistent with the respective platform conventions. Clicking on other components in the GUI execute the callback.

Static Text

Static text controls displays lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively and there is no way to invoke the callback routine associated with it

Frames

Frames are boxes that enclose regions of a figure window. Frames can make a user interface easier to understand by visually grouping related controls. Frames have no callback routines associated with them and only uicontrols can appear within frames (axes cannot).

Placing Components on Top of Frames

Frames are opaque. If you add a frame after adding components that you want to be positioned within the frame, you need to bring forward those components. Use the Bring to Front and Send to Back operations in the Layout menu for this purpose.

List Boxes

List boxes display a list of items and enable users to select one or more items.

The String property contains the list of strings displayed in the list box. The first item in the list has an index of 1.

The Value property contains the index into the list of strings that correspond to the selected item. If the user selects multiple items, then Value is a vector of indices. By default, the first item in the list is highlighted when the list box is first displayed. If you do not want any item highlighted, then set the Value property to empty.

The ListboxTop property defines which string in the list displays as the top most item when the list box is not large enough to display all list entries. ListboxTop is an index into the array of strings defined by the String property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer

Single or Multiple Selection

The values of the Min and Max properties determine whether users can make single or multiple selections:

If Max - Min > 1, then list boxes allow multiple item selection.

If Max - Min <= 1, then list boxes do not allow multiple item selection.

Selection Type

Listboxes differentiate between single and double clicks on an item and set the figure SelectionType property to normal or open accordingly. See Triggering Callback Execution for information on how to program multiple selection.

Triggering Callback Execution

MATLAB evaluates the list box's callback after the mouse button is released or a keypress event (including arrow keys) that changes the Value property (i.e., any time the user clicks on an item, but not when clicking on the list box scrollbar). This means the callback is executed after the first click of a double-click on a single item or when the user is making multiple selections. In these situations, you need to add another component, such as a Done button (push button) and program its callback routine to query the list box Value property (and possibly the figure SelectionType property) instead of creating a callback for the list box. If you are using the automatically generated application M-file option, you need to either:

Set the list box Callback property to the empty string ('') and remove the callback subfunction from the application M-file. Leave the callback subfunction stub in the application M-file so that no code executes when users click on list box items.

The first choice is best if you are sure you will not use the list box callback and you want to minimize the size and efficiency of the application M-file. However, if you think you may want to define a callback for the list box at some time, it is simpler to leave the callback stub in the M-file.

Popup Menus

Popup menus open to display a list of choices when users press the arrow. The String property contains the list of string displayed in the popup menu. The Value property contains the index into the list of strings that correspond to the selected item. When not open, a popup menu displays the current choice, which is determined by the index contained in the Value property. The first item in the list has an index of 1.

Popup menus are useful when you want to provide users with a number of mutually exclusive choices, but do not want to take up the amount of space that a series of radio buttons requires.

Programming the Popup Menu

You can program the popup menu callback to work by checking only the index of the item selected (contained in the Value property) or you can obtain the actual string contained in the selected item.

This callback checks the index of the selected item and uses a switch statement to take action based on the value. If the contents of the popup menu is fixed, then you can use this approach.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

switch val

case 1

% The user selected the first item

case 2

% The user selected the second item
```

% etc.

This callback obtains the actual string selected in the popup menu. It uses the value to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the popup menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the String property from a cell array to a string.

```
function varargout = popupmenu1_Callback(h,eventdata,handles,varargin)

val = get(h,'Value');

string_list = get(h,'String');

selected_string = string_list{val}; % convert from cell array to string

% etc.
```

Enabling or Disabling Controls

You can control whether a control responds to mouse button clicks by setting the Enable property. Controls have three states:

on - The control is operational

off - The control is disabled and its label (set by the string property) is

grayed out.

inactive - The control is disabled, but its label is not grayed out.

When a control is disabled, clicking on it with the left mouse button does not execute its callback routine. However, the left-click causes two other callback routines to execute: First the figure WindowButtonDownFcn callback executes. Then the control's ButtonDownFcn callback executes. A right mouse button click on a disabled control posts a context menu, if one is defined for that control. See the Enable property description for more details.

Axes

Axes enable your GUI to display graphics (e.g., graphs and images). Like all graphics objects, axes have properties that you can set to control many aspects of its behavior and appearance. See Axes Properties for general information on axes objects.

Axes Callbacks

Axes are not uicontrol objects, but can be programmed to execute a callback when users click a mouse button in the axes. Use the axes Button DownFcn property to define the callback.

3.7.6 Plotting to Axes in GUIs

GUIs that contain axes should ensure the Command-line accessibility option in the Application Options dialog is set to Callback (the default). This enables you to issue plotting commands from callbacks without explicitly specifying the target axes.

GUIs with Multiple Axe

If a GUI has multiple axes, you should explicitly specify which axes you want to target when you issue plotting commands. You can do this using the axes command and the handles structure. For example,

axes(handles.axes1)

makes the axes whose Tag property is axes1 the current axes, and therefore the target for plotting commands. You can switch the current axes whenever you want to target a different axes. See GUI with Multiple Axes for and example that uses two axes.

Figure

Figures are the windows that contain the GUI you design with the Layout Editor. See the description of figure properties for information on what figure characteristics you can control.

CHAPTER 4
PROPOSED METHOD

Flow diagram of proposed work

The Fig1 shows the process flow diagram or proposed work. In this paper we used MIAS Dataset that publicly available for download and used. In the second step we pre-processed the dataset. In the pre-processing we have used three different methods for scaled and pre-process dataset. After that applied Deep Learning Neural Network and compute the accuracy. We have seen CNN achieved 98% accuracy

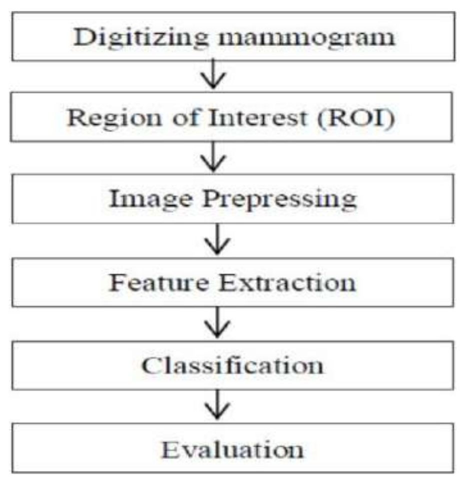

Fig:4 Process Flow Diagram

Methodology

In this paper we have used convolutional neural network for diagnosis breast cancer and also implemented same dataset on other machine learning algorithm such as Neural Network, Support Vector Machine, Random Forest. All paper consists main two parts: predict models, Preprocessing data. In this paper we have used MIAS Dataset that are publicly available for researcher this database is generated from Histopathology images that having 200images of dataset. In the experiment part first, we have pre-processed the dataset and extracted useful feature using histogram and watershed model then implement some encoder and found final training dataset. For the trained the dataset we have used deep learning model convolutional neural network algorithm and achieved 98% accuracy

Pre-processing data

As you know that data pre-processing is a data mining technique that used for filter data in a usable format. Because the real-world dataset almost available in different format. Its not available as per our requirement so its must be fitters the dataset in a understandable format Data preprocessing is a proven method of resolving such issues. Data pre-processing convert the dataset in to usable format for pre-processing we have used standardization method to preprocess the MIAS dataset.

Marker Controlled Watershed Segmentation

The watershed transforms find “Catchment basins” and “watershed ridge lines” in an image by treating it as a surface where light pixels are high and dark pixels are low. Segmentation using the watershed transform works better it we can identify or mark foreground object and background locations

Texture Segmentation Using Texture Filters

In this paper used entropy for creating texture images. Entropy is standard function that return an array value in which each output pixel contains the entropy value of the 9x9 pixel around the corresponding pixel in the input image. The following are some most used filters.

Median Filter

We have used median filter in this paper 12 features that we have used for model trained

TABLE I. TOTAL NUMBER OF SELECTED FEATURES

Fig-4.1

We have tried different 2 segmentation algorithm on same images.

Model implementation

In this stage we have implemented Deep Learning Neural Network algorithm on MIAS data set. Neural network in work on a human biological method. In which we have to pass input and get output. But in these two layer some hidden layer are work and some additional process must be added before calculate final output. These additional processes are added unit of bias, add some of additional hidden layer, calculate some activation function then the final output generated. In this paper we have used following parameters for calculating and trained model.

TABLE II. USED PARAMETERS IN CNN MODEL

Number of input	**12**
Number of Neurons	12
Activation function	Sigmoid
Number of Epochs	30

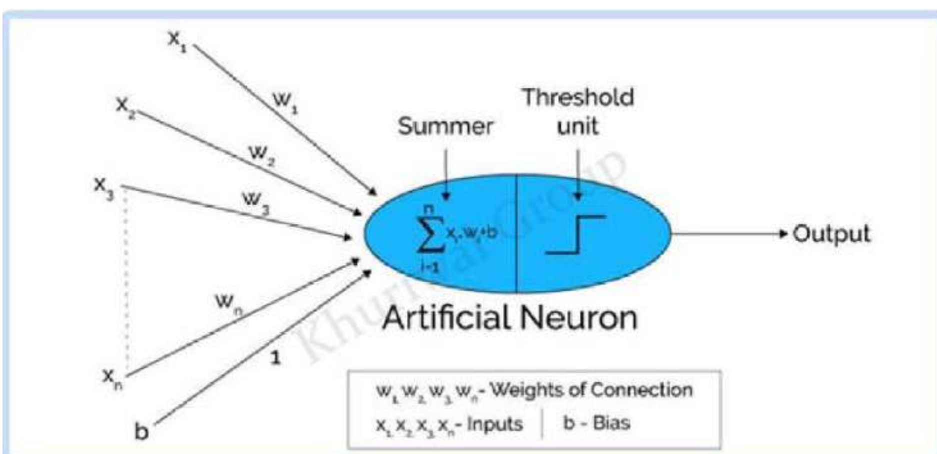

Fig. Shows Neural Network Functionality

When we want to use perceptron bias b = threshold then perceptron rule rewritten. Fig show the basic functionality of the neural network. In which after the fixed position the neurons are fired that is called threshold condition.

TABLE III. CNN MODEL SUMMARY

Trainable	params:	641	
Non-trainable	params:	0	

Fig 4.2

In this paper I have create the four-layer convolutional model in which first is input layer. Convolutional layer, hidden layer and fully connected layers. The total number of neurons is 12 for first input layers and 8 neurons for hidden layers and final 1 neurons in output layers. The following step are briefly describing the experimental in this research.

Step 1: the region of interest was extracted from the abnormal images depending on the images.

Step 2: for improve image quality we have used median filter and histogram equalization method.

Step 3: for classification image we have used deep learning algorithm convolutional neural network.

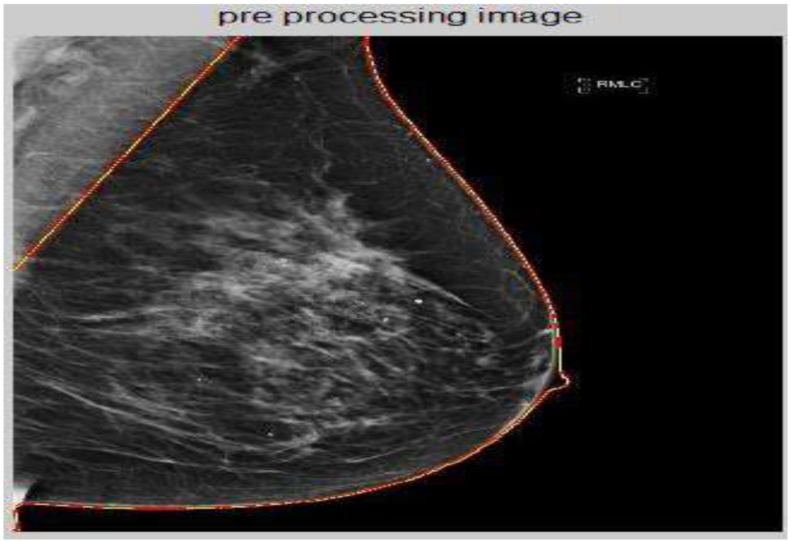
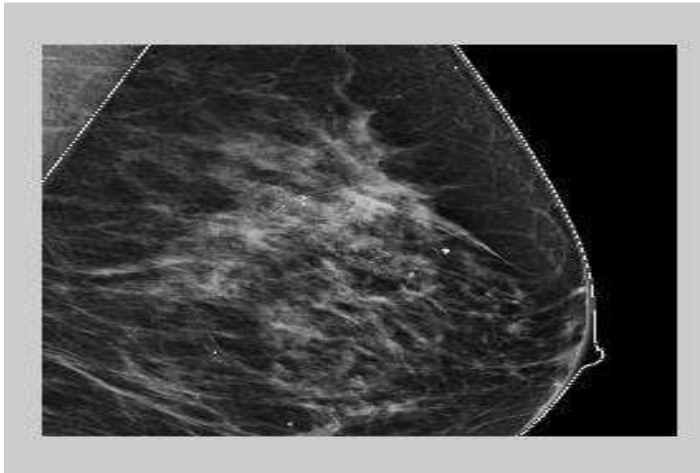
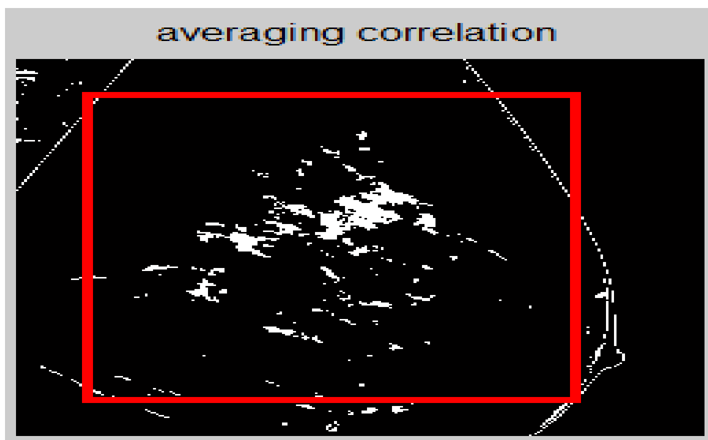
RESULTS







averaging correlation

CHAPTER 6

CONCLUSION AND FUTURE WORK

As we know that deep learning method convolutional neural network mostly used for image dataset classification that why we used convolutional neural network in this paper. After the implementation this paper we have achieved 98% accuracy. As we mention this paper worked on only 12 features only. In future we will try with new features and also try with the real images dataset so that we can achieved best result and accuracy for diagnosis the cancer. In feature we will also try this method on different type in cancer not only for breast cancer.
